The commenter (2390-NMOGA) argues that it is ultimately up to the states to demonstrate how their respective state requirements result in emission reductions equivalent to EG OOOOc. As explained above, the commenter states that Congress intended for states to have wide latitude in developing and submitting state plans that satisfy the requirements of CAA section 111(d). EPA's proposal denies states the flexibility provided to them under the Act and abdicates EPA's responsibility to review state plans by pre-supposing the data possessed by states and their ability to submit satisfactory equivalency demonstrations.

EPA also proposes that states are expected to establish the same form of numerical standards as EPA in state plan equivalency demonstrations. The commenter (2390-NMOGA) reports that California, Colorado, Connecticut, Delaware, Illinois, Maine, Maryland, Michigan, Minnesota, New Jersey, New Mexico, New York, North Carolina, Oregon, Rhode Island, Vermont, Washington, Wisconsin, Massachusetts, Pennsylvania, and the District of Columbia submitted a joint comment on the November 2021 Proposal requesting that EPA permit the use of different numerical standards "consistent with the structure of section 111(d), under which states have wide latitude in developing their plans provided that the required level of emission reduction is achieved."<sup>60</sup> The commenter adds that the EPA acknowledges the state commenters' request, but denies it on the grounds that the "state commenters did not clearly provide specific examples of where a state already has a different form of a numerical standard that would necessitate this flexibility." The commenter states that this reasoning unreasonably places the burden on states to

---

<sup>60</sup> See Docket ID No. EPA-HQ-OAR-2021-0317-1267.

provide an equivalency demonstration in their comments on a proposed rule. According to the commenter, the appropriate forum for a state to provide such an example would be in their individual state equivalency demonstration—not a public comment jointly submitted by several states. EPA’s rationale again abdicates its responsibility to review state plans by presupposing a state’s ability to submit satisfactory equivalency demonstrations.

4. EPA’s concern that a total program evaluation would leave some designated facilities unregulated is contrary to EPA’s interpretation that CAA section 111(d) authorizes states to establish standards of performance that, “in the aggregate,” are equivalent with the presumptive standards.

The commenter (2390-NMOGA) provides that, in *American Lung Association*, the D.C. Circuit expressly rejected EPA’s categorical exclusion of averaging in state plans.<sup>61</sup> Specifically, the court rejected EPA’s rationale that “asymmetrical regulation ‘could have significant localized adverse consequences for public health and the environment.’”<sup>62</sup> The court held that the reasoning failed to support the EPA’s categorical rule—or even EPA’s ban on averaging in that specific instance—because “carbon dioxide emissions do not pose localized concerns at the site of emission.”<sup>63</sup>

Here, the commenter (2390-NMOGA) believes that the EPA does not even try to support its ban on averaging by relying on health-based considerations. Rather, EPA states that if it “were to permit total program equivalence where state programs do not align with the EG, then there could be situations where a state would be allowed to forgo regulating some designated facilities that the EPA has determined are reasonable to control.” The example EPA provides is Colorado’s 15 barrels of oil equivalent (boe)/day threshold for its non-emitting pneumatic controller requirement—a state-based RULOF provision that accounts for the cost of implementing the standard at low-producing facilities.

In essence, the commenter (2390-NMOGA) notes that the EPA justifies its decision to categorically preclude total program evaluations on the grounds that source-by-source equivalency demonstrations will result in greater emission reductions because states with more stringent regulations for some sources, like Colorado, will be required to revise any less stringent regulations to meet the EPA standard. The commenter asserts that this position cannot be squared with the interpretation of CAA section 111(d)—shared by the D.C. Circuit and EPA in all other historic actions—that the statute does not categorically bar averaging and authorize[s] states to establish standards of performance for their sources that, in the aggregate, would be equivalent to the presumptive standards.” Inherent in the ability to demonstrate equivalency in the aggregate, is the fact that some state regulations will be less stringent than the standard established in the emission guidelines. The D.C. Circuit’s decision in *American Lung Association* instructs that for EPA to bar states from submitting plans that rely on averaging, EPA must have a source- and pollutant-specific rationale that is justified and supportable.

---

<sup>61</sup> 985 F.3d at 957.

<sup>62</sup> Id. at 958.

<sup>63</sup> Id.

But under the rationale supplied by EPA in the Proposed Rules, the commenter (2390-NMOGA) states that the agency could never allow state plans to rely on averaging without wholly reversing its position because any future EG that allows state plans to demonstrate equivalency “in the aggregate” will necessarily result in a source or category of sources being subject to regulations less stringent than EPA determined to be reasonable. The commenter contends that adherence to its position in the proposed rules will result in EPA adopting a de-facto categorical ban on averaging emissions under state plans, contrary to the D.C. Circuit’s holding in *American Lung Association*.<sup>64</sup>

### ***19.2.2 Source-by-Source Evaluation***

Comment: Commenter (2286-CO APCD) expresses concern with EPA’s proposed criteria, through which a state may make a source-by-source, designated facility equivalency evaluation. The commenter notes that EPA states that a state program that does not regulate the same pollutant, i.e., VOC versus methane, would not be able to move on to step two, evaluating whether the state program achieves the same or greater emissions reductions as the designated facility presumptive standards.

First, the commenter (2286-CO APCD) notes that many of the presumptive standards in EPA’s proposal will reduce VOC and methane emissions to the same extent. For example, the requirement to reduce methane emissions from fugitive emissions components will require the same work practices as a requirement to reduce VOC or hydrocarbons from components, i.e., through an LDAR program. However, under EPA’s rubric, a state would not be able to demonstrate that their VOC reducing LDAR program achieves the same or greater emissions reductions because the state program specifies VOC rather than methane.

Second, the commenter (2286-CO APCD) adds that states with ozone nonattainment areas classified as moderate or greater must adopt provisions in their SIP based on recommendations in EPA’s Control Technique Guidelines (CTG) when the state has sources in that VOC source category. For the oil and gas sector, EPA published the Oil and Gas CTG in 2016, which required subject states to revise their SIP and submit such revisions to EPA by October 2018. EPA’s Oil and Gas CTG recommends VOC control strategies for many of the same operations and equipment included in EPA’s proposed EG. The commenter notes that these are VOC standards, not methane. Therefore, the commenter asserts that states that were required to adopt SIP provisions based on the recommendations in EPA’s Oil and Gas CTG now have VOC requirements in their SIP that, based on EPA’s proposed equivalency evaluation rubric, cannot be used for purposes of comparing the effectiveness of their state program to EPA’s proposed presumptive standards. Furthermore, the commenter suggests that states may not be able to revise their SIP provisions to align with EPA’s proposed presumptive methane standards because EPA’s CTGs are designed to achieve ozone precursor emissions reductions, not GHG emissions reductions. None of this is discussed in EPA’s proposal and the commenter requests clarification

---

<sup>64</sup> *Am. Lung Ass’n*, 985 F.3d at 957.

from EPA on how to streamline the program evaluation as well as the associated SIP and CAA section 111(d) rules.

Lastly, the commenter (2286-CO APCD) reiterates its concern, as stated in the previous comments submitted on EPA's 2021 proposal<sup>65</sup>, that EPA provide flexibility for states to modify state CAA section 111(d) plans without needing to submit each plan to EPA for approval, as is required for an initial state CAA section 111(d) plan or in response to final revised guidelines published by EPA. The commenter will need flexibility to revise Colorado's rules in a timely manner in response to numerous state and federal directives, as well as technological innovation in the industry. At a minimum, the commenter recommends that EPA allow states to modify their state CAA section 111(d) plans without further EPA approval where the modifications do not result in less stringent regulatory programs or where the changes are minor recordkeeping and reporting program adjustments.

Response II-19-7: Please see discussion of state flexibilities and response to comments section XIII.C.2 of the final preamble.

### ***19.2.3 Application of Stringency***

Comment: Commenters (2249-NACAA, 2343-NYU-School of Law) make recommendations on the applications of stringency. Specific comments provided are presented in the following paragraphs.

Commenter (2249-NACAA) recommends that EPA's rule explicitly state that its emission reduction requirements are a baseline for all agencies, but that state and local regulatory agencies can use their own approaches if their needs are more effectively met with different paths that are overall at least as stringent and health-protective.

The commenter (2249-NACAA) states that the CAA and its section 111 are built on a model of cooperation that requires EPA to work in partnership with states, cities, and counties, among others, and by affording states additional – and essential – flexibility to chart compliance pathways, which can include emission limitations that are at least as stringent as the federal guidelines.

The commenter (2249-NACAA) explains that oil and gas operations also emit other criteria pollutants such as sulfur dioxide and nitrogen oxides, as well as air toxics including benzene, formaldehyde, toluene, ethylbenzene, and xylene. Some clean air agencies may have needs that more urgently prioritize these pollutants (or others) or prioritize specifically vulnerable communities (such as environmental justice communities or those most vulnerable to economic impacts of the rule.) The commenter suggests that the EPA may also wish to offer consistent and transparent discretion to adapt to a variety of disadvantaged community needs and understand with greater precision the economic effects of its rule on specific communities dependent on production. Where an agency can demonstrate reductions using approaches that are driven by other pollutants or that offer locally prioritized benefits of sufficiently demonstrated value, the

---

<sup>65</sup> See Colorado comments at EPA-HQ-OAR-2021-0317-0775.

commenter recommends that EPA work with state and local agencies to meet their goals through this program.

Programmatic requirements may be equivalent, but the commenter (2249-NACAA) notes that wording and specific standards may be different for states with existing programs, and EPA should accommodate these variations. Where programs are less stringent in individual aspects but as or more stringent and protective overall, they suggest that EPA accommodate those tailored approaches that meet that agency's needs. Regarding the application of exemptions to disadvantaged or vulnerable communities, the commenter acknowledges that the EPA intends to allow these considerations in their determination of stringency. The commenter requests that EPA be clear about those criteria and their application before a rule is finalized.

Commenter (2343-NYU-School of Law) expresses that considering stringency in each year allows for more accurate comparisons. The commenter believes that EPA's preferred approach (comparing full-implementation stringency) could undermine Congress's intent that the methane charge be suspended only when EPA has sufficiently regulated methane emissions. For example, the commenter notes that a future administration might promulgate a new methane regulation that is as stringent as the November 2021 proposed rule when each is fully implemented, yet the new regulation might take a decade or longer to ramp up to that stringency. The delay might be due to a glide path to stringency within the new rule,<sup>66</sup> or elongated deadlines for submission, approval, and compliance with state plans, or both. If the equivalency determination were to depend only on stringency when the respective rules are fully implemented, these rules would be "equivalent." However, under the slow-ramping rule, the commenter states that the total emissions reductions would be far less than the November 2021 proposed rule, so a suspension of the methane charge would be unjustified.

Response II-19-8: Please see discussion of state flexibilities and response to comments section XIII.C.2 of the final preamble.

#### ***19.2.4 Quantitative Comparison***

Comment: Commenter (2343-NYU-School of Law) asserts that the equivalency determination should be quantitative to facilitate accurate comparison and to set a standard of best practice for appropriate review in future rulemakings. The commenter contends that qualitative comparisons for subsequent rulemakings may not be straightforward. To conduct a quantitative equivalency determination, the commenter recommends that EPA analyze the November 2021 proposed rule using the same assumptions and methodologies that EPA now uses for the December 2022 supplemental proposal. The commenter states that this would allow an apples-to-apples comparison of the emissions reductions from the two regulations.

---

<sup>66</sup> See, e.g., Standards of Performance for New and Existing Stationary Sources: Electric Utility Steam Generating Units, 70 Fed. Reg. 28,606, 28,617–28,621 (May 5, 2005) (establishing decreasing caps on mercury emissions that achieved maximum stringency in 15 years); Carbon Pollution Emission Guidelines for Existing Stationary Sources: Electric Utility Generating Units, 80 Fed. Reg. 64,662, 64,667 (Oct. 23, 2015) (establishing increasingly stringent performance rates that reach maximum stringency in 15 years); Standards of Performance for Stationary Compression Ignition Internal Combustion Engines, 71 Fed. Reg. 39,154, 39,157 tbl.1 (July 11, 2006) (achieving full stringency in nine years).

The commenter (2343-NYU-School of Law) states that a qualitative approach may be appropriate under the unique circumstances of this rulemaking because the differences between the final rule and the November 2021 proposed rule will likely be relatively minor and point in the direction of increased stringency. But, even though the similarities between the design of the November 2021 proposed rule and the December 2022 supplemental proposal make it possible for EPA to find the December 2022 supplemental proposal at least equivalent without a quantitative analysis, the commenter recommends that EPA conduct a quantitative equivalency determination to set a standard of best practice. The commenter reports, for example, that EPA could promulgate a new regulation in the future that is more stringent in some ways but less stringent in other ways than the November 2021 proposed rule. The commenter asserts that a quantitative approach would better indicate whether that new regulation is at least as stringent as the November 2021 proposed rule. The commenter believes that the EPA has an opportunity now to set a best practice for future rulemakings and that quantitative analysis is most appropriate for the equivalency determination.

Response II-19-9: Please see discussion of state flexibilities and response to comments section XIII.C.2 of the final preamble.

## **19.3 Remaining Useful Life and Other Factors (RULOF)**

### ***19.3.1 EPA Lacks Legal Authority to Require RULOF Provisions***

Comment: Commenter (2202-TXOGA) expresses concern that the proposed provisions to state plan development as compared with the November 2021 proposal are far more than mere “adjustments.” Specifically, the commenter expresses concern that the EPA is now proposing to introduce into the state plan development process what they believe are unprecedented and far-reaching requirements that would radically alter, both in its scope and effect, that regulatory program. Further, as discussed in more detail below, from the publicly available documents in the docket, the commenter states that they are unable to identify the provisions of the CAA that EPA believes provide the legal basis for adopting many of these requirements.

The commenter (2202-TXOGA) contends that the November 2021 proposal said almost nothing about the “remaining useful life and other factors” elements of the state standard-setting process under CAA section 111(d). It did not yet even have occasion to coin the “RULOF” acronym.<sup>67</sup> Instead, the commenter notes that the November 2021 proposal focused almost entirely on the Agency’s proposal to “translate the degree of emission limitation achievable through application of the BSER (i.e., level of stringency) into presumptive standards of performance that [s]tates may use in the development of [s]tate plans for specific emission points.” As the preamble there explained, “[i]n this way, the presumptive standards included in the EG serve a similar purpose as a model rule,” insofar as they are “intended to assist [s]tates in developing their plan

---

<sup>67</sup> This stands in contrast to its usage 165 times in its December 2022 debut.

submissions by providing the [s]tates with a starting point for their standards that are based on general industry parameters and assumptions.”<sup>68</sup>

As for what the December 2022 proposal coins as the “RULOF” element of the state standard development process, the commenter (2202-TXOGA) states that the Agency in its November 2021 Notice provided fairly straightforward description of how that process worked, explaining that, “[t]o the extent that a [s]tate determines the presumptive standards in the final EG are not reasonable for a particular designated facility due to remaining useful life and other factors, the statute requires that the EPA’s regulations under CAA section 111(d) permit [s]tates to consider such factors in applying a standard of performance.” For that reason, the commenter notes that EPA pointed out, the current “implementing regulations at 40 C.F.R. 60.24a(e)” operate to “allow [s]tates to consider remaining useful life and other factors to apply a less stringent standard of performance to a designated facility or class of facilities if one or more demonstrations are made.”

The commenter (2202-TXOGA) continues to state that the EPA went on to announce to that it intended to “provide further clarification on the general process and requirements for accounting for remaining useful life and other factors, including on the reasonableness aspect of the required demonstration,” but that it would be doing so “via a rulemaking to amend the implementing regulations in the near future.” At the same time, the proposal said it “recognize[d] that the oil and natural gas industry” was so “unique” that the “general approach to considering remaining useful life and other factors in the implementing regulations may not be an ideal fit.” After a brief discussion of the factors that EPA believed rendered the industry “unique,” and after noting that the Agency had in the November 2021 notice “deliberately included certain flexibilities (e.g., in cases of technical infeasibility) such that the EPA believes the presumptive standards should be achievable and cost-effective for a wide variety of facilities across the source category,” the preamble opined that it “would likely be difficult for States to demonstrate that the presumptive standards are not reasonable for the vast majority of designated facilities.” That said, the preamble nevertheless solicited comment “as to whether the Agency should include specific provisions regarding the consideration of remaining useful life and other factors in this EG that would supplement or supersede the general provisions in the implementing regulations.”

The commenter (2202-TXOGA) expresses concern that the “specific provisions” now proposed in the December 2022 supplemental proposal regarding “remaining useful life and other factors” would not so much “supplement or supersede” the approach that EPA has been taking since 1977, as it would fundamentally transform the state standard-setting process for existing sources almost beyond recognition. The commenter disagrees with EPA’s radical change in direction of embracing an entirely new view of CAA section 111(d) that seems unrelated to traditional norms

---

<sup>68</sup> EPA went on to say in its November 2021 Notice that, where states might choose to “submit a plan that includes standards of performance that are more stringent than the requirements of the final EG,” such states had “authority to do so under CAA section 116,” and that EPA had the “authority to approve such plans and render them Federally enforceable if all applicable requirements are met.” See 86 Fed. Reg. 63,251 (citing *Union Electric Co. v. EPA*, 427 U.S. 246, (1976)). There is much that is wrong with this assertion on the Agency’s part, as the commenter notes they previously explained. See TXOGA January 2022 Comments at 30-31. TXOGA incorporates those same objections here.

of statutory interpretation. The commenter recommends that EPA reconsider its new direction and revert to the historic one.

As its starting point for explaining why it is now “proposing to supersede the current 40 CFR 60.24a(c) by providing requirements specific to EG OOOOc for the consideration of RULOF in state plans to set a less stringent standard for a particular source,” the commenter (2202-TXOGA) provides that the preamble says that, “[a]s currently written, the RULOF provision in subpart Ba does not provide clear parameters for states on how and when to apply a standard less stringent than the presumptive level of stringency given in an EG to a particular source.” Without acknowledging the fact that parameters for establishing less stringent standards have been in the Agency’s rules for nearly five decades or that such fears have not been realized, the commenter notes that the proposal suggests now that the “references to reasonableness [in current subpart Ba] are potentially subject to widely differing interpretations and inconsistent application among states developing plans.” It goes on to explain that “[w]ithout a clear analytical framework for applying RULOF,” the “current provision may be used by states to set less stringent standards that could effectively undermine the overall presumptive level of stringency envisioned by the EPA’s BSER determination and render it meaningless.”

Further, the commenter (2202-TXOGA) provides that the preamble notes that “CAA section 111(d) does not require states to consider RULOF but requires that the EPA’s regulations ‘permit’ states to do so.” “In other words,” it continues, the Agency must “provide states with the ability to account for RULOF” but, at the same time, states “may instead choose to establish a standard of performance that is the same as the presumptive level of stringency set forth in the EGs.” According to the proposal, the “optionality, rather than mandate, for states to account for RULOF supports the notion that this provision is not intended to undermine the presumptive level of stringency in an EG for the source category broadly.” The commenter expresses that they do not believe that this asserted optionality-versus-mandate structure does not actually support the “notion” the preamble is asserting. The commenter notes, more confounding, is what the preamble says next: “EPA is not aware of any CAA section 111(d) EGs under which an EPA approved state plan has previously considered RULOF to apply a standard of performance that deviates from the presumptive level of stringency.” EPA expresses its hope, therefore, that the “[c]larifying parameters” for RULOF that it is proposing in the December 2022 proposal “may better enable states to effectively use this provision in developing their states plans.” In this context, the commenter states that such a statement seems illogical. If EPA is not aware of any state having ever previously employed the existing RULOF provisions to apply a standard to an existing source that “deviate[d] from the presumptive level of stringency,” then the commenter states it simply does not follow that EPA would now have a concern that “the current provision may be used by states to set less stringent standards that could effectively undermine the overall presumptive level of stringency.” In any event, the commenter contends that CAA section 111(d) does not mandate, or even authorize, an “overall presumptive level of stringency” for a class or category of sources. Instead, they believe it authorizes states to establish standards for individual existing sources based on BSER for that source.

The commenter (2202-TXOGA) states that the “clear analytical framework for applying RULOF” that the December 2022 Supplemental Notice now proposes is composed of:

- (1) “threshold requirements for consideration of RULOF,”
- (2) “adding requirements for calculating a less stringent standard accounting for RULOF,” (
- 3) “adding requirements for consideration of communities most affected by and vulnerable to the health and environmental impacts from the designated facilities being addressed,” and
- (4) “adding requirements for the types of information and evidence the states must provide to support for the invocation for RULOF in a state plan.”<sup>141</sup>

While each of these presents its own concerns, the commenter (2202-TXOGA) provides that the proposal goes even further. After acknowledging that, in its November 2021 proposal, EPA had reversed its recent position and was now proposing to take the position that “states are authorized to include in their state plans, and the EPA is authorized to approve, requirements that are more stringent than the EG under the authority of CAA section 116, as interpreted by the Court in *Union Electric v. EPA*, 27 U.S. 246 (1976),”<sup>69</sup> EPA is “now proposing that under CAA section 111(d), consistent with the authority conferred by CAA section 116, states may consider RULOF to include more stringent standards of performance in their states plans.” The commenter expresses concern that EPA is now proposing to turn CAA section 111(d) on its head, transforming the state standard-setting process into something that Congress plainly never envisioned.

#### a. Statutory and Regulatory Background on RULOF.

The preamble acknowledges that, not all that long ago, the Agency had taken the position that, “as part of the 1977 CAA Amendments ‘Congress effectively ratified the EPA’s implementing regulations’ clear construct [in 40 C.F.R. 40 CFR 60.24(f)] that remaining useful life and other factors are only relevant in the context of setting less stringent standards.” The commenter (2202-TXOGA) contends that not only does the language of 40 CFR 60.24(f)(3) (“[o]ther factors ... that make application of a less stringent standard ... more reasonable.”) provide relevant insight into Congress’s intent at the time it amended CAA section 111(d) in 1977, but it also highlights just how far afield the proposal would take the CAA section 111(d) standard-setting process. The commenter recognizes that EPA may alter statutory interpretations under applicable precedents; to do so, however, requires a sufficient explanation of such changes and that they be supportable under the statutory language and canons of statutory construction.

---

<sup>69</sup> In its November 2021 proposal, the commenter provides that the EPA had “acknowledge[d] that in the Affordable Clean Energy (ACE) rule,” promulgated in July 2019, the Agency “previously took the position that Union Electric does not control the question of whether CAA section 111(d) State plans may be more stringent than Federal requirements.” 86 Fed. Reg. at 63,251. But, said EPA, it “no longer takes this position.” Id. Rather, “[u]pon further evaluation,” the Agency said it now believed that “because of the structural similarities between CAA sections 110 and 111(d), CAA section 116 as interpreted by *Union Electric* requires the EPA to approve CAA section 111(d) State plans that are more stringent than required by the EG if the plan is otherwise in compliance with all applicable requirements.” Id. at 63,251-252. As is discussed elsewhere in their comments, the commenter believes that EPA’s new view of *Union Electric* is misplaced.

As the preamble points out, the “1970 version of CAA section 111(d) made no reference to the consideration of RULOF in the context of standards for existing sources.” While this is true, the commenter (2202-TXOGA) contends that the preamble omits another significant point. Not only did CAA section 111(d), as originally enacted in 1970, contain no mention of states being allowed, in setting “standards,” to “take into consideration, among other factors, the remaining useful life of the existing source to which such standard applies” – the so-called RULOF provision would be added by Congress in 1977 – the “standards” to which CAA section 111(d) referred in 1970 were not “standards of performance” (as that term is defined in CAA Section 111(a)(1)) but, rather, “emission standards.”<sup>70</sup> The commenter reports that Congress did not initially connect the setting of standards for existing sources under CAA section 111(d) to the process by which “standards of performance” are derived (i.e., pursuant to CAA section 111(a)(1)) through the Administrator’s determining the “best system of emission reduction” for the category of sources in question. That connection was first made by EPA itself, in 1975, when it promulgated implementing rules under CAA section 111(d).<sup>71</sup>

The commenter (2202-TXOGA) points out that the stated rationale at the time of adoption for taking this approach, which was not self-evident on the face of CAA section 111(d) as originally enacted, is instructive. After examining the legislative history of what would become CAA section 111(d), the Agency concluded that what Congress intended was that “control of such [i.e., “designated”] pollutants on some basis was necessary,” that, “given the relative lack of information on their health and welfare effects, a technology-based approach (similar to that for new sources) would be more feasible than one involving an attempt to set standards tied specifically to protection of health,” and finally, that “the technology-based approach (making allowances for the costs of controlling existing sources) was a reasonable means of attacking the

---

<sup>70</sup> See CAA section 111(d)(1); 42 U.S.C. § 1857c-6(d)(1) (1970) (“The Administrator shall prescribe regulations which shall establish a procedure similar to that provided by section 1857c-5 of this title [i.e., CAA § 110] under which each State shall submit to the Administrator a plan which . . . establishes emission standards for any existing source of air pollution . . .” (emphasis added)). The generic term “emission standard,” while used throughout the CAA as it was first enacted in 1970, was not specifically defined in the CAA until the CAA Amendments of 1977. See CAA section 302(k); 42 U.S.C. § 7602(k).

<sup>71</sup> Specifically, the commenter provides that the implementing rules first adopted by EPA in 1975 directed that EPA, in publishing guideline documents, was to include an “emission guideline that reflects the best system of emission reduction (considering the cost of such reduction) that has been adequately demonstrated for designated facilities . . .” 40 Fed. Reg. at 53,346 (Nov. 17, 1975). Thus, the terminology employed by EPA here found its origin in the definition of “standard of performance” as that term was first defined in 1970. See CAA section 111(a)(1); 42 U.S.C. § 1857c-6 (“The term ‘standard of performance’ means a standard for emissions of air pollutants which reflects the degree of emission reduction which (considering the cost of achieving such reduction) the Administrator determines has been adequately demonstrated.”). Notably, the definition of “standard of performance” would later be quite significantly amended by the CAA Amendments of 1977 to mean, as relevant here: “. . . (C) with respect to any air pollutant emitted from a particular source to which subsection (d) of this section applies, a standard which the State (or the Administrator under the conditions specified in subsection (d)(2) of this section) determines is applicable to that source and which reflects the degree of emission reduction achievable through the application of the best system of continuous emission reduction which (taking into consideration the cost of achieving such emission reduction, and any non-air quality health and environmental impact and energy requirements) the Administrator determines has been adequately demonstrated for that category of sources.” CAA section 111(a)(1)(C); 42 U.S.C. § 7411(a)(1)(C) (1977). The definition of “standard of performance” would again be significantly amended by the CAA Amendments of 1990 – for reasons not relevant to the issues relevant here – with those changes mostly returning the definition to the wording first used by Congress in 1970, but retaining the expanded language of the parenthetical clause – i.e., “. . . (taking into account the cost of achieving such reduction and any non-air quality health and environmental impact and energy requirements).

problem until more definitive information became known.”<sup>72</sup> In short, the commenter notes that the Agency believed that the congressional conferees had chosen to rewrite what had originally been section 114 “as part of section 111 largely because they intended the technology based approach of that section to extend (*making allowances for the costs of controlling existing sources*) to action under section 111(d).”<sup>73</sup>

Elsewhere in the preamble to the 1975 rules, taking note of the fact that “[m]any commentators” had “apparently confused the degree of control to be reflected in EPA’s EGs under section 111(d) with that to be required by corresponding standards of performance for new sources under section 111(b),” the Agency observed that, “[a]lthough the general principle (application of best adequately demonstrated control technology, considering costs) will be the same in both cases, the degrees of control represented by EPA’s emission guidelines will ordinarily be less stringent than those required by standards of performance for new sources because the costs of controlling existing sources will ordinarily be greater than those for control of new sources.”<sup>74</sup> The commenter (2202-TXOGA) asserts, while not explicitly stated, what EPA was referencing here was the fundamental concept that deriving a standard of performance for a category of new sources, through the ascertainment of the “best system of emission reduction” that can be incorporated at the outset into the design of new sources, involves different considerations than deriving an otherwise equivalent standard of performance for existing sources because any such “best system” would invariably require a more costly retrofit of control technology and may not even be technically feasible.<sup>75</sup> It was this very difference that provided the basis for EPA’s having incorporated into the 1975 rule what was then referred to as the “variance” provision.

As before, the commenter (2202-TXOGA) observes that the preamble discussion from 1975 sheds light on what EPA then had in mind. In rejecting one commenter’s assertion that “neither the letter nor the intent of section 111 allows variances from plan requirements based on application of best adequately demonstrated control systems,” EPA observed that, “[a]lthough section 111(d) does not explicitly provide for variances,” it nevertheless does require consideration of the cost of applying standards to existing facilities.”<sup>76</sup> Moreover, EPA continued, “[s]uch a consideration is inherently different than for new sources, because controls cannot be included in the design of an existing facility and because physical limitations may

---

<sup>72</sup> 40 Fed. Reg. at 53,342 (emphasis added). This approach was all the more reasonable, EPA added, given that, under CAA section 116, states retained any authority they might otherwise have, as a matter of state law, to “adopt more stringent standards if they believed additional control was desirable.” Id. Notably, while subsection (g) of 40 CFR 60.24 provided that “[n]othing in this subpart shall be construed to preclude any State or political subdivision thereof from adopting or enforcing . . . emission standards more stringent than emission guidelines specified in subpart C of this part or in applicable guideline documents,” nowhere in either the rules themselves or in the 1975 preamble discussion did EPA suggest that more stringent requirements, adopted under state law, would be approved (or could be approved) as part of a state’s CAA section 111(d) and thereby become federally enforceable. As is discussed elsewhere in these comments, EPA’s current understanding of the scope and effect of CAA section 116 appears to the commenter (2202-TXOGA) to be somewhat flawed.

<sup>73</sup> 40 Fed. Reg. at 53,342 (emphasis added).

<sup>74</sup> Id. at 53,341.

<sup>75</sup> Cf. *Portland Cement Ass’n v. EPA, v. Ruckelshaus*, 486 F.2d at 391, as discussed supra.

<sup>76</sup> 40 Fed. Reg. at 53,344 (emphasis added).

make installation of particular control systems impossible or unreasonably expensive in some cases.”<sup>77</sup>

Thus, from the outset, in considering the congressional intent underlying CAA section 111(d), the commenter (2202-TXOGA) believes that EPA understood that the establishment and application of technology-based standards for existing sources – which, by definition, are afforded no opportunity to design in any “best system of emission reduction”– involved inherently different considerations than those that apply to new sources. Indeed, the commenter states that the EPA went so far as to assert that CAA section 111(d) itself required that such different considerations be accounted for, even though, as the text of the subsection read upon its original enactment in 1970, it actually said nothing in this regard – i.e., subsection (d) made no mention of “costs” nor, as has been noted, did it then contain what became the so-called RULOF considerations.

#### b. The 2022 New Interpretation.

The new December 2022 supplemental proposal is that “under CAA section 111(d), consistent with the authority conferred by CAA section 116, states may consider RULOF to include more stringent standards of performance in their state plans.” The preamble acknowledges, and the commenter (2202-TXOGA) agrees, that this represents an abrupt and significant departure from a decades-long approach to implementing CAA section 111(d). The commenter notes that the EPA recognizes that, in conducting the recent rulemaking to establish the current RULOF provision found at 40 CFR 60.24a(e), which “governs instances where states seek to apply a less stringent standard of performance to a designated facility,” the Agency had received “comments contending that if states may consider factors that justify less stringent standards,” states must “also be permitted to consider factors that would justify greater stringency than required by an EG, such as more expeditious compliance obligations or the retirement of a source.”<sup>78</sup> “In response to these comments,” EPA further admits, it had explained then that the Agency “interpreted the statutory RULOF provision as intended to authorize only standards of performance that are less stringent than the presumptive level of stringency required by a particular EG.”

The commenter (2202-TXOGA) states EPA now says that it has reevaluated its prior interpretation – i.e., the one to which it adhered for decades and which it had reinforced only a few years ago – and is “now proposing,” for purposes of EG OOOOc at least, to “interpret that the statute authorizes the EPA to permit states to consider other factors that justify application of a more stringent standard to a particular source than required by an EG.” Surprisingly, the commenter notes that the preamble states that EPA has newly found ambiguity in the language of CAA section 111(d). Specifically, having reviewed the phrase “... take into consideration, among other factors, the remaining useful life,” EPA has now determined that, “[a]side from the explicit reference to remaining useful life,” CAA section 111(d) is “silent as to what the ‘other factors’ are that states may consider in applying a standard of performance.”

---

<sup>77</sup> Id.

<sup>78</sup> 87 Fed. Reg. citing EPA’s Responses to Public Comments on the EPA’s Proposed Revisions to Emission Guideline Implementing Regulations at 56 (Docket ID No. EPA–HQ–OAR–2017–0355–26740) (July 8, 2019).

In particular, the commenter (2202-TXOGA) adds that the EPA finds, CAA section 111(d) is actually “silent as to whether the ‘standard of performance’ to be ‘appl[ied]’ to a ‘particular source’ must be a weaker or stronger standard.” Under the new reading of the statutory text, the “only inference that can be drawn from the statutory language is that RULOF may be used to apply a different standard.” Therefore, EPA says, it may “reasonably interpret this ambiguity both as to what the ‘other factors’ are that states may use to apply a standard of performance to a particular source,” and “how such consideration may affect the stringency of such standard.” And it does so notwithstanding its prior statements that Congress had ratified EPA’s previous interpretation that such factors are only relevant in so far as they may support relaxing a standard. EPA proposes that this new interpretation is “reasonable,” suggesting that “if Congress intended the RULOF provision to be used only to allow states to apply less stringent standards,” then Congress would have “clearly specified that its intent” or else “enumerated ‘other factors’ that are appropriate for relaxing the stringency of a standard.”

The commenter (2202-TXOGA) provides that EPA acknowledges that it recently “reasoned that because the variance provision under subpart B is similar to and predated Congress’s addition to CAA section 111(d) as part of the 1977 CAA Amendments,” “Congress [had] effectively ratified the EPA’s implementing regulations’ clear construct that remaining useful life and other factors are relevant only in the context of setting less stringent standards.”<sup>79</sup> But now, the preamble asserts that EPA has “closely reexamined the variance provision in subpart B and the RULOF provision under CAA section 111(d),” such that it can no longer find any indication that “these provisions support the proposition that Congress clearly ratified the aspect of the variance provision in subpart B allowing states to apply only less stringent standards under certain circumstances.”

EPA bases its new position on a number of things that the Agency says this more recent “close reexamination” has raised in its consciousness. Individually, none of the points EPA makes here has much, if any, force, and they shrivel in the light cast by the contemporary interpretation that EPA advanced when it first promulgated rules to implement CAA section 111(d) and, in the course of doing so, first undertook to examine the congressional intent underlying that statutory program. Collectively, the commenter (2202-TXOGA) asserts that EPA’s points do not support the radical reimagining of CAA section 111(d) that the Agency is now proposing.

For example, the commenter (2202-TXOGA) states that now that it has undertaken its “close reexamination,” EPA says that it has come to realize (again, for the first time), that there are “notable differences between the subpart B variance provision that indicate Congress did not intend to incorporate and ratify all aspects of the EPA’s approach regulatory when amending CAA Section 111(d) in 1977.” Specifically, EPA says, for those designated pollutants “found to cause or contribute to endangerment of public health,” 40 C.F.R. Part 60, Subpart B as it currently reads (and as it was initially promulgated), “allows states to apply a less stringent standard under certain circumstances,” unless “EPA provides otherwise in a specific EG for a particular designated facility or class of facilities.” But, EPA continues, “subpart B places no similar exception for states in authorizing them to seek a variance for a standard addressing a pollutant for which the EPA has made a welfare-based, but not [a] public health-based,

---

<sup>79</sup> 87 Fed. Reg. quoting EPA’s Responses to Public Comments on the EPA’s Proposed Revisions to Emission Guideline Implementing Regulations at 57 (Docket ID No. EPA-HQ-OAR-2017-0355-26740 (July 8, 2019)).

endangerment finding under 111(b)(1)(A).” The preamble states that this is significant because the “statutory RULOF provision does not make a similar distinction between public health and welfare-based pollutants.” This is what the proposal cites as indicating one “cannot clearly ascertain whether the statutory RULOF provision” actually “ratified the variance provision under subpart B” at all, “given that certain key elements of the latter are not present in the former.” It goes on to conclude that “[t]here is nothing in CAA section 111(d) or the legislative history that suggests that Congress enacted the statutory RULOF provision by ratifying certain elements of the regulatory variance provision in subpart B but not others.”

According to the commenter (2202-TXOGA), this effort to change positions and thereby walk away from the view that Congress plainly had in mind the regulatory variance provision, first adopted by EPA in 1975, when it amended CAA section 111(d) in 1977 to include what EPA now terms the statutory RULOF provision, is hard to reconcile with the timing and the facts, particularly given that Congress is presumed to be aware of such things when enacting legislation against a regulatory backdrop such as this. They add that it amounts to an assertion that, unless it can be said that Congress adopted the regulatory program in its entirety (i.e., more or less provision-by-provision, word-for-word) in incorporating into the statute the pre-existing regulatory program, there is simply no way of knowing what Congress may have intended and no possibility of ascertaining just where Congress got the idea of the RULOF provision in the first place. As noted, the commenter asserts that assuming an ambiguity in such a case is not consistent with regulatory or case precedent.

If anything, the commenter (2202-TXOGA) believes that the particular example EPA cites to shows a distinction between the regulatory variance provision promulgated in 1975 and the statutory RULOF provision Congress adopted in 1977, arguably cuts against the claim that congressional intent here is unknowable. Under the CAA section 111(d) implementing rules first adopted in 1975, the commenter provides that the variance provision of paragraph (f) only allowed states to establish less stringent standards for sources emitting “health-related” designated pollutants because only those sources were subject to the EPA guideline standards in paragraph (c). Welfare related emitters were not subject to guideline standards, but to the standards developed by a state balancing various factors.<sup>80</sup> In 1977, Congress eliminated the distinction between regulation of health-related emissions and regulation of welfare related emissions. The 1977 amendment subjected all designated sources – not just health related emitters – to the guideline standards and allowed states to relax those standards based on “remaining useful life” considerations like those listed in subparagraph (f) of the 1975 rule.

Next, the commenter (2202-TXOGA) states that the EPA revisits the legislative history of CAA section 111(d) but does so against the backdrop of the last rulemaking that considered the legislative history, i.e., its July 2019 Subpart Ba rulemaking. There, EPA had “asserted that the legislative history of the 1977 CAA Amendments supported its [then] interpretation” that “states may only consider RULOF to apply a less stringent standard.” EPA had taken note of the following statement from the House conference report adopting the amendment to add the statutory RULOF provision: “The section also makes clear that standards adopted for existing sources under section 111(d) of the Act are to be based on available means of emission control (not necessarily technological) and must, unless the state decides to be more stringent, take into

---

<sup>80</sup> 40 CFR 60.24(d).

account the remaining useful life of the existing sources.”<sup>81</sup> EPA acknowledges that, from this, the Agency had previously reasoned that the “caveat that states have the choice to not invoke the RULOF provision and instead ‘be more stringent’ suggests that considering RULOF is only intended to allow a state to make a standard less stringent.”

But now, the commenter (2202-TXOGA) notes that the EPA says, it “finds that its prior reliance on this legislative history was flawed.” Yes, EPA concedes, the cited statement’s reference to “remaining useful life” speaks to a “factor that inherently suggests a less stringent standard.” At the same time, however, EPA goes on to allege, this bit of legislative history is “completely silent as to the ‘other factors’ the statute references.” Thus, as EPA would now have it, “there is no indication that Congress intended to limit the ‘other factors’ that states may apply in developing their plans only to permit less stringent, and not also more stringent standards.” If anything, EPA adds, the “cited statement explicitly acknowledges that states may choose to ‘be more stringent’, which,” as the Agency now construes it, “supports the EPA’s interpretation of the statute to permit states to consider other factors to set standards more stringent than the degree of emission limitation achievable through application of the BSER.”

The commenter (2202-TXOGA) disagrees and finds there is much that is wrong here. First, the commenter finds strained the analysis involved with EPA’s having first decided, upon reconsideration, that the RULOF provision’s reference to “other factors” is ambiguous, and then its construing the fact of there being no overt discussion of “other factors” in the legislative history as confirming that point.<sup>82</sup> It cannot reasonably be disputed that Congress had in view EPA’s 1975 implementing rules when it amended CAA section 111(d) in 1977.

The commenter (2202-TXOGA) asserts that all of the changes which Congress made to the provision at that time speak to this reality – i.e., the change in the wording of CAA section 111(d)(1)(A) and (1)(B) from “emission standards” to “standards of performance,” which was based on EPA’s own decision to base the development of EGs on a standard that reflected the “best system of emission reduction” (see 40 CFR 60.22(b)(5)); the inclusion of the final sentence

---

<sup>81</sup> 87 Fed. Reg. at 74,826 quoting H.R. Conf. Rep. No. 94-1742, (Sep. 30, 1976), 1977 Legis. Hist. at 88. The House conference report’s parenthetical reference here to “available means of emission control (not necessarily technological)” is significant, as it indicates that the conferees clearly had in mind here the extensive changes that the 1977 CAA Amendments would also be making to the definition of “standard of performance” in CAA section 111(a)(1), as was noted above. The point is, the 1977 CAA Amendments would revise the definition of “standard of performance,” as applicable to new sources under CAA section 111(b) but not to existing source under CAA section 111(d), to require, among other things, that a “standard of performance . . . reflect the degree of emission limitation and the percentage reduction achievable through the application of the best technological system of continuous emission reduction . . . .” See CAA section 111(a)(1); 42 U.S.C. § 7411(a)(1) (1977). As noted previously, changes made to the definition of “standard of performance” by the CAA Amendments of 1990 would largely strip away the extensive textual changes wrought by the 1977 CAA Amendments. But what this shows is that, in 1977, the House conferees considering the changes then being proposed to CAA § 111(d) must have also been aware that the definition of “standard of performance” would be changed to expand the parenthetical clause “. . . (taking into account the cost of achieving such reduction) . . . .” to read “. . . (taking into consideration the cost of achieving such emission reduction, and any non-air quality health and environmental impact and energy requirements) . . . .” The significance of this is discussed *infra*.

<sup>82</sup> This is a questionable way to interpret a statute in any event. *Cf. Railway Labor Exec. Ass’n v. National Mediation Bd.*, 29 F.3d 655, 671 (D.C. Cir. 1994) (“Were courts to presume a delegation of power absent an express withholding of such power, agencies would enjoy virtually limitless hegemony, a result plainly out of keeping with Chevron and quite likely with the Constitution as well.”)

in CAA section 111(d)(1), setting forth the RULOF provision, which was based on EPA's having adopted as part of its 1975 implementing rules a "variance" procedure, under which states could provide (but were not obligated to provide) for the "application of less stringent emission standards" (see 40 CFR 60.24(f)); and the last sentence of CAA section 111(d)(2), providing that, when EPA itself is "promulgating a standard of performance" in the case of a state's default, EPA "shall take into consideration, among other factors, remaining useful lives of the sources in the category of sources to which such standard applies," which was derived from the provision in the 1975 rules whereby "upon application by the owner or operator of a designated facility to which regulations proposed and promulgated under this section will apply," EPA was authorized to "provide for the application of less stringent emission standards . . . than those otherwise required by this section in accordance with the criteria specified" in the variance provisions of § 60.24(f)" (see 40 CFR 60.27(e)(2)).

In other words, the commenter (2202-TXOGA) states that *every* change that Congress made to CAA section 111(d) in 1977 can be traced directly back to specific provisions within the implementing rules that EPA had promulgated just two years earlier.

The commenter (2202-TXOGA) points out that the phrase "other factors" is itself derived from the variance provision in the 1975 implementing rules, which warrants being set out in its entirety here:

(f) On a case-by-case basis for particular designated facilities, or classes of facilities, States may provide for the application of less stringent emission standards or longer compliance schedules than those otherwise required by paragraph (c) of this section, provided that the [s]tate demonstrates with respect to each such facility (or class of facility):

(1) Unreasonable cost of control resulting from plant age, location, or basic process design;

(2) Physical impossibility of installing necessary control equipment; or

(3) *Other factors* specific to the facility or class of facility that makes application of a *less stringent standard* or final compliance time significantly more reasonable.

40 CFR 60.24(f)(1)-(3) (1975) (emphases added).

Considering this, the commenter (2202-TXOGA) disagrees with EPA's contention that there is "no indication that Congress intended to limit the 'other factors' that states may apply in developing their plans only to permit less stringent, and not also more stringent standards". The commenter questions that if the reference to "among other factors" in CAA section 111(d) was not originally a reference back to EPA's own invocation of the term in its 1975 implementing rules, just where did the language come from.

According to the commenter (2202-TXOGA), equally strained is the assertion that this new interpretation is supported by the reference in the House conference report that "standards

adopted for existing source under section 111(d) . . . must . . . take into account the remaining useful life” of a given existing source “unless the state decides to be more stringent.” Far from being an “explicit[] acknowledge[ment],” as EPA would now have it, that “states may choose to ‘be more stringent’ when accounting for RULOF in applying a standard of performance to an existing facility, the reference is to the fact that, as CAA section 116 makes clear, a state is not precluded from setting a more stringent standard, as a matter of state law, should it so choose. The commenter asserts that the statement has nothing to do with RULOF. Here again, the commenter believes that the House conference report was almost certainly taking its cue from the provisions of the 1975 implementing rules, which in 1975 expressly provided that “[n]othing in his subpart shall be construed to preclude any [s]tate or political subdivision thereof from adopting or enforcing . . . emission standards more stringent than emission guidelines specified in subpart C of this part or in applicable emission guidelines.”<sup>83</sup>

c. Proposal’s New View of “Other Factors” and the “Consideration of Impacted Communities.”

Having divorced CAA section 111(d)’s use of the term “other factors” from its original statutory context, and having disavowed its own historical understanding of the term as set forth in its own implementing rules, the commenter (2202-TXOGA) believes that the proposed rule’s rationale lands at the place where it is prepared to argue that, because “CAA section 111(d) does not specify what are the “other factors” that the EPA’s regulations should permit a state to consider in applying a standard of performance,” the Agency is thereby afforded open-ended discretion to “identify the appropriate factors and conditions under which the circumstances may be reasonably invoked in establishing a standard less stringent than the EG.” Moreover, it contends, since “CAA section 111(d)(2)’s requirement that the EPA determine whether a state plan is ‘satisfactory’ applies to such plan’s consideration of RULOF in applying a standard of performance to a particular facility,” the Agency “must determine whether a plan’s consideration of RULOF is consistent with section 111(d)’s overall health and welfare objectives.”

The commenter (2202-TXOGA) asserts that the December 2022 proposal advances a significantly new view of what the consideration of “other factors” may entail. As the December 2022 proposal goes on to explain, “[w]hile the consideration of RULOF can be warranted to apply a less stringent standard of performance to a particular facility,” such standards “have the potential to result in disparate health and environmental impacts to communities most affected by and vulnerable to impacts from the designated facilities being addressed by the state plan.” As described, “[t]hose communities could be put in the position of bearing the brunt of the greater health and environmental impacts resulting from that source implementing less stringent emission controls than would otherwise have been required pursuant to the EG.” Finding that a

---

<sup>83</sup> 40 CFR 60.24(g); 40 Fed. Reg. at 53,347. As originally proposed, the implementing rule had provided that states “shall provide for a review of such facility for the purpose of applying less stringent emission standards.” See 39 Fed. Reg. at 36,104 (Oct. 7, 1974). In the final rule, EPA explained that “[s]everal commentators urged that proposed 40 CFR 60.23(e) [now 40 CFR 60.24(f)] be amended to indicate that States are not required to consider applications for variances if they do not feel it appropriate to do so.” 40 Fed. Reg. at 53,344 (emphasis added). EPA agreed with these commenters’ concerns and added that, “[i]n addition, there is some question whether the mandatory review provision as proposed would be consistent with section 116 of the Act, which makes clear that States are free to adopt and enforce standards more stringent than Federal standards.” Id. (emphasis added). “Accordingly,” EPA explained, the “proposed wording has been amended to permit, but not require, State review of facilities for the purpose of applying less stringent standards.” Id.

“lack of consideration to such potential outcomes would be antithetical to the public health and welfare goals of CAA section 111(d) and the CAA generally,” EPA proposes as a requirement in EG OOOOc that states “consider such impacts when applying the RULOF provision to establish” a less stringent standards.

That is to say, the commenter (2202-TXOGA) states that the December 2022 proposal is “to require that, to the extent a designated facility would qualify for a less stringent through consideration of RULOF,” the state, “in calculating such standard,” must “consider the potential health and environmental impacts on communities most affected by and vulnerable to the impacts from the designated facility considered in a state plan for RULOF provisions.” Further, EPA says, in describing this proposal, “state plan submissions seeking to invoke RULOF for a source must identify where and how a less stringent standard impacts these communities.” “In evaluating a RULOF option for a facility,” the Agency continues, “states should describe the health and environmental impacts anticipated from the application of RULOF for such communities,” along with “any feedback the state received during meaningful engagement regarding its draft state plan submission,” including on “any standards of performance that consider RULOF.” Finally, “to the extent that there is a range of options for reasonably controlling a source based on RULOF,” the December 2022 proposal specifies that, in “determining the appropriate standard of performance,” states “should consider the health and environmental benefits to the communities most affected by and vulnerable to the impacts from the designated facility considered in a state plan for RULOF provisions,” and also “provide in the state plan submission a summary of the results that depicts the impacts to those communities.” According to EPA, this “requirement to consider the health and environmental impacts in any standard of performance taking into account RULOF” is “consistent with the definition of ‘standard of performance’ in CAA section 111(a)(1).” As EPA now sees it, “[t]his definition requires the EPA to take into account health and environmental impacts in determining the BSER.” As a consequence, EPA concludes, “state plans must consider health and environmental impacts in determining a source specific BSER informing a RULOF standard,” just as “EPA is statutorily required to take into account these factors in making its BSER determination.”

The commenter (2202-TXOGA) notes that this is a new interpretation of the statute. As the commenter explains below, BSER is a technology-based standard, meaning that EPA is not statutorily required to consider “health and environmental impacts” in determining the BSER for new sources. According to the commenter, Congress did this on purpose because it was establishing minimum technology standards, without regard to air quality classification (attainment/nonattainment) or other factors. To the contrary, CAA section 111(a)(1) sets forth in unambiguous terms how EPA is to go about ascertaining BSER, and accounting for “health and environmental impacts,” as the Agency now contends, while important in other statutory contexts, is not part of that equation here. The commenter agrees because of the purposes of the NSPS program. Thus, it is simply not required for EPA to take these non-BSER factors into account, and because EPA is not required to do so, the commenter asserts that it cannot impose such a requirement on states in establishing their BSER utilizing RULOF.

Returning to first principles here, the commenter (2202-TXOGA) provides that the term standard of performance is defined in CAA section 111(a) as the “best system” of “emission reduction”

that EPA has determined is “adequately demonstrated.” In establishing BSER, the statute provides that EPA must “tak[e] into account” three, and only three, factors related to the system of emission reduction: “the cost of achieving such reduction,” “any non-air quality health and environmental impact,” and “energy requirements.”<sup>84</sup> Under CAA section 111(d), in establishing guidelines for performance standards under state implementation plans, EPA must identify BSER performance standards for classes and types of existing sources, considering the three control system factors identified in CAA section 111(a). States may establish standards less stringent than the presumptive performance standards in EPA guidelines based on consideration of an additional express factor: “remaining useful life.” Finally, EPA must promulgate an existing source performance standard if a state plan is deficient. In establishing that standard, EPA must “take into consideration . . . remaining useful life.” This “useful life” factor (which is unique to existing sources) must be considered “among [the] other factors” relevant to determining BSER. As was noted, in the proposal, EPA views the reference to “other factors” in CAA section 111(d) “as providing discretion for the EPA to identify . . . [additional] appropriate factors” that will govern a state’s establishment of CAA section 111(d) performance standards. EPA premises this conclusion on the assertion that “the statute is silent as to what the ‘other factors’ are that states may consider in applying a standard of performance.” Under this view of the reference to “other factors” in CAA section 111(d), EPA proposes to expand the factors governing standard setting to include consideration of an air quality health or environmental effects of the emissions from existing source, and to use that factor to preclude less stringent standards otherwise justified by application of the “remaining useful life” factor. As has already been noted, the reference to “other factors,” according to EPA, also allows the Agency to authorize states to create new decisional factors that can be used to “set” federally enforceable standards that are “more stringent than the degree of emission limitation achievable through application of the BSER.”<sup>85</sup>

The commenter (2202-TXOGA) contends that it is not accurate to assert that CAA section 111 is “silent” regarding the “other factors” referenced in section 111(d). As noted above, EPA had in the original variance provision in its 1975 implementing rules made explicit reference to “other factors,” while at the same time using language that limited those to factors that “make application of less stringent standard . . . significantly more reasonable,” and Congress certainly had EPA’s rules in view when it amended CAA section 111(d). Further, the commenter adds that

---

<sup>84</sup> As has been noted, while the definition of “standard of performance” in CAA section 111(a)(1), as originally enacted in 1970, identified only one such factor – i.e., “the cost of achieving such reduction” – the CAA Amendments of 1977 expanded the statutory listing to the aforementioned three: i.e., “the cost of achieving such emission reduction, and any non-air quality health and environmental impact and energy requirements.” Furthermore, as has also been explained, the changes made to the definition of “standard of performance” in the 1977 CAA Amendments were also in view of the House conferees considering the changes being made in 1977 to CAA section 111(d).

<sup>85</sup> 87 Fed. Reg. at 74,826. EPA’s selection of BSER in CAA section 111(d) guidance must be consistent with the CAA section 111 decisional criteria, and the guidance will be set aside by a court under CAA section 307(b) where EPA did not observe the statutory limits on BSER. Under EPA’s interpretation of “other factors,” EPA could approve, and make federally enforceable in civil and criminal proceedings, state standards that are not consistent with the statutory limits on BSER standards. In other words, EPA could “federalize” state standards that EPA could not recommend in its CAA section 111(d) guidelines or promulgate for a state under CAA section 111(d)(2). The commenter note that they had previously explained why such an outcome is impermissible. See TXOGA January 2022 Comments at 28-31. It reiterates its position here.

the very definition of “standard of performance” in CAA section 111(a)(1) speaks meaningfully to this issue.

As set forth in CAA Section 111(a)(1), the commenter (2202-TXOGA) specifies that three statutory control system factors are limited, by their terms, to the “costs,” “non-air quality health and environmental effects,” and “energy requirements” of control systems. The commenter notes that nowhere are the “air quality” effects of emissions from a source mentioned. The “air quality” health and environmental effects of source emissions are not a relevant factor under CAA section 111, nor are any additional new factors that may be created by states to justify more stringent standards.

In sum, the commenter (2202-TXOGA) argues that the EPA should not interpret the CAA to delegate to EPA, and to the states, the authority to expand the factors relevant to establishing performance standards, allowing states to adopt, and EPA to approve, federally enforceable standards that are not based on BSER but upon other factors not listed in the statute. The concern is that this would create an open-ended delegation to create new decisional factors, and EPA recognizes that it “cannot anticipate each and every [new] factor” that a state might choose to use in setting more stringent federally enforceable standards. The commenter states that the reference to “other factors” in CAA section 111(d) is not, however, an open-ended delegation for EPA to impose on the states additional “air quality” based decisional factors, or to authorize the states to add decisional factors in setting CAA section 111(d) standards that EPA may approve as federally enforceable standards. The “other factors” are those that Congress listed in CAA section 111(a)(1).

The commenter (2202-TXOGA) expresses serious concerns with EPA’s proposed interpretation. Congress routinely delegates rulemaking powers to federal agencies under the direction of specific statutes. The commenter asserts that rulemaking delegations do not violate the Constitution’s requirement that “[a]ll legislative powers here in granted shall be vested in a Congress,” as long as Congress defines the nature and scope of the delegation.<sup>86</sup> CAA section 111 provides specific statutory criteria for establishing BSER performance standards in CAA section 111(a) and (d). Specifically, the commenter provides that a standard must be “achievable” with “demonstrated” systems selected after “taking into account” the three control system factors. These criteria constrain EPA’s exercise of discretion in promulgating regulations under both CAA section 111(b) and CAA section 111(d). Yet, under EPA’s new interpretation, the commenter notes that the EPA is claiming the authority to impose on states new “air quality” decisional criteria focused on facility emissions, and to authorize states to develop decisional criteria that may be used to establish federally enforceable standards more stringent than BSER. The commenter (2202-TXOGA) asserts that EPA lacks the discretion it claims, as illustrated by *Union Electric Co. v. EPA*,<sup>87</sup> where the Supreme Court rejected petitioners’ claim that EPA must consider economic or technical infeasibility factors in approving state implementation plans under CAA section 110 of the Act. Citing the eight factors set out in CAA section 110, governing states implementation plans, none of which included consideration of economic and

---

<sup>86</sup> U.S. Const., art. I, § 1; see *Touby v. United States*, 500 U.S. 160, 165 (1991) (“So long as Congress ‘lay[s] down by legislative act an intelligible principle to which the person or body authorized to [act] is directed to conform, such legislative action is not a forbidden delegation of legislative power.’”).

<sup>87</sup> 427 U.S. 246 (1976).

technical feasibility, the Court held that EPA had no authority to depart from the statute's terms and consider additional factors.<sup>88</sup>

The commenter (2202-TXOGA) notes that “all legislative powers” in the federal government are vested in Congress. They point out that Congress’ authority to make federally enforceable law therefore may not be delegated unless the delegation is circumscribed by congressionally stated criteria. The commenter contends that an interpretation of CAA section 111(d) that Congress authorized the Agency to expand the decisional factors governing performance standard setting without any statutory guidance and that Congress also allowed EPA to approve more stringent state standards that are based on consideration of factors found nowhere in the statute, would violate separation of powers and the nondelegation doctrine. According to the commenter, allowing an agency to create civil and criminal liability for creation of standards untethered to congressional guidance would raise serious due process problems. Cf. *Touby*, 500 U.S. at 165-66 (suggesting the possibility that “something more than an ‘intelligible principle’” may be required where (as in CAA Section 112) “Congress authorizes another Branch to promulgate regulations that contemplate criminal sanctions.”).

Finally, the commenter (2202-TXOGA) states that it seems worth noting that EPA’s decision to propose this new view of “other factors” in the specific context of proposed EG OOOG is anomalous in and of itself. Early on, EPA had said that, in order to address what it termed the absence of “clear parameters for states on how and when to apply a standard less stringent than the presumptive level of stringency given in an EG to a particular source,” the Agency was “intend[ing] to propose clarifying revisions to this provision [i.e., 40 CFR 60.24a(e)] under the implementing regulations in an upcoming rulemaking that would apply generally to new EG promulgated under CAA section 111(d).” The commenter would have expected EPA to wait to introduce this proposed new view of “other factors” then, in that broader rulemaking.

The final Subpart Ba is published at 88 FR 80480 (November 17, 2023).

#### 19.3.1.1 Proposed Requirements for Setting Emissions Standards Based on RULOF

Comment: Commenter (2428-API) disagrees with components of EPA’s proposed requirements when a state considers setting emission standards. EPA explains that when a state decides to establish a standard of performance based on consideration of remaining useful life and other factors, it must “determine and include, as part of the plan submission, a source specific BSER for the designated facility” . EPA then prescribes criteria that the state must follow in determining BSER and setting a corresponding emissions standard. The commenter (2428-API) believes that this is the first time in this rulemaking (and, to our knowledge, the first time ever) that EPA has interpreted the statute as authorizing and requiring a state to conduct a BSER

---

<sup>88</sup> Id. at 265.

analysis under CAA section 111(d) rather than setting standards of performance based on an EPA BSER determination.

The commenter (2428-API) agrees with EPA that, when a state considers RULOF in setting emissions standards for a particular source or group of sources, it necessarily must conduct a BSER analysis as part of its analysis. The commenter acknowledges that when a state considers RULOF, EPA's own BSER analysis ceases to have meaning because fundamental elements of that analysis – such as the cost assessment and determination that a particular emissions control method is feasible or has been adequately demonstrated – cease to apply to the source(s) covered by the state RULOF analysis.

EPA asserts that “the statute requires the EPA to determine the BSER by considering control methods that it considers to be adequately demonstrated, and then determining which are the best systems by evaluating: (1) The cost of achieving such reduction, (2) any non-air quality health and environmental impacts, (3) energy requirements, (4) the amount of reductions, and (5) advancement of technology” and that “a state must also consider all these factors in applying RULOF for that source.” The commenter (2428-API) agrees that the statute requires the first three criteria to be considered in determining BSER. The commenter agrees that application of these criteria is consistent with the principle that state CAA section 111(d) plans must meet the statutory standard setting criteria. However, the commenter does not agree that the statute specifies or requires that BSER also must be based on an assessment of “the amount of reductions” or “advancement of technology.” The commenter asserts that a state has the discretion to consider these factors, but EPA cannot impose these factors on a state because the statute itself does not require that they be considered.

EPA goes on to assert that a state BSER analysis “must identify all control technologies available for the source and evaluate the BSER factors for each technology, using the same metrics and evaluating them in the same manner as the EPA did in developing the EG using the five criteria noted above.” The commenter (2428-API) disagrees. The commenter states that the state clearly must determine BSER based on the express statutory criteria but argues that the law does not require a state BSER analysis to “identify all control technologies available for the source,” “use the same metrics,” or provide an evaluation “in the same manner” as EPA used in developing its BSER analysis. The commenter asserts that nothing in the law requires a state to follow EPA's preferred method or authorizes EPA to reject a state standard that is based on a BSER determination that employs a different approach than EPA's.

Response II-19-11: Please see the Summary of Public Comments and Responses on Proposed Rule Adoption and Submittal of State Plans for Designated Facilities: Implementing Regulations Under Clean Air Act Section 111(d) (Subpart Ba) Docket ID No. EPA-HQ-OAR-2021-052. The final Subpart Ba is published at 88 FR 80480 (November 17, 2023).

Comment: Commenter (2298-Pioneer) urges EPA to develop a final rule that reflects Congress intention and provide states with latitude in the standards they establish for their existing sources. The commenter notes that CAA section 111(d) provides that it is the states who in their plans establish standards of performance for existing sources, subject to EPA review and approval. And subsection (d) explicitly requires EPA to allow states to "take into consideration, among

other factors, the remaining useful life of the existing source" for which the state plans establish standards of performance.<sup>89</sup> The commenter contends that the existing-source program is, therefore, a "cooperative federalism" program under which Congress intended that states would have considerable flexibility in establishing standards of performance for existing sources.

The commenter (2298-Pioneer) requests that EPA provide adequate flexibility to states in assessing the applicability of RULOF and developing their plans that establish standards of performance for existing sources. The commenter believes that this is in keeping with the text and structure of CAA section 111, as well as with the common-sense observation that it is easier for regulated companies to plan and execute design and operational changes for new and modified sources than for existing sources.

The commenter (2298-Pioneer) expresses concern that EPA seems to interpret the CAA to delegate to EPA, and to the states, the authority to expand the factors relevant to establishing performance standards, allowing states to adopt, and EPA to approve, *more stringent* federally enforceable standards that are not based on BSER but improperly upon "air quality" health and environmental effects of a source's emissions, or upon other factors not mentioned in CAA section 111. In proposing to give states an open-ended delegation to create new decisional factors, EPA concedes that it "cannot anticipate each and every [new] factor" that a state might choose to use in setting more stringent federally enforceable standards. The commenter states, however, that the reference to "other factors" in CAA section 111(d) is not an open-ended delegation/or EPA to impose on the states additional "air quality" based decisional factors, nor an authorization/or the states to add decisional factors in setting CAA section 111(d) standards that EPA may approve as federally enforceable standards. The commenter asserts that the "other factors" are those that Congress listed in CAA section 111(a)(1). No more, no less.

Response II-19-12: Please see the Summary of Public Comments and Responses on Proposed Rule Adoption and Submittal of State Plans for Designated Facilities: Implementing Regulations Under Clean Air Act Section 111(d) (Subpart Ba) Docket ID No. EPA-HQ-OAR-2021-052. The final Subpart Ba is published at 88 FR 80480 (November 17, 2023).

Comment: Commenter (2399-GPA) asserts that the December 2022 supplemental proposed rule's various proposed changes to how states will establish emission limitations for existing sources raises numerous legal and factual concerns. The commenter urges EPA to rethink this approach. To begin, EPA is proposing through the December 2022 supplemental proposal to finalize significant changes to Subpart Ba, governing how States establish existing source performance standards, while simultaneously proposing similar changes through a separate rulemaking.<sup>90</sup> The commenter expresses concern with not only differences between the two proposals, but the December 2022 supplemental proposal suggests EPA has already determined what revisions it will make to Subpart Ba regardless of the public notice and comment process required under the Administrative Procedure Act (APA). The commenter recommends that EPA

---

<sup>89</sup> CAA Section 111(d)(4).

<sup>90</sup> See 87 Fed. Reg. 79,176 (Dec. 23, 2022) ("Proposed Subpart Ba Rule").

await its Ba rulemaking and follow those procedures, rather than create separate procedures in this rule.

More fundamentally, the commenter (2399-GPA) urges EPA to rethink its approach, because its proposal is contrary to Congress' clear direction in the plain language of CAA section 111(d) to grant the states substantial discretion to develop their governing plans for existing sources. Yet, the commenter states that the substance of the EPA's proposal would impose an unprecedented level of federal micro-management over how states would establish emission limitations for existing sources and strip away the discretion that Congress gave to the states under CAA section 111(d). In support of its proposal, EPA has selected out phrases from the statute to create its "satisfactory plan" and "standards of performance" theories for interpreting the Act. But EPA's reading is contradicted by CAA section 111's plain language and structure, as well as case law interpreting that statute.

Even if these proposed revisions were lawful – and the commenter (2399-GPA) believes that they clearly are not – the rationale for imposing them lacks a record basis, includes impermissibly vague requirements, and will have the effect of making states' consideration of facilities' remaining useful life and other factors so onerous as to be practically impossible, despite Congress expressly authorizing states to consider those matters.

Response II-19-13: The EPA disagrees with the commenter's description that suggested EPA proposed to amend subpart Ba through the December 2022 Supplemental Proposal for the NSPS and EG for the oil and natural gas industry (OOOOb and OOOOc). The EPA clarifies that the December 2022 Supplemental Proposal did not propose to amend 40 CFR Part 60 Subpart Ba, but rather proposed that EG OOOOc include certain regulatory provisions that were very similar to, if not the same as, provisions that EPA later proposed to include in subpart Ba. Via a different rulemaking process, the EPA separately proposed amendments to subpart Ba. See 87 FR 79176. The EPA agrees that there was overlap, and even some redundancy, when comparing EPA's proposed EG regulatory text in the December 2022 Supplemental Proposal and the proposal for amending subpart Ba. The EPA further acknowledges that finalizing the same provisions in two separate rules could have been confusing and unnecessarily redundant for both states and tribes but also owners and operators of designated facilities. The EPA explains this further within Section XIII.C of the final rule preamble for OOOOc. Since certain issues that the EPA had proposed within EG OOOOc are now addressed in the final revisions to subpart Ba, and subpart Ba applies to states developing plans under this EG (OOOOc), it would be redundant for EPA to also finalize the same provisions related to these issues within EG OOOOc. As such, EPA is not finalizing certain provisions as proposed in the context of this EG (OOOOc) and is instead deferring to subpart Ba on certain issues as explained in the preamble. The final Subpart Ba is published at 88 FR 80480 (November 17, 2023).

Please see the Summary of Public Comments and Responses on Proposed Rule Adoption and Submittal of State Plans for Designated Facilities: Implementing Regulations Under Clean Air Act Section 111(d) (Subpart Ba) Docket ID No. EPA-HQ-OAR-2021-052.

### 19.3.1.2 EPA Authority to Approve State CAA Section 111(d) Programs That are More Stringent

Comment: Commenter (2428-API) notes that in the original proposal, EPA offered an extensive explanation of why it now believes it has authority to approve state CAA section 111(d) programs that are more stringent than would be required by application of the BSER determined by EPA. That position is expanded in the December 2022 supplemental proposal by EPA's assertion that "states may consider RULOF to include more stringent standards of performance in their state plans". The commenter expresses concern that this position represents a complete reversal of the current Subpart B provision limiting application of "RULOF" to establishing less stringent measures.

EPA now asserts that the term "other factors" is ambiguous and that EPA "may reasonably interpret[] this phrase as authorizing states to consider other factors in exercising their discretion to apply a more stringent standard to a particular source". Moreover, EPA now rejects the idea that the CAA section 111(d) Subpart B variance provisions are relevant in interpreting the scope of the Agency's authority to approve more stringent standards based on consideration of RULOF. EPA also rejects its prior analysis of the legislative history on the grounds that it provides no meaningful guidance to EPA. Lastly, EPA argues that its new interpretation is consistent with the purposes of CAA section 111(d) – i.e., "to require emission reductions from existing sources for certain pollutants that endanger public health or welfare." The commenter (2428-API) asserts that EPA's attempt to reverse its position here is misplaced and is not supported by the law. First, the commenter states that the term "other factors" is not a carte blanche invitation from Congress for EPA to create whatever plausibly "reasonable" new authorities or constraints it might conceive. According to the commenter, the term "other factors" must be interpreted in context. As EPA itself explains, the term "remaining useful life ... is a factor that inherently suggests a less stringent standard." In this context, the commenter suggests that Congress intended the term "other factors" to be interpreted such that "other factors" are applied in the same way (to reduce rather than increase stringency). Because the term "other factors" is a catch-all phrase that follows the more specific instruction to consider a source-specific factor, the commenter asserts that the term "other factors" must be construed in this manner.

Second, the commenter (2428-API) provides that the EPA's position is grounded in its assertion that states are not required "to conduct a source-specific BSER analysis for purposes of applying a more stringent standard" because "[s]o long as the standard will achieve equivalent or better emission reductions than required by EG OOOOc, the EPA believes it is appropriate to defer to the state's discretion to, e.g., choose to impose more costly controls on an individual source." At the same time, the commenter believes that the EPA correctly notes that "its authority is constrained to approving measures which comport with applicable statutory requirements." (EPA may not approve and thereby "federalize" state programs that apply to pollutants and/or affected facilities not covered by EG OOOOc).

The commenter (2428-API) states that it is inconsistent and arbitrary for EPA to assert that a state must conduct a new source-specific BSER analysis if it wants to use RULOF to establish a less stringent standard than would be required under EPA's BSER determination (see *Id.* at

74821), while a state is not similarly constrained when establishing more stringent standards. EPA's assertion that a more stringent standard does not require a BSER analysis because it "will achieve equivalent or better emissions reductions than required by EG OOOOc" cannot be squared with the requirement that alternative state measures must "comport with applicable statutory requirements" – which in this case include the unambiguous requirement that BSER and corresponding emissions standards must be demonstrated in practice and cost effective. The commenter disagrees with EPA's suggestion that it may defer to (and approve) more stringent state requirements simply because they are more stringent because that approach does not ensure that the more stringent standards meet the statutory standard-setting criteria.

Response II-19-14: Please see the Summary of Public Comments and Responses on Proposed Rule Adoption and Submittal of State Plans for Designated Facilities: Implementing Regulations Under Clean Air Act Section 111(d) (Subpart Ba) Docket ID No. EPA-HQ-OAR-2021-052. The final Subpart Ba is published at 88 FR 80480 (November 17, 2023).

#### 19.3.1.3 EPA Does Not Have Authority to Prescribe State Plan RULOF Requirements

Comment: Commenter (2252-PAW) contends that EPA does not have authority to prescribe state compliance plan requirements. The commenter recommends that EPA allow states to continue to lead. The commenter notes that EPA states that "remaining useful life" is one "factor" that CAA section 111(d) explicitly requires that the EPA permit states to consider in applying a standard of performance." and that "the provision does not provide guidance or parameters on when and how a state may do so" and thus takes it upon itself to delineate what a state compliance plan should include. The commenter asserts that this is not an accurate interpretation of the CAA. The commenter contends that Congress explicitly delegated to states the authority to develop compliance programs for existing sources, while allowing them to consider of remaining useful life. The commenter submits that Congress intentionally left great discretion to states to deviate from the EPA's standards. The commenter asserts that states are the governmental entities with expertise in air quality compliance and enforcement and are thus best equipped to make judgement calls regarding requirements for sources under their jurisdiction.

Commenter (2326-AXPC) asserts that EPA must give the states meaningful discretion and flexibility in how they regulate existing sources in their state plans. The commenter contends that CAA section 111(d)(1) requires EPA to allow states to assign standards of performance to existing sources that are not one-size-fits-all, top-down requirements, and that take into consideration the circumstances of those sources.<sup>91</sup>

Regulations of the Administrator under this paragraph *shall* permit the State in applying a standard of performance to any particular source under a plan submitted under this paragraph to take into consideration, among other factors, the remaining useful life of the existing source to which such standard applies.

The commenter (2326-AXPC) states that there are two obvious policy reasons why Congress provided different treatment for existing and new sources. The first is an economic reason:

---

<sup>91</sup> (emphasis added).

retrofitting or altering operations at an existing source to comply with regulations is more burdensome, and in some cases impossible, as compared to designing a newly constructed source. The second is a question of policy and the legal framework of the CAA: Congress knows states are more aware of and better equipped to handle the circumstances of their existing-source fleet than EPA.

The commenter (2326-AXPC) contends that EPA's proposal is inconsistent with the design of the existing source program, and Congress' direction that it allow the states this role. Rather, the commenter asserts that EPA's proposal adds unnecessary burdens on states' ability to exercise the authority Congress directed EPA to allow them, without statutory justification.

EPA proposes to require a state to engage in additional public engagement and to step into the shoes of the EPA itself by conducting its own, source specific BSER analysis before it assigns a standard of performance to a particular existing source that is less stringent than what would result from a direct application of the presumptive requirements in EPA's EGs. The commenter (2326-AXPC) states that Congress did not authorize these additional requirements in CAA section 111(d). The commenter suggests that EPA's motives are in direct conflict with what Congress gave the states through their RULOF authority, and instead proposes a program so onerous for states that they will just accept EPA's requirements and avoid the considerable burden that would be required to exercise their express statutory RULOF authority.

Tellingly, the commenter (2326-AXPC) provides that the EPA requires no additional process for a state that wishes to assign a more stringent standard of performance to an existing source. The commenter asserts that EPA has not justified this different treatment – other than by observing that more stringent standards will lead to greater emissions reductions.

The commenter (2326-AXPC) states that CAA section 111 is not a maximum-achievable-reductions provision, unlike some other provisions of the CAA and other environmental statutes. It requires a careful threshold analysis by EPA as to what systems of emissions reductions are “adequately demonstrated” and what reductions are “achievable,” and it contains language directing EPA to allow states to vary from EPA's own presumptive standards where particular circumstances warrant. The commenter contends that the one-way ratchet created by EPA's split treatment of states confirms its inconsistency with Congress' statutory scheme.

Finally, the commenter (2326-AXPC) asserts that EPA also disregards the statutory scheme when, in what appears to be the first time ever, it proposes to require that states undergo their own version of a BSER analysis before assigning a less stringent standard to an existing source. The commenter states that BSER occurs only in one portion of CAA section 111, in the initial definition of “standard of performance” in CAA section 111(a)(1). In that provision, it is explicitly the EPA Administrator's role to determine BSER. According to the commenter, in constricting states from being able to fully exercise the authority Congress granted them in CAA section 111(d), EPA is blurring the lines, departing from its previously unbroken insistence that BSER is a matter for the EPA, and confusing two distinct roles which could not be clearer under the text and structure of the statute.

The commenter (2326-AXPC) contends that Congress' design for existing-source regulation is quite clear. EPA should determine what reductions existing sources as a categorical matter can be expected to achieve (considering whether and how existing sources differ in this regard from new ones). EPA directly regulates new sources. But *states* set standards of performance for their existing sources in their state plans, with the authority to "take into consideration, among other factors, the remaining useful life of the existing source to which such standard applies." The commenter asserts that EPA's attempt would impose extra hurdles and blur clear statutory lines which is not in keeping with Congress' design. The commenter states that EPA has no authority to impose these requirements, and certainly does not have authority to reject a state plan as not being "satisfactory" for failure to comply with them.

Commenter (2443-NMOGA) contends that the RULOF revisions would require states to conduct multiple BSER analyses, and that EPA fails to justify their change in interpretation and application. The commenter outlines their concerns in the following paragraphs.

a. The proposed RULOF revisions would unreasonably require states to conduct multiple BSER analyses, with additional requirements, contrary to CAA section 111(d).

The commenter (2443-NMOGA) states that the CAA requires EPA to promulgate regulations implementing CAA section 111(d) that permit a state submitting a state plan "to take into consideration, among other factors, the remaining useful life of the existing source to which such standard applies."<sup>92</sup> If a state fails to submit a satisfactory state plan and EPA prescribes a plan for the state, EPA must similarly "take into consideration, among other factors, remaining useful lives of the sources in the category of sources to which such standard applies."<sup>93</sup>

The current RULOF provisions in the section 111(d) implementing regulations allow a state to consider the following factors: (1) unreasonable cost of control resulting from plant age, location, or basic process design; (2) physical impossibility of installing necessary control equipment; or (3) other factors specific to the facility (or class of facilities) that make the application of a less stringent standard or final compliance time significantly more reasonable.<sup>94</sup> The commenter (2443-NMOGA) asserts that EPA is now proposing excessive revisions to the RULOF provisions that will require states to (1) meet specific threshold requirements for the consideration of RULOF; (2) calculate a less stringent standard accounting for RULOF; (3) consider communities most affected by and vulnerable to the health and environmental impacts from the designated facilities being addressed; and (4) provide certain information and evidence to support the invocation of RULOF in a state plan. The commenter objects to the procedural overlay and restrictive standard of evaluation proposed by EPA for states to submit and support RULOF demonstrations that will effectively turn the RULOF provisions in CAA section 111(d) into a dead letter.

The commenter (2443-NMOGA) asserts that EPA does not cite any authority or statutory text supporting its new, restrictive view of RULOF or demonstrate that "Congress meant to so hogtie

---

<sup>92</sup> 42 U.S.C. § 7411(d)(1).

<sup>93</sup> 42 U.S.C. § 7411(d)(2).

<sup>94</sup> 40 CFR 60.24a(e).

the [s]tates” in developing plans under CAA section 111(d).<sup>95</sup> EPA claims that the current RUOF provisions could result in differing interpretations and inconsistent application and should therefore require clear parameters for states on how and when to apply a less stringent standard than the presumptive level of stringency in an EG for a particular source. But the commenter notes that EPA has acknowledged that the application of less stringent requirements is a case-by-case evaluation and should not be subject to overly prescriptive threshold requirements.<sup>96</sup> The commenter believes that Congress directed EPA to permit states to consider a source’s RUOF to acknowledge the basic fact that it is generally more difficult (and costly) for existing sources to retrofit pollution controls than it is for new sources to install them. As EPA explained in a prior rulemaking, “Congress intended the remaining useful life provision to provide a mechanism for states to avoid the imposition of unreasonable retrofit costs on existing sources with relatively short remaining useful lives, a scenario that could result in stranded assets.”<sup>97</sup>

The commenter (2443-NMOGA) states that the EPA has long recognized that states may apply less stringent requirements in its state plans “when economic factors or limitations make such application significantly more reasonable.”<sup>98</sup> In EPA’s initial regulations implementing CAA section 111(d)—before RUOF—EPA recognized that application of the specified standards in an emission guideline “may be unreasonable” when the cost of the upgrades and the emission reductions become disproportionate.”<sup>99</sup> To account for this, EPA promulgated regulations that “provide that [s]tates may establish less stringent emission standards on a case-by-case basis provided that sufficient justification is demonstrated in each case.”<sup>100</sup> In that rulemaking, commenters confused the degree of control to be reflected in EPA’s EGs under CAA section 111(d) with that to be required by corresponding standards of performance for new sources under CAA section 111(b).<sup>101</sup> EPA clarified that:

[a]lthough the general principle (application of best adequately demonstrated technology, considering costs) will be the same in both cases, the degrees of control represented by the Agency's emission guidelines will ordinarily be less stringent than those required by standards of performance for new sources because the costs of controlling existing facilities will ordinarily be greater than those for control of new sources.<sup>102</sup>

And the D.C. Circuit Court of Appeals has explained that the requirement that state standards under CAA section 111(d) must “‘reflect’ the emission guidelines does not mean that they must embody the methods EPA contemplated in identifying the best system; rather, the [s]tates have

<sup>102</sup> *Id.* at 53,341 (emphasis added).

flexibility in determining the specifics of the standards they issue so long as they accomplish the ‘degree of emission limitation’ the EPA calculated based on its ‘best system.’”<sup>103</sup>

The commenter (2443-NMOGA) asserts that EPA has faithfully and consistently implemented its RULOF regulations for over forty years. The commenter notes that EPA revised the RULOF revisions only a few years ago and made no mention at that time of a historical issue with a lack of clarity or clear direction for states under the regulations.<sup>104</sup> But the commenter states that EPA is now proposing that states submit “a source-specific BSER [analysis] for the designated facility” that must be in the same form as the EG OOOOc presumptive standard, in addition to the other demonstration requirements a state must provide for RULOF to be considered in a state plan, including a requirements to evaluate “all control technologies available for the source and evaluate the BSER factors for each technology, using the same metrics and evaluating them in the same manner as the EPA did in developing the EG.” The commenter contends that EPA’s proposal is in stark contrast to its long-standing interpretation and application of RULOF and removes all the flexibility Congress intended to provide states in developing and submitting state plans by requiring states to provide a demonstration even more rigorous than what EPA did for the establishment of NSPS OOOOb. And given that EPA, with very limited exceptions, proposes the same requirements for existing sources that would be subject to EG OOOOc as it does for new sources that would be subject to NSPS OOOOb, it is clear to the commenter that EPA did not already take into account costs for existing sources.

The commenter (2443-NMOGA) suggests that had Congress intended for RULOF demonstrations to require a complete BSER analysis and independent evaluation of alternative technologies, it would have said so.<sup>105</sup> The commenter believes that this was not Congress’s intention and EPA has never interpreted the statute this way. The commenter contends that requiring states to conduct a more rigorous evaluation than what was required for determining BSER in the first place is contradictory to the structure of CAA section 111(d) as they apply to existing sources.

Further, the commenter (2443-NMOGA) expresses concern that many of EPA’s proposed requirements would completely prevent the use of RULOF in the oil and natural gas sector. For example, EPA proposes to require that state plans include a retirement date for the designated facility as an enforceable commitment and requires measures that provide for the implementation and enforcement of retirement. The commenter reports that this requirement is impracticable for the oil and natural gas sector because there are thousands of applicable sources (small in nature) within a state as opposed to a dozen or so large sources. The commenter notes that EPA has made no effort to tailor its RULOF provisions to the source category being regulated. EPA also proposes to limit states to submitting RULOF demonstrations for four categories of designated facilities: oil wells with associated gas designated facilities; storage vessels; pneumatic controllers; and pneumatic pumps. The commenter notes that EPA does not explain or provide

---

<sup>103</sup> *Am. Lung Ass’n.*, 985 F.3d at 942–943.

<sup>104</sup> 84 Fed. Reg. 32,520, 32,524 (July 8, 2019) (“EPA’s role under CAA section 111(d) is narrow. Indeed, CAA section 111(d) tasks states with “establish[ing] standards of performance for any existing source” and “provid[ing] for the implementation and enforcement of such standards of performance.”).

<sup>105</sup> E.g., *W. Virginia v. Env’t Prot. Agency*, 213 L. Ed. 2d 896 (June 30, 2022) (“Agencies have only those powers given to them by Congress, and enabling legislation is generally not an open book to which the agency [may] add pages and change the plot line.” (internal quotations and citations omitted)).

any support for its determination that RULOF is only appropriate for, and should be limited, to these four categories of designated facilities.

The commenter (2443-NMOGA) contends that EPA is again prematurely presuming that states are incapable of submitting satisfactory state plans, yet EPA does not point to any prior examples of states submitting unsatisfactory state plans due to the alleged ambiguity of the current RULOF provisions. The commenter asserts that EPA is attempting to solve a problem that does not yet exist, at the risk of creating great administrative burden to both states and EPA.

b. EPA does not offer a reasoned justification for its change in its long-standing interpretation and application of RULOF.

EPA states that the “RULOF provision [its] proposing in this rule is consistent with how the EPA has approached RULOF in the implementing regulations previously.” The commenter believes that statement is simply not true. The commenter (2443-NMOGA) contends that EPA ignores the significant new procedural requirements being imposed in the RULOF process—and the new standards under which EPA will evaluate and approve RULOF demonstrations. The commenter asserts that proposed requirements and standards are new, more restrictive, and different than how EPA has interpreted and applied CAA section 111(d) for over forty years.<sup>106</sup> As described above, the commenter states that the EPA does not point to any prior examples of states submitting unsatisfactory state plans due to the alleged ambiguity of the current RULOF provisions—nor does EPA provide any actual record evidence of any kind to justify its departure from its longstanding interpretation. According to the commenter, EPA’s failure to acknowledge and justify this departure from its multi-decade interpretation of CAA section 111(d)(1) is arbitrary and capricious.<sup>107</sup>

Commenter (2399-GPA) urges EPA to drop its attempt to revise its rules to limit the discretion given states to implement its authority governing existing sources. According to the commenter, nothing in CAA section 111 provides EPA with the authority to impose what the December 2022 supplemental proposal calls “threshold requirements for considering Remaining Useful Life and Other Factors.” The commenter states that these “threshold requirements” are impermissible substantive conditions on when or how states may exercise the discretion Congress granted the states in considering RULOF to establish existing source emission standards under CAA section 111(d).

Moreover, the commenter (2399-GPA) recommends that EPA likewise not finalize these regulatory changes, which are directly contrary to the text of the statute and the cooperative-federalism structure of CAA section 111(d), which relegates the Agency to a limited role. The commenter argues that EPA cannot unilaterally re-define the roles that Congress assigned to each of EPA and the states through counter-textual interpretations of the terms “satisfactory plan” and “standards of performance.” Further, the proposed multitude of conditions and requirements that states would have to satisfy ill-conceived, lack a record basis, and are collectively so onerous that EPA would deprive states of an option that the commenter believes Congress clearly provided under the statute. For all these reasons (detailed below), the

---

<sup>106</sup> See, *supra*, § II.A.

<sup>107</sup> See, e.g., *Fox Television Stations, Inc.*, 556 U.S. at 515.

commenter recommends that EPA withdraw what they contend are various unlawful conditions on the states' use of RULOF.

a. EPA's role under CAA section 111(d) is limited to establishing procedural regulations while states establish standards of performance.

The commenter (2399-GPA) argues that the EPA has erred in the December 2022 supplemental proposal by improperly seeking to alter the respective responsibilities of EPA and the states under CAA section 111(d)(1). In short, while EPA establishes emission limitations for new sources under CAA section 111(b), the commenter asserts that states establish emission limitations for existing sources under CAA section 111(d) with EPA playing a very limited procedural role. According to the commenter, CAA section 111(d)(1) only permits the Administrator to "prescribe regulations which shall establish a procedure similar to that provided by section 7410 of this title under which each State shall submit to the administrator a plan" for existing sources.<sup>108</sup> Those procedural regulations will differ from section 7410 only in that they "shall permit the [s]tate in applying a standard of performance to any particular source under a plan submitted under this paragraph to take into consideration, among other factors, the remaining useful life of the existing source to which such standard applies."<sup>109</sup>

The commenter (2399-GPA) further argues that CAA section 111(d)(1) does not authorize the Administrator to impose conditions on the approval of a state plan. Therefore, if such authority exists, it must come from section 110. Yet, the commenter states that the December 2022 supplemental proposed rule never examines EPA's authority under CAA section 110. However, the commenter notes that nothing in CAA section 110 provides EPA with any substantive powers in establishing CAA section 111(d)(1) emission limitations. Section 110(k) of the CAA governs EPA's review of state plans and actions on them. Of relevance, EPA must make a completeness find within 60 days indicating whether or not the state plan meets minimum statutory criteria,<sup>110</sup> and either approve, partially approve, conditionally approve, or disapprove a state plan depending upon whether "it meets all of the applicable requirements of this chapter."<sup>111</sup> Thus, the commenter provides that section 7410, as incorporated by section 7411(d), only authorizes EPA to create a procedural framework for the submission, review, and approval (or disapproval) of a state plan. The commenter asserts that approval or disapproval is based on statutory criteria only (i.e., "applicable requirements of this chapter"). The commenter contends that nothing in either section 7410 or section 7411(d) authorizes EPA to impose additional substantive requirements on when states may use RULOF and EPA has not identified any statutory ambiguity that it is interpreting.

Further, the commenter (2399-GPA) states that the D.C. Circuit very recently held that EPA's interpretation of CAA section 111(d) responsibilities is impermissible. EPA cites to *American Lung Association v. EPA*, 985 F.3d 914 (D.C. Cir. 2021) to summarize the 2019 ACE Rule litigation, 87 Fed. Reg. at 74,812, 74,817, but the commenter notes that it ignored the D.C. Circuit's explanation of the different roles that EPA and the states serve under CAA section

---

<sup>108</sup> 42 U.S.C. § 7411(d)(1).

<sup>109</sup> Id.

<sup>110</sup> 42 U.S.C. § 7410(k)(1)(B).

<sup>111</sup> Id. § 7410(k)(3).

111(d). As the court stated: “Once the EPA identifies a best system that meets” the requirements of Section 111(a) “and calculates the degree of emission limitation it allows, the Clean Air Act leaves it to the [s]tates to set their own standards of performance for their existing pollution sources.”<sup>112</sup> “The cooperative-federalism design of [s]ection 7411(d) gives the [s]tates broad discretion in achieving those limitations.”<sup>113</sup> In fact, “under [s]ection 7411(d), the EPA does not impose the ‘best system of emission reduction’ on anyone. Instead, the commenter explains that each state decides for itself what measures to employ to meet the emission limits, and in so doing may elect to consider the ‘remaining useful life’ of its plants and ‘other factors.’”<sup>114</sup> Notably, the commenter believes that this was not merely a concurrence with an agency interpretation that EPA would be free to change in the future; this was the court’s explanation of CAA section 111’s unambiguous “statutory design.”<sup>115</sup> Thus, according to the commenter, both the text of CAA section 111, and a recent D.C. Circuit interpretation of that text, make it clear that Congress did not provide EPA with any authority to regulate how states establish existing source emission limits under CAA section 111(d) or to cabin the “broad discretion” provided to states under that statute.

Response II-19-15: Please see the Summary of Public Comments and Responses on Proposed Rule Adoption and Submittal of State Plans for Designated Facilities: Implementing Regulations Under Clean Air Act Section 111(d) (Subpart Ba) Docket ID No. EPA-HQ-OAR-2021-052. The final Subpart Ba is published at 88 FR 80480 (November 17, 2023).

### ***19.3.2 Opposition to Inclusion of the Remaining Useful Life and Other Factor Provisions***

Comment: Commenter (2399-GPA) asserts that the very premise underlying EPA’s claimed need for standards dictating how States account for a facility’s remaining useful life is incorrect. The commenter provides that nothing in CAA section 111(d) indicates that Congress intended for individual state considerations to avoid “inconsistent application ... across states.” Yet, the commenter states that the EPA bases its proposal on the unsupported notion that states must mimic the process EPA uses in establishing EGs. Hence, EPA proposes to compel each state to include “a source-specific BSER for the designated facility” that considers the same five factors used by EPA, and “must identify all control technologies available for the source and evaluate the BSER factors for each technology, using the same metrics and evaluating them in the same manner as the EPA did in developing the” emission guidelines and the resulting “standard must be in the same form (*e.g.*, numerical rate-based emission standard) as required by the EG OOOOc presumptive standard.” States must also provide analyses of why less stringent emission limitations do not “undermine the control objectives of the EG and CAA section 111(d) itself” and document “the time needed to purchase and install equipment required to comply, the time needed to develop a compliance plan and secure the services of specialized contractors to perform services required for compliance, the expected window of time needed to obtain approvals of outside agencies, the time needed to conduct any required community outreach or public hearings, as well as other potential factors.”

---

<sup>112</sup> 985 F.3d at 962 (emphasis added).

<sup>113</sup> *Id.*

<sup>114</sup> *Id.*

<sup>115</sup> *Id.*

The commenter (2399-GPA) expresses concern that the December 2022 supplemental proposed rule provides no legal or record basis for any of these demands. Rather, EPA simply assumes that consistency in both process and results is demanded by CAA section 111(d). That is directly contrary to the “cooperative-federalism design of Section 7411(d)” that “gives the States broad discretion,”<sup>77</sup> and would reduce States to clerks performing paperwork exercises dictated by EPA. Further, EPA’s statement that its proposed process would “generally address all relevant information that states would reasonably consider in evaluating the emission reductions reasonably achievable for a designated facility,” is not supported by any record evidence. In fact, there is no discussion of the processes that states actually have used in setting existing source standards for any source categories. Thus, the December 2022 supplemental proposed rule declares that greater regulation of state analytical processes is required without any evidence of what states have done in the past, whether states have actually arrived at inconsistent results, and if so, that the inconsistencies are undesirable in some way. Instead, the commenter states that the December 2022 supplemental proposed rule seeks to establish standards based upon hypothetical scenarios and unsupported presumptions. Such an approach is clearly arbitrary and capricious.

Response II-19-16: Please see the Summary of Public Comments and Responses on Proposed Rule Adoption and Submittal of State Plans for Designated Facilities: Implementing Regulations Under Clean Air Act Section 111(d) (Subpart Ba) Docket ID No. EPA-HQ-OAR-2021-052. The final Subpart Ba is published at 88 FR 80480 (November 17, 2023).

Comment: Commenter (2399-GPA) asserts that, even if EPA had the authority to impose new conditions on states’ use of RULOF, the December 2022 supplemental proposed rule fails to provide a rational, record-based reasoning for those conditions. Instead, the commenter states that the December 2022 supplemental proposed rule bases its proposed revisions on a series of hypothetical scenarios that do not withstand serious scrutiny. Again, as the commenter provides elsewhere in their comments, they urge EPA to reconsider its approach.

The commenter (2399-GPA) understands the premise in EPA’s proposal is that its regulations regarding RULOF,<sup>116</sup> which were revised only four years ago, now lack “clear parameters for states on how and when to apply a standard less stringent than the presumptive level of stringency.” States may demonstrate that applying the presumptive standard of performance (1) involves unreasonable costs due to a plant’s age, location, or process design, (2) physically impossible, or (3) involves other factors “that make application of a less stringent standard or final compliance time significantly more reasonable.”<sup>117</sup> The commenter states that the existing regulation employs a rule of reason – a very commonly used standard under the APA – and factor (3) is open-ended, and it must be given that it was Congress’ decision to allow states to consider unenumerated “other factors” instead of creating a definitive list of considerations.

According to the December 2022 supplemental proposed rule, however, 40 CFR 60.24a(e) “does not provide clear parameters for states on how and when to apply” RULOF. More specifically, the commenter (2399-GPA) notes that the EPA worries that “the reference to reasonableness in this provision are potentially subject to widely differing interpretations and inconsistent

---

<sup>116</sup> 40 CFR 60.24a(e).

<sup>117</sup> Id.

application among states developing plans, and by the EPA in reviewing them” that “could effectively undermine the overall presumptive level of stringency envisioned by the EPA’s BSER determination and render it meaningless.” The commenter identifies multiple problems with this rationale.

First, the commenter (2399-GPA) states the rationale is entirely speculative. The December 2022 supplemental proposed rule has not identified any questions that have arisen from the actual application of 40 CFR 60.24a(e). In fact, the December 2022 supplemental proposed rule “did not identify any provision in any of the state oil and natural gas regulations that included a less stringent standard for equipment or operations with a shortened lifespan.” In other words, the commenter states that the EPA has no information showing that the proposed revisions are necessary or helpful, as no state has yet used the RULOF provisions for crude oil or natural gas sources.

Second, the commenter (2399-GPA) states that the concern that states “could” apply RULOF in a way that “effectively undermine[s] the overall presumptive level of stringency envisioned by the EPA’s BSER determination and render it meaningless,” is not only speculative, but it misunderstands CAA section 111(d)’s purpose. The commenter notes that the EPA’s BSER determination in its EGs is always a starting point for states under CAA section 111(d), and therefore, it could never be “meaningless” EPA’s proposal asserts. But most importantly, and contrary to the EPA’s concern, the Congress intended those states, under certain circumstances, be free to implement standards less stringent than EPA’s BSER determination. As one court explained, “[a]s with most legislation, the Clean Air Act amendments reflected a congressional compromise ... As one legislative compromise, the Clean Air Act has less stringent regulations regarding existing power plants as compared to newly constructed sources of electricity. In other words, existing plants were ‘grandfathered’ in recognition of the expense of retrofitting pollution-control equipment.”<sup>118</sup>

Thus, the commenter (2399-GPA) asserts that the entire purpose of CAA section 111(d)’s RULOF provision is to allow states to implement emission limitations less stringent than BSER where the states believe that the remaining useful life – and unenumerated “other factors” – warrant it. According to the commenter, revising the implementing regulations to prohibit, or severely restrict, a state’s ability to implement less stringent emission standards when considering “among other factors, the remaining useful life of the existing source,”<sup>119</sup> is contrary to the statutory purpose, the legislative compromise and the principles of federalism embodied in CAA section 111. As discussed above, the commenter states that the notion that existing source emission limits must hew to “the overall presumptive level of stringency envisioned by the EPA’s BSER determination,” is contrary to the statute’s text and structure, which provide the states’ with “broad discretion” in establishing existing source limits.<sup>120</sup> Thus, the commenter

---

<sup>118</sup> *United States v. EME Homer City Generation LP*, 823 F. Supp. 2d 274, 279 (W.D. Pa. 2011) (citing CAA section 111(d)); see also *WEPCO v. Reilly*, 893 F.2d 901, 909 (7th Cir. 1990) (citing legislative history justifying more lenient emission standards for existing sources).

<sup>119</sup> 42 U.S.C. § 7411(d).

<sup>120</sup> *Amer. Lung Ass’n*, 985 F.3d at 962.

contends that ensuring consistency between CAA section 111(b) new source standards and CAA section 111(d) existing source standards is not a legitimate rationale.

Third, the commenter (2399-GPA) provides that CAA section 111(d) does not indicate that Congress believed that consistency between or among state existing source standards was either necessary or desirable. As the D.C. Circuit explained, “each [s]tate decides for itself what measures to employ to meet the emission limits, and in so doing may elect to consider the ‘remaining useful life’ of its plants and ‘other factors.’”<sup>121</sup> The December 2022 supplemental proposed rule does not identify anything in CAA section 111(d) that justifies a contrary interpretation. The commenter suggests that this means that its concern that “the references to reasonableness in” 40 CFR 60.24a(e) “are potentially subject to widely differing interpretations and inconsistent application among the states,” is directly contrary to the statutory framework in CAA section 111 and the broad discretion afforded to individual states to decide “for itself.”

Fourth, the commenter states that the EPA and states have been implementing air emission standards that incorporate the “remaining useful life” of regulated facilities under the Regional Haze program for decades without any concern for “widely differing interpretations and inconsistent application among states developing plans.” As with CAA section 111(d), the commenter notes that the Regional Haze program gives states primary authority to establish air pollutant emission limitations that consider “the remaining useful life of the source” and other factors.<sup>122</sup> The commenter asserts that EPA and the states have collectively handled several dozen Regional Haze plans since 1999 without any indication that the methodology for state consideration of “remaining useful life” was confusing, inappropriately inconsistent, or frustrating the underlying goals of the Regional Haze program. Thus, according to the commenter, the December 2022 supplemental proposed rule’s claim that CAA section 111(d)’s implementing regulations require significant changes to resolve confusion or improper inconsistency surrounding RULOF is contradicted by the absence of such problems under the Regional Haze program.

Response II-19-17: Please see the Summary of Public Comments and Responses on Proposed Rule Adoption and Submittal of State Plans for Designated Facilities: Implementing Regulations Under Clean Air Act Section 111(d) (Subpart Ba) Docket ID No. EPA-HQ-OAR-2021-052. The final Subpart Ba is published at 88 FR 80480 (November 17, 2023).

Comment: Commenter (2446-IPAA) expresses concern that the RULOF provision is impractical, ignores low production wells, and limits state flexibility. The commenter requests that EPA develop a clear process to assess RULOF. The commenter notes that EPA proposes that state plans should include source by source decisions on the application of RULOF. The commenter believes such an approach would be impractical due to overlapping actions. The commenter

---

<sup>121</sup> Id.

<sup>122</sup> 42 U.S.C. § 7491(g)(2); see also 40 CFR 51.301 (“remaining useful life” included in the definition of Best Available Retrofit Technology); 60 CFR 51.308(d)(1)(i)(A) (States consider “remaining useful life” in establishing Reasonable Progress Goals); 60 CFR 51.308(e)(1)(ii)(A) (determining Best Available Retrofit Technology); 308(f)(2)(i) (emission reduction measures that consider the “remaining useful life”).

notes that at the same time these individual decisions would be considered, the state would be developing its overall plan and would not know whether EPA would approve it.

The commenter (2446-IPAA) also notes that the proposed rule would only allow that cost unreasonableness be considered in a state's demonstration that a source's remaining useful life based on its retirement date reasonably warrants a less stringent standard for only the following types of designated facilities: oil wells with associated gas, storage vessels, pneumatic controllers, and pneumatic pumps. A cost unreasonableness determination would not be allowed for any other designated facility types. The commenter expresses concern that this arbitrary position reflects EPA's intention to limit state flexibility. The commenter notes that increasing operating costs for small wells can have a significant impact on their economic viability. The commenter asserts that this framework, ignores low production wells thereby making the facility uneconomic and drives it to shut down. The commenter reports that many low production wells can continue to operate for decades at production rates that may be in the less than 2 boe/day range while posing minimal methane emissions threats. The commenter contends that federal regulation should not be the cause of their demise and states should have the authority to provide for a regulatory framework that allows their continued operation until their normal end of life.

The commenter (2446-IPAA) notices that EPA seems inordinately concerned that different states could create different RULOF approaches for similar facilities. However, the commenter provides that the nature of oil and natural gas production results in different production challenges that do not appear evident from casual comparisons. The commenter encourages EPA to recognize program differences and the resulting emissions management and economic implications. As a part of the federal state partnership, the commenter urges EPA not to impose uniform regulatory requirements on state plans after the state has addressed the different operations under its jurisdiction.

In another instance of EPA trying to limit state ability to develop regulatory approaches – including RULOF decisions – the commenter (2446-IPAA) notes that the EPA proposes that states must use EPA's BSER development approach. However, the commenter asserts that there is no absolute guarantee that EPA's analytical approach is sound or accurate for every state. Moreover, as shown previously with regard to the fugitive emissions analysis, the commenter suggests that the EPA is so wedded to its component count approach that it distorts results. The commenter reports that states may choose to assess issues differently and thereby produce different approaches based on their experience – which in the context of regulating existing sources is far more comprehensive than EPA's experience since its authority is primarily directed at new sources. Perhaps more significantly, the commenter asserts that EPA has effectively applied its NSPS BSER analysis to its CAA section 111(d) assessment where existing sources are affected. According to the commenter, this transposition of a new source analysis to existing sources fails to follow the Congressional intent evident throughout the CAA that existing sources need to be treated differently than new ones. The commenter contends that the EPA rather cavalierly concludes that its new source BSER applies to existing sources without ever making a full analysis. In these regulations applying to oil and natural gas production operations, the commenter has consistently presented information to EPA that the declining nature of oil and natural gas production requires EPA to assess low production wells differently because – at a minimum – the ability of these sources to absorb additional costs differs significantly from new

sources. The commenter states that Congress went further than just distinguishing between new and existing sources by adding the RULOF process to address even more unique problems. According to the commenter, the EPA fails to meet the task demanded of it in addressing existing source BSER and needs to revise its assessments.

Response II-19-18: Please see RULOF discussion in section XIII.C.3 of the final preamble.

Please see the Summary of Public Comments and Responses on Proposed Rule Adoption and Submittal of State Plans for Designated Facilities: Implementing Regulations Under Clean Air Act Section 111(d) (Subpart Ba) Docket ID No. EPA-HQ-OAR-2021-052. The final Subpart Ba is published at 88 FR 80480 (November 17, 2023).

Comment: Commenter (2037-Climate Action et al) states that, under CAA section 111(d), states have a role in tailoring rules that implement EPA determined standards as applied to particular facilities. The commenter reports that many facilities subject to controls under CAA section 111 are operations that emit only when operating, then are closed and stop emitting at the end of the facilities' useful life. Accordingly, the statute recognizes the concept of "useful life" as a legitimate factor states may consider.<sup>123</sup> For example, a state might determine that an aging power plant, nearing the end of its design life and worth only \$1 million because it can generate power for only one more year, should not be required to install a \$500 million pollution control system that would take months to construct.

But the commenter (2037-Climate Action et al) notes that oil and gas wells, while also subject to federal emission standards under section 111, are quite different from facilities like power plants. If not properly sealed, a well that has little or no remaining value can continue to emit pollutants – the CAA's focus – regardless of whether it is operating, idled, or abandoned. In terms of potential to emit, an unsealed well might be immortal. "Useful life" defies simple application. The commenter requests that EPA define as clearly as it can what conditions will support a decision to exempt wells based on 'remaining useful life,' lest that become a barn door through which resistant jurisdictions can flee without causing facilities to meet federal emission standards. The commenter recommends that EPA should define "useful life" to include the period in which a facility remains in a condition that could emit pollutants, regardless of operational status. For an oil or gas well, the commenter asserts that any condition short of full closure and sealing must be a circumstance that cannot be exempted from emission standards.

The commenter (2307-Climate Action et al) explains that the problem is not merely theoretical. The commenter states that the future life of a well in the petroleum sector is uncertain for at least two reasons. First, the volatile nature of oil and natural gas prices often turn long idle, low-producing wells into valuable assets that receive new investment, a "workover," or are simply put back online because potential returns make the ongoing maintenance and energy

---

<sup>123</sup> 42 U.S.C. section 7411(d) provides, in pertinent part, that "Regulations of the Administrator under this paragraph shall permit the [s]tate in applying a standard of performance to any particular source under a plan submitted under this paragraph to take into consideration, among other factors, the remaining useful life of the existing source to which such standard applies."

consumption cost-effective again. The commenter states for example that California has certainly seen a lot of well re-working in response to rising oil prices.

Secondly, the commenter (2307-Climate Action et al) notes that if the past century teaches us anything, it is that the industry can make incredible, sometimes unexpected technological progress. The commenter notes that they have seen dormant wells be profitably redrilled or re-worked using modern drilling and fracking techniques. As a result, wells and fields that had been written off as having little or no useful life became production stars, not because product prices rose, but because production techniques improved.

Response II-19-19: Please see RULOF discussion in section XIII.C.3 of the final preamble.

The EPA finalizes well closure requirements as part of the fugitives emissions monitoring and repair standards in EG OOOOc. Specifically, owners and operators are required to submit a well closure plan to the Administrator within 30 days of the cessation of production from all wells located at the well site as specified in §60.5420c(a)(4)(i). The well closure plan must include a description of the steps necessary to close all wells at the well site, including permanent plugging of all wells; a description of the financial requirements and disclosure of financial assurance to complete closure; and a description of the schedule for completing all activities in the well closure plan. Owner and operators are required to submit a notification as specified in §60.5420c(a)(4)(ii) of intent to close the well site to the Administrator 60 days before the beginning of well closure activities. Furthermore a survey of the well site using OGI is required, including each closed well, after completing all well closure activities outlined in the well closure plan. If any emissions are imaged by the OGI instrument, then steps must be taken to eliminate those emissions and the source of emissions must be resurveyed. These steps are required to be repeated until no emissions are imaged by the OGI instrument.

The EPA recognizes that the oil and natural gas industry has ongoing maintenance and equipment replacement schedules to ensure proper and safe operations. NSPS OOOOb includes definitions for “reconstruction” and “modification” and specifies when those definitions are met. If a designated facility triggers reconstruction or modification, that source would become an affected facility under NSPS OOOOb. Please refer to the final preamble and NSPS OOOOb for additional discussion.

Please see the Summary of Public Comments and Responses on Proposed Rule Adoption and Submittal of State Plans for Designated Facilities: Implementing Regulations Under Clean Air Act Section 111(d) (Subpart Ba) Docket ID No. EPA-HQ-OAR-2021-052. The final Subpart Ba is published at 88 FR 80480 (November 17, 2023).

### ***19.3.3 Proposed RULOF Criteria***

#### **19.3.3.1 Retirement Dates and Capital Expenditures**

Comment: Commenter (2222-WDXNR) recognizes that an ‘outermost retirement date’ may be reasonable for affected source categories. However, the commenter contends that it is important that EPA solicit public comment on the appropriateness of a date prior to issuing a final rule.

Response II-19-20: Please see RUOF discussion in section XIII.C.3 of the final preamble.

Comment: Commenter (2410-CA AG et al) supports the proposed requirements concerning retirement dates and capital expenditures. The commenter suggests that EPA explain why it is proposing to limit what they consider to be the unreasonable cost criterion to four types of oil and gas facilities. The commenter notes that the state plan must identify the source's retirement date and explain why this date qualifies for imposition of a less stringent standard (i.e., why the cost of control is unreasonable in relation to the retirement date and demonstrate unreasonable cost of control for each of the identified compliance options. The commenter notes that EPA is proposing that the only cost factor that should be considered is whether there is a significant capital investment required to design, purchase, and install equipment. The commenter notes that because controlling methane pollution would not require a significant capital investment for certain types of designated oil and gas facilities, under EPA's proposed approach a less stringent standard based on unreasonable cost would be available for the following types of designated facilities only: oil wells with associated gas, storage vessels, pneumatic controllers, and pneumatic pumps.

Conversely, commenter (2399-GPA) argues that CAA section 111(d)(1) prohibits the proposed "capital investment" limitations to the remaining useful life analysis. The commenter suggests that the EPA's restriction on consideration of cost is likewise unsupported and contrary to the CAA. The commenter states that the December 2022 supplemental proposal "proposes that the only cost factor that" states should be permitted to "consider in a remaining useful life determination of cost unreasonableness is whether there is a significant capital investment required to design, purchase, and install equipment." Under this standard, "EPA does not believe that all types of designated facilities should be eligible for a determination of unreasonable costs associated remaining useful life." Therefore, according to the December 2022 supplemental proposed rule, only "oil wells with associated gas, storage vessels, pneumatic controllers, and pneumatic pumps" would be eligible for a state's consideration of remaining useful life and a "cost unreasonableness determination would not be allowed for any other designated facility types."

Again, the commenter (2399-GPA) states that the EPA does not identify any legal authority for such a requirement. Indeed, the commenter believes that CAA section 111(d)(1) expressly prohibits the proposed requirement: "Regulations of the Administrator under this paragraph shall permit the [s]tate in applying a standard of performance to any particular source ... to take into consideration, among other factors, the remaining useful life of the existing source to which the standard applies." With respect to the state's consideration of remaining useful life, the commenter suggests that this language is unconditional and unlimited. According to the commenter, the state may consider the remaining useful life of "any particular source" or any "existing source." The commenter adds that the only limitation is placed on the Administrator, not the states. The Administrator "shall permit" the consideration of any source's remaining useful life without any suggestion that Congress granted the Administrator the discretion to constrain the states.

Response II-19-21: Please see RUOF discussion in section XIII.C.3 of the final preamble.

Please see the Summary of Public Comments and Responses on Proposed Rule Adoption and Submittal of State Plans for Designated Facilities: Implementing Regulations Under Clean Air Act Section 111(d) (Subpart Ba) Docket ID No. EPA-HQ-OAR-2021-052. The final Subpart Ba is published at 88 FR 80480 (November 17, 2023).

### 19.3.3.2 Impacts of Less Stringent Standards Under RULOF on Impacted Communities

Comment: Commenter (2343-NYU School of Law) recommends that EPA instruct states on how to identify affected communities, how to decide who is vulnerable, and how to analyze impacts to vulnerable communities from adopting less stringent standards based on the facility's remaining useful life.

The commenter (2343-NYU School of Law) recommends that EPA clarify that states must consider the distributional impacts of both the proposed less stringent standard and the alternative if the variance is not granted (i.e., the presumptive level of stringency in the applicable emission guideline from the final rule). For each analysis, the commenter recommends that benefits to each vulnerable community should be disaggregated and, whenever possible, the states' analyses should be quantitative to facilitate comparison. The commenter recommends that EPA help states by providing any available information on quantifying the health harms from the relevant pollutants.

The commenter (2343-NYU School of Law) asserts that once a state has analyzed the allocation of benefits under both scenarios, it would then be in a position to make an informed decision as to whether to pursue a less stringent standard. And, from the perspective of EPA, disaggregating the benefits of each proposed variance would put the agency in a position to evaluate whether ratifying the less stringent standard would harm vulnerable communities, which is prohibited by the Supplemental Proposal when states are relying on a facility's remaining useful life.

Response II-19-22: In the final Implementing Regulations rulemaking, the EPA explained its decision to not finalize the requirement referred to by the commenter. 88 FR 80480 (November 17, 2023). Accordingly, the EPA is also not finalizing such a requirement in this action.

Comment: Commenter (2410-CA AG et al) strongly supports requiring states to consider impacts of a less stringent standard on communities located near the facility. The commenter states that Congress's inclusion of the "other factors" language indicates that additional factors other than remaining useful life could be relevant to determining the appropriate performance standard for individual facilities. Also, the commenter contends that CAA section 111(d)'s language directing that EPA "permit" states to consider remaining useful life indicates that the agency has some discretion regarding how states can apply remaining useful life, among other factors, in establishing performance standards. Given that the purpose of regulating stationary source pollution under CAA section 111 is to address emissions that endanger public health and welfare, the commenter believes that requiring that states take into account how excess pollution (above the level reflected in application of the BSER) may impact the health and welfare of local communities is consistent with the statutory design. Finally, the commenter asserts that EPA's oversight authority in ensuring that state plans do a "satisfactory" job of adopting standards that

reflect the degree of emission reduction from applying the BSER provides additional support for requiring that potential harms from exceeding the EG be adequately considered.

Response II-19-23: In the final Implementing Regulations rulemaking, the EPA explained its decision to not finalize the requirement referred to by the commenter. 88 FR 80480 (November 17, 2023). Accordingly, the EPA is also not finalizing such a requirement in this action.

Comment: Commenter (2428-API) applauds and supports EPA’s overall objective of addressing potential disparate impacts. However, the commenter recommends that EPA consider the proposed requirements to require consideration of EJ impacts because the proposed requirement is not legally supportable. To begin, the commenter notes that the term “other factors” is a generic term in and of itself. But as used in the context of CAA section 111(d), the commenter does not believe that term reasonably means that EJ may be considered in standard setting. First, they provide that CAA section 111(d)(1) states that EPA’s regulations “shall permit” states to consider RULOF in setting existing source emissions standards. This language places responsibility on the states, in the first instance, to determine the “other factors” they deem relevant in setting standards upon consideration of RULOF. According to the commenter, EPA’s role is to review the state determination and not to preemptively specify what factors a state may or may not consider. If a state’s identification and consideration of other factors is reasonable, the commenter states that then EPA cannot reject the state’s determination on the grounds that EPA believes the term “other factors” should be given a different meaning. The commenter argues that the EPA’s proposed approach is inconsistent with the role Congress intended the states to fulfill as part of the CAA’s broader “cooperative federalism” scheme.

Second, the commenter (2428-API) notes that the term “other factors” must be interpreted in context. By specifying that states may consider “remaining useful life,” Congress indicated that source-specific factors are relevant to the states’ determinations. The commenter contends that, since the term “other factors” is a catch-all phrase that follows the more specific instruction to consider a source specific factor, the term “other factors” must be construed in a similar light. They add that this interpretation is particularly true given that “standards of performance” under CAA section 111(a)(1) are technology-based standards that reflect the BSER determined applicable to affected facilities. The commenter asserts that the EPA’s proposed interpretation of “other factors” is inconsistent with this source-specific, technology-based regulatory scheme.

Third, unlike other standards under the CAA, the commenter (2428-API) states that CAA section 111 does not require or allow for standards to be based on an assessment of impacts regarding health or the environment. Where the CAA confers such authority, the commenter notes that it does so expressly and usually in a context where criteria exist to determine the adequacy of such standards. For example, they state that CAA section 112(f) requires impacts to health and the environment to be considered in determining whether Maximum Achievable Control Technology (MACT) based national emission standards for hazardous air pollutants (NESHAP) are adequately protective to health and the environment. The statute specifies that EPA must provide an “ample margin of safety,” as defined in the Benzene Waste NESHAP. CAA section 112(f)(2)(A), (B). The Title I air quality program is also designed in this fashion – with the NAAQS established as the benchmark for acceptable air quality and the guidepost for formulating appropriate state programs.

Here, the commenter (2428-API) points out, CAA section 111 does not provide any indication that EPA must or may consider health or environmental impacts associated with air emissions from affected facilities in determining BSER and in setting emissions standards. For over 50 years, CAA section 111 has properly been construed as a technology-based program designed to prescribe standards based primarily on consideration of the best available technologies that are adequately demonstrated and not cost prohibitive. The commenter states that the EPA's goals here are important but would require standards to be based on impacts analyses of air emissions from affected facilities – an approach that is not incorporated into the CAA section 111 standard setting process.

The commenter (2428-API) adds that the EPA also states that not considering impacts would be “antithetical to the public health and welfare goals of CAA section 111(d) and the CAA generally.” The commenter notes that there is no doubt that protecting public health and welfare are overarching goals of the CAA. However, the commenter does not believe that aspiration does not in itself confer regulatory authority that is not otherwise prescribed by the statute. Congress carefully designed the regulatory tools it intends EPA to use to accomplish an adequate degree of protection to health and welfare. For the reasons explained above, the commenter contends that CAA section 111(d) does not require or allow for consideration of health or environmental impacts in standard setting.

Lastly, the commenter (2428-API) notes that the EPA argues that considering EJ impacts in state standard setting is consistent with the definition of “standard of performance” in CAA section 111(a)(1) and that states must consider such impacts “just as the EPA is statutorily required to take into account these factors in making its BSER determination.” More specifically, EPA asserts that the definition of “standard of performance” “requires the EPA to take into account health and environmental impacts in determining the BSER.” The commenter respectfully disagrees and asserts that there is no language in the CAA section 111(a)(1) definition of “standard of performance” that requires or allows health or environmental impacts associated with air emissions from affected facilities to be factored into standard setting.

As explained above, the commenter (2428-API) states that standards of performance are to primarily be based on technology and cost considerations. The only exception is that “nonair quality health and environmental impact[s] and energy requirements” also must be taken into account in setting standards of performance. CAA section 111(a)(1). The commenter believes that the statute thus is clear that the only “health and environmental impacts” that may be considered in setting a standard of performance are nonair health and environmental impacts. The commenter notes that the provision traditionally has been interpreted to require EPA to consider cross-media impacts (e.g., wastewater created by an air emissions scrubber) so as not to create a different environmental issue through technical requirements meant to address air quality. Because the analysis that EPA would require here would focus on air emissions impacts, the commenter asserts that it cannot be grounded in the requirement to consider nonair quality health and environmental impacts. Moreover, because the statute specifies that only nonair quality health and environmental impacts may be considered in standard setting, the commenter believes that the EPA is precluded from interpreting general language in CAA sections 111(a)(1) or 111(d)(1) as somehow authorizing consideration of air quality-based health or environmental impacts.

For all these reasons, the commenter (2428-API) requests that EPA reconsider the proposed requirement to require consideration of environmental justice (EJ) impacts when states or EPA implement the RULOF provision.

Response II-19-24: Please see the Summary of Public Comments and Responses on Proposed Rule Adoption and Submittal of State Plans for Designated Facilities: Implementing Regulations Under Clean Air Act Section 111(d) (Subpart Ba) Docket ID No. EPA-HQ-OAR-2021-052. The final Subpart Ba is published at 88 FR 80480 (November 17, 2023).

Comment: Commenter (2399-GPA) contends that the proposed health and welfare components of state emission limitations have no legal or record basis and are impermissibly vague. The commenter provides that the December 2022 supplemental proposed rule imposes several additional demands on states related to impacted communities. These include requiring states “to consider the potential health and environmental impacts on communities most affected by and vulnerable to the impacts from the designated facility considered in a state plan for RULOF provisions,” implement “meaningful engagement requirements,” and “describe the health and environmental impacts anticipated ... along with any feedback the state received during meaning engagement.”

The commenter (2399-GPA) supports the important policy goal to protect impacted communities, but not one that EPA is authorized to require states to address as part of a state’s consideration of RULOF. The commenter notes, however, that the text of CAA section 111(d)(1) speaks only of a state’s “consideration” of “the existing source to which such standard applies.” Congress did not require or authorize any other considerations, such as impacts to health or welfare – impacts that Congress frequently included in various CAA analyses when it chose to do so. The commenter states that CAA section 111(d) is specific as to what states may consider (“among other factors, the remaining useful life of the existing source”) and never compels states – through words like “shall” or “must” – to consider anything at all. The commenter suggests that, had Congress intended to direct states to consider generalized “overall health and welfare objectives” in CAA section 111(d) it would have done so.

In addition, the commenter (2399-GPA) states that the record EPA has proffered here does not support the specific mandate that EPA would impose on states through this regulation. First, the commenter notes that the December 2022 supplemental proposed rule declares that these new requirements are necessary “[i]n order to address the potential exacerbation of health and environmental impacts to vulnerable communities as a result of applying a less stringent standard.” The commenter provides that EPA has not, however, offered data or analysis regarding the likelihood of any designated facility, or group of designated facilities, of impacting the health of any vulnerable community or the extent of any such potential impacts. Therefore, there is no record basis supporting the proposal.

Second, the commenter (2399-GPA) provides that the proposed regulatory text is significantly different in several important respects from the preamble explanation providing the supporting rationale. The proposed regulatory text requires a state to demonstrate that the “increased emissions for the duration of the remaining useful life will not result in negative impacts to the surrounding communities, including those most affected by and vulnerable to the health and

environmental impacts of the plan.” Again, the commenter states that the EPA and states may choose to conduct this type of analysis that may offer significant data for the government to consider in fashioning policy, but this language is significantly problematic here in the following respects:

- The state must make some demonstration that the facility’s remaining life emissions “will not result in negative impacts to surrounding communities.” The proposed language does not define a “negative impact” or explain what a state must demonstrate. Neither the preamble nor the proposed regulatory language describes how a state may satisfy EPA that these emissions are acceptable.
- The preamble claims that states must analyze emissions for vulnerable communities, which are not defined. The proposed regulatory language requires a much broader analysis; one that includes all “surrounding communities.” Neither the preamble nor the proposed regulatory language defines “surrounding communities,” so as proposed, states will have no way of knowing how far their analysis must go.
- The need to provide some analysis of emissions, presumably including their concentration and dispersion, over the facility’s remaining life implies that some form of air modeling will be required. For many sources this will be a significant burden layered onto the additional burdens of these regulations imposed on sources and State regulators. However, for other designated facilities, which may include individual pieces of equipment, such as a pneumatic controller, neither the preamble nor the proposed regulatory language provides any indication of what kind of demonstration EPA is expecting.

Therefore, the commenter (2399-GPA) believes that the December 2022 supplemental proposed rule provides a defective rationale for one set of health and welfare requirements while proposing regulatory language that would impose very different requirements. The requirements in the proposed regulatory language are never explained and, therefore, lack the necessary “reasoned explanation.” And, finally, “[e]lementary administrative law norms of fair notice and reasoned decision-making demand that” an agency define what it requires of regulated parties. Here, the proposal (whether that be the December 2022 supplemental proposed rule’s preamble or the proposed regulatory language) does not define key terms (“vulnerable communities,” “surrounding communities,” “those most affected by and vulnerable to the health and environmental impacts of the plan,” “negative impacts”), the type of analysis required, such as air modeling or some unspecified qualitative analysis, or what a state must demonstrate to EPA in order to obtain approval. Therefore, according to the commenter, even if EPA had the legal authority to impose these requirements, they lack record support, are unexplained, impermissibly vague, and otherwise arbitrary and capricious.

Response II-19-25: Please see the Summary of Public Comments and Responses on Proposed Rule Adoption and Submittal of State Plans for Designated Facilities: Implementing Regulations Under Clean Air Act Section 111(d) (Subpart Ba) Docket ID No. EPA-HQ-OAR-2021-052. The final Subpart Ba is published at 88 FR 80480 (November 17, 2023).

### 19.3.3.3 Contingency Requirements

Comment: Commenter (2399-GPA) states that the December 2022 supplemental proposed rule also proposes “contingency requirements” that would effectively convert a state’s determination that applying EGs to a facility is not reasonably cost-effective into a binding permit term. Two such examples provided in the December 2022 supplemental proposed rule would be that, (1) if low oil prices would make application of the emission guidelines to a facility unreasonably expensive then a federally enforceable permit conditions would require the facility to shut down if oil prices increased (making the emission guidelines more cost effective), and (2) if a short remaining useful life makes application of the emission guidelines unreasonably cost-effective, then the facility’s retirement date must become a federally enforceable permit condition requiring it to shut down on that date.

The commenter (2399-GPA) urges EPA to reconsider this approach. According to the commenter, nothing in the statute authorizes these restrictions on defining the implementation of RULOF – and none is cited in the proposal. Nor does the record for the proposal indicate that such conditions have been used or would be needed. According to the commenter, these “contingency requirements” address purely hypothetical scenarios without any consideration of what states have done in setting emission limits under CAA section 111(d). In addition, EPA previously rejected the requirement to make a facility’s retirement date a federally enforceable permit condition, in a similar circumstance. Under the 2005 Regional Haze Rule, EPA rejected a commenter’s request that, “to the extent that assertions regarding a plant’s remaining useful life influences the BART decision, there must be an enforceable requirement for the plant to shut down by that date.”<sup>124</sup> The commenter provides that the EPA rejected the request, explaining that the CAA would require such a plant to either shut down at the retirement date, face an enforcement action, or install best available retrofit technology (BART) controls. In other words, the facility would be able to adapt to any changes in condition. The commenter states that the December 2022 supplemental proposed rule not only changes EPA’s position on this issue but does so without explanation or even a recognition that it is changing its position.

Response II-19-26: Please see the Summary of Public Comments and Responses on Proposed Rule Adoption and Submittal of State Plans for Designated Facilities: Implementing Regulations Under Clean Air Act Section 111(d) (Subpart Ba) Docket ID No. EPA-HQ-OAR-2021-052. The final Subpart Ba is published at 88 FR 80480 (November 17, 2023).

Comment: Commenter (2410-CA AG et al) notes that where a state seeks to rely on a designated facility’s operational conditions—such as the source’s remaining useful life or restricted capacity—as a basis for setting a less stringent standard, EPA proposes to require enforceable conditions for that facility in the state plan to address the scenario where a source’s operations change. This requirement would address operating conditions such as operation times, operational frequency, process temperature or pressure, and other conditions that are subject to the discretion and control of the designated facility. The commenter supports imposing contingency requirements in instances where a less stringent standard is based on an operational constraint within a facility’s control. The commenter agrees with EPA that, in the absence of an

---

<sup>124</sup> 70 Fed. Reg. 39,104, 39,127 (July 6, 2005).

enforceable requirement, a subsequent (unforeseen) change in a facility's operations could result in foregone emission reductions and undermine the level of stringency in the EG.

Response II-19-27: Please see the Summary of Public Comments and Responses on Proposed Rule Adoption and Submittal of State Plans for Designated Facilities: Implementing Regulations Under Clean Air Act Section 111(d) (Subpart Ba) Docket ID No. EPA-HQ-OAR-2021-052. The final Subpart Ba is published at 88 FR 80480 (November 17, 2023).

#### 19.3.3.4 Fundamentally Different

Comment: Commenter (2399-GPA) notes that, to satisfy RULOF, EPA has created criteria based on cost, physical impossibility, or technical impracticability, and “other factors specific to the facility (or class of facilities) that are fundamentally different from the factors considered in the determination of the best system of emission reduction” in EPA’s EGs.

The commenter (2399-GPA) urges EPA to reconsider the “fundamentally different” criteria, as they believe it is flawed in at least two ways. First, “fundamentally different” is just as vague and ambiguous as “reasonable,” the word that EPA claims requires additional definition. Second, it practically requires that a state demonstrate that EPA’s presumptive standards are arbitrary and capricious in a specific application. According to the commenter, nothing in CAA section 111(d) indicates that Congress intended for states to consider RULOF only in extreme, outlier scenarios that are “fundamentally different.”

In fact, the commenter (2399-GPA) provides that the December 2022 supplemental proposed rule illustrates how impractical RULOF would become under this “fundamentally different” criterion by claiming that states must demonstrate that BSER costs “would be exorbitant, greater than the industry could bear and survive, excessive, or ‘unreasonable.’” In a more specific example, the December 2022 supplemental proposed rule asserts that, where EPA estimated that the cost-effectiveness of the wet seal centrifugal compressor emission standard to be \$711 per ton of methane removed, to demonstrate unreasonable cost, a State would have to determine that for an “affected facility in their state, the cost effectiveness was \$71,000 per ton of methane removed.” (emphasis added). The commenter contends that the notion that states can only justify unreasonable costs by demonstrating, to EPA’s satisfaction, that cost-effectiveness will be two orders of magnitude higher than the BSER estimate has no basis in the statute, is patently arbitrary and capricious, and would effectively preclude any state from ever establishing emission limitations based on methods that Congress authorized under CAA section 111(d). The December 2022 supplemental proposed rule protests that it only provided the example “for illustrative purposes” and that states do not necessarily need to demonstrate that costs will “be two orders of magnitude higher than the presumptive standard to be considered unreasonable.” However, the commenter notes this is the only example that the December 2022 supplemental proposed rule provided using a cost-effectiveness comparison. Both EPA and courts could refer to this example as indicating that EPA’s interpretation of “unreasonable costs” should require a cost difference so extreme that even four or five times the BSER cost-effectiveness (*i.e.*, approximately \$2,850 to \$3,550 per ton of methane removed) would not be enough to be “unreasonable.”

Comment: Commenter (1633-NRDC) with the supplemental proposal that variances for remaining useful life or other factors should not be granted without a demonstration that a specific source is “fundamentally different” from the other members of the category or subcategory to which it belongs under EPA’s emission guideline. “Fundamentally different” means more than just some difference. It means that the source must be so different that it is not rational to include it in the same set as the other sources in the category or subcategory.

Commenter (1633-NRDC) notes that the proposed rules elaborate the three conditions set forth in the 1975 rules to incorporate this requirement of fundamental difference. The proposed rules explain, for example, that a minor variation in cost-per-ton of emission controls will not make a source fundamentally different from the other members of the category. Some source-to-source cost variation is inevitable in any category. The agrees with EPA’s examples that suggest what is required is an order-of-magnitude difference in cost-per-ton.

Commenter (1633-NRDC) also supports the proposed distinction between capital and operating costs. EPA may determine in an emission guideline that a standard which entails a significant capital cost has a reasonable cost per-ton and is warranted by health and environmental benefits because the capital expenditure can be amortized over a given number of years of operation. The same requirement may have a substantially higher cost-per-ton and may deliver fewer health and environmental benefits if applied to a source that will imminently retire. If that difference is on the order-of-magnitude scale mentioned above, it may be possible for the source to demonstrate to the state, and the state to demonstrate to EPA, that this source is in fundamentally different situation compared with the longer-lived sources on which the guideline was based, and that a variance is appropriate.

Commenter (1633-NRDC) adds conversely, requirements such as leak detection and repair involve operating costs but no significant capital costs. Those annual or per-instance operating costs do not vary with the remaining lifetime of the source. Their cost-effectiveness requires no amortization period. For these requirements there is no basis for determining that a source scheduled to retire soon faces fundamentally different costs than those faced by the category’s general membership. The commenter supports EPA’s proposed determination that remaining useful life variances cannot be granted for LDAR and similar requirements.

Commenter (1633-NRDC) supports EPA’s proposed requirement that retirement dates be enforceable for sources applying for remaining useful life variances.

Response II-19-28: Please see the Summary of Public Comments and Responses on Proposed Rule Adoption and Submittal of State Plans for Designated Facilities: Implementing Regulations Under Clean Air Act Section 111(d) (Subpart Ba) Docket ID No. EPA-HQ-OAR-2021-052. The final Subpart Ba is published at 88 FR 80480 (November 17, 2023).

Comment: Commenter (2410-CA AG et al) notes that the current regulations contain certain threshold criteria that must be triggered for a state to establish a less stringent standard based on the remaining useful life of a facility (or other factors). The commenter contends that while

retaining the threshold requirements in the current regulations that refer to an unreasonable cost of control resulting from plant age, location, or basic process design or physical impossibility of installing necessary control equipment, EPA proposes to modify the current “catchall” third criterion to apply if a state demonstrates that there are other factors specific to the facility (or class of facilities) “that are fundamentally different from the factors considered in the establishment of the emission guidelines.” For example, if the state could demonstrate that the cost-per-ton of pollution reduction at a particular facility would be significantly higher than estimated by EPA in its BSER analysis, that facility may be evaluated for a less stringent standard. The commenter notes that states would not be permitted to invoke the RULOF provision based on minor, non-fundamental differences. The commenter supports EPA’s revisions to the threshold requirements for applying RULOF. The commenter contends that the “fundamentally different” language adds clarification on applying the other factors and is consistent with variance provisions in the Clean Water Act and other environmental laws.

Response II-19-29: Please see the Summary of Public Comments and Responses on Proposed Rule Adoption and Submittal of State Plans for Designated Facilities: Implementing Regulations Under Clean Air Act Section 111(d) (Subpart Ba) Docket ID No. EPA-HQ-OAR-2021-052. The final Subpart Ba is published at 88 FR 80480 (November 17, 2023).

#### 19.3.3.5 Variances

##### *Variance Guidance*

Comment: Commenter (1633-NRDC) asserts that EPA must define clear rules to guide states and other stakeholders on when a variance is warranted or what alternative emission limit and compliance deadline should apply. The commenter believes that an absence of rules gives rise to the potential for unequal treatment of similar cases by states or EPA and may incentivize a race to the bottom at the expense of public health and environmental protection. The commenter notes, as explained in the proposal, the 1970 CAA made no provision for source-specific variances. The commenter provides that EPA’s 1975 implementation rules allowed states some leeway for differentiation for specific sources within a category or subcategory through a variance process.

Response II-19-30: Please see the Summary of Public Comments and Responses on Proposed Rule Adoption and Submittal of State Plans for Designated Facilities: Implementing Regulations Under Clean Air Act Section 111(d) (Subpart Ba) Docket ID No. EPA-HQ-OAR-2021-052. The final Subpart Ba is published at 88 FR 80480 (November 17, 2023).

##### *Variance Legal Considerations*

Comment: Commenter (2433-EDF et al) recommends that RULOF provisions that allow variances are the exception rather than the norm to maintain the regulation integrity. The commenter strongly supports the December 2022 supplemental proposal’s RULOF provisions which outline the application and review process for variances, as well as the criteria required for each such variance. The commenter provides comments on the processes (etc) in the following paragraphs.

a. The application and review process for RULOF variances

Under the proposal, a state must identify and explain the basis for the variance request, identify all other possible systems of emission reduction for the source, and select an alternative “best system” from this list, as well as a degree of emission limitation based on that system. The state must then impose an enforceable performance standard for the source that reflects the degree of emission limitation associated with the alternative best system and that otherwise complies with CAA section 111(d)’s implementation regulations.

The commenter (2433-EDF et al) asserts that it is critical that in the final rule, EPA establish these provisions as binding requirements (as it has done in the proposal) rather than merely presumptive suggestions (an option for which it requests comment). The commenter believes that non-binding provisions would open the door for states to grant variances for various other reasons that EPA would have to assess on a case-by-case basis. As explained below, the commenter contends that was exactly the problem with the 1975 and 2019 implementing regulations. The commenter believes that the problem would be exacerbated by the large number of sources in the oil and natural gas sector; administrative necessity by itself is sufficient reason for EPA to put binding requirements on variances.

The supplemental proposal also maintains certain conditions that are essential to prevent abuse of the RULOF provision. First, it prohibits states from issuing variances merely because a source wishes to use a different system of emission reduction than the agency’s designated “best system.” The standard set by the state must achieve the degree of emission reduction as provided by the emissions guideline unless the conditions for variances are met. Second, the proposal requires that any operating conditions serving as the basis for a variance be included in the plan as federally enforceable requirements for the source in question. Third, with respect to age-based variances in particular, the proposal establishes a heightened standard of specificity, requiring states to demonstrate that the unit’s retirement date conflicts with at least one of five factors needed to fully satisfy EPA’s guidelines. The commenter (2433-EDF et al) acknowledges that together, these requirements will help prevent abuse of RULOF-based variances while still providing the regulatory flexibility that Congress contemplated in enacting CAA section 111(d).

b. The conditions for receiving RULOF variances.

The commenter (2433-EDF et al) believes that the proposal places reasonable limitations on the circumstances under which variances may be granted. The commenter reports that the 1975 and 2019 regulations stated, without elaboration, that states may establish more lenient standards for an affected source if they demonstrate at least one of three conditions:

- (1) Unreasonable cost of control resulting from plant age, location, or basic process design;
- (2) Physical impossibility of installing necessary control equipment; or

(3) Other factors specific to the facility (or class of facilities) that make application of a less stringent standard or final compliance time significantly more reasonable.<sup>125</sup>

The commenter (2433-EDF et al) asserts that this language gave states too much room for interpretation and does little to prevent state-based variances from being granted to sources that exhibit no exceptional characteristics compared to the other members of their category or subcategory. The commenter supports the additional restraints that EPA has included in the December 2022 supplemental proposal on the issuance of variances that serve a critical function by helping to ensure that variances are reserved for only truly extraordinary circumstances. Below, the commenter discusses the conditions that EPA has established and provides recommendations for further refinement and improvement of the RULOF provisions from what was proposed in the December 2022 supplemental proposal.

i. Condition #1: Variances based on compliance costs.

The commenter (2433-EDF et al) urges EPA to remove or limit “unreasonable costs of control resulting from . . . basic process design” as a basis for granting variances in the first clause.<sup>126</sup> The commenter acknowledges that this term is not new to EG OOOOc—it also appeared in the 1975 and 2019 regulations—however the commenter questions what purpose it serves, or what it even means. If a source’s “basic process design” requires using outdated technology that cannot incorporate the BSER at a reasonable cost, then that is no reason to grant the source a relaxed standard, particularly since EPA’s “best system” *must* reflect reasonable costs as a general matter. The commenter contends that it does not contravene Congress’s intent if certain obsolete sources end up retiring rather than incurring the costs required to install the “best system” technology, particularly where doing so would not result in stranded assets. The commenter recommends that EPA thus limit the first category of variances to unreasonable costs based on plant age or location. Alternatively, the commenter recommends that the agency provide clearer guidance and limitations on when states may grant variances reflecting “basic process design” considerations.

The commenter (2433-EDF et al) also strongly supports EPA’s proposal to limit possible RULOF variances based on compliance costs resulting from a source’s remaining useful life to only four subcategories of sources in the oil and gas source category: oil wells with associated gas, storage vessels, pneumatic controllers, and pneumatic pumps. The commenter agrees with EPA’s explanation that these are the only sources that must make significant capital expenditures to comply with the proposed EG OOOOc standards.

The commenter (2433-EDF et al) also supports EPA in —appropriately—not permitting variances based on age-related compliance costs for affected facilities other than the four types noted above. In the commenter’s submission on the November 2021 proposal, they explained that Congress’s primary reason for enacting the RULOF provision was to avoid imposing otherwise unreasonable capital costs on an aging facility that will close before the period assumed for amortizing those costs for other members of the relevant category or subcategory.<sup>127</sup>

---

<sup>125</sup> 40 CFR 60.24(f), 60.24a(e).

<sup>126</sup> Proposed 40 CFR 60.5365c(a)(1).

<sup>127</sup> See 2022 Joint Environmental Comments, *supra* note 1, at 214–15.

The commenter states that this concern simply does not apply where compliance requires no significant upfront capital investment in the first place—which is true for all the EG OOOOc-affected sources apart from oil wells with associated gas, storage tanks, and pneumatic equipment. The commenter agrees that the supplemental rule’s RULOF provisions therefore adhere to Congress’s intent and ensure that sources do not receive a windfall in terms of relaxed standards merely because they are old and nearing retirement.

The commenter (2433-EDF et al) describes another way to see the same point: the annualized cost-effectiveness of a measure that has no upfront capital investments is the same regardless of the remaining useful life of the source. Since EPA determined the annualized cost-effectiveness of the measure to be reasonable in setting BSER, that annualized cost-effectiveness remains reasonable for a source with a relatively short remaining useful life. In other words, the commenter states that remaining useful life does not create any difference between the aging facility and EPA’s BSER determination under these circumstances, let alone a “fundamental difference.”<sup>128</sup>

The commenter (2433-EDF et al) asserts that even for sources that do require capital investments for compliance, the supplemental rule appropriately establishes at least *three* other important limiting conditions before they can qualify for a variance. *First*, as EPA explains in the preamble, costs associated with a source’s remaining useful life must not merely increase for a variance to be warranted, but must rise to the level of *unreasonableness*, as determined by the agency, in terms of dollars spent per ton of pollution abated. The commenter agrees that this is wholly appropriate as it responds to Congress’s concern about stranded assets without allowing sources to wrongly benefit from reasonable increases in control costs and does not account for a particular sources’ margin of profitability, a consideration that should not be relevant to pollution control decisions. As already noted, a cost differential must be fundamental, not minor, to be considered unreasonable.

*Second*, the supplemental proposal requires sources receiving age-based variances for any reason—including reasons unrelated to cost—to demonstrate that “[t]he increased emissions for the duration of the remaining useful life will not result in negative impacts to the surrounding communities, including those most affected by and vulnerable to the health and environmental impacts of the plan.” The commenter (2433-EDF et al) believes that this is a critically important guardrail that appropriately balances the need for regulatory flexibility with CAA section 111’s lodestar of health and environmental protection, and it also specifically requires an evaluation of how vulnerable communities will be affected by variances. The commenter asserts that this sort of balancing fully aligns with the language of CAA section 111(d), which does not direct that sources are necessarily entitled to age-based variances under any particular circumstances. Rather, the provision *allows* states to “*take into consideration*” RULOF when establishing performance standards for particular sources. States must weigh these considerations against other factors—namely, health and environmental impacts—when determining whether to grant a variance.

---

<sup>128</sup> As discussed in greater detail below, the commenter urges that the “fundamentally different” language that EPA proposes to include under the third variance condition (i.e., the “other factors” condition) apply to all conditions for receiving a variance under CAA section 111(d).

The commenter (2433-EDF et al) encourages EPA to extend this community-protection requirement to all variance requests, regardless which clause they fall under. As currently written, the proposed RULOF provisions requires that states “consider the potential health and environmental impacts and benefits of control to any community most affected by and vulnerable to impacts from the designated facility” whenever it calculates a less stringent standard for a source, regardless of the variance category. The commenter believes that this is an improvement from the status quo, but it is less protective than the condition that applies specifically to age-based variances, which *prohibits* a state from granting a less stringent standard for any source unless it can demonstrate that the increased emissions resulting from the variance “not result in negative impacts to the surrounding communities.” The commenter recommends that EPA include this requirement regardless of the variance clause the state is invoking when calculating a less stringent standard for any source.

*Third*, for any source receiving an age-based variance, the state must establish a federally enforceable retirement commitment in the plan. This will discourage unwarranted variance applications and will ensure that excess pollution resulting from variances will be of limited duration. However, the commenter (2433-EDF et al) urges EPA to improve this requirement in several regards. First, the proposal does not specify any timeframe within which a source receiving an aged-based variance must retire. The commenter requests that EPA clarify this to require that a source receiving a variance of this nature retire at the expiration of the amortization schedule that the source owner has used to demonstrate unreasonable compliance cost, subject to a reasonable capital recovery window and interest rate specified by EPA. Furthermore, the proposed regulations provide that “if a designated facility’s retirement date is imminent, the plan may apply a standard that reflects the designated facility’s business as usual.” The commenter notes that EPA does not define “imminent” in this context, leaving it susceptible to an inappropriately expansive definition in state plans. The commenter requests that EPA establish a clear definition that limits “imminent” retirements to those that are very near—no more than one to two years.

The commenter (2433-EDF et al) further urges EPA to drop the proposed “escape hatch” that would allow a source benefiting from a variance to abrogate its retirement commitment. Specifically, the commenter recommends that EPA delete this provision: “If an owner or operator of such a designated facility elects not to retire the designated facility as scheduled, the designated facility must achieve compliance with the standard listed in the Model Rule for the designated facility by the date otherwise required for the designated facility.”<sup>129</sup> The commenter contends that this is inherently contradictory: a retirement date cannot be “an enforceable commitment” if a source may “elect[] not to retire” by that date. Even if the source in question must meet the unmodified standards after that point, there is no provision for making up the extra pollution allowed during the variance period. Furthermore, the commenter adds that they believe that this provision will allow sources and states to adopt spurious retirement dates that they never intend to honor, effectively delaying compliance with the original standard.

In fact, the commenter (2433-EDF et al) asserts that if the “escape hatch” provision were to be used, it would undermine the equivalency determination EPA must make under the IRA. In this case, the commenter suggests that the state plan at issue might fall short of achieving the

---

<sup>129</sup> Proposed 40 CFR 60.5365c(4).

emission reductions that would have resulted if the emission standards in the November 2021 proposed emission guidelines were fully implemented. Furthermore, the commenter states that CAA section 111(d) plans must be subject to “similar” procedures as CAA section 110 SIPs. The commenter notes that among those procedures is an anti-backsliding provision, CAA section 110(l), which prohibits revisions that interfere with the national ambient air quality standards (NAAQS) or other requirements of the Act. This suggests such backsliding, as in the case here of a plan that replaces a retirement with a provision that allows the source to continue to emit pollution, should not be allowed.

ii. Condition #2: Variances based on impossibility or technical infeasibility.

The commenter (2433-EDF et al) urges EPA to amend the second clause to remove “technological infeasibility . . . of installing necessary control equipment” as a potential basis for a variance.”<sup>130</sup> The commenter states that under the 1975 and 2019 regulation this clause was limited to situations of “physical impossibility.” The commenter expresses concern that “technical infeasibility” is a highly imprecise term that is susceptible to abuse and overapplication, and EPA has provided no definition or guidance on the term. There may, for example, be instances in which a source must undertake some small, additional, and cost-effective modification in order to install a control technology and on that account seek—inappropriately—a variance based on “technically infeasible.”

The commenter (2433-EDF et al) states that to the extent that a source truly is uniquely situated from a technical standpoint, the third variance clause already encompasses it with the “fundamental difference” limitation that we recommend apply to all three clauses (see below). The commenter suggests that it is not clear what other bases for technological infeasibility these clauses would not already cover, particularly since EPA has also already proposed to allow the application of alternative standards at certain facilities based on technical infeasibility.<sup>131</sup> Accordingly, the commenter urges EPA to remove “technical feasibility” as a basis for allowing variances, or at least to make clear that it too is subject to the requirement of fundamental difference. If the agency does retain this factor, the commenter requests that EPA provide much more specific guidance and limitations on its application.

iii. Condition #3: Limiting “other factors” to “fundamentally different factors.”

The commenter (2433-EDF et al) contends that under the 1975 and 2019 RULOF provisions, the non-specific “other factors” exemption in clause (3) is vulnerable to abuse by sources seeking to avoid otherwise applicable pollution control requirements. However, the commenter notes that the December 2022 supplemental proposal now inserts important limiting factors into the “other factors” exemption process. First, the “other factors” category now reads as follows: “other factors . . . that are fundamentally different from the factors considered in the determination of the best system of emission reduction in the emission guidelines.” The commenter states that “fundamentally different” means more than just “some difference.” Rather, the commenter

---

<sup>130</sup> Proposed 40 CFR 60.5365c(a)(2).

<sup>131</sup> For example, the commenter states that the EPA has proposed to allow flaring of associated gas at oil wells if it is technically infeasible to route to a sales line, use onsite, use for another beneficial use, or reinject or inject the gas. 87 Fed. Reg. at 74780.

suggests that the source must be so different that it is not rational to expect it to achieve the same degree of emission limitation as other sources in the category or subcategory. The commenter supports the “fundamentally different” qualifier in that it will prevent a state from displacing EPA’s judgment regarding the emission limitation that reflects the BSER for a category or subcategory on minor and unexplained or unproven grounds.

The commenter (2433-EDF et al) states that EPA has employed this definition of “fundamentally different” for decades in the context of the Clean Water Act. There, EPA may grant a “fundamentally different factor” variance from national effluent limitations for a specific point source.<sup>132</sup> But that variance is only permissible in abnormal circumstances, such as when imposing the national effluent limitation would result in a removal cost “wholly out of proportion” with EPA’s estimated removal costs.<sup>133</sup> Thus, under one of the CAA’s companion statutes, a “minor difference” will not justify a “fundamentally different factor” variance. The commenter asserts that there is no reason to read EPA’s proposed language here any differently.

Furthermore, as noted above, the commenter (2433-EDF et al) urges EPA to extend the “fundamentally different” qualifier to all three variance clauses. Any variance is appropriate only if the emission guideline EPA did not already consider the factors at play in determining the emission limitation that reflects the “best system of emission reduction” for the relevant source category or subcategory. For example, the first clause permits variances based on unreasonable costs resulting from plant location. The commenter recommends that a state should have to demonstrate that compliance cost differences for the source seeking a variance are “fundamentally” different from the costs that are representative of other sources in the relevant category or subcategory. Likewise, under the second clause, to invoke “physical impossibility,” a state should have to demonstrate that a source’s physical configuration poses an obstacle so fundamental that the emission limitation cannot be met at all, or only at fundamentally (order of magnitude) higher cost compared to other members of the relevant category or subcategory.

The commenter (2433-EDF et al) suggests that EPA provide greater clarity in the regulatory text regarding the nature of “fundamental differences.” According to the preamble, a “fundamental difference” must relate to a particular factor that is relevant to EPA’s determination of the “best system” for a category or subcategory, on the one hand, and that same factor as applied to the specific facility seeking a variance. Yet the proposed rule’s regulatory text does not quite capture this: it refers to “other factors specific to the facility (or class of facilities) that are fundamentally different from the factors considered in the determination of the best system of emission reduction in the emission guidelines.” The commenter states that this text could be interpreted to allow states to grant variances based on extra-statutory factors that EPA did not and could not have considered in setting BSER, such as local political opposition to stringent regulations.

Instead, the commenter (2433-EDF et al) suggests that the provision should read along the following lines: “other factors considered by EPA in determining the best system of emission reductions which, when applied to the specific facility, are fundamentally different from EPA’s finding for the category or sub-category.” Thus, when EPA asks whether there are “other considerations” under which variances are appropriate,” those considerations themselves must

---

<sup>132</sup> See 40 CFR pt. 125, subpart D.

<sup>133</sup> 40 CFR 125.31(b)(3)(i) (emphasis added).

be relevant to the statutory factors EPA considered in determining BSER, such as cost and degree of emissions reduction, even while the application of those factors to the facility in question result in fundamental differences.

c. Granting RULOF variances for source limitations that are more stringent than EPA's proposed guidelines.

Finally, the commenter (2433-EDF et al) supports EPA's interpretation of CAA section 111(d) as allowing EPA to approve a state plan with standards for a category, subcategory, or individual source that are *more* stringent than the emission limitations in EPA's guidelines.

Since 1975, the commenter (2433-EDF et al) states that the EPA has interpreted the statute to require state plans that are "*no less stringent* than the corresponding emission guideline(s)," <sup>134</sup> a formulation that clearly contemplates more stringent standards. According to the commenter, this squares with the CAA itself, which directs EPA to approve only those plans that are "satisfactory." <sup>135</sup> The commenter believes that the notion that EPA could reject as somehow less than "satisfactory" a state plan that not only achieved but exceeded the emission reductions required by the agency's guidelines would contradict the logic of the Supreme Court's holding in *Union Electric Company v. EPA*. <sup>136</sup> There, the commenter provides that the Court ruled that EPA may not reject a SIP under CAA section 110 of the Act on the grounds that the plan exceeds the minimum federal requirements. <sup>137</sup> As the Court explained, legislative history, along with the "structure and purpose" of the Act, confirm that SIPs must "meet the '*minimum* conditions' of the [provision]," but that "[b]eyond that, if a [s]tate makes the legislative determination that it desires a particular air quality by a certain date and that it is willing to force technology to attain it or lose a certain industry if attainment is not possible," EPA may not thereby reject the plan on the grounds that it is too stringent. <sup>138</sup>

As the court further explained, CAA section 116 of the Act specifically preserves state authority to adopt standards more protective than EPA's under this provision of the statute. Thus, the commenter notes that if EPA were permitted (or required) to reject SIPs as *overly* (as opposed to insufficiently) protective of health and the environment,

[it] would not only require the Administrator to expend considerable time and energy determining whether a state plan was precisely tailored to meet the federal standards, but would simultaneously require States desiring stricter standards to enact and enforce two sets of emission standards, one federally approved plan and one stricter state plan. We find no basis in the Amendments for visiting such wasteful burdens upon the States and the Administrator, and so we reject the argument of Amici. <sup>139</sup>

---

<sup>134</sup> 40 CFR 60.24(c), 60.24a(c).

<sup>135</sup> 42 U.S.C. § 7411(d)(2)(A).

<sup>136</sup> 427 U.S. 246 (1976).

<sup>137</sup> Id. at 265.

<sup>138</sup> Id. at 264-65 (emphasis added).

<sup>139</sup> Id. at 264.

The commenter (2433-EDF et al) contends that all these principles apply equally to CAA section 111(d) plans as to CAA section 110 plans. Indeed, the commenter states that Congress explicitly modeled CAA section 111(d) on CAA section 110, directing the Administrator to “establish a procedure similar to that provided by section 7410 of this title”<sup>140</sup> by which a state submit plans achieving the federal emission reduction requirements for sources within their borders. Thus, for all the reasons described in *Union Electric*, the commenter believes that the EPA rightly concludes that it may not reject section 111(d) state plans that are more stringent than the federal emission guidelines.

Response II-19-31: Please see RULOF discussion in section XIII.C.3 of the final preamble.

Please see the Summary of Public Comments and Responses on Proposed Rule Adoption and Submittal of State Plans for Designated Facilities: Implementing Regulations Under Clean Air Act Section 111(d) (Subpart Ba) Docket ID No. EPA-HQ-OAR-2021-052. The final Subpart Ba is published at 88 FR 80480 (November 17, 2023).

#### ***19.3.4 Information Sources***

Comment: Commenter (2337-KDHE) asserts that there is no legitimate reason for EPA to restrict sources of information if sources are adequately documented according to established principles in scientific literature. The commenter contends that proposing a list of sources – and requiring EPA regional offices decide whether a source meets requirements - is contrary to the goal of cooperative federalism and has nothing to do with legitimacy, verifiability, or transparency.

Response II-19-32: The EPA has not finalized the provision referred to in this comment.

#### ***19.3.5 Low Producing Well Considerations***

Comment: Commenter (2337-KDHE) states that environmental justice (EJ) is an “other factor” in the context of RULOF. The commenter recommends that EPA waive compliance of proposed monitoring requirements for low production wells for EJ reasons, at least in the following counties: Barber, Chautauqua, Coffey, Finney, Grant, Greenwood, Haskell, Kearny, Ness, Rooks, Russell, Seward, Stafford, Stevens, Wilson, and Woodson.

The commenter (2337-KDHE) reports that of its total 105 counties, Kansas has 29 counties that currently have more than 1,000 producing oil and/or gas wells within their borders. Among these, there are 16 counties, found chiefly in the southwest and southeast parts of the state, which the 2020 U.S. Census shows to have at least one EJ demographic index at least five percent above the corresponding average U.S. value.<sup>141</sup> The commenter states that the demographic indices analyzed were persons less than five, persons greater than or equal to 65, percent people of color, percent limited English speaking households, less than high school education, and persons in poverty. The commenter notes, for example, Stevens County, which had 2,159 producing wells in 2021, shows limited English-speaking households 7.9 percent above the U.S.

---

<sup>140</sup> 42 U.S.C. § 7411(d)(1).

<sup>141</sup> See <https://www.census.gov/quickfacts/>.

average (21.7%), and shows persons with less than high school education 15.0 percent above the U.S. average (11.1%). Moreover, the commenter reports that the 2020 average population density for these 16 counties is 10.3 persons per square mile, which is 89 percent below the national average (93.8 persons per square mile). The commenter states that in these rural counties the oil and gas industry is a primary economic mainstay, and that the closure of producing wells has serious negative impacts to surrounding communities.<sup>142</sup> The commenter provides that in this respect and combined with the certain knowledge that owners and operators of low producing wells cannot afford to comply with the proposed rule as written, the rule is not promoting EJ; on the contrary, the commenter believes that the rule would itself instead seriously impact many EJ communities.

Response II-19-33: The EPA has not finalized separate requirements for low production wells. However, the EPA has finalized standards for fugitive emissions that take into account the size of the well. See section X.A of the final rule preamble.

Comment: Commenter (2240-Rose Rock) recommends that EPA allow states more flexibility to develop specific requirements for existing sources without overburdening state resources. The commenter asserts that the proposed rule will vastly increase the resources required to manage and regulate existing sources without providing a means for additional funding. The commenter reposts that the Oklahoma Department of Environmental Quality (OK DEQ) has estimated that under the proposed rule, the number of oil and gas permitted facilities would go from approximately 10,000 to over 200,000. Most of these facilities are low producing and have low emissions.

Response II-19-34: The EPA does intend on working with tribes and states to develop plans tailored to the factors concerning the states. The plan development process, under which performance standards for existing sources are established within their jurisdiction and have the discretion to consider remaining useful life and other factors, is one that Congress established through the text and structure of CAA section 111(d). See discussions in section V.B.2.<sup>143</sup> and section V.B.3.<sup>144</sup> of the December 2022 Supplemental and section XIII of the final preamble and final rule, Adoption and Submittal of State Plans for Designated Facilities: Implementing Regulations Under Clean Air Act Section 111(d) at 88 FR 80480, November 17, 2023, and its corresponding Summary of Public Comments and Responses on Proposed Rule Adoption and Submittal of State Plans for Designated Facilities: Implementing Regulations Under Clean Air Act Section 111(d) (Subpart Ba) Docket ID No. EPA-HQ-OAR-2021-052.

The new standards will work hand-in-hand with new resources and programs in the Inflation Reduction Act, which will incentivize early implementation of innovative methane reduction technologies and support methane mitigation and monitoring activities. These efforts will achieve greater methane emissions reductions more quickly. For more information on the IRA, the Administration has created a guidebook that provides an overview of the clean energy, climate mitigation and resilience, agriculture, and conservation-related tax incentives and

---

<sup>142</sup> See "Marginal Well Report (2016)" [https://iogcc.ok.gov/sites/g/files/gmc836/f/marginal\\_well\\_2016-final.pdf](https://iogcc.ok.gov/sites/g/files/gmc836/f/marginal_well_2016-final.pdf) found at <https://iogcc.ok.gov/publications>.

<sup>143</sup> 87 FR 74812.

<sup>144</sup> 87 FR 74816.

investment programs, including who is eligible to apply for funding and for what activities. See <https://www.whitehouse.gov/cleanenergy/inflation-reduction-act-guidebook/> .

Comment: Commenter (2283-Endeavor Energy) recommends that EPA take additional time to develop EGs that reflect the realities of older existing sources as required by the CAA. The commenter reports that because many older sites do not produce as much oil or gas, these new compliance obligations could very well alter the "remaining useful life" of the well and cause wells to be shut in or prematurely abandoned. The commenter states that this is the case for many producers and could have far-reaching impacts on domestic oil and gas production. The commenter expresses concern that the overly prescriptive and inflexible approach proposed by EPA does not properly reflect the CAA statutory requirement that directs EPA to ensure that its EGs permit the states to take remaining useful life and other factors in account-

Response II-19-35: Please see discussion in section XIII.C. of the final preamble regarding state's flexibilities in establishing standards in state plans.

Comment: Commenter (2201-WVHC) urges EPA to avoid any possibility that states could make categorical exclusions of small gas wells. The commenter believes that an attempt to provide state flexibility has the potential to create an enormous, dangerous loophole that makes the rule much less effective. The commenter reports that West Virginia has tens of thousands of small gas wells that are either abandoned and have no production that is collected and sold or have small production. A substantial fraction of these wells are leaking methane into the atmosphere. Collectively—and in some cases individually—the commenter reports that these legions of small wells are making a dramatic contribution to the problem of leaking methane.

Response II-19-36: Please see discussion in section XIII.C. of the final preamble regarding state's flexibilities in establishing standards in state plans.

Comment: Commenter (2434-Private Citizen) urges EPA to make the RULOF provisions very strict, so that it is rare for a state to be able to grant an exemption based on RULOF. Older or smaller gas wells often leak quite a large amount of methane and VOCs, and exempting these older or smaller wells due to limited Remaining Useful Life would still harm human health. Companies need to be responsible for wells that they own, and make sure they don't hurt children and seniors even if the well is not being used. They need to be capped and sealed, and tested to be sure the seal is working properly and no methane is leaking.

Response II-19-37: Please see RULOF discussion in section XIII.C.3 of the final preamble.

## **19.4 Considerations of Impacted Communities**

### ***19.4.1 Support for Meaningful Engagement***

Comment: Several commenters (2177-Ute, 2249-NACAA, 2296-NMED, 2303-NTAA, 2447-CleanAir) express support for meaningful engagement. Some of the commenters specifically request that EPA provide relevant guidance and training material and allow for new and existing technology. Examples of some of the comments provided are presented in the following

paragraphs. Commenter (2177-Ute) agrees that states must coordinate with tribes that are within the borders of the state, and coordinate with neighboring tribes in the same manner as neighboring states. The commenter asserts that it is important to consider that methane is not a regional pollutant, and there are no NAAQS in place. The commenter states that reduction, or increases in, methane would not have a significant impact on neighboring states or tribes. The commenter states that there could be significant impact if a state or tribal plan caused operators to install combustion equipment (generators, air compressors, etc.) to comply with proposed regulations, and this equipment caused increases in criteria pollutant and ozone precursors, which caused or contributed to NAAQS violations.

Commenter (2447-CleanAir) requests that EPA provide guidance on undertaking robust, inclusive and meaningful outreach and engagement with affected communities and tribes when developing state plans to establish methane reduction standards for existing sources as prescribed under section 111 (d) of the CAA, while also intervening when states that do not submit plans for EPA review and do not have existing and/or refuse to develop new programs that are as effective as the presumptive standards.

Commenter (2303-NTAA) requests that EPA provide assistance and resources, including funding, to Tribes, if they want it, to develop and implement plans and/or permitting programs. Additionally, with respect to Tribes that have standards or requirements in place prior to finalizing this rulemaking, the commenter requests that EPA continue its work with them to promote ease of implementation and consistency with this rulemaking.

Commenter (2249-NACAA) supports robust public engagement, especially with underserved and disproportionately impacted communities, and requests that EPA provide specific criteria and assist implementing agencies by providing resources, guidance, training, and other support.

The commenter (2249-NACAA) notes that EPA's December 2022 supplemental proposal calls for a "robust and meaningful public participation process" with provisions "to require states to identify and conduct meaningful engagement with underserved and overburdened communities as they develop state plans." Further, the commenter notes that this outreach and engagement would include sharing information with all stakeholders throughout the plan development process and seeking their input before a plan is adopted and submitted to EPA. This commenter reports that this aligns with their commitment to environmental justice.<sup>145</sup> Should EPA mandate more robust public engagement and make it a federal requirement for plan approval, the commenter asserts that EPA must be more specific about what will be approvable and be up-front about providing guidance to states that identifies communication objectives as well as outlining the process and methods of engagement.

The commenter (2249-NACAA) notes that some states have conducted robust analyses and implemented sophisticated programs, but not all agencies have done this work. Where agencies have completed their own analyses and developed tools and programs in consultation with their local communities and advisory groups, the commenter recommends that EPA allow these to

---

<sup>145</sup> NACAA's "Mission & Values" and "Statement & Direction for Racial Justice" are available at [http://www.4cleanair.org/sites/default/files/Documents/NACAAMissionValuesGoalsandRacialJusticeStatement-10\\_19\\_2020-noQ.pdf](http://www.4cleanair.org/sites/default/files/Documents/NACAAMissionValuesGoalsandRacialJusticeStatement-10_19_2020-noQ.pdf).

serve compliance needs, rather than simply mandating national adoption of federal tools. Some of the commenter's members are at the cutting edge of achieving meaningful involvement of vulnerable communities in agency decision-making, with programs that have far longer track records and that are more robust than anything at the federal level. The commenter recommends that EPA draw from and benefit from their experience. State and local programs with deep experience in advancing clean air protection with and for vulnerable communities have learned that these efforts are very time- and resource-intensive, not just for agencies but for the communities themselves. Given the tremendous variety of communities, their needs, and their constraints, the commenter urges EPA to set expectations realistically and allow for the flexibility to truly meet the unique needs of these communities, as well as to reflect the economics and demographics of individual states.

Commenter (2296-NMED) supports EPA's meaningful engagement and reasonable notice requirements. The commenter recommends that EPA permit both new and traditional communication technologies to qualify as meaningful public engagement. The commenter believes that requiring states to share information and solicit input from stakeholders at critical junctures during plan development will ensure communities have abundant opportunities to participate in the plan development process.

The commenter (2296-NMED) asserts that the proposal to give the reasonable notice requirement additional and separate meaning from "public hearing" will ensure that the public has reasonable notice of relevant information, as well as the opportunity to participate in the state plan development. The commenter contends that requiring states to provide this opportunity to stakeholders directly addresses a major issue of environmental inequity: the ability for stakeholders to participate in the process that determines impacts and risks to their health and environment. According to the commenter, requiring the opportunity for stakeholders to participate will necessitate that a state not only holds a public hearing but guarantees all interested stakeholders have the chance to participate in the development process.

The commenter (2296-NMED) reports that modern communications technology has made it much easier for states to effectively communicate with various communities and stakeholders. While there may be barriers involving accessibility to these technologies that should be considered, the commenter recommends that these technologies should still be utilized during the meaningful engagement process. These technologies include video conferencing, social media, and smart phone apps. The commenter states that video conferencing can be an effective planning tool that allows for planners and state officials to communicate with community members and other stakeholders.

Commenter (2315-NY DEC) recommends the development of a plan that identifies communication objectives, as well as outlines the process and methods of engagement. The commenter has a history of community engagement with respect to air quality concerns and therefore recommends that EPA look to some of their previous work on the Peace Bridge Air Study,<sup>146</sup> Albany's South End Neighborhood Air Quality Initiative,<sup>147</sup> Tonawanda Community

---

<sup>146</sup> <https://www.dec.ny.gov/chemical/83984.html>.

Air Quality Study,<sup>148</sup> Brookhaven Air Quality Improvement Actions,<sup>149</sup> Dunn Landfill<sup>150</sup> and their Community Air Screen Program.<sup>151</sup>

Response II-19-38: Please see the discussion on the topic of meaningful engagement in section XIII.C.6 of the final preamble.

Please see the Summary of Public Comments and Responses on Proposed Rule Adoption and Submittal of State Plans for Designated Facilities: Implementing Regulations Under Clean Air Act Section 111(d) (Subpart Ba) Docket ID No. EPA-HQ-OAR-2021-052. The final Subpart Ba is published at 88 FR 80480 (November 17, 2023).

#### ***19.4.2 Meaningful Engagement Criteria are Unclear and Burdensome***

Comment: Several commenters (2157-TDEC, 2186-MDNR, 2218-TCEQ, 2222-WDNR, 2237-ICND, 2258-MSD, 2288-NDDEQ, 2310-MDEQ, 2319-ADEM, 2322-ADEE, 2323-ADEQ, 2330-KDAQ, 2393-OSEE) express concern with the lack of clarity surrounding meaningful engagement criteria. The commenters request that EPA provide clear definitions and evaluation criteria that EPA will use to determine if sufficient meaningful engagement was completed. In general, the commenters recommend that the meaningful engagement requirements be removed. Some commenters question the need for additional requirements where requirements are included in existing state programs. The commenters believe additional requirements are burdensome and unnecessary. Examples of some of the comments provided are presented in the following paragraphs.

Commenters (2237-ICND, 2288-NDDEQ) note that North Dakota has procedures to address meaningful engagement, including Title VI and Environmental Justice. The commenters contend that EPA's rule as proposed includes vague requirements of "development of public participation strategies" and "early outreach, sharing information, and soliciting input." The commenters believe that these requirements all appear to be already met through the established public hearing requirements along with the Title VI and Environmental Justice programs. By including meaningful engagement as a requirement of the state plan, and as such as part of the "minimum criteria for completeness" but not defining explicitly how it must be fulfilled, the commenters assert that EPA also hides the criteria by which it will judge the plans and plan revisions. The commenters view the requirements around "meaningful engagement" to be either too vague to confidently fulfill under the threat of EPA disapproval, or duplicative of the already established and widely accepted public hearing process.

Commenter (2222-WDNR) requests that EPA provide clear evaluation criteria that EPA will use to determine if sufficient meaningful engagement was done during the state plan development process and how EPA will consider this meaningful engagement criteria when assessing approvability of state plans. The commenter recommends that EPA provide states general criteria to identify the meaningful engagement process necessary given the state-specific factors covered

---

<sup>148</sup> <https://www.dec.ny.gov/chemical/59464.html>.

<sup>149</sup> <https://www.dec.ny.gov/chemical/111038.html>.

<sup>150</sup> <https://www.dec.ny.gov/chemical/117071.html>.

<sup>151</sup> <https://www.dec.ny.gov/chemical/81629.htm>.

by the state plan. The commenter suggests that these factors could include the total emissions reductions expected by the rule and geographic proximity of large emission sources.

The commenter (2222-WDNR) notes that states seeking to adopt EPA's model rule language have little flexibility to modify regulatory requirements in response to public input. The commenter recommends that EPA take responsibility to ensure its model rule and federal plan process meets the stated meaningful engagement criteria before finalizing model rule language and allow states to reference EPA's process when adopting EPA language.

Commenter (2186-MDNR) requests that EPA provide clarity on what constitutes meaningful engagement with the target populations and the specific actions necessary during the state development process to meet this new requirement. The commenter requests clarification on the criteria used to evaluate meaningful engagement in state plans. Specific questions include:

*Identifying overburdened areas:*

1. What is the definition of an overburdened or underserved area?
2. What are the process and data sets states need to use to identify these areas?
3. What is the process for selecting the extent of such areas?
  - a. Should these areas be defined as a small neighborhood or multi-block area, is it a census tract, is it a city, is it a township, is it a county, is it an entire metropolitan statistical area, could it be an entire state or multi-state region?
4. How close to an affected facility does the overburdened area need to be located to be considered impacted by the action?

*Meaningful engagement requirements for overburdened areas:*

1. What are the minimum requirements for states to ensure they are complying with the new meaningful engagement provisions?
  - a. Are states required to hold a meeting in every identified area?
  - b. Are virtual meetings allowed, or do they need to be in-person?
  - c. Does one meeting satisfy the requirement, or must states hold numerous public engagement meetings?
  - d. Are newspaper ads or mail outs required?
  - e. At what stage in the plan development process do the new engagement practices need to occur: e.g., before any work is done, before the public comment period, during the public comment period, after the public comment period, all of these?

The commenter (2186-MDNR) reports that the state Air Program strives to provide meaningful public engagement in all state plans it develops, meeting and usually exceeding all required public notice and comment requirements. However, when EPA establishes new administrative or

procedural requirements that states must follow, the commenter asserts that clarity and certainty is essential. The commenter contends that the proposed rule does not provide this, and states will struggle trying to ensure they are meeting these requirements if the final rule does not clearly answer all these questions.

Additionally, the commenter (2186-MDNR) notes that this new meaningful engagement requirement requires state resources. The commenter contends that federal grants or other new funding mechanisms will be necessary to assist states with these new requirements. The resources needed will vary depending on some of the answers to the questions listed above by the commenter. The commenter reports that businesses and governments across the country are struggling to recruit and retain qualified staff members to carry out essential duties. The commenter urges EPA to recognize this reality and adequately address it as it considers the new requirements it promulgates.

Commenter (2330-KDAQ) requests that EPA provide clarity on what it means to perform meaningful engagement. The commenter contends that it is inappropriate to require additional meaningful engagement without clearly stating expectations. Further, the commenter asserts that EPA's intention "to propose similar meaningful engagement provisions to this provision under the implementing regulations in a separate upcoming rulemaking that would apply generally to new EG promulgated under CAA section 111(d)." is a piecemeal approach that is not sufficient to allow meaningful comment on this proposed rulemaking. The commenter recommends that EPA re-propose the complete rulemaking in its entirety and with full requirements so that the impacts can be evaluated.

The commenter (2330-KDAQ) states that EPA requesting public comment on broad topics of meaningful engagement does not allow states to evaluate the costs or implications of actual requirements. The commenter believes that this is more appropriate for an Advanced Notice of Proposed Rulemaking and not a proposed rule.

The commenter (2330-KDAQ) supports the flexibility of requesting alternate meaningful engagement procedures that in fact provide for adequate notice to and meaningful engagement of the public. The commenter already provides regulatory notice to the public throughout the process of any regulatory change through its State Legislature and certain permitting actions. The commenter states that this is especially important where EPA is expanding meaningful engagement procedures in a way that has not been previously required.

Commenter (2323-ADEQ) expresses concern that the vagueness in EPA's approach to "meaningful engagement" could lead to confusion and inconsistent results. The commenter requests that EPA either provide additional structure regarding this requirement or remove it from EPA's proposed completeness criteria for this EG.

The commenter (2323-ADEQ) agrees that it is important to engage the pertinent stakeholders in the development of state plans (and state implementation plans) that will impact them. However, the commenter notes that the proposed rule does not make it clear what steps are necessary for this state plan submittal to be meet the completeness criteria. While the draft rule seems to be written broadly to account for a wide range of circumstances nationwide, the commenter believes

that it leaves the meaning subject to interpretation. Generally, the commenter urges EPA to provide flexibility for states to allow them to address their local needs and conditions. However, the commenter expresses concern that the vagueness of these proposed requirements could lead to unnecessary level of conflict regarding their interpretation as to what is satisfactory for a completeness determination.

The commenter (2323-ADEQ) notes that while the rule provides factors that must be considered by the state, it is unclear how EPA will assess the adequacy of strategies to address these barriers to participation. Compared to the current SIP requirements in 40 CFR Part 51, Subpart F, which provides clear directions for states in their SIP development process, the commenter believes that the proposed rule's approach is rather nebulous. According to the commenter, the vague definition of meaningful engagement and EPA's ability to find a plan incomplete or disapprove if EPA determines the engagement to not meet that vague definition, could lead to a scenario where state plans are disapproved because EPA disagrees with the outreach approach selected by the state, intruding upon the outreach and plan development process that has traditionally been the states' expertise and knowledge of their own state.

Therefore, the commenter (2323-ADEQ) requests that EPA either more clearly define what actions are necessary to satisfy the meaningful engagement requirement or de-couple the meaningful engagement from the completeness determination. The commenter believes that providing greater clarity for these requirements will help states focus their outreach efforts in the most effective manner, based on their unique knowledge of issues within each state, while preserving scarce agency resources.

Commenter (2310-MDEQ) requests that EPA provide more specificity regarding meaningful public engagement because the proposed definition is subjective and open to interpretation, which may differ between states and EPA. The commenter contends that approvability of a state plan cannot be decided on subjective criteria. In addition, the commenter requests that EPA engage meaningfully with the oil and gas producing states.

Commenter (2258-MSD) recommends that EPA eliminate the new requirements for meaningful engagement. The commenter notes that each state has mandated procedures that must be followed when adopting new regulations, including public comment and public hearings. The commenter notes that EPA's existing regulations at 40 CFR 60.23a outline the basic requirements for state plan adoption while respecting individual state differences. The commenter contends that the requirements in 40 CFR 60.23a are adequate.

Commenter (2218-TCEQ) asserts that EPA's proposed meaningful engagement requirements are burdensome and unnecessary. They explain that states are already required to provide public notice and do so through a variety of mechanisms that have been previously approved by the EPA. The commenter recommends that the proposed meaningful engagement requirements and modification of the EPA's interpretation of "reasonable notice" be excluded. However, if the EPA moves forward to finalize the requirements, the commenter urges EPA to provide states with specific criteria for what is required and what would be approvable in a state plan regarding these requirements. To ensure states have adequate opportunity to provide feedback, the commenter recommends that EPA propose and take public comments on a clear definition of

pertinent stakeholders and guidance on how to identify pertinent stakeholders and specific requirements for “reasonable notice” for purposes of the state plan. The commenter recommends that the definition and guidance be finalized with the rule and at least three years before a state plan is due. If the EPA requires reasonable notice and meaningful engagement in state plans, the commenter recommends that EPA clearly describe what would be approvable while allowing states flexibility to meet the requirements. In addition, the commenter states that EPA must propose and take public comment on the requirements before finalizing them.

The commenter (2218-TCEQ) notes that completeness criteria for state plans is found at 40 CFR 40 CFR 60.27a(g) and includes public participation requirements that require states to conduct at least one public hearing after reasonable notice. The commenter states that these criteria are and have been adequate to ensure stakeholder and public participation in the development of the state plan. Therefore, the commenter believes they should not be changed for this plan. Additionally, they suggest that existing public notice requirements which do not address meaningful engagement requirements are appropriate and already adequately provide for public engagement with state actions to develop state plans. The commenter states that it is not evident that adding ill-defined engagement provisions would substantively improve the state plan development process; however, adding such provisions would significantly burden states with new costs associated with attempting to interpret and implement the provisions with no clear criteria for EPA approval.

The commenter (2218-TCEQ) reports that they meet state and federal notice public participation requirements by making materials publicly available, accepting public comments, and publishing public notices of public meetings and rule and state plan revisions. The commenter makes the public aware of proposals using a variety of venues including its website, various listservs, newspapers, the Texas Register, and social media outlets. In addition, formal public comments can be made electronically, at public hearings, via U.S. Mail or fax, or hand delivery. The commenter reports that they also amended public notice and participation requirements in 30 Texas Administrative Code (TAC) Chapters 39 and 55 in 2021 and developed agency public participation and language access plans to ensure meaningful public participation for new actions; changes to agency policies, procedures, general permits, and regulations that may affect the public; and for activities that are likely to have significant interest from the public and the regulated communities. New requirements include alternative language notices for public meetings, interpretation services at public meetings, evaluation of the need to provide responses to comments in alternative languages, the provision of plain-language summaries for proposed projects as well as the translation and posting of the summaries on the commission’s website when alternative language publication is required. The commenter provides that EPA has found that their public notice and participation measures to be adequate and offers no defensible reason why public notice and participation opportunities should be changed for this state plan.

While the proposed meaningful engagement requirements are not clearly described, the commenter (2218-TCEQ) believes that resources needed to fulfill them will be significant and burdensome to states. According to the commenter, fulfilling meaningful engagement requirements will cause states to incur costs associated with identifying and contacting stakeholders, renting of rooms or spaces for multiple public meetings, travel, and associated staff time. The commenter states that it is also overly burdensome for the EPA to require states to

conduct meaningful engagement when adopting the model rule since the EPA already conducted meaningful engagement when setting the standards. The commenter notes that Texas is a large state and based on the December 2022 proposed supplemental rulemaking, there will be a vast number of affected facilities located throughout the state. Further, the commenter believes that the proposed 18 months to submit state plans is insufficient with the additional time needed to meet these requirements.

Commenter (2157-TDEC) states that meaningful engagement should not be required for states that adopt EPA's standard with no exceptions for RUOF as it is assumed that EPA has already conducted meaningful engagement prior to issuing its own guidelines. Therefore, the commenter believes that additional engagement efforts by states for the same plan are unnecessarily duplicative and superfluous. If the EPA proceeds with this requirement, the commenter requests EPA clarify what a state will be expected to do with the information learned during meaningful engagement regarding a state plan that adopts EPA's requirements verbatim.

The commenter (2157-TDEC) reports that Tennessee's Uniform Administrative Procedures Act, procedures established by the Tennessee Governor's Office, and EPA rules and procedures require all state plans to include regulatory provisions for the: 1) review of pre-draft rule by EPA's regional office, 2) review and approval by the Tennessee Governor's Office, 3) preview of the draft rule to the Tennessee Air Pollution Control Board, 4) posting of proposed rule on Secretary of State's administrative register website at least 45 days prior to public hearing, 5) an EPA-mandated 30-day public notice, 6) an EPA 30-day pre-hearing review, 7) a public hearing conducted by TDEC, 8) TDEC's review of and response to public comments, 9) approval by Tennessee Air Pollution Control Board, 10) review of adopted rule by Governor's Office, 11) approval of adopted rule by Attorney General's Office, 12) filing of final rule with Secretary of State's Office, 13) a 120-day post-filing period for the rule to become effective, and 14) review of final rule by General Assembly's Joint Government Operations Committee. The commenter reports that the process will take up almost all the 18-month regulatory timeframe for submitting a plan to EPA for approval and cannot be initiated until the Division of Air Pollution Control has developed a draft state plan<sup>152</sup>. The commenter contends that EPA's shortened timeframe to prepare state plans makes the additional "meaningful engagement" required by the December 2022 proposal nearly impossible. The commenter urges EPA to consider whether plans completed in 18 months or meaningful engagement is the priority of the agency.

Commenter (2322-ADEE) believes that the meaningful engagement requirements are burdensome and may be difficult for states to achieve due to the increased amount of stakeholders. The commenter questions why state plans would need to demonstrate additional "meaningful engagement" outreach efforts, when EPA has deemed the proposed rule to have inconsequential effects on communities that are the focus of the executive order.

The commenter (2322-ADEE) notes that the December 2022 supplemental proposal removes the 3-ton per year threshold triggering requirements for "wellhead only sites," and many more communities and stakeholders would need to be included in state outreach than the original

---

<sup>152</sup> Because this rule has the potential to substantially add to our workload, the commenter states that Tennessee will also need to consider whether other rule changes are necessary to cover the increased workload with new or increased fees.

proposal, which already included a vast number of stakeholders. The commenter states that the varying degrees of interest level, knowledge, and economic dependence on regulated sources that spans this diverse group of stakeholders will require state regulators to engage in intense targeted framing and explication of highly technical information. The commenter explains that it will not be a one-size outreach effort, and to produce fact sheets, presentations, and hold meetings on this scale will require months for states to prepare. The commenter contends that several more months will be necessary to roll out to the public in “meaningful engagement.” The commenter adds that the process is not intended to be a one-way street when engaging with stakeholders, and collaboration requires a public information and education period, a period to allow for presentation of stakeholder concerns, a period of time for regulator consideration and response to those concerns, and in many cases, further explanation and rationale developed and presented to support regulator decisions where stakeholders are not satisfied with initial responses. They further add that a state could expect this process to stretch out from eight to twelve months prior to beginning administrative procedures for rulemaking and SIP proposal, which themselves take an additional twelve to eighteen months to complete.

The commenter (2322-ADEE) contend that the rushed timeline EPA proposed leaves them with the following choices:

- a) forego submitting a plan and decide whether to take delegation of a federal plan;
- b) submit a plan based on EPA’s BSER without the ability to consider remaining useful life and other factors as allowed under the CAA or provide adequate meaningful engagement; or
- c) miss the deadline for submittal by performing its due diligence in engagement and technical analysis prior to adopting a plan.

The commenter (2322-ADEE) believes that the first and second options create an illusory collaborative environment, in which interested parties who present their concerns to state regulators will feel disenfranchised, as there will be little room for change once outreach begins. According to the commenter, this has a real possibility of degrading the community-regulator relationship. The commenter believes that EPA’s efforts to include all relevant stakeholders in information sharing and decision-making may cause more harm than good in this instance. Lastly, the commenter states that the third option results in wasted effort as missing the deadline would trigger a requirement for EPA to develop and implement a federal plan.

Commenter (2393-OSEE) requests that EPA re-assess the meaningful engagement requirements. The commenter supports robust public participation in state rulemaking efforts and provides that it already has existing mechanisms in place. The commenter reports that the state conducts public participation processes in accordance with the law. The commenter’s current method of notifying its citizens of hearings and other opportunities for public comment is through its website and through a dedicated listserv using GovDelivery. The commenter believes that the burden on the state to reach out to nearly every community across the state in some individual way and list the pertinent stakeholders in its state plan would waste valuable resources and staff

time and only delay actual implementation of the provisions of the emissions guidelines by delaying the state's ability to create a CAA section 111(d) plan.

In addition, the commenter (2393-OSEE) asserts that many states will be either using EPA's model rule or justifying equivalency of state rules that are already in place. The commenter believes that it is entirely possible that a state plan using the EPA-prescribed BSER will, during the meaningful engagement period, receive comments from the community that the state has not gone far enough in its plan. The commenter believes that this creates a logistical and regulatory conundrum since, theoretically, EPA's rulemaking should be presumptively approvable. Furthermore, they add that some states cannot be more stringent than federal rules. The commenter reports that other states, like Oklahoma, are required to meet additional statutory burdens when promulgating rules more stringent than corresponding federal rules. In either case, the result is often that the state requirements remain equivalent to the federal requirements. Therefore, the commenter states that "meaningful engagement," as proposed by EPA and when taken to its logical conclusion, sets up states and the public for confusion and frustration due to a potential disconnect between the perceived outcomes. Thus, the commenter asserts that EPA's concept of meaningful engagement is more appropriate on the federal level before EPA sets the regulatory baseline.

The commenter (2393-OSEE) reports that this same idea is borne out by comments made at EPA's "Pre-proposal outreach-Meaningful Engagement Discussion with Communities" held on July 26, 2022 (Docket Document ID #EPA-HQ-OAR-2021-0317-1526). The very first commenter stated that "meaningful engagement should start with an expectation that through their feedback, stakeholders will have the ability to change the outcome." The commenter went on to say that "there needs to be a process created where community members have a sense that their comments will have an effect on the final outcome." Another commenter similarly stated, "if engagement has no impact, people do not see the point in participating in the process." Additional similar ideas and concerns can be found throughout the Question-and-Answer document. When asked at what point in the regulatory process should engagement begin, one commenter said "as soon as ideation turns to staff consideration. After the feasibility is considered, it is already too late to begin attempting engagement." By this commenter's standards, by the time the state is trying to implement EPA's EGs into state rules and a state plan, it is much too late for meaningful engagement.

The commenter (2393-OSEE) acknowledges that state plans that incorporate RULOF in their decision-making is one place where meaningful engagement truly has meaning. The commenter states that when RULOF is taken into consideration for a facility, the facility may no longer be strictly following the model rule requirements but rather be granted alternate requirements. In these scenarios, the commenter recommends that the public should have an opportunity to review and comment if they object to the RULOF decisions made by the state. This allows the public to potentially affect a change in what the state was proposing (i.e., meaningful engagement). The state will also have a defined audience for its meaningful engagement as it would be appropriate to engage the communities nearby the RULOF facilities.

Commenter (2319-ADEM) asserts that additional meaningful engagement requirements are redundant in many cases. The commenter notes that EPA has already required states to consider disadvantaged communities when developing permits/rules in these areas.

Additionally, the commenter (2319-ADEM) asserts that most states do not have the adequate resources that would be required to conduct outreach to the extent that this proposal would require. The commenter states that depending on the type of industry for which a rule or plan is being developed, outreach of this type could be extremely resource-intensive and nearly impossible to ensure that all affected communities are directly contacted. For example, the commenter points out that there are gas and oil well heads located throughout many states. The commenter contends that to ensure that each community located near one of the well heads are directly contacted would undoubtedly exceed the financial and physical resources of most of these states. The commenter believes that notification in prominent and regional newspapers and similar publications is the only practical way to provide reasonable, cost-effective, and efficient outreach in these areas.

Response II-19-39: Please see the discussion on the topic of meaningful engagement in section XIII.C.6 of the final preamble.

Please see the Summary of Public Comments and Responses on Proposed Rule Adoption and Submittal of State Plans for Designated Facilities: Implementing Regulations Under Clean Air Act Section 111(d) (Subpart Ba) Docket ID No. EPA-HQ-OAR-2021-052. The final Subpart Ba is published at 88 FR 80480 (November 17, 2023).

Comment: Commenter (2393-OOSEE) notes a typographical error in the proposed language of 40 CFR 60.5363c(a)(6), which currently reads:

(5) Certification and evidence of meaningful engagement on such plan or plan revisions as specified in §60.5365c, including a list of identified pertinent stakeholders and a summary of the engagement conducted, a summary of stakeholder input received, and a description of any action or changes made as a result of the engagement.

The commenter (2393-OOSEE) believes that the reference to 40 CFR 60.5365c should instead be 40 CFR 60.5366c for meaningful engagement. Furthermore, the commenter adds that Table 2 and Table 4 are currently fully titled “Table 2 to Subpart OOOOb” and “Table 4 to Subpart OOOOb.” The commenter requests that EPA update the names of the tables to reflect they are part of EG OOOOc.

Response II-19-40: Please see the discussion on the topic of meaningful engagement in section XIII.C.6 of the final preamble.

Please see the Summary of Public Comments and Responses on Proposed Rule Adoption and Submittal of State Plans for Designated Facilities: Implementing Regulations Under Clean Air Act Section 111(d) (Subpart Ba) Docket ID No. EPA-HQ-OAR-2021-052. The final Subpart Ba is published at 88 FR 80480 (November 17, 2023).

### ***19.4.3 Affected Community Definition***

Comment: Several commenters (2202-TXOGA, 2218-TCEQ, 2237-ICND, 2288-NDDEQ, 2343-IPI NYU) request that EPA provide guidance and definitions of pertinent stakeholder definition. In general, the commenters assert that EPA's language is unclear. Examples of some of the comments provided are presented in the following paragraphs.

Commenter (2218-TCEQ) believes that the proposed definition of pertinent stakeholders at 40 CFR 60.5366c(b) is not adequate for states to identify individuals or groups with whom meaningful engagement should be conducted for purposes of a state plan. The vagueness of the proposal may increase the likelihood of legal challenges to state plans or state plan disapproval because the EPA's interpretation of the requirements is not clear. The commenter contends that EPA must propose specific criteria that states may use to identify stakeholders as "most" affected as well as acceptable methods for states to use to make such a determination before meaningful engagement requirements are finalized. As proposed, the commenter states it is not clear how states would identify pertinent stakeholders, what criteria the EPA would use to determine whether pertinent stakeholders identified by states are appropriate, or that the criteria would not change in the future. The commenter asserts that states, not the EPA, are in the best position to identify pertinent stakeholders for their plans.

Commenters (2237-ICND, 2288-NDDEQ) note that "pertinent stakeholders" "include, but are not limited to, industry, small businesses, and communities most affected by and/or vulnerable to the impacts of the plan or plan revision". The commenters believe that the current "pertinent stakeholder" language inclusion of the phrase "but are not limited to" is over-generalized. While it is appropriate that entities most affected/vulnerable to the impacts should be involved, the commenters believe that the language is too broad.

The commenters (2237-ICND, 2288-NDDEQ) contend that it would make sense that a pertinent stakeholder should at least be within the political boundary that the plan or plan revision applies, however proximity is not addressed. As wind-borne pollutants ignore such political boundaries, the commenter questions whether the State of Minnesota is a "pertinent stakeholder", being predominantly downwind of North Dakota. In the same manner the commenter questions whether the State of Montana, with multiple oil and gas fields straddling the state border with North Dakota, and whether Canada with similar fields on North Dakota's international northern border are "pertinent stakeholders".

Commenter (2202-TXOGA) recommends that EPA identify "communities most affected by and vulnerable to the impacts from the designated considered in a state plan for RULOF provisions." The commenter notes that EPA expresses an expectation that "these communities will be identified by the state as pertinent stakeholders under the proposed meaningful engagement requirements" which suggests that EPA has something in the nature of geographical proximity in mind. But where the designated pollutant at issue is a GHG, and the "impacts" from the emissions of that GHG are identified as stemming from the global phenomenon of anthropogenic climate change, the commenter believes that "communities most affected by and vulnerable to" any given designated facility would not necessarily be people living in close proximity but rather

people living in different locales throughout the country (and throughout the world). The commenter believes that identifying stakeholders using geographic criteria is not reasonable.

Commenter (2343-NYU-School of Law) recommends that EPA provide guidance on identifying affected communities, and vulnerable populations. The commenter suggests that communities be identified by first determining which pollutants would be more prevalent under the less stringent standard – and by how much. Then, they suggest that states identify the relevant affected communities for each of these pollutants in light of the pollutant’s media, exposure pathways, and exposure factors related to human behaviors. The commenter notes that affected communities may include not only the individuals who live within the areas where people are exposed, but also anyone who works or recreates there.

The commenter (2343-NYU-School of Law) recommends that EPA assist states by providing information on which pollutants would generally be expected to increase because of less stringent standards and information about their typical spatial distributions, exposure pathways, and exposure factors. It would be the responsibility of states to apply this information at the facility level based on site-specific considerations. At a specific facility, the commenter believes that it could be possible to analyze how wind patterns would shape the distribution of air pollutants under a less stringent standard.<sup>153</sup>

In short, to analyze exactly which communities would be affected by a less stringent standard, the commenter (2343-NYU-School of Law) states that it is necessary to think through which pollutants will increase and how the physical properties of those pollutants will translate into increased doses for individuals in specific areas. If states attempted to identify affected communities by selecting inappropriate (e.g., too large) geographic units, the commenter believes that it would create an inaccurate picture of whose health might be impacted by adopting a less stringent standard. They add that the same would be true if a state did not consider which communities live downwind of an air pollutant.

The commenter (2343-NYU-School of Law) notes that neither the December 2022 supplemental proposal nor the proposed regulatory text provides authoritative guidance on how states should identify, among all affected communities, the subset of people who are particularly vulnerable. Instead, the December 2022 supplemental proposal notes generally that “increased vulnerability of communities may be attributable, among other reasons, to both an accumulation of negative and lack of positive environmental, health, economic, or social conditions within these populations or communities.”

The commenter (2343-NYU-School of Law) recommends that EPA provide additional direction on identifying vulnerable communities so that states can more accurately assess how adopting less stringent standards for specific facilities would affect these groups. The commenter contends that increasing the accuracy of state assessments would improve the quality of decision-making and prevent harm to vulnerable communities that might have been obscured by flawed or incomplete analyses. Additionally, the commenter believes that more guidance from EPA on identifying vulnerable communities would help standardize states’ analyses, which would allow

---

<sup>153</sup> See Revesz & Yi, *supra* note 41, at 86.

EPA to more consistently evaluate requests to adopt less stringent standards and thus promote regulatory certainty for states.

The commenter (2343-NYU-School of Law) reports that there are multiple types of guidance that EPA could offer states in the final rule about how to identify vulnerable communities among the affected communities. The commenters suggests that the EPA might enumerate minimum considerations relevant for identifying vulnerable groups. They add that these considerations might include any factors that dictate a community's cumulative dose of a pollutant, such as proximity to other sources of emissions and shared behavior (e.g., occupation). Separately, the commenter notes that a community may be vulnerable to a pollutant, not because of other exposures, but because of other factors that cause it to suffer worse health harms than others would experience at the same dose. These susceptibility factors include pre-existing disease, age, access to medical care, stress, diet, and exposure to similarly acting toxins.

Additionally, because states may face data constraints when identifying vulnerable communities, the commenter (2343-NYU-School of Law) recommends that EPA help states by including certain data and resources in the final rule. For example, for each pollutant that is relevant in this context, the commenter suggests that EPA indicate which communities have historically been most vulnerable. Or, the commenter suggests that the EPA might point states to resources that would help them estimate cumulative doses and susceptibility factors for each pollutant. The commenter recommends that EPA advise whether there is any overlap between the factors that would make a community vulnerable to increased pollution from a less stringent standard at a particular facility and the factors that cause a community to be "disadvantaged" (and thus prioritized for Justice40 investments) according to the Council on Environmental Quality's recent Climate and Economic Justice Screening Tool. Similarly, the commenter suggests that EPA examine whether any data available through EPA's EJ Screen tool (e.g., ozone or air toxics cancer risk) may assist states in identifying communities that would be vulnerable to increased pollution from application of a less stringent standard at a facility.

Response II-19-41: Please see the discussion on the topic of meaningful engagement in section XIII.C.6 of the final preamble.

Please see the Summary of Public Comments and Responses on Proposed Rule Adoption and Submittal of State Plans for Designated Facilities: Implementing Regulations Under Clean Air Act Section 111(d) (Subpart Ba) Docket ID No. EPA-HQ-OAR-2021-052. The final Subpart Ba is published at 88 FR 80480 (November 17, 2023).

#### ***19.4.4 Consultation Between EPA and State, Tribes, and Local Air Agencies***

Comment: Several commenters (2220-WDEQ, 2225-WESTAR, 2241-UDNR, 2296-NMED, 2403-PAO) request that EPA engage with oil and gas-producing states, Tribes, and local air agencies that will be affected by this rule. Some commenters identify specific agencies and highlight the need for continued engagement. Specific comments provided are presented in the following paragraphs.

Commenter (2241-UDNR) requests that EPA continue to coordinate with the State's County Resource Management Plans (RMPs), particularly Utah's top natural gas producing counties of Uintah, Carbon, Duchesne, and San Juan. Further, the commenter adds that EPA ensure that current and future actions taken in furtherance of the proposed rule remain consistent with said plans to the maximum extent possible.

Commenter (2296-NMED) provides comments on EPA coordinated engagement regarding emissions crossing state borders. The commenter suggests that states, local governments, community organizations, and other stakeholders may find it helpful to create organized groups that can help address interstate air quality issues. For example, the commenter participates in the Four Corners Air Quality Group, which could serve as a model for such coordination. The commenter reports that New Mexico, along with the Navajo Nation, Colorado, Arizona, and Utah meet regularly to address common air quality issues in the region. The commenter explains that the Four Corners Air Quality Group also has a variety of different stakeholders including community members and organizations and industry leaders. They add that the goals and functions of any cross-border groups can, and should, be crafted to the unique needs of the area(s) in which they serve. These organizations can open a dialogue between all stakeholders and include government officials and staff members who can directly address any issues of concern.

Commenter (2225-WESTAR) urges EPA to recognize states' roles as regulatory partner and foster a sense of shared accountability. The commenter requests that EPA do more to engage with oil and gas-producing states, tribes, and local air agencies that will be affected by this rule.

The commenter (2225-WESTAR) notes that states have the responsibility for implementing many important air quality rules, objectives, and policies. The commenter contends that EPA and states' relationship is based on a foundation of transparency and early collaboration. However, the commenter reports that as it applies to the promulgation of this rule in particular, states have felt early collaboration and meaningful engagement to be lacking. The commenter believes that EPA has missed a wealth of information and practical control program knowledge as well as the broadest perspective of how emissions for this sector are managed, by not reaching out through the standing western and national oil and gas working groups that bring together state, tribal, and local air quality agencies.

Commenter (2225-WESTAR) requests that EPA do more to engage with oil and gas-producing states, tribes, and local air agencies that will be affected by this rule. The commenter expresses that states have the responsibility for implementing many important air quality rules, objectives, and policies. The commenter believes that it is critical that a relationship exists between EPA and states that recognizes states' roles as regulatory partners, fosters a sense of shared accountability, and is based on a foundation of transparency and early collaboration. The commenter asserts that, as it applies to the promulgation of this rule in particular, states have felt early collaboration and meaningful engagement to be lacking. The commenter contends that EPA has missed a wealth of information and practical control program knowledge as well as the broadest perspective of how emissions for this sector are managed, by not reaching out through the

standing western and national oil & gas working groups that bring together state, tribal, and local air quality agencies.

The commenter (2225-WESTAR) believes that a plan to meet with state, tribal, and local air agencies, gather necessary information, and conduct analyses to address the control concepts proposed are all necessary steps to develop effective and efficient regulations. The commenter previously encouraged EPA to provide ample time for public comment and engagement. However, the commenter notes that EPA did not engage or provide opportunities to engage in potentially constructive dialogues with states, tribes, and local air agencies between the November 2021 proposed rule and the December 2022 publication of the supplemental proposal. The December 2022 supplemental proposal significantly broadens the November 2021 proposal, and the commenter contends that local air agencies were not given adequate time to assess the impact these significant policy and technical requirements may have on their air programs. According to the commenter, a 60-day comment period makes it difficult for states, Tribal, and local air programs to provide more substantial comments and input based on their experience and knowledge. Commenter (2220-WDEQ) urges EPA to conduct meaningful engagement with state agencies to gather perspectives and input. The commenter supports workable flexibilities instead of a “one-size-fits-all” approach to implementing environmental laws. The commenter recommends that EPA consider workable flexibilities in developing a final rule and urges EPA to engage with state co-regulators early and often to ensure that any new regulation is appropriate and can be reasonably implemented.

The commenter (2220-WDEQ) reports that there is a large number of recurring concerns with the proposed regulatory texts that are shared by other state-level agencies. The commenter asserts that this amplifies implementation issues. The commenter states that state-level regulatory agencies serve as co-regulators with EPA. To develop effective environmental regulations that both achieve emission reductions and can be practicably implemented, the commenter stresses the importance that EPA conduct meaningful engagement with state agencies to gather perspectives and input for formulating final rules. The commenter expresses disappointment that EPA did not respond to reasonable comment period extension requests on the supplemental proposal from Association of Air Pollution Control Agencies (AAPCA) state, local, and tribal member agencies Kentucky Department of Air Quality (KY DAQ), Oklahoma Department of Environmental Quality (KDEQ) Pennsylvania Department of Environmental Protection (PA DEP), Texas Commission on Environmental Quality (TCEQ), the Ute Indian Tribe, and Wyoming Department of Environmental Quality (WDEQ), as well as AAPCA itself.

The commenter (2220-WDEQ) further notes that state plan requirements were not the only overlapping area of concern cited by other state agencies and air quality organizations in the supplemental proposal. The commenter requests that EPA consider the other overlapping concerns raised by the Western States Air Resources Council (WESTAR) in its comments on the supplemental proposal. The commenter states that WESTAR serves as the multi-jurisdictional organization for state, local, and tribal member agencies in the Western U.S. and represents a broad spectrum of air quality perspectives. The commenter reports that members of WESTAR have raised overlapping concerns with the state plan requirements, requirements pertaining to the Super Emitter Response Program, etc., within the December 2022 supplemental proposal indicates that there are significant implementation issues with the supplemental proposal.

The commenter (2220-WDEQ) asserts that EPA has not meaningfully engaged with state agencies on either the original or supplemental proposal. The commenter reports that EPA did not respond, acknowledge nor engage with the commenter upon submission of comments. The commenter acknowledges that EPA conducted a sparse number of virtual public listening and stakeholder engagement sessions on the proposed rule in summer 2021, there were none held in the interim between the close of the public comment period on the November 2021 proposed rule and the issuance of the December 2022 supplemental proposal. Furthermore, the commenter notes that EPA held no in-person meetings with state agencies to our knowledge, and the commenter was not provided with the opportunity to engage in constructive dialogues with EPA about the proposed rule or supplemental proposal.

The commenter (2220-WDEQ) reports that in the supplemental proposal, EPA has clearly focused on the concept of “meaningful engagement.” However, in the commenter’s experience, EPA has not followed these practices in its promulgation of the original proposed rule or the supplemental proposal.

The commenter (2220-WDEQ) believes that it is disingenuous and unreasonable for EPA to propose such extensive meaningful engagement requirements that state, local, and tribal agencies must follow in developing state plans when EPA has not adhered to any of those same requirements in the development of the proposed rules. The commenter believes that EPA is enacting a double-standard that is not consistent with its own legal requirements it proposes for state-level agencies. Furthermore, the commenter asserts that EPA’s actions are not consistent with the basic tenets of cooperative federalism.

Commenter (2429-WOC) states that there is a continued need for state consultation cooperation and support through the state implementation process to ensure that the rule is effective and politically durable.

The commenter (2429-WOC) states that Wyoming is a rural, conservative state that is heavily dependent on the taxes paid by the fossil fuel industry. The commenter contends that Wyoming experienced the whiplash of agency rulemaking from administration to administration. The commenter encourages EPA to recognize the limited capacity of state environmental agencies to respond to the administrative and staffing burden the supplemental rules likely impose. Specifically in Wyoming, a combination of Covid-era state budget cuts and agency position vacancies will make the implementation of these rules difficult without considerable federal resources and support. The commenter encourages EPA to be proactive in its outreach efforts to work with state agencies, involve them in decision making, and be responsive to their concerns. The commenter also encourages strong federal coordination and assistance in helping to identify funding opportunities from recent legislation (such as the Inflation Reduction Act (IRA) and Bipartisan Infrastructure Act) that might provide assistance, recognizing that the states most in need of these resources will likely have the fewest resources to independently pursue them.

Commenter (2403-PAO) requests that EPA coordinate with states and incorporate ways to reduce process requirements to allow states the flexibility (as allowed by the CAA) to develop and implement state specific requirements for existing emission sources. The commenter (2403-PAO) asserts that by dividing regulatory authority under CAA section 111 into separate

programs for new and existing sources, Congress clearly recognized that existing sources are less able to comply with new regulatory requirements than new sources. The commenter notes that if states do not adhere to the presumptive standards for existing sources, state delegated agencies would be required to conduct lengthy analysis and write major regulations or face imposition of a federal plan. The commenter contends that EPA is basically forcing states to “accept” the proposed standards.

Response II-19-42: The EPA’s extensive public engagement in the development of this action is discussed in section VII of the final rule preamble. The EPA remains committed to working with states as they develop and submit state plans to the Agency for review. The EPA strives to maintain consistency in its collaboration with states to ensure that implementation of the EG will be uniform.

Please see the Summary of Public Comments and Responses on Proposed Rule Adoption and Submittal of State Plans for Designated Facilities: Implementing Regulations Under Clean Air Act Section 111(d) (Subpart Ba) Docket ID No. EPA-HQ-OAR-2021-052. The final Subpart Ba is published at 88 FR 80480 (November 17, 2023).

#### ***19.4.5 Prescription of Meaningful Engagement Requirements Exceed EPA’s Regulatory Authority***

Comment: Several commenters (2202-TXOGA, 2258-MSA, 2292-WVAG et al, 2428-API) assert that EPA does not have authority under the CAA to prescribe meaningful engagement requirements. Examples of provided comments are presented in the following paragraphs.

Commenter (2258-MSA) expresses concern that EPA could reject a state plan, no matter how environmentally stringent its provisions are, based solely on EPA’s opinion regarding the extent of “meaningful engagement”. The commenter asserts that the CAA only empowers EPA to evaluate the environmental adequacy of a state plan.

Commenter (2202-TXOGA) states that EPA has failed to identify the source of its authority under CAA to impose meaningful engagement requirements. The commenter notes that the proposed approach requires further explanation. The commenter reports that while the December 2022 supplemental proposal has provided considerably more detail regarding the parameters of its proposed “meaningful engagement” requirements, EPA has failed to identify the source of its authority under the CAA to impose such requirements on the states.<sup>154</sup> The commenter states that the preamble merely makes reference to CAA section 111(d), points to the “public health and welfare objectives of section 111(d)” of the CAA in “regulating specific existing sources,” and concludes that it is “reasonable to require meaningful engagement as part of the state plan development public participation process in order to further these objectives.” According to the commenter, whether the proposed new “meaningful engagement” requirements are “reasonable”

---

<sup>154</sup> The commenter notes that EPA states providing notification of public engagement through the internet may not be sufficient because there “cannot be a presumption that such notification is adequate in reaching all those who are impacted by a CAA section 111(d) state plan and would benefit the most from participating in a public hearing.” 87 Fed. Reg. at 74,829. Historically, public notice has been provided in the *Federal Register*, either in print copy or on the internet, and Congress has not indicated that such notice is insufficient as a legal matter.

or not in this context cannot substitute for identifying the source of authority to impose them on state agencies, particularly without providing an explanation of what “meaningful engagement” even means. The commenter adds that the preamble invokes CAA section 301(a)(1), describing that residual rulemaking provision, as it has previously done in analogous circumstances, as an open-ended grant of authority to the Agency to “prescribe such regulations ‘as are necessary to carry out to [its] functions under [the CAA].’” The commenter suggests that resorting to CAA 301(a)(1) here is telling, in that it reveals no express grant of authority for the proposed “meaningful engagement” requirements exists. The commenter reports that set forth in a section of the CAA entitled “Administration,” CAA section 301(a)(1) references the authority of the Administrator “to prescribe such regulations as are necessary to carry out his functions” under the CAA. The commenter states that this language, which speaks to the Administrator’s having some limited authority to adopt rules in furtherance of his own “functions” under the CAA, has never been construed as conferring on EPA any sort of open-ended, substantive authority to adopt whatever rules the Agency may deem to be necessary to advance policy goals. To the contrary, the commenter reports that in those cases where the U.S. Court of Appeals for the D.C. Circuit has addressed the matter, the court has emphasized the circumscribed reach of the Administrator’s rulemaking authority under CAA section 301(a)(1).<sup>155</sup>

The commenter (2202-TXOGA) believes that even this caselaw may be read as overstating the scope of EPA’s authority under CAA section 301(a)(1), insofar as it appears that, to date, the D.C. Circuit has not had occasion to focus on the potential significance of Congress’s use of the term “functions” in the provision. The commenter reports more details in this respect in *Gonzales v. Oregon*,<sup>156</sup> where the Supreme Court had occasion to address a provision of the Controlled Substances Act (“CSA”) – i.e., 21 U.S.C Section 871(b) – the language of which parallels in significant part that of CAA section 301(a)(1), and which provides that the Attorney General of the U.S. “may promulgate and enforce any rules, regulations, and procedures which he may *deem necessary* and appropriate for *the efficient execution of his functions* under this subchapter.” (emphases added). After observing that the “limits on the Attorney General’s authority to define medical standards for the care and treatment of patients” under other portions of the CSA “bear . . . on the proper interpretation of § 871(b),” the Court found that the provision’s reference to the Attorney General’s being authorized to “best determine how to execute ‘his functions’” did not extend so far as to allow the Attorney General to “define the substantive standards of medical practice as part of his authority.”<sup>157</sup> The Court explained that it “would go . . . against the plain language of the text to treat a delegation for the ‘*execution*’ of *his functions* as a further delegation to define other functions well beyond the statute’s specific grants of authority.”<sup>158</sup> “When Congress chooses to delegate a power of this extent,” the Court continued, “it does so *not by referring back to the administrator’s functions* but by giving authority over the provisions of the statute he is to interpret.”<sup>159</sup>

---

<sup>155</sup> See, e.g., *NRDC v. EPA*, 749 F.3d 1055, 1063 (D.C. Cir. 2014) (“EPA’s authority to issue ancillary regulations is not open-ended, particularly when there is statutory language on point.”); accord *American Petroleum Institute v. EPA*, 52 F.2d 1113 (D.C. Cir. 1995); *NRDC v. Reilly*, 976 F.2d 36 (D.C. Cir. 1992); *Sierra Club v. EPA*, 719 F.2d 436 (D.C. Cir. 1983).

<sup>156</sup> 546 U.S. 243 (2006).

<sup>157</sup> *Id.* at 264.

<sup>158</sup> *Id.* at 264-65.

<sup>159</sup> *Id.* at 265.

The commenter (2202-TXOGA) notes that EPA indicates a view that the “proposed meaningful engagement requirements” would serve to “effectuate the EPA’s *function* under CAA section 111(d) in prescribing a process under which states submit plans to implement the statutory directives of this section.” But under the Court’s reasoning in *Gonzales*, the promulgation of rules establishing preferred “meaningful engagement” requirements are not an obvious “function” of the Administrator within the meaning of CAA section 301(a)(1), insofar as EPA can point to nothing that either directs or authorizes the Administrator to adopt such rules. And, in any event, by characterizing the proposed new requirements as “effectuating” EPA’s “function” under CAA section 111(d) in “prescribing a process under which states submit plans to implement the statutory directives of this section,” the commenter believes that EPA is tacitly conceding that the new requirements are not “*necessary* to carry out [the Administrator’s] functions” under the CAA. After all, the commenter contends that a process under which states submit such plans has been in place for nearly 50 years now, without there being any such requirements in place. Given this, the commenter believes that such requirements are not readily characterized as “necessary,” within the meaning of CAA section 301(a)(1).

Commenter (2292-WVAG et al) asserts that the CAA does not support EPA’s proposal to dictate day-to-day details of state administrative processes while measuring those processes against some undisclosed standard. The commenter expresses concern with the lack of guidance provided to states. The commenter notes that EPA has constructed new obstacles to the successful approval of a state plan submitted under CAA section 111(d), particularly through what they state are ambiguous “meaningful engagement” requirements, and requirements for more community engagement. The commenter contends that the agency ominously warns that insufficient “demonstrations” of “meaningful engagement” can now be “grounds for the EPA to find the submission incomplete or to disapprove the plan.” The commenter notes that EPA has provided little guidance on how to meet these new requirements. Instead, they state that the EPA has offered only an “example”—a description of its efforts in developing the proposed rule—that it then declares the new “minimum.” The commenter believes that even this “example” is heavy on the vagaries, as when EPA obliquely says that it “engaged with community leaders ... by hosting a meeting with [the] EJ community.” The commenter notes that states are now told that they, too, must identify such “vulnerable” communities—even including communities that are outside the state. In short, rather than preserving the discretion that CAA section 111(d) anticipated, the commenter states that EPA proposes to dictate administrative processes.

Commenter (2428-API) asserts that EPA does not have authority under CAA to dictate meaningful engagement requirements. The commenter supports full and fair public process in the development and implementation of CAA programs. The commenter believes that all affected entities should have reasonable opportunity to know about and participate in the development of regulations that affect their interests. The commenter contends, however, that EPA can encourage meaningful engagement but that it cannot be a required element of approvable state CAA section 111(d) programs, for the following reasons.

First, the commenter (2428-API) asserts that CAA section 111(d) states only that EPA shall establish a “procedure similar to that provided by section 7410 of this title under which each [s]tate shall submit to the Administrator a plan.” This requirement to establish a “procedure” for “submit[ting] ... a plan” unambiguously is directed only at the review and approval process as

between the states and EPA and is not directed at the plan development process that must be followed by the state. In other words, the commenter states that CAA section 111(d) directs EPA to emulate only some of the CAA section 110 requirements – not all of them. The commenter therefore asserts that CAA section 111(d) does not allow EPA to impose upon the states any measures related to the process by which they develop their plans. According to the commenter, it only provides authority to set up a process by which EPA reviews and approves the adequacy of standards of performance and the measures adopted by the states to implement and enforce such standards.

Second, to the extent that a “reasonable notice” standard applies to the development of state plans under CAA section 111(d), the commenter (2428-API) asserts that it is the states’ responsibility to ascertain what is reasonable – not EPA’s. The commenter notes that CAA section 111(d) is one of many CAA provisions where Congress intentionally split responsibility between EPA and the states. Indeed, they point out that under this “cooperative federalism” scheme, “air pollution control at its source is the primary responsibility of [s]tates and local governments.” CAA section 101(a)(3). In the earliest days of the CAA, the commenter notes that the U.S. Supreme Court confirmed that the CAA “gives the Agency no authority to question the wisdom of a [s]tate’s choices of emission limitations” if the limitations accomplish the goals of the CAA.<sup>160</sup>

The commenter (2428-API) contends that implicit in the notion of cooperative federalism is that states not only have wide latitude to determine appropriate emissions limitations, but also have similarly wide latitude in the legal and regulatory processes by which such limitations are established. Thus, to the degree a “reasonable notice” obligation is imposed upon the states by CAA section 111(d), the commenter asserts that states have primary authority and responsibility to determine how to implement this requirement. While EPA has responsibility to review and approve state programs, the commenter asserts that it may not require states to follow what it believes to be the most reasonable notice procedures. Instead, the commenter believes that the EPA must approve any state notice requirements that are facially reasonable, even if those are not the procedures EPA itself would have selected.

Third, even if EPA has authority to define what constitutes “reasonable notice” during the development of state plans, the commenter (2428-API) contends that the proposed “meaningful engagement” requirement goes beyond what EPA may reasonably require. To begin, the commenter states that the term “notice” unambiguously means notification of those with interest in the matter at hand. The commenter believes that the proposed requirements to engage with particular groups in particular ways (e.g., states must seek to overcome “barriers to participation” by “pertinent stakeholders”) and make targeted outreach go well beyond the nominal statutory obligation of notification. The commenter notes that EPA may “think [its] approach makes for better policy, but policy considerations cannot create an ambiguity when the words on the page are clear.”<sup>161</sup> However, the commenter states that Congress has imposed no explicit requirements and stated no intent in CAA section 111 or anywhere else in the CAA related to accomplishing

---

<sup>160</sup> *Train v. NRDC*, 421 U.S. 60, 79 (1975).

<sup>161</sup> *SAS Institute Inc. v. Iancu*, 138 S. Ct. 1348, 1358 (2018).

any particular environmental justice goals or outcomes. According to the commenter, the word “notice” cannot carry as much meaning as EPA believes it should.

As for CAA section 301, the commenter (2428-API) states that it has long been understood that that provision does not “provide [EPA] Carte blanche authority to promulgate any rules, on any matter relating to the Clean Air Act, in any manner that the [EPA] wishes.”<sup>162</sup> Here, CAA section 301(a)(1) is inapplicable because creating a new category of procedural requirements is not “necessary” for the Administrator “to carry out his functions under this chapter.” CAA section 301(a)(1). The commenter believes that EPA’s intentions are commendable, but that the proposed “meaningful engagement” procedures are not “necessary” as that term is used in CAA section 301.

Lastly, the commenter (2428-API) asserts that EPA’s proposed “meaningful engagement” procedures are not adequately clear and objective. As noted above, the commenter notes that Congress has not spoken in the CAA to the issue of environmental justice. The commenter explains that the EPA and interested parties are without guidance as to whether the issue should be addressed under the CAA and, if so, how.<sup>163</sup> Moreover, the commenter believes that EPA’s criteria for determining the adequacy of state “meaningful engagement” efforts are vague and EPA’s authority under its proposed rules to accept or deny a state’s efforts is not bounded by any readily objectively discernable principles. The commenter questions: 1) how does EPA determine the manner of required engagement with any particular stakeholders? 2) How does EPA decide what constitutes an actionable “linguistic, cultural, institutional, geographic, [or] other barrier” and, where such barriers are determined to exist, whether the state’s proposed approach is sufficient? 3) What measures are needed for state programs to be adequately inclusive? The commenter states that the statute does not expressly address those questions and EPA has not addressed these questions in its proposed rule. As a result, the commenter asserts that the proposed rule is vague, unmoored to the statute, and unless corrected, would be arbitrary and capricious.<sup>164</sup>

Response II-19-43: EPA has separately finalized meaningful engagement requirements in the final Implementing Regulations rulemaking, 88 FR 80480 (November 17, 2023).

Please see the Summary of Public Comments and Responses on Proposed Rule Adoption and Submittal of State Plans for Designated Facilities: Implementing Regulations Under Clean Air Act Section 111(d) (Subpart Ba) Docket ID No. EPA-HQ-OAR-2021-052.

---

<sup>162</sup> *North Carolina v. EPA*, 531 F. 3d 896, 922 (D.C. Cir. 2008) (internal quotes and citations omitted).

<sup>163</sup> It is notable that the 2022 “Inflation Reduction Act” included the most significant amendments to the CAA in decades and specifically targeted Environmental Justice concerns, yet Congress stopped short of amending CAA section 111 or the other existing substantive CAA programs to require or allow consideration of EJ. In other words, Congress expansively addressed EJ, but did so by providing copious funding to address the issue and chose not to create obligation or authority to otherwise address or consider EJ in implementing the existing CAA substantive programs.

<sup>164</sup> *Motor Vehicle Mfrs. Assn. v. State Farm*, 463 U.S. 29, 43 (1983).

#### ***19.4.6 Improvements to EJ Screen Tool***

Comment: Commenter (2186-MDNR) recommends improvements to EPA’s environmental justice screening and mapping tool, EJ Screen. The commenter states that EJ Screen is likely the tool that states will use to screen for areas that may be considered overburdened or underserved, and thus the focus of the new community engagement requirements. However, the commenter notes that EJ Screen does not offer any information regarding the locations of oil and natural gas facilities. The commenter contends that if data regarding proximity to oil and natural gas facilities was available in EJ Screen, similar to that of superfund proximity, it could benefit states in prioritizing community engagement activities during development of the state CAA section 111(d) plans.

Response II-19-44: EPA acknowledges the commenter’s suggestions.

### **19.5 Components of State Plan Submission**

#### ***19.5.1 Presumptive Standards Model Rule Language***

Comment: Commenters (2249-NACAA, 2425-TSC) support the creation of model rule language that can be incorporated directly or by reference into state plans. Some of the specific comments provided are presented in the following paragraphs.

Commenter (2425-TSC) supports the development of a model rule for use in state plans. The commenter recognizes the need for a consistent regulatory regime for tracking and limiting methane emissions. The commenter notes that although some states have promulgated rules to regulate the emission of methane from this sector, there are still many places where oil and gas operations are largely unregulated. The commenter agrees with EPA’s assertion<sup>165</sup> that the success of this rulemaking will depend largely on the effectiveness of the state plans adopted in coordination with EPA.

The commenter (2425-TSC) further supports EPA’s proposal to create presumptive standards based on “general industry parameters and assumptions,” which states may use as a “model rule” in the development of state plans. The commenter agrees that it will allow states to create standards that would be equivalent to the presumptive standards, in the aggregate. In addition, the commenter supports the provision that would allow states to include requirements that are more stringent than the guidelines because of, “early retirements, effects on local communities, and availability of control technologies that allow a source to achieve greater emission reductions,” provided states can demonstrate their efficacy. The commenter notes that the proposal gives states the discretion and flexibilities to meet EGs through aggregate reduction from their sources and allows methods like trading and averaging. The commenter cautions, however, that as EPA moves forward with EGs for states governing existing sources, EPA

---

<sup>165</sup> EPA, “Regulatory Impact Analysis for the Proposed Standards of Performance for New, Reconstructed, and Modified Sources and Emissions Guidelines for Existing Sources: Oil and Natural Gas Sector Climate Review,” Oct 2021. [https://www.epa.gov/system/files/documents/2021-11/proposal-ria-oil-and-gas-nsp-eg-climate-review\\_0.pdf](https://www.epa.gov/system/files/documents/2021-11/proposal-ria-oil-and-gas-nsp-eg-climate-review_0.pdf).

ensure that these guidelines are not undercut by efforts to provide flexibility to states to carry over less stringent provisions from any existing state programs.

Commenter (2249-NACAA) supports the development of an example state plan and model rule language for each segment of the oil and gas industry regulated by adopted rule that can be incorporated directly or by reference to meet EPA's EGs. The commenter asserts that while there are some state programs that are already being implemented or well developed in the proposal stage, many agencies will benefit from a model rule. The commenter believes that the opportunity to adopt preapproved rule language, in addition to the option to develop a unique state plan in accordance with the guidelines, is consistent with the CAA's cooperative approach and will expand state compliance options while conserving state resources.

Similarly, commenter (2418-SD DANR) recommends that EPA simplify the rule making process to allow state's plan to adopt parts or all the federal plan by reference.

Response II-19-45: EPA acknowledges the commenter's support for the model rule.

Comment: Commenter (2363-CEMC) supports EPA allowing states to use approved alternative test methods in their state plans—rather than require a state having to go through a separate “equivalency” demonstration for such methods. The commenter believes EPA's approach is important and valuable because, by the time that states are developing and submitting their EG OOOOc plans, the agency will hopefully have approved several methods. The commenter states that this will make it possible for state plans to authorize or require the use of technologies that provide improved detection and more precise quantification.

Response II-19-46: The EPA acknowledges the commenters support and clarifies in section XIII.C.2 of the final rule preamble how we intend the steps of the source-by-source equivalency determination to work with regards to the approval of alternative technologies.

Comment: Commenter (2218-TCEQ) requests that EPA reduce the volume of reports required to be submitted. Given the potentially hundreds of thousands of sites in Texas subject to this proposed rule, the state will not be able to process the number of reports, notifications and requests required to be submitted under this rule. The commenter states that each report is detailed and extensive and examples include increment of progress, corrective action plans, well closures plans, notification of intent to close, notification of compliance report, notifications under 40 CFR 60.7(a)(1), (3), and (4) and 40 CFR 60.15(d), annual reports, performance test reports, semiannual reports, additional reporting under alternative GHG standards for fugitive emissions components designated facilities and covers and closed vent systems, alternate fugitive emission standards, and requests for Alternative Means of Emissions Limitation under 40 CFR 60.5399c. The commenter asserts that the volume of reports and the amount of information submitted is more than state agencies can reasonably oversee.

Response II-19-47: Please see section X.N of the final rule preamble.

Comment: Commenter (2428-API) points out that EG OOOOc model rule language makes eight references to a 40 CFR 60.5933c, one of which gives its title as “Alternative Means of Emissions

Limitation.” However, the commenter notes that there is no actual section in EG OOOOc with that number or title.

Response II-19-48: The EPA acknowledges this was an inadvertent drafting error in the proposed model rule text. The EPA has corrected this error in the final EG OOOOc rule text.

### ***19.5.2 Emissions Inventory Requirements***

Comment: Several commenters (2218-TCEQ, 2286-CDPHE, 2296-NMED, 2393-OSEE, 2410-CA AG et al) support the use of existing emissions inventory data to fulfill state plan requirements. Commenter (2218-TCEQ) supports the use of the Greenhouse Gas Reporting Program (GHGRP) data. Commenters (2296-NMED, 2393-OSEE) do not support the use of GHGRP data due to the large reporting threshold. Examples of some of the comments provided are presented in the following paragraphs.

Commenter (2410-CA AG et al) recommends that EPA allow states to use existing emission inventories and emissions data, even if that data may not be fully aligned with the designated facilities in the EG. The commenter reiterates their initial proposal comments that existing inventories and EGs should be allowed provided that the data submitted by the state is rigorous and comprehensive enough to accurately capture emissions from the oil and natural gas industry.

Commenter (2218-TCEQ) supports using the annual emissions inventory data reported by the oil and gas industry as part of the GHGRP to fulfill the EG OOOOc state plan emissions inventory requirement for these sources. The commenter supports EPA’s use of GHGRP data to supersede the requirements of 40 CFR 60.25a(a) for the purposes of the proposed EGs so that state plans are not required to include an inventory and emissions data. The commenter asserts that if EPA decides instead to require states to collect, assess, and report annual GHG emissions inventory data, the resource burden would be staggering. Based on previous efforts to inventory ozone precursor emissions, the commenter estimates that approximately 21,000 additional sites would be required to report annually, a 10-fold increase of the current number of reporting point sources. The commenter reports that it would need to hire 50 additional full-time employees to perform basic quality assurance of reported data, and additional database and information technology (IT) resources would be required to handle the increase in reporting sources. Even with additional employees and adequate IT infrastructure, the commenter estimates it would take two to three years to collect and report each year’s GHG emissions data to EPA due to the immense number of sources.

Commenter (2286-CO APCD) supports EPA’s proposal to supersede the requirements of 40 CFR 60.25a(a) for purposes of the proposed EG so that state plans do not have to include an inventory and emissions data as described. The commenter appreciates EPA’s recognition of the complexity related to identifying all the designated facilities and associated emissions as defined in EPA’s proposed EG. The commenter states that Colorado does require extensive reporting by the oil and gas owners and operators in Colorado, and this reporting does show frequent emissions, operational, and ownership changes. Should EPA finalize the requirements related to providing emissions inventories with a state CAA section 111(d) plan as proposed, the

commenter will certainly look to holistically utilize its state-wide inventory and emissions data in developing and supporting Colorado's CAA section 111(d) plan.

Commenter (2296-NMED) also supports EPA's proposal to supersede the requirements of 40 CFR 60.25a(a) for purposes of this EG, and to provide options for the use of different types of emissions data to represent the same general type of information. The commenter supports EPA's proposal to allow states flexibility to utilize existing inventories and emissions data to develop their SIPs as they pertain to EG OOOOc. The commenter does not support the use of GHGRP data but supports allowing states the ability to use other available existing inventory information, so long as the inventory adequately captures data, or estimates emissions from, all potentially affected facilities.

The commenter (2296-NMED) states that the GHGRP includes emissions data from covered sources that exceed 25,000 metric tons per year of CO<sub>2</sub>e. This high threshold eliminates the sources emitting less than 25,000 metric tons per year of GHG. The commenter believes that the GHGRP data should not be used because it would exclude the emissions from thousands of smaller upstream oil and gas facilities, which in the aggregate represent a significant amount of GHG and criteria pollutant emissions.

The commenter (2296-NMED) notes that EPA has identified over 15,000 oil and natural gas facility owners and operators, one million producing onshore oil and natural gas wells, 5,000 gathering and boosting facilities, over 650 natural gas processing facilities, and 1,400 transmission compression facilities. The commenter reports that in New Mexico alone, there are over 1,600 permitted oil and natural gas facilities and nearly 55,000 completed oil and natural gas wells. EPA recognizes, and the commenter agrees, that due to the large number of existing oil and natural gas sources and the frequent change of configuration and/or ownership, it may not be practical to require states to compile emissions data in the same way as is typically done for other industries. The commenter adds that the EPA recognizes that states may not have a GHG emissions inventory of all designated facilities already available and that creating such an inventory would be resource intensive. The commenter has collected many years of data on criteria pollutants from Title V sources; and in 2021, the commenter conducted a comprehensive minor source emissions inventory of criteria pollutants. However, a GHG emission inventory for all minor sources has yet to be accomplished for New Mexico, although the commenter is currently planning and working toward conducting a GHG emission inventory from all minor sources. As EPA acknowledges, and the commenter is experiencing, creating such an inventory is time consuming and resource intensive. The commenter agrees with EPA that a highly detailed GHG emissions inventory is not necessary for states to develop standards of performance, and that such standards of performance could be developed using a different type of emissions inventory data.

Commenter (2393-OSEE) reports that Oklahoma regulations state that any source of regulated air pollutants must submit an emission inventory. The December 2022 supplemental proposal would make methane a regulated air pollutant, and thus the commenter notes that for Oklahoma, it could bring in the potential requirement to inventory 202,647 wells, regardless of where EPA obtains the data from to satisfy the requirements of 40 CFR 60.25a(a).

Commenter (2393-OSEE) does not support the use of GHGRP data to satisfy the requirements of 40 CFR 60.25a(a). The commenter believes that the GHGRP data do not accurately represent the needed information. The commenter explains that the GHGRP does not identify all affected sources, as it has a high threshold for reporting. Also, the commenter states that GHGRP does not always utilize actual measurements; and the GHGRP has default emission factors and default equipment counts built in that reporters must utilize. Instead of utilizing GHGRP information, the commenter recommends that EPA accept emissions data for these facilities in accordance with the provisions of the Air Emissions Reporting Requirements (AERR), with detailed requirements for designated facilities that are classified as AERR Type A and B sources and the use of alternative methods (e.g., a nonpoint tool) for designated facilities that would be classified as nonpoint sources under the AERR. The commenter reports that AERR already has emissions thresholds for what should be inventoried as a point source, and what is being captured in the NEI as a nonpoint source. The commenter believes that the rule should align with the AERR thresholds and requirements and suggests that using the NEI would give a much more comprehensive accounting of facilities and provide more accurate emissions.

The commenter (2393-OSEE) provides a comparison of GHGRP and NEI data specifically for the oil and gas sector in Oklahoma, where GHGRP includes 70 facilities<sup>166</sup>, while the NEI accounts for 73,138 facilities<sup>167</sup>. The commenter notes that the threshold for a reportable “facility” to GHGRP is 25,000 metric tons CO<sub>2</sub>e. For companies with wellheads, the company must add up all their wellhead assets in a basin to see if they meet the threshold and if they do, all those wellheads get reported as a single facility. The commenter states that this means that many, possibly most, of the wellheads would be missed in every basin, as there are many small operators in this sector. Conversely, the commenter provides that the EPA's Nonpoint Oil & Gas Tool used for compiling the NEI pulls data from Enverus (formerly DrillingInfo), to account for a vastly larger number of facilities, including both large and small operators.

Commenter (2393-OSEE) suggests that the EPA support state and local agency efforts to incorporate existing research findings into emissions estimates for the oil and gas sector. According to the commenter, researchers have investigated emissions from various facility types in the oil and gas sector. According to the commenter, many of these efforts have been in collaboration with oil and gas companies, university researchers, and representatives from environmental advocacy organizations. However useful this work has been, little of this work has been incorporated directly into the emissions estimates that have been incorporated into the EPA's triennial National Emissions Inventories (NEI). To ensure that valuable research findings are properly incorporated into emissions estimates (including notably the NEI), the commenter suggests that the EPA fund work by states and local agencies, in collaboration with university researchers and the EPA contractors, to evaluate research findings and incorporate results, where warranted, into emissions estimates submitted to the NEI. The commenter contends that state agencies do not currently have the resources to do this on their own.

---

<sup>166</sup> GHGRP figure obtained from EPA Flight tool for 2021, filtered for Oklahoma. The count includes Petroleum and Natural Gas Systems.

<sup>167</sup> NEI figure obtained from combination of EPA Nonpoint Oil & Gas Tool for Oklahoma and the Oklahoma Department of Environmental Quality's submission of relevant point sources. 71,683 sources from EPA Nonpoint Oil & Gas Tool for Oklahoma for 2020, plus 1,455 sources submitted as point sources to EPA for 2020.

Response II-19-49: Please see the discussion and response to comments in section XIII.C.5 of the final preamble.

### ***19.5.3 Source-Specific BSER***

Comment: Commenter (2410-CA AG et al) supports the source-specific BSER requirement. The commenter states that the BSER factors encompass all the information relevant to a state's determination of an appropriate emission standard for a facility to which the remaining useful life or other factors could properly apply.

The commenter (2410-CA AG et al) notes that EPA proposal would require the state plan submission to identify all control technologies available for the source and evaluate the BSER factors (cost, non-air quality health and environmental impacts, energy requirements, amount of reductions, and advancement of technology) for each technology.

Response II-19-50: EPA acknowledges the commenter's support.

### ***19.5.4 Process for States to Develop State Plans***

Comment: Commenter (2399-GPA) contends that the December 2022 supplemental proposal is neither the vehicle for proposing revisions to Subpart Ba, nor should it assume that such proposed revisions are already effective.

First, the commenter (2399-GPA) recommends that EPA address any potential changes to the process for states to develop state plans under EPA's separate, pending rulemaking to revise subpart Ba, not this rulemaking.

The Supplemental Proposed Rule's preamble explains EPA would conduct "a source-by-source evaluation" to determine whether a state's submitted program may be deemed equivalent to the proposed presumptive standards. However, the commenter (2399-GPA) state that those criteria are not found in 40 CFR Part 60, Subpart Ba, which governs EPA's review of state plans submitted under CAA section 111(d). EPA notes that it is proposing to revise Subpart Ba through a separate rulemaking, but the commenter adds that the proposed Subpart Ba rule also does not contain or reference the proposed "five basic criteria" described in the December 2022 supplemental proposed rule. The commenter asserts that it is illogical for EPA to be using preamble language to attempt to fashion separate criteria for just this proposal.

EPA also proposes major revisions to when states may consider facilities' RULOF to establish less stringent emission limits for a facility or class of facilities. Here, the commenter (2399-GPA) notes that the December 2022 supplemental proposed rule is clearly mandating that states use the new criteria for RULOF that are not found in existing regulations. Instead, the December 2022 supplemental proposed rule incorporates new standards from the proposed Subpart Ba Rule.

The commenter (2399-GPA) urges EPA to reconsider this approach. By proposing the same or similar revisions in two separate rules, EPA gives the appearance that the Proposed Subpart Ba Rule is a *fait accompli*, already determined by EPA to be effective in practice before it was even

proposed, much less before EPA considered public comments on the Subpart Ba Rule and finalized it. According to the commenter, this is impermissible under the APA.<sup>168</sup>

Instead, the commenter (2399-GPA) recommends that EPA withdraw the portion of the December 2022 supplemental proposed rule that purports to implement revisions to Subpart Ba so that the proposed Subpart Ba Rule may proceed separately and under the normal rulemaking process. The commenter asserts that this does not need to delay this rulemaking. In the meantime, the commenter recommends that EPA simply proceed under existing regulations for state plans while the agency finalizes revisions to subpart Ba.

Response II-19-51: Please see Response II-19-13. EPA does not agree with the commenter regarding their characterization of the APA and the associated caselaw cited. The commenter's citation to the APA is not on-point to the situation here, and the cited caselaw is not relevant here. EPA did consider all comments submitted both on this rulemaking's two proposals as well as those comments submitted on the proposal to amend subpart Ba via a different rulemaking process.

## **19.6 Timing of State Plan Submissions and Compliance Times**

### ***19.6.1 18-Month Plan Submission Timeframe is Inadequate***

Comment: Several commenters (2157-TDEC-DAQ, 2220-WDEQ, 2222-WDNR, 2224-WSARC, 2237-ICND, 2241-UDNR-PLPCO, 2292-WVAG, 2296-NMED, 2310-MDEQ, 2322-ADEE, 2330-KYDAQ, 2393-OOSEE, 2403-PAO, 2410-COAG, 2418-SDDANR, 2446-IPAA) state that the December 2022 proposed rule, if finalized, does not provide adequate time for plan development and state administrative processes for adopting a plan to regulate existing sources. The commenters cite several concerns with the timeframe proposed. The commenters request that the EPA consider the impracticability of the criteria established in 40 CFR 60.5365c of the proposed regulatory text for EG OOOOc and afford states with greater flexibility to effectively implement a State Plan. Examples of some of the specific comments provided are included in the following paragraphs.

Commenter (2446-IPAA) also states that the 18-month schedule to develop state plans will be inadequate for source-by-source determinations. The commenter reports that states will need far longer and that the more low production wells that are in a state, the longer it will need to be.

Commenters (2330-KYDAQ, 2403-PAO) outline factors that affect the time needed for states to develop and submit a plan to the EPA, including:

---

<sup>168</sup> See, e.g., *Nat'l Tour Brokers Ass'n v. United States*, 591, F.2d 896, 902-03 (D.C. Cir. 1978) (the purpose of the APA's public comment provision is so that the agency may "benefit from the expertise and input of the parties who file comments" and "maintain[ ] a flexible and open-minded attitude towards its own rules"); *U.S. Steel Corp. v. EPA*, 595 F.2d 207, 214-15 (5th Cir. 1979) (agency must "ensure that affected parties have an opportunity to participate in and influence agency decision making at an early stage, when the agency is more likely to give real consideration to alternative ideas").

- The volume of sources (the EPA has identified over 15,000 oil and gas owners and operators, around 1 million producing onshore oil and gas wells, about 5,000 gathering and boosting facilities, over 650 natural gas processing facilities, and about 1,400 transmission compression facilities),
- Limited air regulatory experience of sources,
- Time necessary to create an accurate source inventory,
- The proper notification to those sources and information requests from sources,
- Permit development
- Meaningful engagement and public participation,
- Any regulatory changes that would be necessary before submitting a state plan.
- Additional time would be necessary if the EPA does not propose a Model Rule.
- Develop and draft plans that include the required components, such as standards of performance and implementation measures for such standards.
- Adoption of the plans through their required administrative processes before submitting them to the EPA.

Commenter (2322-ADEE) states that CAA section 111(d)(1) and the EPA's implementing regulations under 40 CFR 60.24a(e) require that states be allowed the opportunity to propose a method other than the EPA's BSER to achieve the required emission reductions (or to propose a standard of performance less stringent than the presumptive standard of performance under a given EG, depending on the affected source's RULOF). The commenter notes that the proposed rule does not address this issue nor its impact on the timeline proposed.

Commenter (2344-ADEE) notes that the average timeline in Arkansas to develop and submit to the EPA a state plan that addresses a straightforward requirement is eighteen months, because of the numerous federal and state administrative procedures required for such an action. The commenter suggests that plans including controversial or complex regulations, such as the December 2022 proposed rule, can reasonably be expected to take longer. Further, the commenter adds that the more complex the standard-setting process, the more time states will need to gather information from designated facilities and perform analyses to set appropriate standards consistent with EGs.

Another commenter (2224-WSARC) provides that many states already have oil and gas control programs in place and will have to follow the EPA's outlined criteria to determine if those programs are equivalent to EG OOOOc. The commenter adds that this includes analyzing and potentially modeling impacted sources, evaluating emission inventories, consulting stakeholders, and examining compliance and enforcement needs, among numerous other actions. In addition to devoting resources toward the implementation of EG OOOOc for previously unregulated sources, state, Tribal, and local air agencies will also need to devote time and resources to review how EG OOOOc documentation fulfills the NSPSs KKK, OOOO, or OOOOa requirements. Since there are many more existing sources than new, modified, and reconstructed sources, the commenter states that these plans will be complex and take time to develop.

Commenter (2220-WDEQ) states that the supplemental proposal, as written, leaves states with the options of adopting the model rule or attempting to undertake an infeasible amount of work given the timeframes allocated. The commenter notes that the only workable option for some

states that have significant oil and gas development operations may be to adopt the EPA's model rule. The commenter suggests that this pathway denies the states their legal right to consider a source's RULOF as established in the CAA (i.e., undertaking a case-by-case application of state-determined standards of performance). The commenter notes that for states to exercise their statutorily mandated authority, the EPA should not dictate emission limits and time schedules.

The commenter (2220-WDEQ) notes that even if state agencies were to adopt the model rule as proposed, the 18-month timeline would not provide states with sufficient time for meeting the requirements. The commenter provides that EG OOOOc requires that states that adopt the model rule submit an inventory of designated facilities and an inventory of emissions from affected designated facilities in its written request for delegation of the Federal plan. The commenter suggests that this would require the state to undertake a state-level information collection request (ICR) that requires allocating sufficient time for sources to respond, along with significant time for state to compile the responses and the required emissions inventory.

Several commenters (2220-WDEQ, 2296-NMED, 2393-OOSEE) state that the burden of gathering an inventory of designated facilities in accordance with 40 CFR 60.5363c(a) alone warrants a longer timeframe. The commenters note that the EG includes thousands of additional sources for oil and gas states. They add that, rarely does an EG affect so many existing sources.

Commenter (2296-NMED) proposes that the EPA grant states with a substantial number of covered sources additional time as needed. The commenter states that this rulemaking will impact more sources in New Mexico (the second largest crude oil producer in the nation and one of the top ten states for natural gas production) than virtually every other state in the nation and impart a significant workload on the state resources, making it difficult to complete a state plan in 18-month timeframe.

Another commenter (2220-WDEQ) states that Wyoming has tens of thousands of sources that could be subject to the proposed requirements of EG OOOOc and that the state air quality division's program currently covers over 18,000 operating single-well sites and compressor stations, and that number does not consider the increase in specific equipment subject to the supplemental proposal's requirements, such as pneumatic pumps and controllers. The commenter expresses concern with the proposed timeline given the workload associated with making the required demonstrations for the thousands of sources in Wyoming, given the factors they face (e.g., remaining useful life, technical infeasibility, etc.).

Several commenters (2220-WDEQ, 2237-ICND, 2393-OOSEE) mention state rulemaking often takes at least a year to go from proposed to effective. In addition to gathering the source inventory and promulgating a state rule, the commenter notes that a state also must determine which facilities might be affected by RULOF in 40 CFR 60.5365c. To consider the remaining life of a source, the commenter explains that states must be able to determine the compliance timeline by considering factors such as the source's anticipated retirement date, costs and benefits of an available technology, and technology that has already been deployed. The commenters request that the EPA provide flexibility in allowing states to consider the remaining useful life of affected facilities, realistically achievable standards, and the timelines in which those standards could be met.

Several commenters (2220-WDEQ, 2222-WDNR, 2393-OOSEE, 2241-UDNR-PLPCO) note that the rule also includes an additional requirement of "meaningful engagement" in 40 CFR 60.5363c(a)(6) and 40 CFR 60.5366c that presumably requires additional outreach beyond what states typically conduct during a routine rulemaking and state CAA section 111(d) plan development. The commenters note that the consequential time and resources required for addressing these requirements would further overburden existing state staff resources and require additional time to for meaningful engagement and cooperation between the state, the EPA, and the tribal nations to address shared jurisdictions.

Commenter (2220-WDEQ) provides that they have significant expertise in meaningful engagement with a comprehensive spectrum of stakeholders and crafting effective regulation for existing sources. According to the commenter, the rulemaking process requires an internal draft development phase, numerous outreach meetings to stakeholders, and two Air Quality Advisory Board meetings. At the Air Quality Advisory Board meeting for one proposal, the state agency received significant comment that prompted additional review and revisions, and an Environmental Quality Council hearing. In all, the commenter reports that it took more than 18 months of development, stakeholder engagement, and statutory process for that proposed rule to become effective. The commenter emphasizes that the example proposed rule only addressed existing sources in one region of the state, and that the work necessary to implement the supplemental proposal will affect sources statewide.

Several commenters (2157-TDEC-DAQ, 2224-WSARC, 2237-ICND, 2292-WVAG, 2393-OOSEE) assert that, in addition to the EPA receiving inadequate or incomplete plans, there are potential risks or consequences of not providing adequate time to develop state plans.

Commenter (2393-OOSEE) notes that the EPA will be facing the need to develop a federal plan and implement the EGs themselves. The commenter suggests that the EPA does not seem to have the manpower to do this adequately. According to the commenter, recent experiences with the Municipal Solid Waste Landfill Emission Guidelines and the subsequent Federal Implementation Plan (FIP) have shown that even with a relatively small number of sources, the EPA is unprepared to receive and review the documentation required.

Another commenter (2237-ICND) states that it may lead to a similar event to what the U.S. experienced with the EPA's highly rushed and consequently inadequate NSPS OOOO and NSPS OOOOa regulations. According to the commenter, these recent NSPS OOOOa regulations were obviously not well vetted since NSPS OOOOb is newly proposed and subsequently EG OOOOc will retroactively 'correct' errors, inconsistencies, and items overlooked under NSPSs OOOO/OOOOa. The commenter suggests that this issue could have been avoided altogether if the EPA had simply meaningfully engaged with oil and gas producing states as the EPA developed these regulations.

Commenter (2157-TDEC-DAQ) indicates that a possible consequence of the EPA's action would be to federalize a portion of the CAA, to subvert a state's ability to develop the best plan for that state, and to undermine the federal-state partnership that the Act envisions.

Response II-19-52: Please see the discussion and response to comments on the timing of state plan submittals in section XIII.E. of the final preamble.

Comment: Commenter (2241-UDNR-PLPCO) states that the state of Utah already has an established program to regulate oil and gas emission sources, though focused on VOC emissions. The plan the state is to develop is required to be equivalent to the EPAs proposed NSPS OOOOb and EG OOOOc requirements, thus includes methane emissions from oil and gas sources. As methane is not a pollutant that has been previously regulated by the State of Utah, it is unrealistic for the state to collect an emission inventory, understand the monitoring and quantification of potential methane emissions, determinate stakeholders and have meaningful engagement, evaluate equivalency of current standards to the proposed NSPS OOOOb and EG OOOOc requirements and understand the impacts of compliance with the plan, all in 18 months. The commenter notes that, considering the long-time frame taken previously by the EPA to prepare and promulgate a FIP for the Uinta Basin (UB) ozone NAAQS, Utah is again uncertain the EPA or the Ute Tribe will develop this plan in a timely manner once again leaving the UB in a situation where there are unequal regulatory requirements on adjacent lands in a shared airshed.

Response II-19-53: Please see the discussion and response to comments on the timing of state plan submittals in section XIII.E. of the final preamble. The EPA clarifies that the EG OOOOc does not require states to develop emissions inventories (see preamble discussion XIII.C.5.). Nor does EG OOOOc require a state to leverage their existing state programs for purposes of their plan submittal, but rather as discussed in preamble section XIII.B.2, offers state the flexibility to do so if they choose. Lastly the EPA is not finalizing the provision for meaningful engagement in EG OOOOc. Rather, since similar revisions to subpart Ba are now final at 88 FR 80480 (November 17, 2023), and are therefore applicable to the EG OOOOc, state plans must be submitted according to the provisions in 40 CFR 60.23a(i) which requires states to document in their plan submittals how they provided meaningful engagement with the pertinent stakeholders. Please see section XIII.C.6 of the preamble.

Comment: Several commenters (2157-TDEC-DAQ, 2220-WDEQ, 2296-NMED, 2330-KYDAQ, 2410-COAG, 2418-SDDANR) provide recommendations for a timeline for state plan development and submission. Specific comments are provided in the following paragraphs.

Commenter (2157-TDEC-DAQ) states that an 18-month deadline may be sufficient for states that do not use RULOF and perform the minimum amount of engagement for a plan that mirrors what the EPA has set forth, but more time is required for states that do not adopt the EPA's EGs as written or to conduct any additional engagement. Specifically, the commenter notes that a state may not initially know RULOF is required. Therefore, the commenter adds that the state will need to identify specific facilities and assess whether those facilities can comply with the rule as written. The commenter explains that the amount of time required to complete this step cannot be determined with certainty, but six to eight months is our best estimate (one to two months to identify and contact potentially affected facilities, one to three months for the facility to send a response, and one to two months to review the facilities' responses). Then, once all information is collected and reviewed, states will need to develop their CAA section 111(d) plans. This step can probably be completed in one year if the state elects not to use RULOF for any facilities. The commenter notes that states that must establish standards based on RULOF

are likely to need a minimum of six additional months to complete this step<sup>169</sup>. The commenter provides that this estimate does not include the additional time that will be required to comply with the EPA's meaningful engagement requirements. Therefore, the commenter believes that 24 months is the minimum amount of time that would be required to submit a CAA section 111(d) plan that includes RULOF. The commenter states that they do not know how much time will be required to comply with the EPA's meaningful engagement requirements, but it seems likely that a further extension of three to six months would be necessary. With all these requirements considered, the commenter believes that 30 months is necessary for states to develop CAA section 111(d) plans. The commenter contends that considering the required engineering analyses and meaningful engagement requirements<sup>170</sup>, any shorter deadline will foreclose a state's ability to consider RULOF as allowed by CAA section 111(d).

Commenters (2220-WDEQ, 2410-CA AG et al) request that the EPA extend the effective date for the supplemental proposal and allocate more time to implement the requirements of the proposed EGs. Commenter (2410-CA AG et al) urges EPA to establish the shortest time frame necessary to accommodate the administrative procedures of the states charged with implementing the guideline.

Commenter (2296-NMED) urge that EPA grant states with a substantial number of covered sources additional time as needed.

Commenter (2330-KYDAQ) suggests extending the deadline for state plan submissions to a minimum of 24 months after a final EG is published.

One commenter (2418-SDDANR) agrees it is possible to submit a plan to the EPA within 18 months if everything runs smoothly. However, the commenter recommends the EPA allow for an extension in cases where the state rulemaking process is delayed or held up by significant opposition.

Several commenters (2222-WDNR, 2225-WSARC, 2237-ICND, 2241-UDNR-PLPCO, 2310-MDEQ, 2322-ADEE, 2393-OOSEE, 2403-PAO) requests that the EPA extend the submission timeline contained in 40 CFR 60.23a(a)(1) to three years.

Response II-19-54: Please see the discussion and response to comments on the timing of state plan submittals in section XIII.E. of the final preamble.

### ***19.6.2 18-Month Plan Submission Timeframe is Too Long***

Comment: Commenters (2201-WVHC, 2433-EDF et al) state that the 18-month submission period is too long.

---

<sup>169</sup> The commenter notes that EPA frequently requests consultation and submittal of pre-draft documents prior to the public comment period, and these steps can add substantially to the timeline.

<sup>170</sup> The DC Circuit's 2021 vacature of the Subpart Ba requirements in *Am. Lung Assoc. v. EPA*, 985 F.3d at 991 (D.C. Cir. 2021) addressed EPA's general requirement to submit state plans within three years but did not foreclose a longer deadline where circumstances warrant.

Commenter (2201-WVHC) suggests that six months would be plenty; and that a year would be more than enough.

Commenters (2392-Earthjustice et al, 2433-EDF et al) urge the EPA to retain the 15 months provided in the general provisions for plan submittals under the EG OOOOc rules.

Commenter (2433-EDF) contends that the agency offers no evidence in either rulemaking to suggest that state-level administrative processes are different for oil and gas sources than for any other source category, and so offers no reason why 18 rather than 15 months are necessary to accommodate state plan development in this category. Although the agency claims in a footnote to the CAA section 111(d) implementation proposal that a longer timeline is necessary in EG OOOOc “due to the size and variety of emission sources in the oil and gas sector,”<sup>171</sup> the commenter notes that this justification appears nowhere in the EG OOOOc preamble itself and does not support an 18-month rather than 15-month submission period in any event.

Commenter (2433-EDF et al) asserts that, particularly given the urgent nature of climate change, the EPA must ensure that its proposed EG OOOOc are implemented as swiftly as possible. The commenter urges the EPA to apply the proposed default 15-month timeline for state plan submissions under EG OOOOc rather than the extended 18-month period. Similarly, they encourage the EPA to consider adopting a more accelerated timeframe than 12 months for state plan approval and recommend that EPA instead explore whether a 9-month (or even shorter) window is feasible.

Response II-19-55: Please see the discussion and response to comments on the timing of state plan submittals in section XIII.E. of the final preamble.

### ***19.6.3 Specific State/Tribal Issues with 18-month Timeframe for Plan Submission***

Comment: Commenter (2241-UT DNR) expresses concerns regarding the timeliness of federal action and resources to implement the proposed requirements. The commenter states that most oil and gas sources in Utah are in the UB where there is shared air quality jurisdiction with the state, the EPA, and Ute Tribe over oil and gas emissions. The commenter notes that the 2017 oil and gas emission inventory for the UB indicates that 80 percent of the VOC emissions are from sources under the EPA and tribal regulatory control. This has been acknowledged by the EPA with the issuance of the “Federal Implementation Plan for Managing Emissions from Oil and Natural Gas Sources on Indian Country Lands Within the Uintah and Ouray Indian Reservation in Utah” published in the December 8, 2022 (87 FR 75334). There is a one-year implementation time period for existing sources to implement and comply with the FIP, which is February 6, 2024. The commenter provides that the FIP reflects standards and requirements established by UDAQ many years ago and though very much supported and appreciated, it was not issued until almost five years from designation as an ozone nonattainment area (NAA) in 2018.

With the proposed FIP, the commenter (2241-UT DNR) states that these new proposed EPA standards under NSPS OOOO, the BLM’s “Waste Prevention, Production Subject to Royalties, and Resource Conservation” proposed rules, and the EPA’s December 2022 proposal updating

---

<sup>171</sup> 87 Fed. Reg. at 79181 n.8.

requirements to the “Adoption and Submittal of State Plans for Designated Facilities: Implementing Regulations Under the Clean Air Act Section 111(d)” there is a large amount of regulation proposed to address emissions from oil and gas sources. As such, they add that there is a large amount of complexity and uncertainty for states in how to manage all these changes and understand how they all interconnect and function together in the proposed short time frames. The commenter further adds that federal agencies will also have to effectively resource, manage and implement these programs in the UB where they have jurisdiction over most impacted sources. As such the commenter requests that the EPA engage with the Utah Department of Air Quality (UDAQ) and the Ute Tribe in a meaningful and timely way such that we can effectively and reasonably manage our resources and provide clear regulatory guidance to impacted sources. The commenter contends that there should be more time provided to fully understand these changes and implement them effectively.

Response II-19-56: Please see the discussion and response to comments on the timing of state plan submittals and compliance timelines in section XIII.E. of the final preamble.

Comment: Commenter (2427-UPA) states that adequate implementation timing and clarity must be provided for areas subject to a federal plan under proposed 40 CFR 60.5368c. The commenter contends that much of the oil and gas production within the Uinta Basin occurs on Tribal lands within the Uintah and Ouray (U&O) Reservation and owned by the Ute Tribe. The commenter notes that, if the Tribe does not develop and submit an implementation plan to meet the EG OOOOc requirements, these Tribal lands will be subject to the EPA federal plan.

Commenter (2427-UPA) notes that the proposed EG OOOOc requires states and Tribes to submit a state plan for the EPA approval within 18 months of the date of publication of the final rule in the *Federal Register*. If the EPA does not develop its federal plan in a timely way, it will be difficult or impossible for operations on the Tribal lands to comply within the proposed timing, written as proposed and measured from the state plan submittal deadline. For example, the commenter states that it took the EPA nearly three years from proposal to final publication to develop the U&O FIP, a shorter and less complex rule. They add that it took the EPA nearly twice as long to develop the U&O FIP than the 18 months proposed for states and Tribes to develop their individual plans. The commenter suggests that, if the EPA needs similar time to develop the Federal plan for EG OOOOc as it used to develop the U&O FIP, this will severely cut into the compliance time. According to the commenter, with a shorter compliance time, operators may not be able to comply timely, and could potentially be forced to shut in wells until they can install the required equipment. The commenter believes that this scenario would result in a disproportionate impact on the Ute Tribe.

Thus, the commenter (2427-UPA) recommends that, for areas subject to the Federal plan, the final EG OOOOc should allow 36 months from the effective date of the Federal plan for compliance implementation. The commenter contends that anything less than that will have a disproportionate negative effect on operations on Tribal lands and on the Ute Tribe

Response II-19-57: Please see the discussion and response to comments on the timing of state plan submittals in section XIII.E. of the final preamble.

Comment: Commenter (2193-CARB) states that the EPA assumes that California and Colorado have requirements at least as stringent as those in the proposed rule for many of the sources covered by the supplemental proposal. However, the commenter notes that the "presumptive standards" as outlined in the December 2022 supplemental proposed rule are not in alignment with California's requirements. These "presumptive standards" include numerous variables based upon the designated facility type, whether a particular type of alternative testing is approved, and ambiguity in the super emitter program that the commenter states may require California to enact numerous regulations and therefore not be able to meet an 18-month CAA section 111(d) Plan deadline. The commenter adds that the facility designation itself makes it extremely problematic for a state to draft and implement any proposed CAA section 111(d) Plan given it must determine whether it would classify under the "two or more" heading or the "centralized production" heading or whether it has compressor stations, whether the optional periodic screening may apply, or any other such variables just to analyze which testing methods are required. The commenter suggests that facilities themselves are likely to dispute their classification, making implementation and enforcement plans even more difficult when drafting the CAA section 111(d) Plan. Furthermore, the commenter provides that the proposed December 2022 supplemental rule requires that any state plan that includes RUOF for a less stringent standard to apply for a particular facility go through the public comment and community stakeholder engagement process as well.<sup>172</sup>

The commenter (2193-CARB) believes states will need more than 18 months to comply, with the possibility of significantly more time should any issues of equivalency determinations arise. For instance, additional regulations would delay California's time in issuing a 111(d) Plan by at least six months to 24 months total. In the event California does not need to adopt any additional regulations to comply with the December 2022 supplemental proposed rule, an 18-month deadline is possible. However, the commenter requests that EPA include a consideration in this deadline allowing states sufficient time to take regulations through the administrative process in the event their rules are not at least as stringent as those in the new December 2022 supplemental proposed rule.

The commenter (2193-CARB) also strongly encourages the EPA to streamline Leak Detection and Repair (LDAR) requirements in favor of a more uniform approach, include all approved advanced technologies in the Emissions Measurement Center website, and administer the super emitter program, to ensure states can complete their CAA section 111(d) Plans in a timelier manner.

Response II-19-58: Please see the discussion and response to comments on the timing of state plan submittals in section XIII.E. of the final preamble. Please see the discussion in section XI.B. with regards to EPA's final provisions for allowing advanced methane detections work practice.

#### ***19.6.4 36-Month Compliance Timeframe Concerns***

Comment: Several commenters (2288-NDDEQ, 2237-NDIC, 2296-NMED, 2403-PAO, 2423-Coterra Energy) express concerns with the 36-month compliance timeframe and state that adequate implementation time is needed to accomplish successful emission reductions.

---

<sup>172</sup> Id.

Commenter (2423-Coterra Energy) notes that the EPA's proposed rules for new, modified, and reconstructed facilities are complex, far reaching and will affect tens of thousands of facilities. The commenter explains that the proposed EGs for existing sources will further dramatically expand the number of affected facilities. These new requirements will require oil and gas operators across the country to take numerous actions regarding equipment. They provide that constraints on supplies of compliant pneumatic controllers and pneumatic pumps are a particular concern. The commenter notes that the oil and gas industry certainly is not the only industry experiencing these supply chain issues; it is an economy-wide problem. Nevertheless, the commenter believes that the scope and breadth of these new rules will exacerbate existing delays in acquiring equipment on this scale. The commenter asserts that it is imperative that the EPA take these challenges into account before finalizing those provisions in the proposed rules that will mandate acquisition of new equipment.

The commenter (2423-Coterra Energy) further notes that the cumulative burden of new regulations supports the need for additional time for implementation. The commenter encourages the EPA to consider several factors in deciding on implementation timelines. The interrelationship of NSPSs OOOO, OOOOa, and OOOOb; and EG OOOOc are far from clear as other stakeholders make clear in their comments. For example, they suggest that it is unclear when NSPS OOOOa sources become subject to EG OOOOc. Further, an unprecedented number of sources will be subject to the rule. They add that supply chain delays will only further complicate implementation of these new requirements.

Commenter (2403-PAO, 2446-IPAA) recommends that the EPA set the compliance date with new state regulations for existing sources based on the approval of the state plans rather than their submission date. The commenter explains that, since states and the regulated community will not know if the state regulations will be approved or whether the EPA will be proposing a federal plan until the EPA acts, compliance should be based on final EPA action.

Commenters (2288-NDDEQ, 2237-NDIC) urge EPA to provide adequate time for states to meaningfully consider EPA final action and develop a state plan accordingly. Especially due to the lack of additional funding, the commenters believe that no less than 36-months should be allotted to states for plan development and submission. The commenters assert that this will allow states to fully consider the final EG OOOOc language and properly determine the best implementation for the state, especially when considering how best to account for items such as remaining useful life. The commenters add that continuing with the currently proposed 18-month deadline will likely result in inadequate and incomplete state plans, similar to what the U.S. has experienced with EPA's inadequate NSPS OOOO and NSPS OOOOa regulations. The commenters contend that these recent regulations were not well vetted since NSPS OOOOb is newly proposed and EG OOOOc will retroactively 'correct' errors, inconsistencies, and items overlooked under NSPS OOOO/OOOOa. Of note, the commenters believe that this issue could have been avoided altogether if EPA had meaningfully engaged with oil and gas producing states as EPA developed these regulations. The commenters assert that while meaningful engagement, in this context, should have happened between North Dakota (and other oil and gas states) and EPA, it did not happen and resulted in poor regulations [or half-baked regulations].

Response II-19-59: Please see the discussion and response to comments on the compliance timeline in section XIII.E. of the final preamble.

Comment: Commenter (2304-PIOGA) states that conventional operators and Pennsylvania Department of Environmental Protection (PADEP) are ill-equipped to comply with the proposed EG OOOOc. While the commenter understands that the compliance deadline for existing sources subject to EG OOOOc is years away, the commenter is not confident that the industry and the regulatory structure will be prepared to comply. According to the commenter, without any apparent concern for state regulators, the EPA is proposing in the December 2022 supplemental proposal a regulatory program dependent on component counts, which is not something either PADEP or existing sources have tracked or the basis for a regulatory framework. The commenter reports that industry already experiences difficulties with getting permits from PADEP in a timely manner. The commenter explains that the December 2022 supplemental proposal will bring thousands, if not tens of thousands, of sources under PADEP's regulatory authority. The commenter states that the PADEP does not have the work force to address that additional responsibility. The commenter adds that the PADEP's typical response to a shortage of people to do the work is to increase permitting fees – placing additional financial burdens on the sources least capable of absorbing the additional costs. The commenter notes that these additional costs on owners/operators of conventional wells is not at all accounted for in the EPA's BSER analysis.

Response II-19-60: Please see the discussion and response to comments on the compliance timeline in section XIII.E. of the final preamble.

#### ***19.6.5 36-Month Compliance Timeframe is Too Much Time***

Comment: One commenter (1659-CRP-PSPA) states that they urge the EPA to reconsider this timeline. The fact that designed facilities require more time to fix their polluting infrastructure should not be a burden that the public must be forced to endure and suffer. They urge the EPA to require a rapid review process and prioritization for states with higher methane emissions from designated facilities, such as Pennsylvania.

Response II-19-61: Please see the discussion and response to comments on the compliance timeline in section XIII.E. of the final preamble.

Comment: Several commenters (2028-WMCG, 2284-Kairos, 2392-Earthjustice et al, 2410-CA AG et al, 2433-EDF et al) suggest that for standards that do not require the installation of new equipment the compliance timeline should be accelerated. Commenters specifically note affected facilities other than oil wells with associated gas, storage vessels, pneumatic controllers, and pneumatic pumps such as alternative leak detection programs. According to commenters, LDAR programs and alternative leak detection programs can be implemented relatively quickly and inexpensively compared to equipment retrofits. According to commenter (2410-CA AG et al), the EPA has failed to justify why such a lengthy compliance period would be necessary for these types of sources. The commenter adds that the desire to simplify compliance and ease the burden on industry operators is not a valid basis for this time frame under the statute and not warranted by these circumstances. These standards do not require changes to pneumatics devices or

installation of storage tank controls, system shutdowns or equipment purchases that could be impacted by supply chain shortages and delays. The commenters suggest a timeline for compliance for these facilities of no more than six months to one year after the EPA's approval of a state plan.

Commenter (2284-Kairos) note the advantages of phasing-in leak detection programs for EG OOOOc include owners and operators being provided with both an emissions reduction and economic benefit, alleviation of administrative burden and potential justification to allow more relaxed phase-in timelines in other areas where it may be necessary to minimize industry burden.

Commenters (2028-WMCG, 2284-Kairos) recommend that EPA consider incentivizing a separate, earlier phase-in period for control strategies that do not involve significant capital expenditures or retrofits. Commenter (2284-Kairos) suggests that this could be used to balance emissions from areas of the rule that may require additional time to implement.

Commenters (2392-Earthjustice et al, 2433-EDF et al) indicate that the EPA should further consider accelerated timelines for sources that require equipment replacement. Commenter (2433-EDF) suggests that the EPA consider adopting a shorter timeline such as 24 to 30 months after plan submission deadlines for sources that do require capital expenditures for compliance.

Commenter (2392-Earthjustice et al) suggests the EPA remove proposed provisions that allow existing sources to avoid compliance with the agency's proposed EGs based on RULOF exemptions.

Response II-19-62: Please see the discussion and response to comments on the compliance timeline in section XIII.E. of the final preamble.

Comment: Commenter (2343-NYU School of Law) recommends that the EPA reconsider whether to accelerate the timeline for compliance with state plans for select performance standards. The commenter notes that the EPA should reconsider whether the benefits of the proposed three-year uniform deadline may be overstated and whether the urgency of the health and environmental harms that state plans will address merits a shorter deadline for compliance to increase net benefits for society. According to the commenter, the EPA has given some consideration to the need for speed but given the December 2022 supplemental proposal's significant health and environmental benefits, the EPA should reevaluate the feasibility of a more aggressive compliance schedule that would allow these benefits to be realized sooner.

The commenter (2343-NYU School of Law) recommends that to select which standards of performance merit an earlier compliance deadline, the EPA should apply the nine factors that it identified for this very purpose in the December 2022 supplemental proposal (e.g., supply-chain issues). However, in lieu of the existing second and ninth factors ("[t]he cost of equipment" and "overall methane emissions reduction that will result from control of existing sources under the [emissions guideline]"), the commenter suggests that it would be preferable to examine net benefits. Compared to methane emissions reductions alone, looking to net benefits would allow for consideration of all relevant costs and benefits—including benefits from methane's co-

emissions—when evaluating whether to prioritize compliance with one standard of performance over another.

The commenter (2343-NYU School of Law) continues that, the nine factors indicate that the EPA should substantially shorten the timeline for existing sources to comply with the super-emitter response program. The EPA’s concerns about the costs of simultaneous implementation across the sector and planning burdens do not apply to this program. For the same reasons that 14 days is too long to wait before acting on a single super-emitter event, the commenter states that three years is too long to wait for the entire program.

The commenter (2343-NYU School of Law) suggests that in instances where the EPA has differentiated between subcategories of affected facilities, the EPA should further consider accelerating compliance for select subcategories if doing so appears more net beneficial than subjecting all designated facilities to the same deadline. The commenter provides that staggering compliance across tiers within a single EG could reduce the planning burden on entities in a given year and help prevent bottlenecks for specialized equipment and services by spreading compliance deadlines out over time.

For instance, the commenter (2343-NYU School of Law) points out the consideration of fugitive emissions at wells, a category that the EPA already divides into four tiers with different monitoring requirements based on the number of wells at the site and the presence of major equipment. The commenter states that EPA could apply the same nine factors discussed above to designate one or more tiers of wells subject to an accelerated compliance timeline. The commenter adds that the EPA could conduct a similar assessment for its four potential subcategories for pneumatic controllers (well sites, gathering and boosting stations, transmission and storage compressor stations, and natural gas processing plants).

The commenter (2343-NYU School of Law) notes that this tiering of compliance deadlines may increase net benefits relative to waiting three years for all four tiers because a subset of the December 2022 supplemental proposal’s benefits would be achieved sooner and thus accrue over the additional time. While annual costs would also accrue over the additional time, the commenter believes that the benefits would most likely exceed the costs to the same extent as they are projected to do so for future years.

Response II-19-63: Please see the discussion and response to comments on the compliance timeline in section XIII.E. of the final preamble.

#### ***19.6.6 Conflicting Timelines***

Comment: Commenter (2220-WDEQ) brings to the EPA’s attention potential conflicting requirements in the supplemental proposal and the EPA’s proposed rule for *Adoption and Submittal of State Plans for Designated Facilities: Implementing Regulations Under Clean Air Act Section 111(d)*, and potentially other regulations.

The commenter (2220-WDEQ) notes that the revised deadline in 40 CFR part 60 subpart Ba 40 CFR 60.23a (“Adoption and submittal of State plans; public hearings”), reduced from three years

to 15 months, conflicts with the 18-month State Plan deadline specified in the proposed regulatory text for EG OOOOc. While the commenter acknowledges the EPA’s statement “unless otherwise specified in the applicable subpart,” they are concerned that the 18-month proposed deadline for submitting State Plans could be altered to the 15-month deadline specified in the proposed revisions to Subpart Ba once both proposed rules are finalized. As noted in other comments provided the commenter already considers an 18-month deadline to be impracticable; and a 15-month timeframe would set an entirely impossible bar for state agencies to attempt to hurdle.

Additionally, the commenter (2220-WDEQ) notes that there are numerous other areas in which the supplemental proposal may have overlapping impacts with another proposed federal rule: BLM’s *Waste Prevention, Production Subject to Royalties, and Resource Conservation* proposed rule. The commenter agrees with and supports the comments of the Wyoming Oil and Gas Conservation Commission (WOGCC) related to the specific overlapping requirements. The commenter asserts that it is important that the EPA thoroughly reviews the supplemental proposal and other proposed and existing regulations and make corrections that ensure there are no conflicting technical or implementation requirements in the final rules.

Response II-19-64: Please see the discussion and response to comments on the compliance timeline in section XIII.E. of the final preamble. The EPA notes that the BLM rulemaking is not yet final.

### ***19.6.7 Other Plan Submission and Compliance Timeline Considerations***

#### **19.6.7.1 Timelines for State Plan Submission and Compliance**

Comment: Several commenters (2237-NDIC, 2249-NACAA, 2293-Holmes, 2301-US CoC, 2427-UPA, 2502-RGISC) provide comments for EPA to consider when establishing the timelines for state plan submission and compliance.

Commenters (2237-NDIC, 2249-NACAA) request that EPA provide adequate timelines to meaningfully consider EPA’s final action, develop and implement state plans.

Commenter (2249-NACAA) recommends that EPA engage with agencies to determine whether proposed timelines offer sufficient time for administrative rulemaking and meaningful public engagement. The commenter also recommends that EPA provide clear guidance in the determination of when a plan becomes applicable.

The commenter (2249-NACAA) notes that the separately proposed CAA section 111 implementation rule published in the *Federal Register*<sup>173</sup> by EPA on December 23, 2022, changes the deadline for the provision of plans, shortening the time to submit a state plan under CAA section 111 to EPA from 3 years to 15 months. The proposed December 2022 supplemental rule also reflects a shortened compliance window, in this case to 18 months. The

---

<sup>173</sup> (“Adoption and Submittal of State Plans for Designated Facilities: Implementing Regulations Under Clean Air Act Section 111[d]”, 87 Fed. Reg. 79176) Online at <https://www.federalregister.gov/documents/2022/12/23/2022-27557/adoption-and-submittal-of-state-plans-for-designated-facilities-implementing-regulations-under-clean>.

commenter states that for more complex requirements under CAA section 111 that would fall under the proposed December 23, 2022, implementing regulations for which EPA does not provide model rules, more time may be needed to develop the required state plan.

The commenter (2249-NACAA) states that EPA's proposed December 2022 supplemental rule also creates changes in the determination of when a plan becomes applicable. The commenter notes that regulations under Subpart B determined that a plan came into effect once approved by EPA; the proposed supplemental determines that applicability begins when a plan is proposed by the state agency. The commenter believes that this will create confusion and regulatory uncertainty under a hypothetical circumstance where a state plan is subsequently disapproved by EPA.

Commenter (2301-US CoC) notes that these burdens and implementation timeline can be reduced by allowing states to rely on existing state regimes to limit the amount of change in regulatory requirements that both the state regulators and regulated industry will face. As a result, they suggest that it may be feasible to shorten the implementation timelines if the EPA provides sufficient flexibility to the states to use existing regimes.

Commenter (2427-UPA) states that any shortening of the timing in the final rule could result in significant implementation problems and possible need to shut in wells until equipment can be procured and installed. Shutting in wells could lead to energy shortages and consumer price escalation nationwide. The commenter also recommends inclusion of a provision for case-by-case extensions. This would provide a backstop should unforeseen problems create more difficulties with labor or supply chains. Case-by-case extensions could be modeled after those provided in the U&O FIP in 40 CFR Part 49 §49.4169(c).

Response II-19-65: Please see the discussion and response to comments on the compliance timeline in section XIII.E. of the final preamble.

#### 19.6.7.1 Accelerated Schedule Pathway

Comment: Commenter (2433-EDF et al) encourages the EPA to consider providing an additional pathway for states that would like accelerated submission and consideration of state plans, or alternatively an accelerated FIP schedule for states that choose at the outset not to submit a plan. The commenter believes that this would ensure that states have in place enforceable emission limits for existing sources as early as 2024.

Commenter (2270-Private Citizen) supports the reduction of methane emissions but contends that the implementation and enforcement process does not address the urgency needed to address climate change under the currently proposed timeline. The commenter notes that the EPA's current timeline indicates that states and industry must comply with these new requirements by 2028. The commenter asserts that is not sufficient, even assuming there is 100% compliance.

Commenter (2356-Earthworks et al.) urges the EPA to move as quickly as possible to implement and finalize these rules. The commenter states that communities and the climate are being harmed right now. According to the commenter, it is critical that EPA moves quickly to finalize

national rules. Once the ink dries and these rules are enacted, states must quickly work to write SIPs to show how they will implement and enforce new federal standards on the ground. In cases where a SIP falls short of meeting federal standards, the EPA must swiftly issue a FIP to eliminate industry self-policing and regulatory capture.

Response II-19-66: Please see the discussion and response to comments on the compliance timeline in section XIII.E. of the final preamble.

#### 19.6.7.2 Alignment with of State/Tribal/Federal Plans

Comment: Commenter (2177-Ute Indian Tribe) states that for development of any deadlines for state or tribal plans, the EPA should also consider deadlines for federal plans and align these deadlines. There should not be a difference in the deadlines for implementation and compliance with FIP/SIP/TIP. This ensures an equitable and level regulatory playing field for all areas.

Response II-19-67: Please see the discussion and response to comments on the compliance timeline in section XIII.E. of the final preamble.

#### 19.6.7.3 Methane Emissions Reduction Program (MERP)

Comment: Commenter (2301-US CoC) states that the Methane Proposal would require states to submit their compliance plans within 18 months after final publication of the EGs. The commenter notes that the EPA states that this deadline is consistent with the requirement of CAA section 111(d) that the EPA promulgate procedures “similar” to CAA section 110 and the D.C. Circuit’s directive to “engage meaningfully with the different scale” of the CAA section 111(d) and 110 plans, while also considering impacts to public health and welfare. Ahead of this deadline, the commenter recommends that the EPA work closely with the states and Tribes on an expedient approval process in recognition that this will provide much-needed regulatory certainty for the industry and in recognition that the IRA allows for exemptions from the newly introduced methane emissions charges under the MERP—which will soon take effect in 2025—if the EPA regulations addressing methane emissions (1) are in effect in all states, and (2) will “result in equivalent or greater emissions reductions as would be achieved” by the November 2021 Notice. Given the substantial potential costs of the methane emissions charges, the commenter urges the EPA to take the MERP exemption deadline into consideration in its approval process and encourages the EPA to work both internally and with state and tribal regulators to ensure a smooth and efficient process. The commenter contends that doing so will effectuate congressional intent behind the MERP and promote regulatory clarity for the entire sector.

Response II-19-68: Please see the discussion and response to comments on the compliance timeline in section XIII.E. of the final preamble. EPA notes that the implementing framework for the MERP is being addressed in separate EPA actions outside the scope of this rulemaking.

### ***19.6.8 Federal/Tribal Plans***

Comment: Commenter (2222-WDNR) provides that the EPA notes concern in the December 2022 supplemental proposal about achieving emissions reductions quickly to produce necessary climate and air quality benefits. Understanding it will be infeasible for some states to submit an approvable state plan on timelines identified in this rule, the commenter suggests that the EPA could preemptively address this concern by proposing and finalizing a federal plan expeditiously.

Response II-19-69: Please see the discussion and response to comments on the compliance timeline in section XIII.F. of the final preamble.

Comment: Commenter (2181-Ute Indian Tribe) recommends that EPA consider developing reservation specific FIP or assist tribes with developing Tribal Implementation Plan (TIP) for sources located within Indian country. The commenter recommends that EPA consider the timeliness of FIP and/or TIP development to coincide with state plans.

The commenter (2181-Ute Indian Tribe) states that the proposed regulations do not directly impose requirements on existing sources. Rather, states must submit plans for the EPA's approval that are at least as effective as the presumptive standards in EG OOOOc. The commenter notes that many states already have oil and gas emission control programs in place, and the EPA has outlined criteria to assist those states in determining whether those existing programs are equivalent to EG OOOOc. The commenter contends that this approach leaves sources located in Indian country in uncertainty as sources in Indian country are not under state regulation.

Response II-19-70: Please see the discussion and response to comments on the compliance timeline in section XIII.F. of the final preamble.

### ***19.6.9 EPA's Administration Deadlines***

Comment: Commenter (2326-AXPC) states that as a preliminary matter, they acknowledge that the EPA in the December 2022 supplemental proposal did not propose deadlines for the EPA's own functions as part of the CAA section 111(b) existing-source regulatory process.<sup>174</sup> They intend to submit comments on the EPA's separate proposal, *Adoption and Submittal of State Plans for Designated Facilities: Implementing Regulations Under Clean Air Act Section 111(d)*, 87 Fed. Reg. 79,176 (Dec. 23, 2022), whose comment period closes on February 27, 2023, in which we will address the EPA's proposed deadlines.

However, because, reading the terms of the two proposals together, the commenter (2326-AXPC) states that some of the deadlines proposed in that separate proposed revision to the "implementing regulations" generally governing the EPA's administration of the existing-source program will apply to proposed new EG OOOOc, they are presenting their observations,

---

<sup>174</sup> See 87 Fed. Reg. at 74,831-33.

concerns, and suggestions on the proposed deadlines under that action as part of their comments as well.

The commenter (2326-AXPC) does not believe that the EPA will delay its ability to make determinations that the conditions for exemptions from the methane fee program under the IRA are met by providing itself sufficient time to make completeness determinations and approve state programs under EG OOOOc.

The commenter (2326-AXPC) notes that their comments here are directed to the EPA's intention to apply certain deadlines proposed in the "implementing regulations" proposal to EG OOOOc.<sup>175</sup> Due to the overlapping comment periods and the interrelated nature of the two proposals, the commenter feels it is better to file partially redundant comments on the two proposals rather than risk raising the comments in an incorrect forum.

The commenter's (2326-AXPC) general observation on the EPA's proposed deadlines is that, when the EPA imposes deadlines on itself to perform functions to which Congress assigned no statutory deadline, the EPA is creating new obligations on itself which are potentially enforceable under "deadline" suits brought by outside parties under CAA section 304.<sup>176</sup>

If the EPA imposes deadlines on itself that are not long enough, the commenter (2326-AXPC) states that it runs the risk of the timing and prioritization of its tasks being set not by itself or by Congressional direction, but rather by litigation brought by outside interest groups. The commenter explains that the experience of the NAAQS program and its associated state- and federal-planning process, replete with statutory deadlines as it is, is a cautionary example: where deadlines cluster, and where the EPA has to respond to many state submissions subject to those deadlines, or take state-by-state action on its own subject to other deadlines, many or most deadlines will not be met in the first instance, will be subject to "deadline suit" litigation, and will end up with new deadlines imposed via settlement or court order – often out of control of the EPA and the states, or at a faster pace than is appropriate.

The commenter (2326-AXPC) notes that this familiar scenario in cases where Congress *has* imposed statutory deadlines is more reason for the EPA to ensure that it gives itself adequate time when selecting deadlines of its own choosing. This concern is especially pressing in this rulemaking, which will initiate the most complicated existing-source implementation process the EPA has yet managed in over 50 years of administering the CAA, with most if not all states containing jurisdictional existing sources requiring a CAA section 111(d) plan, and many states containing an unusually high number (thousands or more) of existing sources that are unusually complex and variegated—as the EPA forthrightly acknowledges in the Supplemental Proposal.<sup>177</sup>

---

<sup>175</sup> [See *id.*] (EPA intends to apply some deadlines proposed in the separate "implementing regulations" proposal to Subpart OOOOc and intends to finalize the "implementing regulations" proposal "not later than" it finalizes Subpart OOOOc).

<sup>176</sup> [See, e.g., *California v. EPA*,] 360 F. Supp. 3d 984, 991 (N.D. Cal. 2018) (Congress intended in Section 304 "to waive sovereign immunity for the EPA's failure to perform nondiscretionary duties mandated by regulations").

<sup>177</sup> See generally, 87 Fed. Reg. at 74,832-34.

The commenter (2326-AXPC) recommends that EPA finalize a mechanism under which a state can ask for and receive an extension of their submittal deadline if the state demonstrates to the Administrator that its situation is sufficiently complex or otherwise unique that the general assumptions, findings, or rationale underlying the deadlines that the EPA does finalize do not apply in its case. The commenter adds that EPA should also consider finalizing such a mechanism to provide itself with an extension for its own deadlines to make completeness determinations, decisions to approve or disapprove submitted state plans, and to issue federal plans where special circumstances warrant. However, they suggest that these extension mechanisms would not be advisable if they required an additional round of notice-and-comment rulemaking, as that would divert additional the EPA resources from working with states on their plan development, submittal, review, and approval.

If the EPA does not adopt this type of extension mechanism, the commenter (2326-AXPC) recommends the following specific changes to the deadlines proposed at 87 Fed. Reg. 79,182, Table 1 as they will apply to final EG OOOOc:

- Where the EPA proposes two months for the EPA to determine whether a state plan submittal is complete, the commenter urges the agency to provide itself with no less than four months. Two months is an unusually short deadline in the context of the complexity of the task before the EPA and the high number of state plan submittals the EPA is likely to receive – all likely clustered around the deadline for submission of such plans. The proposed two-month deadline is particularly likely to create a “logjam” scenario of missed deadlines at the outset of the state-plan review process, accompanied by a heightened risk of diversion of resources to “deadline suits” as described above.
- Where the EPA proposes 12 months for the EPA to issue a federal plan after disapproving a state plan or determining that a state has failed to submit a complete plan, the commenter urges the agency to provide itself with no less than 18 months. The EPA should give itself at least as much time to draw up its plan as it’s giving the states to draw up their plans. The December 2022 supplemental proposal explicitly states: “18 months is the minimum period of time in which the EPA finds that most states can expeditiously create and submit a plan that meets applicable requirements for EG OOOOc.”<sup>178</sup> For the same reason, the EPA should provide itself with at least that same period of time. The EPA indeed may wish to consider providing itself with more time than it provides the states, given that the states as local and primary regulators are presumably more familiar with the characteristics of their existing-source fleets than is the EPA as a general, federal regulator.

Response II-19-71: Please see the discussion and response to comments on the timelines applicable to EPA action in section XIII.F. of the final preamble.

## **19.7 State Implementation Resources**

Comment: Commenters (2218-TCEQ, 2222-WDNR) request that EPA provide additional resources (e.g., guidance, tools, templates) to assist states and local air agencies to adequately

---

<sup>178</sup> Id. at 74,834.

develop and implement the requirements of EG OOOOc (and NSPS OOOOb). Examples of some of the comments provided are presented in the following paragraphs.

Commenter (2218-TCEQ) requests that additional resources be made available to states and regulatory authorities to assist with implementation and enforcement of NSPS OOOOb and EG OOOOc. The commenter asserts that guidance documents, workbooks, reporting forms, templates, flow charts, video tutorials, and other resources would greatly benefit the delegated administrator in implementation of the new monitoring, recordkeeping, and reporting requirements contained within the rules. The commenter also requests that a guidance document, similar to the small business compliance guide for NSPS OOOOa, be developed and provided as a tool to help the regulated community understand the complex regulatory requirements. The commenter requests that a guidance document be available to assist regulated entities with submitting required notifications, data, reports, and approval requests. The commenter suggests that guidance should address where and to whom the relevant reports or notifications should be submitted and provide information summarizing deadlines or schedules for each type of report or notification. The commenter also requests that a template be available for regulated entities to use to assist in providing required information where applicable.

Commenter (2222-WDNR) requests that EPA provide resources to state and local agencies for the development of construction and operating permits as well as resources to support agencies' compliance assistance programs. The commenter asserts that the proposed rule would add to the number of permitted facilities and to the complexity of rules included in the permits. The commenter states that the proposed rule would result in an influx of permit applications from sources seeking to install additional combustion equipment to control emissions, and site-specific monitoring plans that must be reviewed, approved, and correctly incorporated into operating permits through permit revisions.

Commenter (2247-Ohio Environmental Protection Agency (Ohio EPA)) states each of the AVO reports will need to be submitted to Ohio EPA for review to determine the compliance status of the well operator and confirm that the AVO was completed and done correctly. Assuming the four required AVO inspections each year result in one annual AVO report, and it takes an hour to review each report, there would be 52,250 hours per year worth of work. That means Ohio EPA would have to hire 26 new employees just to review the AVO reports. If you add in the work needed to evaluate other reports that need to be submitted and the work needed for inspecting the facilities to ensure they are in compliance, then the number of employees could easily triple. This is a very large increase in workload for Ohio EPA. To hire these staff, the current air program at Ohio EPA does not have extra resources to apply to this endeavor and will need additional funding. EPA has not provided any recommendations for how states are to fund this additional work. EPA has also not provided a mechanism or funding stream that will be used to fund this work. It is incumbent on EPA to provide substantial more resources to the states to meet the increasing obligations placed on states by the federal government.

Response II-19-72: The EPA does intend on working with tribes and states to develop plans tailored to the factors concerning the states. The plan development process, under which performance standards for existing sources are established within their jurisdiction and have the discretion to consider remaining useful life and other factors, is one that Congress established

through the text and structure of CAA section 111(d). See discussions in section V.B.2.<sup>179</sup> and section V.B.3.<sup>180</sup> of the December 2022 Supplemental and section XIII of the final preamble and final rule, Adoption and Submittal of State Plans for Designated Facilities: Implementing Regulations Under Clean Air Act Section 111(d) at 88 FR 80480, November 17, 2023, and its corresponding Summary of Public Comments and Responses on Proposed Rule Adoption and Submittal of State Plans for Designated Facilities: Implementing Regulations Under Clean Air Act Section 111(d) (Subpart Ba) Docket ID No. EPA-HQ-OAR-2021-052.

The new standards will work hand-in-hand with new resources and programs in the Inflation Reduction Act, which will incentivize early implementation of innovative methane reduction technologies and support methane mitigation and monitoring activities. These efforts will achieve greater methane emissions reductions more quickly. For more information on the IRA, the Administration has created a guidebook that provides an overview of the clean energy, climate mitigation and resilience, agriculture, and conservation-related tax incentives and investment programs, including who is eligible to apply for funding and for what activities. See <https://www.whitehouse.gov/cleanenergy/inflation-reduction-act-guidebook/>.

## **19.8 EPA State Plan Approval Authority**

### ***19.8.1 “Satisfactory” State Plan Approval***

Comment: Commenter (2252-PAW) expresses concern with EPA’s attempt to set an unrealistic bar within its authority to ensure state plans are satisfactory. The commenter states that the CAA gives EPA authority to review states plans to ensure they are “satisfactory”. The commenter notes that in crafting a presumptive standard for existing sources, EPA is asserting that only state plans achieving equal to or greater emission reductions than what EPA has proposed will be approved. The commenter reports that synonyms for satisfactory include adequate, good enough or fine. Instead, the EPA is setting a bar of requiring state plans be exemplary, flawless, or perfect, or face disapproval. The commenter contends that Congress intended plans to be satisfactory, which acknowledges that each state will come to varying conclusions about what is appropriate to require of existing sources. This is another area where the commenter believes that the EPA needs to revise its posture to that of what they assert Congress expressly provided.

Commenter (2428-API) urges EPA to provide more flexibility in approving state programs. The commenter highlights a flaw in EPA’s approach is its proposal to give substantive meaning to the statutory obligation that it must approve state plans that are “satisfactory.” CAA section 111(d)(2)(A). The commenter notes for example, that EPA explains that “it is the EPA’s responsibility to determine whether a state plan is “satisfactory”. EPA further explains that “the most reasonable interpretation of a “satisfactory plan” is a CAA section 111(d) plan that meets the applicable conditions or requirements, including those under the implementing regulations that the EPA is directed to promulgate pursuant to CAA section 111(d).”

---

<sup>179</sup> 87 FR 74812.

<sup>180</sup> 87 FR 74816.

The commenter (2428-API) contends that by EPA's reasoning, all elements of its CAA section 111(d) implementing regulations become mandatory state obligations because, if a state does not in EPA's eyes satisfy the regulations, the state program is not "satisfactory" to EPA. Similarly, the commenter asserts that EPA gets to decide whether a state plan is "satisfactory" based on EPA's judgment as to whether the plan meets EPA's conception of the "overall health and welfare objectives" of CAA section 111(d). In other words, the commenter notes that EPA uses the term "satisfactory" to bootstrap its own policy and legal preferences into mandatory approvability criteria.

The commenter (2428-API) believes that EPA's interpretation is inconsistent with the plain words of the statute and, in any event, unreasonably expands EPA's authority to prescribe or prohibit particular outcomes under state CAA section 111(d) programs. The commenter notes that the statute simply says that state plans must be "satisfactory." According to the commenter, the word "satisfactory" naturally connotes that EPA must approve any state plan that meets the statutory standard setting criteria and that otherwise meet the nominal procedural rules that EPA is required to establish to guide submission and review/approval of state plans. The commenter contends that the word "satisfactory" does not reasonably confer upon EPA the authority to demand particular outcomes (e.g., meeting EPA's self-determined "health and welfare objectives") or to impose substantive constraints not otherwise specified by CAA section 111(d). The commenter states that EPA's effort to give more meaning to the word "satisfactory" is inconsistent with the law and a misplaced effort to expand the Agency's authority under CAA section 111(d).

Response II-19-73: Please see the final Implementing Regulations rulemaking, 88 FR 80480, and the Summary of Public Comments and Responses on Proposed Rule Adoption and Submittal of State Plans for Designated Facilities: Implementing Regulations Under Clean Air Act Section 111(d) (Subpart Ba) Docket ID No. EPA-HQ-OAR-2021-052.

Comment: Commenter (2446-IPAA) questions EPA's use of a dated definition of "satisfactory". The commenter expresses concern with the substantial difference in definitions. The commenter assumes that EPA wants to establish a different standard to constrain the state flexibility that Congress chose to establish.

The commenter (2446-IPAA) asserts that there are several elements of the EPA proposal that are designed to maintain control by EPA and limit states. It begins with something as simple as the definition of "satisfactory" in the context of approving state plans that provide for less stringent regulations of sources based on Congress providing that:

Regulations of the Administrator under this paragraph shall permit the State in applying a standard of performance to any particular source under a plan submitted under this paragraph to take into consideration, among other factors, the remaining useful life of the existing source to which such standard applies.

The commenter (2446-IPAA) provides that the EPA has characterized the authority to consider RULOF. As EPA notes: CAA section 111(d)(2)(A) authorizes the EPA to promulgate a Federal plan for any state that "fails to submit a satisfactory plan" establishing standards of performance

under CAA section 111(d)(1). Accordingly, the EPA interprets "satisfactory" as the standard by which the EPA reviews state plan submissions. Consequently, EPA presents what the commenter believes is a strained assessment of the definition of "satisfactory":

Additionally, while states have discretion to consider RULOF under CAA section 111(d), it is the EPA's responsibility to determine whether a state plan is "satisfactory," which includes evaluating whether RULOF was appropriately considered. The relevant dictionary meaning of "satisfactory" is "fulfilling all demands or requirements." The American College Dictionary 1078 (C.L. Barnhart, ed. 1970). Thus, the most reasonable interpretation of a "satisfactory plan" is a CAA section 111(d) plan that meets the applicable conditions or requirements, including those under the implementing regulations that the EPA is directed to promulgate pursuant to CAA section 111(d), including the provisions governing the application of RULOF.

The commenter (2446-IPAA) questions why EPA has chosen this particular 1970 dictionary as the relevant dictionary. The commenter notes that other contemporary dictionaries: such as the 1975 American Heritage Dictionary define "satisfactory" as "giving satisfaction; sufficient to meet a demand or requirement; adequate", the contemporary Merriam-Webster Online Dictionary definition is "adequate", and the Oxford American English Dictionary Online definition is "good enough for a particular purpose". The commenter contends that this substantial difference in definitions is intended because EPA wants to establish a different standard to constrain the state flexibility that Congress chose to establish. The commenter states that similar issues arise elsewhere in the CAA section 111(d) proposal.

Response II-19-74: Please see the final Implementing Regulations rulemaking, 88 FR 80480, and the Summary of Public Comments and Responses on Proposed Rule Adoption and Submittal of State Plans for Designated Facilities: Implementing Regulations Under Clean Air Act Section 111(d) (Subpart Ba) Docket ID No. EPA-HQ-OAR-2021-052.

### ***19.8.2 EPA State Plan Approval/Disapproval of Less Stringent Alternative Standards Based on RULOF Exceeds EPA's Authority***

Comment: Commenters (2218-TCEQ, 2292-WV AG et al, 2399-GPA) specifically highlight that they believe that the EPA is exceeding its statutory authority under CAA section 111(d) as it relates to EPA having the ability to approve/disapprove of alternative standards under a submitted state plan that are less stringent than EPA's proposed presumptive standards based on RULOF.

Commenter (2218-TCEQ) states that EPA is exceeding its authority under CAA section 111(d) with the proposed requirement in 40 CFR 60.5363c that standards of performance for designated facilities must be at least as protective as the EGs unless the EPA approves alternate standards under 40 CFR 60.5365c. Under proposed 40 CFR 60.5363c(a)(4), the EPA's proposed requirements for the state plan specify that the standards of performance included in the plan must be at least as protective as the EPA's EGs, unless the EPA approves alternative standards under 40 CFR 60.5365c. The proposed provisions under 40 CFR 60.5365c allow for the EPA to approve less stringent standards of performance. The commenter contends that EPA did not

explain in the preamble about the choice of wording in 40 CFR 60.5363c(a)(4). However, the commenter asserts that protectiveness and stringency are not necessarily equivalent. Further, the commenter asserts that 40 CFR 60.5365c(e)(1)(vii) requires that, if the less stringent standard is established based on remaining useful life, the increased emissions for the duration of the remaining useful life will not result in negative impacts to the surrounding communities, including those most affected by and vulnerable to the health and environmental impacts of the plan.

The commenter (2218-TCEQ) also notes that in the recently proposed revisions to the state plan implementation regulations in 40 CFR Part 60, Subpart Ba, EPA proposed to only require states, in calculating a less stringent standard, to consider the potential pollution impacts and benefits of control to communities most affected by and vulnerable to emissions from the designated facility. The preamble language associated with 40 CFR 60.5365c(e)(1)(vii) appears to mirror the language proposed with the implementation regulations, stating "...to the extent a designated facility would qualify for a less stringent standard through consideration of remaining useful life and other factors (RULOF), the state, in calculating such a standard, must consider the potential health and environmental impacts on communities most affected by and vulnerable to the impacts from the designated facility considered in a state plan for RULOF provisions." However, the commenter notes that the rule language proposed in 40 CFR 60.5365c(e)(1)(vii) does not require consideration of impacts but actually prohibits a state from adopting a less stringent standard if there are negative impacts. Additionally, the commenter notes that the demonstration required to satisfy 40 CFR 60.5365c(e)(1)(vii) as proposed involves a health and environmental protectiveness evaluation of the local community around each specific facility where the state would consider establishing a less stringent standard. The commenter asserts that EPA did not evaluate protectiveness at a local level in establishing the proposed EGs to the degree that 40 CFR 60.5365c(e)(1)(vii) would require the state to demonstrate, as EPA acknowledges in the preamble. However, the commenter states that CAA section 111(d) does not specify the state plan be at least as protective.<sup>181</sup> The commenter believes that EPA is exceeding its authority by requiring protectiveness reviews if a state proposes less stringent standards for a facility that considers the facility's remaining useful life. Furthermore, the commenter believes that EPA is also holding the state to a standard of evaluation far beyond that used by the EPA when establishing the proposed emission guidelines. Further, the EPA has not defined negative impacts and, as written, the requirement appears to go beyond health and environmental factors, which could hold the state to evaluating impacts on factors beyond the state's authority to regulate.

Further, commenter (2218-TCEQ) asserts that this proposal prohibits many states from utilizing their statutorily given discretion and therefore impermissibly constrains state authority, rather than providing a regulatory scheme that allows states to adopt alternative standards based on RULOF.

The commenter (2218-TCEQ) contends that the state plan requirements proposed by EPA are so onerous and time-consuming as to eviscerate the authority given to states by Congress to consider RULOF in adopting alternative standards for certain sources. The commenter believes

---

<sup>181</sup> See CAA section 111(d)(1) ("... Regulations of the Administrator under this paragraph shall permit the State in applying a standard of performance to any particular source under a plan submitted under this paragraph to take into consideration, among other factors, the remaining useful life of the existing source to which such standard applies.")

that the proposal will force states with large numbers of affected sources to adopt the model rule and eliminate the discretion provided in CAA section 111(d). The commenter asserts that EPA cannot take away through regulation authority given to states by Congress. CAA section 111(d) states in relevant part: “Regulations of the Administrator under this paragraph shall permit the State in applying a standard of performance to any particular source under a plan submitted under this paragraph to take into consideration, among other factors, the remaining useful life of the existing source to which the standard applies.” Proposed new 40 CFR 60.5365c requires states intending to apply a less stringent standard on a particular source due to RULOF to provide a multi-faceted demonstration of unreasonable cost, technical infeasibility, and other factors specific to the facility. The commenter contends that if the alternative standard is based on remaining useful life, several additional factors must be considered. For example, proposed 40 CFR 60.5365c(b)(1) requires the state to identify all available control technologies and evaluate each system using the same factors and metrics used by EPA. The commenter believes that states should not be required to evaluate control technology that EPA has previously excluded from the BSER based on technological or economic feasibility. The only control technologies that should be relevant to the determination under 40 CFR 60.5365c(b)(1) are control technologies that achieve less emission reductions than the technology determined by EPA to represent BSER. Further, the commenter asserts that requirement that states evaluate technologies using the same factors and metrics is unreasonable because the EPA has not disclosed all factors and metrics used in evaluating all technologies when it determined BSER. Additionally, as the commenter discussed previously, the EPA’s three requirement in 40 CFR 40 CFR 60.5365c(e)(1)(vii) concerning negative impacts would force states to perform protectiveness evaluations for any source that the state decides to set an alternate standard based on remaining useful life. Such evaluations could require extensive modeling to determine impacts for the proposed control level as well as EPA’s BSER control level. The commenter reports that Texas has a substantial number of oil and gas facilities with many that legitimately cannot cost-effectively or technically meet the applicable EGs because of their age, production capability, location, etc. If only a small fraction of these sources request or require an alternative standard demonstration, it will be virtually impossible to complete and timely submit a state plan while also meeting state rule development requirements and the additional “meaningful engagement” requirements imposed by this rule. According to the commenter, for states with considerable oil and gas development, the result will be adoption of the model rule with no opportunity for sources to receive an alternative standard based on RULOF, as the CAA allows. The commenter asserts that EPA’s state plan requirements for submitting plans and consideration of RULOF for certain sources is written in such a way that it does not actually “permit” states to do so in practice. Rather than providing a regulatory scheme that allows states to adopt alternative standards based on RULOF, this proposal prohibits many states from utilizing their statutorily given discretion and therefore impermissibly constrains state authority.<sup>182</sup>

Commenter (2292-WV AG et al) contends that the proposal appears to try to push states into abandoning their local-level discretion by saddling states with significant new obligations any time that discretion is employed. The commenter notes that CAA section 111(d) allows states to apply a more lenient standard by considering “among other factors, the remaining useful life of

---

<sup>182</sup> See *American Corn Growers Assn. v. EPA*, 291 F3d. 1 (D.C. Cir.) (vacating an EPA rule in part because its requirements were “inconsistent with the Act’s provisions giving the states broad authority over [Best Available Retrofit Technology] determinations...”).

the existing source” for each facility.<sup>183</sup> The commenter contends that EPA traditionally interpreted this freedom to apply in three scenarios: (1) when the cost from plant age, location, or process design is unreasonable; (2) when there is a “physical impossibility of installing [the] necessary control equipment”; and (3) when other factors make a less stringent standard “significantly more reasonable.” Yet under the proposal, the commenter notes that states must offer EPA an extensive justification for using lower standards to reflect remaining useful life, sometimes calling for precision that may be impossible to achieve when talking about future events. Among other things, the commenter notes that states must now show how their systems are “fundamentally different” than EPA contemplated before invoking their statutorily guaranteed discretion to consider remaining useful life. Further, the collection of specific requirements for invoking that factor—which includes contingencies, restrictive cost considerations, and impacted-communities analysis narrows the “range of permissible choices to the [s]tates” from that which Congress determined was appropriate.<sup>184</sup> For instance, the commenter states that no reasonable justification exists for limiting a state’s cost considerations to capital expenditures alone.

In effect, the commenter (2292-WV AG et al) asserts that the proposed rule replaces the state “laborator[ies]” for regulating methane at existing sources with one national administrative setup.<sup>185</sup> The commenter states that EPA admits as much. The commenter reports that EPA complains that under the current scheme, “two states could consider [remaining useful life] for two identically situated designated facilities and apply completely different standards of performance.” The commenter contends that is precisely what cooperative federalism permits, because California and West Virginia may (and do) view the collective impact from cost, structure, or other factors on a source’s remaining useful life differently. These different views may derive, for instance, from the different composition of a particular state’s energy portfolio—and may lead to equally good air quality across the board. The commenter asserts that Congress invited this state-by-state variation, and EPA cannot contradict what Congress made clear in statute.<sup>186</sup> The commenter states that CAA section 111(d) entrusts states to use standards that are more lenient on certain sources because of—among other discretionary factors—remaining useful life.<sup>187</sup>

Commenter (2399-GPA) asserts that EPA lacks authority to impose conditions on states’ use of RULOF. The commenter argues that the “standards of performance” interpretation is unreasonable, and impermissible. Support for their position is provided in the following paragraphs.

*The Supplemental Proposed Rule’s “Satisfactory Plan” Interpretation is Contradicted by the Statute and is Unreasonable.* The commenter (2399-GPA) contends that in support of its proposal, EPA relies on an erroneous interpretation of CAA section 111(d), as EPA would substantially alter the roles of EPA and the states established by statute’s text and structure and recognized by the D.C. Circuit, based on a strained and implausible reading of CAA section

---

<sup>183</sup> 42 U.S.C. § 7411(d).

<sup>184</sup> *Wis. Dep’t of Health & Fam. Servs. v. Blumer*, 534 U.S. 473, 495 (2002).

<sup>185</sup> *New State Ice Co. v. Liebmann*, 285 U.S. 262, 311 (1932) (Brandeis, J., dissenting).

<sup>186</sup> *Nat’l Ass’n of Home Builders v. Defs. of Wildlife*, 551 U.S. 644, 665 (2007).

<sup>187</sup> 42 U.S.C. § 7411(d).

111(d)(2)(A). The commenter notes that sub-section governs federal implementation plans promulgated where a “[s]tate fails to submit a satisfactory plan” as the Administrator “would have under section 7410(c) of this title in the case of failure to submit an implementation plan.” Instead of naturally interpreting this sub-section as providing EPA with the authority to issue federal emission standards for existing sources whenever a state either fails to submit a plan or the plan is disapproved (a reading that tracks the referenced Section 7410(c)), the commenter notes that EPA proposes to read the term as giving it a superpower to limit the states’ authority in the first place. According to EPA, the phrase “satisfactory plan” grants EPA vast and unprecedented powers to impose extensive conditions that restrict how states establish existing source emission limitations. According to the December 2022 supplemental proposed rule, “the most reasonable interpretation of a ‘satisfactory plan’ is a CAA section 111(d) plan that meets the applicable conditions or requirements, including those under the implementing regulations that the EPA is directed to promulgate pursuant to CAA section 111(d), including the provisions governing the application of RULOF.” The commenter contends that this interpretation violates several basic rules of statutory construction and is, therefore, not a reasonable (or even permissible) reading of Section 111.

To begin, commenter (2399-GPA) suggests that the EPA’s interpretation merely begs the question. It declares that EPA has the authority to regulate a state’s use of RULOF because a “satisfactory plan” must comply with EPA regulations governing a states’ use of RULOF. Thus, the commenter believes that the December 2022 supplemental proposal presupposes an authority to regulate the states without actually trying to find such an authority in CAA section 111(d)(1) – an impossible task, given the subsection’s text and structure, as well as the D.C. Circuit’s ruling.

Further, the commenter (2399-GPA) asserts that EPA’s “satisfactory plan” interpretation violates basic principles of statutory construction. Thus, the commenter states that it is not a reasonable construction of CAA section 111(d)(1) and will warrant no deference in court.<sup>188</sup> For instance, the commenter notes that the interpretation reads the following statutory terms out of the text:

- Under CAA section 111(d)(1), the Administrator is limited to “prescrib[ing] regulations which shall establish a procedure similar to that provided by Section 7410 of this title.” Under the “satisfactory plan” interpretation, the Administrator would have virtually unlimited substantive powers to establish existing source standards of performance by prohibiting states from exercising their own discretion, not the mere power to “establish a procedure.”
- Under CAA section 111(d)(1), “each state,” not EPA, “establishes standards of performance for any existing source for any air pollutant.” Under the “satisfactory plan” interpretation, EPA would dictate how standards of performance for existing sources would be established, not States.
- Under CAA section 111(d)(1), “the state,” not EPA, “take[s] into consideration, among other factors, the remaining useful life of the existing source to which such standard applies.” Under the “satisfactory plan” interpretation, the states’ “consideration” of RULOF would be so circumscribed by EPA as to become a mere mechanical exercise of endorsing EPA’s emission guidelines.

---

<sup>188</sup> See *Chevron USA Inc. v. NRDC, Inc.*, 467 U.S. 837, 844 (1984) (courts will only defer to “a reasonable interpretation made by the administrator of an agency”).

- Under CAA section 111(d)(2), EPA only has the authority described in Section 7410(c). That section allows for a FIP when a SIP is disapproved for a failure to comply with the statutory requirements of section 7410(k)(1)(A). Nothing in section 7410(c) provides EPA with authority to create new standards with which a state plan must comply. Under the “satisfactory plan” interpretation, Congress’ cross-reference to section 7410(c) would be meaningless and the sub-section’s language would effectively terminate after the phrase “fails to submit a satisfactory plan.”

In fact, the commenter (2399-GPA) states that EPA’s “satisfactory plan” interpretation improperly re-writes CAA section 111(d) as to render the majority of CAA section 111(d)(1)’s text, and half of CAA section 111(d)(2)(A)’s text, superfluous.<sup>189</sup> The commenter contends that the December 2022 supplemental proposed rule’s “satisfactory plan” approach is not a permissible interpretation of the statute, much less a reasonable one.

Further, the commenter (2399-GPA) asserts that the “satisfactory plan” interpretation does not consider the overall context and structure of Section 111. A “reasonable statutory interpretation must account for both ‘the specific context in which ... language is used’ and ‘the broader context of the statute as a whole.’”<sup>190</sup> The commenter contends that the “satisfactory plan” interpretation would make Congress’ clear decision to split the responsibility for establishing standards of performance between EPA (new sources) and the States (existing sources) completely illusory as, despite the text and structure, EPA would dictate standards of performance under both subsections.

And, finally, the commenter (2399-GPA) reports that the “satisfactory plan” interpretation is of a type that courts have strongly and repeatedly disfavored. “Congress, we have held, does not alter the fundamental details of a regulatory scheme in vague terms or ancillary provisions – it does not, one might say, hide elephants in mouseholes.”<sup>191</sup> The commenter notes that courts are especially skeptical of such interpretations where, as here, an agency appeals to “vague terms or ancillary provisions” to overcome specific statutory delegations of authority.<sup>192</sup> The commenter states that here, the December 2022 supplemental proposed rule uses the vague and ancillary term “satisfactory plan” – residing in CAA section 111(d)(2)(A) – to wrench away the clear authority that Congress provided to states in CAA section 111(d)(1). The commenter asserts that nothing in the term “satisfactory plan,” or its surrounding context, indicates that Congress intended to modify CAA section 111(d)(1), much less provide EPA with the power to constrain the States’ “broad discretion” under that subsection.<sup>193</sup>

*The Supplemental Proposed Rule’s “Standards of Performance” Interpretation is Unreasonable and Impermissible.* The Supplemental Proposed Rule separately argues that “there is a fundamental obligation under CAA section 111(d)” that existing source emission limits “reflect the degree of emission limitation achievable through the application of the BSER, as determined by the EPA.” (emphasis added). This argument claims that, because Section 111(d) uses the term “standard of performance,” then Congress silently intended for EPA to establish existing source emission limits under CAA section 111(d)(1), not the States. For the same reasons as the “satisfactory plan” interpretation, the commenter contends that “standard of performance” interpretation is an impermissible and unreasonable one that lacks a statutory basis, contradicts CAA section 111(d)’s text and structure, and violates basic principles of statutory construction.

Response II-19-75: Please see the final Implementing Regulations rulemaking, 88 FR 80480, and the Summary of Public Comments and Responses on Proposed Rule Adoption and Submittal of State Plans for Designated Facilities: Implementing Regulations Under Clean Air Act Section 111(d) (Subpart Ba) Docket ID No. EPA-HQ-OAR-2021-052.

Comment: Commenter (2202-TXOGA) expresses disappointment that EPA failed to consider its concern regarding EPA’s misreading of *Union Electric* and what they believe is a misunderstanding of CAA section 116. The commenter urges EPA to reconsider its position and maintain an open mind on the proper interpretation of CAA section 116, as the terms that EPA employs in describing this important statutory savings clause indicate a serious error in EPA’s thinking regarding the scope and meaning of the provision. The commenter provides the following legal commentary to justify their position.

The commenter (2202-TXOGA) notes that, without discussing comments, EPA made but a single reference to the *Union Electric* decision in the December 2022 supplemental proposal notice. Moreover, in so doing, they contend that EPA did nothing more than repeat the fact that, in its November 2021 proposal, the Agency had “proposed that states are authorized to include in their state plans, and the EPA is authorized to approve, requirements that are more stringent than the EG under the authority of CAA section 116, as interpreted by the Court in *Union Electric v. EPA*, 27 U.S. 246, (1976).” And, EPA stated it was “now proposing” to go even further, that, “under CAA section 111(d), consistent with the authority conferred by CAA section 116, states may consider RULOF to include more stringent standards of performance in their state plans.”

The commenter (2202-TXOGA) asserts that CAA section 116 does not operate to grant “authority” to anyone, not to states and not to EPA. The commenter contends that is not what the provision is about, rather *it is a savings clause*. The commenter states that it preserves that state authority which might otherwise exist under state law. The commenter argues that it in no way creates authority, and it was necessary to distinguish those provisions where in fact, preemption was being created, such as under Title II. Indeed, the commenter asserts that CAA section 116 serves only to affirm that, except in certain specified instances, the CAA does not *preempt* states from exercising whatever authority they might otherwise possess, *as a matter of state law*, to establish their own emission standards and other requirements pertaining to sources within their jurisdiction.

Put simply, the commenter (2202-TXOGA) argues that CAA section 116 does not operate as an independent grant of authority to states to set their own more stringent emission standards, nor does it serve to authorize (much less require) EPA to approve, under CAA section 111(d), more stringent standards that a state may choose to adopt as a matter of state law. The commenter expresses concern that EPA now persists in characterizing CAA section 116 as constituting some sort of grant of “authority” – either to states to adopt more stringent standards of performance, or to the Agency itself to “approve” (and thereby make federally enforceable) any such emission standards under CAA section 111(d). The commenter contends that EPA misunderstands the meaning and effect of CAA section 116.

The commenter (2202-TXOGA) reports that nothing in the Supreme Court’s *Union Electric* decision lends credence to EPA’s position. In the ACE Rule, the commenter believes that the EPA had correctly recognized that the *Union Electric* decision “specifically evaluated whether the EPA has the authority to approve” a state implementation plan under CAA section 110 that is “more stringent than what is necessary to attain and maintain” the NAAQS.<sup>194</sup> In addressing itself to that question, the Court in *Union Electric* had “specifically looked to the requirements in CAA section 110(a)(2)(A) as part of its analysis,” a provision that is “wholly separate and distinct from CAA section 111(d).”<sup>195</sup>

The commenter (2202-TXOGA) notes that the December 2022 proposal says that EPA has changed its mind, that, upon further evaluation, it has come to believe, in light what it says it views as the “structural similarities” between CAA section 110 and CAA section 111(d), that CAA section 116 “as interpreted by *Union Electric*” requires the Agency to reverse itself. If EPA properly took account of the concerns that the commenter and others have raised, however, the commenter believes that the EPA would have put itself in the position to understand that, given the structural *dissimilarities* between CAA section 110 and CAA section 111(d), nothing in *Union Electric* provides support to the new proposed interpretation. The commenter urges EPA to focus further evaluation on the proper reading of *Union Electric*.

The commenter (2202-TXOGA) states that the issue that lay at the heart of *Union Electric* was whether the EPA Administrator was allowed to consider claims of “economic and technology infeasibility” in the course of the Administrator’s “approving or rejecting a state implementation plan” under CAA section 110. As first enacted in 1970 (and as it reads today), the commenter provides that CAA section 110 specified eight criteria that the Administrator was to assess in determining whether or not to approve a state’s implementation plan.<sup>196</sup> Where the Administrator determined that a plan met all those criteria, the Administrator was required to approve such plan.<sup>197</sup> Since, as the Court observed, a reviewing court, in addressing a petition for review, could only consider claims of “economic and technological infeasibility” if the Administrator himself was allowed to do so under CAA section 110, it was necessary for the Court first to “address ourselves to the scope of the Administrator’s responsibility.”<sup>198</sup> For the Administrator’s

<sup>194</sup> 84 Fed. Reg. 32,560.

<sup>195</sup> Id.

<sup>196</sup> CAA section 110(a)(2)(A)-(H).

<sup>197</sup> CAA section 110(a)(2) (“The Administrator *shall approve* such plan . . . if he determines that it was adopted after reasonable notice and hearing and that” the plan satisfied the criteria specified in subparagraphs (A) through (H).) (emphasis added).

<sup>198</sup> 427 U.S. at 256.

part, the Court noted, his position “is that he has no power whatsoever to reject a state implementation plan on the ground that it is economically or technologically infeasible.”<sup>199</sup>

After undertaking its own examination of the “relevant provisions of the Clean Air Amendments of 1970” – i.e., the commenter (2202-TXOGA) states that the aforementioned CAA section 110(a)(2)(A)-(H) – as well as “their legislative history,” the Court found itself in agreement with EPA that “Congress intended claims of economic and technological infeasibility to be wholly foreign to the Administrator’s consideration of a state implementation plan.”<sup>200</sup> The CAA “place[s] the primary responsibility for formulating pollution control strategies on the [s]tates,” the Court observed, but at the same time the CAA subjected states to “strict minimum compliance requirements,” with those requirements being of a “technology-forcing character.”<sup>201</sup> In this respect, then, the Court said, those requirements “are expressly designed to force regulated sources to develop pollution control devices that might at the time appear to be economically or technologically infeasible.”<sup>202</sup> “This approach,” the Court continued, is “apparent on the face of § 110(a)(2).”<sup>203</sup> Insofar as CAA section 110(a)(2) “sets out eight criteria that an implementation plan must satisfy,” and provides that, “if these criteria are met,” the “Administrator ‘shall approve’ the proposed state plan,” the Court found it “quite clear” that the “mandatory ‘shall’” established that the Administrator “is not to be concerned with factors other than those specified.”<sup>204</sup> None of the eight factors listed under CAA section 110(a)(2), the Court opined, “appears to permit consideration of technological or economic infeasibility.”<sup>205</sup> “Nonetheless,” the Court said, “if a basis is to be found for allowing the Administrator to consider such claims, it must be among the eight criteria,” so it was there that the parties’ arguments were focused.<sup>206</sup>

First, the commenter (2202-TXOGA) reports it was “suggested that consideration of claims of technological and economic infeasibility is required by the first criterion” – i.e., that the “primary air quality standards be met ‘as expeditiously as practicable but . . . in no case later than three years . . .’ and that the secondary air quality standards be met within a ‘reasonable time.’”<sup>207</sup> The

<sup>199</sup> Id. The Court then noted that it had “previously accorded great deference to the Administrator’s construction of the Clean Air Act.” Id., citing *Train v. NRDC*, 421 U.S. at 75.

<sup>200</sup> 427 U.S. at 256.

<sup>201</sup> Id. at 256-57, quoting *Train v. NRDC*, 421 U.S. at 91.

<sup>202</sup> Id. at 257.

<sup>203</sup> Id.

<sup>204</sup> Id.

<sup>205</sup> Id. at 257. At this point, the Court noted that a “[c]omparison of the eight criteria of § 110 (a) (2) with other provisions of the Amendments bolster this conclusion.” Id. at 257 n.5. “Where Congress intended the Administrator to be concerned about economic and technological infeasibility,” the Court continued, “it expressly so provided.” Id. For example, the Court said, CAA sections “110(e), 110(f), 111(a)(1), 202(a), 211(c)(2)(A), and 231(b) of the Amendments

all expressly permit consideration” of economic and technological infeasibility,” whereas Section 110(a)(2) contains no such language.” Id.(emphasis added). Thus, even though the issue was not specifically before the Court in *Union Electric*, the Court in passing had occasion to take notice of the structural differences existed between CAA Section 110 and CAA Section 111(a)(1), with the latter provision (as it read in 1970) defining “standard of performance” to mean a “standard for emissions of air pollutants which reflects the degree of emission limitation achievable through the application of the best system of emission reduction which (taking into account the cost of achieving such reduction) the Administrator determines has been adequately demonstrated.”

<sup>206</sup> Id. at 257.

<sup>207</sup> Id. at 257-58, quoting CAA section 110(a)(2)(A).

argument advanced was that “what is ‘practicable’ or ‘reasonable’ cannot be determined without assessing whether what is proposed is possible.”<sup>208</sup> This argument, the Court found, “does not survive analysis.”<sup>209</sup> As the Court reasoned, CAA section 111(a)(2)(A)’s “three-year deadline for achieving primary air quality standards, was “central to the Amendments’ regulatory scheme,” and, as “both the language and the legislative history of the requirement make clear, it leaves no room for claims of technological or economic infeasibility.”<sup>210</sup> After a careful review of the relevant legislative history, the Court determined that the “Conference Committee and, ultimately, the entire Congress” had come to accept the “Senate’s three-year mandate for the achievement of primary air quality standards.”<sup>211</sup> The “clear import of that decision,” the Court found, is that the “Administrator must approve a plan that provides for attainment of the primary standards in three years even if attainment does not appear feasible.”<sup>212</sup>

Having disposed of the principal argument of the petitioner, the commenter (2202-TXOGA) adds that the Court then took note of the argument of one of the amici. This amicus had claimed that the states “are precluded from submitting implementation plans more stringent than federal law demands” by the second criterion of CAA section 110(a)(2) – i.e., that the plan “contain such control devices ‘as may be necessary’ to achieve the primary and secondary air quality standards.”<sup>213</sup> The contention of the amici was that an “overly restrictive plan is not ‘necessary’ for attainment of the national standards and so must be rejected by the Administrator.”<sup>214</sup> As the Court explained it, the “principal support for this theory of amici lies in the fact that,” while the House and Senate versions of CAA section 110(a)(2) had “both expressly provided that the States could submit for the Administrator’s approval plans that were stricter than the national standards required,” the “section as enacted contains no such express language.”<sup>215</sup> According to the amicus brief, as the Court characterized its argument, the “Conference Committee must have decided to require state implementation plans simply – and precisely – to meet the national standards.”<sup>216</sup>

But the commenter (2202-TXOGA) states that the Court would not accept that. The “argument of amici,” the Court said “proves too much,” in that a Conference Committee “lacks power to make substantive changes on matters about which both Houses agree.”<sup>217</sup> Moreover, the Court pointed out, in this case the Conference Report had “expressly note[d] that both the Senate and House bills would allow [s]tates to submit plans more stringent than the national standards demand,” and the amici “offers no suggestion that the Conference bill intended to change that result, even if it could.”<sup>218</sup> “And while the final language” of CAA section 110(a)(2)(B) may have ended up being “less explicit than the versions originally approved by the House and the Senate,” the Court concluded, “the most natural reading of the ‘as may be necessary’ phrase in

---

<sup>208</sup> Id. at 258.

<sup>209</sup> Id.

<sup>210</sup> Id.

<sup>211</sup> Id. at 259.

<sup>212</sup> Id.

<sup>213</sup> Id. at 262, quoting CAA section 110(a)(2)(B).

<sup>214</sup> Id. at 262.

<sup>215</sup> Id., citations omitted.

<sup>216</sup> Id.

<sup>217</sup> Id. at 262-63.

<sup>218</sup> Id. at 263.

context is simply that the Administrator must assure that the minimal, or ‘necessary,’ requirements are met,” not that he “detect and reject any state plan more demanding than federal law requires.”<sup>219</sup>

Having found the *amicus* argument to be without basis as a matter of law, the commenter (2202-TXOGA) reports that the Court then added that its reading of the statutory language and legislative history was “further supported by *practical considerations*.”<sup>220</sup> The Court took note that “Section 116 of the Clean Air Act . . . provides that the States may adopt emission standards stricter than the national standards.”<sup>221</sup> The amici had argued that “such standards must be adopted and enforced independently of the EPA-approved state implementation plan.” In response, the Court observed that “this construction of §§ 110 and 116 . . . would not only require the Administrator to expend considerable time and energy determining whether a state plan was precisely tailored to meet the federal standards,” but, as well, would “simultaneously require [s]tates desiring stricter standards to enact and enforce two sets of emission standards, one federally approved plan and one stricter state plan.”<sup>222</sup> Finding “no basis in the Amendments for visiting such wasteful burdens upon the States and the Administrator,” the Court rejected the *amicus*’s argument.<sup>223</sup>

As the foregoing review of *Union Electric* shows, according to the commenter (2202-TXOGA), what EPA now appears to think the Court said and held in *Union Electric* is not what the Court said and held at all. The commenter states that the EPA’s contention that “[r]equiring [s]tates to enact and enforce two sets of standards, one that is a federally approved CAA section 111(d) plan and one that is a stricter [s]tate plan” would run “directly afoul of the court’s *holding* that there is no basis for interpreting CAA section 116 in such manner”<sup>224</sup> is misplaced. The commenter contends that the Court in *Union Electric* offered no such “holding” with respect to CAA section 116.<sup>225</sup> To the extent the Court set forth any “interpretation” of CAA section 116 at all, it offered nothing more than the observation that, in light of the “practical considerations” involved, it could find “no basis in the Amendments” – i.e., in the interaction of CAA section 110(a)(2)(B) and CAA section 116 – for accepting *amici*’s claim that a state should be required in such circumstances to “enact and enforce two sets of emission standards.” Insofar as the

---

<sup>219</sup> Id.

<sup>220</sup> Id. (emphasis added).

<sup>221</sup> Id. at 263-64.

<sup>222</sup> Id. at 264. The Court here noted that the “burden” on the Administrator to determine whether a state plan was “precisely tailored to meet the federal standards” would be “particularly onerous in view of the facts that Congress gave the Administrator only four months in which to evaluate each plan submitted . . . and that all state plans are submitted at approximately the same time.” Id. at 264 n.11.

<sup>223</sup> Id. at 264 (emphasis added).

<sup>224</sup> See 87 Fed. Reg. at 63,252.

<sup>225</sup> The actual holding of *Union Electric* is to be found in its conclusion that “claims of economic or technological infeasibility may not be considered by the Administrator in evaluating a state requirement that primary ambient air quality standards be met in the mandatory three years.” 427 U.S. at 265. The Court further concluded that, as states “may submit implementation plans more stringent than federal law requires and that the Administrator must approve such plans if they meet the minimum requirements of § 110(a)(2),” it follows that the language of CAA section 110(a)(2)(B) “provides no basis for the Administrator ever to reject a state implementation plan on the ground that it is economically or technologically infeasible.” Id. In light of this, according to the commenter, the question at hand is not so much whether the Court’s discussion of CAA section 116 constitutes any part of its “holding” but whether, in context, that discussion can even be said to rise above the level of dicta.

circumstances involved in *Union Electric* are altogether distinct from those presented by EPA's approval of state plans under CAA section 111(d), the Agency's assertion that it would somehow "run afoul" of *Union Electric*'s "holding" unless it were to approve (and thereby render federally enforceable) state standards that are more stringent than the presumptive standards based on EPA's determination of BSER, cannot be credited. *Union Electric* demands no such outcome. The commenter asserts that the decision speaks not at all to any such outcome.

Similarly, the commenter (2202-TXOGA) argues that nowhere did the Court "interpret[] CAA 116" in a manner that establishes that EPA is "*require[d]* to approve CAA section 111(d) [s]tate plans that are more stringent than required by the EG," where such plans are "otherwise i[n] compliance with all applicable requirements."<sup>226</sup> EPA contends that the Court in *Union Electric* had "rejected a construction of CAA sections 110 and 116 that measures more stringent than those required to attain the NAAQS" could not "be approved into federally into a federally enforceable . . . (SIP) but must be adopted and enforced only as a matter of [s]tate law."<sup>227</sup> Even so, in rejecting such a "construction of CAA section 110 and 116," the Court had no occasion to speak to the separate question of whether EPA is authorized to approve (much less that EPA is required to approve) under CAA section 111(d) standards or requirements adopted under state law that are more stringent than EPA's presumptive standards. The commenter and others have already explained why the fundamental differences between CAA section 110 (the provisions of which were at issue in *Union Electric*) and CAA section 111(d) (the provisions of which were not at issue), dictate that the Supreme Court's decision does not control here. And, of course, not that long ago the commenter notes that the EPA thought the same itself.<sup>228</sup>

But, the commenter (2202-TXOGA) states, the preamble adheres to the position, arguing that, "[w]hile the BSER and the NAAQS are distinct from one another in that the former is technology-based and the latter is based on ambient air quality," both CAA section 111(d) and CAA section 110 are "structurally similar in that [s]tates must adopt and submit to the EPA plans which include requirements to meet the objectives of each respective section."<sup>229</sup> But that is as far as the "similarities" go, and the commenter contends that is not nearly far enough to make such a case. To the contrary, the commenter contends that the dissimilarities between the two provisions are manifest.

The commenter (2202-TXOGA) provides that the plan called for under CAA section 111(d)(1) is "a plan which . . . establishes standards of performance for any [covered] existing source . . ." A standard of performance reflects the degree of emission limitation achievable through application of BSER "which (taking into account [cost, non-air quality effects and energy requirements]) [is] . . . adequately demonstrated." Accordingly, as has previously been noted, a "standard of performance" that set forth a degree of emission limitation which was *more stringent* than that which would be achievable through the application of BSER would not be a "standard of performance" at all – not one that is consistent with the definition set forth in CAA [s]ection 111(a)(1), that is. When *Union Electric* was decided, the commenter states that plans under CAA

---

<sup>226</sup> See 86 Fed. Reg. at 63,251-52.

<sup>227</sup> Id. at 63,252.

<sup>228</sup> See 84 Fed. Reg. at 32,560 ("EPA believes that *Union Electric* does not control the question of whether CAA section 111(d) state plans may be more stringent than federal requirements.")

<sup>229</sup> Id.

section 110 required “emission limitations . . . as may be necessary to assure attainment and maintenance” of the ambient standards and were to be tailored by states based on the types of emissions and emission sources in the attainment/non-attainment area at issue. While BSER defines a “degree of emission limitation” which establishes both a floor and a ceiling for a standard of performance, ambient standards set only a floor. According to the commenter, under CAA section 110, there is no ceiling restricting the stringency of an emission limitation that “attains” an ambient standard, or a limitation that “maintains” air quality at a level below the ambient standard.

The commenter (2202-TXOGA) argues that this fundamental difference between plans that states are directed to submit under CAA section 110(a)(2) and those that states are called on to submit under CAA section 111(d) is stark and serves to distinguish EPA’s review of state plans under CAA section 111(d) from the situation which concerned the Court in *Union Electric*, where (under the *amicus*’s view of things) EPA would have been required to “expend considerable time and energy determining whether a state plan was precisely tailored to meet the federal standards.”<sup>230</sup> The commenter notes that this “practical consideration” is not in play with respect to the Agency’s review of state plans under CAA section 111(d). They state that any standard of performance or other requirements that might be adopted by a state, under state law, which were more stringent than the presumptive standards of performance derived from EPA’s determination of BSER would be readily identifiable.<sup>231</sup>

As for the Court’s additional observation that, under the *amici*’s view of CAA section 110(a)(2), the commenter (2202-TXOGA) provides that it states “desiring stricter standards” would be required to “enact and enforce two sets of emission standards, one federally approved and one stricter state plan,” such an outcome would impose no “wasteful burden” on states in the context of CAA section 111(d).<sup>232</sup> For those states that might choose to adopt, as a matter of state law, more stringent requirements for existing sources, the commenter adds that CAA section 111(d) requires that those separate more stringent state standards be precluded from the state’s CAA section 111(d) plan. In contrast to the situation in *Union Electric*, where EPA’s approval of a state’s implementation plan that included more stringent requirements than might be “necessary” to “insure attainment and maintenance of [the] primary and secondary standards” did not run afoul of CAA section 110(a)(2), were the Agency to approve, under CAA section 111(d), requirements more stringent than would be warranted under EPA’s BSER determination, that would most assuredly violate the CAA. CAA section 111(d) provides that the “regulations” that EPA is to “prescribe” are to “establish a procedure . . . under which each State shall submit to the Administrator a plan which . . . establishes standards of performance” for existing sources. The commenter asserts that CAA section 111(d) says nothing of EPA’s being authorized to approve, and thereby render federally enforceable, state-law based requirements that, being more stringent than EPA’s BSER determination, cannot constitute “standards of performance.” The commenter

---

<sup>230</sup> 427 U.S. at 264.

<sup>231</sup> Further, the commenter states that unlike in the case of CAA section 110 (as it read upon enactment in 1970), which the Court in *Union Electric* observed subjected the Administrator to a schedule where he was afforded, statutorily, “only four months in which to evaluate each plan submitted,” which would make “particularly onerous” any requirement by which the Administrator had to determine whether a state plan was “precisely tailored to meet the federal standards,” EPA can under CAA section 111(d) set for itself, through legislative rulemaking, the schedule by which it will review state plans, to see if they are “satisfactory.”

<sup>232</sup> 427 U.S. at 264.

believes that it follows therefore, on the face of CAA section 111(d), that EPA does not have such authority, for it would authorize EPA to approve states to enforce as federal law a standard that EPA itself could not have issued.<sup>233</sup> The commenter concludes that nothing in what the Court held in *Union Electric* says otherwise.

Response II-19-76: Please see the final Implementing Regulations rulemaking, 88 FR 80480, and the Summary of Public Comments and Responses on Proposed Rule Adoption and Submittal of State Plans for Designated Facilities: Implementing Regulations Under Clean Air Act Section 111(d) (Subpart Ba) Docket ID No. EPA-HQ-OAR-2021-052.

### ***19.8.3 EPA State Plan Approval of More Stringent Alternative Standards Based on RULOF is Consistent with EPA's Authority***

Comment: Commenter (2410-CA AG et al) supports EPA's interpretation in the December 2022 supplemental proposal that the statute authorizes EPA to permit states to consider other factors that justify application of a more stringent standard to a particular source than required by the EG.

The commenter (2410-CA AG et al) states that in the December 2022 supplemental proposal, EPA proposes that under CAA section 111(d), consistent with authority reserved to states pursuant to section 116 of the CAA, states may consider other factors to include more stringent standards of performance in their state plans. In reconsidering its previous interpretation in the ACE rule, EPA proposes to interpret that the statute authorizes EPA to permit states to consider other factors that justify application of a more stringent standard to a particular source than required by the emissions guideline.<sup>234</sup>

The commenter (2410-CA AG et al) agrees with EPA's explanation that there is nothing in the language of CAA section 111(d) suggesting that EPA has the authority to preclude states from determining that it is appropriate to regulate certain sources within their jurisdiction more strictly than otherwise required by federal requirements. And the commenter agrees that the inclusion of the "other factors" language in CAA section 111(d) demonstrates that Congress envisioned that states could consider additional circumstances—such as effects on local communities—in determining standards of performance for specific facilities.

Response II-19-77: Please see the final Implementing Regulations rulemaking, 88 FR 80480, and the Summary of Public Comments and Responses on Proposed Rule Adoption and Submittal of State Plans for Designated Facilities: Implementing Regulations Under Clean Air Act Section 111(d) (Subpart Ba) Docket ID No. EPA-HQ-OAR-2021-052.

---

<sup>233</sup> According to the commenter, this stands in contrast to a situation in which a state adopts requirements that provide assurance it will meet the NAAQS, with some level of comfort. We note that EPA has never taken the position that a state's adoption of a more stringent ambient air quality standard, such as those state Ambient Air Quality Standards (AAQS) adopted by California, are themselves subject to SIP requirements.

<sup>234</sup> EPA has proposed a similar interpretation in the context of its proposed section 111(d) implementing regulations.

## **19.9 Section 111(d) Implementing Regulations**

Comment: Commenters (2222-WDNR, 2446-IPAA) note that, in a separate action, EPA proposed updates to the general implementation provisions for state plan development under CAA section 111(d).

Commenter (2222-WDNR) notes that EPA identified several areas in the methane proposal where the general implementing regulations would apply to state plan development. Therefore, the commenter recommends that EPA consider all applicable comments received in the general implementation regulation docket (EPA-HQ- OAR-2021-0527) when finalizing the methane NSPS and EG for oil and natural gas sources.

Similarly, commenter (2446-IPAA) recommends that EPA assess the two proposals together because EPA has indicated that for those issues not directly addressed in the EG OOOOc proposal, the provisions of the general regulations would apply. However, the commenter recognizes that this creates a problem because the two different proposals have different completion schedules.

The commenter (2446-IPAA) suggests that the intent of Congress in crafting CAA section 111(d) was to create a program to fill the potential gaps regulating existing sources of emissions when new source regulations were created for pollutants that were neither criteria pollutants nor hazardous air pollutants, both of which have existing source provisions. Because CAA section 111(d) was written long before EPA decided to regulate GHG, the commenter believes that it did not envision a circumstance where there would be a million existing sources to address. The commenter believes that this difference is substantial regarding the structure of state programs and the structure of EPA's CAA section 111(d) requirements. The commenter adds that they believe that some of these issues are inherent in the challenges of regulating so many sources; whereas others result from EPA putting its thumb on the balance to limit state options.

Response II-19-78: Please see the final Implementing Regulations rulemaking, 88 FR 80480, and the Summary of Public Comments and Responses on Proposed Rule Adoption and Submittal of State Plans for Designated Facilities: Implementing Regulations Under Clean Air Act Section 111(d) (Subpart Ba) Docket ID No. EPA-HQ-OAR-2021-052.

## **19.10 Implementation Authority – EPA Coordination with State, Tribal and Local Government Regulatory Authorities**

Comment: Commenter (2403-PAO) requests that EPA coordinate with states and incorporate ways to reduce process requirements to allow states the flexibility (as allowed by the CAA) to develop and implement state specific requirements for existing emission sources.

The commenter (2403-PAO) asserts that by dividing regulatory authority under Clean Air Act section 111 into separate programs for new and existing sources, Congress clearly recognized that existing sources are less able to comply with new regulatory requirements than new sources. The commenter notes that if states do not adhere to the presumptive standards for existing sources, state delegated agencies would be required to conduct lengthy analysis and write major

regulations or face imposition of a federal plan. The commenter contends that EPA is basically forcing states to “accept” the proposed standards.

Commenter (2219-WOGCC) expresses concern with EPA proposing regulations outside of its authority and the burden placed on operators. The commenter recommends that EPA remove the proposed requirements and propose regulations only on issues that it is granted authority over.

The commenter (2219-WOGCC) reports that the Wyoming Oil and Gas Conservation Commission is the state regulatory agency for the oil and gas industry in Wyoming. The commenter notes that they regulate all aspects of wells in the state including rules on venting and flaring, well drilling and completions, well operations, and well plugging, while the Wyoming Department of Environmental Quality (WDEQ) regulates air quality at oil and gas locations. In addition to WOGCC and WDEQ regulations, wells on federal lands must also comply with Bureau of Land Management (BLM) regulations, inserting layers of regulations and regulatory agencies that operators must consider.

The commenter (2219-WOGCC) contends that the proposed rule creates yet another regulatory burden that will be placed on wells and operators in Wyoming. When evaluated in conjunction with the recently announced BLM rule on waste prevention the commenter asserts that these rules become sometimes duplicative, sometimes conflicting, but always burdensome on operators to navigate how to remain in compliance with each. According to the commenter, not only does EPA's proposed rule place these burdens on an operator related to air quality regulations, but they believe that EPA is proposing regulations outside of its authority on issues such as well plugging and financial assurance. The commenter asserts that these issues are clearly within the state's and BLM's regulatory authority, not EPA.

Commenter (2292-WV AG et al) expresses concern that the proposal departs from CAA's statutory text and cooperative federalism. The commenter notes that the commenter previously commented (in their comments on the November 2021 proposal) that the EPA's proposed rule departed from the CAA's statutory text and cooperative federalism regime. The commenter contends that the December 2022 supplemental proposal ignores those concerns—and indeed worsens them. The commenter identified two problematic aspects of the December 2022 supplemental proposal. First, EPA suggests tightening the proposed requirements under CAA section 111(b) for methane and VOC emissions from sources that began construction, modification, or reconstruction after November 15, 2021. The commenter notes that these requirements include proposed standards for emission sources that have never been regulated in this way before. Second, EPA proposes to impose the first nationwide EG for states to reduce methane emissions from existing facilities.

The commenter (2292-WV AG et al) asserts that EPA proposes to flout the CAA's text by trying to regulate sources that cannot be (and have not been) regulated and attempts to recast existing sources as new sources. The commenter asserts that EPA action ignores the collaborative role the states play in methane regulation, ignoring Congress and the states' essential role. The commenter argues that the December 2022 supplemental proposal threatens to relegate the states to mere side players by limiting their legislatively endowed discretion in unreasonable and arbitrary ways.

Response II-19-79: Please see discussion of state flexibilities and response to comments section XIII.C.2 of the final preamble; discussion of the applicability date in section IX of the final preamble; and section IV.A and V regarding the EPA's authority and legal basis for this action.

## **19.11 Develop Existing Source Standards Under a Separate Rulemaking**

Comment: Commenter (2283-Endeavor Energy) recommends that EPA conduct existing source standards separate from new source standards, otherwise they believe that EPA risks finalizing EGs that are arbitrary, capricious, overly burdensome, and unworkable in practice, which would undermine EPA's goal of creating durable methane regulations. As EPA has noted in the past, the commenter provides that EPA is "proposing (or publishing) an emission guideline after promulgation of the corresponding standard of performance" allows EPA to "benefit from the comments on the standard of performance in developing the emission guideline."<sup>235</sup> The commenter asserts that is equally true here: When EPA proposed NSPS OOOOa, the commenter states that it did not simultaneously propose EGs for methane at that time. The commenter agrees that this was appropriate, as it would allow for EPA to first benefit from the experience and information gained from observing ways in which NSPS OOOOa was, and was not, effective before applying any standards to the much larger universe of existing sources. The commenter notes that NSPS OOOOa has not been in place for very long, due to the legal challenges/changes. As a result, the commenter suggests that the EPA does not yet have sufficient information about the effects or effectiveness of the various requirements it has imposed to limit methane emissions and therefore lacks sufficient information to determine what requirements would be appropriate and effective for existing sources. In addition, the commenter adds that the EPA has not yet received and reviewed comments on its new proposed NSPS OOOOb, which introduces several additional requirements beyond NSPS OOOOa that have not yet been tested in the field and which are likely to present meaningful implementation challenges. In consideration of these meaningful information gaps, the commenter recommends that EPA withdraw the proposed EG OOOOc and wait to propose what they believe would be a more appropriate set of regulatory requirements for existing sources with the benefit of additional information and experience.

The commenter (2283-Endeavor Energy) states that eventual existing source EGs must be less stringent than the NSPS requirements in recognition of the very different set of burdens and considerations at play when regulating existing sources. Specifically, the commenter believes that the proposed EGs should appropriately accommodate other factors, such as the remaining useful life of existing sources, as required by the CAA.<sup>236</sup> The commenter recommends that EPA's reflect the CAA's recognition that there are a fundamentally different set of considerations when regulating existing sources for the first time. Like many operators, the commenter states that they have already planned and budgeted for equipment upgrades at new or modified well sites, but upgrades at the older, existing sites will be more costly to make and will need to be made at far more sites than for new or modified sites. Depending on the specific well site, the commenter provides that these capital upgrade costs could fundamentally alter economics associated with operating an existing well or be entirely infeasible to implement. For example, the commenter explains that many existing well sites contain a limited number of

---

<sup>235</sup> See, e.g., 40 Fed. Reg. 53,340, 53,345 (Nov. 17, 1975).

<sup>236</sup> 42 U.S.C. §741 l(d)(l).

controllers, most do not have flares located on site, and the complete retrofit of these sites is likely cost-prohibitive based on well economics. The commenter states that the EPA's proposal will require installing and retrofitting a broad range of equipment, including installing electric compressors for air controls, retrofitting all controllers to air systems, installing vapor recovery units on all tanks, installing new low- and high-pressure flares, and installing meters to monitor the volumes sent to flares. In addition, the commenter reports that many older well sites do not have access to on-site electricity or a sale line for natural gas because the sites were not built with these considerations in mind. And due to the remote locations of many of these existing sites in the Midland Basin, these kinds of infrastructure upgrades will be extremely costly or entirely outside of an operator's control.

The commenter (2283-Endeavor Energy) asserts that because many older sites do not produce as much oil or gas, the new compliance obligations could very well alter the "remaining useful life" of the well and cause wells to be shut in or prematurely abandoned. The commenter reports that this is true for many producers and could have far-reaching impacts on domestic oil and gas production. The commenter states that CAA section 111(d)(1) explicitly directs EPA to ensure that its EGs permit the states to take remaining useful life and other factors in account. However, the commenter contends that the overly prescriptive and inflexible approach proposed by EPA does not properly reflect this statutory requirement. The commenter recommends that in addition to revising the actual EGs, EPA must revise its economic analysis to reflect the fact that the economics of EPA's proposed EGs are fundamentally different and more burdensome to the industry than the NSPS.

The commenter (2283-Endeavor Energy) expresses concern that there are insufficient number of contractors who can meet the needs of all operators in the Midland Basin, and "scaling up" too quickly would pose risks if contractors are forced to rely on new personnel who do not have qualifications, training, and experience to perform the necessary upgrades. The commenter notes that this is just one example of why EPA cannot and should not assume that just because requirements have proven to be feasible for the much smaller pool of new or modified sources that operators are also able to implement these requirements more broadly for their existing sources.

The commenter (2283-Endeavor Energy) therefore recommends that EPA take the time to fundamentally revisit its proposed EGs after coordinating with the states, who have decades of experience regulating these sites, and operators, who likewise understand the practical realities of implementing these proposals. The commenter encourages EPA staff to visit a variety of well sites in our basin and others to better understand the nature of these facilities and the geography where we are operating. By spending the necessary time up front to understand the industry, the commenter believes that the EPA can craft durable and workable requirements that will better serve the environment and the public in the long run and avoid issuing a rule that cannot survive legal challenges.

Response II-19-80: Please see discussion of standards of performance and state flexibilities, and response to comments, section XIII.C of the final preamble.

## Chapter 20. Impacts of the Proposed Rule

### 20.1 Regulatory Analysis

#### *20.1.1 Costs and Benefits of Proposed Rule*

##### 20.1.1.1 Costs and Benefits Analyses

Comment: Commenters (2219-WOGCC, 2257-MOGA, 2399-GPA) believe that the cost benefit analysis is insufficient as proposed. Comments received are provided in the following paragraphs.

Commenter (2257-MOGA) asserts that EPA must address the potential costs and problems associated with a breach of contract before expanding regulations to existing sources. Further, the commenter asserts that EPA must include these costs and ramifications in their cost per ton of methane reduction to adequately represent the true costs of imposing future regulations on industry.

The commenter (2257-MOGA) asserts that EPA did not solicit comments from the oil and gas production industry and small businesses or attempt to understand the potential impacts of the proposed regulations on existing contracts. The commenter reports that before a well is drilled or a facility is constructed, surface and underground asset contracts are prepared and presented to the landowners for review, discussion, modifications and final authorization. These contracts allow the potential producing company to enter the property for review, acknowledgment of the complication in the terrain and apply for additional permits and contracts, negotiate with the landowner for mineral rights, access fees and mineral distributions. Additional contracts with utilities, transportation companies, pipeline operators and regulators are prepared, reviewed and signed before a well is drilled and determined to be commercial and viable. The commenter asserts that all the above-mentioned contractual obligations become null and void if the well is not economically sustainable.

Commenter (2399-GPA) urges EPA to improve their cost and benefits analysis before making any determination on whether certain regulatory requirements are cost effective for the midstream industry. The commenter contends that EPA's analysis includes significant oversights with respect to the midstream industry. The commenter notes that owners and operators of gathering and boosting compressor stations do not own the gas that they process and, therefore, recoup no financial benefits from reducing lost gas as EPA assumed. Further, the commenter states that several necessary costs were omitted, such as compressor monitoring costs, installation costs, and the need for vapor recovery units. The commenter recommends that EPA examine cost-effectiveness on a single pollutant basis and correct its cost-effectiveness analysis. Their comments follow:

- EPA Should Examine Cost-Effectiveness on a Single Pollutant Basis. In reviewing whether control costs for the midstream sector are reasonable, EPA should look at the full cost of control as applied to each pollutant – VOCs [volatile organic compounds] and methane. Each pollutant should be evaluated separately as to whether the system would

or would not be cost-effective in determining whether to require the control. Here, based on our review to date, when the proper set of costs are considered, it is plain that controls for centrifugal compressors at gas plants are not cost-effective.

EPA has long looked at whether the cost of a particular system of control is reasonable by considering the costs associated with such control, including capital costs and operating costs, determining the emission reductions that the control can achieve, and then evaluating whether a particular control achieves that emission reduction cost effectively. In this context, EPA has calculated a control's "cost-effectiveness" by taking the annualized cost of implementing an air pollution control option divided by reductions realized annually for that pollutant.

In this rulemaking, EPA has looked at cost-effectiveness using a single pollutant approach but has also considered a "multi-pollutant" evaluation that divided control costs between VOCs and methane and then evaluated the cost-effectiveness of the control based on that reduced cost. 86 Fed. Reg. 63155 (Nov. 15, 2021). We urge EPA not to apply the so-called multi-pollutant approach in this case. Rather, in evaluating whether a particular "standard of performance" is appropriate here, EPA should look at each pollutant separately. This hews most closely to the direction of Congress. Section 111 requires EPA to consider a standard that reflects the degree of emission reduction achievable through the best system of emission reduction "taking into account the cost of achieving such reduction" as well as other factors. 42 U.S.C. § 7411(a)(1). In this case, the cost of achieving "such reduction" of methane is the full cost of control, not an apportioned cost or shared cost. The fact that there may be other benefits from installing the controls does not change the statutory requirement.

Not only is this approach consistent with statutory language, it is the right policy choice here. The fundamental purpose behind EPA's regulation is reducing methane emissions, and thus it is the cost-effectiveness of the system of reduction for that pollutant that should be evaluated. E.g., 87 Fed. Reg. 63113 (Purpose of the Regulatory Action). But for the presence of methane emissions, it seems highly improbable that EPA would be embarking on this expansive effort to develop new regulations. Nor does this result in double counting of the cost of controls as others have suggested – it merely evaluates each pollutant on its own merits to assess whether "such reduction" meets the cost criteria in the statute.

- EPA Should Correct its Cost-Effectiveness Analysis for Midstream, Because Gathering and Boosting Compressors See No Financial Benefits. In several locations throughout the Supplemental Proposed Rule, Regulatory Impact Analysis [RIA], and TSD [Technical Support Document], EPA asserts that gathering and boosting facilities own the natural gas in their systems and would directly benefit from capturing gas that would otherwise be lost. This is incorrect. Gathering and boosting facilities, and other midstream facilities, are typically paid a fee to prepare it for delivery to an interstate pipeline system. This is true even in large integrated companies that own both the production facilities and midstream facilities (e.g., gathering and boosting compressors, processing plants). The production segment and the midstream segment are separate business units, and the

production segment still pays a fee to the midstream segment for processing. This makes the midstream segment much more like transmission and storage segment facilities instead of production facilities.

Because the Clean Air Act [CAA] requires EPA to take “into account the cost of achieving” emission reductions, 42 U.S.C. § 7411(a)(1), EPA should revise and update its cost estimates to reflect the lack of financial benefits to the midstream sector. Given EPA’s focus on the alleged benefits from enhanced recovery of methane, it is critical for EPA to correct its analysis and revise its cost effectiveness determination as applied specifically to the midstream sector. The commenter previously raised this issue, and urges EPA to correct the record and redo its analysis for this proposed regulation. The commenter provides further details in the submission attachment Exhibit A 6-7.

Commenter (2219-WOGCC) suggests that the EPA did not conduct an accurate or complete evaluation of the costs and benefits of the proposed rule. The commenter notes that EPA does not fully compare the cost of compliance against the actual benefits resulting from the proposed rule. Instead, EPA compares cost of compliance against the total capital expenditures of the entire oil and gas industry sector and cost of compliance against sector level revenues. The commenter adds that the EPA then cherry-picks the years that it uses for the comparison of capital expenditures and revenues. EPA mentions that although capital expenditures from 2020 were available, since that year was affected by coronavirus disease (COVID-19) they would not use it, instead utilizing data from 2019. EPA reaches back even further when looking at revenues and utilizes industry revenues from 2017 when comparing costs and sector wide revenue. Unfortunately, the commenter states that industry will not be able to use the same argument when spending capital to comply with this rule.

The commenter (2219-WOGCC) explains that industry must deal with commodity price fluctuations and evaluate how to allocate capital, but if oil and gas prices drop in the future due to another COVID-19-like situation or any other issue that causes price fluctuations, it must still comply with this costly and burdensome rule. By cherry-picking the best years for capital expenditures and revenues, the commenter suggests that EPA attempts to obscure the actual costs of this rule on industry.

According to the commenter (2219-WOGCC), if EPA completed an appropriate cost and benefit analysis, it would tell a significantly different story. But the commenter states that EPA did provide some information that hints at the true costs and benefits. EPA estimates that the equivalent annual value (EAV) of the increase in compliance costs is \$1.7 billion (per year) without considering revenue from product recovery and \$1.2 billion (per year) when factoring in the revenue from product recovery. Thus, it will cost industry at least \$1.2 billion per year from 2023 through 2035 (and beyond) to comply with just the New Source Performance Standards (NSPS) and Emissions Guidelines (EG) of this proposed rule. So, the commenter provides that when conducting just a very generalized evaluation of the costs and benefits, this rule places very high costs of compliance on the industry and returns very little in benefits.

Although this review does indicate truer costs to the industry, the commenter (2219-WOGCC) suggests that it still is not entirely accurate. The commenter contends that the EPA decided to

obscure the true cost of compliance on industry by combining costs of compliance of the entire rule and comparing those across industry as a whole. The commenter states that a more accurate analysis would be to split the higher producing unconventional wells from low producing oil and gas wells sometimes known as stripper wells. The commenter notes that the cost to comply for these low producing stripper wells will be significant, which do not return the same revenue to industry as the higher producing conventional wells. By considering all of these types of wells together, the commenter suggests that the EPA has buried the severe impact on low producing wells in the revenues generated by the higher producing unconventional wells.

Response II-20-1: For a complete discussion of EPA's analysis conducted in accordance with E.O. 12866, in which it projected the emissions reductions, costs, and benefits that may result from this final rulemaking, see the Final Rule preamble at Section II.C, as well as the accompanying RIA.

To the extent that commenter (2257-MOGA) asserts that EPA should have considered the potential impacts of the NSPS OOOOb and EG OOOOc on existing contracts, it is unclear to the EPA exactly how the commenter suggests it should have done so. Commenter neither provides any specific data or analysis to support its argument, nor explains how any such analysis might have affected the EPA's establishment of standards of performance. It is unclear to the EPA how any analysis of contracts would have influenced the final rule.

EPA disagrees with the commenter's (2219-WOGCC) assertion that it cherry-picked analysis years for the comparison of estimated costs to sector-level capital costs and revenues. EPA maintains that 2019 was a sensible choice for an analysis of capital costs due to the COVID-19 pandemic, but the analysis for the Final Rule presents results for four years, 2018–2021, including two pre-pandemic and two post-pandemic years (see Chapter 5 of the Final Rule TSD), without changing the overarching conclusions. In addition, as explained in the December 2022 Proposal, the revenue data is from 2017 because that is the most recent year available.

EPA disagrees with commenter's (WOGCC) assertion that the rule would have a severe impact on low-producing wells. The commenter does not provide data to substantiate this claim nor define severe impacts. EPA also developed a financial analysis of marginal, or stripper, oil and natural gas wells in Chapter 6 of the Final Rule TSD. EPA finds that marginal wells may continue to operate at low or negative profits rather than be shut-in and plugged due to a variety of reasons, including low operating costs, high plugging costs, low state bonding requirements, accounting practices, and tax credits available to the oil and gas industry. Regarding the cost-effectiveness analysis for midstream, EPA calculated the annual costs and cost effectiveness values considering savings for gathering and boosting facilities. While EPA recognizes that in many cases, midstream facilities do not own the natural gas and would not recognize these savings, this is not universally true. However, it should be noted that all the final BSERs options selected for the final rule were determined to be cost effective without consideration of those natural gas savings. In other words, BSER determinations were not impacted by assumptions regarding natural gas savings.

In response to the comment that requests that EPA examine cost-effectiveness on a single pollutant basis when evaluating controls for reducing VOC and methane emissions from new

sources, we consider a control's cost effectiveness under both a "single-pollutant cost effectiveness" approach and a "multipollutant cost effectiveness" approach in order to appropriately take into account that the systems of emission reduction considered in this rule typically achieve emission reductions of multiple pollutants simultaneously and therefore result in a multiplicity of climate and public health benefits. For a detailed discussion of these cost approaches, please see section VIII.B (How does the EPA evaluate control costs in this final action?) of the final rule preamble as well as section IX.B (How does EPA evaluate control costs in this action?) of the November 2021 Proposal preamble<sup>1</sup> and section III.E (How does the EPA consider costs in this supplemental proposal?) of the December 2022 Supplemental Proposal preamble.<sup>2</sup> We believe that both the single and multipollutant approaches are appropriate for assessing the reasonableness of the multipollutant controls considered in this action. The EPA has considered similar approaches in the past when considering multiple pollutants that are controlled by a given control option. See e.g., 80 FR 56616–6617; 73 FR 64079–64083 and EPA Document ID Nos. EPA–HQ–OAR–2004–0022–0622, EPA–HQ–OAR–2004–0022–0447, EPA–HQ–OAR–2004–0022–0448.

In response to comment that the EPA should correct its cost-effectiveness analysis for midstream, because gathering and boosting compressors see no financial benefits, the EPA acknowledges the commenter's input. While EPA recognizes that in many cases, midstream facilities do not own the natural gas and would not recognize these savings, this is not universally true. However, it should be noted that all the final BSERs options selected for the final rule were determined to be cost effective without consideration of those natural gas savings. In other words, BSER determinations were not impacted by assumptions regarding natural gas savings.

In addition, Section 2.4 of the RIA text notes that operators in the gathering and boosting, processing, and transmission and storage segments of the industry do not typically own the natural gas they transport. From a social perspective, the increased financial returns from natural gas recovery accrues to entities somewhere along the natural gas supply chain and should be accounted for in a national-level analysis, as they represent benefits to society regardless of whether producers, consumers, or both realize those benefits. In the long run, no single entity bears the entire burden of compliance costs or fully appropriates the financial gain of the additional revenues associated with natural gas recovery. The change in economic surplus resulting from natural gas recovery is likely to be spread across different market participants. The compliance costs and revenues are kept within a given source category and the costs and revenues are not allocated across agents.

Comment: Commenter (2241-UDNR) notes that while it may be true that the EPA's new rule will "increase recovery of natural gas that otherwise would go to waste, valued at \$690 million in 2030 alone,"<sup>3</sup> the Proposed Rule does not seem to contemplate that the rule will instead leave

---

<sup>1</sup> 86 FR 63154-63157.

<sup>2</sup> 87 FR 74718-74719.

<sup>3</sup> U.S. EPA, EPA Training on 2021 Proposal to Reduce Air Pollution from the Oil and Natural Gas Industry: Day 1, United States Environmental Protection Agency, available at: <https://www.youtube.com/watch?v=7VWAEcF65qU> (2021); see also <https://www.epa.gov/system/files/documents/2021-11/epas-proposed-oil-and-gas-rules.presentation-11.2.2021.pdf>.

tons of natural gas stranded and unproduced. Due to the added costs associated with compliance (again imposed on the oil and gas operators), the commenter argues that many oil and gas sources would become uneconomical to extract. While the State/commenter is supportive of finding innovative ways to reduce air pollution and methane emissions, the assert that it must be done in a way that equitably allocates costs and benefits, and without jeopardizing the resilience of the State's oil and gas industry.

Response II-20-2: The EPA disagrees with commenter's (UDNR) assertion that the rule would leave tons of natural gas stranded. The commenter does not provide data to substantiate this claim. EPA's analysis, presented in Section 4.1 of the RIA, estimates that the reduction in U.S. natural gas production as a result of the Final Rule would be approximately 0.75% or less. In addition, EPA also developed a financial analysis of marginal, or stripper, oil and natural gas wells in Chapter 6 of the Final Rule TSD. EPA finds that marginal wells may continue to operate at low or negative profits rather than be shut-in and plugged due to a variety of reasons, including low operating costs, high plugging costs, low state bonding requirements, accounting practices, and tax credits available to the oil and gas industry. To the extent that any marginal wells might be plugged in relation to anything contained within this rulemaking (which is speculative), the analysis suggests that they would be extremely low-producing wells, and therefore the impact of lost revenue would be minimal.

Comment: In support of the proposed rule, commenter (2425-TCS) weighs in that, in addition to taxpayer-funded incentives under the Inflation Reduction Act (IRA), the projected costs for industry represent a small fraction of their overall capital expenditures. The commenter states that the equivalent annual value (EAV) of net compliance costs of the Supplemental Proposal is \$1.4 billion (\$2019). According to Mercer Capital,<sup>4</sup> 28 selected exploration and production (E&P) companies, both global and independent, operating in Bakken, Appalachia, Permian, and Eagle Ford, reported \$138 billion in capital expenditures in 2019 and were expected to spend \$109 billion in 2022. Therefore, the commenter notes that the annual compliance cost is roughly 1.3% of 2022 capital expenditures of the selected companies and likely a lower percentage of total annual capital expenditures of the entire U.S. upstream oil and gas sector. The commenter adds that E&P spending is also expected to increase both internationally and in North America by at least 14% in 2023, according to the 2023 Evercore ISI E&P Spending Outlook.<sup>5</sup> U.S.-based supermajors like ExxonMobil and Chevron have both announced increased 2023 capital budget.<sup>6</sup>

Response II-20-3: EPA acknowledges the supportive comment.

#### 20.1.1.2 Benefits Overestimated/Underestimated

Comment: Commenter (2339-INGAA) suggests that a lopsided cost-benefit analysis that accounts for the global costs of greenhouse gas (GHG) emissions over a centuries-long time

---

<sup>4</sup> Sebastien Elzein, "E&P Capital Expenditures Set to Rise, but Remain Below Pre-Pandemic Levels," Mercer Capital, April 22, 2022. <https://mercercapital.com/energyvaluationinsights/ep-capital-expenditures-set-to-rise-but-remain-below-pre-pandemiclevels/>.

<sup>5</sup> Evercore ISI, 2023 E&P Spending Outlook.

<sup>6</sup> Carolyn Davis, "North American E&P Spend to Increase 14% in 2023; Maintain in Appalachia, Grow in Haynesville," Natural Gas Intel, Jan 19, 2023. <https://www.naturalgasintel.com/north-american-e-maintain-in-appalachia-grow-in-haynesville/>.

horizon, while failing to provide a similarly expansive estimate of the social benefits of energy, overestimates the costs and underestimates the benefits of investments in energy infrastructure. The commenter asserts that the EPA has effectively encouraged such lopsided analysis by submitting comments to Federal Energy Regulatory Commission (FERC) that have urged FERC to use the social cost of greenhouse gas (SC-GHG) in evaluating proposed natural gas pipeline projects under the Natural Gas Act.<sup>7</sup> The commenter notes they have explained in its own comments to FERC, this would lead to a distorted analysis that is biased against the benefits of natural gas, given that FERC's analysis of proposed projects does not quantify the myriad long-term, global social benefits of energy in a similarly wide-ranging manner.<sup>8</sup>

According to the commenter (2339-INGAA), neither EPA's Draft Report nor EPA's RIA contends with this fundamental problem: namely, that if a cost-benefit analysis purports to estimate costs at a global scale and over centuries-long future time horizons, it must do so for benefits as well.<sup>9</sup> The commenter asserts that the EPA must address this problematic asymmetry if it continues to employ SC-GHG estimates—particularly as applied to energy infrastructure projects.

Response II-20-4: To the extent that the commenter references comments submitted by the EPA to another federal agency in a separate and distinct agency action, such comment is out of scope.

The way that the EPA estimated the monetized climate benefits of emission reductions expected from these final rules using estimates of the social cost of methane are explained in detail in the Final Rule preamble in Sections II.C and XVI.E.

The EPA notes that a rule that affects GHG emissions may also affect the production or consumption of goods and services, in which case it could create costs and benefits for businesses and households that either produce or use those goods and services. These costs and benefits are important to include in an analysis of the rule's impacts but are not the result of changes in GHG emissions from the rule and, therefore, it would be inappropriate to try and include them in the SC-GHG used to value changes in GHG emissions. In other words, the SC-GHG is not a measure of social welfare from the consumption of goods and services whose production results in GHG emissions, nor is it intended to capture other positive or negative externalities associated with the production of those goods and services. Similarly, the SC-GHG is not intended to capture the benefits or costs to society from the production and consumption of goods and services associated with regulatory compliance, or the impacts from changes in other emissions that may also occur as a result of regulatory compliance. The SC-GHG is just one component of a larger analysis that includes consideration of other potentially relevant impacts of a policy, including the social costs of compliance, labor market changes, and changes in emissions of other pollutants, as appropriate for the specific analysis. A more detailed response

Comment: Commenters (2393-ODEQ/OSEE), commenting on “super-emitters”, state that monitoring and control costs are expected to display a heavy-tailed data distribution; and EPA’s cost estimates likely significantly underestimate monitoring and control costs by assuming an incorrect data distribution. The commenters note that the heavy-tailed data distribution that characterizes emissions from this sector (and many others) adds complexity to attempts to estimate aggregate emissions from the sector. In contrast, phenomena that display a normal or Gaussian distribution provide simpler approaches because, for example, the mean, median, and mode of the data set are the same. As a result, the sum of the values of all data points may be estimated by multiplying the median value by the total number of data points. However, the commenters assert that this will not work for a heavy-tailed data distribution, because a relatively small number of data points occupying space in the long tail (high end) of the data distribution account for an oversized share of total emissions. They add that the attempts to estimate total emissions by multiplying the median value by the total number of sources will significantly underestimate total sector emissions.

According to the commenters (2393-ODEQ/OSEE), this principle is well understood and various attempts to address this issue are underway in various forums. But a similar phenomenon occurs with regard to costs of control and monitoring. After reviewing several documents released by the EPA, the commenters’ engineers and environmental program specialists noted a similarly troubling aspect of EPA’s attempt to estimate the cost of controls and monitoring. A description of the approach EPA used to estimate costs is reproduced by the commenters below.

The commenters (2393-ODEQ/OSEE) note that the cost analysis presented in the supplemental notice of proposed rulemaking (SNPR) RIA reflects a nationwide engineering analysis of compliance cost and emissions reductions, of which there are two main components. The first component is a set of representative or model plants for each regulated facility, segment, and control option. The characteristics of the model plant include typical equipment, operating characteristics, and representative factors including baseline emissions and the costs, emissions reductions, and product recovery resulting from each control option. The second component is a set of projections of activity data for affected facilities, distinguished by vintage, year, and other necessary attributes (e.g., oil versus natural gas wells). Impacts are calculated by setting parameters on how and when affected facilities are assumed to respond to a particular regulatory regime, multiplying activity data by model plant cost and emissions estimates, differencing from the baseline scenario, and then summing to the desired level of aggregation. 87 Fed. Reg. 74712.

The commenters (2393-ODEQ/OSEE) contend that it appears that EPA has inadvertently assumed that the cost of controls and the cost of monitoring follow a normal or Gaussian distribution and, therefore, total costs may be estimated by multiplying median (in this case “model plant”) costs by the total number of facilities of that type. If this is indeed the case, the commenter suggests that the EPA would be making the same error in estimating costs that EPA is trying to avoid when estimating emissions.

Furthermore, the commenters (2393-ODEQ/OSEE) add that the increased cost of implementing appendix K for all monitoring should be factored into the evaluation of the annual costs of the fugitive emissions monitoring and repair requirements.

To implement the appendix K certification program for the camera, training of technicians (section 10), longer monitoring of components due to dwell time rest break requirements (section 9.4 and 9.5), and video storage of leaks (section 9.7.1), it is expected to increase the cost to conduct an optical gas imaging (OGI) fugitive monitoring program at Compressor Stations and Natural Gas Plants when compared to OGI monitoring costs currently. The commenters state that the requirements for a “Senior OGI camera operator” of 1,400 hours seems a high bar to cross and how this affects the cost of future OGI contractors and industry operators should be accounted for in the future cost/benefit of implementing the appendix K OGI monitoring proposed in NSPS OOOOb and EG OOOOc.

The commenters (2393-ODEQ/OSEE) assert that it will take additional time and effort to develop a better estimate of the cost of control and monitoring using a more accurate statistical approach than the one EPA has used in this proposal. Further, they state that the current estimates are likely to substantially understate the costs of monitoring and control. They conclude by stating that modifications to the SNPR are warranted to address these undercounted costs.

Response II-20-5: The EPA disagrees with the commenter’s assertion that the EPA assumes an incorrect data distribution for costs of compliance. The commenter claims that the costs of control follow heavy-tailed distributions but provides no data to support these claims. Please see the Final Rule Preamble at Section VIII.B (How does the EPA evaluate control costs in this final action?) for a detailed discussion of how EPA considers control costs in this rule and the information that it relied on in making its BSER determinations.

With regards to the request that the EPA include the increased cost of implementing the Appendix K protocol for all OGI monitoring in the evaluation of the annual costs of the fugitive emissions monitoring and repair requirements, the EPA is only requiring owners and operators to comply with Appendix K at natural gas processing plants, and not for fugitive emissions components not located at natural gas processing plants. For natural gas processing plants, the November 2021 TSD provides costs for OGI monitoring though not specifically costs for implementing Appendix K at natural gas processing plants. See Chapter 10 (Equipment Leaks from Natural Gas Processing Plants) of the November 2021 Proposal Technical Support Document (TSD).<sup>10</sup>

Comment: Commenter (2359-CEI) states that the EPA estimates that, during 2023-2035, its preferred option (“primary proposal”) will generate \$55 billion in climate benefits, \$13 billion in compliance costs, \$7.2 billion in net compliance costs (i.e. \$13 billion minus \$5.5 billion in recovered product sales), and net benefits of \$48 billion.<sup>11</sup> The proposal thus looks like an amazing deal, with climate benefits exceeding compliance costs by 4.2 to 1 or (factoring in product recoveries) 7.6 to 1. Upon inspection, however, the commenter contends that those

---

<sup>10</sup> EPA-HQ-OAR-2021-0317-0166.

<sup>11</sup> RIA, Table 5-4, p. 5-7.

benefits are make-believe, and the proposal would impose enormous costs for undetectably small benefits. The commenter notes that the reductions in climate-related damages, estimated at \$55 billion, account for 100 percent of the proposal's monetized benefits. The vast majority of climate damages are attributed to the direct and indirect effects of global warming. How much warming would the proposal avert? They add that neither the proposal itself nor the accompanying RIA explicitly addresses that question. The commenter suggests that the EPA's proposal is not reasonable if the climate benefits are illusory. They add that an unreasonable regulation may be challenged as arbitrary and capricious.

Response II-20-6: The SC-GHG is the monetary value of the net harm to society from emitting a metric ton of that GHG into the atmosphere in a given year. In principle, the SC-GHG is a comprehensive metric that includes the value of all future climate change impacts (both negative and positive), including changes in net agricultural productivity, human health effects, property damage from increased flood risk, changes in the frequency and severity of natural disasters, disruption of energy systems, risk of conflict, environmental migration, and the value of ecosystem services. The SC-GHG, therefore, also reflects the societal net benefit of reducing emissions of the GHG by a metric ton. The SC-GHG is the theoretically appropriate value to use when conducting benefit-cost analyses of policies that affect GHG emissions. In practice, data and modeling limitations restrain the ability of SC-GHG estimates to include all physical, ecological, and economic impacts of climate change, implicitly assigning a value of zero to the omitted climate damages. The estimates are, therefore, a partial accounting of climate change impacts and likely underestimate the marginal benefits of abatement.

Comment: Commenter (2241-UDNR) states they are concerned that the cost of implementing proposal measures may do much to harm the oil and gas industry's resilience in the state. For example, they note that it may be true that the key components of the proposal will yield nearly \$4.5 billion in net climate benefits a year, with said benefits being enjoyed by all citizens. However, the Proposal would also "require states to reduce methane emissions from hundreds of thousands of existing sources nationwide for the first time"<sup>12</sup> which would require oil and gas operators to retrofit and update existing infrastructure to standards at costs which have not yet been fully quantified. Not only would the compliance costs be passed down to the producers, but the commenter states that it would increase the cost of product recovery. Thus, they note that while the net benefits may be somewhat equitably distributed, the costs would be unevenly borne by the States and oil and gas operators.

Response II-20-7: The EPA disagrees with the commenter's assertion that the compliance costs will significantly harm the oil and gas industry's resilience in the state (Utah), particularly since Commenter's claim is not supported by any specific data or analysis. To the extent that the Final Rule affects states with oil and gas production more than states without oil and gas production, such is the case for all regulated sources across CAA section 111, states that host regulated facilities are indeed more likely to notice impacts. Nonetheless, as explained in further detail below, the EPA has determined that the costs of controls associated with the BSER for the final NSPS OOOOb and EG OOOOc are reasonable. In reaching this determination, the EPA

<sup>12</sup> 5 SEMPRA, ECA LNG – A World-Class Project to help Power the Global Energy Transition, Sempra Infrastructure, available at: <https://semprastructure.com/news-and-events/spotlight-stories/eca-lng-a-world-class-project-to-help-power-the-global-energy-transition> (2022).

conducted numerous cost analyses, described in detail in Section XII of the November 2021 Proposal, Section IV of the December 2022 Supplemental Proposal, and section XI of the Final Rule, as well as the technical support documents in the docket for this rulemaking. In addition, EPA notes that it estimated the value of product recovery as a result of the Final Rule, in Section 2.5 of the Final RIA, at \$7.4 billion to \$11 billion in 2019\$, with approximately 90% of that product recovery being captured by producers.

Comment: Commenter (2343-NYU School of Law) states that, in the RIA, EPA demonstrates that the December 2022 supplemental proposal sets standards at a level of stringency that is net beneficial, with the monetized benefits alone greatly exceeding the monetized costs.<sup>13</sup> However, the commenter suggests that the EPA makes analytical assumptions that lead it to likely underestimate the full benefits of the December 2022 supplemental proposal.

Commenter (2343-NYU School of Law) provides that, in the RIA, EPA itself acknowledges that “some amount of both benefits and costs would likely continue after 2035,” and “note[s] that toward the end of [their] analytical time horizon, undiscounted net costs are relatively steady from year to year (Table 2-9) while undiscounted monetized climate benefits (Table 3-4) are rising each year.” On this basis, EPA concludes, “It is therefore plausible that significant net benefits would continue in the years after 2035.”<sup>14</sup> EPA additionally estimates that the Supplemental Proposal will reduce 3,500,000 short tons of methane, 920,000–960,000 short tons of volatile organic compound (VOC) emissions, and 37,000–39,000 short tons of hazardous air pollutants (HAP), annually between 2026 and 2035.<sup>15</sup> For VOC and HAP, the annual reductions are all projected to increase between 2026 to 2035. If comparable emissions reductions of these pollutants continue for some number of years after 2035, that would yield significant non-climate benefits. Given these trends in annual costs and benefits and the continuation of the standards past 2035, it is highly likely that the December 2022 supplemental proposal will result in additional benefits after 2035.

The commenter (2343-NYU School of Law) recommends that EPA seek to extend its analysis to consider the likelihood that the standards will reduce emissions beyond 10 years. Even if EPA does not extend its analytical timeframe, it should include a discussion of benefits beyond 2035 as an unquantified benefit. Lastly, while extending the time horizon would better capture the full benefits of its proposed standards, EPA can still find that the standards are cost-beneficial without this information.

Commenter (2355-Constellation Energy) states that EPA must consider unquantified and ancillary benefits. The commenter contends that economic principles and best practices for agency rulemaking dictate that consideration of costs and benefits of any section 111 rule include all quantifiable and unquantifiable, direct and indirect costs and benefits.<sup>16</sup> The commenter notes that Executive Order 12866 governing agency rulemaking provides that “agencies should assess all costs and benefits” of proposed regulatory actions, and, for “significant regulatory action,” must assess “benefits anticipated from the regulatory action (such as, but not limited to,

---

<sup>13</sup> RIA, *supra* note 3, at 161–62 tbl.5-4 (projecting net benefits of \$34 billion with a 3 percent discount rate).

<sup>14</sup> RIA, *supra* note 3, at 167.

<sup>15</sup> *Id.* at 64 tbl.3-2.

<sup>16</sup> Indirect benefits may also be called ancillary benefits or co-benefits.

the promotion of the efficient functioning of the economy and private markets, the enhancement of health and safety, the protection of the natural environment, and the elimination or reduction of discrimination or bias).<sup>17</sup> Similarly, guidance from the Office of Management and Budget directs agencies to “look beyond the direct benefits and direct costs of your rulemaking and consider any important ancillary benefits and countervailing risks. An ancillary benefit is a favorable impact of the rule that is typically unrelated or secondary to the statutory purpose of the rulemaking . . . .”<sup>18</sup> Further, EPA’s long-standing practice is to include in a cost-benefit analysis benefits that are not directly intended by the rulemaking.<sup>19</sup>

Commenter (2462-Private Citizen) notes the financial benefits from the new rule, but states that the benefits are an underestimate. The new methane rules provide \$670 million in net benefits, based on detailed analyses.<sup>20</sup> The commenter provides that this number comes from the fact that reducing methane emissions also means recovery of methane for sale, estimated at \$88 million per year. When the financial benefits in climate control, compliance costs and recovery of methane are all considered, they state that the net benefit is \$670 million per year. The commenter adds that this total does not include the substantial cost benefits from reduced illnesses associated with air pollution such as VOCs and particulates known to accompany methane emissions.

Commenter (2353-CrownQuest) suggests that the EPA based this rule on the SCC, as there isn’t even an attempt to quantify the benefits from the calculated VOC and HAP reductions the EPA acknowledges at face value would not justify the costs imposed.

Response II-20-8: The EPA has addressed several of commenters’ points in the Final Rule RIA. First, the EPA extended the nationwide net benefits analysis horizon in the RIA beyond 2035 to 2038 but declined to extend the analysis further due to the significant uncertainties in projected long-run sectoral trends. In addition, the EPA notes that the monetized climate benefits associated with the 2023–2038 CH<sub>4</sub> emission reductions reflect the discounted stream of benefits resulting from those emission reductions over a much longer time horizon (out to 2300). Second, the EPA has added the quantification of the impact of changes in VOC releases via their impact on ozone formation in the Final RIA. However, the EPA is currently unable to estimate or monetize the impact of changes in HAPs releases due to data limitations (see Response I-20-3 in Chapter 20 of Volume I of the RTC for more information).

#### 20.1.1.3 Use of the Interim Social Cost of GHGs Under this Action

Comment: Commenter (2292-WV AG, et al) states that the EPA uses flawed measures like the so-called “social cost of carbon” to justify excessive costs that will have real consequences.

<sup>19</sup> U.S. Environmental Protection Agency, Guidelines for Preparing Economic Analyses (Dec. 17, 2010), <https://www.epa.gov/sites/default/files/2017-08/documents/ec-0568-50.pdf>.

<sup>20</sup> EPA 2022 Regulatory Impact Analysis of the Supplemental Proposal for the Standards of Performance for New, Reconstructed, and Modified Sources and Emissions Guidelines for Existing Sources: Oil and Natural Gas Sector Climate Review EPA-452/R-22-007.

According to the commenter, the purported climate benefits could fall anywhere within a breathtakingly broad range—from \$19 billion to \$130 billion.<sup>21</sup>

Response II-20-9: As explained in the Proposed Rule and Final Rule, the assessment of benefits described in the RIA is presented solely for the purposes of complying with E.O. 12866 and providing the public with a complete depiction of the impacts of the rulemaking. It is wholly distinct from the BSER determinations in this Final Rule, which are based on the statutory factors the EPA is required to consider under section 111(a) of the CAA (including cost, energy requirements and non-air quality health, and environmental impacts).

The distributions of SC-GHG estimates reflect uncertainty in key model parameters chosen by the Interagency Working Group (IWG) such as the sensitivity of the climate to increases in greenhouse gas emissions, as well as uncertainty in default parameters set by the original model developers. The IWG selected SC-GHG values for use in regulatory analyses. For each emissions year, four values are recommended. Three of these values are based on the average SC-GHG from three integrated assessment models (IAMs), at discount rates of 2.5, 3, and 5 percent. In addition, there is extensive evidence in the scientific and economic literature on the potential for lower-probability, but higher-impact outcomes from climate change, which would be particularly harmful to society and thus relevant to the public and policymakers. The fourth value is thus included to represent the marginal damages associated with these lower-probability, higher-impact outcomes. Accordingly, this fourth value is selected from further out in the tail of the distribution of SC-GHG estimates; specifically, the fourth value corresponds to the 95th percentile of the frequency distribution of SC-GHG estimates based on a 3 percent discount rate. The central value is the average of SC-GHG estimates based on the 3 percent discount rate. For purposes of capturing uncertainty around the SC-GHG estimates in regulatory impact analysis, the IWG emphasizes the importance of considering all four SC-GHG values.

Comment: Commenter (2403-PAO) states that the EPA estimated the climate benefits of methane emission reductions expected from this Proposed Rule using the “Technical Support Document: Social Cost of Carbon, Methane, and Nitrous Oxide Interim Estimates under E.O. 13990 (IWG 2021)” published in February 2021 by the Interagency Working Group (IWG) on the SC-GHGs. However, they note that EPA does not consider the many benefits of oil and natural gas and how EPA’s actions may have broad implications here in the U.S. and abroad. For example:

- Oil and natural gas play an indispensable role in providing products and solutions to improve human health and welfare, power the global economy, and make modern life possible,<sup>22</sup>
- Oil and natural gas companies play a significant role in state economies, contribute to state and local taxes, and royalties that pay for schools, universities, roads, and various

---

<sup>21</sup> See EPA, REGULATORY IMPACT ANALYSIS OF THE SUPPLEMENTAL PROPOSAL FOR THE STANDARDS OF PERFORMANCE FOR NEW, RECONSTRUCTED, AND MODIFIED SOURCES AND EMISSIONS GUIDELINES FOR EXISTING SOURCES: OIL AND NATURAL GAS SECTOR CLIMATE REVIEW 17 (Nov. 2022), <https://bit.ly/3X6ltYQ>.

<sup>22</sup> American Fuels and Petrochemical Manufacturers, website information on May 5, 2022.

essential services, provide good paying direct and indirect jobs, and improve the communities they work and reside in,<sup>23</sup>

- Oil and natural gas companies developing U.S. resources can provide the world affordable, reliable natural gas and crude oil in the most environmentally responsible manner as compared to oil and gas development elsewhere in the World, and
- Clean-burning natural gas has enabled the U.S. to become the global leader in greenhouse gas emissions reductions.<sup>24</sup>

The commenter (2403-PAO) requests that EPA factor into its Social Cost of Carbon (SCC) cost benefit analysis the many benefits (as described above) of oil and natural gas.

Response II-20-10: A rule that affects GHG emissions may also affect the production or consumption of goods and services, in which case, it could create costs and benefits for businesses and households that either produce or use those goods and services. These costs and benefits are important to include in an analysis of the rule's impacts but are not the result of changes in GHG emissions from the rule and therefore, it would be inappropriate to try and include them in the SC-GHG used to value changes in GHG emissions. In other words, the SC-GHG is not a measure of social welfare from the consumption of goods and services whose production results in GHG emissions, nor is it intended to capture other positive or negative externalities associated with the production of those goods and services. Similarly, the SC-GHG is not intended to capture the benefits or costs to society from the production and consumption of goods and services associated with regulatory compliance, or the impacts from changes in other emissions that may also occur as a result of regulatory compliance. The SC-GHG is just one component of a larger analysis that includes consideration of other potentially relevant impacts of a policy, including the social costs of compliance, labor market changes, and changes in emissions of other pollutants, as appropriate for the specific analysis.

Comment: Several commenters weighed in on EPA's decision to use the interim Social Cost of Methane (SCM) established in the IWG on SC-GHGs recently published Technical Support Document (2021 TSD)<sup>25</sup> in evaluating the costs and benefits of the Supplemental Proposal.

Commenters (2212-UCS, 2410-CA AG et al, 2343-NYU School of Law, 2355-Constellation Energy, 2397-U.S. Climate Alliance) support EPA's decision to use the interim SCM established in the IWG recently published 2021 TSD, and express support for the proposal's accompanying draft report, *The Social Cost of Greenhouse Gases: Estimates Incorporating Recent Scientific Advances*. Examples of some of the high-level support positions are included in the following paragraphs.

---

<sup>23</sup> <https://oerb.com/economic-impact/>; <https://www.txoga.org/2021eeir/>; [https://www.nmoga.org/natural\\_gas\\_and\\_oil\\_industry\\_critical\\_to\\_new\\_mexico\\_post\\_pandemic\\_recovery?utm\\_campaign=\\_icymi\\_new\\_report&utm\\_medium=email&utm\\_source=nmoga](https://www.nmoga.org/natural_gas_and_oil_industry_critical_to_new_mexico_post_pandemic_recovery?utm_campaign=_icymi_new_report&utm_medium=email&utm_source=nmoga).

<sup>24</sup> Global CO<sub>2</sub> Emissions in 2019, IEA, February 2020; U.S. Energy-Related Carbon Dioxide Emissions, 2019, U.S. Energy Information Administration (EIA), September 2020.

<sup>25</sup> EPA-HQ-OAR-2021-0317-0005, Interagency Working Group on Social Cost of Greenhouse Gases, Technical Support Document: Social Cost of Carbon, Methane, and Nitrous Oxide Interim Estimate Under Executive Order 13,990 (Feb. 2021) (hereinafter, "2021 TSD").

Commenter (2397-U.S. Climate Alliance) applauds the inclusion and utilization of updated estimated values for the SC-GHG in the proposal's accompanying draft report, the *Social Cost of Greenhouse Gases: Estimates Incorporating Recent Scientific Advances*. The commenter asserts that properly accounting for the societal costs of a changing climate is key to crafting effective state and federal policies and achieving our shared net-zero climate goals. EPA's updated approach is particularly timely as we continue to await action from the IWG on the *Social Cost of Greenhouse Gases*, reestablished by President Biden in January 2021, whose current interim estimates — based on work conducted between 2010 and 2016 — are outdated and substantially underestimate climate costs.

Commenter (2355-Constellation Energy) asserts that, only with a full accounting of the damages associated with incremental emissions of methane and other GHGs to property, human health, agricultural resources, and natural resources can the real cost of climate inaction be understood. They recommend that Federal agencies incorporate the SC-GHGs in all relevant areas of decision-making including regulatory analyses, and the SCM is the appropriate value to use in conducting benefit-cost analyses and estimating the climate impacts of policies that affect methane emissions. They also believe that it is appropriate for the RIA for the Supplemental Proposal to consider EPA's sensitivity analysis of the SCM that incorporates recent research addressing recommendations of the National Academies of Sciences, Engineering, and Medicine.<sup>26</sup> The commenter adds that they support EPA's work on this important undertaking while the IWG's work continues, since underestimates of the SCM and other GHGs result in inadequate regulation of GHG emissions and market disincentives for investment in cleaner energy sources. As a critical member of the IWG, the commenter states that the EPA is an agency with technical and economic expertise that makes it well-suited to establish a SC-GHG.

Commenter (2212-UCS) states that EPA has taken an important and necessary step by issuing the draft Report on the *Social Cost of Greenhouse Gases: Estimates Incorporating Recent Scientific Advances* in September 2022<sup>27</sup> and incorporating those findings as a sensitivity analysis within the supplemental's RIA. The commenter notes that the separate and ongoing IWG process is important for standardizing an update to the intergovernmental SC-GHG values; however, while the IWG process continues it is important that EPA still incorporate its understanding of numerous updates in science, economics, and best practice as an additional point of context given the relevance and timeliness of the issue to this rulemaking. While EPA makes clear that the rulemaking is not predicated on these supplemental values, the rulemaking benefits from their incorporation to provide fuller context for the potential impact of this rule.

---

<sup>26</sup> U.S. Environmental Protection Agency, Regulatory Impact Analysis of the Supplemental Proposal for Standards of Performance for New, Reconstructed, and Modified Sources and Emissions Guidelines for Existing Sources: Oil and Natural Gas Sector Climate Review 189 (Nov. 2022); see also U.S. Environmental Protection Agency, Supplementary Material for the Regulatory Impact Analysis for the Regulatory Impact Analysis for the Supplemental Proposed Rulemaking, "Standards of Performance for New, Reconstructed, and Modified Sources and Emissions Guidelines for Existing Sources: Oil and Natural Gas Sector Climate Review" EPA External Review Draft of Report on the Social Cost of Greenhouse Gases: Estimates Incorporating Recent Scientific Advances, September 2022, [https://www.epa.gov/system/files/documents/2022-11/epa\\_scghg\\_report\\_draft\\_0.pdf](https://www.epa.gov/system/files/documents/2022-11/epa_scghg_report_draft_0.pdf).

<sup>27</sup> U.S. EPA, EPA External Review Draft of Report on the Social Cost of Greenhouse Gases: Estimates Incorporating Recent Scientific Advances, September 2022 (Docket ID No. EPA-HQ-OAR-2021-0317).

Commenter (2343-NYU School of Law) believes EPA properly relies on the interim estimates of the SCM from the IWG in the RIA. They note that the EPA also includes a sensitivity analysis of the monetized climate benefits with updated estimates of the SCM [SC-CH<sub>4</sub>] from EPA's draft September 2022, *Report on the Social Cost of Greenhouse Gases: Estimates Incorporating Recent Scientific Advances*. EPA finds that "for all emissions years the range of the climate benefits resulting from this sensitivity analysis is higher in magnitude than the monetized climate benefits using the IWG's recommended interim SC-CH<sub>4</sub> estimates."<sup>28</sup> The commenter states that the September 2022 update faithfully implements the roadmap laid out in 2017 by the National Academies of Sciences, and, while it represents a significant increase over the climate-damage valuations from the IWG, that increase is consistent with the widespread economic consensus, including the IWG's own repeated recognition that its valuations are underestimates.<sup>29</sup>

Therefore, the commenter (2343-NYU School of Law) suggests that the monetized climate benefits in the RIA are likely lower-bound estimates, and EPA underestimates the December 2022 supplemental proposal's associated climate benefits. Indeed, the commenter notes that even the higher estimates from the September 2022 report are conservative.<sup>30</sup>

Commenters (2410-CA AG et al) support the use of the interim value for SCM established in the 2021 TSD as representing the best available estimate of the long-term cost to society of increasing methane emissions now.<sup>31</sup> Although the IWG is currently in the process of reviewing comments on how to improve and update the SC-GHG, including the SCM,<sup>32</sup> for now the interim value for SCM established in the 2021 TSD represents the best available estimate of the long-term cost to society of increasing methane emissions now.<sup>33</sup> Moreover, the commenter notes that the SC-GHG does not dictate the outcome of any specific agency rulemaking, including this one. Here, EPA considers the SCM in evaluating the costs and benefits of the Supplemental Proposal,<sup>34</sup> but nowhere suggests that those values were used to determine the best system of emission reduction (BSER) for the oil and natural gas sector, or that they will be determinative of its ultimate decision.<sup>35</sup> The commenter adds that the SCM is simply one additional tool for monetizing some of the benefits of a regulation that would otherwise be non-monetized, not a thumb on the scale of agency cost-benefit analyses.

Response II-20-11: EPA thanks the commenters for their supportive comments. A detailed response to comments pertaining to EPA's draft September 2022, *Report on the Social Cost of*

*Greenhouse Gases: Estimates Incorporating Recent Scientific Advances* can be found in the Appendix of this RTC.

Comment: Several other commenters (2218-TCEQ, 2227-WEA, 2237-ICND, 2254-PBPA, 2301-U.S. Chamber of Commerce, 2359-CEI, 2399-GPA, 2339-INGAA) oppose the use of the use of the interim value for SCM established in the 2021 TSD and in the proposal's accompanying draft report, *The Social Cost of Greenhouse Gases: Estimates Incorporating Recent Scientific Advances*. Examples of some of the high-level opposition positions are included in the following paragraphs.

Commenter (2359-CEI) notes that, although the EPA has separately published and invites comment on new SC-GHG estimates incorporating recent research,<sup>36</sup> the proposal's benefit calculations rely on the February 2021 TSD, which the agency considers "the most appropriate estimate of the SC-CH<sub>4</sub> until revised estimates have been developed reflecting the latest, peer-reviewed science."<sup>37</sup> As a general observation, the commenter believes that the SC-GHG estimates are too speculative, and too easily manipulated for political purposes, to inform regulatory decisions.

Commenter (2254-PBPA) states that the EPA's approach does not consider the fact that domestic oil and gas production often has a lower carbon-footprint than the energy sources that would otherwise be used in the absence of such production. They state that the proposed EGs could result in accelerating the abandonment of existing well sites, but EPA has not quantified the additional emissions that could result from having to source energy from alternative locations.

The commenter (2254-PBPA) contends that the EPA's social cost of carbon (SCC) report showcases the lack of fair consideration and myopic use of scientific information. The report declares eliminating all U.S. oil and gas production and transportation would increase the U.S. economy between \$600 billion to \$3 trillion per year (3-10% of the U.S. GDP). Never does the report consider the benefits hydrocarbon production provides to our society. The extrapolated benefit of eliminating all oil and gas production shows the lack of real-world understanding in academia. The EPA should instead acknowledge how the U.S. increased its GDP while decreasing GHG emissions over the past ten years. At the same time, the commenter reports that states like Texas require weatherization and operations in cold and hot weather events to save lives, economic output, and prosperity. According to the commenter, making a rule that creates hard economic loss while not fully considering the ramifications of said rule sets a dangerous precedent for society.

<sup>36</sup> EPA, Supplementary Material for the Regulatory Impact Analysis for the Supplemental Proposed Rulemaking, "Standards of Performance for New, Reconstructed, and Modified Sources and Emissions Guidelines for Existing Sources: Oil and Natural Gas Sector Climate Review" EPA External Review Draft of Report on the Social Cost of Greenhouse Gases: Estimates Incorporating Recent Scientific Advances, September 2022, [https://www.epa.gov/system/files/documents/2022-11/epa\\_scghg\\_report\\_draft\\_0.pdf](https://www.epa.gov/system/files/documents/2022-11/epa_scghg_report_draft_0.pdf) (hereafter External Review Draft).

<sup>37</sup> 87 FR 74713.

Commenter (2399-GPA) states that the EPA recognizes that the SCM interim values, released pursuant to Executive Order 13990,<sup>38</sup> have not been finalized. They add that they and other commenters have not yet had responses to their comments identifying significant deficiencies associated with these interim values.<sup>39</sup> Indeed, the commenter asserts that recognizing the values require further scientific study, EPA and other agencies have begun an expert peer review of the administration's social cost analyses.<sup>40</sup> According to the commenter, until that peer review process is conducted and subject to public review and comment, it is inappropriate for EPA to consider the interim values to support its Supplemental Proposed Rule.

Commenter (2237-ICND) suggests that the EPA's asymmetrical cost benefit analysis for the Supplemental Proposal relies on an ideological global "social cost of greenhouse gas" that purports to confer benefit on the global public that consequently are to be achieved through a rule the costs of which are to be borne solely by the U.S. public. However, the commenter notes that when correctly considering only the domestic social cost of GHGs, the Supplemental Proposal will not benefit the U.S. and will instead impose a net cost on the U.S. public of \$7.4 billion (in 2019 dollars). Less than 15% of the global social cost of GHG benefits claimed by EPA for this proposed rule will accrue to the U.S. public, which would nonetheless pay the full tab to subsidize these claimed global benefits. The commenter adds that the EPA is not authorized by the CAA to rely on cumulative global climate benefits to justify the costs imposed solely on North Dakota and the nation by the Supplemental Proposal. The commenter asserts that the EPA's authority to promulgate Section 111 regulations is not based in cumulative ideologically based global climate benefits, but rather upon technically based "air pollution prevention and control programs." 42 U.S.C. § 7410(b)(4).

Commenter (2218-TCEQ) states that the RIA and supplemental analysis are flawed because the SCM metric used significantly inflates the climate benefits resulting from this rule. The commenter suggests that the SCM method EPA uses is artificially high and relies on unrealistic assumptions on the direct benefit to global climate due to the methane reductions anticipated by this rule. The commenter adds that the methane emission reductions achieved are a fraction of the emissions of GHGs globally that must be reduced to stabilize global temperatures. Thus, they say that the EPA's metric of climate benefits relies primarily on presumed efforts that will occur internationally and not on the mitigation efforts of this proposal. The commenter states that although the EPA claims the monetized benefits analysis using a revised SCM is "entirely distinct" from the proposed statutory BSER determinations, this exercise unjustifiably inflates the climate benefits of the proposed regulatory scheme. According to the commenter, the EPA attempts to justify burdensome requirements across all oil and gas sources by establishing an extremely high cost per ton of methane. The commenter notes that, if the benefits of the regulation are the avoided cost of GHG emissions on the climate, EPA admits in their sensitivity analysis that these benefits will not be realized by imposition of the regulations in the 2023 to 2035 timeframe.

<sup>38</sup> Exec. Ord. 13,990, Protecting Public Health and the Environment and Restoring Science to Tackle the Climate Crisis, 86 Fed. Reg. 7,037 (Jan. 25, 2021).

<sup>39</sup> GPA Midstream, Comments Submitted on 86 Fed. Reg. 24,669 (May 7, 2021) (submitted June 21, 2021). GPA Midstream incorporates those comments here by reference. A copy is attached as Exhibit B.

<sup>40</sup> <https://www.epa.gov/environmental-economics/scghg-td-peer-review>

Commenter (2339-INGAA) states that, at the outset, the EPA’s use of its own SC-GHG estimates is contrary to Executive Order (E.O.) 13990. That order re-established the IWG, specified its membership (including EPA), and set out a process for the IWG to follow in establishing SC-GHG figures.<sup>41</sup> The order states that the IWG “shall” proceed by publishing interim SC-GHG figures within 30 days and final SC-GHG figures by January 2022, and also directs the IWG to provide recommendations regarding “a process for reviewing and, as appropriate, updating” the SC-GHG estimates and the underlying methodologies on which they are based.<sup>42</sup> Most critically, E.O. 13990 states that “agencies shall use” the IWG’s interim SC-GHG estimates “when monetizing the value of changes in greenhouse gas emissions.”<sup>43</sup>

Here, the commenter (2339-INGAA) asserts that the EPA has acted contrary to those instructions by issuing and employing its own entirely different SC-GHG estimates. EPA’s course is not only contrary to E.O. 13990’s instruction that executive agencies, including EPA, “shall use” the IWG’s interim figures (i.e., not other estimates of their own choosing), but is puzzling given that EPA itself is a member of the IWG. According to the commenter, the order clearly articulates a process for the IWG to follow, which does not include individual member agencies issuing and employing their own SC-GHG estimates. The commenter suggests that the EPA’s proper course is to work as a member of the IWG to assist in that ongoing group process, not to promulgate its own unilateral issuances in contradiction to the process contemplated in E.O. 13990.

According to the commenter (2339-INGAA), EPA attempts to justify its approach by noting that the IWG invited agencies to use different discount rates in sensitivity analyses for RIAs.<sup>44</sup> But they contend that the EPA went well beyond merely using alternative discount rates in its sensitivity analysis—it issued its own entirely different SC-GHG estimates, based on significant methodological changes at every step of the analytic process. It is one thing to conduct a sensitivity analysis that considers lower and higher discount rates,<sup>45</sup> and quite another to issue a new SC-GHG analysis that gives the clear impression of being intended to supersede and replace the IWG’s work product in toto. The commenter asserts that the EPA has accordingly acted contrary to E.O. 13990’s instructions.

The commenter (2339-INGAA) contends that the EPA’s decision to issue its own SC-GHG estimates that are based on significantly altered methodologies and depart drastically upward from the IWG’s interim estimates threatens to bring back the cross-agency inconsistency the IWG was created to alleviate. Despite its status as a member of the IWG itself, the commenter states that the EPA has essentially re-created the situation that existed in 2008, when the IWG

<sup>41</sup> 86 Fed. Reg. 7,037, 7,040-41 (Jan. 25, 2021).

<sup>42</sup> *Id.* at 7,040.

<sup>43</sup> *Id.*

<sup>44</sup> RIA at 68; see Interim TSD at 4, 21.

<sup>45</sup> The IWG’s Interim TSD suggested that agencies could use lower discount rates in sensitivity analyses, without mentioning the possibility of also using higher discount rates. See Interim TSD at 4, 21. INGAA disagrees with that one-sided focus. The purpose of a sensitivity analysis is to see how plausible alternative inputs and assumptions would affect a cost-benefit analysis; it therefore makes sense to consider an ample range of reasonable alternative inputs in such a sensitivity study. Cf. Circular A-4, Regulatory Analysis at 41 (Sept. 17, 2003), <https://tinyurl.com/mtvsn3jx> (hereinafter Circular A-4 (2003)). Given the credible arguments for higher discount rates in this context—and especially in light of the fundamentally normative and policy-based nature of the choice of discount rate—it would be reasonable to consider both higher and lower discount rates in a sensitivity analysis. See *infra* Part II.C.

was first convened, including, as it apparently did then, endorsing SC-GHG values higher than those used by other agencies. If EPA's rationale is accepted, the commenter states that other agencies might follow suit, adding further to the inconsistency and confusion.

Commenter (2339-INGAA) notes that the EPA's departure is particularly puzzling given the absence of any clear reason for doing so. EPA's only stated rationale for issuing its own completely revised SC-GHG estimates in spite of the ongoing IWG process is to provide alternative values for a sensitivity analysis.<sup>46</sup> But that sensitivity analysis simply delivers the unsurprising verdict that regulations to reduce GHG emissions, which EPA has already determined deliver more benefits than costs, perform even better in a cost-benefit analysis when a higher value is placed on GHG emissions reductions.<sup>47</sup> Respectfully, it is obscure how this finding is expected to improve the quality or informativeness of EPA's RIA for the present rulemaking.<sup>48</sup> Interested parties can only infer that EPA's issuance of its own SC-GHG estimates may signal a broader intent to deviate from the IWG's estimates in the future.

Response II-20-12: A detailed response to comments pertaining to EPA's draft September 2022, *Report on the Social Cost of Greenhouse Gases: Estimates Incorporating Recent Scientific Advances* and the general use of SC-GHG estimates in policy analysis can be found in the Appendix of this RTC.

Comment: Commenter (2179-KIOGA) states that, in addition, in the cost benefit analysis, the EPA uses an interim SCC value of \$51 per ton. The \$51 per ton SCC includes global climate change impacts that are outside the jurisdiction of the EPA. We believe the EPA should use the most recent SCC of \$7 per ton that was limited to climate change impacts within the U.S. The commenter adds that they also find it disconcerting that the EPA references conflicting global warming (GWP) potentials for methane (80, 30, 29.8, 27.2, and 25) throughout the proposal instead of using the established GWP used for emissions inventory purposes.

Response II-20-13: A detailed response regarding the use of global SC-GHG estimates can be found in the Appendix of this RTC where responses are provided on comments pertaining to EPA's September 2022 *Draft Report on the Social Cost of Greenhouse Gases: Estimates Incorporating Recent Scientific Advances*.

Comment: Commenter (2401-State of Wyoming) states Wyoming's DEQ and WOGCC have a long history of responsibly regulating the oil and gas industry. The commenter provides a complete regulatory process, from permitting to plugging. Wyoming consistently ranks among the top states for oil and gas production from onshore federal minerals. Approximately 65 percent of the total oil production and 79 percent of the total gas production in the state is

---

<sup>46</sup> RIA at 78 ("While [the IWG] process continues, the EPA is taking the opportunity in this RIA to present a sensitivity analysis of the monetized climate benefits of this proposed action using an updated set of SC-CH<sub>4</sub> estimates, newly developed by EPA . . ."); see also Supplemental NOPR, 87 Fed. Reg. at 74,843 (similar).

<sup>47</sup> See generally RIA at 189-96.

<sup>48</sup> The purpose of a sensitivity analysis is to see how changing assumptions may affect a cost-benefit analysis. See Circular A-4 (2003) at 41. As Circular A-4 (2003) explains (and common sense confirms), the primary value of such an exercise is to find "switch points"—critical parameter values at which estimated net benefits change sign or the low cost alternative switches." Id. EPA's sensitivity analysis does not point to any such "switch points." Instead, the sensitivity analysis seems largely oriented toward buttressing conclusions EPA has already reached.

produced from federal minerals. Oil and gas production takes place in 21 of Wyoming's 23 counties and directly employs over 9,000 people. Taxes on production contribute over a billion dollars annually to state and local governments.

Commenter (2401-State of Wyoming) states the majority of Wyoming oil and gas producers are not multinational companies and the additional level of federal regulations is duplicative. The costs levied on the producers and our agencies far outweigh the environmental benefit. This is particularly true in this proposal since EPA does not provide an accurate or thorough cost and benefit analysis. This proposal will have a disproportionate effect on Wyoming producers as a whole, but particularly on the small operators of stripper wells. In addition, the supplemental proposal places onerous implementation requirements upon DEQ's Air Quality Division given the massive increase of affected facilities and the corresponding mountain of additional requirements pertaining to compliance, permitting, emissions inventories, the development of State plans and other air quality aspects under Wyoming's primacy, making implementation infeasible. The scale of impact on the people of Wyoming from impractical and burdensome new regulations on the oil and gas sector cannot be overstated.

Commenter (2401-State of Wyoming) notes in evaluating the economic impacts, EPA utilizes the social cost of carbon, methane, and nitrous oxide among other asserted social benefits. These societal benefit values are necessary to justify a rule that costs more to comply with than it ends up benefitting. What is left out of the economic analysis are costs to society resulting from the proposed rule, with these costs being born by local communities and their families, schools, and budgets of these local governments. Not only will society lose the benefits of royalties, taxes, and jobs that are lost when wells are prematurely shut in, but also by incurring increased prices to all Americans for transportation fuel, heating their homes, food and all other items we use that are impacted by increased fossil fuel prices. The premature shut in of wells results in one of two outcomes: Either oil and gas prices will increase or will be made up in other countries. Society loses by paying higher costs or the environmental impact of shifting production to nations that do not produce oil/gas under the same regulatory standards found in the states. Simply put, the people of Wyoming and the US lose. If EPA uses societal benefits to justify the economic impact of this rule it should also use the societal costs to conduct a full and complete economic analysis, including localized impacts.

Response II-20-14: The EPA disagrees with the commenter's assertion that the costs of compliance with the Final Rule outweigh the environmental benefits, for the reasons explained in detail in the Final Rule Preamble, Section VIII.B. The commenter provides no specific data or analysis to contest the EPA's assessment, as presented in the Final RIA. The commenter makes general, unsupported claims about premature shut in of wells and increasing commodity prices, but EPA's analysis suggests that the overall impacts of the rule on production and prices will be small (see Response II-20-2).

In response to the comment that the December 2022 Supplemental Proposal places onerous implementation requirements upon DEQ's Air Quality Division, the EPA notes that the Information Collection Request (ICR) and supporting statements for the November 2021 Proposed Rule and the December 2022 Supplemental Proposal included detailed estimates of the time and resources required by state agencies to develop and implement the EGs. Similar to the

claims about cost of compliance, the commenter did not provide any specific comments on that analysis [or offer any information that might change the analysis]. These impacts are also contained in the ICR and supporting statements for the December 2022 Supplemental Proposal and the final rule. With regard to the EPA's estimated reporting and recordkeeping burden for the December 2022 Supplemental Proposal, see the ICR Supporting Statements located at Document ID Item Nos. EPA-HQ-OAR-2021-0317-0144 (NSPS OOOO and NSPS OOOOa), EPA-HQ-OAR-2021-0317-1556 (NSPS OOOOb), EPA-HQ-OAR-2021-0317-1553 (EG OOOOc), for this action located at Docket ID No. EPA-HQ-OAR-2021-0317. Updated ICR Supporting Statements for this final action are also located in Docket ID No. EPA-HQ-OAR-2021-0317.

The final rule also includes changes that will reduce the burden on state agencies and sources subject to standards developing in accordance with the emission guidelines. For example, for the NSPS OOOOb, the EPA has concluded that only sources constructed, modified, or reconstructed after the date of the Supplemental Proposal (December 6, 2022) should be considered new sources for the purposes of NSPS OOOOb. Changing this date to December 6, 2022, from the November 15, 2021, reduces the number of existing new sources that will need to comply with NSPS OOOOb, thereby allowing more time to plan and meet implementation challenges. For details, please see discussion in section IX (Interaction of the Rules and Response to Significant Comments Thereon), subsection A (What date defines a new, modified, or reconstructed source for purposes of the final NSPS OOOOb?) of the final rule preamble. The EPA has also provided an alternative compliance timeline in the NSPS OOOOb final rule for process controllers and pumps required to meet a zero-emission standard (i.e., final rule allows up to one year from the publication date of the final rule). See section XI.D.4 (Compliance dates) of the final rule preamble for a discussion on the compliance dates finalized for process controllers (which also applies for pumps).

In addition, for the EG OOOOc, the EPA is finalizing a compliance timeline of 36 months from the deadline for state plan submittals, which provides owners and operators of designated facilities time to plan and meet any increased implementation demands. When the compliance timeline of 36 months is considered in conjunction with the state plan submittal deadline of 24 months, that means that sources could have up to 5 years between when the EG are final and when they are required to fully comply with the applicable standards of performance. The EPA believes that any concerns with the planning and implementation of requirements, which commenters speculate could be an issue, would likely be addressed by industry and regulators in that timeframe. See section XIII.E.3 (Compliance timelines) of the final rule preamble for EPA's response to comments regarding the compliance timeline required under the EG.

#### 20.1.1.4 Supplemental Proposal is not Cost-Effective

Comment: Several commenters (2314-Miller Energy, 2254-PBPA, 2220-WDEQ, 2200-NuEnergy, 2179-KIOGA, 2283-Endeavor Energy, 2252-PAW) assert that the supplemental proposal is not cost-effective, unfairly impacts older, existing operations and small businesses, and/or provide references supporting the increased costs. Examples of comments are provided in the following paragraphs.

Commenter (2314-Miller Energy) notes that the oil-and-gas industry is unique from most in the fact that the industry does not have the ability to dictate selling price. Without an ability to push the cost of increased regulatory requirements downstream, many operators will be unable to offset the capital-investment costs for the proposed monitoring equipment. The commenter urges EPA to consider this factor when considering the cost-benefit analysis for each production tier.

Commenter (2254-PBPA) states that the proposed rule is a massive expansion of NSPS OOOOa's requirements, especially regarding recordkeeping, and EPA significantly underestimates the compliance costs. The commenter recommends that EPA develop recordkeeping requirements based on critical operations rather than a one-size-fits-all box. The commenter believes that EPA's recordkeeping estimate is a significant underestimation. The commenter asserts that the estimated effort required to complete annual reports is likely to be much more intensive than the estimated hours of recordkeeping, especially by smaller operators and small businesses that make up a large portion of the EG OOOOc facilities. The commenter states that this rule is complex and forces a diverse group of operations and sites into a one-size-fits-all box. The commenter notes that EPA collected data from NSPS OOOOa for over 12 years but does not cite this data or its effect on targeted facilities' emissions once in the entire rule.

Commenter (2220-WDEQ) asserts that the proposed NSPS OOOOb many new requirements affect nine different types of equipment or processes at oil and natural gas well sites, six different types of equipment or processes at natural gas gathering and boosting compressor stations, six different types of equipment or processes in the natural gas processing segment, and five different types of equipment or processes in the transmission and storage segment. These requirements come with expensive control and compliance costs that operators will have to absorb.

The commenter (2220-WDEQ) contends that even more problematic, however, is the manner in which the new requirements in EG OOOOc mirror many of the requirements in NSPS OOOOb. The commenter states that there are exorbitant and even infeasible costs associated with retrofitting certain control requirements on all existing sources considered affected facilities under the rule. Furthermore, the definitions of such affected facilities have also been expanded for many different types of equipment. The commenter notes that the number of existing facilities in Wyoming that would have to undergo costly retrofitting procedures, in addition to the increased monitoring and compliance burdens, would be massive. At this time, it is impossible to know exactly what the economic impacts would be to operators and the feasibility of continuing their operations and retaining employees, but it is reasonable to assume that they would be significant. There are several additional areas of concern pertaining to the potentially infeasible costs associated with the proposed requirements in EG OOOOc:

- Smaller operators might incur the expense of a third-party contractor to even determine which facilities on their sites are subject to OOOOc requirements.
- The massive increase in affected facilities and required frequency of inspections will require much more driving time to complete all of the necessary inspections, resulting in the unintended consequence of creating more vehicle emissions.
- Completing each inspection will require significantly more time from both operators and state compliance staff – and the overall number of inspections will jump significantly.

- The cost to hire qualified third-party contractors to perform some of the OGI fugitive emissions monitoring required under the supplemental proposal will be significant and infeasible for some smaller operators. Furthermore, it's possible that contractor costs will escalate from current levels due to the increased demand.
- There are a limited number of qualified Senior OGI camera operators based on the requirements of Appendix K and the process of achieving such a qualification is very lengthy.
- Operators will generally have to dedicate more time and resources to performing OGI inspections, which will potentially consume available resources that would otherwise be dedicated to performing ongoing compliance duties. As a result, it is possible that operators will not be able to make repairs in as timely of a manner, resulting in increased emissions. This would appear to be an unintended consequence of the inordinate workload associated with the compliance requirements in the supplemental proposal.

Commenter (2200-NuEnergy) states that the EPA is not justified in proposing new regulations and capital investments to reduce emissions if the target is moved every 2 or 4 years. The commenter asserts that the proposed regulations unfairly penalize small businesses who made capital investments over the last several years to meet regulatory standards only to have new proposed regulations before promised recovery of initial capital investments. The commenter disagrees with EPA using a static \$3.13 per thousand cubic feet (MCF) for their economic analysis. The commenter notes that EPA does not release equations, variables, documentation, references and/or assumptions to determining the cost effects of capital investments, operational changes, increased monitoring, contract labor and interrupted production to improving the reductions in hydrocarbon emissions, yet the EPA is free to assume their estimations and assumptions are industry standards for the cost benefit analysis.

The commenter (2220-WDEQ) states that the industry cannot sustain regulatory costs at the current \$74 per barrel and \$2.44 per mcf of natural gas and the consequences are unknown when oil and natural gas prices drop to \$35 per barrel of oil and \$1.50 per million standard cubic foot (mscf) of natural gas.

Further, the commenter (2220-WDEQ) questions EPA's determination that the proposed regulations are cost effective. The commenter notes that EPA did not consult small businesses, and that all production operations are not equal. The commenter questions EPA's process and qualifications to make this determination.

Finally, the commenter (2220-WDEQ) notes that EPA used the mid-2021 economic conditions as a basis for cost benefit analysis to evaluate the anticipated costs to owners and operators. The commenter asserts that their mid-2021 financial conditions have changed, that warrants a re-evaluated cost benefit analysis.

Commenter (2179-KIOGA) provides examples of Kansas small oil and gas companies' NSPS OOOOa compliance costs in Table 2 of their comment letter. [Table 2. Compliance Activities and Costs required by NSPS OOOOa.] The commenter states that operating costs will increase from Leak Detection and Repair (LDAR) survey costs, reporting costs, and additional capital investment to meet emissions reductions.

Further, the commenter (2179-KIOGA) asserts that projects in Kansas and other areas in the U.S. will not realize an economic benefit for developing compliance programs. The commenter notes that EPA is expecting owners and operators to capture methane and use the sales to offset compliance costs. The commenter contends that most of the gas that is not being sold today costs too much for owners and operators to collect, process, transport, and sell into the natural gas market. If projects to collect, process, and sell gas were economically attractive, companies would have already made the investment. The commenter notes that many wells drilled and produced in Kansas have associated gas that needs to be purified to make it pipeline quality, which is a significant investment for a small volume of produced gas.

Additionally, the commenter (2179-KIOGA) reports, according to Energy Information Administration (EIA), the Henry Hub contract price for natural gas is expected to average \$4.90/Mcf in 2023. The commenter performed Monte Carlo simulations around expected Kansas gas production, gas quality, compliance cost, operating cost, and product pricing. The outcome of their simulations shows that none of the scenarios are profitable (positive Net Present Value (NPV)) and any management team would reject the investment opportunity. The commenter asserts that every well drilled will only have additional compliance costs added and no economic benefit will be realized. The commenter states that this is another example where a Federal Agency issues a national level regulation without considering the impact across the country. EPA's "one size fits all" regulation format failed to consider local conditions.

Commenter (2283-Endeavor Energy) requests that EPA withdraw its proposed EG OOOOc requirements and separately propose more appropriate requirements for existing sources once it has had the opportunity to gain insights from the implementation of NSPS OOOOa and NSPS OOOOb (if finalized). The commenter recommends that EPA craft EGs that reflect the realities of older, existing sources as required by the Clean Air Act (CAA).

The commenter (2283-Endeavor Energy) notes that EPA is presently proposing essentially identical requirements for both new and existing sources. As EPA is aware, the commenter notes that existing sources make up a much larger body of sources as compared to new, modified, or reconstructed sources subject to NSPS requirements. This is true both as a total number of sources, and as a percentage of most operators' facilities. For example, the commenter notes that their well sites are existing sources under the proposed definitions, as are about 90 percent of their tank batteries. Beyond just the sheer numbers of additional sources that will be impacted, it will be more costly and burdensome to implement these requirements at each existing well site because older, existing sites would require far more equipment upgrades, retrofitting, and other operational changes. The commenter contends that these older sites were not designed with these sorts of requirements in mind. The commenter estimates that changes needed to comply with the proposed EG OOOOc will be a substantial economic burden on older wells that have limited production to offset the cost of compliance, which will force operators to prematurely shut in such wells.

Commenter (2252-PAW) asserts that EPA misinterprets its authority under Section 111 of the CAA. The commenter notes that the EPA is charged with determining appropriate emission controls for new facilities while incorporating consideration of the cost of those controls and the correlating emission reductions. For existing facilities, the EPA's two responsibilities are to

establish a procedure by which states are to submit a plan which details the emission controls it intends to require; and reviewing state compliance plans to ensure they are “satisfactory”. Instead, the commenter contends that EPA is proposing comprehensive and expensive emissions controls and leak detection requirements for oil and gas facilities.

Response II-20-15: As discussed in section VIII.B (How does EPA evaluate control costs in this final action?) of the final rule preamble, the final standards will impose some new costs on industry. Many of the standards, however, reflect control mechanisms and measures that many companies and sources around the country are already implementing — again, without deleterious effect on industry as a whole — which shows not only that such controls are “adequately demonstrated” but also underscores their reasonableness from a cost perspective. The EPA provides the cost effectiveness estimates for reducing VOC and methane emissions for various control options considered in the November 2021 Proposal and the December 2022 Supplemental Proposal, as well as in section XI of this preamble and associated TSDs.

In response to commenters that express concerns related to many of the new requirements under EG OOOOc, reflecting many of the requirements under NSPS OOOOb, where that is the case, it is because BSER was the same, considering any potential retrofit costs.

For EPA’s response to comments on impacts to small businesses, see responses to comments in section 20.3.5 (Small Business Considerations) of this Chapter.

In support of EPA’s use of a “static” natural gas price at \$3.13 (\$/1000 ft<sup>3</sup>) (the average price for 2022) in analyses, while the natural gas price may be volatile, from a long-term perspective, this estimate was and is reasonable to use in analyses. It is important to note, however, that while the \$3.13 (\$/1000 ft<sup>3</sup>) was used in differing BSER analyses to represent the price of natural gas when calculating the natural gas cost savings that would be associated with various regulatory options, the calculated gas savings estimates illustrate the benefits of varying regulatory options being considered but are not used as a sole determinant of what constitutes BSER. Notably, this offset does not apply where the owner or operator does not own the gas and would not likely realize the monetary value of the natural gas saved (e.g., transmission stations and storage facilities). Commenter (2220-WDEQ) is correct that NSPS OOOOb (and EG OOOOc) include requirements for a number of different types of affected/designated facilities that could be present at oil and natural gas sites. However, not all sites will have every type of affected facility/designated facility that would be subject to requirements under the final rule. Nonetheless, the EPA considered this comment and other similar comments concerned about the compliance costs when developing the final requirements under NSPS OOOOb and EG OOOOc.

Also, as discussed in Response II-20-25 of this Chapter, the EPA includes key areas where options were chosen to reduce regulatory burden. For example, EPA revised its proposed fugitive emissions monitoring requirements at well sites to allow for AVO inspections at sites with little or no equipment, which EPA believes disproportionately alleviates regulatory burden on small businesses without sacrificing significant environmental benefits. In other instances, several compliance options are provided to owners and operators based on specific concerns raised by commenters. In addition to providing several compliance alternatives for affected facilities under NSPS OOOOb and designated facilities under EG OOOOc, the EPA has also

considered issues such as lingering supply chain issues and increased demand for equipment and services when establishing compliance, and repair and delay of repair provisions included in the final NSPS OOOOb and EG OOOOc rules to account for parts not being available.

For the NSPS OOOOb, the EPA has concluded that only sources constructed, modified, or reconstructed after the date of the Supplemental Proposal (December 6, 2022) should be considered new sources for the purposes of NSPS OOOOb. Changing this date to December 6, 2022, from the November 15, 2021, reduces the number of existing new sources that will need to comply with NSPS OOOOb, thereby allowing more time to plan for compliance. For details, please see discussion in section IX (Interaction of the Rules and Response to Significant Comments Thereon), subsection A (What date defines a new, modified, or reconstructed source for purposes of the final NSPS OOOOb?) of the final rule preamble. The EPA has also provided an alternative compliance timeline in the NSPS OOOOb final rule for process controllers and pumps required to meet a zero-emission standard (i.e., final rule allows up to one year from the publication date of the final rule). See section XI.D.4 (Compliance dates) of the final rule preamble for a discussion on the compliance dates finalized for process controllers (which also applies for pumps).

For the EG OOOOc, the EPA is finalizing a compliance timeline of 36 months from the deadline for state plan submittals, which provides owners and operators of designated facilities time to plan and meet any increased labor demands. When the compliance timeline of 36 months is considered in conjunction with the state plan submittal deadline of 24 months, that means that sources could have up to 5 years between when the EG are final and when they are required to fully comply with the applicable standards of performance. The EPA believes that this provides the regulated industry sufficient time to plan and comply with the EG. See section XIII.E.3 (Compliance timelines) of the final rule preamble for EPA's response to comments regarding the compliance timeline required under the EG.

Additionally, both NSPS OOOOb and EG OOOOc include provisions that could be pursued for an alternative but equivalent compliance option under NSPS OOOOb or equivalent or less stringent requirements considering remaining useful life and other factors (RULOF) under EG OOOOc under a state plan. 40 CFR 60.5399b (What are the alternative means of emission limitations for GHG and VOC emissions from well completions, liquids unloading operations, centrifugal compressors, reciprocating compressors, fugitive emissions components, and process unit equipment affected facilities; and what are the alternative fugitive emissions standards based on state, local, and tribal programs?) of NSPS OOOOb provides procedures for the submittal and approval of alternative means of emission limitation for GHG and VOC based on work practices for well completions, liquids unloading operations, centrifugal compressors, reciprocating compressors, fugitive emissions components and process unit equipment affected facilities. See section XIII.C (Establishing Standards of Performance in State Plans) of the final rule preamble for state plan requirements and sub-section XIII.C.3 (Remaining useful life and other factors (RULOF)) of the final rule preamble for a summary of the RULOF provisions that have been finalized in the subpart Ba rulemaking (codified at 40 CFR part 60, subpart Ba).

Regarding statements by commenter (2254-PBPA) that the EPA underestimated the reporting and recordkeeping, the EPA notes that the Information Collection Request (ICR) and supporting

statements for the November 2021 Proposed Rule and the December 2022 Supplemental Proposal included detailed estimates of the time and resources necessary for compliance. The commenter did not provide any specific comments on that analysis [or offer any information that might change the analysis]. These impacts are also contained in the ICR and supporting statements for the December 2022 Supplemental Proposal and the final rule. Regarding EPA's estimated reporting and recordkeeping burden for the December 2022 Supplemental Proposal, see the ICR Supporting Statements located at Document ID Item Nos. EPA-HQ-OAR-2021-0317-0144 (NSPS OOOO and NSPS OOOOa), EPA-HQ-OAR-2021-0317-1556 (NSPS OOOOb), EPA-HQ-OAR-2021-0317-1553 (EG OOOOc), for this action located at Docket ID No. EPA-HQ-OAR-2021-0317. Updated ICR Supporting Statements for this final action are also located in Docket ID No. EPA-HQ-OAR-2021-0317.

### ***20.1.2 Office of Management and Budget (OMB) Circular A-4 (Subject: Regulatory Analysis)***

Comment: Commenter (2220-WDEQ) states that in the RIA for the supplemental proposal, EPA relies on flawed SCM metrics. The commenter encourages EPA to consider the abundant information and analyses that explain why the assumptions made by EPA's Integrated Assessment Models (IAMs) are inaccurate.

In particular, the commenter (2220-WDEQ) directs EPA to, and incorporates herein, a pair of comment letters authored on the "Technical Support Document: Social Cost of Carbon, Methane, and Nitrous Oxide Interim Estimates under Executive Order 13990." These letters were submitted by Wyoming Governor Mark Gordon and Missouri Attorney General Eric Schmitt (undersigned by Attorneys General of 18 States, including Wyoming), and point out the flawed nature of these metrics.<sup>49,50</sup> As noted in Governor Gordon's letter, the commenter states that the discount rate and the equity weights used to aggregate monetized impacts cause immense uncertainty; the discount rates are extremely low, placing disproportionate weight on future impacts of methane emissions, while devaluing the economic and social benefit created from present-day processes that emit greenhouse gases. The Attorneys General reinforced this point in their comments; the section titled, "The Current Social Costs of Greenhouse Gases Are Deeply Flawed and Cannot Be Fixed by Making More Wild Guesses," explains:

- IAM-based damages analyses are arbitrary
- Calculating global damages is inappropriate
- (The assumptions use) an improper time horizon
- (The assumptions) fail to include 7% discount rate baseline
- The 2021 TSD improperly relies on outdated science

The commenter (2220-WDEQ) adds that the methodologies and metrics used in EPA's calculations have been repeatedly called into question. As the Attorneys General note in their

---

<sup>49</sup> Comment Letter on "Technical Support Document: Social Cost of Carbon, Methane, and Nitrous Oxide Interim Estimates under Executive Order 13990," Wyoming Governor Mark Gordon, submitted June 21, 2021, to the Office of Information and Regulatory Affairs of the Office of Management and Budget.

<sup>50</sup> Comment Letter on "Technical Support Document: Social Cost of Carbon, Methane, and Nitrous Oxide Interim Estimates under Executive Order 13990," Attorney General of Missouri Eric Schmitt and Attorneys General of 18 other undersigned States, submitted June 21, 2021, to the Office of Management and Budget.

comments, “MIT economist Robert Pindyck has found: *an IAM-based analysis suggests a level of knowledge and precision that is nonexistent and allows the modeler to obtain almost any desired result because key inputs can be chosen arbitrarily.*”<sup>51</sup> There is an abundance of supplemental evidence outlining the inaccuracy of IAM-based analyses and the modeled assumptions used to calculate the societal value of reducing emissions of methane....

...EPA’s flawed methodologies for calculating the social cost of methane in the supplemental proposal dramatically overstate societal benefits while significantly underestimating the costs to states and regulated entities to implement the rule. EPA should start over-using a realistic predictor of the actual costs and benefits. When it does, the commenter states that it is confident that the costs of the supplemental proposal will substantially outweigh its benefits.

Response II-20-16: EPA has incorporated recent advancements in the climate science and economics peer-reviewed literature using a modular approach to SC-GHG estimation in the *Report on the Social Cost of Greenhouse Gases: Estimates Incorporating Recent Scientific Advances*. Responses regarding the time horizon, global focus, and discounting approach used in the SC-GHG estimates applied in the Final RIA can be found in the Appendix of this RTC where responses are provided on comments pertaining to EPA’s September 2022 *Draft Report on the Social Cost of Greenhouse Gases: Estimates Incorporating Recent Scientific Advances*.

The Final Report on the Social Cost of Greenhouse Gases, which is included as Supplementary Material to the Final RIA, discusses the use of Integrated Assessment Models (IAMs) in SC-GHG estimation, and the modular approach adopted in the SC-GHG estimates used in the Final RIA for this action. Regarding the comments about Pindyck (2013)<sup>52</sup>, EPA notes that an article in the peer-reviewed literature, Weyant (2014)<sup>53</sup> addressed this issue as follows:

“While Pindyck’s observations about the empirical weaknesses of IAMs or calculations of the SCC are worthy of careful study, the conclusion that IAMs are therefore useless fundamentally misconceives the enterprise. IAMs and the SCC are conceptual frameworks for dealing with highly complex, non-linear, dynamic, and uncertain systems. The human mind is incapable of solving all the equations simultaneously, and modeling allows making “If... then...” analyses of the impacts of different factors. The models have provided important insights into many aspects of climate-change policy.”

---

<sup>52</sup> Robert S. Pindyck, *Climate Change Policy: What do the Models Tell Us?*, National Bureau of Economic Research Working Paper 19244, at 16 (2013).

<sup>53</sup> Weyant, J., 2014. Integrated assessment of climate change: state of the literature. *Journal of Benefit-Cost Analysis*, 5(3), pp.377-409.

Furthermore, Pindyck has consistently noted that modeling and damage category considerations are not a reason to abandon the social cost of greenhouse gases; Pindyck has consistently supported updating the IWG's past estimates (Pindyck 2013<sup>54</sup>, 2017<sup>55</sup>, 2019<sup>56</sup>, 2021<sup>57</sup>).

Comment: Commenter (2344-IER) argues that EPA continues to ignore Circular A-4 (2003) and the requirement of a 7 percent discount rate. The commenter states that, instead of following Circular A-4 (2003), as regulatory agencies have done for twenty years, EPA now wishes to arbitrarily disregard the principles and regulatory analysis established in that document. They add that they believe that this is inappropriate as well as arbitrary and capricious. The commenter provides that, to justify not including a 7 percent discount rate, EPA states:

OMB Circular A-4 (2003) recognizes that special considerations arise when applying discount rates if intergenerational effects are important. In the IWG's 2015 Response to Comments, OMB—as a co-chair of the IWG—made clear that “Circular A-4 (2003) is a living document,” that “the use of 7 percent is not considered appropriate for intergenerational discounting,” and that “[t]here is wide support for this view in the academic literature, and it is recognized in Circular A-4 (2003) itself.”<sup>58</sup>

The commenter (2344-IER) notes that the EPA's description here is intentionally misleading and wrong. Circular A-4 (2003) has a section on intergenerational discounting. It specifically contemplates the ethical issues with intergenerational discounting. For example, Circular A-4 (2003) states:

Some believe, however, that it is ethically impermissible to discount the utility of future generations. That is, government should treat all generations equally. Even under this approach, it would still be correct to discount future costs and consumption benefits generally (perhaps at a lower rate than for intragenerational analysis), due to the expectation that future generations will be wealthier and thus will value a marginal dollar of benefits or costs by less than those alive today. Therefore, it is appropriate to discount future benefits and costs relative to current benefits and costs, even if the welfare of future generations is not being discounted. Estimates of the appropriate discount rate appropriate in this case, from the 1990s, ranged from 1 to 3 percent per annum.<sup>59</sup>

<sup>59</sup> OMB, Circular A-4 (2003), at 35-36.

After explaining this, as well as the difficulty of determining discount rates for longer time horizons, the commenter (2344-IER) provides that Circular A-4 (2003) states, “If your rule will have important intergenerational benefits or costs you might consider a further sensitivity analysis using a lower but positive discount rate in addition to calculating net benefits using discount rates of 3 and 7 percent.”<sup>60</sup> In other words, under Circular A-4 (2003), EPA may include lower discount rates in its analysis and EPA may include a sensitivity analysis, however, this should be “in addition to calculating net benefits using discount rates of 3 and 7 percent.”

The commenter (2344-IER) contends that the EPA’s continued mischaracterization of the requirements of Circular A-4 (2003) is concerning. Circular A-4 (2003) specifically contemplates and allows other discount rates in addition to 3 and 7 percent. The commenter states that it is unclear why EPA would continually choose to willfully ignore and mischaracterize the requirements of Circular A-4 (2003) other than to obfuscate the impacts of proposed regulation to the American people and the courts. The commenter adds that this is especially true because there is value in providing additional information. As Nobel prize winner William Nordhaus explained:

There are many perspectives through which to view the future costs and benefits of policies to slow global warming. These perspectives differ in terms of normative assumptions, national interests, estimated behavioral structures, scientific data and modeling, risk aversion, and the prospects of future learning. No sensible policymaker would base the globe’s future on a single model, a single set of computer runs, or a single national or ethical perspective. Sensible decision making requires a robust set of alternative scenarios and sensitivity analyses to determine whether some rabbit has in the dead of night jumped into the hat and is responsible for unusual results.<sup>61</sup>

The commenter (2344-IER) asserts that, to have a robust set of alternative scenarios, EPA has to include a scenario with a 7 percent discount rate.

Response II-20-17: A detailed response regarding the omission of SC-GHG estimates using the 7% discount rate can be found in the Appendix of this RTC where responses are provided on comments pertaining to EPA’s September 2022 *Draft Report on the Social Cost of Greenhouse Gases: Estimates Incorporating Recent Scientific Advances*.

In addition, EPA notes that the RIA provides estimates for the costs and non-GHG benefits at 2%, 3%, and 7% discount rates.

Comment: Commenter (2359-CEI) suggests that the EPA defends the Obama and Biden administrations’ practice of comparing domestic regulatory costs to global climate benefits, noting, for example, that international trade, investment, and tourism create “spillover pathways” that make other nations’ problems our problems as well.<sup>62</sup> Whatever the merits of that argument, the commenter states that it does not alter the fact that Americans bear most of the costs of

---

<sup>60</sup> OMB, Circular A-4 (2003), at 36.

<sup>61</sup> William D. Nordhaus, A Review of the Stern Review on the Economics of Climate Change, 45 J. of Econ. Lit. 686, at 701, Sept. 2007.

<sup>62</sup> RIA, p. 3-9.

regulations on the U.S. gas industry while non-Americans reap most of the purported climate benefits asserted for the proposed rule.

The commenter (2359-CEI) adds that, however valid it may be to present an estimate of global climate benefits, those should be reported separately from estimated domestic benefits, as OMB Circular A-4 (2003) directs.<sup>63</sup> The commenter asserts that there is no scientific or ethical justification for hiding the comparatively smaller domestic benefits of U.S. climate regulations.

Response II-20-18: A detailed response regarding the use of global SC-GHG estimates can be found in the Appendix of this RTC where responses are provided on comments pertaining to EPA's September 2022 *Draft Report on the Social Cost of Greenhouse Gases: Estimates Incorporating Recent Scientific Advances*.

Comment: Commenter (2343-NYU School of Law) notes that the RIA limits its analysis to impacts that occur between 2023 and 2035.<sup>64</sup> The commenter requests that EPA better explain the justification for and expected implications of the selected time horizon, including whether the agency expects—as is often the case—that significant benefits will accrue beyond 2035.<sup>65</sup> Though EPA concedes that “it would be desirable to analyze impacts beyond 2035,” the commenter states that it concludes that “limited information available to model long-term changes in practices and equipment use in the oil and natural gas industry make the choice of a longer time horizon infeasible.”<sup>66</sup> It further claims that, “[i]n a dynamic industry like oil and natural gas, technological progress is likely to change control methods to a greater extent over a longer time horizon, creating more uncertainty about impacts of the” proposed standards.<sup>67</sup> The commenter recommends that EPA consider how other agencies have made predictions for the oil and gas industry further into the future.<sup>68</sup>

The commenter (2343-NYU School of Law) provides that, as Circular A-4 (2003) notes, “[t]he time frame for [an agency’s] analysis should cover a period long enough to encompass all the important benefits and costs likely to result from the rule.”<sup>69</sup> Even if predicting the impacts that these proposed standards will have after 2035 is difficult, failing to assess (either quantitatively

<sup>68</sup> See, e.g., BOEM 2022 PEIS, *supra* note 6, at iii; ENERGY INFO. AGENCY, ANNUAL ENERGY OUTLOOK 2022 WITH PROJECTIONS TO 2050: NARRATIVE 2, 26–36 (2022), <https://perma.cc/D5D7-T4JJ> (modeling the production and consumption of oil and natural gas until 2050 under multiple assumptions and methodologies including consideration of technological changes, laws, and regulations).

<sup>69</sup> Off. of Mgmt. & Budget, Circular A-4, at 15 (2003), <https://perma.cc/X8JM-YZMT> [hereinafter Circular A-4 (2003)].

or qualitatively) any impacts after that time would be tantamount to assuming those impacts would be negligible or zero. According to the commenter, the greater likelihood is that new standards would have long-term effects that—while perhaps difficult to predict with precision—would be nontrivial compared to the baseline. Put differently, EPA’s proposed standards would very likely change the oil and gas sector in ways that would last well beyond 2035 compared to a world in which it changed nothing, even if more precise predictions would be difficult to develop.

Response II-20-19: The EPA extended the analysis horizon beyond 2035 to 2038 but declined to extend the analysis further due to the significant uncertainties in projected long-run sectoral trends; see Section 5.2 in the Final RIA for additional discussion. EPA notes that while EIA has made projections for oil and gas production and consumption beyond 2050, the modeling approaches are far different than those employed by EPA and do not require the detailed representation of emissions needed to assess regulatory impacts. While the EPA does not dispute that the regulation may change the oil and gas sector in ways that extend beyond the analysis horizon of the RIA, it maintains that such impacts are sufficiently speculative that little additional value would be gained by further extending the analysis.

Comment: Commenter (2254-PBPA) notes that the EPA estimated the impacts of changes in GHGs using an updated estimate for SCC and SCM. In 2021, the SCC was \$51/ton and the SCM was \$1,500/ton. As part of this proposal, the EPA has adopted an SCC of \$190/ton and an SCM of \$1,900/ton. The commenter states that, not only does the Proposed Rule include a massive increase in the estimate for the SCC and SCM, but the Proposed Rule incorrectly evaluated global benefits, instead of domestic benefits, and applied the incorrect discount rate.

The commenter (2254-PBPA) states that they know that EPA failed to properly evaluate benefits and used the incorrect discount rate because President George W. Bush’s OMB issued Circular A-4 in 2003 to ensure agencies use a “standardiz[ed]” way of “measur[ing] and report[ing]” the “benefits and costs of Federal regulatory actions.”<sup>70</sup> Circular A-4 (2003) contains two foundational principles: first, agencies are to use a 3 and 7 percent discount rate; second, agencies are to consider domestic—rather than global—costs and benefits.

However, the commenter (2254-PBPA) contends that the EPA ignored these principles and applied multiple discount rates of 2.5, 3, and 5 percent – ultimately 3% was the selected rate. The commenter adds that Circular A-4 (2003) also instructs agencies to make domestic effects the basis of their analysis: “Your analysis should focus on benefits and costs that accrue to citizens and residents of the United States. Where you choose to evaluate a regulation that is likely to have effects beyond the borders of the United States, these effects should be reported separately.”<sup>71</sup> Yet, the commenter complains that the EPA openly relied on global effects in developing its 2022 SCC and SCM estimates.

---

<sup>70</sup> Circular A-4, at 1 (September 17, 2003).

<sup>71</sup> Id. at 15. Courts have recognized this unmistakable direction to focus on domestic, rather than global, effects. See *Wyoming v. United States Dep’t of the Interior*, 2020 WL 7641067, at \*21 (D. Wyo. Oct. 8, 2020) (noting that Circular A-4 (2003) mandates a national focus); *State v. Bureau of Land Mgmt.*, 286 F. Supp. 3d 1054, 1069 (N.D.

The commenter (2254-PBPA) concludes by asserting that the Proposed Rule should not be finalized until EPA revises its analysis to be consistent with Circular A-4 (2003).

Commenter (2237-ICND) states that the EPA's reliance on EO 13990 does not excuse it from its obligations under the CAA to justify the Supplemental Proposal based on national, and not global benefits allegedly associated with the Proposal. OMB Circular A-4 (2003), on which EPA relies, specifically directs EPA to focus its analysis "on benefits and costs that accrue to citizens and residents of the United States." (Circular A-4 (2003) at E.1.) Where an agency chooses to evaluate a regulation that is "likely to have effects beyond the borders of the United States, these effects should be reported separately" (id.). The commenter contends that the EPA has violated the direction of Circular A-4 (2003), explicitly stating that it has not calculated a domestic social cost of GHGs that would allow an "apples-to-apples" evaluation of the domestic costs of the Supplemental Proposal against the domestic benefits.

Conversely, commenter (2208-CCES et al) states that the EPA appropriately accounts for global climate damages in the Draft Update, following the approach consistently applied by the Working Group that EPA first adopted under the George W. Bush administration.<sup>72</sup> Including climate impacts that originate abroad but affect domestic welfare is consistent with Circular A-4 (2003)'s guidance that agency analysis incorporate effects "that accrue to citizens and residents of the United States" and to also report "effects beyond the borders of the United States."<sup>73</sup> The commenter adds that they believe that EPA correctly identifies numerous pathways through which the use of global climate-damage valuations captures critical climate-change impacts that affect the U.S. and its citizens but do not originate within the country's borders. For one, as EPA explains, U.S. economic, national security, public health, and humanitarian concerns are "inextricably linked to the rest of the world" such that climate-change impacts that originate in foreign countries will inevitably spill over into the U.S., affecting global supply chains, migration patterns, and security risks.<sup>74</sup> EPA also recognizes that "climate change will directly impact U.S. interests that are located abroad," highlighting the millions of U.S. citizens living abroad, the more than \$6 trillion in U.S. assets located abroad, the more than 500 U.S. military bases located abroad, and U.S. resources in the global commons such as fisheries.<sup>75</sup>

Response II-20-20: A detailed response regarding the use of global SC-GHG estimates and the omission of SC-GHG estimates using the 7% discount rate can be found in the Appendix of this RTC where responses are provided on comments pertaining to EPA's September 2022 *Draft*

---

Cal. 2018) ("While Plaintiffs argue that the same Circular directs BLM to encompass 'all the important benefits and costs likely to result from the rule,' including 'any important ancillary benefits,' it does not specifically mandate that agencies consider global impacts."). Reflecting this clear directive, "the typical agency practice is, in fact, to leave foreign impacts out of cost-benefit analyses entirely." Arden Rowell, Foreign Impacts and Climate Change, 39 Harv. Envtl. L. Rev. 371, 373 (2015); Smith Decl. 18 ("Circular A-4 (2003) still requires that analysis results be presented for both the 3% and 7% discount rates, and for domestic benefits alone.").

## **20.2 Impacts to Regulatory Agencies**

Comment: Several commenters (2179-KIOGA, 2220-WDEQ, 2222-WDNR, 2225-WESTAR, 2237-NDIC, 2247-OH EPA, 2288-NDDEQ, 2292-WVAG et al, 2294-OOGA, 2330-KDAQ, 2310-MDEQ, 2322-AR DEQ, 2337-KDHE, 2393-OSEE, 2403-PAO, 2418-SDDANR) express concern that the proposed rule imposes a significant burden on state resources. Many of the commenters are specifically concerned with the impacts anticipated due to the EG implementation workload requirements. Commenters contend that the burden may impact implementation. Several commenters request that EPA provide additional funding to states, tribes and local air agencies to plan for and implement the proposed rules. Examples of some of the comments provided are presented in the following paragraphs.

Commenter (2222-WDNR) expresses concern with the significant workload required to identify existing facilities affected by the EG due to EPA failing to provide a list of affected facilities.

Commenter (2247-OH EPA) expresses concern about the amount of work associated with the EGs because of the large number of wells in existence. The commenter requests that EPA provide adequate time. The commenter reports that according to Ohio's Department of Natural Resources, Ohio currently has more than 53,000 operating oil & gas wells. The commenter states that currently, Ohio EPA regulates only a subset of these wells – only the horizontally fracked wells that have been installed since in 2011. This amounts to about 725 well sites. The commenter states that these wells are currently regulated under the General Permit (GP) program where each well site gets issued a permit with standard terms and conditions. The commenter notes that upon the adoption of revised rules to take into account EPA's proposal, the state will need to update the General Permits. The commenter reports that this will be a resource intensive process. The commenter adds that there are 52,250 unregulated wells. The commenter states that Ohio has not regulated these wells because the level of VOC emitted from each well were minor. However, under these proposed rules, the commenter notes that Ohio will need to regulate substantially more wells.

Commenter (2403-PAO) expresses concern with EPA unnecessarily burdening state delegated agencies with excessive requirements if they don't adhere to the Proposed Rule's presumptive standards for existing sources. Commenter (2322-AR DEQ) expresses concern that the EPA's Proposed Rule contains requirements for entities spanning the entire range of production volume, from the largest producing well-pads to single well-heads that are purely domestic in nature and used for home heating. The commenter reports that their agency currently permits approximately 200 facilities in the oil and natural gas sector through its Office of Air Quality. The Arkansas Department of Energy and Environment's Oil and Gas Commission (OGC) currently permits approximately 19,000 oil and gas wells, 1700 tank batteries, and 5000 miles of natural gas pipeline and other potentially affected sites. Under the Proposed Rule, the commenter states that their agency will become responsible for the implementation, development of compliance strategy and determination, and enforcement for over 60,000 sources. The number of sources will likely increase as development continues to meet the energy needs of Arkansas and

surrounding states that gain energy stability from marketable Arkansas products. The commenter asserts that the state simply cannot expand capacity under current constraints to adequately permit and enforce both the delegated NSPS and a state plan for existing sources under the Proposed Rule.

Commenter (2294-OOGA) notes that the Ohio EPA will be responsible for the permitting, compliance/enforcement actions, and other planning efforts for the 62,000 oil and natural gas wells in Ohio. The costs and resources (e.g., administrative staff, office space, and training) necessary significantly exceed Ohio EPA's current budget and personnel. Add the 2-year compliance timeframe, and a herculean order becomes an almost certain impossibility.

Similarly, commenter (2393-OSEE) is concerned about the significant cost of the implementation of a compliance and enforcement program for such a massive amount of facilities. Without additional funding from EPA, the commenter states that resources will be stretched very thin. The commenter believes that this could create an environment where some companies try to take advantage of these limitations and make no good faith effort to comply with EG OOOOc. The commenter notes that companies that do comply are placed at an economic disadvantage, thus creating an unlevel playing field.

Commenter (2418-SDDANR) disagrees with EPA's assertion that the proposal does not meet the requirement for an unfunded mandate because the estimated costs are less than \$100 million. The proposed EG will require the implementation of the proposed rulemaking, inform the affected sources, and perform compliance activities on those sources. The commenter estimates that there are hundreds of sources in South Dakota that are not currently affected by air permitting that could be subject to the proposed emission guidelines. South Dakota's federal funding received to implement its existing programs has been stagnant for over 20 years. The commenter asserts that EPA continues to ask states to do more with its existing resources without additional funding.

Commenter (2225-WESTAR) notes that states acknowledge that this ambitious agenda, coupled with implementing programs under the Inflation Reduction Act (IRA), will be demanding, especially given understaffing issues at both the federal and state levels. Not having a clear picture of funding mechanisms, whether it's potential IRA funding or other funding streams, means states, tribes, and local air agencies cannot clearly plan for what it may take to implement all requirements under the proposed rule. The commenter asserts that the cost burden for agencies with large numbers of oil and gas facilities is not insignificant, and with no additional funding to air agencies identified, state, tribal, and local air agency programs will be strained.

Commenter (2292-WVAG et al) provides that West Virginia's environmental regulatory agency noted that implementing EPA's timetable of existing source monitoring in West Virginia alone could cost over \$278 million each year.<sup>76</sup> The commenter asserts that these costs will increase due to the extra requirements of the December 2022 supplemental proposal. For example, the states' implementation plans will add significant compliance costs because the states must follow

---

<sup>76</sup> See W. Va. Dep't of Env't Prot., Comment Letter on Proposed Rule Establishing New Standards of Performance for New and Modified Sources of Methane In the Oil and Natural Gas Sector 2 (Jan. 14, 2022), <http://bit.ly/3HQDjdU>.

various new calculation and monitoring requirements to invoke remaining useful life, and community outreach.

Commenter (2179-KIOGA) asserts that the proposed rule imposes a burden and insurmountable costs for the state. The commenter notes that there are over 62,000 oil wells and over 20,000 natural gas wells in Kansas. Other comparable states estimated costs to develop and implement this proposed rulemaking to be over \$40 million annually. Furthermore, the commenter asserts that these states estimate the cost on the proposed timing (final compliance within 2 years) is even more outrageous at over \$278 million annually. The estimate includes 2,708 additional full time equivalent persons to be hired. Kansas would incur similar costs.

Commenter (2220-WDEQ) believes that EPA did not realistically evaluate impacts to states and notes that EPA has not provided funding to states. The commenter notes that as a nationally prominent producer of oil and natural gas, Wyoming will bear a disproportionate burden to implement this rule compared to many other affected states. As of October 2022, Wyoming ranked eighth nationally in oil production<sup>77</sup> and for the 2021 calendar year, Wyoming ranked ninth in marketed production of natural gas.<sup>78</sup> Furthermore, the commenter notes that Wyoming has 16 of the nation's 100 largest natural gas fields, including the Pinedale and Jonah fields, which rank among the top 10.<sup>79</sup> According to the Wyoming State Geological Survey, Wyoming operators were on track to produce about 90 million barrels of oil in 2022.<sup>80</sup> The commenter states that because of the state's CAA primacy programs and other regulatory authority over Wyoming's extensive oil and gas industry, all areas in the state are meeting ambient air quality standards. The commenter notes that state programs cover over 18,000 operating single well sites and compressor stations. The number of these sites alone is significant, but it pales in comparison to the increase in specific equipment that would be subject to the proposed rule such as pneumatic pumps and controllers.

As such, the commenter (2220-WDEQ) contends that the supplemental proposal imposes compliance assurance costs on Wyoming without providing the funding to meet these additional federal regulatory burdens. For more than a decade, the commenter notes that federal funds have only provided about 7 percent of the state's budget, with the rest coming from operator-paid fees or the State's General Fund. With the additional costs that will be imposed on Wyoming to implement the supplemental proposal, the proportion of federal funds will be further decreased, and the burden shifted to Wyoming's citizens and industry to shoulder the difference.

The commenter (2220-WDEQ) asserts that those costs are of a magnitude that is simply unworkable for the state (and likely other state regulatory agencies) with no significant environmental outcomes. The proposed requirements pertaining to fugitive emissions monitoring and repair programs, including monitoring for fugitive emissions with optimal gas imaging (OGI), impose a massive reciprocal workload for state agencies. Conducting the compliance

<sup>80</sup> Wyoming State Geological Survey, Erin A. Campbell, Director and State Geologist, "Oil & Natural Gas Resources in Wyoming," January 2023 Summary Report.

inspections, reports, and emissions inventories work commensurate with the requirements of the supplemental proposal places an overwhelming strain on agency staff and financial resources. The enormous increase in workload would require hiring additional full-time employees (FTE), as well as training costs, equipment costs, and other associated costs. But the proposed rule does not fairly take these costs into consideration.

The commenter (2220-WDEQ) notes that the EPA projects that the number of incrementally impacted facilities will increase immensely between 2025 and 2026. For example, EPA notes that affected well site fugitives will jump from 31,000 to 520,000 between those two years (increasing by 16.77 times). Affected transmission and storage compressor stations will jump from 0 to 1,900. Applicable pneumatic devices will jump from 167,600 to 1,400,000 (increasing by 8.35 times), affected liquids unloading operations will jump from 15,000 to 260,000 (increasing by 17.33 times). The commenter asserts that it is not possible to definitively assess the scope of impacts upon facilities in Wyoming because there are not defined requirements included in the proposed rule. However, if the commenter applies a rough estimate of an incremental jump of roughly ten times, or even five times, for its statewide affected facility impacts, the associated costs to the agency would be immense.

The commenter (2220-WDEQ) reports that currently, state staff complete about 1,000 Full Compliance Evaluations (FCEs) on oil and gas sites annually, with an additional 1,500 site visits or Partial Compliance Evaluations (PCEs). The staff also reviews more than 26,000 reports annually. The commenter provides that State compliance staff that undertakes this work includes 22 positions that span from entry-level engineers to senior-level engineers, with an annual salary and fringe benefit cost to the agency of nearly \$3 million.<sup>81</sup> Given the tight window for reviewing the massive scope of the proposed rule, it is difficult for the commenter to provide a precise estimate of the number of additional reports that will need to be undertaken, the amount of additional time needed to conduct an FCE as a result of the added inspection requirements, and the increased number of FCEs, PCEs, and site visits that will be necessary. However, given the estimated incremental jump of statewide affected facilities, the commenter notes it is beyond dispute that the supplemental proposal will have a massive impact upon the workload of the State's compliance program – and, given the number of existing FTE, would have a severe impact upon the number of other inspections that could be completed annually.

Furthermore, the commenter (2220-WDEQ) asserts that the proposed specifications in Appendix K relating to such things as the required performance of qualifying infrared cameras and required training and verification, impose significant additional costs to the agency. The commenter estimates that initial training costs alone to certify staff in operating OGI cameras would initially be roughly \$80,000 to \$100,000. The cost of purchasing and regularly maintaining necessary OGI equipment to comply with the requirements is estimated at \$1.3 million. There are also additional concerns regarding the 1,400 survey hour requirement (including 40 hours in the past 12 months) necessary to qualify senior OGI camera operators in Appendix K, as well as the initial field training requirements for other operators. The commenter has concerns regarding the qualified personnel requirements for conducting the necessary inspections; given the more restrictive parameters. The commenter states that it would have to redirect staff resources to meet these requirements, which would inhibit the agency's ability to meet other compliance

---

<sup>81</sup> Cost statistics regarding FTE/Additional FTE provided by WDEQ's Administration Division.

obligations. Moreover, they state that there would likely be higher travel costs to the agency given the significant increase in site visits.

The commenter (2220-WDEQ) provides that it is impossible to provide specific costs to the agency to fulfill the compliance demands of the supplemental proposal in the condensed timeframe allocated by EPA for submitting comments. However, given the incremental jump in affected facilities, a general idea of some of the inspection requirements, and associated training costs, equipment costs, travel costs, and other costs, it is reasonable to assume the agency would have to hire significantly more staff. The commenter provides that the associated cost of hiring even five additional compliance staff (one of whom would be at a senior level) would cost the agency \$670,000 annually. These estimates, coupled with the costs identified above, would impose an immediate financial burden on the agency of about \$2.1 million, which does not account for recurring annual employee costs, recurring equipment maintenance and update costs, recurring future travel costs, office space and equipment costs, etc. The commenter asserts that the supplemental proposal also will likely require hiring additional full time equivalent (FTE) support (or contractor support) for completing the state plan requirements and other implementation provisions. Adding three FTE under their State Implementation Plan & Rule Development section would result in an additional \$390,000 annual burden, bringing the annual salary and fringe benefit burden associated with the supplemental proposal to \$1,060,000 for eight additional positions. In total, they report that the immediate financial burden on the agency would be nearly \$3 million, which is more than a 10 percent increase in the State agency's current total budget.<sup>82</sup>

Commenter (2220-WDEQ) states that the RIA does not represent the potential costs that state-level regulatory agencies will have to bear to meet the implementation requirements of the supplemental proposal. The commenter notes that the RIA only represents the projected compliance costs and projected regulatory costs as applied to the oil and natural gas markets. The commenter explains that State agencies will incur significant costs to meet the compliance requirements, reporting and recordkeeping requirements, requirements for developing State Plans, and conducting the consequential meaningful engagement required in the supplemental proposal. In order for the commenter (representing the Wyoming Department of Environmental Quality) to effectively address the immense increase in workload associated with the supplemental proposal, additional staff would need to be added to its programs for Compliance, State Implementation Planning and Rule Development, and potentially other areas. Based on February 2023 cost estimates, the commenter anticipates an immediate financial burden to the agency of nearly \$3 million (which includes a one-time cost for purchasing and maintaining technical equipment and training staff to meet the requirements of the supplemental proposal, as well as an annual cost for employing, at a minimum, eight additional staff to perform the activities associated with the supplemental proposal).<sup>83</sup> The commenter provides a full breakdown of the resulting costs to their agency from the supplemental proposal in Section 5 and Section 8 of their comments.

---

<sup>82</sup> Cost statistics regarding FTE/additional FTE provided by WDEQ's Administration Division; cost-estimates regarding compliance duties associated with the proposed rule provided by AQD's Compliance Program.

<sup>83</sup> Cost statistics regarding FTE/Additional FTE provided by WDEQ's Administration Division; cost-estimates regarding compliance duties associated with the supplemental proposal provided by AQD's Compliance Program.

The commenter (2220-WDEQ) notes that the EPA attempts to address the cost burden associated with the supplemental proposal on pages 74844-74845 of the preamble (D. Unfunded Mandates Reform Act (UMRA)). The commenter provides that the EPA considers the EG-associated costs as a result of NSPS OOOOc as follows:

The EPA is proposed under CAA section 111(d) and does not impose any direct compliance requirements on designated facilities, apart from the requirement for states to develop state plans. As explained in section XIV.G. of the November 2021 proposal and section V of this supplemental proposal, the EG also does not impose specific requirements on tribal governments that have designated facilities located in their area of Indian country. The burden for states to develop state plans following promulgation of the rule is estimated to be below \$100 million in any one year. Thus, the EG is not subject to the requirements of section 203 or section 205 of the UMRA.

The commenter (2220-WDEQ) recommends that the EPA recognize that even though a rulemaking is projected by EPA to fall below the \$100 million economic impact, there may nevertheless be a significant fiscal impact on a state's economy and/or on a state's regulatory program. State economies vary in size and certain industries have varying degrees of influence on state economies. Furthermore, the commenter explains that state implementing agencies vary across the country in size and available funding; not all states have the same resources or staffing available for implementing a plan that dramatically increases the demand on existing resources to regulate the universe of affected sources in that state. The costs to state agencies not only include the development of state plans, as cited by EPA in its cost-burden analysis, but also includes the implementation of those plans. The commenter adds that this problem is further complicated by the nationwide challenge that both federal and state agencies are experiencing in recruiting and retaining qualified air quality staff. This issue is further exacerbated by the large number of proposed rules that EPA is promulgating and associated unfunded mandates. It is reasonable that EPA considers this in its impacts of the supplemental proposal.

The commenter (2220-WDEQ) suggests that the supplemental proposal has an outsized impact upon states like Wyoming whose economies are resource-dependent. They add that the proposal will have an outsized impact upon agencies like theirs that may have significantly smaller staffing and less funding available compared to other state agencies. A "one-size-fits-all" approach to the benefits and costs associated with implementing a rulemaking does not reflect how a rulemaking may affect certain states differently than others. The commenter states that the fact that EPA did not provide specific figures in the RIA for the costs to state-level agencies to implement the supplemental proposal is problematic and lacks transparency. Furthermore, they add that the cumulative cost totals for implementing the supplemental proposal nationally do not show the disproportionate manner in which certain agencies like theirs are more heavily burdened than other states. The commenter contends that it is crucial that EPA takes this into consideration when promulgating a final rule and that the federal government provides states with the funding for staffing and resources necessary for implementation of state plans.

Commenter (2310-MDEQ) requests commensurate funding to develop and implement the proposed rule. The commenter asserts that the current rate of regulatory activity proposed by EPA is unprecedented, while long term funding to states has remained flat. The commenter notes

that states are struggling with financial resources needed to adequately staff the increase in workload. The commenter adds that not only are states struggling to retain and recruit staff, but regional EPA offices are also operating with fewer staff. Rather than adding more burden to a stressed system, the commenter believes that this is EPA's opportunity to develop appropriate timelines and ensure adequate funding to their co-regulators, the states, to ensure their goals of increased environmental protection can be met.

Commenter (2337-KDHE) reports that the proposed EGs would impose a burden and insurmountable costs for Kansas. The commenter contends that the proposed rule is flawed since it pertains to state implementation of the EGs but ignores the costs to the states to implement the EGs for existing sources. The commenter reports that there are approximately 78,000 active oil wells and 28,000 active natural gas (including coalbed methane (CBM)) wells<sup>84</sup> within the state.

Although the commenter (2337-KDHE) has not done an in-depth cost analysis at this time, an estimate regarding the potential impact on the state to develop and implement the proposed rule (without any additional sources or activities where EPA solicited comment), based on approximately 106,000 permitting actions, compliance efforts, and other planning related activities to develop a state rule and State Plan in accordance with the proposal, would be enormous. The commenter reports that 93 of the 105 counties in Kansas have oil and gas well activity.

The commenter (2337-KDHE) notes that in the preamble, EPA states their commitment to providing "aid and guidance" to states. The commenter contends that "aid and guidance" are not an acceptable substitute for adequate funding needed for this proposed federal initiative being imposed upon the state. The commenter notes that EPA does not include costs for the states to comply with the EGs. The commenter asserts that states, not affected facilities, are subject to the EGs; therefore, this proposed rule is flawed since it pertains to state implementation of the EGs but ignores the costs to the states to implement the EGs for existing sources.

Commenters (2288-NDDEQ, 2237-NDIC) separate funding comments into two categories: initial funding for the development of a state plan implementing EG OOOOc and initial funding for implementation of NSPS OOOOb requirements, and ongoing funding to assist with ensuring continued compliance with both the state plan and NSPS OOOOb.

First, the commenters (2288-NDDEQ, 2237-NDIC) express concern regarding the apparent lack of resources provided for the development of a state plan addressing designated facilities in the oil and gas sector. The commenters are unaware of any additional federal funding being allocated to already resource constrained state budgets. The commenters request that EPA explain how states are to successfully take on this additional regulatory burden without adequate funding.

Second, the commenters (2288-NDDEQ, 2237-NDIC) note that in addition to submitting these comments, it is evaluating the revised proposal for its full impact upon sources within the state. Even so, the evaluation so far has revealed an expansive list of requirements for owners and operators that the commenter will have to review and investigate to determine how best to implement compliance actions. Unlike EPA, the commenters strongly believe that it is critical to

---

<sup>84</sup> According to the table at <https://www.kgs.ku.edu/PRS/countyStats.html>.

conduct a combination of compliance oversight including field inspections, onsite record reviews, and company audits, in addition to EPA's preferred approach or report review only. The commenters state that regulation without active and collaborative oversight is meaningless and burdensome. However, all this effort takes considerable resources that EPA has so far offered no assistance for. The commenters are concerned with its commitment that "[f]or most designated facilities, the EPA proposes to conclude that compliance with the implementing state or Federal plan that is consistent with the presumptive standards in EG OOOOc would constitute compliance with the older NSPS because the presumptive standards proposed for EG OOOOc result in the same or greater emission reductions than the current standards in the older NSPS." If the EPA goes forward with this commitment, they state that it will require that they devote resources (of which EPA has not provided) towards the implementation of EG OOOOc for previously unregulated sources, but also to devote NSPS KKK, OOOO, and OOOOa resources towards reviewing EG OOOOc documentation to determine if that documentation fulfills the NSPS KKK, OOOO, or OOOOa requirements. According to the commenters, if EPA believes that the proposed EG OOOOc could result in the same emission reductions as current programs, then the proposal for additional regulatory actions are burdensome without environmental benefit. The commenters assert that EPA must show empirical data that the proposed regulations actually improve environmental protection over the existing state/federal regulations and if they do then EPA must provide resources commensurate with the intended regulation. If either of these cannot be accomplished, then the commenters recommend that EPA retract the proposed regulation in its entirety.

Commenter (3845-ND Congress) reports that the EPA's proposed rule will impose additional costs on North Dakota agencies. The commenter notes that NDDEQ required multiple additional full-time employees and millions of dollars in appropriated funds to accept delegation of NSPS OOOOa several years ago. The commenter is worried that the EPA's proposed rule creates new obligations on new sources and would require regulation of existing sources as well. The commenter contends that this goes well beyond the scope of NSPS OOOOa and will require significantly more resources for NDDEQ to implement. However, the commenter argues that the EPA has provided no additional funding for the state. In fact, the commenter contends that the rule is likely to diminish state funds via reductions in royalties and taxes. The proposed rule's unfunded new mandates will strain the NDDEQ's ability to adequately enforce its existing regulations.

Commenter (2225-WESTAR) notes that EPA has over 100 actions on its Fall 2022 Regulatory Agenda, including major nationwide rules with broad applicability. In October 2022, EPA proposed the Prevention of Significant Deterioration (PSD) and Nonattainment New Source Review (NNSR): Reconsideration of Fugitive Emissions Rule and then in December 2022, proposed updated requirements to the Adoption and Submittal of State Plans for Designated Facilities: Implementing Regulations Under the Clean Air Act Section 111(d). Along with the Bureau of Land Management's November 2022 proposed rule for Waste Prevention, Production Subject to Royalties, and Resource Conservation, the intertwined impacts of all these rules feel very uncertain. The commenter reports that Western state, tribal, and local air agencies are concerned about the unknown comprehensive effect of advancing these actions simultaneously.

The commenter (2225-WESTAR) provides that states acknowledge that an ambitious regulatory agenda, coupled with implementing programs under the Inflation Reduction Act (IRA), will be demanding, especially given understaffing issues at both the federal and state levels. The

commenter asserts that not having a clear picture of funding mechanisms, whether it's potential IRA funding or other funding streams, means states, tribes, and local air agencies cannot clearly plan for what it may take to implement all requirements under the proposed rule. The commenter notes that the cost burden for agencies with large numbers of oil and gas facilities is not insignificant, and with no additional funding to air agencies identified, state, tribal, and local air agency programs will certainly be strained. The commenter states that state, tribal, and local air agencies will need additional funding from EPA to successfully plan for and implement the requirements.

Commenter (2330-KDAQ) states that EPA's complicated and piecemeal approach in this proposal has not provided meaningful opportunity to comment on the proposed rulemaking. The commenter is unable to fully evaluate the sources and source inventory under this rulemaking as proposed; however, the commenter has estimated approximately 60,000 sources that may become subject to the requirements in the proposed rule. The commenter estimates that the need to add a minimum of 100 staff to evaluate sources, create agency identification numbers, draft permits, and do inspections and monitor compliance.

The commenter (2330-KDAQ) asserts that the rulemaking potentially affects sources that have never been subject to permitting under the CAA. The commenter expects that many sources are unfamiliar with air quality regulations, and they will need significant technical assistance in all areas of compliance and permitting. For example, continued monitoring until wells are permanently plugged as proposed in this rulemaking could potentially require years and years of monitoring and oversight by state regulatory agencies. The commenter contends that EPA support to state regulatory agencies is needed to provide this additional service.

Response II-20-21: The EPA appreciates regulatory agencies' concerns regarding the impact the final rule would have on state resources. the EPA notes that the Information Collection Request (ICR) and supporting statements for the November 2021 Proposed Rule and the December 2022 Supplemental Proposal included detailed estimates of the time and resources required by state agencies to develop and implement the emission guidelines. While these commenters provided information related to their anticipated burden, they did not provide any specific comments on that analysis [or offer any information that might change the analysis]. These impacts are also contained in the ICR and supporting statements for the December 2022 Supplemental Proposal and the final rule. With regard to EPA's estimated reporting and recordkeeping burden for the December 2022 Supplemental Proposal, see the ICR Supporting Statements located at Document ID Item Nos. EPA-HQ-OAR-2021-0317-0144 (NSPS OOOO and NSPS OOOOa), EPA-HQ-OAR-2021-0317-1556 (NSPS OOOOb), EPA-HQ-OAR-2021-0317-1553 (EG OOOOc), for this action located at Docket ID No. EPA-HQ-OAR-2021-0317. Updated ICR Supporting Statements for this final action are also located in Docket ID No. EPA-HQ-OAR-2021-0317. See also the response II-20-14.

With respect to commenter's (2220-WDEQ) assertion that the RIA does not include state implementation costs for the rule, EPA notes that the costs estimated and presented in the ICRs

are significantly smaller than the estimated compliance costs of the rule, so their inclusion would not meaningfully affect the estimated net benefits of the rule.

As discussed under section XVII.D (Unfunded Mandates Reform Act (UMRA)), the burden for states to develop state plans following promulgation of the rule is estimated to be below \$100 million in any 1 year. See also section VII.B (Paperwork Reduction Act (PRA)) of the final rule preamble for EPA's estimate of the recordkeeping and reporting requirements under NSPS OOOOa, NSPS OOOOb, and EG OOOOc. For EG OOOOc, the annual burden for the states (averaged over the first 3 years following promulgation) is estimated to range from 166,000 to 208,000 hours at a total annual labor cost of between \$21 to \$26 million.

### **20.3 Unfunded Mandates Reform Act (UMRA)**

Comment: Commenter (2219-Wyoming Oil and Gas Conservation Commission (WOGCC)) states that, in consideration of the Unfunded Mandate Reform Act (UMRA), EPA does not evaluate the full impact of the proposed rule on state and local governments. The commenter notes that not only will these governments be required to develop state plans, but also EPA appears to imply that well closure requirements will be implemented on orphaned wells. The commenter believes if that is the case then the states would be required to conduct emissions monitoring and leak repair on orphan wells, supply well closure and financial assurance plans to EPA, and ultimately will be required to plug significant numbers of wells that are orphaned because of this rule. The commenter adds that these government entities will lose royalties and taxes associated with the significant number of wells that would be prematurely shut in and plugged or orphaned because of this rule.

Response II-20-22: With respect to the commenter's claim that a significant number of wells would be prematurely shut in and plugged or orphaned, EPA notes that the commenter did not provide specific data to support this assertion. EPA developed a financial analysis of marginal, or stripper, oil and natural gas wells in Chapter 6 of the Final Rule TSD. EPA finds that marginal wells may continue to operate at low or negative profits rather than be shut-in and plugged due to a variety of reasons, including low operating costs, high plugging costs, low state bonding requirements, accounting practices, and tax credits available to the oil and gas industry. To the extent that any marginal wells might be plugged in relation to anything contained within this rulemaking (which is speculative), the analysis suggests that they would be extremely low-producing wells, and therefore the impact of lost revenue would be minimal. In addition, to mitigate the impact of orphaned wells, the Inflation Reduction Act (IRA) provides \$700 million for methane and greenhouse gas mitigation activities for conventional marginal wells. The Department of Energy and the EPA have issued a joint Notice of Intent to provide grants up to \$350 million for conventional marginal well plugging as an initial effort to distribute the IRA funds. The goal of marginal well funding from the IRA is to offset the cost of plugging low producing wells. Additionally, the federal money reduces the possibility that the operator files for bankruptcy and orphans their well(s).

See also section XVI.D (Unfunded Mandates Reform Act (UMRA)) of the final rule preamble. The EG is promulgated under CAA section 111(d) and does not impose any direct compliance requirements on designated facilities, apart from the requirement for states to develop state plans.

As explained in section XIV.G of the November 2021 Proposal and section V of the December 2022 Supplemental Proposal,<sup>85</sup> the EG also does not impose specific requirements on tribal governments that have designated facilities located in their area of Indian country. The burden for states to develop state plans following promulgation of the rule is estimated to be below \$100 million in any 1 year. Thus, the EG is not subject to the requirements of section 203 or section 205 of the UMRA.

## **20.4 Economic Impacts**

### ***20.4.1 Economic Benefits***

Comment: Several commenters (2331-MHA Nation, 2171-IEEFA, 2209-PLS, 2367-BlueGreen Alliance, 2429-WOC) assert that the proposed rule will result in economic benefits including job security and job creation. Some of the specific comments received are provided below.

Commenter (1609-Qnergy, Inc.) and other U.S. companies are investing significant resources in on-shoring their supply chain to guarantee on-time delivery of methane mitigation products. The commenter already expanded its production capacity by 60% to meet the surging demand with the goal to provide lead time of six weeks or less. The commenter expects that the IRA and other government programs will promote U.S. methane mitigation technologies.

Commenter (2331-MHA Nation) appreciates the proposed rule's economic and environmental benefits. The commenter appreciates that the proposed rules are projected to increase recovery of natural gas. The commenter states that increased gas recovery on the Fort Berthold Reservation would deliver more revenue to fund vital tribal programs.

Commenter (2171-IEEFA) believes that the proposed rules will assist operators in achieving higher future profit margins. The commenter states that the ability of a company to control emissions should yield a commensurate proved reserves benefit. As better usage of LDAR technologies and other solutions required by the EPA are installed, the commenter suspects that a one percent to five percent incremental bump in natural gas production will follow from higher retentions. The commenter states that this production increase will occur with relatively de minimis production and exploration costs, thereby resulting in higher profit margins.

Commenter (2209-PLS) requests that EPA strengthen the proposed rule to mitigate against climate change and protect outdoor recreation. Specifically, the commenter asks that EPA;

- Eliminate routine flaring and ensure that oil and gas operators capture all correlated gas from their operations and strictly limit flaring of methane gas unless necessary for maintenance and safety.
- Apply applicable emission restrictions to storage tanks, which was not included in the November 2021 proposal or the supplemental rule.

---

<sup>85</sup> See 86 FR 63256 (November 15, 2021) and 87 FR 74702 (December 6, 2022).

- Expand the Super Emitter Response Program proposal to provide for well-defined guidance and funding to enable broad local community and third-party monitoring for emission compliance.

The commenter (2209-PLS) provides details on the importance of the outdoor recreation economy, and methane pollution's negative impacts. The commenter states that healthy public lands bring quality of life, visitors, and business investment to nearby communities through outdoor recreation. Outdoor recreation businesses rely on access to public mountains, rivers and deserts, and the country has increasingly seen terrible climate change related disasters in recent years. The commenter believes that without strong, common-sense protections against methane and other harmful pollution from oil and gas developments, the \$862 billion<sup>86</sup> outdoor recreation industry will suffer. The commenter notes that climate change uniquely affects outdoor recreation,<sup>87,88</sup> fundamentally changing public land use patterns and stunting economic opportunities. The commenter reports that the evidence<sup>89</sup> of climate change is overwhelming: 16 of the hottest years on record took place between 2000 and 2017, and the 9 most devastating wildfires in American history took place after the year 2000. According to the United Nations' climate science body, methane is responsible for 30 percent<sup>90</sup> of the climate change we are experiencing today, and oil and gas is the largest industrial source of methane pollution, accounting for a third of emissions.

The commenter (2209-PLS) notes that in 2019 Congress held a hearing on the effects of climate change on outdoor recreation, where the Outdoor Alliance testified to the many harms inflicted on the quality of the outdoor recreation experience, health impacts and safety concerns for recreationists, and damage to the outdoor recreation economy.<sup>91</sup> Climate change harms the outdoor recreation industry by causing less snowpack, water insecurity such as low river flows, basic access lost to public lands during fire season (year-round now in some places), and many other detrimental impacts. The commenter notes that the outdoor industry<sup>92</sup> brings millions of jobs to communities across the country in many ways. Recreation visitors bring needed dollars to cities and towns that have recreation assets like rivers, trails, and other outdoor spaces where fishing, hunting, boating, hiking, skiing, biking, climbing, and a long list of other outdoor

---

<sup>86</sup> The Bureau of Economic Analysis calculates the economic output of outdoor recreation to be \$862 billion, surpassing industries such as mining, utilities, farming and ranching, and chemical products manufacturing. See <https://recreationroundtable.org/economic-impact/>.

<sup>87</sup> See Climate Change is Changing the Face of Outdoor Recreation, National Recreation and Park Association, found at <https://www.nrpa.org/parks-recreation-magazine/2017/october/climate-change-is-changing-the-face-of-outdoor-recreation/>.

<sup>92</sup> See Outdoor Recreation Satellite Account, U.S. and States, 2021, Bureau of Economic Analysis, found at <https://outdoorindustry.org/advocacy/>.

activities take place. Outdoor recreation companies and businesses across a range of industries, both large and small, are choosing to locate in these communities because their employees want to live in places with access to the great outdoors. Across the country, communities that have previously depended primarily upon resource extraction have begun to diversify their economies into the recreation sector. The commenter asserts that promulgating this proposed Methane Rule—along with implementing best practices and using newly developed technologies will protect and improve air quality in oil and gas communities across the country that want to expand regional outdoor recreation economies. The commenter understands the need for energy production, but states that it is time to acknowledge the cost of methane pollution to local communities. Allowing oil and gas operators to use old technology will damage air quality and prohibit communities from diversifying their economies.

Commenter (2367-BlueGreen Alliance) states that jobs in the methane emissions mitigation industry have the potential to provide pathways into the middle class for millions of workers and families, and to support millions of high-skilled, high-wage jobs—particularly in manufacturing. As this sector grows, support is needed to ensure that the jobs created are good-paying, safe, accessible union jobs, especially for those historically underrepresented in these jobs.

The commenter (2367-BlueGreen Alliance) notes a 2021 report from Datu Research, *Find, Measure, Fix: Jobs in the U.S. Methane Emissions Mitigation Industry*, further explains existing technologies with a focus on identifying and exhibiting companies that produce the products and services. They found that this sector is growing rapidly. Today there are 33 percent more firms manufacturing methane mitigation technologies than in 2014, and 90 percent more firms providing installation and other services than in 2017:

- At least 215 firms manufacture methane mitigation equipment in the U.S. and/or offer services;
- 70 percent of methane mitigation firms qualify as small businesses;
- Methane mitigation companies provide U.S. jobs in at least 748 locations across 47 states; and
- The methane mitigation industry employs at least 35 key job types<sup>93</sup>

[See Figure B Map of the contiguous U.S. of the commenter’s letter. Figure B Map shows where methane emissions mitigation firms are located.<sup>94</sup>]

The commenter (2367-BlueGreen Alliance) asserts that with full and continuing adoption of 2021 Proposed Rule leak reducing technologies and practices at new and modified oil and gas facilities, this would result in net creation of over 85,000 job-years.<sup>95</sup> While the commenter is currently working on updating their economic modeling to provide a complete picture of the emissions reduction and job creation potential of the EPA’s 2022 Supplemental Proposed Rule,

---

<sup>93</sup> Datu Research, *Find, Measure, Fix: Jobs in the U.S. Methane Emissions Mitigation Industry*, 2021. Available online: <https://www.daturesearch.com/wp-content/uploads/Datu-2021-Methane-Emissions-MitigationIndustry.pdf>.

<sup>94</sup> Environmental Defense Fund, *Find Measure Fix: Jobs in the U.S. Methane Emissions Mitigation Industry*, July 2022. Available online: [https://www.edf.org/sites/default/files/us\\_methane\\_mitigation\\_industry\\_report.pdf](https://www.edf.org/sites/default/files/us_methane_mitigation_industry_report.pdf).

<sup>95</sup> Based upon internal BGA research. Note that the jobs estimates reported here are more appropriately called “job-year equivalents.” Each “job” represents an increase in demand for employment sufficient to employ one-person full time for one year.

their preliminary analysis suggests that the 2022 supplemental would amplify the job creation potential of the 2021 proposal by improving emissions monitoring, reducing flaring, and expediting technological deployment. In many ways, the commenter states that job creation from the EPA's proposed standard is supported by the infrastructure investments needed to mitigate methane leaks. The Business Roundtable notes, for example, that over a 20-year period, every additional \$1 invested in infrastructure drives roughly \$3.70 in additional economic activity.<sup>96</sup> Especially when done at scale, they believe that infrastructure investments will drive new employment opportunities. The commenter asserts that the proposed rule will drive infrastructure investment as a critical step to reduce fugitive methane emissions — in this case to reduce such emissions by an estimated 36 million cumulative short tons over the period 2023 through 2035, along with 9.7 million tons of VOCs and 390,000 tons of HAPs.<sup>97</sup>

Based on their modeling of the 2021 Proposed Rule, the commenter (2367-BlueGreen Alliance) asserts that the impacts of this rule will be generally positive. The commenter expects that both the construction and manufacturing sectors will show positive gains in employment as they both produce and install critical upgrades in a variety of oil and gas operations which deliver the estimated emission reductions. This is because the emissions reduction technologies modeled, specifically in leak detection and repair (LDAR), are more labor intensive than the oil and gas extraction industry on average and can produce increased net revenues by reducing waste. As a result, job losses that result from reduction in traditional extraction operations are more than offset by a shift to jobs required to sustain emissions reduction efforts. Many of these new jobs could be filled by workers with skills and experience in the oil and gas industry.

The commenter (2367-BlueGreen Alliance) notes that under the 2022 Supplemental Proposed Rule, EPA has incorporated technological flexibility into the standards to promote innovation, including giving firms the ability to utilize a diverse array of technologies to observe leaks. The commenter contends that in making these modifications, EPA provides full access to the technologies in the burgeoning methane mitigation industry, providing a potential catalyst for further job growth.

The commenter (2367-BlueGreen Alliance) asserts that the new Super Emitter Response Program potentially opens a pathway for groups like labor unions to qualify as third-party monitors, expanding the number of high-quality jobs created by this action.

The commenter (2367-BlueGreen Alliance) states that the need to implement and operate advanced equipment and apply more comprehensive leak detection and mitigation technologies over time suggests jobs directly created in the oil and gas sector would not require relocation—the skilled local workforce will already be in place. While some jobs would engage engineering

<sup>97</sup> U.S. EPA, Regulatory Impact Analysis for the Supplemental Proposed Standards of Performance for New, Reconstructed, and Modified Sources and Emissions Guidelines for Existing Sources: Oil and Natural Gas Sector Climate Review, October 2021. Available online: <https://www.epa.gov/system/files/documents/2022-12/Supplemental-proposal-ria-oil-and-gas-nsps-egclimate-review-updated.pdf>.

and other technical professions requiring advanced degrees, they mostly also employ high-skilled labor and trades professions complementing the current workforce at oil and gas operations.

The commenter (2367-BlueGreen Alliance) asserts that creating and sustaining jobs is tied strongly to the investment and implementation of a well-defined set of cost-effective technologies and practices in the oil and gas sector. The skill level needed, and consistent nature of leak detection and mitigation activities entailed by the methane standard—employed industry-wide—offer a new avenue for job sustainment compared to ‘business as usual.’ These activities will also rely on the existing oil and gas workforce, which is a good-paying, highly unionized sector.

The commenter (2367-BlueGreen Alliance) notes that many of the energy technology techniques and equipment date back several decades to the 20th century. The commenter contends that newer, less leak-prone machinery for oil and gas operations is increasingly available; a Datu report identifies 584 employment locations (referred to in the report as “employee locations”) for manufacturing, assembling, and providing installation and other services for methane mitigation technologies that could help reduce leaks and achieve the emissions reduction goals of the EPA methane standard.<sup>98</sup>

Commenter (2429-WOC) asserts that the economic case for federal methane regulations is compelling, and consumer demand for a low carbon fuel economy is growing.

The commenter (2429-WOC) notes that, nationally, it is estimated that oil and gas operators waste \$2 billion in methane annually, or enough to heat the homes of 10 million Americans a year.<sup>99</sup> For public and tribal lands, recent analysis of emissions and lost revenue is estimated at nearly \$500 million worth of gas in 2019 alone.<sup>100</sup> Numerous policy and government analyses have shown that reducing methane waste from oil and gas operations is one of the most feasible and cost effective ways to reduce GHG emissions.<sup>101</sup> In many cases, wasted methane can be captured and sold, paying for most, if not all, of the additional work needed to capture it. Recent data from the International Energy Agency suggest that up to 45 percent of wasted methane emission can be prevented at no net cost to industry.<sup>102</sup>

The commenter (2429-WOC) asserts that minimizing the waste of a valuable and non-renewable fuel source also has direct economic benefit to states and local jurisdictions that derive and depend on revenues from mineral severance taxes. The commenter estimates that in Wyoming between \$51 million to \$96 million worth of natural gas is lost due to intentional flaring, venting and careless leaks each year. This translates to \$8.8 million to \$16.1 million lost in annual royalty payments to the state. Of this amount, \$3.4 million to \$6.5 million was lost ad valorem revenue (property tax that goes directly to counties) that could have gone to the purchase of emergency equipment, or road and bridge repair, or human services like public health nurses and

---

<sup>98</sup> Datu Research, Find, Measure, Fix: Jobs in the U.S. Methane Emissions Mitigation Industry, 2021. Available online: <https://www.daturesearch.com/wp-content/uploads/Datu-2021-Methane-Emissions-MitigationIndustry.pdf>.

<sup>99</sup> EDF Research Summary: <https://www.edf.org/climate/methane-studies>.

<sup>101</sup> International Energy Agency: Curtailing Methane Emissions from Fossil Fuel Operations. Oct. 2021.

<sup>102</sup> Id.

libraries.<sup>103</sup> The commenter asserts that these are critical revenue streams that taxpayers and budget-strapped communities deserve to see for the depletion of finite natural resources, particularly given ongoing statewide budget cuts.

Additionally, the commenter's (2429-WOC) experience in Wyoming suggests that there are tangible employment and economic benefits associated with developing a strong methane regulation economy. Currently, there are approximately 13 businesses in the methane emission mitigation industry in the state.<sup>104</sup> The commenter states that some of these businesses manufacture equipment needed for leak detection and repair work, while others are more focused on consulting and compliance services. As the standards around methane emissions are raised, this sector is poised to grow and create new jobs, helping Wyoming modernize its oil and gas infrastructure and stay competitive as consumer energy preferences change to favor low-carbon fuel sources.

Additionally, the commenter (2429-WOC) notes that in the last decade, demand for low-carbon and carbon-neutral fuel sources has increased dramatically, largely in response to consumer consciousness around climate change, and decreasing costs for renewable energy.<sup>105</sup> <sup>106</sup> Several of Wyoming's biggest oil and gas operators have already recognized this trend and are seizing on the opportunity by reducing sources of wasted methane in response to growing consumer demand for less carbon-intensive energy. Increasingly, emissions-intensive sources of natural gas represent an increasing liability for companies and investors, both domestically and abroad. The commenter notes, for example, in 2020 the French government blocked a \$7 billion liquified natural gas contract with U.S. producers over concerns that the gas was "too dirty."<sup>107</sup> Similarly, major institutional investors like BlackRock have started considering climate risk and vulnerability as investment criteria, and investor interest in funds with Environmental, Social, and Governance (ESG) benchmarks have skyrocketed in recent years. The commenter notes that these trends are expected to continue as governments, businesses, and citizens take measures to reduce carbon emissions in the future, and companies failing to mitigate environmental and social impacts will face increasing investor scrutiny and backlash.<sup>108</sup>

Response II-20-23: EPA acknowledges the challenge in assessing the employment impact of the regulation and acknowledges that there may be positive employment impacts in some locations and sectors. EPA is unable to quantify either positive or negative employment impacts at this time due to a lack of sufficient data, which commenters have not provided.

Comment: Commenter (2248-NDPC) states that they do not believe the RIA performed for the November 21 proposal, and now the supplemental proposal appropriately justifies the economic burden of the proposed regulation on domestic oil and natural gas producers. The commenter expresses concern that the proposed rule will force producers to plug and abandon wells before their end of useful life. They report that this will have an economic impact on the North Dakotans and the Three Affiliated Tribes (Mandan, Hidatsa, Arikara) that are paid royalties for the oil and natural gas production. The commenter encourages careful consideration of the potential economic burdens on North Dakota's citizens and oil and natural gas producers when performing the regulatory impact analysis, including the useful life of equipment and wells.

The commenter (2248-NDPC) contends that over-regulation of the oil and natural gas industry increases production costs and discourages investment in the industry with little if any, environmental benefit. This can lead to higher electricity, heating fuels, food, and transportation prices, which disproportionately impacts low-income Americans. The commenter adds that, as inflation has increased, they have seen tangible evidence of this over the last few years.

Response II-20-24: With respect to the commenter's suggestion that the RIA does not appropriately justify the economic burden of the regulation, the EPA notes that the EPA's standard-setting duties and authority are derived under section 111 of the CAA, and its decisions are made within the confines of that authority. Although the EPA must consider the costs of control, it is not required to base the setting of standards on a broad-ranging benefit-cost analysis, and it has not done so here. The RIA prepared by the EPA under Executive Order 12866 may inform the standard-setting process, but it cannot provide the direct basis for the standards, nor does not "create any right or benefit, substantive or procedural, enforceable at law or equity by a party against the United States..." (Executive Order 12866, Section 10).

With respect to the commenter's concern that the rule will force producers to plug and abandon wells before their end of useful life, EPA also developed a financial analysis of marginal, or stripper, oil and natural gas wells in Chapter 6 of the Final Rule TSD. EPA finds that marginal wells may continue to operate at low or negative profits rather than be shut-in and plugged due to a variety of reasons, including low operating costs, high plugging costs, low state bonding requirements, accounting practices, and tax credits available to the oil and gas industry. To the extent that any marginal wells might be plugged in relation to anything contained within this rulemaking (which is speculative), the analysis suggests that they would be extremely low-producing wells, and therefore the impact of lost revenue would be minimal.

Finally, with respect to price impacts, EPA models the impact of the rule on oil and natural gas supply in Section 4.1 of the Final RIA. EPA estimates that the reduction in U.S. oil production as a result of the Final Rule would be approximately 1.05% or less, while the reduction in gas production would be approximately 0.75% or less. EPA estimates that the impact on natural gas prices will be \$0.06/Mcf or less, and the impact oil prices will be \$0.25/bbl or less. These represent changes of approximately 1.76% and 0.33%, respectively.

#### ***20.4.2 Negative Economic Impacts***

Comment: Several commenters (2179-KIOGA, 2200-NuEnergy, 2205-Kriebel, 2211-Lambda Energy, 2220-WDEQ, 2223-TAEP, 2238-SOOGA, 2241-UDNR, 2248-NDPC, 2257-MOGA, 2279-US SBA, 2292-WVAG et al, 2294-OOGA, 2301-US CC, 2308-NSWA, 2309-NSWA, 2314-Miller Energy, 2322-ADEQ, 2403-PAO, 2446-IPAA, 2625-Fore Energy, 2696-Peters et al) assert that that the proposed rule will result in reduced production and associated revenues, an increased number of abandoned wells, job losses, and inflation, and that it unfairly impacts small businesses and underserved communities, and/or provide studies and references quantifying the negative impacts. Examples of these comments are presented in the following paragraphs. For additional comments on adverse impacts to small businesses, see section 20.3.5 of this Chapter. For additional comments on impacts on underserved communities, see section 20.5 of this Chapter.

Commenter (2292-WVAG et al) writes about the unnecessary costs of the Proposed Rule. The compliance costs have increased to \$1.8 billion annually from 2023 to 2035 compared to \$1.1 billion for the proposed rule. The Supplemental Proposal appears indifferent to the serious cost consequences it will place on the industry—making it one of the most expensive regulatory efforts the Biden administration has proposed.<sup>109</sup> For example, EPA recognized in the Proposed Rule that regulatory costs could be especially burdensome on smaller production operations and excluded them from the proposed fugitive emissions monitoring. 86 Fed. Reg. at 63,170. But the Supplemental Proposal would instead expand this frequent leak monitoring to all natural gas well sites (including wellhead-only sites), regardless of their estimated emissions. Now, all operators must conduct monthly, bimonthly, quarterly, or semiannual inspections or monitoring, depending on facility type—a costly undertaking. The Supplemental Proposal would also require emissions monitoring to continue until a facility has been “closed, including plugging the wells at the site and submitting a well closure report.” Thus, a huge class of defunct wells will now lead to continuing costs unless a producer is able to jump through a series of administrative hoops. And the agency has imposed strict zero-emission standards on pneumatic controllers (based on its sweeping judgment that such a standard is feasible at every site save a few in Alaska) and a zero-emission standard for pneumatic pumps. It is not even clear that these requirements can be met with tools readily available through existing supply chains. New and onerous requirements on flaring and dry-seal compressors also seem to lack any reasonable cost-benefit analysis to justify them.

Commenters (2314-Miller Energy, 2200-NuEnergy, 2625-Fore Energy) state that the proposed regulation conflicts with the State of Michigan’s Office of Oil, Gas and Mineral (OOGM) regulations. The commenters note that the premature plugging and abandoning of otherwise currently profitable marginal wells leaves valuable resources in the ground and is contrary to OOGM’s directive to prevent waste in the State of Michigan.

---

<sup>109</sup> See Regulation Rodeo, AM. ACTION F. (2022), <http://bit.ly/3XZ52Pa> (last visited Feb. 3, 2023) (select “2021,” “2022,” and “2023” years).

Commenter (2625-Fore Energy) states that the proposed rules may decrease marginal wells life expectancy or result in well closure resulting in a forfeiture of the remaining reserves. The commenter recommends that EPA consider marginal well operations.

The commenter (2625-Fore Energy) contends that over the decades of the industry's operations, more regulatory rules have been written and been imposed on the business to improve environmental conditions and protect landowners' properties and recover the ultimate reserves from the wellbores and finally, properly plug and abandon the wells to protect groundwater and the adjacent air. The commenter asserts that during the first five decades of production, these goals were achievable because the gradual production decline still supplied funds to accomplish all manners of operations. Today the fees, charges and risk analysis are steep with profit margins boarding on bankruptcies. The commenter states that the decline rates for new successful wells is ten to twenty time higher than the major production of the 1940's and 1950's and is classified as marginal well status. The proposed rules may lead to well closures, causing loss of a portion of the remaining reserves, which could still be recoverable.

The commenter (2625-Fore Energy) states that decline rates play an important role in the management of wells, economic implications, capital investments, royalty, and environmental management. The commenter contends that this technique allows forecasting of the assets and preparation for the life remaining of the well(s) and the associated facilities. The commenter notes that without better understanding of the future rules projected to be imposed on the industry, producers may just walk away from their operations leaving the states and the state regulators with – orphan sites” to handle at tremendous costs. The commenter believes that changes to the federal CAA need to be clear to understand, workable for the producers to implement and substantially less costs for small businesses and marginal well producers.

Commenter (2314-Miller Energy) states that the proposed rule will result in an increased number of abandoned wells if small operators determine they cannot sustain operations with adequate profit margins. The commenter asserts that some operators may decide to abandon operations and transfer their liability to the state or federal government. That liability transfer impacts tax dollars and resources the government could have used elsewhere.

The commenter (2314-Miller Energy) notes that even with the state/federal bodies taking liability of abandoned wells, the wells likely do not receive the same attention from governmental officials as they do when managed by trained operators like the commenter. Lack of resources and knowledgeable oversight can create a large environmental impact on communities when releases occur.

Commenter (2308-NSWA) asserts that a review is necessary, given the likely resulting loss of production would cause higher energy costs for all Americans, job loss for oil and gas employees – the “hard working folks” President Biden talked about in his State of the Union – and lost revenue for local governments, businesses, and royalty owners (often retirees on fixed incomes).

Commenter (2292-WVAG et al) urges EPA to abandon its proposed rule and instead develop reasonable rules that protect a crucial sector to the economy. The commenter agrees that reducing methane emissions is a noble goal, one that industry is already working towards. The

commenter notes that the oil sector reduced methane emissions relative to production by 60 percent between 2011 and 2020.<sup>110</sup> The commenter reports that other reduction efforts are underway, like the Oil & Gas Methane Partnership 2.0 and the Texas Methane & Flaring Coalition. However, the commenter asserts that top-down, heavy-handed government control crushes the American energy sector. The commenter believes that the correct path to balance energy needs and environmental concerns is achieved by looking to American ingenuity and innovation, fostered by private initiative and state leadership.

Commenter (2301-US CC) states that the oil and natural gas industry is critical to U.S., and policies affecting the industry can have long-ranging repercussions. The commenter notes that the U.S. possesses enormous oil and natural gas deposits and has seen a marked revival in production due to advanced extraction techniques, leading to the nation becoming one of the world's largest producers of oil, natural gas, and related products. The DOE has characterized these trends as a "renaissance in oil and gas production in the U.S. over the past decade."<sup>111</sup> In 2019, the U.S. produced record levels of crude oil (12.2 million barrels per day) and natural gas (40.7 trillion cubic feet), increases of 11.3 percent and 10.6 percent from 2018 levels, respectively.<sup>112</sup> The U.S., as a result, enjoyed its best energy security since 1970<sup>113</sup> and became a net energy exporter for the first time since 1952.<sup>114</sup> The commenter contends that these achievements are due in no small part to America's shale revolution and advances in hydraulic fracturing technology.<sup>115</sup>

Beyond production statistics and industry trends, the commenter (2301-US CC) provides that the America's oil and natural gas industry is integral to the broader American economy. The production, transport, and refining of oil, natural gas, and related products creates well-paying jobs in a number of areas where such opportunities may otherwise be in short supply. The U.S. oil and natural gas industry's total employment impact is estimated at 11.3 million domestic jobs, or 5.6 percent of total U.S. employment.<sup>116</sup> And each direct job in the oil and natural gas industry supports an additional 3.5 jobs elsewhere in the U.S. economy.<sup>117</sup> Moreover, they add that these

<sup>113</sup> Id. (Table 1). In fact, after the United States received a record-high risk score of 100.9 in 2011, its score fell in seven of the subsequent eight years to a record low of 70.1 in 2019—a 5.5 percent decrease from 2018. Id. At 4.

<sup>114</sup> See U.S. Energy Info. Admin. ("EIA"), U.S. Energy Facts Explained, <https://www.eia.gov/energyexplained/us-energy-facts/imports-and-exports.php> (last updated June 10, 2022).

<sup>115</sup> See GEI, Index of U.S. Energy Security Risk, *supra* note 6, at 4 ("The application of hydraulic fracturing, horizontal drilling, and advanced seismic imaging has unlocked a tremendous oil and gas resource, turning energy scarcity into abundance."); see also DOE, Valuation of Energy Security, *supra* note 5, at 12 (attributing the United States' growth in oil and natural gas production to "technical innovation and entrepreneurial initiative").

<sup>116</sup> See PWC & Am. Petroleum Inst., Impacts of the Oil and Natural Gas Industry on the U.S. Economy in 2019. See [api-pwc-economic-impact-report.pdf](https://api-pwc-economic-impact-report.pdf).

<sup>117</sup> Id. At E-2.

jobs are spread throughout the country, as 31 states boast at least 100,000 jobs directly or indirectly supported by the oil and natural gas industry.<sup>118</sup>

The commenter (2248-NDPC) reports that North Dakota is ranked third in the nation in oil production, and their members produce 98 percent of the oil in North Dakota. North Dakota produced approximately 2.97 billion cubic feet of natural gas per day and 394 million barrels of oil in 2021, contributing significantly to supplying clean and cost-effective energy for Americans and America's energy independence. As an industry, they are proud of their environmental record and take their responsibility very seriously to be good stewards of the environment and lands on which we operate.

To demonstrate the significance of the oil and natural gas industry to North Dakota's economy, the commenter (2248-NDPC) notes that the taxes from oil and natural gas production accounts for 51 percent of North Dakota's tax revenue. Since 2008, the commenter reports that North Dakota's oil extraction and production tax revenues have generated over \$26 billion and provided over \$1.8 billion for education and \$5.9 billion in funding for communities and infrastructure across the state. The taxes have also contributed \$6.9 billion to the North Dakota Legacy Fund, which creates a perpetual source of revenue for the state's general fund and tax relief for its citizens.

Commenter (2220-WDEQ) urges EPA to consider the negative economic impacts in its cost-benefit analysis. The commenter contends that the supplemental proposal will have immense impacts upon Wyoming's economy that are not considered quantitatively or qualitatively in the RIA. The commenter points to the Wyoming State Geological Survey's January 2022 summary report titled "Oil & Natural Gas Resources in Wyoming" to explain the importance of oil and gas development to the State:

Oil and gas severance taxes and royalties contribute funding to state highway and county road construction and maintenance; water projects; local governments; school districts, scholarships, and the University of Wyoming and community colleges; and state-government agencies. Combined, oil and natural gas brought in more than \$372,000,000 in severance taxes for the state coffers during fiscal year 2021.<sup>119</sup>

The direct and indirect employment of tens of thousands of workers, as cited in the summary report:

In 2019, when Wyoming oil production was at an all-time high, these oil and gas extraction and support workers received upwards of \$1.1 billion in total wages to spend in their communities.

---

<sup>118</sup> Id.

<sup>119</sup> Wyoming State Geological Survey, Erin A. Campbell, Director and State Geologist, "Oil & Natural Gas Resources in Wyoming," January 2022 Summary Report.

Commenter (2257-MOGA) contends that the proposed rule will have major negative impacts on communities, and small businesses. The commenter urges EPA to consider the economic impacts.

The commenter (2257-MOGA) asserts that job losses would result from facility closures, layoffs of key personnel who keep the operations productive, marginal producing wells becoming uneconomic because of excessive regulatory obligations and the expense of those consulting charges to measure the nominal fugitive emissions or capital investments towards emission reduction. The commenter notes that once the producers close their doors and exit the small towns they support, the service companies have no clients to service, so they close their doors. This “snowball” effect results in once vibrant communities becoming ghost towns with only a spotlight to designate as an existing village.

The commenter (2257-MOGA) reminds EPA that many “underserved or overburdened communities” are often located in rural areas where oil and gas drilling and production provide jobs and sustains local economies. The commenter contends that the proposed rules will likely result in the early plugging of marginal wells that cannot absorb the initial implementation and ongoing costs of the proposed regulations. The plugging of wells will have a direct impact on associated small businesses, including hotels, restaurants, service, retail and other “mom and pop” stores that rely on the oil and gas industry to survive.

The commenter (2257-MOGA) asserts that the negative effects on small businesses will have large scale effects. Employment, income tax generation, private and government royalties, leasing contracts, restaurants, hotels, small communities, and families will be negatively affected.

The commenter (2257-MOGA) highlights the EPA data table provided to all Small Business Advocacy Review (SBAR) panel participants in June 2021. The table indicates that approximately 98.8-99 percent of all oil companies are owned by small businesses and that approximately 92.9-93.7 percent of all natural gas companies are owned by small businesses. [Referenced Table in the commenter’s letter: Total number of firms and small business percentage across multiple NAICS/Industry sectors.]

The commenter (2257-MOGA) notes that in Michigan alone, their membership constitutes around 650 members, many of which are small business and include oil and gas companies, environmental consultants, service and vendor companies, accounting and legal firms, general contractors, electricians, plumbers, welders and surveyors. In total, the oil and gas industry in Michigan directly or indirectly employs roughly 47,000 voting residents.

The commenter (2257-MOGA) presents a “Production Decline Curve” graph and notes initial production is significantly higher in the first years following completion. Higher initial production allows for the upfront consideration of long-term cost allocation, planning and implementation of new regulatory requirements such as determination, monitoring, calculations and reporting. [Comment letter includes a production decline curve graphic: Production Decline Curve (Exponential Decay Function). Age of production (years) on x-axis and BOE/Day on y-axis for 18 wells.]

The commenter (2257-MOGA) states that the proposed future EG, which include existing and marginal wells, do not allow initial capital investment or longevity planning considerations during initial high-margin return-on-investment realization. The commenter notes that many marginal wells in Michigan are often 3<sup>rd</sup> & 4<sup>th</sup> succession owner wells. The initial high-volume production was realized by previous owners. Each successive sale was based on an updated production formation reserve analysis and projected longevity of the marginal production. Should the EPA decide to include existing and marginal wells with the proposed NSPS regulations, small entity oil and gas producers with aging marginal wells would not have the associated production to substantiate an initial capital investment combined with ongoing annual costs based on diminishing economic return. This successive ownership paradigm represents a significant majority of oil and gas wells in Michigan.

Commenter (3604-Riverside Operating Company) owns and operates over 5,000 natural gas wells in northern Michigan and expresses concerns with respect to the proposed regulations, namely, inadequate review time to comment on these new rules, economic impact on marginal wells and the overall cost burden, as well as increased operational challenges in northern Michigan (*e.g.*, lack of sunlight in the winter months preventing solar power from being a viable option along with hundreds of well sites located in remote rural areas). The commenter supports the comments submitted by the IPAA and MOGA.

Commenter (2179-KIOGA) believes that EPAs proposed regulation will add to the cost of doing business and result in net job loss. The commenter reports that many of the operators in the upstream oil and gas segment operated at a loss in 2020 and 2021. A combination of crude oil demand destruction caused by the COVID-19 pandemic and a concurrent crude oil supply shock had a profound impact on the small businesses that make up the independent oil and gas industry in Kansas and across the nation. Owners/operators and their contractors cut capex by as much as 60 percent and cut operating costs by 30 percent or greater. Nearly 5,000 wells were shut-in in Kansas during 2020 with a loss of nearly \$810 million in lost oil output. Kansas producers worked in 2021-2022 to optimize supply chain relationships, improve operating efficiencies, and refocus capex on the most resilient short-cycle projects.

The commenter (2179-KIOGA) asserts that at a time when owners/operators are searching for ways to reduce operating costs to survive, EPA proposed methane regulation will likely measurably add to the cost of doing business. The commenter believes that owners/operators will be required to employ additional staff for field surveys/maintenance activities and documentation burdens. However, the commenter expects that this regulation will result in a net loss in jobs from the industry because expenditures will be required for compliance activities, not new revenue generation. Empirical evidence suggests LDAR testing on each Kansas lease would cost the Kansas oil and gas industry an estimated \$100 million annually. The commenter questions the need for the documentation requirements and recommends that EPA reduces these requirements.

Further, the commenter (2179-KIOGA) states that many of the small businesses that make up the Kansas oil and gas industry do not have the knowledge required to perform a fugitive emissions survey or to perform air emissions calculations for a well that has existed for multiple generations. These entities should not be burdened with having to figure out how to do so or

burdened with hiring, and paying for, an environmental consultant to perform the survey and calculations on their behalf.

The commenter (2179-KIOGA) urges EPA to consider the scope of the issue. The commenter notes that oil and natural gas production systems account for about 1.2 percent of the U.S. Greenhouse Gases Inventory (GHGI). Low production wells account for about 10-11 percent of U.S. production; therefore, their emissions would be in the 0.10-0.20 percent range of the GHGI. There are about 1,000,000 existing oil and natural gas wells. Approximately 150,000 of these wells have been regulated under NSPS OOOO and now NSPS OOOOa. That number grows each year. Of the remainder, 770,000 are low production wells. Nationally, low production wells average about 2.5-2.7 barrels per day if they are oil wells and 22- 24 mcf/d if they are natural gas wells.

The commenter (2179-KIOGA) contends that subjecting these wells to the NSPS LDAR requirements puts them in severe economic jeopardy. Even EPA recognized this reality when it did not impose this LDAR program on low production wells in its October 2016 Control Techniques Guidelines (CTG) for existing oil and natural gas production facilities operating on Ozone Nonattainment areas.

Further, the commenter (2179-KIOGA) urges EPA to consider the different emissions profiles between high and low production wells. The commenter agrees with the January 2021 International Energy Agency (IEA) regulatory roadmap and toolkit focused on “Driving Down Methane Leaks from the Oil and Gas Industry” that details that, “understanding the nature and magnitude of your emissions will be critical to designing sound regulations.”

The commenter (2179-KIOGA) reports that one key aspect of the independent component of the oil and natural gas production industry is its breadth — spanning from large, high production wells to low production wells. These wells do not all have the same emissions profiles, and those different profiles should be considered in regulations. The commenter notes that low production wells are those that produce 15 barrels/day (or 90 mcf/d) or less. The national average low production oil well is about 2.5 barrels/day, and the low production natural gas well is about 24 mcf/d. Of the roughly one million active oil and natural gas wells in the U.S., about 750,000 are low production wells, typically operated by small businesses. The commenter asserts that the regulatory structure applied to low production wells is significant because their viability is so dependent on their cost of operation.

Commenter (2211-Lambda Energy) contends that the proposed regulations will result in marginal well closures, job losses, and additional abandoned wells. The commenter states that the additional financial burden and increased costs of the proposed regulations would make uneconomic and, in all likelihood, require the shut in, between 200 to 300 marginal wells, and would result in the loss of at least 15 jobs of well operators and processing, gathering, and back-office personnel. The commenter notes that these closures would also result in significant lost revenue to the company and its employees, vendors and royalty owners, the largest of which is the Michigan Department of Natural Resources. In addition, the commenter states that these regulations might also result in many wells being abandoned and ending up in the State of Michigan’s orphan well plugging program, and thus shifting that liability to taxpayers.

Commenter (2294-OOGA) states that the Supplemental Proposal threatens the continued viability of the oil and gas industry in Ohio. The economic ramifications of a rulemaking that potentially halts further development of oil and natural gas in Ohio cannot be ignored as the industry generated approximately \$97 Billion in investments in Ohio since 2011,<sup>120</sup> and provides nearly 200,000 Ohio jobs.<sup>121</sup> Relatedly, the areas in which the oil gas industry predominantly operates and, in turn, provides necessary and critical services – i.e., overburdened and underserved rural communities (e.g., southeast Ohio) – are the areas that will suffer the economic consequences. The commenter notes that this effectively results in “inverse” environmental justice in these communities. That is, rural families and farmers whose homes are heated by the oil/natural gas supplied directly from a production well lose the direct energy source when wells are closed and are forced to bear the costs of switching to other energy sources; jobs are lost; tax revenues are lost; and investment in critical infrastructure comes to a halt.

Commenter (2292-WVAG et al) asserts that the proposed rule will increase the costs of production – especially for low production wells. The commenter contends that, since more low-producing wells are owned by small businesses, many small businesses will be forced to close (in return for little benefit). The commenter notes that with 80 percent of U.S. wells producing fewer than 15 barrels a day, the compliance costs and associated closure will seriously hurt American consumers.<sup>122</sup>

The commenter (2292-WVAG et al) expresses concern with the scale of the proposed rule. The commenter notes that West Virginia alone has over 55,000 active and 12,000 inactive oil & gas wells. But even West Virginia’s production and facilities numbers are small when compared to places like Texas—which currently monitors approximately 161,000 active oil wells and 87,000 active gas wells—or other states like Alaska, Louisiana, Oklahoma, and North Dakota. The commenter states that the Supplemental Proposal will result in significantly increasing costs at hundreds of thousands of facilities. The commenter expresses concern that the Supplemental Proposal excludes a meaningful analysis and discussion of whether these increases would fall within a reasonable range. Instead, the commenter notes that EPA satisfied itself by declaring that the “\$1,970/ton of methane reduction” was below the \$2,185/ton threshold that it found reasonable six years ago. The commenter contends that, without any supporting data or analysis, these numbers are next to meaningless; it is not enough for EPA to note that it has done something similar before and dub its cost-benefit analysis complete.

Commenter (2322-ADEQ) contends that EPA did not adequately consider the impacts on small businesses and marginal well owners and operators. The commenter asserts that removing the 3 ton per year (tpy) creates an unmanageable number of sources for regulatory authorities to inspect and permit. Further, the commenter states that removing the threshold also disproportionately causes negative economic effects for individuals and families in rural areas (i.e., underserved communities) who receive minimal financial benefits from small sources located on their private property. The commenter disagrees with EPA’s decision to promulgate

<sup>120</sup> [https://cdn.bfldr.com/AHJE351Z/at/jrb837bsbpc3gn3x5zksqtpc/Shale\\_Dashboard\\_Q3Q4\\_2021\\_FINAL\\_45\\_.pdf](https://cdn.bfldr.com/AHJE351Z/at/jrb837bsbpc3gn3x5zksqtpc/Shale_Dashboard_Q3Q4_2021_FINAL_45_.pdf).

<sup>121</sup> [https://ohiolmi.com/\\_docs/OhioShale/2021AnnualShale.pdf](https://ohiolmi.com/_docs/OhioShale/2021AnnualShale.pdf).

<sup>122</sup> U.S. ENERGY INFO. ADMIN., THE DISTRIBUTION OF U.S. OIL AND NATURAL GAS WELLS BY PRODUCTION RATE 3 (Dec. 2022), <https://bit.ly/3jqWhOI>.

the Proposed Rule. The commenter urges EPA to include exemptions for small sources as initially proposed, and to thoroughly evaluate the effect that the requirements will have on small businesses and individual families who have domestic wells on their property.

The commenter (2322-ADEQ) notes that in 2022 approximately 16,000 oil and gas wells were producing in Arkansas by approximately 300 operators.<sup>123</sup> The commenter notes that Eighty-five percent of the 7,000 producing oil wells in southern Arkansas and fifty percent of the 9,000 producing natural gas wells in northern Arkansas are “stripper” or marginal producing wells. These wells cannot provide sufficient financial benefit to the well operators to fund the additional measures required for compliance with the Proposed Rule. According to 2020 Census data, 58 oil and gas producers in Arkansas reported having fewer than five employees. The commenter notes that most of these marginal production wells are located in rural areas of the state, where annual income is typically on the lower end of the scale, and the Proposed Rule will negate the income currently generated for the landowners and tax revenues for those small communities.

The commenter (2322-ADEQ) states that the average household income in Arkansas in 2019 was \$47,600; compared to national percentiles using EPA’s EJ screening tool, a majority of the state falls within the 60 to 90<sup>th</sup> percentile for “low-income,” with a good portion falling into the 90-100<sup>th</sup> percentile.<sup>124</sup> The commenter notes that the oil and gas industry is a significant contributor to local economies and individual financial stability in rural areas in the state where employment opportunities are often limited. Census data from 2017 established that over 3,700 employees reported as working in the oil and gas industry in Arkansas. The average annual salary in the state for oil and gas industry jobs in 2017 was just over \$52,000, 10 percent higher than the average salary statewide. The commenter contends that this is a substantial portion of revenue that makes its way back into the coffers of rural communities that lack the combined resources of more populated communities. The commenter states that the Proposed Rule burdens small producers and individual owners in a way that threatens to cause closures and shutdowns at otherwise productive and economically beneficial well sites, and the impact to rural communities (where a majority of these wells are located) has not been properly considered or explored by EPA.

The commenter (2322-ADEQ) contends that states rich in energy production and energy resources used for nationwide benefit historically have populations of lower socioeconomic status; these citizens welcome oil and natural gas activities and the resulting energy production in their communities because it provides stable tax revenue and well-paying jobs in areas where economic development (and employment) is scarce. The commenter recommends that EPA consider that these already economically burdened states and populations inherently bear more of the weight for any requirements imposed on the oil, gas, and energy industries.

Commenter (2446-IPAA) urges EPA to consider the proposed rules forced shutdown of oil and natural gas production that will result in lost revenue, lost jobs, impact on secondary businesses, negative impact on the American economy, and worldwide impacts.

---

<sup>123</sup> Arkansas Oil and Gas Commission.

<sup>124</sup> <https://ejscreen.epa.gov/mapper/> Arkansas map, low income filter, shown by county.

The commenter (2446-IPAA) notes that supply disruptions occur around the world at a regular frequency. The disruptions may last for a few months (i.e., a terrorist bombs a transportation pipeline, and the pipeline needs to be repaired) to several years (i.e., economic penalties enacted to encourage Iran to abandon their nuclear program). The commenter notes that in some cases, the supply disruption only serves to redirect where oil is processed (the U.S. cannot purchase Venezuelan crude oil, but other countries such as China may process the crude oil). Unlike a supply disruption, when low production wells are plugged, the production will never be recovered.

The commenter (2446-IPAA) states that if low production wells are shut down, this will take approximately ten percent of the American oil production and natural gas production offline, and approximately one percent of world oil production offline. This change in production will have long term, negative consequences for the American economy from higher energy prices and from the loss of jobs. When low production wells are plugged, this production is lost forever.

The commenter (2446-IPAA) contends that EPA needs to consider these negative consequences in the economic analysis of the proposed regulation. For example, the direct lost revenue to oil and natural gas companies and royalty owners if American oil production is diminished will be almost \$30 billion per year (1,000,000 barrels of oil x \$80/barrel x 365 days per year). This does not include the secondary financial loss to service companies or other businesses that derive revenue from oil and gas production (such as restaurants, automotive companies, accounting companies, office supply stores, and legal firms).

The commenter (2446-IPAA) reports that historically, when the crude oil supply and demand balance has been disrupted by two to three percent, there have been large changes in the price of crude oil. While the U.S. does not have specific controls in place to manage the balance of supply and demand (it permits market forces to drive the supply and demand balance), OPEC actively controls production to balance supply and demand. OPEC only has 3 million to 5 million barrels/day of spare capacity to manage the supply and demand changes. The commenter states that the supply and demand balance is typically controlled within one to three percent of worldwide crude oil production. Permanently removing a million barrels of production will have a measurably negative impact on the long-term supply of crude oil. The negative impact will be measured by higher crude oil prices.

Additionally, the commenter (2446-IPAA) urges EPA to include “economic” considerations in the rule language for certification. The Supplemental Proposal acknowledges that economic feasibility can be factored in to determining when is appropriate to utilizing an unloading method that vents to the atmosphere. However, the commenter notes that the proposed regulatory language in the context of record keeping and certification makes no mention of economic feasibility:

I certify that the technical and safety infeasibility justification of needing to use a non-zero emitting liquids unloading method for all liquids unloading events at the well affected facility was prepared under my direction or supervision. Based on my professional knowledge and experience, and inquiry of personnel involved in the

infeasibility justification, the certification submitted herein is true, accurate, and complete.<sup>125</sup>

According to the commenter (2446-IPAA), there are limited instances where an engineer or qualified professional would certify “infeasibility” – pour enough money at a particular issue, most technical and/or safety issues can be resolved or are “feasible.” The “economic” considerations allowed for the Supplemental Proposal must be included in the rule language for the certification.

Commenter (2238-SOOGA) states that the Supplemental Proposal is overloaded with stringent emissions standards and related compliance requirements that are impractical, technically infeasible, cost-prohibitive, overly burdensome, and otherwise unreasonable. The commenter contends that the impacts of such requirements are disproportionately borne by small businesses and operators of low production wells. Relatedly, the commenter notes that the areas in which the oil gas industry predominantly operates and, in turn, provides necessary and critical services – i.e., overburdened and underserved rural communities such as found in southeast Ohio and western West Virginia – are the areas that will suffer the economic consequences stemming from the Supplemental Proposal. The commenter asserts that this effectively results in environmental injustice and social injustice in these communities. That is, rural families and farmers whose homes are heated by an oil/natural gas production well are forced to bear the costs of switching to other energy sources such as burning wood and/or coal which may be more detrimental to the environment and indoor air quality. Consequently, jobs are lost; tax revenues are lost; and investment in critical infrastructure comes to a halt.

Response II-20-25: With respect to overall oil and natural gas production and prices, EPA disagrees with commenters’ assertions that the regulation would have profound impacts. Several commenters allege severe impacts but fail to provide specific information to support those claims. EPA models the impact of the rule on oil and natural gas supply in Section 4.1 of the Final RIA. EPA estimates that the reduction in U.S. oil production as a result of the Final Rule would be approximately 1.05% or less, while the reduction in gas production would be approximately 0.75% or less. EPA estimates that the impact on natural gas prices will be \$0.06/Mcf or less, and the impact oil prices will be \$0.25/bbl or less. These represent changes of approximately 1.76% and 0.33%, respectively.

With respect to marginal wells, EPA disagrees with the suggestion of one commenter (2446-IPAA) that all low production wells could be shut down, resulting in a loss of 10% of domestic production. EPA notes that it developed a financial analysis of marginal oil and natural gas wells in Chapter 6 of the Final Rule TSD. EPA finds that marginal wells may continue to operate at low or negative profits rather than be shut-in and plugged due to a variety of reasons, including low operating costs, high plugging costs, low state bonding requirements, accounting practices, and tax credits available to the oil and gas industry. In any case, the analysis suggests that to the extent that any marginal wells might be plugged in relation to anything contained within this rulemaking (which is speculative), the analysis suggests that they would be extremely low-producing wells.

---

<sup>125</sup> Page 250 of the Proposed Regulatory Text at <https://www.epa.gov/controlling-air-pollution-oil-and-natural-gas-industry/epa-issues-supplemental-proposal-reduce>.

Also with respect to marginal wells, EPA rejects commenter's (2179-KIOGA) suggestion that methane emissions from low production wells are proportionate to their production levels. Recent studies have suggested that low production, or marginal, wells account for roughly half of methane emissions from oil and natural gas production (see Chapter 6 of the TSD).

With respect to impacts on small businesses and rural communities, EPA notes the revised IRFA and FRFA provides an extensive discussion of regulatory flexibility alternatives and notes key areas where options were chosen to reduce regulatory burden on small businesses. For example, EPA revised its proposed fugitive emissions monitoring requirements at well sites to allow for AVO inspections at sites with little or no equipment, which EPA believes disproportionately alleviates regulatory burden on small businesses without sacrificing significant environmental benefits. Additionally, both NSPS OOOOb and EG OOOOc include provisions that could be pursued for an alternative but equivalent compliance option under NSPS OOOOb or equivalent or less stringent requirements considering remaining useful life and other factors (RULOF) under EG OOOOc under a state plan. 40 CFR 60.5399b (What are the alternative means of emission limitations for GHG and VOC emissions from well completions, liquids unloading operations, centrifugal compressors, reciprocating compressors, fugitive emissions components, and process unit equipment affected facilities; and what are the alternative fugitive emissions standards based on state, local, and tribal programs?) of NSPS OOOOb provides procedures for the submittal and approval of alternative means of emission limitation for GHG and VOC based on work practices for well completions, liquids unloading operations, centrifugal compressors, reciprocating compressors, fugitive emissions components and process unit equipment affected facilities. See section XIII.C (Establishing Standards of Performance in State Plans) of the final rule preamble for state plan requirements and sub-section XIII.C.3 (Remaining useful life and other factors (RULOF)) of the final rule preamble for a summary of the RULOF provisions that have been finalized in the subpart Ba rulemaking (codified at 40 CFR part 60, subpart Ba).

With respect to potential employment impacts, EPA acknowledges the challenge in assessing the employment impacts of the regulation. To the extent that regulatory costs lead to reduced production, sector employment could be reduced, though this is not guaranteed as firms could simultaneously reallocate expenditures on productive inputs away from capital and towards labor because of the regulation. In addition, as noted by some commenters, the regulation may also increase employment by increasing the demand for compliance-related labor. The net effect is ambiguous without sufficient data, which hasn't been provided by commenters.

In response to the commenter that provides examples where the December 2022 Supplemental Proposal's expanded requirements, the EPA addressed affected facility/designated facility requirements specific comments that parallel this commenter's concerns under other Chapters of this RTC. For EPA's response to comment on well site fugitive emissions requirements, see Volume II, Chapter 4 (Fugitive Emissions from Well Sites, Centralized Production Facilities, and Compressor Stations) of this RTC. This Chapter also includes EPA's responses to comments on well closure requirements (see section 4.1.6 Well Closure Requirements) of Volume II, Chapter 4. For EPA's response to comments on process controllers and pumps, see Volume II, Chapters 7 (Process Controllers) and 8 (Pumps).

With regards to the December 2022 Supplemental Proposal proposed dry seal compressor requirements, see discussion in section XI.G.1 (Redefining the affected facility to include centrifugal compressors with dry seals and the proposed standard) of the final rule preamble. Based on comments received on the December 2022 Supplemental Proposal, the EPA has revised the proposed volumetric flow rate performance standard for centrifugal compressors with dry seals to be 10 scfm/seal (i.e., representing a maximum flow rate applicable to all dry seals).

For the liquids unloading comment, where the commenter urges EPA to include “economic” considerations in the rule language for certification, see section XI.F.3.b (Recordkeeping and reporting requirements) of the final rule preamble. As a work practice standard, the engineering certification statement that would be required under the December 2022 Supplemental Proposal, which would have required an explanation of why it is infeasible to utilize a non-venting method due to technical, safety, or economic reasons, is unnecessary and has been removed from the final rule.

See also section X (Summary of Final Standards NSPS OOOOb and EG OOOOc) of the final rule preamble for a summary of the final affected facility/designated NSPS OOOOb and EG OOOOc requirements.

Comment: Commenter (2219-WOGCC) states that they are the state regulatory agency for the oil and gas industry in Wyoming. They report that their agency regulates all aspects of wells in the state including rules on venting and flaring, well drilling and completions, well operations, and well plugging, while the Wyoming Department of Environmental Quality (WDEQ) regulates air quality at oil and gas locations. In addition to WOGCC and WDEQ regulations, they note that wells on federal lands must also comply with BLM regulations, inserting layers of regulations and regulatory agencies that operators must consider.

The commenter (2219-WOGCC) complains that the EPA proposed rule creates yet another regulatory burden that will be placed on wells and operators in Wyoming. When evaluated in conjunction with the recently announced BLM rule on waste prevention, they contend that these rules become sometimes duplicative, sometimes conflicting, but always burdensome on operators to navigate how to remain in compliance with each. Not only does EPA's proposed rule place these burdens on an operator related to air quality regulations, but the commenter states that the EPA is proposing regulations outside of its authority on issues such as well plugging and financial assurance. According to the commenter, these issues are clearly within the state's and BLM's regulatory authority, not EPA. The commenter asserts that the EPA should remove the proposed requirements and suggest regulations only on issues that it is granted authority over.

Response II-20-26: Once the EPA establishes NSPS for a particular source category, the EPA is required in certain circumstances to issue EG to reduce emissions from existing sources in that same source category. Specifically, CAA section 111(d) requires that the EPA prescribe regulations to establish procedures under which states submit plans to establish, implement, and enforce standards of performance for existing sources for certain air pollutants to which a Federal NSPS would apply if such existing source were a new source. The EPA addresses this CAA requirement both through its promulgation of general implementing regulations for CAA section 111(d) as well as through specific EG. Please see section IV.A. of the final preamble of additional discussion on EPA's statutory obligations under CAA section 111. Furthermore, to be

clear, the final EG OOOOc in no way impacts states' ability to regulate sources under state law. Please see discussion of state flexibilities and response to comments section XIII.C.2 of the final preamble.

Please see section VI.A in the final preamble discussing related federal actions. EPA notes that certain Federal agencies also regulate aspects of the oil and natural gas industry pursuant to their own authorities. For example, BLM specifically has the express authority and responsibility to regulate both for the prevention of waste and the protection of the environment for operations on Federal and Indian lands. This responsibility includes promulgating regulations to reduce the waste of natural gas from oil and gas leases administered by the BLM.

Lastly, please see the final Supporting Statement for EG OOOOc in the docket for this rulemaking, which EPA estimates information collection activity burden for the states.

### ***20.4.3 Energy Impacts***

Comment: Several commenters (2166-ODNR, 2202-TOGA, 2241-UDNR, 2248-NDPC, 2301-US CC, 2308-NSWA, 2466-IPAA, 2544-PBPA) assert that the supplemental proposal has substantial direct negative effects on energy supply and energy security and/or provide studies and references supporting the adverse impacts. Some of the commenters note that decreasing U.S. production will result in increased oil and gas production in countries with lenient or non-existent environmental regulations, thereby increasing global emissions. Other commenters urge EPA to consider the effects of diminished energy supply and downstream effects when finalizing the proposed rule and recommend that EPA balance requirements with support for maintaining domestic oil and gas production. Examples of some of the comments are presented in the following paragraphs.

Commenter (2241-UDNR) states the rule has potential negative impacts on all Utahns. For example, they note that there is a looming global LNG shortage. As a consequence, "[n]atural gas utilities try to dampen price increases for their customers by hedging and purchasing natural gas in advance at lower prices, but there is nothing they can do about global supply shortages. Ultimately, the price increases are passed on to customers, who have no option but to pay the higher bills." These increased prices passed to consumers hurts low-income Americans the most. For example, "for many struggling families, higher prices can mean being forced to choose between heat, food or medication. About 29% of Americans who were surveyed had to reduce or forego expenses for basic household necessities to pay an energy bill in the last year, according to the U.S. Census Bureau. And that was before natural gas prices started to rise." The commenter provides a graph in their comment letter that illustrates a sharp increase in consumer prices (from the U.S. Energy Information Administration), which shows that nearly half of all U.S. households heat with natural gas, and that these "households that use natural gas as the primary space heating fuel will spend about \$930 this winter, 28 % more than they spent last winter." [Comment letter includes a table that shows U.S. average house expenditures with various heating methods between Oct-Mar. Costs are given for a base case, assuming 10 percent colder, and 10 percent warmer temps.]

Commenter (2241-UDNR) states that there is also a direct relationship between higher energy prices and a correlating food security issue is highlighted in other sources. The commenter states that these "[u]nexpected increases in energy prices (also called energy price shocks) can adversely affect food security; purchasing food and gasoline and paying utility bills compete for the same limited resources of low-income households. For poor families, rising energy prices create a difficult tradeoff between buying enough food, staying warm, or having enough gas for the car. Energy price shocks may be particularly detrimental to low-income households because they have fewer resources available to absorb the unplanned higher expense. While previous research has indicated that low-income households reduce the amount of food they buy in response to unexpected increases in energy prices, it is not clear whether these price shocks are large enough to dent a family's food security."<sup>126</sup>

The commenter (2241-UDNR) notes this correlation is backed up by a recent study conducted by the USDA Economic Research Service, which "explored the relationship between energy price shocks and food security, as well as two other measures of food hardship or distress, and found that price shocks in each energy source in the analysis—gasoline, natural gas, and electricity—caused an increase in the probability of a household becoming food insecure and/or experiencing two other food-distress indicators. The magnitude of the response was higher for low-income households compared to the average response for all households."<sup>127</sup> Accordingly, the requests consideration on how the proposed rule will contribute to potential energy shortages and what they believe could be the threat of disastrous correlating energy shocks.

Commenter (2241-UDNR) believes as EPA moves forward with the proposed rule/supplemental proposal, the state would encourage it to examine in depth the potential negative implications and hardships that will be imposed on Utahns and Americans nationwide if this rule is finalized. As stated, they conclude that there is a looming natural gas shortage in this country, and if rules are put in place that make production of said natural gas even harder, then surely they believe we will see negative social justice and environmental justice ramifications (such as those described above) manifest themselves in the form of increased human suffering.

Commenter (2301-US CC) explains that, at the consumer level, energy costs represent a sizable portion of American consumer's budgets, whether it be the prices consumers pay at the pump, the amounts spent on power or heating bills, or the price tags on countless consumer goods.<sup>128</sup> Oil and natural gas are critical to allowing Americans to affordably power the vehicles that deliver their products or allow them to commute to work, and represent the vast majority of

<sup>128</sup> See DOE, Valuation of Energy Security, *supra* note 5, at 31–34; Josh Mitchell, Soaring Energy Prices Raise Concerns About U.S. Inflation, Economy, Wall St. J. (Oct. 10, 2021), [https://www.wsj.com/articles/soaring-energy-prices-raise-concerns-about-u-s-inflation-economy11633870800?st=rx3j3jxhf6ivnp7&reflink=desktopwebshare\\_permalink](https://www.wsj.com/articles/soaring-energy-prices-raise-concerns-about-u-s-inflation-economy11633870800?st=rx3j3jxhf6ivnp7&reflink=desktopwebshare_permalink).

energy consumed for these transportation purposes.<sup>129</sup> In fact, transportation costs are the second-largest expense for most households' annual budgets, often accounting for as much as 20 percent to 25 percent of annual income.<sup>130</sup> Further, half of all American households rely on natural gas for heating their homes and water, cooking, and drying clothes, making them especially sensitive to fluctuations in the price of natural gas.<sup>131</sup> Because much of this energy-related consumer spending is essential, "[c]onsumers can't easily cut [energy] consumption on short notice, as they can with discretionary purchases, so higher prices act as a tax, draining the money they have available to spend on other goods and services."<sup>132</sup> When consumers elect to instead cut discretionary spending, the reduction carries negative consequences for the broader economy and helps explain why high energy prices often precede recessions.<sup>133</sup>

Moreover, the commenter (2301-US CC) adds that natural gas has become essential to the electric generation and industrial sectors. In fact, since 2005, the annual consumption of natural gas has grown by nearly 41 percent, or 9 trillion cubic feet, with the electric generation (up 60 percent) and industrial (up 28 percent) sectors comprising nearly 90 percent of the increase in annual consumption.<sup>134</sup> Natural gas has displaced other power generation sources to become the primary fuel for electric power generation over the past 10 years.<sup>135</sup> Further, manufacturers use oil and natural gas as a feedstock or as a fuel for production. A stable supply of oil and natural gas is critical to ensure adequate production of petrochemicals, medical devices, plastics, solvents, fertilizers, and many other products that American consumers use on a regular basis.<sup>136</sup>

Commenter (2301-US CC) recommends that EPA also recognize the wide variety of landscapes and regions production occurs, often remote locations with limited infrastructure or onsite personnel. The commenter contends that by imposing requirements that assume the regular availability of on-site staff or electricity, EPA risks undermining U.S. energy diversity by reducing the economic viability to continue operating at many of these locations, particularly when they contain existing sources that would be subject for the first time to methane regulations.

The commenter (2301-US CC) states that energy security plays a key role in the U.S.' economic success by ensuring the availability of affordable, reliable, and diversified sources of energy

capable of fueling our national economy.<sup>137</sup> In an increasingly global energy market, the U.S. has grown more vulnerable to foreign energy disruption—including not just political disruptions, but also cybersecurity threats, extreme weather events, and other sources of risk to affordability, reliability, and/or availability.<sup>138</sup> The commenter asserts that the recent surge in domestic production, however, has helped safeguard America’s energy security from such foreign disruptions, while simultaneously helping the entire global energy market weather such volatilities. The commenter notes that the Department of Energy (DOE) has found that increased production of oil and natural gas has “improved domestic, and thus global, energy security in a variety of ways” and has repeatedly prevented spikes in energy prices that could threaten both the U.S. and global economy.<sup>139</sup> The commenter believes that the U.S. is fortunate to presently have a stable supply of domestic oil and natural gas production, but this valuable supply is vulnerable to dissipation if overly burdensome regulatory regimes, or other factors, impede the development of available resources.

The commenter (2301-US CC) states that the impact that energy shortages and reliance on foreign energy sources can have on economic stability—and the counterbalancing benefits of strong domestic production—has been highlighted by recent events in Europe. In contrast to the U.S., which has a stable domestic supply of natural gas, Europe imports much of its natural gas supply—including a significant percentage from Russia—and is therefore far more vulnerable to geopolitical disruptions. The commenter asserts that the ongoing Ukraine crisis has placed this vulnerability on full display, as reductions in natural gas imports from Russia have spurred an energy crisis across the continent.<sup>140</sup> The commenter reports that the European Union, as a result, has had to mitigate shortages with voluntary and mandated energy rationing measures,<sup>141</sup> and consumers have had to grapple with sharp price increases in everyday consumers goods, as the prices for energy inputs skyrocket.<sup>142</sup> Further, many of Europe’s industrial sectors have struggled to keep operating.<sup>143</sup> And the downstream consequences of the energy crisis are wide-ranging and will likely be felt for years to come: “The IMF calculated in mid-July that for Hungary, Slovakia, and the Czech Republic a full cut off of natural gas from Russia could drop GDPs by up to 6 percent. Global economic growth would drop by 2.6 percent in 2022 and another 2 percent in 2023. On a human level, some people will not have heating this winter; others will

have to choose between warmth and food.”<sup>144</sup> It has been the influx of U.S.-produced liquified natural gas (LNG) to European markets that has helped blunt some of the more devastating consequences of the European energy crisis.<sup>145</sup>

By contrast to the European Union, the commenter (2301-US CC) asserts that one key factor in the relative stability of U.S. energy prices is supply diversity, which “reduces the likelihood that disruptions to supply or threats to production areas, trade, or distribution routes—whether caused by weather, terrorism, or geopolitics—significantly disrupt U.S. access to physical energy supplies.”<sup>146</sup> In addition to global geopolitical events like those noted above, domestic disturbances can hinder the ability to get energy to consumers. The commenter notes that localized weather events could cause certain sources of energy to be taken offline for periods of time, meaning that redundancy in the availability of energy sources is important to ensuring that our economy is able to continue to function smoothly. In addition, heat waves and winter freezes can result in short term and localized spikes in energy demand, as there are regions of our country that are particularly vulnerable to such disruptions because of concentrations of supply or transportation issues. Because oil and natural gas can be strategically stored without relying on battery storage, they are better suited for preparing for an energy disruption than are many renewable energy sources.<sup>147</sup>

The commenter (2301-US CC) states that, fortunately, the U.S. oil and natural gas industry is already “highly diversified because it is comprised of many privately held businesses that respond to market forces to increase or decrease production of oil and natural gas.”<sup>148</sup> Domestic oil and natural gas production also provides source diversity because it occurs over a broad set of geographic regions, so that significant oil and natural gas production is possible from eastern states such as Pennsylvania, to Texas and southwestern states like New Mexico, to Colorado and Wyoming in the west, as well as North Dakota and Alaska.

The commenter (2301-US CC) notes that even as the U.S. has attained record levels of oil and natural gas production and, in turn, increased its energy security, the nation has seen a sharp decline in GHG emissions. Overall CO<sub>2</sub> emissions from fossil fuel combustion have decreased by 1,409.4 million metric tons of CO<sub>2</sub> equivalent (MMT CO<sub>2e</sub>) relative to 2005 levels—a

<sup>148</sup> See DOE, Valuation of Energy Security, *supra* note 5 [See U.S. Dep’t of Energy (“DOE”), Valuation of Energy Security for the United States 12 (2017), [https://www.energy.gov/sites/prod/files/2017/01/f34/Valuation%20of%20Energy%20Security%20for%20the%20United%20States%20\(Full%20Report\)\\_1.pdf](https://www.energy.gov/sites/prod/files/2017/01/f34/Valuation%20of%20Energy%20Security%20for%20the%20United%20States%20(Full%20Report)_1.pdf)], at 12.

decrease of approximately 24.5 percent.<sup>149</sup> From 2019 to 2020, emissions decreased by 509.7 MMT CO<sub>2e</sub>, or approximately 10.5 percent.<sup>150</sup> The commenter reports that this is due in large part to the transition to natural gas from more carbon-intensive fossil fuels, such as coal, especially in the electricity generation sector and industrial sectors.<sup>151</sup> Further, the commenter notes that the U.S. oil and natural gas production sector has maintained a much lower methane emission intensity than many of its foreign counterparts and is far superior to the intensity of many Organization of Petroleum Exporting Countries (OPEC) nations.<sup>152</sup> Thus, the domestic oil and natural gas industry already plays an important role in reducing America's overall carbon footprint.

The commenter (2301-US CC) states that oil and natural gas has a significant role to play in the ongoing energy transition. For example, natural gas is providing, and will continue to provide, the reliable, flexible, baseload power that enables increased deployment of intermittent renewable sources. This will remain a critical factor as renewable generators address challenges to deployment at the scale necessary to meet America's energy needs. The commenter contends that those challenges include, among others, permitting complications,<sup>153</sup> reliable access to markets in rare earth metals and critical minerals that serve as critical components for batteries, electric vehicles, solar panels, and wind turbines;<sup>154</sup> and the weather dependency of many renewable generation sources that lack reliable battery storage and deployment.<sup>155</sup> Further, petrochemicals and petroleum products are important base materials for renewable infrastructure, such as the layers of copolymers between photovoltaic solar panels<sup>156</sup> and the plastics, resins, and fiberglass in wind turbines.<sup>157</sup> Finally, given the current technological limitations and

ongoing deployment of presently scarce grid-scale batteries, generators that combust fossil fuels will be necessary to ensure sufficient “capacity”—the capability of the generators linked to a grid to produce energy on demand—to prevent brownouts or, worse, blackouts. Natural gas-fired power plants are often the “peaking plants,” or “peakers,” that can run on demand and provide capacity during periods of high demand.

Commenter (2248-NDPC) states that the oil and natural gas industry is an integral part of the U.S. and North Dakota’s economies. In 2021, oil and natural gas accounted for 68 percent of the energy consumption in the U.S..<sup>158</sup> The commenter contends that affordable energy prices generally benefit all sectors of the American public, and cost-effective regulation of the energy industry can benefit human health and the environment.

Commenter (2166-ODNR) contends that the supplemental notice will result in the removal of a large amount of oil and gas from the marketplace, increasing energy costs to the public. The commenter notes that the supplemental notice addresses the cost of implementation, and the costs/benefits to society from reducing emissions. These costs focus on the “social costs”; however, the commenter states that the supplemental notice does not account for increased costs for alternate sources of energy due to loss of natural gas production if the wells are plugged rather than implementing emission control equipment.

Commenter (2466-IPAA) states that as natural gas has become more of an internationally traded commodity – one that has critical implications today in Europe due to the Russian invasion of Ukraine – loss of American natural gas in the world market can disrupt its stability both nationally and internationally.

Commenter (2254-PBPA) asserts that the proposed rules will reduce the total production of oil and gas in the US over the coming decades. The commenter notes that an EPA internal analysis concluded this rule would cause a loss of at least 200 million barrels of oil (equal to 28 percent of the US strategic petroleum reserve’s capacity) over the evaluated time frame. Concurrently, the EPA also reportedly underestimated the likely reduction in oil and gas production. The commenter states that hydrocarbon use in society has undeniably led to significant improvements in human life and the standard of living. Examples from the past 200 years include the world’s population increasing by seven billion, life expectancy more than doubling, and global extreme poverty levels falling from 50 percent to 10 percent. The commenter notes that human life has flourished as hydrocarbon use has increased. The commenter believes that it is a wasted opportunity to dismiss the benefits of hydrocarbon production in the US and internationally (the climate standard the EPA has chosen to use).

Commenter (2308-NSWA) asserts that the regulation will increase emissions globally due to reduced domestic production as it is curtailed -- or in some places shuttered. The commenter believes that such action will result in increased imports of oil and natural gas from producing countries with lower environmental and labor standards (i.e., India, China, Russia). The commenter contends that destabilizing national security implications of such a shift are obvious.

---

<sup>158</sup> U.S. EIA.

The commenters (2308-NSWA) urge EPA to undertake a robust analysis, made publicly available prior to the implementation of the rule, to determine whether the result of the rule will be to raise production – and thereby emissions – in other producing countries and regions around the world to meet what will continue to be growing U.S. and global demand. The commenters believe that this analysis should by no means be limited to oil and natural gas, as numerous industrial processes and manufacturing have been exported overseas; however, as the EPA is contemplating new regulations on domestic oil and natural gas production, the commenters urge the analysis to begin there.

Commenter (2202-TOGA) notes that EPA recognizes the potential for additional extraction of foreign oil and natural gas, which is not produced as efficiently or effectively as the same domestically. The commenter states that the RIA's for both the November 2021 and December 2022 proposed rules detail the significant adverse effects on energy supply. Further, the commenter asserts that the maximum projected annual decreases in oil and natural gas production exceeds the OMB benchmarks - reductions in crude oil supply, in excess of 20 million barrels per year and natural gas production in excess of 40 million mcf per year - for adverse effects. Therefore, the commenter contends that the proposed rule will show an adverse impact on the supply of oil and natural gas including diminished supply, increased costs.

Response II-20-27: EPA disagrees with commenters' assertions that the regulation would have profound impacts on domestic oil and natural gas production. Several commenters assert severe impacts but fail to provide specific information to support those claims. EPA models the impact of the rule on oil and natural gas supply as a result of the Final Rule in Section 4.1 of the Final RIA EPA estimates that the reduction in U.S. oil production would be approximately 1.05% or less, while the reduction in gas production would be approximately 0.75% or less. EPA estimates that the impact on natural gas prices will be \$0.06/Mcf or less, and the impact oil prices will be \$0.25/bbl or less. These represent changes of approximately 1.76% and 0.33%, respectively.

With respect to comments regarding household energy burden, EPA notes the analysis presented in Section 4.3.6 of the Final RIA and reiterates that it estimates the commodity price impacts of the final rule to be small. Finally, with respect to comments on the impact on GHG emissions of changes in oil imports, EPA is unable to quantify the impact due to data limitations. However, the relatively small estimated increase in imports suggests that the net effect on GHG emissions will be negligible.

Comment: Commenter (2218-TCEQ/RRC) states that the RIA demonstrates that significantly curtailing natural gas from the U.S. (and increasingly foreign) energy portfolio to achieve a stable climate is a major policy question that the FCAA is ill-suited to address. ("[T]he maximum projected decrease in natural gas production exceeds the benchmark for adverse effects, so this analysis indicates the proposed NSPS OOOOb and EG OOOOc constitutes a significant energy action (as defined by EO 13211, Actions Concerning Regulations That Significantly Affect Energy Supply, Distribution, or Use)." (Regulatory Impact Analysis, EPA-452/R-21-003, p. 4-8, October 2021.)

The commenter (2218-TCEQ/RRC) provides that the electric generation from U.S. produced natural gas is a growing segment of the electric energy market both domestically and abroad as

coal powered fleets are retired and natural gas demand in Europe and Asia continues to grow. The commenter contends that Congress did not intend for the Act to drive such a significant change in the development of domestic energy supply that will have global scale impacts. (“Under our precedents, this is a major questions case. In arguing that FCAA §111(d) empowers it to substantially restructure the American energy market, EPA ‘claim[ed] to discover in a long-extant statute an unheralded power’ representing a ‘transformative expansion in [its] regulatory authority.’ *West Virginia v. EPA*, 142 S.Ct. 2587, 2610 (2022) citing *UARG v. EPA*, 134 S.Ct. 2427 (2014)). The commenter notes that the FCAA is intended to address and mitigate a real and significant threat to human health and the environment through regulation of domestic emissions. Agencies have only the authority granted to them by Congress and no such grant to address global climate change or transform international energy supply exists in the CAA. The commenter suggests that, in the RIA, using a metric for cost avoidance that is extremely speculative to weigh against the cost of regulation, and the cost to global natural gas supply, indicates the FCAA’s inadequacy for addressing climate change. “The RIA focuses on the elements of this proposal that are likely to result in quantifiable cost or emission changes compared to a baseline without the proposal that incorporates changes to regulatory requirements induced by the Congressional Review Act (CRA) resolution. We estimated the cost, emissions, and benefit impacts for the 2023-2035 period.” 87 FR 74712.

Response II-20-28: The Final Rule is readily distinguishable from the Clean Power Plan and thus, under *West Virginia v. EPA*, 142 S.Ct. 2587 (2022), does not present a major question. *West Virginia* made clear that the application of the major questions doctrine is limited to “certain extraordinary cases.” *Id.* at 2609. The Clean Power Plan was such a case primarily because there, the EPA determined the best system of emission reduction to be directly shifting generation from certain types of electricity generating plants to other types of electricity generating plants. *Id.* at 2610-11. The Supreme Court contrasted the Clean Power Plan’s generation-shifting control measure with “the sort of ‘systems of emission reduction’ [the EPA] had always before selected— ‘efficiency improvements, fuel-switching,’ and ‘add-on controls’—as ‘more traditional air pollution control measures.’” *Id.* at 2611 (quoting the Clean Power Plan, 80 Fed. Reg. 64784). The Court recognized that such “traditional air pollution control measures” “may end up causing an incidental loss of ... market share [of the regulated sources],” but emphasized that there is “an obvious difference” between issuing that type of rule and issuing a rule like the Clean Power Plan, *id.* at 2613 n.4, and in that way, the Court indicated that the “incidental” impacts of “traditional air pollution control measures” would not mean that such a measure would rise to the level of an “extraordinary case[]” that would raise a major question. The Court also noted as another reason why the Clean Power Plan raised a major question was that its generation-shifting control measure took the form of a cap-and-trade program, which Congress had “considered and rejected multiple times.” *Id.* at 2614 (citations omitted).

This rule is readily distinguishable from the Clean Power Plan. It is based on “traditional air pollution control measures,” and those control measures are not designed to shift production from one type of source to another. Any such shifts are “incidental” impacts from the “traditional ... measures.” The EPA has long applied such at the source measures stationary sources under CAA Section 111. *See, e.g.*, “Phosphate Fertilizer Plants; Final Guideline Document Availability,” 42 FR 12022 (March 1, 1977); “Standards of Performance for New Stationary Sources; Emission Guideline for Sulfuric Acid Mist,” 42 FR 55796 (October 18, 1977); “Kraft

Pulp Mills, Notice of Availability of Final Guideline Document,” 44 FR 29828 (May 22, 1979); “Primary Aluminum Plants; Availability of Final Guideline Document,” 45 FR 26294 (April 17, 1980); “Emission Guidelines and Compliance Times for Municipal Solid Waste Landfills,” 81 FR 59276 (August 29, 2016). In addition, EPA does not believe that the final NSPS OOOOb and EG OOOOc will transform the domestic energy supply or transform international energy supply. Rather, any impacts on oil and gas production from this final rule are marginal, on the order of one percent.

Moreover, has Congress not “considered and rejected multiple times” these control measures. On the contrary, in June 2023, when Congress adopted the Congressional Review Act joint resolution to disapprove the 2020 Policy Rule, it made clear that it expected the EPA to regulate methane emissions from new and existing sources in the oil and gas source category. See H.R. Rep. No. 117–64, 3-5 (2021) (Report by the House Committee on Energy and Commerce concerning H.J. Res. 34, to disapprove the 2020 Policy Rule) (stated that the oil and gas source category “is the largest industrial emitter of methane in the U.S.,” and that “regulation of emissions from new and existing oil and gas sources, including those located in the production, processing, and transmission and storage segments, is necessary to protect human health and welfare, including through combatting climate change, and to promote environmental justice.”); 167 Cong. Rec. S2282 (April 28, 2021) (statement by Sen. Heinrich) (Senate floor statement from Senate sponsors of H.J. Res. 34 stated that “methane is a leading contributing cause of climate change,” whose “emissions come from all segments of the Oil and Gas Industry,” and that “we encourage EPA to strengthen the standards we reinstate and aggressively regulate methane and other pollution emissions from new, modified, and existing sources throughout the production, processing, transmission and storage segments of the Oil and Gas Industry under section 111 of the CAA.”).

Comment: Commenter (2227-WEA) noted that, in a 2017 study the Enhanced Oil Recovery Institute (EORI) at the University of Wyoming examined costs of using electricity in upstream oil and natural gas.<sup>159</sup> The 2017 EORI study evaluated whether, as a result of expanding use of distributed generation, utility provided power was a low-cost option for new oil and natural gas development. The study concluded that the cost of electricity in their Wyoming study area ranged from \$7 to \$18 per barrel of oil and as a result marginal wells were being shut in. The commenter states that shutting in wells will result in production decreases, lost revenue for governments and other public entities dependent upon taxes and fees and lost revenue for the utility, all of which will subsequently detrimentally affect the local economy. The commenter suggests that it is not clear that EPA has fully considered such regional-specific challenges in the lower 48 states in the development of the proposed rules, but such challenges need to be considered on a regional basis, just as they were for Alaska. The commenter contends that expanding the electric grid in many parts of the region is particularly challenging given the economic, geographic, public land, and weather challenges that exist and provides the following recommendations:

---

<sup>159</sup> “Oilfield Electrification: Collaboration Between Producers and Utilities Can Result in a Win-Win,” Omar Urquidez, Burns & McDonnell, 2021.

- Supplement the RIA to more thoroughly account for the regional developmental and implementation challenges associated with electrification of oil and natural gas operations.
- In the supplemental RIA make better use of information on the regional difficulties in implementing electric power to replace pneumatic power.
- More thoroughly document how the significant climate, geographic, topographic, and existing power grid obstacles are to be overcome to have a reliable alternative to electricity that can be developed and operated in an economically viable and operationally dependable manner.
- The proposed NSPS OOOOb and EG OOOOc regulations should be modified to take into full consideration the obvious regional electricity factors that would result from a more comprehensive supplemental RIA.
- EPA should supplement the RIA to more thoroughly examine the availability, functionality, economics and reliability of using electricity as a key resource in eliminating pneumatic controller emissions.
- EPA needs to take a more exhaustive look at lower 48 states' regional challenges associated with the power grid pertaining to obstacles such as climate, permitting, environmental, geography, and topography, accommodating for such factors as was done for Alaska.

Response II-20-29: EPA disagrees with the commenter's assessment that the RIA needs to assess regional implementation challenges associated with the electrification of oil and natural gas operations. While the RIA attempts to model important region-specific factors where possible (e.g., in the assignment of region-level major equipment distributions to model well sites), its primary purpose is to provide a best-estimate assessment of the nationwide impacts of the rule. Due to data limitations, EPA cannot feasibly account for local conditions across the country, and the commenter does not provide the necessary data to address these limitations.

With respect to the 2017 EORI study, the cost of electricity cited by the commenter is for bringing grid-based line power to the site, which is not a requirement of the rule. When assessing the possibility of using a generator to supply power, an option permitted under the rule, the study authors find that option to be less expensive in most cases. In addition, the study authors do not model the possibility of using solar photovoltaic systems with battery storage, which EPA finds to be an even more cost-effective option than a natural gas-powered generator in many cases.

The EPA considered these and other comments regarding regional differences and access to electricity when developing the final requirements under the final NSPS OOOOb and EG OOOOc rules. For example, as discussed in a response to a comment related to access to electricity for process controllers in Volume II, Chapter 7 (Process Controllers), subsection 7.2.2 (Access to Reliable Electricity), Response II-27-7, although the final rule maintains that sources outside of Alaska must meet the zero emission standard, there are several options available to such sites to meet the NSPS and EG. These include the use of solar-powered process controllers, the use of electric process controllers powered by a generator, the use of compressed air-driven process controllers powered by a generator, and routing emissions to a process. The EPA also notes that solar-powered process controller systems include batteries that are typically sized to contain a 10-day power supply, and this battery power ensures continuous process controller

operations. This would also apply for pumps (see Volume II, Chapter 8 (Pumps), subsection 8.2.2 (Access to Electricity), Response II-8-17).

Comment: Commenter (2219-WOGCC) In evaluating the economic impacts, EPA utilizes the social cost of carbon, methane, and nitrous oxide among other asserted social benefits. These societal benefit values are necessary to justify a rule that in reality costs more to comply with than it ends up benefitting. What is left out of the economic analysis are costs to society that will result from the implementation of the proposed rule. Not only will society lose the benefits of royalties, taxes, and jobs that are lost when wells are prematurely shut in and plugged, society will lose by incurring increased prices for fueling their vehicles, heating their homes, food or other goods, and all other items that society uses on a daily basis that are impacted by increased fossil fuel prices. The premature shut in and plugging of wells can only result in two outcomes. Either oil and gas prices will increase due to elimination of a portion of the supply or the loss in supply will be made up in other places. In either scenario society loses. Society loses by paying higher costs or it loses because of the environmental impact of shifting production to nations that do not produce oil/gas as cleanly and efficiently as the U.S. and incurs further environmental impacts by transporting that oil/gas to the U.S. In particular, the people of Wyoming lose. The costs of methane reduction in this rule are disproportionately born by the people of Wyoming and other oil and gas producing states. If EPA is utilizing societal benefits in justifying the economic impact of this rule it should also use the societal costs and conduct a full and complete economic analysis and consider localized impacts.

Response II-20-30: With respect to the comments regarding premature shut in and plugging of wells, EPA notes that it developed a financial analysis of marginal oil and natural gas wells in Chapter 6 of the TSD. EPA finds that marginal wells may continue to operate at low or negative profits rather than be shut-in and plugged due to a variety of reasons, including low operating costs, high plugging costs, low state bonding requirements, accounting practices, and tax credits available to the oil and gas industry. In any case, the analysis suggests that to the extent that any marginal wells might be plugged in relation to anything contained within this rulemaking (which is speculative), the analysis suggests that they would be extremely low-producing wells, and so the impacts on overall production and royalties would be minimal.

Comment: Commenter (2353-CrownQuest Operating, LLC.) states current monthly report estimates of recordkeeping for this proposed rule is over 880,000 hours per year for NSPS OOOOb and 2.2 million hours for EG OOOOc, with an estimated cost of over \$224 million annually for the industry, which is a significant underestimation. There are over 500,000 facilities between NSPS OOOOb and EG OOOOc that the EPA estimates to be covered by this rule. The commenter states all the estimated reporting applied to fugitive emissions facility annual reports would equate to about 6 hours per year. It is likely to be much more intensive than the estimated hours of recordkeeping, especially by smaller operators and small businesses that make up a large portion of the EG OOOOc facilities. This rule is complex and forces a diverse group of operations and sites into a one-size-fits-all box for a national agency to manage, which is ineffective regulation. This rule makes a critical, widely divergent, dispersed industry ask permission before operating. It will devastate oil and gas production, especially the future development of new oil and gas reservoirs.

Commenter (2353-CrownQuest Operating, LLC.) argues the EPA should instead focus on the recordkeeping that has shown to be effective based on critical operations. Making gathering and reporting on multiple types of data mandatory will create more data than can be analyzed or useful. For example, the EPA collected data from NSPS OOOOa for over 12 years but does not cite this data or its effect on targeted facilities' emissions once in the entire rule. This proposed rule is a massive expansion of NSPS OOOOa's requirements, especially regarding recordkeeping.

Commenter (2353-CrownQuest) states that there is no doubt that these proposed rules will reduce the total production of oil and gas in the U.S. over the coming decades. An EPA internal analysis concluded this rule would cause a loss of at least 200 million barrels of oil (equal to 28% of the US strategic petroleum reserve's capacity) over the evaluated time frame. Concurrently, the commenter adds that the EPA also reportedly underestimated the likely reduction in oil and gas production.

The commenter (2353-CrownQuest) notes that hydrocarbon use in society has undeniably led to significant improvements in human life and the standard of living. Examples from the past 200 years include the world's population increasing by seven billion, life expectancy more than doubling, and extreme poverty levels falling from 50% to 10%. Human life has flourished as hydrocarbon use has increased. The commenter suggests that it is a wasted opportunity to dismiss the benefits of hydrocarbon production in the U.S. and internationally (the climate standard the EPA has chosen to use).

The commenter (2353-CrownQuest) provides that the EPA states, "this rule will save enough gas to heat 3.5 million homes in the winter". According to the commenter, this statement points out the EPA's biased analysis and skewed calculations. The RIA calculates the rule will save 2,037 BCF of CH<sub>4</sub> from 2023 to 2035 but also cause the loss of 2,825 BCF of natural gas. The commenter suggests that a more appropriate statement by the EPA would be, "this rule will reduce the gas supply and leave 1.4 million homes without fuel in the winter". The commenter adds that this rule shows the EPA has a fundamental lack of understanding of the impact of these rules and the benefits of hydrocarbon access, especially for the poorest people.

Response II-20-31: The recordkeeping and reporting requirements in the rule that apply for each affected/designated facility represent the minimum level of tracking and documentation necessary to ensure compliance with the rule. EPA emphasizes that recordkeeping and reporting are vital components of compliance assurance and believes the recordkeeping and reporting requirements established in the final rule are reasonable and appropriate.

The EPA spent a significant effort in finalizing the specific cost elements used to estimate the recordkeeping and reporting burden when preparing estimates for the 2020 NSPS OOOOa rulemaking in order to address multiple comments received that the EPA had significantly underestimated the time and cost to complete the recordkeeping and reporting requirements (especially associated with the fugitive emissions program) under NSPS OOOOa. The majority of these costs and assumptions were retained in the recordkeeping and reporting burden analyses included in the December 2022 Supplemental Proposal and the final rule estimates, including the assumption of 22 wellsites per company-defined area and for gathering and boosting compressor

stations 7 stations per company defined area. See section VII.B (Paperwork Reduction Act (PRA)) of the final rule preamble for EPA's estimate of the recordkeeping and reporting requirements under NSPS OOOOa, NSPS OOOOb, and EG OOOOc.

The commenter provides no data or analysis to support the assertion that "EPA also reportedly underestimated the likely reduction in oil and gas production."

Comment: Commenter (2241-UDNR) contends that, while the U.S. could be taking a positive role in the international gas supply situation as a result of the Ukraine war by "opening the valve" on U.S. supplies and sending that liquid natural gas (LNG) to our North Atlantic Treaty Organization (NATO) allies in Europe, instead, natural gas production in the U.S. is down due to the anti-fossil fuel policies of the current administration, which have made investors hesitant to invest in natural gas projects.<sup>160</sup> For example, the commenter notes that, as of December 19, 2022 natural gas production in Utah is 194,602,919 thousand cubic feet (MCF), which is the lowest level of production in Utah since 1984.<sup>161</sup> For comparison, the commenter notes that the highest level of natural gas production in Utah came in 2012 with 490,575,308 MCF produced. While Europe continues to slog through the natural gas shortage quagmire, here in the U.S. through regulatory burden we are hamstringing our own operators and contributing to the artificial shortage which not only harms our economy at home, but hurts our allies overseas. From a purely economic standpoint, the commenter suggests that it would make sense to take advantage of this opportunity to bolster the U.S. economy. From an international relations standpoint, it makes sense to export the LNG we have in abundance here in the U.S. to our foreign allies, strengthening them in the uncertain geopolitical world we all live in, and strengthening our own economic and political position in the process.

As such, the commenter (2241-UDNR) believes that adding to necessary infrastructure (such as by building an LNG export facility somewhere on the west coast) would provide a better market for Intermountain West natural gas, help supply LNG to other countries and reduce their reliance on coal in the process. One such port was proposed at Coos Bay, Oregon, namely the Jordan Cove project. However, the project never saw completion as environmental activists and other groups successfully fought the project and the associated pipeline.<sup>162</sup> Due to such opposition, natural gas producing states (such as Utah) are having to look to other areas along the Pacific Rim as options for exporting their natural gas and getting it to market. For example, Utah is looking outside the U.S. to Mexico in an effort to access a "replacement port" for its goods. The port (with LNG export capabilities), is located in Ensenada, Mexico and is slated for completion in 2024.<sup>163</sup> While this port has the potential to provide the much needed potential export facilities

<sup>162</sup> Andrew Selsky, Controversial plan for Jordan Cove natural gas terminal in Southern Oregon abandoned, Associated Press, available at: <https://www.registerguard.com/story/news/environment/2021/12/01/jordan-cove-natural-gas-terminal-abandoned-southern-oregon-lng/8830677002/> (2021).

<sup>163</sup> SEMPRA, ECA LNG – A World-Class Project to help Power the Global Energy Transition, Semptra Infrastructure, available at: <https://semprainfrastructure.com/news-and-events/spotlight-stories/eca-lng-a-world-class-project-to-help-power-the-global-energy-transition> (2022).

for Utah and other Intermountain States, it is the State's recommendation that similar projects be encouraged here in our own nation, so that our producers can get their product from the oil patch to international markets without having to take unnecessary additional steps by first exporting the product to Mexico.

In sum, the commenter (2241-UDNR) notes that Europe and the rest of the world is facing a natural gas shortage. Exporting the abundant gas here in the U.S. would alleviate the pressures faced in Europe, while simultaneously reducing global coal reliance. However, they suggest that U.S. policies and environmental regulations are hampering our collective ability to produce and export more LNG, exactly in the moment when the world stage needs it most. As such, it is their recommendation that the EPA look at ways to encourage production – not restrict it through overburdensome regulations.

Response II-20-32: EPA disagrees with commenter's assertion that the rule will significantly inhibit oil and natural gas production. EPA models the impact of the rule on oil and natural gas supply as a result of the Final Rule in Section 4.1 of the Final RIA. EPA estimates that the reduction in U.S. oil production would be approximately 1.05% or less, while the reduction in gas production would be approximately 0.75% or less. EPA estimates that the impact on natural gas prices will be \$0.06/Mcf or less, and the impact oil prices will be \$0.25/bbl or less. These represent changes of approximately 1.76% and 0.33%, respectively.

#### ***20.4.4 Labor Availability Issues***

Comment: Commenters (2223-Texas Alliance of Energy Producers, 2283-Endeavor Energy, 2241-UDNR, 2305-Williams) express concern with labor shortages impacting the ability to meet requirements.

Commenter (2223-Texas Alliance of Energy Producers) notes the EPA has indicated in-house training and specialization on this is the best way to control cost, but that option is not always available to small businesses. The prospect for contract or outsourcing this requirement would place undue burden on small operators and cost estimates should reflect regional variability and rural workforce considerations that will show dramatic differences in price per service. Many of the commenter's members have made clear that they lack the adequate staff and resources to meet this new requirement should it be implemented for all facilities.

Commenter (2305-Williams) states that, in addition to increased equipment demand, there will also be an increased demand on specialized skill workers that could add further delays. If the EPA expects facilities to modify existing control devices to accommodate both new and existing sources, they suggest EPA allow more time for compliance. Installing new flow meters, testing ports, or net heating value measurement tools on existing control device lines handling multiple units or sources involves "hot tap" safety protocols. The commenter reports that this is specialized work that is typically handled by only a small handful of qualified contractors. In-house staff typically do not perform hot tap work. Therefore, for example, if EPA expects an entire industry to modify existing flares, the compliance deadline must account for the relatively small labor pool available to perform that work.

Commenter (2283-Endeavor Energy) contends that the manpower required to convert over all of the existing well sites across the Midland Basin to comply with the EGs as proposed is not available. The commenter notes that the region currently has a 2 percent unemployment rate. The commenter estimates that it would take an average work crew of four men about two weeks to make the conversions necessary for the average existing well site in the Midland Basin to come into compliance with proposed EG OOOOc. In order to meet just the needs of their operations, the commenter estimates it would take 320 qualified workers working full time for a year.

Based on their experience, the commenter (2283-Endeavor Energy) does not believe there are a sufficient number of contractors who can meet the needs of all operators in the Midland Basin, and "scaling up" too quickly would pose risks if contractors are forced to rely on new personnel who do not have qualifications, training, and experience to perform the necessary upgrades. This is just one example of why they believe the EPA cannot and should not assume that just because requirements have proven to be feasible for the much smaller pool of new or modified sources that operators are also able to implement these requirements more broadly for their existing sources.

Commenter (2241-UDNR) notes that recent data released by the U.S. Bureau of Labor Statistics shows that of the eight major industry sectors in America, five of them have recovered and now exceed pre-pandemic employment levels, while three of those sectors have yet to recover.<sup>164</sup>

The commenter (2241-UDNR) notes that the figure provided in their comment letter shows, of the three sectors that have not yet recovered, one of them is the "Mining and Logging sector." [Figure provided in comment letter: Timeseries graph from Feb 2020-Dec 2022, showing the change in employment level in various industry sectors (construction, government, retail trade, education, etc.)] The commenter adds that this particular sector includes several smaller sectors, namely agriculture, forestry, fishing, hunting, mining, quarrying, and oil and gas extraction.<sup>165</sup> The commenter provides that while the oil and gas extraction industry is not directly accounted for individually on the table, it is included in the overall "Mining and Logging" sector, which as shown, is still struggling to recover to pre-COVID employment levels.

At a time when the entire oil & gas industry (as well as the mining and logging sector as a whole) is struggling to recover from the last few years of economic slowdown and employment shortages, the commenter (2241-UDNR) believes that EPA should help the industry recover – not stifle it while it's struggling.

Response II-20-33: The EPA considered these and other comments expressing concern over labor availability issues when developing the final rule requirements for NSPS OOOOb and EG OOOOc.

For the NSPS OOOOb, the EPA has concluded that only sources constructed, modified, or reconstructed after the date of the Supplemental Proposal (December 6, 2022) should be

---

<sup>164</sup> 4 U.S. Department of Labor, Bureau of Labor Statistics: Employment Situation Summary, January 6, 2023 (Table B-1).

<sup>165</sup> 5 USBLS, Industries at a Glance: Natural Resources and Mining, U.S. Bureau of Labor Statistics, available at: <https://www.bls.gov/iag/tgs/iag10.htm> (2023).

considered new sources for the purposes of NSPS OOOOb. Changing this date to December 6, 2022, from the November 15, 2021, reduces the number of existing new sources that will need to comply with NSPS OOOOb, thereby allowing more time to address labor availability concerns. For details, please see discussion in section IX (Interaction of the Rules and Response to Significant Comments Thereon), subsection A (What date defines a new, modified, or reconstructed source for purposes of the final NSPS OOOOb?) of the final rule preamble. The EPA has also provided an alternative compliance timeline in the NSPS OOOOb final rule for process controllers and pumps required to meet a zero-emission standard (*i.e.*, final rule allows up to one year from the publication date of the final rule). See section XI.D.4 (Compliance dates) of the final rule preamble for a discussion on the compliance dates finalized for process controllers (which also applies for pumps).

For the EG OOOOc, the EPA is finalizing a compliance timeline of 36 months from the deadline for state plan submittals, which provides owners and operators of designated facilities time to plan and meet any increased labor demands. When the compliance timeline of 36 months is considered in conjunction with the state plan submittal deadline of 24 months, that means that sources could have up to 5 years between when the EG are final and when they are required to fully comply with the applicable standards of performance. The EPA believes that any concerns with possible equipment or staffing shortages, which commenters speculate could be an issue, would likely be addressed by industry and regulators in that timeframe. See section XIII.E.3 (Compliance timelines) of the final rule preamble for EPA's response to comments regarding the compliance timeline required under the EG.

#### ***20.4.5 Small Business Considerations***

Comment: Several commenters (2187-WB Osborn, 2200-NuEnergy, 2205-Kriebel, 2220-WDEQ, 2223-TAEP, 2238-SOOGA, 2241-UDNR, 2248-NDPC, 2254-PBPA, 2257-MOGA, 2279-SBA, 2294-OOGA, 2314-Miller Energy, 2322-AR DEQ, 2403-PAO, 2446-IPAA, 2625-Fore Energy, 2696-Peters et al, 3845-ND Congress) note that impacts of the proposed rule will disproportionately impact small businesses and request EPA give special consideration to the small business impacts of the rule. Some of the specific comments provided are included in the following paragraphs.

Commenter (2322-AR DEQ) asserts that the Proposed Rule, if finalized, represents a substantial expansion in the scope of sources regulated under their agency's air pollution control program; is anticipated to have major economic impacts for the state, particularly for small business operators and property owners who currently have financial interests in oil and gas operations.

Commenter (2322-AR DEQ) goes further, with the addition of thousands of new qualifying sources performing quarterly OGI, and without consideration of additional testing required for larger sources, the commenter anticipates a considerable increase in emission testing observations per year under the Proposed Rule. Increases in testing would stretch agency staff and resources thin. This would likewise be compounded by the fact that the rural nature of these locations will create substantial travel times between sites. Significantly increasing the number of additional sources to permit and inspect creates the need for additional permitting staff to process the onboarding of so many new sources and for additional enforcement staff when

noncompliance with requirements is noted. Though many sources could likely qualify for a general permit, there would still be a need for additional permit engineers and supporting administrative staff dedicated to oil and gas permit processing as well as customer service, due to the sheer volume of new sources.

Commenter (2322-AR DEQ) believes a regulation, rule, or requirement is only as effective as the compliance strategies and enforcement actions that actually govern it. Without a viable method for checking to ensure that all requirements are being met by all sources subject to the Proposed Rule, there is a potential to create an uneven economic advantage for those who choose to ignore the regulatory requirements. For some, it could be viewed as less burdensome to pay a penalty on the rare chance noncompliance is discovered than it is to comply.

Commenter (2446-IPAA) contends that the proposed regulations negatively impact low production wells. The commenter notes that most of the wells are operated by small businesses that are not able to distribute the additional compliance cost across many wells or high volume of production. The commenter states that these regulations disproportionately impact small businesses in every oil producing state, and the service companies that support the operators. Most of the small operators do not have the technical resources to be able understand EPA's requirements and implement the required programs. The commenter states that EPA will need to provide resources to assist the small businesses with compliance.

Commenter (2223-TAEP) contends that small operators —the vast majority in Texas and across the nation -- stand to be exponentially more affected by the implementation of “one-size-fits-all” approach of the proposed rule. The commenter notes for example, many of those small operators operate actively producing wells in the U.S. that produce 15 barrels of oil equivalent/90 MCF of gas or less per day. The commenter expresses concern that the proposed rule – for reasons detailed in the producers association comments -- will result in making those wells uneconomic, likely leading to shuttering, simply as a result of its implementation. The commenter states that any rule that imposes a cost on the operator would clearly disadvantage smaller operators relative to larger operators, and adversely impact communities across Texas that rely on small businesses. The commenter contends that no rule adopted by EPA should have the effect of putting oil and gas companies of any size out of business, or significantly changing the economics of the operations.

The commenter (2223-TAEP) urges EPA to continue to work closely with the Small Business Administration (SBA) to minimize and streamline regulatory requirements and burdens stemming from the rule. The commenter notes that their members and others continue to proactively address and reduce methane emissions from our operations and related work. Examples include:

- Texas Methane and Flaring Coalition, a coalition of trade groups and companies, including oil and gas operators of all sizes, established to track methane and flaring data in Texas and consider a group of industry best practices to monitor and reduce emissions in ways that do not impose economic harm on Texas producers.
- Modern production techniques, like hydraulic fracking, have brought substantial environmental benefits to the U.S. The dramatic decrease in carbon dioxide emissions is

due to fracking and the increased production and use of natural gas in the electricity sector.

- According to the state's oil and gas regulator, the "Railroad Commission production data shows that the percentage of natural gas flared compared to the natural gas produced from oil and gas wells in Texas dropped from a high of 2.29 percent in June 2019 to 0.65 percent in May 2021. During the same period, the volume of gas flared decreased by approximately 73 percent."<sup>166</sup>

Commenter (2187-WB Osborn) contends that the proposed regulations are so voluminous and complex that they, as a company with less than 20 employees, have not had time or resources to fully assess the impacts of these proposed rules and their impact to their business. The commenter asserts that it is unfair that small oil and gas operators are forced to allocate their limited resources to understanding, debating, and ultimately modifying their operations to comply with the proposed rules, if they are adopted.

The commenter (2187-WB Osborn) estimates that using their existing legal resources at \$750.00/hour, 120 hours of research, applicability assessment and construction of recommendations, an added cost to their operations of \$90,000/month would be required to completely understand the EPA proposed rules. The commenter reports that this expenditure is required to fairly and responsibly address the issues raised by these proposed rules to the benefit of our company and its stakeholders. The commenter notes that this amount represents a 42 percent increase in their monthly operating costs, with no additional benefit to our company.

Commenter (2205-Kriebel) expresses concern with the disconnect with understanding the differences between a large natural gas & oil producer (i.e., Shell, BP) and a small marginal natural gas & oil producer (approximately 100 employees or less). The commenter asserts that this misunderstanding appears to have led to an excessive NSPS proposal that imposes a strong cost burden on the marginal well producer.

Commenter (2200-NuEnergy) contends that the rules discriminate against small businesses and make fair competition in a free-market economy unattainable. The commenter notes that the proposed rules are designed to be one size fits all which does not make sense when comparing emissions from a large production well to a marginal well. The commenter states that the economics of compliance and the emissions reductions will be drastically different, yet the proposed rules seem to ignore that fact. The commenter adds that in their brief review of the proposed EPA regulations, it appears that they potentially conflict with the State of Michigan's Office of Oil, Gas and Mineral (OOGM) rules and regulations. It appears that the premature plugging and abandoning of otherwise currently profitable marginal wells affect the OOGM's directive to prevent waste in the State of Michigan. The commenter notes that this is bad for Michigan and small businesses.

Commenter (2403-PAO) states that many small oil and gas businesses will be negatively impacted. The commenter requests that EPA recognize the importance and benefits of marginal wells to the U.S., the State of Oklahoma, small businesses, and rural environmental justice

---

<sup>166</sup> <https://www.rrc.texas.gov/news/072821-flaring-trends/>.

communities that depend on the oil and gas industry, in its rulemaking process. The commenter contends that the RIA does not address how a well(s) producing an average of 1.43 barrels per day (Bpd) and/or 18 Mcfpd can be economically viable under the new multiple source requirements. The commenter asserts that the Proposed Rule will impact existing wells, especially low producing, marginal oil and gas wells that provide the state with direct revenue in the form of royalties, taxes, and indirect economic benefits through employment and other economy-enhancing activity.

The commenter (2403-PAO) notes that tax code provisions define a low producing well as one producing 15 Bpd of oil equivalent or less. The Interstate Oil and Gas Compact Commission (IOGCC) defines a marginal well as a well that produces 10 barrels of oil or 60 Mcf of natural gas per day or less.<sup>167</sup> In Oklahoma, there are approximately 28,000 marginal oil wells (with an average production of 1.43 Bpd) and approximately 45,000 marginal gas wells (with an average 18 thousand cubic feet per day [Mcfpd]); however they contribute approximately 9.5 percent and 12 percent, respectively, to Oklahoma's total production.<sup>168</sup> The commenter states that these types of wells are important to their members and the state's economy, and they are typically operated by small businesses. Small businesses in the Mining, Quarrying, and Oil and Gas Extraction industry in Oklahoma employ over 20,000 people, or over 50.5 percent of the private workforce employed in that sector in 2017. Additionally, the commenter states that marginal wells provide a significant share of the U.S. domestic oil and natural gas output and economic contributions. The IOGCC states that since approximately 2006, marginal wells have produced oil and natural gas valued at nearly \$30 billion annually, or approximately 10 percent of the total value of oil and natural gas produced domestically.

Commenter (2314-Miller Energy) urges EPA to consider the impact this regulation would have on small oil producers and their ability to compete with the big-industry players. The commenter states that the one-size-fits-all approach discriminates against small businesses and make fair competition in a free-market economy unattainable.

As a small business in Michigan with less than 50 employees and marginal-stripper wells, the commenter (2314-Miller Energy) states that it does not have the same resources as the big players in the industry. The commenter asserts that the proposed regulations would have a larger impact on their sustained operations than large businesses.

Commenter (2248-NDPC) contends that these burdensome and duplicative environmental regulations will cause more damage than good to the economics of North Dakota, impacting disadvantaged communities and small businesses.

The commenter (2248-NDPC) states that many of North Dakota lessees are small businesses that run wells with little room for changes that would render their wells uneconomical. Even though these wells are considered small producers, they make up a large portion of the wells in North Dakota and across the nation. The commenter asserts that the lessees will now be faced with a choice to continue their livelihood at great expense that may never be recovered or to abandon those locations. The commenter notes that the loss of this production not only impacts the energy

---

<sup>167</sup> IOGCC, Marginal Wells: Fuel for Economic Growth, 2016.

<sup>168</sup> Ibid.

security of the nation, but the economic security of thousands of North Dakotans. These small producers support other small service businesses that will also be forced into uncertain economic situations. According to a 2021 economic impact study, almost 50,000 jobs in North Dakota are a result of the oil and natural gas industry with a payroll totaling \$4.5 billion dollars. The commenter states that, operating under the current regulatory oversights and requirements, families are provided with the opportunity to make a living wage and support themselves and their families.

Commenter (ND Congress-3845) provides that small oil and natural gas producers are key contributors to North Dakota's economy. In addition to paying royalties and taxes, the commenter reports that these producers create jobs for North Dakotans directly through employment and indirectly through supporting local businesses. However, small producers often have thin margins restricting their operational flexibility. The commenter states that the EPA's proposed rule would impose costly additional requirements on single wellhead sites, many of which are owned by small, independent producers. Small producers are disproportionately impacted by the proposed rule due to the high costs of equipment needed for compliance. They also face a potential lack of availability of equipment, as compared to large producers. Further, the commenter suggests that the EPA's prescriptive compliance requirements will limit operational flexibility and prevent small producers from implementing innovative new approaches. Once EPA's rule becomes effective, the commenter state that many small producers will find that their operations are now uneconomical. As a result, the commenter believes that the EPA's proposed rule will force many small producers out of business, thereby reducing royalties, taxes, and jobs within North Dakota.

Commenter (2696-Peters et al) requests that EPA include more consultation with small producers and consider the unique needs of those small and family-owned businesses. The commenter states that while many larger entities can comply with new regulations, smaller companies may struggle to adopt technologies mandated by EPA, thus further highlighting the importance of technology flexibility.

Commenter (2241-UDNR) encourages EPA to acknowledge/incorporate environmental justice, community involvement and small business impacts this rule will have. The commenter notes that many of the oil and gas sources in Utah are located in rural areas where the oil and gas industry have a large economic impact. The commenter encourages EPA to continue to support flexibility with these rules to ensure balance with economics and protection of human health and the environment. The commenter notes that there are many low- producing wells within the state and small businesses that own and operate those wells will need support and time to understand requirements, acquire and install new equipment and make necessary procedural changes. The commenter encourages EPA to allow a longer implementation time for such low producing wells.

Commenter (2254-PBPA) states that the EPA should have considered the EG OOOOc costs and impacts of the RIA on small businesses. The commenter asserts that the EPA's proposed BSERs are restrictive, limit state implementation, and significantly affect a much larger universe of small businesses. For example, Texas's (using the Railroad Commission's 2021 production data) top 22 operating entities account for 55% of Texas' production, while the smallest 2,477 entities

account for less than 1%. The commenter reports that these proposed rules will primarily impact those smaller operators. The total production from those entities was 31,055 BOPD and 99,710 MCFPD (36 BCF/year) from 29,520 leases equaling 3 MCFPD per lease. The commenter adds that the proposed regulations will have a significant adverse impact on small businesses based on the capital, operating increases, and regulatory burden; and that the proposed BSER's recordkeeping and reporting will make operating these leases uneconomic for many small businesses.

Commenter (2257-MOGA) recommends that EPA consider including past estimates on cost recovery estimates to be honored from previous rulemaking justifications and allow small businesses the opportunity to recover capital costs before making future initial investments. As proposed, the commenter states that the new regulations keep moving the standards beyond the reach of many small businesses that have diligently complied with previous rules.

The commenter (2257-MOGA) states that many small businesses subject to emissions reduction requirements outlined in NSPS OOOO and NSPS OOOOa have succeeded in reducing emissions based on their implementation of the regulations and ask why these small businesses should now be penalized for their success? The commenter recommends the EPA provide small businesses with prior documented capital investment during recent and current regulations an "Exemption Classification" from new capital investment in the proposed regulations to allow cost recovery from promised, yet unrealized returns on capital investment.

The commenter (2257-MOGA) adds that the State of Michigan views early plugging and abandonment of wells with remaining production horizons as waste. Part 615 of the state's regulatory framework stipulates the minimization of waste by efficiently managing operational endeavors to achieve maximum resource recovery. Many of Michigan's small entity producers facilitate this mandate by minimizing operational costs, negotiating production contracts, adjusting operational production schedules and minimizing all costs when available. Michigan's small entity and small business producers require flexibility to meet the State of Michigan's objective to maximize resource recovery. The commenter contends that the proposed NSPS and EG regulations would burden Michigan's small business marginal well producers with significant costs to achieve less than the maximum resource recovery, which directly contradicts the State of Michigan's laws regarding the waste of state resources.

Commenter (2257-MOGA) notes that their review of historic rule changes to the CAA found that the Act required changes in 1967, 1970, 1977 and 1990. The commenter suggests that these dates provided a large enough gap to go through the sequence of product changes and allow producing companies to recover initial capital investment before updating to a more effective device. However, recently the EPA has implemented new regulations or modifications to regulations in 2012, 2016, 2020, 2021 and now in 2023. The commenter states that each prior regulation developed cost-based estimates to include an estimated time of return based on the capture and sale of emissions. The commenter believes the EPA must explain and include discussion and their rationale for revolving standards over a short period of time compared to historical changes to the CAA.

The commenter (2257-MOGA) emphasizes that that small businesses and marginal well operators do not have the luxury of continuous capital investment for new technology. According to the commenter, during the NSPS OOOO and NSPS OOOOa rulemaking efforts, many of Michigan's small business producers spent significant capital investments in their operations without recovering the initial capital investment costs promised in the regulations. The commenter believes that the aggregate and restrictive cost burden based on revolving regulations every 2 to 4 years, without an adequate baseline to assess the effectiveness, has become excessive and is not sustainable for small businesses with limited operating budgets.

Commenter (2279-US SBA) states that the proposed rule disadvantages small businesses. The commenter recommends that EPA consider and present explicitly the impacts of its rule on all small businesses, including those that are operating existing sites. The commenter recommends that EPA consider how the disadvantages to small business affect the cost-effectiveness of its proposal and consider a range of different size categories.

The commenter (2279-US SBA) notes that calculations of cost-effectiveness rely on averages of costs across the whole industry, reflecting economies of scale for equipment and human resources that are not available to many small businesses. The commenter states that compliance timelines assume priority access to equipment and materials that are not available to small businesses. In addition, annualization over the full lifetime of equipment assumes longer-term financing that is often not available to small businesses.

Commenter (2294-OOGA) states that small businesses being forced to close presents a scenario that is inherently contrary to the Supplemental Proposal – i.e., there may be thousands more abandoned wells that may or may not be properly closed.

Response II-20-34: EPA provides small business analysis in the revised IRFA (found in Section 4.3 of the December 2022 RIA) and FRFA (found in Section 4.4 of the Final RIA). As a general matter, EPA's position is that, for the purposes of RFA compliance, only the NSPS OOOOb is relevant at the time of promulgation of this final rule; compliance with the RFA regarding the EG OOOOc will be addressed as part of the process of developing the federal plan. Still, much of the discussion of regulatory flexibility alternatives in the revised IRFA found in the December 2022 RIA and the FRFA found in the final rule RIA apply to affected sources under each subpart.

In the revised IRFA and FRFA, EPA provides an extensive discussion of regulatory flexibility alternatives and notes key areas where options were chosen to reduce regulatory burden on small businesses. For example, EPA revised its proposed fugitive emissions monitoring requirements at well sites to allow for AVO inspections at sites with little or no equipment, which EPA believes disproportionately alleviates regulatory burden on small businesses without sacrificing significant environmental benefits. In addition, EPA's analysis suggests that sites with little to no equipment are less likely to be impacted by process controller and pump requirements.

In response to comments regarding marginal wells, EPA developed a financial analysis of marginal oil and natural gas wells in Chapter 6 of the Final Rule TSD. EPA finds that marginal wells may continue to operate at low or negative profits rather than be shut-in and plugged due to a variety of reasons, including low operating costs, high plugging costs, low state bonding

requirements, accounting practices, and tax credits available to the oil and gas industry. Moreover, to mitigate the impact of abandoned wells, the Inflation Reduction Act (IRA) provides \$700 million for methane and greenhouse gas mitigation activities for conventional marginal wells. The Department of Energy and the EPA have issued a joint Notice of Intent to provide grants up to \$350 million for conventional marginal well plugging as an initial effort to distribute the IRA funds. The goal of marginal well funding from the IRA is to offset the cost of plugging low producing wells. Additionally, the federal money reduces the possibility that the operator files for bankruptcy and orphans their well(s). EPA is unable to assess the viability of the owners and operators of the marginal wells, and as such, EPA is therefore unable to predict which firms will be most adversely affected by regulatory costs.

In response to comments that state that the EPA must perform small business-specific cost evaluation for all sources under the proposed rule using a more granular approach to the cost-effectiveness analysis and that unique aspects of small businesses were not considered in the development of analyses, we disagree. When conducting BSER for affected facilities/designated facilities, one aspect is to evaluate the cost of a control. As part of that evaluation, the EPA considers various associated costs, including capital costs and operating costs (and retrofit costs and challenges), including costs provided by commenters (including small businesses). While our analyses do not reflect every known scenario and equipment configuration, the EPA addresses unique circumstances presented by commenters where it is supported. As an example, see section XI.G.6 (Wet seal compressors equipped with a seal oil gas separation system utilized on the Alaska North Slope (ANS)) of the final rule preamble, where a commenter provided information to support an alternative performance-based volumetric flow rate standard for wet seal compressors equipped with a seal oil gas separation system utilized on the ANS.

As discussed in section VIII.B (How does EPA evaluate control costs in this final action?) of the final rule preamble, the final standards will impose some new costs on industry (including small businesses). Many of the standards, however, reflect control mechanisms and measures that many companies and sources around the country are already implementing – again, without deleterious effect on industry as a whole – which shows not only that such controls are “adequately demonstrated” but also underscores their reasonableness from a cost perspective. The EPA provides the cost effectiveness estimates for reducing VOC and methane emissions for various control options considered in the November 2021 Proposal and the December 2022 Supplemental Proposal, as well as in section XI of this preamble and associated TSDs. See also Volume II, Chapter 4 (Fugitive Emissions from Well Sites, Centralized Production Facilities, and Compressor Stations), section 4.3.4 (Small Business/Cost Concerns) comments and responses on small business/cost concerns related to fugitive emissions requirements.

Also, as noted above, the revised IRFA and FRFA provides an extensive discussion of regulatory flexibility alternatives and notes key areas where options were chosen to reduce regulatory burden on small businesses. In addition to providing several compliance alternatives for affected facilities under NSPS OOOOb and designated facilities under EG OOOOc, the EPA has also considered issues such as lingering supply chain issues and increased demand for equipment and

services when establishing compliance, and repair and delay of repair provisions included in the final NSPS OOOOb and EG OOOOc rules to account for parts not being available.<sup>169</sup>

Additionally, both NSPS OOOOb and EG OOOOc include provisions that could be pursued for an alternative but equivalent compliance option under NSPS OOOOb or equivalent or less stringent requirements considering remaining useful life and other factors (RULOF) under EG OOOOc under a state plan. 40 CFR 60.5399b (What are the alternative means of emission limitations for GHG and VOC emissions from well completions, liquids unloading operations, centrifugal compressors, reciprocating compressors, fugitive emissions components, and process unit equipment affected facilities; and what are the alternative fugitive emissions standards based on state, local, and tribal programs?) of NSPS OOOOb provides procedures for the submittal and approval of alternative means of emission limitation for GHG and VOC based on work practices for well completions, liquids unloading operations, centrifugal compressors, reciprocating compressors, fugitive emissions components and process unit equipment affected facilities. See section XIII.C (Establishing Standards of Performance in State Plans) of the final rule preamble for state plan requirements and sub-section XIII.C.3 (Remaining useful life and other factors (RULOF)) of the final rule preamble for a summary of the RULOF provisions that have been finalized in the subpart Ba rulemaking (codified at 40 CFR part 60, subpart Ba).

For other comments arguing that EPA's one-size fits all approach does not adequately address the variability across the industry and EPA's responses, see Volume I, Chapter 23 (Miscellaneous Other Comments), section 23.17 (One-Size Fits All Approach) of this RTC document.

Comment: Commenter (2257-MOGA) believes the EPA has not considered or incorporated comments and concerns regarding the technical and financial infeasibility resulting from limited and condensed interactions with the small business segment of the oil and gas production industry before proposing new regulations. The commenter states that they participated as a small entity representative (SER) on the SBAR Panel Process required under the Regulatory Flexibility Act (RFA), as amended by the Small Business Regulatory Enforcement Fairness Act (SBREFA). These online Zoom meetings were hosted by the SBA and the EPA on June 29, 2021, July 29th, 2021, and August 3, 2021.

The commenter (2257-MOGA) reiterates several of their comments submitted to the EPA on August 12, 2021, to highlight their concern with what they believe is the EPA's lack of consideration and incorporation of SER's concerns and comments prior to the publication of the current proposed regulations:

- The commenter is concerned with the EPA's apparent lack of knowledge, specious characterization and generalization of the oil and gas production environment. Major production equipment is not fragile. Vessels, tanks, lines, wellheads, etc. were designed to withstand the elevated pressures and greater flow rates, so their usefulness matched the production. Today, these same vessels, tanks, lines, wellheads, etc. maintain their integrity because they are properly serviced and maintained and can safely handle the corresponding

---

<sup>169</sup> See sections XI.A.1.e (Delay of repair due to parts unavailability) of the final rule preamble for example.

natural operational decline of oil and gas production to levels far below the originally designed pressure and flow rates.

- Depletion of the producing formation is critical to understanding the actual operational oil and gas production regime, economic viability and the associated potential for emissions. Without site visits and experience gained from daily engagement with operational parameters, equipment and knowledge of producing formation dynamics, a regulator or special interest group couldn't possibly know how the proposed rule changes will affect each production profile of the numerous production basins throughout the United States. The commenter feels the EPA is publishing rules that do not pertain to any realistic operations within the oil and gas production industry segment and is largely driven by special interest groups that do not have the experience and intimate knowledge of each production regime. Once again, a "one-size-fits-all" approach is discriminatory and would place a tremendous financial burden on small business operators based on incorrect assumptions and data.

Response II-20-35: In the revised IRFA and FRFA, EPA provides an extensive discussion of regulatory flexibility alternatives and notes key areas where options were chosen to reduce regulatory burden on small businesses. While, as a general matter, EPA's position is that, for the purposes of RFA compliance, only the NSPS OOOOb is relevant at the time of promulgation of this final rule, much of the discussion of regulatory flexibility alternatives in the revised IRFA found in the December 2022 RIA and the FRFA found in the final rule RIA apply to affected sources under each subpart. As an example, EPA revised its proposed fugitive emissions monitoring requirements at well sites to allow for AVO inspections at sites with little or no equipment, which EPA believes disproportionately alleviates regulatory burden on small businesses without sacrificing significant environmental benefits. In addition, EPA's analysis suggests that sites with little to no equipment are less likely to be impacted by process controller and pump requirements.

For the comment arguing that EPA's one-size fits all approach does not adequately address the variability across the industry and EPA's responses, see Volume I, Chapter 23 (Miscellaneous Other Comments), section 23.17 (One-Size Fits All Approach) of this RTC document.

Comment: Commenters (2168-INOGA, 2172-KOGA, 2179-KIOGA, 2322-ADEQ, 2393-OSEE et al) request that EPA reinstate the low production well exemption that was included in the previous rule and/or exclude small sources.

Commenters (2168-INOGA, 2172-KOGA) note that most of their members meet the definition of a small business. Members are disproportionately affected because they operate low production wells and do not have the technical capabilities to read and implement a regulation such as this proposal without substantial support. The commenters provide support by providing guidance and responding to EPA with comments that reflect the challenges of their members. The commenters request that EPA provide common-sense, cost-effective regulations, that can be implemented by all our members. The commenters note that many of their members have limited staffing available to manage day to day office activities and field maintenance work. The commenters state that exempting wells with a production level less than 15 barrels per day (or equivalent gas production) will provide significant relief for small businesses without measurable environmental impacts. The commenters believe that EPA's concerns about low

producing wells not being inspected (and leaks being repaired) by small businesses is not an accurate perspective.

Commenter (2179-KIOGA) urges EPA to exempt small businesses from the proposed rule. The commenter asserts that the proposed emission guidelines impose a burden and insurmountable costs for the small businesses.

Commenter (2322-ADEQ) urges EPA to reconsider including small sources in the scope of the Proposed Rule's requirements. The commenter expresses concern with this subset of existing well sites owned by individuals, farmers, small business operators, and family limited partnerships. The commenter notes that many rural households use natural gas production from wells located on their property, either through ownership or lease. The commenter contends that EPA has not fully analyzed the financial burden on homeowners, small business operators, and farmers that would result from the Proposed Rule, and the RIA does not address the costs resulting from new requirements for this subset of sources.

Commenter (2393-OSEE et al) objects to EPA eliminating the 3 tpy exemption threshold. The commenter notes that low-emitting wells which would fall below this exemption threshold are likely to be older wells, often referred to as stripper wells or marginal wells. ("Marginal" in this usage refers to the marginal profitability of these wells.) In spite of their low per-well productivity and profitability, the vast majority of existing wells are classified as stripper or marginal wells. The operation of these wells is important to Oklahoma's economy. The commenter notes that; "the tens of thousands of other older, marginal wells...represent a significant portion of Oklahoma's production and tax base.", "Most of the marginal wells are in rural areas, where they help the jobs and income [in] those parts of the state," "Marginal — or stripper — wells are defined as those that produce no more than 15 barrels of oil or 90,000 cubic feet of natural gas per day. Those wells represent the vast majority of the operational wells in Oklahoma and throughout the country. While their production is overshadowed by the newer, much more prolific horizontal wells, marginal wells promise to continue boosting the state and national economy well into the future", and "In Oklahoma, more than 90 percent of the state's 39,530 oil wells produced less than 15 barrels per day, while only 2.5 percent of the wells produced more than 100 equivalent barrels a day, according to a report the U.S. Energy Information Administration released this week."<sup>170</sup>

In spite of the low productivity of each stripper well, the commenter (2393-OSEE et al) states that the large number of stripper wells yields a significant amount of production in aggregate as is explained in the following analysis provided by the U.S. Energy Information Administration (EIA):

Stripper wells, or wells that produce small volumes, represent an important but decreasing share of total U.S. oil and natural gas production. These wells are characterized as producing no more than 15 barrels of oil equivalent per day (boe/d) over a 12-month period. EIA estimates that there were about 380,000 stripper oil wells (so

<sup>170</sup> "Older, Marginal Wells Increase Nationwide," by Adam Wilmoth, The Oklahoman, December 15, 2017, online: <https://www.oklahoman.com/story/business/energy-resource/2017/12/15/older-marginal-wells-increase-nationwide/60555210007/>.

called because they are stripping the remaining oil out of the ground) in the United States operating at the end of 2015, compared to about 90,000 nonstripper oil wells.

The commenter (2393-OSEE et al) notes that wells become stripper wells through the normal decline of producing wells, some of which may have at one time been very prolific. These wells usually have low ongoing maintenance costs and relatively low transportation costs to move their products to distribution systems. As long as these wells are economically feasible, they are kept active and may continue to produce for many years.

The commenter (2393-OSEE et al) adds that despite each stripper well's small individual production, their large number ensures a significant contribution to total oil production. The production share of oil stripper wells has fallen from a high of 19 percent in 2008 to an estimated 10 percent in 2015.<sup>171</sup>

The commenter (2393-OSEE et al) explains that low maintenance costs and the fact that these wells are already tied into existing infrastructure (existing pipelines and transportation hubs) allows these wells to continue producing even though the profitability of each well is low. The commenter states that the vast number of wells not only provides a significant amount of crude oil and natural gas, but operating these wells employs a significant number of workers whose jobs would be eliminated were these wells to cease operation. The National Stripper Well Association (NSWA) quotes an Interstate Oil & Gas Compact Commission<sup>172</sup> estimate that closing U.S. stripper wells would result in the loss of 142,844 jobs.<sup>173</sup> A significant fraction of that impact would be felt in rural Oklahoma, impacting communities that can least afford to lose those jobs. Preserving the exemption threshold is essential to mitigating the negative impact of the proposed rule and maintaining the economic foundation for a number of socio-economically distressed Oklahoma communities.

Further, the commenter (2393-OSEE et al) notes that emissions from stripper wells are low. The U.S. DOE study on methane emissions from marginal wells reported average emissions ranging from 0.26 to 0.56 tons per year.<sup>174</sup> These wells are simply not large sources of emissions. If EPA is concerned about existing wells with emissions below the threshold becoming super-emitters, the commenter suggests this could be mitigated by a more efficient satellite-focused super-emitter detection and response program. In combination, these policies would eliminate the cost burden to low-emitting oil and gas operators, maintain employment in socio-economically distressed rural communities, and mitigate risk of significant methane emissions.

---

<sup>171</sup> U.S. EIA, "Stripper Wells Accounted for 10% of U.S. Oil Production in 2015," June 29, 2016, online: <https://www.eia.gov/todayinenergy/detail.php?id=26872#>. EIA estimates that stripper wells contributed 7 percent of U.S. oil and natural gas in 2021. See the report, "The Distribution of U.S. Oil and Natural Gas Wells by Production Rate", U.S. EIA, December 2022, p. 9, online: [https://www.eia.gov/petroleum/wells/pdf/full\\_report.pdf](https://www.eia.gov/petroleum/wells/pdf/full_report.pdf).

<sup>172</sup> See <http://nswa.us/stripper-wells/>.

<sup>173</sup> EPA estimates the annual fugitive emission monitoring cost for a single well site or a single centralized production battery to be \$2,100. (See 87 Fed. Reg. 74728.) This cost will push the majority of stripper wells into closure.

<sup>174</sup> The results of the DOE study are referenced in the preamble at 87 Fed. Reg. 74729. Bowers, Richard L., "Quantification of Methane Emissions from Marginal (Low Production Rate) Oil and Natural Gas Wells," United States, available online: <https://www.osti.gov/biblio/1865859/>.

Response II-20-36: In the revised IRFA and FRFA, EPA provides an extensive discussion of regulatory flexibility alternatives and notes key areas where options were chosen to reduce regulatory burden on small businesses. While, as a general matter, EPA's position is that, for the purposes of RFA compliance, only the NSPS OOOOb is relevant at the time of promulgation of this final rule, much of the discussion of regulatory flexibility alternatives in the revised IRFA found in the December 2022 RIA and the FRFA found in the final rule RIA apply to affected sources under each subpart. As an example, EPA revised its proposed fugitive emissions monitoring requirements at well sites to allow for AVO inspections at sites with little or no equipment, which EPA believes disproportionately alleviates regulatory burden on small businesses without sacrificing significant environmental benefits. In addition, EPA's analysis suggests that sites with little to no equipment are less likely to be impacted by process controller and pump requirements.

In response to comments regarding marginal wells, EPA developed a financial analysis of marginal oil and natural gas wells in Chapter 6 of the Final Rule TSD. EPA finds that marginal wells may continue to operate at low or negative profits rather than be shut-in and plugged due to a variety of reasons, including low operating costs, high plugging costs, low state bonding requirements, accounting practices, and tax credits available to the oil and gas industry. Moreover, to mitigate the impact of abandoned wells, the Inflation Reduction Act (IRA) provides \$700 million for methane and greenhouse gas mitigation activities for conventional marginal wells. The Department of Energy and the EPA have issued a joint Notice of Intent to provide grants up to \$350 million for conventional marginal well plugging as an initial effort to distribute the IRA funds. The goal of marginal well funding from the IRA is to offset the cost of plugging low producing wells. Additionally, the federal money reduces the possibility that the operator files for bankruptcy and orphans their well(s). EPA is unable to assess the viability of the owners and operators of the marginal wells, and as such, EPA is therefore unable to predict which firms will be most adversely affected by regulatory costs.

Also with respect to marginal wells, EPA notes that recent studies, including the DOE study cited by one commenter (2393-OSEE et al), have suggested that low production, or marginal, wells account for roughly half of methane emissions from oil and natural gas production (see Chapter 6 of the TSD).

Comment: Commenter (2220-WDEQ) specifically refers to the overall impacts that EPA's monitoring requirements in the supplemental proposal will have because it now considers the amount and types of equipment at a site, rather than estimated emissions. The commenter expresses concern that many existing stripper wells could be burdened with onerous monitoring requirements. They add that many of these smaller sites simply cannot shoulder the financial burden associated with these requirements and the economic ramifications could be significant. According to the Wyoming Oil & Gas Conservation Commission (WOGCC), in 2019, there were 6,848 stripper wells in Wyoming that produced a total of 6,959,356 BBLs of oil for the year and in 2020, there were 6,524 stripper wells in Wyoming that produced a total of 5,970,758 BBLs of oil. According to the State of Wyoming Geological Survey, 288 companies, each producing less than 1 percent of Wyoming's total crude oil production, together account for 18 percent of the statewide production of crude oil; 181 companies, each producing less than 1 percent of Wyoming's total natural gas production, together account for 11 percent of the

statewide natural gas production.<sup>175</sup> The commenter notes that these small companies will be most significantly impacted by the requirements of the supplemental proposal, particularly those proposed in EG OOOOc, and some have indicated that they may have to shut in production because they cannot meet the compliance requirements in the supplemental proposal. According to the commenter, this will result in potentially significant adverse impacts to local communities around Wyoming.

The commenter (2220-WDEQ) emphasizes that stripper wells constructed after 1973 have already received permits under WDEQ's New Source Review program to address VOC emissions, and consequently methane emissions. The commenter anticipates that many of these wells may be further subject to the OGI monitoring requirements in the supplemental proposal. They add that there are an indeterminate number of stripper wells that will have to shutter operations due to the impossible cost of compliance with OGI monitoring requirements, and the consequential loss of jobs and mineral revenues could have damaging impacts upon Wyoming's economy, all while no significant environmental benefits occur from the onerous new proposed regulations.

The commenter (2220-WDEQ) suggests that the EPA represents the disproportionately high compliance costs specifically associated with EG OOOOc in the preamble and the RIA. In Tables 1-4 and 1-5 of the RIA, EPA indicates that the Net Compliance Costs and Compliance Costs are roughly 2.5 to 3 times higher for EG OOOOc than NSPS OOOOb over the period of 2023-2035, depending on the discount rate applied and whether present value or estimated annual value are considered. The commenter notes that it is difficult to know the true economic impact that the proposed regulations will have in Wyoming, but it is clear that small operators will be especially hard hit by the proposed EG OOOOc regulations. The commenter asserts that the economic viability of smaller operators, as well as site-specific and control program-specific considerations, must be taken into consideration when promulgating final regulations. The commenter notes that there are nuances to oil and gas production that are regionally specific and state-specific, and a set of blanket regulations simply does not account for these issues for operators in Wyoming.

Response II-20-37: In the revised IRFA and FRFA, EPA provides an extensive discussion of regulatory flexibility alternatives and notes key areas where options were chosen to reduce regulatory burden on small businesses. While, as a general matter, EPA's position is that, for the purposes of RFA compliance, only the NSPS OOOOb is relevant at the time of promulgation of this final rule, much of the discussion of regulatory flexibility alternatives in the revised IRFA found in the December 2022 RIA and the FRFA found in the final rule RIA apply to affected sources under each subpart. As an example, EPA revised its proposed fugitive emissions monitoring requirements at well sites to allow for AVO inspections at sites with little or no equipment, which EPA believes disproportionately alleviates regulatory burden on small businesses without sacrificing significant environmental benefits. In addition, EPA's analysis suggests that sites with little to no equipment are less likely to be impacted by process controller and pump requirements.

---

<sup>175</sup> Wyoming State Geological Survey, Erin A. Campbell, Director and State Geologist, "Oil & Natural Gas Resources in Wyoming," January 2023 Summary Report.

In response to comments regarding marginal wells, EPA developed a financial analysis of marginal oil and natural gas wells in Chapter 6 of the Final Rule TSD. EPA finds that marginal wells may continue to operate at low or negative profits rather than be shut-in and plugged due to a variety of reasons, including low operating costs, high plugging costs, low state bonding requirements, accounting practices, and tax credits available to the oil and gas industry. Moreover, to mitigate the impact of abandoned wells, the Inflation Reduction Act (IRA) provides \$700 million for methane and greenhouse gas mitigation activities for conventional marginal wells. The Department of Energy and the EPA have issued a joint Notice of Intent to provide grants up to \$350 million for conventional marginal well plugging as an initial effort to distribute the IRA funds. The goal of marginal well funding from the IRA is to offset the cost of plugging low producing wells. Additionally, the federal money reduces the possibility that the operator files for bankruptcy and orphans their well(s). EPA is unable to assess the viability of the owners and operators of the marginal wells, and as such, EPA is therefore unable to predict which firms will be most adversely affected by regulatory costs.

Finally, EPA disagrees with the commenter's assessment that the estimated compliance costs associated with the EG OOOOc are disproportionately high. The discrepancy in estimated costs in the RIA between the NSPS OOOOb and the EG OOOOc are a function of the difference in the estimated numbers of affected facilities. EPA estimates that there will be far more EG OOOOc than NSPS OOOOb-affected facilities over the analysis horizon. By construction, the estimated costs will be roughly proportionate to the estimated number of affected facilities (see Section 2.2 of the Final RIA for more discussion on methodology).

#### ***20.4.6 Regional Considerations***

Comment: Commenter (2227-WEA) requests that EPA recognize and integrate regional differentiators in all aspects of the RIA, including differences between regions of the lower 48 states. Regionally differing economic, operational, and development parameters in the lower 48 states, just as with Alaska, play a key role in the resulting economic impacts that oil and natural gas rules create, including revenue and costs, and the feasibility of the implementation of proposed rules such as NSPS OOOOb and EG OOOOc.

As an example, the commenter (2227-WEA) states that associated gas for use in processes such as generating electricity and replacing functions like pneumatic controllers and pneumatic pumps will have characteristics that vary widely in different regions. For instance, the State of Colorado employs a default crude oil gas-to-oil-ratio of 23 standard cubic feet per barrel (scf/bbl) and the State of Utah has a default value of 17 scf/bbl for the Uinta Basin where the type of oil produced varies enough such that values as low as 5 scf/bbl are not uncommon. The Bureau of Land Management (BLM) recently used a value of 43 scf/bbl in evaluating the feasibility of using associated gas for on-site processes. The commenter recommends that all of these types of data be factored into an RIA, such as those for NSPS OOOOb and EG OOOOc, demonstrating the importance of regional considerations in the impact of the regulations. Specific recommendations provided include:

- Supplement the RIA by conducting a more thorough analysis that will account for significant regional challenges and differentiators that occur in distinctive parts of the

lower 48 states, such as the undeveloped, wide-open and topographically difficult expanses, and extreme weather conditions of the Rocky Mountain States.

- Analyze the regulatory impacts on a finer geographic scale than the broad-brush, one-size-fits-all, nationwide approach reflected in the proposed regulations.
- Modify proposed NSPS OOOOb and EG OOOOc regulations to account for unique economic, operational, and development challenges that exist as key differentiators across the broad spectrum of environments across the U.S.

Response II-20-38: EPA disagrees with the commenter's assessment that the RIA needs to assess regional implementation challenges associated with the electrification of oil and natural gas operations. While the RIA attempts to model important region-specific factors where possible (e.g., in the assignment of region-level major equipment distributions to model well sites), its primary purpose is to provide a best-estimate assessment of the nationwide impacts of the rule. Due to data limitations, EPA cannot feasibly account for local conditions across the country, and the commenter does not provide the necessary data to address these limitations.

## **20.5 Emissions Reductions and Associated Impacts**

### ***20.5.1 Oil and Natural Gas Sector Emissions***

Comment: Commenter (2168-INOGA) notes that the EPA states that the Oil and Gas segment is the largest industrial emitter of methane. In the preamble of prior rule makings, EPA published a table of the largest methane emitting industries. The commenter states that this table/analysis has not been provided in this rule making. According to the commenter, in the prior rule makings, EPA's own data shows the reduction in methane and VOC emissions over time, with (post-2016) and without (pre-2016) regulations imposed by EPA. The data tables in prior rule making do not support EPA's claim that the Oil and Gas segment is the largest industrial emitter of methane.

According to the Global Methane Initiative (GMI), the Oil and Gas segment is not the largest industrial emitter [the commenter adds Figure 1: Emissions by Sector in million metric tons of carbon dioxide equivalent (MMTCO<sub>2</sub>e)].<sup>176</sup> Table 1 [included in attachment to the commenter's letter] provides the U.S. EPA's Sector, Source, and Subsource fields were mapped to GMI sectors and categories.

Commenter (2168-INOGA) provides that data collected from EPA's website shows that Waste is the largest industrial emitter of methane in the U.S. (2021 data). Using the database provided by EPA and filtering for only methane emissions, the commenter notes that the Waste category emits almost 93 million metric tons of CO<sub>2</sub>e verses the Petroleum and Natural Gas Systems segment at less than 71 million metric tones of CO<sub>2</sub>e.

Response II-20-39: Based on the latest data under the U.S. Greenhouse Gas Inventory, the EPA maintains that the largest industrial emitter of methane is the oil and natural gas industry. The waste sector methane emissions data in the commenter-provided cite includes several different

---

<sup>176</sup> <https://www.globalmethane.org/methane-emissions-data.aspx>.

industrial sources — wastewater, manure management, municipal solid waste (landfills), other waste.

See section III.B.2 (Emissions from the oil and natural gas source category) of the final rule preamble for a characterization of emissions from the oil and natural gas source category and summary of the U.S. methane emissions by sector (million metric tons carbon dioxide equivalent (MMT CO<sub>2</sub> Eq.) (See Table 7)).

See also See section II (Executive Summary), subsections A (Summary of the Major Provisions of this Regulatory Action) and B (Purpose of the Regulatory Actions), and section IV (Statutory Background and History) of the final rule preamble for support for the development of the NSPS OOOOb standards and EG OOOOc presumptive standards.

Comment: Commenter (2172-KOGA) states that the oil and gas industry would like to verify the actual performance of EPA's prior rule making verses the claims that were made when the rules were initially promulgated. The commenter makes the following inquires:

- Were prior rule makings successful at reducing emissions, as claimed during the development of the regulation?
- If EPA's rules failed to meet the advertised expectations, why is this current rule being promulgated?
- Does the actual performance data justify the actions, or is this a politically motivated rulemaking to increase the compliance burdens (i.e., operating costs) on the oil and gas industry?

According to the commenter (2172-KOGA), EPA should be required to show the data from prior rule makings, illustrating the expected emissions reductions and the actual emissions reductions prior to promulgating more significant regulations on the oil and gas industry.

Response II-20-40: The November 2021 Proposed Rule at Section I.A and the Final Rule at Section II.A discuss the purpose of this regulatory action in great detail. Commenter cites no authority for its contention that the EPA is required to verify the "performance" of prior rulemakings as a necessary component of promulgating this rulemaking, and the EPA is not aware of any such requirement.

Comment: Commenter (2257-MOGA) questions the EPA's use of 2019 emission data to justify the current proposed regulations. The commenter states that, based on historic rulemaking efforts, if the full implementation of NSPS OOOOa did not begin until roughly 2018 (considering the 2-year and 90-day court stay), how can the EPA determine the effectiveness of the NSPS OOOOa regulations and justify the new proposed regulations? The commenter reports that Michigan producers have been successful in reducing emissions through NSPS OOOO and NSPS OOOOa regulations. The commenter cites emissions reduction data from three small businesses that have invested significant capital to achieve emissions reductions without the EPA allowing enough time to recover costs. The commenter believes that the EPA should allow more time to evaluate current regulations applied to new sources and future modifications of

previously non-regulated sources before amending regulations resulting in another substantial economic burden on small business producers.

Response II-20-41: This commenter provided a similar comment on the November 2021 Proposal, see Volume I, Chapter 23 (Miscellaneous Other Comments), subsection 23.6.1 (General Opposition) Response I-23-14 for a response to this comment.

Comment: Commenter (2403-PAO) suggests that the EPA overestimates emissions and reduction benefits. The commenter states that the EPA estimated the quantity of emissions and potential reductions using its data that contains emission factors (EFs) and estimation methodologies that do not reflect actual emissions. In some instances, the commenter states that the EFs and estimation methodologies significantly overestimate emissions from sources e.g., pneumatic and liquids unloading. The commenter contends that the EPA's use of inaccurate emission data has erroneously justified excessive requirements for existing wells. Congress recognized this issue and incorporated into the Inflation Reduction Act a requirement for EPA to revise its Greenhouse Gas Reporting Program (GHGRP) Rule to allow reporting entities to collect and submit empirical emission data. The commenter requests that EPA reconsider its emission data and the associated regulatory requirements for the various emission sources located at existing wells. In addition, the commenter asserts that the EPA must update its emission factors and methodologies to reflect actual emissions from the oil and gas industry.

Response II-20-42: The commenter asserts that the EPA overestimates emissions and emissions reduction benefits because the underlying data used (e.g., GHGRP and GHGI data) contain emission factors, and that data should be based on actual emissions. The EPA believes that the use of average emissions factors based on the best available data will mean that some sources will have baseline emissions and emissions reductions based on the rule that will be overestimated for some sources and underestimated for other sources. Best available data will always evolve.

The EPA reviewed available data during the course of this rulemaking, including data submitted by commenters. Additionally, EPA has recently taken up multiple rulemakings, including NSPS OOOOb, revisions to 40 CFR part 98 subpart W (greenhouse gas reporting rule), and the Methane Emissions Reduction Program which will generate data to better quantify emissions from this sector. NSPS OOOOb and EG OOOOc include required methods for measuring emissions from various sources, such as control devices on affected facilities/designated facilities, in the final rulemaking.

With regards to the comment that EPA's use of what they contend is "inaccurate" emission data has erroneously justified excessive requirements for existing wells, we disagree. Many of the standards established for existing wells reflect control mechanisms and measures that many companies and sources around the country are already implementing — again, without deleterious effect on industry as a whole — which shows not only that such controls are "adequately demonstrated" but also underscores their reasonableness from a cost perspective. Also, as discussed in the final rule preamble, these final actions stem from the EPA's authority and obligation under CAA section 111 to directly regulate categories of new stationary sources that cause or contribute to endangerment from air pollution and to promulgate EG for states to

follow in regulating existing sources (designated facilities) in the source category. See section II (Executive Summary), subsections A (Summary of the Major Provisions of this Regulatory Action) and B (Purpose of the Regulatory Actions), and section IV (Statutory Background and History) of the final rule preamble for support for the development of the NSPS OOOOb standards and EG OOOOc presumptive standards.

**Comment:** Commenter (2460-Private Citizen) believes if the EPA is to properly monitor emissions and the changes in emissions over time, these emissions need to be listed in precise, meaningful terms. Worldwide data on emissions are frequently listed, on an annual basis, in either English tons or metric tonnes. The commenter also suggests that they could also be listed as volume of natural gas per time unit, which could be converted to tons or tonnes after it is normalized by using the percentage of methane in the natural gas produced at a given well-pad. The commenter notes that they would also need to know the gross production (or gross transport, gross material processed. etc.) to see whether emissions are approaching a minimum value.

Commenter (2460-Private Citizen) finds reporting emissions in carbon-dioxide equivalents on a 100-year basis is simply not meaningful. It deemphasizes the contribution made to global warming by methane in the first years after it is released. Reporting equivalence over one decade would make clear how important it is to drastically cut emissions in the next 10-15 years.

**Response II-20-43:** Methane is a powerful greenhouse gas. Methane is 28 times as potent as CO<sub>2</sub> over a 100-year time frame, and historical emissions of methane have contributed about a third of today's warming. Methane also contributes to increases in global tropospheric ozone levels, which damages human health and ecosystems. This action will contribute to reductions in methane emissions. However, only looking at relative impacts over the next 20 years is an incomplete comparison of methane and CO<sub>2</sub> impacts. The 100-year GWP value is more consistent with temporal valuation used elsewhere in US government cost benefit analyses. See, e.g., Sarofim and Giordano (2018, <https://esd.copernicus.org/articles/9/1013/2018/>) and Mallapragada and Mignone (2020, <https://link.springer.com/article/10.1007/s10584-019-02486-7>) which show that the 100-year GWP is equivalent to valuing future impacts with discount rate of about 3%, which is also the OMB Circular A-4 (2003) recommended discount rate for social goods.<sup>177</sup> A 20-year GWP would be equivalent to valuing future impacts at a much higher discount rate, which is inconsistent with how EPA (and many others) recommend valuing future damages and damages avoided. A 20-year GWP is not a good solution for avoiding tipping points: because it is a relative measure, using a 20-year GWP would lead to increased CO<sub>2</sub> emissions to balance reduced CH<sub>4</sub> emissions, which would reduce the probability of near-term tipping point exceedances at the cost of increasing the probability of passing tipping points in the longer term.

**Comment:** Commenter (2334-Liveable Arlington) states the EPA's new methane rules must be finalized soon and implemented with great urgency to protect communities like Arlington where resident exposure to fracking emissions is constant, has been happening for a long time, and severe because of mere 300 feet setbacks and high well density. The rules and monitoring

---

<sup>177</sup> OMB Circular A-4 (2023) recommended a discount rate of 2.0% for such goods, which would be even less consistent with a 20-year GWP.

systems required for urban drilling in places like Arlington and its neighboring cities in the Barnett shale must be more stringent, with severe penalties for non-compliance.

Commenter (2334-Liveable Arlington) states EPA must also use the supplemental rulemaking to follow through on their commitment to community monitoring programs and work to incorporate emission monitoring results generated by community groups. This important step would allow the agency to accept and prioritize monitoring results from communities and ensure major leaks that are harming nearby communities are fixed more quickly. Incorporating community programs will expand EPA's capacity to identify and fix leaks at sites across the country and help curb methane waste and pollution.

Commenter (2334-Liveable Arlington) argues the EPA must recommend safe setbacks between fracking operations and protected uses and exposed residents. In Arlington, Total Energies and other drillers frack next door to many daycares, for instance with no safeguards at distances of 300 feet between the wellheads and the main structure of the childcare facility. The commenter also recommend that the EPA require fenceline monitoring with data reported in real time at fracking sites at distances less than 1500 feet from homes, schools, daycares, and medical facilities.

Commenter (2334-Liveable Arlington) adds Tarrant County in Texas is a special case - here there are the most residents living close to drilling than any other county in America. Even with the best technology in place, burning dirty fossil fuels places future generations at extreme risk from climate change. While supporting a rapid shift to clean, renewable energy, the commenter strongly urges the EPA to implement much tougher emissions rules for new AND existing oil and gas facilities in the interim, to help preserve not just a Liveable Arlington, but also a Liveable Planet for our children.<sup>178</sup>

Response II-20-44: See Chapter 23 (Miscellaneous Other Comments), subsection 23.2.1 (Climate Change and Air Quality Impacts on EJ Communities), Response II-23-7, for response to similar comments provided by this and other commenters.

Comment: Commenter (2334-Liveable Arlington) states the EPA must recommend safe setbacks between fracking operations and protected uses and exposed residents. In Arlington, Total Energies and other drillers frack next door to many daycares, for instance with no safeguards at distances of 300 feet between the wellheads and the main structure of the childcare facility.

Commenter (2334-Liveable Arlington) stresses methane has more than 80 times the warming power of carbon dioxide over the first 20 years after it reaches the atmosphere. Even though CO<sub>2</sub> has a longer-lasting effect, methane sets the pace for warming in the near term. Methane set a record for the second year in a row, scientists reported, just as the UN's panel on climate change warned the world is running out of time to rein in fossil fuel emissions. Methane — the second

---

<sup>178</sup> [Comment includes 3 images/photos of fracking in Arlington that show proximity to homes and daycares. Moreover, comment includes a table of the EJScreen Report (Version 2) .25 miles ring centered at 32.740292, -97.098904, Texas, EPA Region 6 (100pprox.. pop: 1006. Also included is a link to Jan 2023 public hearings Eventbrite page and the following link, <https://drive.google.com/file/d/1K-bdJG7LDnEG-Ycnls-loRAheJV9Lp7/view>, to addition Liveable remarks – already excerpted elsewhere].

largest contributor to the human-caused climate crisis after carbon dioxide — increased by 17 parts per billion in 2021. According to the National Oceanic and Atmospheric Administration, this is the largest amount since measurements began nearly 40 years ago.

Commenter (2334-Liveable Arlington) adds toxic pollutants released alongside methane, such as VOCs, can worsen asthma and respiratory disease while toxics like benzene increase the risk of cancer, cause immune system damage and developmental problems. Living near unconventional oil & gas wells has been shown to shorten life spans for residents 65 and older.

Response II-20-45: See Chapter 23 (Miscellaneous Other Comments), subsection 23.2.1 (Climate Change and Air Quality Impacts on EJ Communities), Response II-23-7, for response to similar comments provided by this and other commenters.

Comment: Commenter (2320-American Public Gas Association (APGA)) asks EPA, with any future regulatory action, to not forget that natural gas is the significant driver behind the declines in emissions in our country.<sup>179</sup> The agency should recognize that continued natural gas use paired with responsible production will further these reductions in GHG emissions.<sup>180</sup>

Response II-20-46: EPA believes that the finalized NSPS OOOOb and EG OOOOc will help ensure responsible production of oil and natural gas.

Comment: Commenter (2227-WEA) argues the proposed rule will adversely affect the supply, distribution, and use of energy, resulting in higher costs to consumers. The preamble clearly states that the proposed rules will have a significant adverse effect on energy supplies and consumption:

“This action, which is a significant regulatory action under Executive Order 12866, has a significant adverse effect on the supply, distribution or use of energy. The documentation for this decision is contained in the Regulatory Impact Analysis for the Proposed Standards of Performance for New, Reconstructed, and Modified Sources and Emissions Guidelines for Existing Sources: Oil and Natural Gas Sector Climate Review prepared for the November 2021 proposal and the Regulatory Impact Analysis of the Supplemental Proposal for the Standards of Performance for New, Reconstructed, and Modified Sources and Emissions Guidelines for Existing Sources: Oil and Natural Gas Sector Climate Review for this action.”<sup>181</sup>

Commenter (2227-Western Energy Alliance) believes certain provisions in the proposed rules could render significant oil and natural gas facilities in the United States, particularly marginal wells, uneconomic to operate, further constraining domestic supply, increasing energy prices, and making America more dependent on oil and natural gas produced overseas, beyond EPA’s

---

<sup>179</sup> The U.S. Energy Information Administration reported that switching to natural gas accounted for almost two thirds of the CO<sub>2</sub> emission reductions from 2006 to 2014.

<sup>180</sup> United States Environmental Protection Agency, “Inventory of U.S. Greenhouse Gas Emissions and Sinks: 1990-2020,” <https://www.epa.gov/ghgemissions/inventory-us-greenhouse-gas-emissions-and-sinks>.

<sup>181</sup> Standards of Performance for New, Reconstructed, and Modified Sources and Emissions Guidelines for Existing Sources: Oil and Natural Gas Sector Climate Review, 87 Fed. Reg. 74702 December 6, 2022.

jurisdiction. EPA has ignored the fact that the rules will force the shutting in of wells in the United States and result in more imports from less regulated countries, ultimately increasing global greenhouse gas emissions and introducing other negative externalities.

Response II-20-47: EPA models the impact of the rule on oil and natural gas supply in Section 4.1 of the Final RIA. EPA estimates that the reduction in U.S. oil production would be approximately 1.05% or less, while the reduction in gas production would be approximately 0.75% or less. EPA estimates that the impact on natural gas prices will be \$0.06/Mcf or less, and the impact oil prices will be \$0.25/bbl or less. These represent changes of approximately 1.76% and 0.33%, respectively.

With respect to the comment regarding marginal wells, EPA also developed a financial analysis of marginal, or stripper, oil and natural gas wells in Chapter 6 of the Final Rule TSD. EPA finds that marginal wells may continue to operate at low or negative profits rather than be shut-in and plugged due to a variety of reasons, including low operating costs, high plugging costs, low state bonding requirements, accounting practices, and tax credits available to the oil and gas industry. To the extent that any marginal wells might be plugged in relation to anything contained within this rulemaking (which is speculative), the analysis suggests that they would be extremely low-producing wells.

Finally, EPA estimates that the change in oil imports would be an increase of 1.05% or less but are unable to quantify the impact on GHG emissions of changes in imports. However, the relatively small estimated increase in imports suggests that the net effect on GHG emissions will be negligible.

### ***20.5.2 Secondary Impacts***

Comment: Commenters (2223-TAEP, 2308-NSWA) express concern that the oil and gas production decrease in the U.S. will result in increased global production and emissions.

Commenter (2308-NSWA) asserts that the regulation will increase emissions globally due to reduced domestic production as it is curtailed -- or in some places shuttered. The commenter believes that such action will result in increased imports of oil and natural gas from producing countries with lower environmental and labor standards (i.e., India, China, Russia). The commenter believes that reducing production in the U.S. will result in higher emissions, higher costs to consumers, and have the opposite effect of EPA's proposed regulation.

The commenters (2223-TAEP, 2308-NSWA) urge EPA to undertake a robust analysis, made publicly available prior to the implementation of the rule, to determine whether the result of the rule will be to raise production -- and thereby emissions -- in other producing countries and regions around the world to meet what will continue to be growing U.S. and global demand. The commenter believes that this analysis should by no means be limited to oil and natural gas, as numerous industrial processes and manufacturing have been exported overseas; however, as the EPA is contemplating new regulations on domestic oil and natural gas production, the commenters urge the analysis to begin there.

Commenter (2223-TAEP) contends that EPA must account for the negative externalities of reducing domestic production in favor of overseas competition. This would result in higher overall emissions and the commenter states that EPA must prepare a detailed analysis to reduce overall global emissions by harnessing American production and innovation.

The commenter (2223-TAEP) urges EPA to re-consider adopting regulations that may negatively affect the U.S. domestic production of crude oil and natural gas, as doing so will do nothing to affect the demand for those products. In fact, the successful application of the methane rule now under consideration is utterly dependent on maintaining or growing production in the U.S., and in Texas. The commenter asserts that a responsible and effective regulatory structure that allows the U.S. domestic oil and gas industry to flourish, not flounder, is the key to the achievement of the desired environmental benefits. The commenter contends that emissions are global in nature, and reducing domestic production in favor of production in other regions results in greater environmental harm, not less.

Response II-20-48: The commenter (TAEP) did not provide data to substantiate the claim that oil and gas production decrease in the U.S. will result in increased global production and emissions. EPA models the impact of the rule on oil and natural gas supply in Section 4.1 of the Final RIA. EPA estimates that the reduction in U.S. oil production would be approximately 1.05% or less, while the reduction in gas production would be approximately 0.75% or less. EPA estimates that the change in oil imports would be an increase of 1.05% or less but are unable to quantify the impact on GHG emissions of changes in imports. However, the relatively small estimated increase in imports suggests that the net effect on GHG emissions will be negligible.

Comment: Commenter (2223-TAEP) notes the emissions-reducing benefits of sufficient infrastructure to move crude oil and natural gas from the field to the marketplace-emissions from production operations decline as sufficient pipeline and other takeaway infrastructure is in place. The commenter requests that EPA consider this important relationship when imposing these regulations in a way that may limit the development of pipelines and other infrastructure by making it more expensive.

Response II-20-49: The EPA agrees that access to a pipeline and other takeaway infrastructure often provides for regulatory options that mitigate emissions to the atmosphere (e.g., routing gas to a sales line). In fact, for both new and existing well affected facility associated gas sources, BSER was determined to be routing to a sales line. The EPA allows for beneficial uses of the associated gas that are equivalent to routing to a sales line, but routing to a sales line is BSER. In general, routing to a process or sales line is encouraged under NSPS OOOOb and EG OOOOc, as such, the final rules are not anticipated to limit the development of pipelines or other infrastructure.

Comment: Commenter (2248-NDPC) urges EPA to consider secondary emissions impacts in its analysis (e.g., from manufacturing and transportation related equipment, construction equipment, and removal and disposal of equipment before the end of its useful life). The commenter states that EPA is proposing significant new requirements on low-emitting sources without considering the resulting secondary emissions. The commenter notes that typically, NSPS regulations only apply to criteria pollutants, and evaluating secondary emissions is not appropriate. However,

since this NSPS also regulates methane, the commenter believes that EPA's actions could have a more significant negative global impact than the small source the EPA is trying to control.

Response II-20-50: EPA disagrees that it needs to consider lifecycle emissions impacts in its analysis of the final rule. While EPA agrees that in certain circumstances such analyses might be important, the finalized requirements are sufficiently similar in nature to current industry practices that they will not drastically affect upstream or downstream emissions in the manufacturing or disposal processes. To the extent that any such impacts occur, they would likely be covered by other regulatory regimes. Moreover, commenter does not provide any analysis, data or legal authority that supports the need for such an analysis from EPA.

See section VIII.B (How does the EPA evaluate control costs in this final action?) of the final rule preamble. The EPA does not quantify lifecycle emissions impacts, but EPA does consider secondary emissions of regulatory options when determining BSER.

### ***20.5.3 General Climate and Air Quality Impacts***

Comment: Commenter (2344-IER) notes that EPA presents a sensitivity analysis of the monetized climate benefits using a set of SC-CH<sub>4</sub> estimates that incorporates recent research addressing recommendations of the National Academies of Sciences, Engineering, and Medicine (2017). The EPA notes that the benefits analysis is entirely distinct from the statutory BSER determinations proposed herein and is presented solely for the purposes of complying with E.O. 12866.<sup>182</sup> The commenter suggests that one reading of this is that EPA does not consider climate change impacts to be legally relevant when establishing BSER, but rather, EPA is including these impacts because of E.O 12866. If this is the case, the commenter states that the EPA does not clearly explain this argument.

The commenter (2344-IER) provides that key statutory provision for setting BSER is CAA section 111(a)(1) which reads, “the best system of emission reduction which (taking into account the cost of achieving such reduction and any nonair quality health and environmental impact and energy requirements) the Administrator determines has been adequately demonstrated.”<sup>183</sup> EPA has stated that “In determining the BSER, EPA considers technical feasibility, cost, non-air quality health and environmental impacts, and energy requirements.”<sup>184</sup>

Commenter (2344-IER) suggests that the problem is that EPA's description of climate impacts of methane does not include air quality impacts. In the Regulatory Impact Analysis, EPA states:

Methane is the principal component of natural gas. Methane is also a potent greenhouse gas (GHG) that, once emitted into the atmosphere, absorbs terrestrial infrared radiation, which in turn contributes to increased global warming and continuing climate change. Methane reacts in the atmosphere to form ozone, which also impacts global temperatures. Methane, in addition to other GHG emissions, contributes to warming of the atmosphere,

---

<sup>182</sup> 87 Fed. Reg. at 74713.

<sup>183</sup> 42 U.S.C. 7411(a)(1).

<sup>184</sup> EPA, Fact Sheet: The Affordable Clean Energy Rule (ACE), [https://www.epa.gov/sites/default/files/2019-06/documents/bser\\_and\\_eg\\_fact\\_sheet\\_6.18.19\\_final.pdf](https://www.epa.gov/sites/default/files/2019-06/documents/bser_and_eg_fact_sheet_6.18.19_final.pdf) change impacts of methane reductions in setting BSER.

which over time leads to increased air and ocean temperatures, changes in precipitation patterns, melting and thawing of global glaciers and ice sheets, increasingly severe weather events, such as hurricanes of greater intensity, and sea level rise, among other impacts.<sup>185</sup>

The commenter (2344-IER) states that these could be “non-air quality health and environmental impacts” and EPA could be considering them in setting BSER, but EPA does not describe what it is including in its analysis. The commenter requests that the EPA clarify if it is considering climate impacts in setting BSER for these sources.

Response II-20-51: The Final Rule preamble at Section VIII.B explains in detail how the EPA considered cost in setting standards of performance in NSPS OOOOb and EG OOOOc, which, under the requirements of CAA Section 111(a)(1), reflect the application of the best system of emission reduction adequately demonstrated. Both as part of evaluating the cost-effectiveness of potential systems of emission reduction and more broadly, the EPA has considered the amount of emission reductions of, as applicable, VOC and/or methane, achievable through application of the BSER identified in the Final Rule. These reductions are intended to address the endangerment to public health and welfare (including the climate impacts) that undergird the EPA’s promulgation of standards and Emission Guidelines for this sector. See discussion in Section III for the EPA’s discussion of emissions and impacts of the sector; Section V for the Legal Basis for the Final Rule; and Section VIII.B of the Final Rule preamble for discussion of the EPA’s evaluation of the advantages and disadvantages of this action.

Separately, the Final Rule preamble at Section II.C explains in detail how the EPA projected the emissions reductions, costs, and benefits that may result from this final rulemaking, in accordance with the requirements of E.O. 12866. As explained in the Final Rule Preamble Section II.C, the benefits analysis conducted pursuant to E.O. 12866 is distinct from the BSER determinations, which are based on the statutory factors the EPA is required to consider under section 111(a) of the CAA (including cost, energy requirements and non-air quality health, and environmental impacts). The E.O. 12866 assessment described in the Final Rule Preamble and in the RIA is presented solely for the purposes of complying with E.O. 12866 and providing the public with a complete depiction of the impacts of the rulemaking.

Comment: Commenter (2367-BlueGreen Alliance) states that methane standards result in climate, public health, and economic benefits. The commenter states that the proposed rule will expedite technology deployment and emissions reduction.

The commenter (2367-BlueGreen Alliance) notes that low-cost, proven measures and technologies are already commercially available to cut methane emissions from the oil and gas sector by 65 percent in the next five years.<sup>186</sup> While some companies have moved to adopt these

---

<sup>185</sup> Environmental Protection Agency, Regulatory Impact Analysis of the Supplemental Proposal for the Standards of Performance for New, Reconstructed, and Modified Sources and Emissions Guidelines for Existing Sources: Oil and Natural Gas Sector Climate Review, p. 64, Nov. 2022.

<sup>186</sup> Clean Air Task Force, Reducing Methane from Oil and Gas, December 2020. Available online: [https://cdn.catf.us/wp-content/uploads/2020/04/21092556/Path\\_to\\_65pc\\_OG\\_reductionDec2020\\_update.pdf](https://cdn.catf.us/wp-content/uploads/2020/04/21092556/Path_to_65pc_OG_reductionDec2020_update.pdf).

improvements voluntarily,<sup>187</sup> the prospects of keeping gas in the system with available and cost-effective mitigation technology could improve with a larger market and level regulatory playing field among energy companies. The commenter notes that some states, such as Colorado, already have strong methane pollution standards in place. These standards have resulted in climate, public health, and economic benefits while stabilizing industry by reducing energy waste.<sup>188</sup>

Despite these readily available mitigation options, the commenter (2367-BlueGreen Alliance) contends that voluntary efforts by oil and gas companies have been uneven<sup>189</sup> and limited regulations leave out most sources and sites, leading to emissions growth.<sup>190</sup> The proposed rule reflect the necessity to reduce waste and pollution at new, modified, and existing sources. The commenter asserts that having the standard in place also provides an opportunity for companies to innovate in methane mitigation technology and strategies and provides greater regulatory certainty for the industry over the long run.

Commenter (2367-BlueGreen Alliance) also states that reducing methane leaks yields benefits to workers, communities, and climate.

The commenter (2367-BlueGreen Alliance) asserts that the threat of catastrophic climate change has reached a crisis point. According to IPCC's Sixth Assessment Report, the window to prevent the worst effects of warming is rapidly closing.<sup>191</sup> The commenter contends that keeping the world on its target of 1.5°C of warming will require immediate action to reduce the emission of greenhouse gasses. Of the GHGs being emitted, methane is one of the most potent, with one ton of methane in the atmosphere having over 80 times the warming impact of a ton of carbon dioxide (CO<sub>2</sub>) in the twenty years after it is emitted.<sup>192</sup> While methane emissions occur in many sectors, the oil and gas sector stands together with agriculture as the largest source of this pollution in the U.S. The commenter states that methane is emitted from oil and gas infrastructure like wells, compressor stations, and processing plants alongside other dangerous compound, such as VOCs, which form smog and soot, and carcinogens like benzene,

formaldehyde, and acetaldehyde.<sup>193</sup> The communities facing the greatest public health risk from these harmful air pollutants are in states with the greatest amount of oil and gas development, including New Mexico, Texas, Colorado, Pennsylvania, Oklahoma, Louisiana, West Virginia, and North Dakota.

The commenter (2367-BlueGreen Alliance) notes that, across the country, nearly 14 million people living in one of 236 counties in 21 states face a cancer risk greater than the EPA's one-in-a-million threshold for concern due to oil and gas alone.<sup>194</sup> Oil and gas sector air pollution is particularly harmful to workers that serve in that industry, who face serious long term health challenges as a result of their labor. Emissions reduction for this sector can significantly improve air quality for workers and communities, preventing 255,000 premature deaths and more than half a million asthma-related emergency room visits globally each year.<sup>195</sup>

The commenter (2367-BlueGreen Alliance) contends that the nation's energy sector has made significant strides to increase the efficiency of gas and oil systems in recent years. However, emissions of methane and other pollutants continue to harm the economy and the environment by jeopardizing the health of workers and communities, wasting resources, and worsening climate change. Moreover, recent research suggests emissions from oil and gas activities are significantly underestimated in the EPA's latest greenhouse gas inventory.<sup>196</sup> In fact, the International Energy Agency's (IEA) 2022 Global Methane Tracker analysis found that national governments underestimated methane emissions from the energy industry globally by 70 percent.<sup>197</sup>

Commenter (2335-Karro) stated that the benefits of the proposed regulations are greatly appreciated, especially that EPA estimates that the supplemental proposal would:

- Avoid an estimated 36 million tons of methane emissions from 2023 to 2035, the equivalent of 810 million metric tons of carbon dioxide – nearly the same as all greenhouse gases emitted from coal-fired electricity generation in the U.S. in 2020.
- Yield \$3.1 to \$3.2 billion in climate benefits per year, with total net benefits (after taking the costs of the rule into account) valued at \$34 to \$36 billion from 2023 through 2035.
- Increase recovery of natural gas -- valued at \$3.3 to \$4.6 billion from 2023 through 2035 (based on forecasted prices) – that otherwise would go to waste.

<sup>196</sup> Harvard SEAS, "Oil and natural gas production emit more methane than previously thought". March 22, 2021. Available online: <https://www.seas.harvard.edu/news/2021/03/oil-and-natural-gas-production-emitmore-methane-previously-thought>.

<sup>197</sup> IEA, "Methane emissions from the energy sector are 70% higher than official figures", February 23, 2022. Available online: <https://www.iea.org/news/methane-emissions-from-the-energy-sector-are-70-higherthan-official-figures>.

The commenter (2335-Karro) adds that seldom do we see a proposed rulemaking from any government agency that goes so far to helping achieve the Administration's stated climate goals.

Commenter (2249-NACAA) notes that the EPA has updated its figures in the supplemental proposal and now finds the programs would reduce 36 million tons of methane emissions from 2023 to 2035. While this is a lower volume than was estimated in the initial November 2021 proposal, the commenter suggests that these methane reductions would still significantly reduce harms and offer public health protections on a local basis and would help address the ongoing crisis facing the planet's climate. While not a criteria pollutant covered by the NAAQS, methane remains a potent climate pollutant with a global warming potential nearly 30 times that of CO<sub>2</sub>.

Commenter (2209-PLS) states that oil and gas industry is one of the largest sources of methane pollution in the US, and studies show that reducing oil and gas methane is the easiest and most effective action we can take to address climate change. The commenter reports that, according to the International Energy Agency, half of global oil and gas methane emissions can be eliminated at no net cost. The commenter notes that many companies in the oil and gas industry support a strong EPA Methane Rule;<sup>198</sup> and both large and independent oil and gas operators have committed to end routine flaring. The commenter provides the following examples: ExxonMobil committed to end routine flaring across its assets in the Permian Basin by 2022, BP committed to end routine flaring by 2025 in its U.S. onshore operations, and many more have signed on to the World Bank's goal of ending routine flaring worldwide by 2030.<sup>199</sup>

Response II-20-52: EPA acknowledges the supportive comments.

Comment: Commenter (2293-Holmes) expressed that they appreciate EPA sharing estimates of climate benefits over the 2023 to 2035 period to be \$48 billion at a 3-percent discount rate, and that "these values represent only a partial accounting of climate impacts from methane emissions and do not account for health effects of ozone exposure from the increase in methane emissions." Numbers mentioned in the RIA, such as "global ozone-related mortality benefits of CH<sub>4</sub> emissions reductions, which are not included in the social cost of methane valuations, [are estimated] to be \$800 to \$1,800 per metric ton of methane emissions" are useful at some level. What would be more helpful at the state level, though, would be a set of clearly prescribed methane and other social cost of greenhouse gas cost valuations that can readily be applied to energy and environmental policy making and utility regulation.

Response II-20-53: A detailed response regarding the damage categories omitted from EPA's SC-GHG estimates and the use of these estimates in policy can be found in the Appendix of this RTC where responses are provided on comments pertaining to EPA's September 2022 *Draft Report on the Social Cost of Greenhouse Gases: Estimates Incorporating Recent Scientific Advances*.

<sup>198</sup> See <https://www.reuters.com/business/environment/us-unveils-crackdown-methane-starting-with-oil-gas-rules-2021-11-02/>, [https://www.bp.com/en\\_us/united-states/home/news/press-releases/bp-statement-on-proposed-methane-rules.html](https://www.bp.com/en_us/united-states/home/news/press-releases/bp-statement-on-proposed-methane-rules.html).

<sup>199</sup> See About the ZRF ([worldbank.org](https://www.worldbank.org)).

Comment: Commenter (2413-CEI) states that the reductions in climate-related damages, estimated at \$55 billion, account for 100 percent of the proposal's monetized benefits. According to the commenter, the vast majority of climate damages are attributed to the direct and indirect effects of global warming. The commenter inquires "How much warming would the proposal avert?" The note that neither the proposal itself nor the accompanying RIA explicitly addresses that question.

However, the commenter (2413-CEI) provides that other information in the RIA combined with EPA's climate policy model allows us to estimate the proposal's potential effects on global surface temperatures using the agency's own forecasting assumptions.

The commenter (2413-CEI) provides that the proposed standards are projected to eliminate 910 million metric tons (MMT) of carbon dioxide-equivalent (CO<sub>2</sub>e) methane emissions during 2023-2035.<sup>200</sup> The EPA's *Model for the Assessment of Greenhouse Gas Induced Climate Change*, better known as MAGICC,<sup>201</sup> calculates the temperature effects of emission scenarios under different climate sensitivity assumptions. Climate sensitivity is a term used to describe how much warming results after the climate system fully adjusts to a doubling of CO<sub>2</sub>e greenhouse gas concentration.

The commenter (2413-CEI) goes on to note that the proposal's reduction of 920 MMT CO<sub>2</sub>e over 13 years averages about 71 MMT per year. [Table provided in comment letter shows estimated emission changes from NSPS OOOOb and EG OOOOc proposals for methane, VOC, and HAP.] In 2019, the commenter notes that U.S. GHG emissions in CO<sub>2</sub>e were about 6.6 billion metric tons.<sup>202</sup> A reduction of 71 MMT is about one-tenth of 1 percent of 2019 U.S. GHG emissions. Using MAGICC, the commenter reports that they get the following predicted temperature reductions by 2050 and 2100:

- 4.5°C sensitivity, 0.005°C reduction by 2050, 0.014°C reduction by 2100
- 3.0°C sensitivity, 0.004°C reduction by 2050, 0.011°C by 2100
- 2.0°C sensitivity, 0.003°C reduction by 2050, 0.008°C by 2100<sup>203</sup>

For perspective, the commenter (2413-CEI) provides that the standard deviation for measuring changes in global annual average surface temperature is 0.11°C.<sup>204</sup> Thus, the proposal's projected effects on global warming are undetectable. By the same token the proposal's potential effects on weather patterns, crop yields, coastal flooding, polar bear populations, and other climate-related environmental conditions would also be undetectable. Of greater policy relevance, they state that such benefits are too small to be experienced by people and other living things. They suggest that benefits that can neither be detected nor experienced are so in name

---

<sup>200</sup> RIA, Table 1-3, p. 1-10.

<sup>201</sup> <https://magicc.org>.

<sup>202</sup> EPA, Inventory of U.S. Greenhouse Gas Emissions and Sinks: 1990-2019, <https://www.epa.gov/ghgemissions/inventory-us-greenhouse-gas-emissions-and-sinks-1990-2019>.

<sup>203</sup> These estimates are linear extrapolations and not strictly correct because radiative forcing equations are logarithmic. Nonetheless, the calculations suffice as first order approximations.

<sup>204</sup> The standard deviation of the surface (land-ocean) temperature record is about 0.11 degrees C. See J. Hansen, et. Al. 1999. GISS Analysis of Surface Temperature Change. *Journal of Geophysical Research*, Vol. 104, No. D24, 30,997-31,022, <https://agupubs.onlinelibrary.wiley.com/doi/pdf/10.1029/1999JD900835>.

only. They argue that illusory “benefits” should not be weighed in the same scales with multi-billion-dollar compliance costs that verifiably impose measurable burdens on identifiable people and businesses.

Response II-20-54: EPA modeled emissions and emissions reductions of GHGs controlled by the standards (i.e., CH<sub>4</sub>); monetized the benefits of those emissions reductions (SC-GHG); and in addition, section 2020 (a) (1) does not require quantification of some degree of harm either to find contribution to endangerment, or (2) find that emission reductions will have some significant degree of harm reduction. Moreover, the rule results in "meaningful mitigation of greenhouse gas emissions" — over 1.5 billion metric tons of CO<sub>2</sub>e over the program's lifetime. Id. at 331 (reduction of 960 million metric tons of CO<sub>2</sub>e emissions provides meaningful mitigation).

The SC-GHG is the monetary value of the net harm to society from emitting a metric ton of that GHG into the atmosphere in a given year. In principle, the SC-GHG is a comprehensive metric that includes the value of all future climate change impacts (both negative and positive), including changes in net agricultural productivity, human health effects, property damage from increased flood risk, changes in the frequency and severity of natural disasters, disruption of energy systems, risk of conflict, environmental migration, and the value of ecosystem services. The SC-GHG, therefore, also reflects the societal net benefit of reducing emissions of the GHG by a metric ton. EPA's *Report on the Social Cost of Greenhouse Gases: Estimates Incorporating Recent Scientific Advances* shows that even small reductions in GHG emissions and small reductions in temperature will have significant climate mitigation benefits.

Comment: Commenter (2413-CEI) states that the proposal aims to plug, prevent, or limit CH<sub>4</sub> releases from a wide variety of structures, equipment, and processes:

As natural gas moves through the necessarily interconnected system of exploration, production, storage, processing, and transmission that brings it from wellhead to commerce, emissions primarily result from intentional venting, unintentional gas carry-through (e.g., vortexing from separator drain, improper liquid level settings, liquid level control valve on an upstream separator or scrubber does not seat properly at the end of an automated liquid dumping event, inefficient separation of gas and liquid phases occurs upstream of tanks allowing some gas carry-through), routine maintenance, unintentional fugitive emissions, flaring, malfunctions, abnormal process conditions, and system upsets. These emissions are associated with a range of specific equipment and practices, including leaking valves, connectors, and other components at well sites and compressor stations; leaks and vented emissions from storage vessels; releases from natural gas-driven pneumatic pumps and controllers; liquids unloading at well sites; and venting or under-performing flaring of associated gas from oil wells.

In all, the commenter (2413-CEI) notes that the EPA itself expects regulatory authorities to manage nearly 1 million supply-chain links. Specifically, the proposed NSPS apply to an estimated 36,150 entities, components, or operations in 2023. When existing source EG take effect in 2026, a staggering 968,320 entities will be subject to new, stricter, or expanded CH<sub>4</sub>

regulation, according to the RIA.<sup>205</sup> [See Table 2-5 of the RIA. Projection of Incrementally Impacted Affected Facilities Under the Primary Proposed NSPS OOOOb and EG OOOOc Option, 2023 to 2035.]

The commenter (2413-CEI) states that since methane is the main component of natural gas and a saleable product, oil and gas producers, processors, and transmitters already have strong financial incentives to plug leaks and capture fugitive emissions. The commenter asks what benefit-cost calculation makes the proposed regulatory surge a smart investment of public and private resources?

The commenter (2413-CEI) asserts that the EPA estimates that, during 2023-2035, its preferred option (“primary proposal”) will generate \$55 billion in climate benefits, \$13 billion in compliance costs, \$7.2 billion in net compliance costs (i.e., \$13 billion minus \$5.5 billion in recovered product sales), and net benefits of \$48 billion.<sup>206</sup> The proposal thus looks like an amazing deal, with climate benefits exceeding compliance costs by 4.2 to 1 or (factoring in product recoveries) 7.6 to 1. Upon inspection, however, the commenter asserts that those benefits are “make-believe” and that the proposal would impose enormous costs for undetectably small benefits.

Near the end of the proposal, the commenter (2413-CEI) states that the EPA asserts that its climate-benefit calculations are not a factor influencing regulatory stringency: “However, we emphasize that the monetized benefits analysis is entirely distinct from the statutory BSER determinations proposed herein and is presented solely for the purposes of complying with E.O. 12866.”<sup>207</sup> The commenter (2413-CEI) asserts that this disclaimer does not shield the proposal from litigation risk. E.O. 12866 itself serves a more basic rule of reason. As the Supreme Court stated in its review of the Mercury Air Toxics Standards (MATS) rule in *Michigan v. EPA*: “One would not say that it is even rational, never mind ‘appropriate,’ to impose billions of dollars in economic costs in return for a few dollars in health or environmental benefits . . . No regulation is ‘appropriate’ if it does significantly more harm than good.”<sup>208</sup>

The commenter (2413-CEI) contends that the EPA’s proposal is not reasonable if the climate benefits are illusory. An unreasonable regulation may be challenged as arbitrary and capricious.

Response II-20-55: The EPA disagrees with the commenter’s contention that the climate benefits of this rulemaking are “make-believe” or “illusory,” and also disagrees with the notion that the Final Rule will impose “enormous costs for undetectably small benefits.” In addition, the EPA has carefully considered how the Supreme Court’s ruling in *Michigan v. EPA*, 576 U.S. 743

---

<sup>205</sup> EPA, Regulatory Impact Analysis for the Proposed Standards of Performance for New, Reconstructed, and Modified Sources and Emissions Guidelines for Existing Sources: Oil and Natural Gas Sector Climate Review, October 2021. <sup>206</sup> RIA, Table 5-4, p. 5-7.

<sup>207</sup> 87 FR 74843. BSER stands for “best system of emission reduction.” Clean Air Act section 111 performance standards are to reflect the degree of emission limitation achievable by the best system of emission reduction, taking into consideration cost, energy requirements, and non-air environmental impacts.

<sup>208</sup> *Michigan v. E.P.A.*, 576 U.S. 743, 752 (2015), <https://supreme.justia.com/cases/federal/us/576/14-46/case.pdf>.

(2015) applies to this rulemaking. For a detailed discussion of both issues, the EPA refers the commenter to the Final Rule preamble at Section VIII.B.

Comment: Commenter (2313-Plevin-Foust) urges the EPA to update the SC-GHG estimates with a uniform value of life equal to the value assigned to an American. The commenter argues that this may significantly increase the SC-GHG and states that this is in America's self-interest for the following reasons:

*Climate stability:* A higher social cost of carbon will spur businesses and governments at all levels to reduce greenhouse gas emissions more quickly and dramatically. We'd all become more concerned about climate change and willing to innovate more quickly to the green economy we know we must create. It could speed the development of carbon sinks like ocean kelp farms and healthy soil. Our example would goad other countries to do the same, decreasing the risk of cascading climate system failures and species extinctions that can't be reversed.

*Global influence:* The social cost of carbon that we adopt will likely be copied by Canada, another high-emitting country, and other nations. Our ties with allies and other nations would be strengthened. Whereas, if EPA continues to rank the lives of other nations' citizens far lower than our own (even as our historic greenhouse gas emissions lead to further climate crises that endanger and kill their citizens), such self-dealing, hypocrisy, and racism will alienate us from even our closest allies.

*Security and Immigration:* The Pentagon has ranked the climate emergency as the greatest threat to peace and global stability. Increased droughts and hunger will lead to more wars and threats to democracies worldwide. The more unlivable the global South becomes, the more the world and especially the U.S. will be overwhelmed with climate refugees, as we already are at our southern border. Setting a higher social cost of carbon will help us prevent the worst outcomes from occurring and keep us safer as a result.

*Economics:* A higher social cost of carbon could spur the development of new renewable energy technology or methods to remove carbon from the air, which the U.S. could then export to the rest of the world. Implementing a green economy faster will create even more jobs. Fewer climate catastrophes will preserve our economy whereas more climate disasters could slow, then sink it.

*Health:* Higher temperatures; dangerous weather events; smoke from forest fires; drought, species extinction, and consequent hunger; increased diseases spread by mosquitoes and other pests – these are just a few of the health dangers Americans face from global heating. A higher social cost of carbon would galvanize our nation to act more quickly to cut greenhouse gas emissions and avoid the worst of these outcomes, saving countless American lives.

Response II-20-56: A detailed response regarding the EPA's valuation of mortality risk when calculating the SC-GHG can be found in the Appendix of this RTC where responses are provided on comments pertaining to EPA's September 2022 *Draft Report on the Social Cost of Greenhouse Gases: Estimates Incorporating Recent Scientific Advances*.

Comment: Commenter (2222-WDNR) states that while they do not anticipate the proposed rule will significantly decrease VOC emissions from sources in Wisconsin, several states that significantly contribute to ozone nonattainment or maintenance along the Lake Michigan shoreline have large oil and natural gas sectors. The commenter adds that the upwind VOC emissions reductions from this proposed rule may be significant and may improve Wisconsin's ability to attain and maintain ozone standards.

Response II-20-57: EPA acknowledges the supportive comment.

#### ***20.5.4 Hazardous Air Pollutant Impacts***

Comment: Commenter (2343-NYU School of Law) states that the EPA qualitatively discusses the co-benefits of HAP emissions reductions in the RIA and reports the total HAP emissions reductions expected from the December 2022 proposal, but it does not break those reductions down by individual pollutants or assign any monetary value to such figures.<sup>209</sup> As a result, the commenter believes that the EPA's estimate of total monetized benefits understates the health and environmental gains from the rule again. Even if EPA is currently unable to monetize the benefits of reducing HAP emissions, they suggest that it should strive to improve that capacity for its analysis of future regulations.

In the RIA's qualitative discussion of the HAP-related impacts, the commenter (2343-NYU School of Law) notes that the EPA explains that, "[w]ith the data available, it was not possible to estimate the change in emissions of each individual HAP," and that "methodology and data limitations" preclude "monetiz[ing] the health benefits of reductions in HAP."<sup>210</sup> As with VOCs, the commenter suggests that the EPA present any additional quantitative information available to it, such as the estimation of individual HAP reductions from the December 2022 proposal, even if incomplete or uncertain, and acknowledge any relevant limitations of that information.<sup>211</sup> In accordance with SAB's recommendation, EPA should prioritize estimating the HAP-related benefits associated with future regulations, as failing to do so leads to an underestimation of monetized benefits.<sup>212</sup> An assessment of HAP emission reductions for the December 2022 proposal and its alternatives, as compared to only a baseline discussion of HAP emission effects for the oil and gas industry, would provide more useful information for improving the distributional analysis to more fully examine effects on near-source communities.

Response II-20-58: We are currently unable to estimate or monetize the impact of changes in HAPs releases due to data limitations, most notably the lack of sufficient emission location specificity to perform such analyses. The HAP impacts available in EPA's 2017 AirToxScreen dataset are provided for the entire oil and natural gas sector, which includes sources outside the scope of this regulation. We do not have current modeling of HAP impacts specific to only the

---

<sup>209</sup> Id. at 161–62 tbl.5-4 (estimating that the Supplemental Proposal would abate about 390,000 short tons of HAP emissions).

<sup>210</sup> Id. At 84–85.

<sup>211</sup> Circular A-4 (2003), *supra* note 10, at 27 ("If you are not able to quantify the effects, you should present any relevant quantitative information along with a description of the unquantified effects").

<sup>212</sup> SAB DRAFT REPORT, *supra* note 16, at 15.

sources subject to the regulation; therefore, we cannot estimate risks, including any reductions, solely attributed to the source category.

### ***20.5.5 Monetization of the Health and Ozone Benefits as a Result of Emissions Reductions***

Comment: Commenter (2343-NYU-School of Law) states that, in the RIA, EPA qualitatively discusses the co-benefits of VOC emissions reductions and reports the total VOC emissions reductions expected from the December 2022 supplemental proposal, but EPA does not assign any monetary value to these reductions except in Appendix C to the RIA.<sup>213</sup> As a result, the commenter contends that the EPA's estimate of total monetized benefits understates the health and environmental gains from the rule—most likely significantly. While appropriately recognizing the limitations and uncertainties underlying its calculations in Appendix C to the RIA, the commenter suggests that EPA discuss the magnitude of the monetized health benefits it estimates from reducing VOC emissions in its main regulatory analysis.

Commenter (2343-NYU-School of Law) expresses that the EPA discusses two categories of benefits associated with reducing VOC emissions: those related to ozone and those related to fine particulate matter (PM<sub>2.5</sub>).<sup>214</sup> EPA explains that, to calculate ozone impacts from changes in VOC emissions, it requires information about the spatial patterns in these emissions changes, and further, to estimate the ozone health effects from the December 2022 supplemental proposal it requires information on the relative proximity of expected VOC and ozone changes to population.<sup>215</sup> EPA explains that it “ha[s] not characterized VOC emissions changes at a finer spatial resolution than the national total due to data and resource constraints.”<sup>216</sup>

However, commenter (2343-NYU-School of Law) provides that in Appendix C, EPA presents an illustrative screening analysis of ozone-related health benefits based on modeled oil and natural gas VOC contributions to ozone concentrations as they occurred in 2017, but it does “not include the results of this screening analysis in the estimate of benefits (and net benefits) projected from this proposal.”<sup>217</sup> This analysis estimates that the combined monetized benefits of avoided morbidity health effects and avoided long-term ozone mortality would be \$7.2 billion between 2023–2035 (under a 3% discount rate).<sup>218</sup> While EPA acknowledges the various uncertainties and limitations of this calculation, the commenter notes that if it considers this to be an accurate representation of the rough magnitude of the benefits associated with VOC emission reductions, it should discuss its approximate size and significance in the main analysis while recognizing the relevant limitations.

---

<sup>213</sup> RIA, *supra* note 3, at 161–62 tbl.5-4 (estimating that the Supplemental Proposal would abate about 9,700,000 short tons of VOC emissions).

<sup>214</sup> Id. at 79, 81–82. EPA explains that it does not monetize PM<sub>2.5</sub>-related benefits due to its need for air-quality monitoring and because “it is unlikely that the VOC emissions reductions projected to occur under this proposal would have a large contribution to ambient secondary organic carbon aerosols.” Id. at 82. Accordingly, this paragraph instead focuses on the ozone-related impacts.

<sup>215</sup> Id. at 79

<sup>216</sup> Id.

<sup>217</sup> Id.

<sup>218</sup> Id. at 208.

In the RIA's discussion of both ozone and PM<sub>2.5</sub>-related impacts of VOC emissions, the commenter (2343-NYU-School of Law) states that the EPA states that "in future regulatory impact analyses supporting other regulations, the EPA plans to account for the emissions impacts of the oil and natural gas [new source performance standards] and [existing source emissions guidelines] in the baseline for the analysis."<sup>219</sup> Given the magnitude of ozone health effects associated with VOC emissions, the commenter recommends that the EPA prioritize estimating the spatial distribution of VOC changes so that it might include a better monetized estimate of these health effects for relevant future rules.

Response II-20-59: EPA includes an analysis of the impact of changes in VOC releases via their impact on ozone formation in Section 3 of the final RIA. The monetized benefits associated with those changes in VOC are included in the main net benefits estimation.

Comment: Commenter (2343-NYU School of Law) recommends that EPA consider incorporating its estimate of the health benefits associated with reducing exposure to methane-related ozone into the social cost of methane.<sup>220</sup> If it chooses not to incorporate these effects into the social cost of methane, they suggest that EPA include these monetized impacts in its assessment of other costs and benefits in the RIA. The commenter suggests that failing to do so leads to significant underestimation of the benefits associated with the December 2022 proposal. Indeed, the commenter notes that the EPA's SAB draft report explains that published literature demonstrates that "the monetized value of this ozone-attributable health response is comparable to the climate-related social cost of methane, so that leaving out this impact leads to a large underestimate of the total benefits."<sup>221</sup>

The commenter (2343-NYU School of Law) explains that SAB notes that deriving a monetized estimate of the health benefits of reducing exposure to ozone via methane emissions reduction is not analytically dependent on precise modeling of the spatial distribution of methane emissions given "the relatively long (decadal) residence time of methane in the atmosphere."<sup>222</sup> The SAB advises that EPA can draw from published literature and the experience of scientists from EPA for estimating a monetized value.<sup>223</sup> This literature suggests that the value could be tens of billions of dollars in health benefits between 2023-2035.<sup>224</sup> Considering this, the commenter

<sup>222</sup> Id. at 14.

<sup>223</sup> Id.

<sup>224</sup> The United Nations Environment Programme estimates the monetized mortality effects due to ozone from methane emissions to be \$2,500 per metric ton of methane. UNITED NATIONS ENVIRONMENT PROGRAMME, GLOBAL METHANE ASSESSMENT: BENEFITS AND COSTS OF MITIGATING METHANE EMISSIONS (2021) <http://www.unep.org/resources/report/global-methane-assessment-benefits-and-costs-mitigating-methane->

suggests that EPA heed the SAB's recommendation to monetize these benefits. If EPA believes it cannot provide these monetized benefits, they suggest that EPA should explain its reasoning.

Response II-20-60: The respiratory-related deaths associated with exposure to ozone produced from methane emissions are discussed in Section 3.7 of the Final RIA. In that section, EPA provides an illustrative calculation, based on recently published literature, of what the scale of the monetized benefits could be from this methane-ozone mechanism, but more work is required before incorporating those quantified benefits into the main net benefits analysis. Instead, EPA lists decreases in methane-related ozone resulting from the rule as unquantified benefits.

A detailed response regarding the omitted impact categories, including the health effects of methane-related ozone, from the SC-GHG estimates can be found in the Appendix of this RTC where responses are provided on comments pertaining to EPA's September 2022 *Draft Report on the Social Cost of Greenhouse Gases: Estimates Incorporating Recent Scientific Advances*.

Comment: Commenter (2293-Holmes) expresses that they were pleased to see the EPA's RIA document identify, in the Figure C-4 map, the Uinta Basin as a significant source of VOC-related ozone. They also expressed disappointment that the RIA did not provide an updated analysis of methane-related ozone impacts in the Uinta Basin and elsewhere. The commenter notes that the RIA admits that "[I]n remote areas, methane is a dominant precursor to tropospheric ozone formation."

The commenter (2293-Holmes) notes that the Uinta Basin is a remote area. Ozone is a very real problem there and bound to get worse absent active positive federal intervention. The RIA observes that ozone health effects include "asthma attacks, hospital and emergency department visits, lost school days, and premature respiratory mortality." It's no surprise, then, that healthcare clinics in Uinta Basin are advertising for more respiratory therapists. The commenter suggests that the RIA could have done a better job of investigating a leading oil and gas industry factor that is negatively impacting rural Utahns.

Response II-20-61: The respiratory-related deaths associated with exposure to ozone produced from methane emissions are discussed in Section 3.7 of the Final RIA. In that section, EPA provides an illustrative calculation, based on recently published literature, of what the scale of the monetized benefits could be from this methane-ozone mechanism, but more work is required before incorporating those quantified benefits into the main net benefits analysis. Instead, EPA lists decreases in methane-related ozone resulting from the rule as unquantified benefits.

---

emissions. For illustrative purposes, if EPA used that number to estimate a lower-bound estimate (because it excludes morbidity effects), it would find that the Supplemental Proposal could generate approximately \$66.8 billion in health benefits from reduced ozone-related methane from 2023 to 2035. This calculation assumes EPA's estimated reductions in methane emissions due to the Supplemental Proposal (RIA *supra* note 3, at 162 tbl.5-4) of 36,000,000 short tons, converted to 32,658,649 metric tons, where the emissions reductions are distributed equally annually, and a 3 percent discount rate.

## 20.6 Environmental Justice Analysis

Comment: Commenter (2343-NYU School of Law) states that the EPA properly includes an environmental justice analysis in the RIA. But they recommend that EPA strengthen the distributional analysis to capture the distributional impacts of the Supplemental Proposal more fully. To further improve its analysis, they suggest that EPA look to recent scholarship, which has identified key features of meaningful distributional analysis.<sup>225</sup> They further urge EPA to consider the recommendations of its Science Advisory Board (SAB) on improving the environmental justice analysis for the Supplemental Proposal.<sup>226</sup>

The commenter (2343-NYU School of Law) recommends that EPA strengthen the consideration of distributional impacts in the Supplemental Proposal in five key ways: (1) estimate the distributional impacts of the Supplemental Proposal and its alternatives in addition to the baseline; (2) address data limitations and further quantify important impacts; (3) integrate consideration of cumulative environmental burdens on affected communities; (4) fully integrate the results of its analysis into its final decision; and (5) treat distributional effects like unquantified impacts in its decision-making. The commenter notes that these practices would be consistent with EPA’s Guidelines on Conducting Economic Analyses which clarify that “evaluating a program’s distributional effects is an important complement to benefit-cost analysis.”<sup>227</sup> By improving its distributional analysis, the commenter notes that EPA can improve its understanding of how to reduce harms to overburdened communities and fulfill its strategic goal to advance environmental justice.<sup>228</sup>

In the RIA, the commenter (2343-NYU School of Law) notes that the EPA conducts a baseline analysis, which identifies existing disparities in the populations exposed to emissions from the oil and gas source category through both qualitative and quantitative means. However, the commenter states that this baseline analysis, by its nature, does not analyze the distributional impacts of the Supplemental Proposal or its alternatives. Instead, EPA’s analysis finds, at a general level, that the current negative impacts of methane, HAP, and VOC emissions fall disproportionately on certain communities, and the agency accordingly believes that the Supplemental Proposal, by reducing these emissions in general, will improve health and welfare in these communities.

According to the commenter (2343-NYU School of Law), baseline understanding of disproportionate burdens created by the source category is helpful but should be accompanied by an analysis that evaluates the distribution of impacts resulting from the Supplemental Proposal and any incremental differences from adopting EPA’s proposed alternatives. Indeed, the

<sup>227</sup> EPA ECONOMIC ANALYSIS GUIDELINES, *supra* note 37, at 10-1.

<sup>228</sup> See, e.g., EPA, FY 2022–2026 EPA STRATEGIC PLAN 32–34 (2022), <https://perma.cc/3YXC-ZUAB>.

commenter notes that President Biden’s Memorandum on Modernizing Regulatory Review calls for analysis of “distributional consequences . . . to ensure that regulatory initiatives appropriately benefit and do not inappropriately burden disadvantaged, vulnerable, or marginalized communities.” To fully assess how the rule will affect environmental justice community health and welfare, the commenter recommends that the EPA analyze the distributional consequences of the Supplemental Proposal.

In addition, the commenter (2343-NYU School of Law) recommends that EPA analyze the distributional implications of each alternative—consistent with Circular A-4 (2003)’s guidance that “‘an examination of alternative approaches’ [is] one of the three basic elements of ‘a good regulatory analysis.’”<sup>229</sup> This analytical step is a natural extension of EPA’s existing alternatives analysis, which already assesses the costs and benefits of a more stringent alternative and a less stringent alternative.<sup>230</sup> By considering alternatives in its assessment of distributional impacts, EPA would be better able to weigh not only the respective net benefits, but also the distribution of costs and benefits when comparing alternatives. If the distribution of impacts under one alternative is desirable enough—for example, because it increases the health and safety of already unfairly overburdened communities—that may justify selecting that alternative over one with greater net benefits but a less desirable distribution of impacts.

The commenter (2343-NYU School of Law) notes that the EPA has several potential ways to apply these long-standing directives to consider distributional effects. One way is to treat desirable (or undesirable) distributional effects as unquantified benefits (or costs) that it compares alongside other costs and benefits.<sup>231</sup> This comparison would mean valuing distributional impacts similarly to any other unquantified cost or benefit in its analysis. In this way, the agency can understand the tradeoffs in scenarios in which the value of achieving certain distributional goals merits leaving at least some net benefits on the table. Again, this is consistent with the treatment of unquantified effects. EPA, like other agencies, is expected to weigh unquantified effects against monetized costs and benefits in accordance with its judgment and expertise.<sup>232</sup>

The commenter (2343-NYU School of Law) adds that the EPA has a long history of considering unquantified effects, including in the Supplemental Proposal, where EPA has explained that many benefits were unable to be quantified.<sup>233</sup> EPA guidance is also clear that EPA should consider unquantified costs and benefits in its analysis.<sup>234</sup> In cases, with “potentially important effects that cannot be quantified, the analyst should include a qualitative discussion of benefits results” and that “discussion should explain . . . the reasons for believing that these non-

Riverkeeper, Inc.*, 556 U.S. 208, 235 (2009) (Breyer, J., concurring in part and dissenting in part) (writing approvingly of EPA’s ability to “describe environmental benefits in non-monetized terms and to evaluate both costs and benefits in accordance with its expert judgment and scientific knowledge”).

<sup>233</sup> RIA, *supra* note 3, at 10, 60.

<sup>234</sup> EPA ECONOMIC ANALYSIS GUIDELINES, *supra* note 37, at 7-49.

quantified effects may be important for decision making.”<sup>235</sup> EPA should apply the same treatment to distributional effects.

Additionally, the commenter (2343-NYU School of Law) recommends that EPA coordinate internally and externally with other agencies and with OMB to conduct its distributional analysis for this rule in a manner that contributes to achieving a standardized approach to distributional analysis across the federal government.

Additional comments relating to the use of OMB Circular A-4 (2003) are presented in section 22.1.2 of this Chapter.

Response II-20-62: The EPA agrees with the commenters that a strengthened distributional analysis of both baseline and the policy option is important to perform when feasible to do so. Due to the availability of new ozone spatial surfaces that reflect the policy option’s estimated air pollution changes, EPA was able to add an expanded distributional EJ analysis to the final RIA that assesses the distributional impacts of both the baseline and the policy option. In addition, new population subgroup variables have been added to the analysis to better capture cumulative risks, most notably, the life expectancy variable which serves as a proxy to identify communities with exposure to more risks over the course of their lifetime that lead to a lower life expectancy on a community-level. EPA believes that these improvements to the environmental justice analysis better reflect the Circular A-4 (2003) and Circular A-4 (2023) Guidance and the recent Executive Orders on environmental justice that direct analysts to more thoroughly consider the distributional impacts of proposed policy.

Comment: Commenter (2392-Earthjustice et al) states that, in line with EPA Guidance, the RIA for the Supplemental Proposal analyzes environmental justice impacts as categorized by demographic groups.<sup>236</sup> This commenter notes that they take a different approach, instead analyzing first some of the impacts associated with oil and gas infrastructure and pollution,<sup>237</sup> and thereafter integrating demographic specific data and experiences. The commenter notes that they utilize this approach to emphasize that adverse health, economic, and climate vulnerability impacts are commonly experienced across communities.

Response II-20-63: EPA acknowledges the commenter’s clarifications.

---

<sup>235</sup> Id.

<sup>236</sup> See U.S. Env’t Prot. Agency, Regulatory Impact Analysis of the Supplemental Proposal for the Standards of Performance for New, Reconstructed, and Modified Sources and Emissions Guidelines for Existing Sources: Oil and Natural Gas Sector Climate Review at 106-36 (2022), <https://www.epa.gov/system/files/documents/2022-12/Supplemental-proposal-ria-oil-and-gas-nsps-eg-climate-review-updated.pdf>.

<sup>237</sup> Joint Environmental Justice Commenters note that this comment letter does not contain a comprehensive recitation of the disparate impacts that oil and gas development and pollution have on low-income communities and communities of color. Rather, this provides numerous examples of how the oil and gas industry has outsized impacts on these communities.

Comment: Commenters (2393-ODEQ/OSSE) report that staff performed a review of the RIA<sup>238</sup> for the November 2021 Proposal as well as the RIA for the SNPR.<sup>239</sup> A longer review time was needed to allow adequate review of the SNPR RIA due to the complexity of the SNPR and the associated documents. However, the commenters state that, as was the case for the November 2021 Proposal and stated in their 2021 Comments, they found the approach taken in the RIA for the SNPR to be inadequate. Further, they add that it does not appear that EPA sufficiently addressed the issues raised in their 2021 Comments. The commenters suggest that there are still details that warrant a more rigorous analysis by EPA.

The commenters (2393-ODEQ/OSSE) state that one issue of concern is the lack of any detailed projections of likely reductions in oil and gas employment. While there are economic projections showing impacts on future oil and gas prices and production, there does not appear to be a concrete projection of the reduction in employment that would likely be associated with adoption of the proposed regulations. This is particularly concerning in Oklahoma due to the number of marginal wells that remain in operation and whose financial viability may be precarious. Further, the commenters add that the jobs in the oil and gas sector are particularly well-paying when compared to alternatives, especially in rural areas and, because job losses are likely to be localized, the effects are magnified in those communities.

The commenters (2393-ODEQ/OSSE) note that the SNPR RIA, beginning on page 126, explains the baseline approach used to evaluate employment impacts in Section 4 of the RIA:

The EPA also conducted a baseline analysis to characterize potential distributional impacts on employment. A reduction in oil and natural gas activity could have a negative effect on employment among oil and natural gas workers. This could also reduce employment, earnings, and tax revenues in oil and natural gas intensive communities.<sup>95</sup> Any effect on oil and natural gas workers or oil and natural gas intensive locations would be a local and partial equilibrium effect. In general equilibrium, there could be other and potentially offsetting effects in other regions and sectors.

....

Comparing workers in the oil and natural gas sector to workers in other sectors, oil and natural gas workers may have higher than average incomes, be more likely to have completed high school, and be disproportionately Hispanic. People living in some oil and natural gas-intensive communities concentrated in Texas, Oklahoma, and Louisiana, may have disproportionate income levels, rates of high school completion, and demographic composition.

<sup>238</sup> U.S. EPA, “Regulatory Impact Analysis for the Proposed Standards of Performance for New, Reconstructed, and Modified Sources and Emissions Guidelines for Existing Sources: Oil and Natural Gas Sector Climate Review,” (RIA), EPA-452/R-21-003, October 2021 ([https://www.epa.gov/system/files/documents/2021-11/proposal-ria-oil-and-gas-nsps-eg-climate-review\\_0.pdf](https://www.epa.gov/system/files/documents/2021-11/proposal-ria-oil-and-gas-nsps-eg-climate-review_0.pdf)).

<sup>239</sup> U.S. EPA, “Regulatory Impact Analysis of the Supplemental Proposal for the Standards of Performance for New, Reconstructed, and Modified Sources and Emissions Guidelines for Existing Sources: Oil and Natural Gas Sector Climate Review,” (RIA), EPA-452/R-22-007, November 2022 (<https://www.epa.gov/system/files/documents/2022-12/Supplemental-proposal-ria-oil-and-gas-nsps-eg-climate-review-updated.pdf>).

The commenters (2393-ODEQ/OSSE) state that this information appears unchanged from the RIA for the November 2021 Proposal and lends support to the contention that the economic impacts of this rulemaking will likely be significantly harmful to rural communities dependent on this industry. It is with this concern in mind that the commenters again recommend that EPA consider economic impacts of this rulemaking with the same level of granularity and diligence that was used in evaluating the rulemaking's benefits for environmental justice communities. The importance of oil and gas jobs is further emphasized by the information in Table 4-8 of the SNPR RIA which shows that the average income for oil and natural gas workers is \$110,000 while the average income for other workers in "oil and gas communities" is \$42,000. Thus, for every oil and gas job lost, even if there is a new non-oil and gas job created in the same community, they report that there will be a net loss of \$68,000 with additional spillover effects in the community.<sup>240</sup>

The commenters (2393-ODEQ/OSSE) cite Page 128 of the December 2022 supplemental notice of proposed rulemaking RIA that sets forth data used to develop the analysis:

This analysis uses 5-year ACS data from 2015-2019 retrieved from IPUMS. This is approximately 16 million individual ACS responses. Oil and natural gas workers are identified by working in industries with a NAICS code that begins with "211." Those are "Oil and natural gas Extraction," as well as the sub-industries "Crude Petroleum Extraction" and "Natural Gas Extraction."

Response II-20-64: EPA acknowledges the challenge in assessing the employment impacts of the regulation. To the extent that regulatory costs lead to reduced production, sector employment could be reduced, though this is not guaranteed as firms could simultaneously reallocate expenditures on productive inputs away from capital and towards labor because of the regulation. In addition, as noted by some commenters, the regulation may also increase employment by increasing the demand for compliance-related labor. The net effect is ambiguous without sufficient data, which hasn't been provided by commenters.

Comment: Commenter (2393-ODEQ/OSSE) remains concerned that EPA's analysis is too vague and broad-brush. The commenter believes that the rule would, if adopted, undermine EPA's goal of expanding environmental justice.

The commenter (2393-ODEQ/OSSE) states that jobs in the oil and natural gas sector are engines of Oklahoma's rural economy.<sup>241</sup> In rural Oklahoma, issues of environmental justice are closely tied to the success of the oil and natural gas industry. The commenter contends that any policy that undercuts employment in the oil and natural gas sector will harm the economic foundation

---

<sup>240</sup> In the original RIA, the average income for oil and natural gas workers was the same as in the SNPR RIA (\$110,000); in the SNPR RIA, the average income for other workers increased from \$40,000 to \$42,000.

<sup>241</sup> See, for example, the article, "Feeling the Pain: In Rural Oklahoma, Oilfield Communities See the Ups and Downs of Oil and Gas Industry Firsthand," by Cody Bannister, February 11, 2021, available online: <https://www.thepetroleumalliance.com/feeling-the-pain-in-rural-oklahoma-oilfield-communities-see-the-ups-and-downs-of-oil-and-gas-industry-first-hand/>.

of rural Oklahomans. In fact, they note that even the New York Times recently published an article acknowledging that:

People of color make up 24 percent of the rural population. Close to half of rural Native Americans and more than half of rural Black Americans live in a distressed county. That's compared with 18 percent of rural whites. Anyone serious about racial equity must also be serious about rural America.<sup>242</sup>

The commenter (2393-ODEQ/OSSE) notes that EPA has not made or documented important inquiries, such as how many marginal wells are expected to close as a result of the proposed rules, how many jobs are expected to be lost, and which communities are likely to experience those losses. It may be challenging to attempt to address these issues with sufficient rigor, but an attempt is certainly warranted to justify policies that will have disproportionate impacts on some communities to benefit the entire public. The commenter supports the evaluation of environmental impacts on environmental justice communities, however, they believe that the EPA's preliminary analysis does not account for the full range of this rulemaking's potential impacts and could result in unintended consequences for communities dependent on oil and gas economies, which could include overlooked environmental justice communities.

Further, the commenter (2393-ODEQ/OSSE) states that the December 2022 proposal includes policies that, if adopted as proposed, would worsen the concerns raised in the commenter's November 2021 comments. The commenter explains that the requirement that all existing wells undergo annual fugitive emissions monitoring (with no exemption for older, lower-producing wells) will likely render many of those older wells too expensive to operate resulting in job losses in older, rural communities that are not currently seeing new oil and natural gas exploration activities. The commenter believes that low-income rural communities are experiencing many negative socio-economic problems that will only be exacerbated if the December 2022 proposal is adopted.

In addition, the commenter (2393-ODEQ/OSSE) believes that the proposed super-emitter response program runs the risk of privileging wealthier communities (or well-supported environmental advocacy organizations) at the expense of marginalized communities and smaller, less well-resourced oil and natural gas companies. The commenter contends that wealthier communities are more likely to hire expensive consultants to ensure they are equipped with the latest and most expensive technology. They add that well-resourced environmental advocacy organizations can observe activities in hot spots or areas of concern to their donor base, but those observations may not be well-evidenced due to a lack of expertise. The commenter believes that smaller oil and natural gas operators may be inundated with frivolous complaints from individuals or organizations with resources but not necessarily the expertise to set forth credible claims.

---

<sup>242</sup> "A Policy Renaissance Is Needed for Rural America to Thrive," by Tona Pipa (Senior Fellow at the Center for Sustainable Development at the Brookings Institution and leader of the Reimagining Rural Policy Initiative), from the New York Times, online, published December 27, 2022, <https://www.nytimes.com/2022/12/27/opinion/rural-america-left-behind-places.html>.

Response II-20-65: In response to the commenter, EPA developed a financial analysis of marginal oil and natural gas wells in Chapter 6 of the Final Rule TSD. EPA finds that marginal wells may continue to operate at low or negative profits rather than be shut-in and plugged due to a variety of reasons, including low operating costs, high plugging costs, low state bonding requirements, accounting practices, and tax credits available to the oil and gas industry. With the available data and the complexity described, EPA cannot estimate the impacts of the final regulation on the owners or operators of marginal wells and is not able to offer an estimate of how many wells would be plugged, if any.

Comment: Commenters (2254-PBPA, 2257-MOGA, 2304-PIOGA, 2393-ODEQ/OSEE, 2447-Clean Air for the Long Haul) urge EPA to expand the economic impact analysis on small rural “underserved or overburdened communities”.

Commenter (2257-MOGA) reminds EPA that many of these “underserved or overburdened communities” are often located in rural areas where oil and gas drilling and production provide jobs and sustains local economies. The commenter expresses concern that the proposed rules will likely result in the early plugging of marginal wells that cannot absorb the initial implementation and ongoing costs of the proposed regulation, directly impacting associated small businesses, including hotels, restaurants, service, retail and other “mom and pop” stores that rely on the oil and gas industry to survive.

Commenter (2393-ODEQ/OSEE) expresses concern that the December 2022 proposal does not provide fair consideration of the economic impacts in distressed rural communities that may not meet EPA’s threshold of “environmental justice community.” The commenter finds that the December 2022 proposal would do additional damage to communities that rely heavily on oil and gas employment, especially those located in rural parts of Oklahoma. The commenter strongly encourages EPA to broaden its evaluation of the costs and benefits of this rulemaking to incorporate economic effects with the same level of granularity that was used in targeting communities living in proximity to facilities that would be subject to this rulemaking. The commenter notes that, in particular, EPA has not adequately examined how these policies will affect employment in economically distressed rural communities in states like Oklahoma. In order to ensure that just policies are adopted, the commenter recommends that EPA reconsider the December 2022 proposal and allocate time and resources to properly weigh the economic impacts on vulnerable communities, especially rural communities, as carefully as the environmental benefits are evaluated.

The commenter (2393-ODEQ/OSEE) references a study by Price Waterhouse that was performed for the American Petroleum Institute, which determined that the oil and gas sector was responsible (including direct and indirect employment) for 16.7 percent of the Oklahoma workforce.<sup>243</sup> The commenter adds that many oil and gas jobs employ residents of rural

---

<sup>243</sup> “Impacts of the Oil and Natural Gas Industry on the US Economy in 2019,” prepared by PricewaterhouseCoopers LLP, prepared for the American Petroleum Institute, July 2021, available on-line: <https://www.api.org/-/media/Files/Policy/American-Energy/PwC/API-PWC-Economic-Impact-Report.pdf>.

communities.<sup>244</sup> To assess the possible impacts of job losses in those communities, the work performed by the U.S. Department of Agriculture's (USDA's) Economic Research Service investigated economic, social, and demographic factors that affect the poverty status of residents of rural communities. The commenter notes that for 2019, the USDA estimated Oklahoma's statewide poverty rate at 15.1 percent with 19.7 percent of Oklahoma's children living in poverty.<sup>245</sup> Rural counties, especially in the southeastern part of the state are particularly impacted by poverty.<sup>246</sup> The commenter explains that the availability of middle-class oil and gas jobs in rural Oklahoma mitigates the poverty experienced in many of these communities.

The commenter (2393-ODEQ/OSEE) expresses concern that the data set EPA used was exclusively from the oil and gas extraction segment and does not appear to include the drilling, treatment, storage, or transmissions segments. Further, both the RIA for the November 2021 Proposal and the SNPR RIA used Public Use Microdata Area (PUMA) data to identify oil and gas communities. The commenter contends that this level of analysis is insufficiently specific in identifying impacts on rural areas. This assertion is demonstrated by the map (Figure 4-9 on p. 129 of the SNPR RIA) which shows the relatively large size of each PUMA. In addition, they note that the oil and gas PUMAs shown in the map cover more than half the state of Oklahoma. In contrast, the environmental justice communities in EJScreen<sup>247</sup> are identified with much finer granularity. The commenter questions whether and to what degree this analysis inherently biases the evaluation of costs and benefits, thereby possibly privileging certain communities compared to others.

The commenter (2393-ODEQ/OSEE) notes that Table 4-9 in the December 2022 proposal RIA provides demographic data for the entire group of PUMAs with high oil and gas intensity. This analysis is used to draw various conclusions concerning the ethnic make-up, educational attainment, and income of residents in these areas compared with other areas with lower oil and gas intensity. By aggregating the high oil and gas PUMAs for these analyses, the commenter states that EPA fails to give a sufficiently granular analysis of the impacts of the types of rural communities found in Oklahoma. The commenter contends that this contrasts with EPA's approach in evaluating impacts on environmental justice communities.

According to the commenter (2393-ODEQ/OSEE), while the analysis in the December 2022 proposal RIA (see Table 4-10 and Figure 4-10 of the December 2022 proposal RIA) provides some greater specificity, the commenter believes it is still insufficient and fails to meet the standards EPA uses for evaluating environmental justice communities. Notable in Figure 4-10 of the December 2022 proposal RIA is just how large a fraction of the state of Oklahoma is included in the PUMAs evaluated.

---

<sup>244</sup> See, for example, the article "Feeling the Pain: In Rural Oklahoma, Oilfield Communities See the Ups and Downs of Oil and Gas Industry Firsthand," by Heidi Brandes, February 11, 2021, available on-line on the web page of The Petroleum Alliance: <https://www.thepetroleumalliance.com/feeling-the-pain-in-rural-oklahoma-oilfield-communities-see-the-ups-and-downs-of-oil-and-gas-industry-first-hand/>.

<sup>245</sup> U.S. Department of Agriculture, Economic Research Service, Rural Poverty & Well-Being, state poverty rate data available on-line: <https://data.ers.usda.gov/reports.aspx?ID=17826>.

<sup>246</sup> County data are available from the link cited in Footnote 5 by selecting "Oklahoma."

<sup>247</sup> See <https://www.epa.gov/ejscreen>.

Commenter (2254-PBPA) recommends that EPA evaluate the impact of the proposed rule on the economically disadvantaged. The commenter states that the EPA properly acknowledges “[t]his action, which is a significant regulatory action under Executive Order 12866, has a significant adverse effect on the supply, distribution or use of energy.” Inevitably, the commenter notes that this rule will have a direct impact on consumers. The commenter believes that chilling domestic production will do nothing to address consumer demand for fuels and will likely increase fuel prices resulting in additional inflation on the prices of consumer goods as it becomes more expensive to manufacture and transport basic goods.

The commenter (2254-PBPA) states that it is not clear that the EPA has fully considered or discussed the environmental justice implications of the increased cost of production that will result from implementation of the proposed rule. The commenter recommends that EPA evaluate the impact of the proposed rule on the economically disadvantaged who must devote a greater portion of their limited budgets to items such as energy costs. The commenter explains that these consumers cannot readily reduce their home heating/cooling or transportation needs. The commenter notes that EPA’s Regulatory Impacts Analysis (RIA) notes that EPA didn’t do any regional modeling to determine if people living in poorer conditions would suffer from reduced hydrocarbon production. As the EPA points out, oil and gas prices are inelastic, which means if the U.S. cannot produce oil and gas, other countries will. The commenter asserts that production forced overseas leads to an increased cost for American consumers. According to the commenter, such increases tend to have a disproportionate impact on economically disadvantaged communities.

Commenter (2304-PIOGA) asserts that EPA has failed to consider or evaluate the proposal impact on communities that rely on the conventional oil and natural gas industry. The commenter contends that any requirements associated with enhanced community involvement must be balanced, i.e., EPA and the states should be just as focused on the benefits the industry brings to the community as they are on potential negative ramifications.

The commenter (2304-PIOGA) notes that the December 2022 supplemental proposal would require states to engage in enhanced community engagement with the laudable intent of engaging communities that have historically been disenfranchised and perhaps disproportionately impacted negatively by "industry." The commenter contends that any requirements placed on the states related to enhanced community engagement need to understand and account for the positive impacts of the oil and natural gas industry in rural communities. The commenter reports that often, the oil and natural gas industry, particularly the conventional, or low production, well portion of the industry, is the primary, if not only economic driver for the region. In most situations, the landowner where the well is drilled is provided "free gas" or "house gas". Often the landowner is provided a certain royalty associated with the gas that is removed from the property. The commenter states that in the case of low production wells, the economic benefit to the landowner may not appear to be much, but in the end, it could be the difference between "selling the farm" and not. Additionally, the commenter notes that certain rural communities are not served by "big oil" or unconventional natural gas wells and interstate pipelines. Without the conventional low production wells, families would lose the ability to utilize natural gas to heat their homes and/or run their business and would have to rely upon energy sources with greater emissions than natural gas.

Commenter (2447-Clean Air for the Long Haul) states EPA estimates abandoned wells emitted 263,000 metric tons of methane in 2019.<sup>248</sup> However, other research has shown there is an underestimation.<sup>249</sup> Apart from contributing significantly to climate change, these wells pose environmental, health, and safety hazards.<sup>250</sup> While an estimated 9 million people live in the vicinity of 81,000 inactive and unplugged orphan wells with no owner of record,<sup>251</sup> It is people of color who are most exposed to these threats as in the case of environmental justice communities in California.<sup>252,253</sup> It is crucial that a proximity analysis of abandoned and unplugged wells in relation to disadvantaged communities where more stringent monitoring and enforcement should occur and ensure that owners and operators of these wells take necessary remedial actions outlined in submitted closure plans to properly plug and prevent methane leaks.

Response II-20-66: EPA acknowledges the challenge in assessing the employment impacts of the regulation. To the extent that regulatory costs lead to reduced production, sector employment could be reduced, though this is not guaranteed as firms could simultaneously reallocate expenditures on productive inputs away from capital and towards labor because of the regulation. In addition, as noted by some commenters, the regulation may also increase employment by increasing the demand for compliance-related labor. The net effect is ambiguous without sufficient data, which hasn't been provided by commenters. EPA further assesses that the spatial scale of the analysis is appropriate for consideration of employment impacts. Smaller spatial units would not be appropriate because they would omit consideration of inter-county economic relationships including commuting by industry workers as well as indirect effects. Recent research finds economic impacts in both producing counties and the surrounding region.<sup>254</sup>

With respect to commenters' assertions regarding small businesses and low production wells, see Response II-20-34. With respect to commenters' assertions regarding commodity prices and household energy burden, see Response II-20-27.

In response to commenter that requests that the EPA require a proximity analysis of abandoned and unplugged wells in relation to disadvantaged communities where more stringent monitoring

and enforcement should occur, in response to comments on the November 2021 Proposal, the EPA did not propose any requirements for these sources in the December 2022 Supplemental Proposal. The EPA is finalizing well closure requirements, but no requirements are being finalized for abandoned wells, unplugged wells, or wells that are plugged insufficiently. As stated in section X.A (Fugitive Emissions from Well Sites, Centralized Production Facilities, and Compressor Stations) of the final preamble, EPA is finalizing well closure requirements under the fugitives monitoring requirements for actively producing wells. The final well closure requirements will prevent well sites from becoming orphaned or left in an idled and unplugged state with no form of emissions monitoring and repair. See RTC Volume II Chapter 4, section 4.1.6 (Well Closure Requirements) for response to comments on the well closure plan associated with the fugitive monitoring requirements. See 40 CFR 60.5397b(l) of NSPS OOOOb and 40 CFR 60.5397c(l) of EG OOOOc for the final well closure requirements. Comment: Commenter (2392-Earthjustice) states that low- income communities and communities of color are disproportionately left with economic burdens resulting from oil and gas development, while the wealth created by this development is exported out of the communities where resource extraction occurs. The commenter highlights the disparate economic impacts associated with oil and gas production as they are experienced by Latin, rural, and low-income communities.

The commenter (2392-Earthjustice) notes that EPA’s economic environmental justice analysis in the RIA focused on the narrow issue of household energy expenditures and potential disparate impacts of increased cost due to regulation. However, as is demonstrated below, the adverse economic impacts associated with oil and gas production are broader than potential increases in energy costs. An accurate accounting of the economic impacts should consider the distribution of economic benefits and burdens, and their cumulative effects on impacted communities.

The commenter (2392-Earthjustice) believes, and multiple studies have found, that the local economic benefits of oil and gas production are overstated. A 2012 study of the local economic benefits associated with natural gas production across counties in Colorado, Texas, and Wyoming found that natural gas production had “modest” effects on employment and income, and that “ex-ante estimates of the number of jobs created by developing the . . . Marcellus shale gas formation[] may have been too large.”<sup>255</sup> Likewise, a 2014 study analyzing labor market conditions at the county level in nine states found only a “modest” impact on local employment and wage effects.<sup>256</sup>

Furthermore, the commenter (2392-Earthjustice) reports that research shows that much of the wealth generated by oil and gas production leaves the communities where extraction takes place. A 2015 study analyzed the distribution of economic costs and benefits associated with shale gas development in Denton, Texas.<sup>257</sup> The study found that “residents own[ed] 1 percent of the total

Rev., Jan. 2014, at 119, 120, [https://www.kansascityfed.org/Economic%20Review/documents/1621/Production\\_of\\_Natural\\_Gas\\_From\\_Shale\\_in\\_Local\\_Economies\\_A\\_Resource\\_Blessing\\_or\\_CurseD4.pdf](https://www.kansascityfed.org/Economic%20Review/documents/1621/Production_of_Natural_Gas_From_Shale_in_Local_Economies_A_Resource_Blessing_or_CurseD4.pdf).

<sup>257</sup> Matthew Fry et al., Fracking and Environmental (In)justice in a Texas City, 117 Ecological Econs. 97, 97 (2015), <https://omeka.library.unt.edu/files/original/1f215096dd897cc492c3b94c157724a297193ccf.pdf>.

value extracted” from approximately 280 active gas wells between 2002 and 2013.<sup>258</sup> After analyzing the distribution of costs and benefits, the study concluded that “there is a disproportionate distribution of [shale gas development]’s burdens and benefits in Denton, with non-mineral owners paying the environmental and health risks without receiving direct economic benefits and others reaping the benefits without being exposed to the risks.”<sup>259</sup>

Response II-20-67: EPA calculates distributional impacts beyond household energy expenditures. In Section 4.3 of the RIA, EPA quantitatively or qualitatively considers disparate climate change and ozone impacts, air toxics impacts, and employment and related local production value impacts. In contrast to the commenter’s claim, EPA finds that oil and gas producing communities have similar proportions of Hispanic residents and similar incomes to the rest of the country.

EPA notes that recent studies find that oil and gas production is associated with substantial employment in both producing and nearby counties, and that a large share of the associated royalty payments go to leaseholders in the same county as the lease. EPA acknowledges that some specific communities’ resource rights may largely be held by non-residents.<sup>260</sup>

EPA is unable to estimate location-specific employment impacts of the Rule. EPA considers potential disparate impacts in Section 4.3 of the RIA including potential disparate impacts in climate impacts, ozone impacts, air toxics, employment effects, and energy price changes. EPA is unable to calculate changes in wealth generated by oil and gas production by income group.

Comment: Commenter (2392-Earthjustice et al) states that communities of color are disproportionately located near flaring sites. A recent study analyzed demographics in three basins—the Permian, Western Gulf (Eagle Ford Shale), and Williston (Bakken shale)—that account for 83% of unconventional oil and gas flaring in the U.S. from 2012 to 2020.<sup>261</sup> The commenter notes that the study unequivocally concluded that “[b]lack, indigenous, and people of color [are] disproportionately exposed to flaring.”<sup>262</sup> Analyzing the Permian and Western Gulf basins, the study found that “Blacks were more likely to live within 5 [kilometers] of a flare . . . than other groups.”<sup>263</sup> Likewise, the analysis of the Williston basin found that “Native American and Hispanic populations were the most likely to live near flares.”<sup>264</sup>

The commenter (2392-Earthjustice et al) adds that these findings are reflected in the experiences of Indigenous communities residing on the Fort Berthold Indian Reservation in North Dakota. The Reservation is home to the three affiliated tribes of the Mandan, Hidatsa, and Arikara (MHA

<sup>264</sup> Id.

Nation) and once encompassed fertile agricultural lands along the Missouri River.<sup>265</sup> But the U.S. Army Corps of Engineers' construction of the Garrison Dam in the 1940s flooded significant portions of the Reservation, forcing residents to move into the higher badlands where agricultural development was not possible.<sup>266</sup> The MHA Nation then became reliant on oil and gas development for much needed revenues.<sup>267</sup> [Comment letter includes figure depicting George Gillette, chairman of the Fort Berthold Indian Tribal Council, weeping as the Secretary of the Interior signs an agreement forcing the MHA Nation to sell lands for the Garrison Dam.]

Commenter (2392-Earthjustice et al) states that with this development came significant adverse impacts on Reservation residents. In 2019, North Dakota accounted for 38% of the nation's vented and flared natural gas,<sup>268</sup> and an outsized portion of that flaring now happens on the Fort Berthold Reservation. From 2012 to 2020, nearly 20% of all flaring in North Dakota occurred on the Fort Berthold Reservation.<sup>269</sup> McKenzie county, which includes part of the Reservation, has the most flares of any county nationally, and virtually all the residents of this county live within 5 kilometers (about 3.2 miles) of more than 100 flares.<sup>270</sup> A 2018 analysis also found that people living on the Fort Berthold Reservation are 2 times more likely to live within a half-mile of an oil and gas facility, compared to the rest of North Dakota.<sup>271</sup>

Before they used to say that in North Dakota, you can see a dog run away for days. You look at the Bakken oil patch, and you see all the orange [from flaring]. They say you can see it from the space station. It looks like a Christmas tree, all the orange.

- Delvin Rabbithead, president of Fort Berthold Protectors of Water and Earth Rights.

Response II-20-68: EPA acknowledges the comment.

Comment: Commenter (2303-NTAA) notes that methane emissions disproportionately burden indigenous communities. For example, the Navajo Nation has 65% higher methane emissions from oil and gas companies than the national average.<sup>272</sup> The commenter cites a recent analysis by Environmental Defense Fund and Taxpayers for Common Sense found that indicates that oil

Citizen Scientists Are Fighting Back" (July 13, 2022), <https://nexusmedianews.com/methane-is-leaking-over-native-grounds/> (citing Environmental Defense Fund, "New Report Reveals Scale of Natural Gas Waste on Navajo Nation Lands," (Mar. 21, 2019), <https://www.edf.org/media/new-report-reveals-scale-natural-gas-waste-navajo-nation-lands>); American Lung Association, "State of the Air" 2022 Report Cards: New Mexico, San Jan County, <https://www.lung.org/research/sota/city-rankings/states/new-mexico/san-juan>.

and gas companies on public and tribal lands wasted over \$500 million worth of gas in 2019, suggesting that these emissions are an issue across tribal lands.<sup>273</sup>

Commenter (2697-STA) supports the work of the EPA in engaging with and assisting tribes across the U.S. in the effort to mitigate methane and other harmful air pollutants. Tribal communities contribute the least to climate change but are disproportionately impacted by it, making this an essential component of environmental justice and holding emitters accountable.

Response II-20-69: EPA acknowledges the supportive comments.

Comment: Commenter (2245-Private Citizen) notes that, as individuals with disabilities and on limited income, the commenter and their partner, along with many of our neighbors in the Port Towns area who are seniors, do not have the resources or funds to relocate to safer and more affordable homes. They ask the EPA to consider the financial and physical impact of climate change on the people who live along the rivers and borders of the oceans.

Response II-20-70: The EPA estimates the cost of climate change impacts and benefits of avoided climate change based on the Social Cost of Greenhouse Gases (SC-GHG). The SC-GHG is a metric that puts the effects of climate change (inclusive of adaptation costs) into monetary terms to help policymakers understand the economic impacts of decisions that would increase or decrease greenhouse gas emissions. The EPA uses SC-GHG estimates to monetize the climate benefits from the GHG emissions reductions expected under the final rule within the regulatory impact analysis (RIA) conducted under Executive Order 12866.

As discussed in Section 3.2 of the Final RIA included in the docket, the SC-GHG is the monetary value of the net harm to society from emitting a metric ton of that GHG into the atmosphere in a given year. In principle, the SC-GHG is a comprehensive metric that includes the value of all future climate change impacts (both negative and positive), including changes in net agricultural productivity, human health effects, property damage from increased flood risk, changes in the frequency and severity of natural disasters, disruption of energy systems, risk of conflict, environmental migration, and the value of ecosystem services. The SC-GHG, therefore, also reflects the societal net benefit of reducing emissions of the GHG by a metric ton. In practice, data and modeling limitations restrain the ability of SC-GHG estimates to include all physical, ecological, and economic impacts of climate change. EPA is continuously reviewing developments in the scientific literature on the SC-GHG, including more robust methodologies for estimating damages from emissions, and looking for opportunities to further improve SC-GHG estimation going forward.

Comment: Commenter (1685-Private Citizen) provides 31 pages of comments on the historical context of the presidential executive orders, and the court decisions around cumulative impacts that are required for the EPA to consider. The commenter argues, for example, that there is no implementation of EPA's framework for a Cumulative Risk Assessment in the current draft of regulations for GHGs and December 2022 Methane Supplemental considerations. In 20 years,

---

<sup>273</sup> Griot, O, et al., Onshore Oil and Natural Gas Operations on Federal and Tribal Lands in the United States: Analysis of Emissions and Lost Revenue (Jan. 26, 2023), available at <https://www.edf.org/media/new-study-quantifies-natural-gas-wasted-us-public-and-tribal-lands>.

the commenter notes that EPA has not codified this into any environmental regulations. Instead, they argue that permitting continues without regard to the overburdened fence line and frontline communities suffering the health and social impacts caused by industry pollution.

Response II-20-71: EPA acknowledges the comments about cumulative risk assessment and is currently in the process of developing cumulative risk assessment methods for our quantitative environmental justice analyses. In the interim, the Oil and Gas rulemaking utilizes the “life expectancy” and “redlining” variables as a proxy to identify communities with higher or lower exposure to cumulative risks. EPA continues to improve its methodology based on its framework for a Cumulative Risk Assessment as well as guidance from multiple Executive Orders and intend to more accurately assess cumulative risk in future rulemakings.

## Chapter 21. Statutory and Executive Reviews

### 21.1 Executive Order 12866: Regulatory Planning and Review and Executive Order 13563: Improving Regulation and Regulatory Review

Comment: Commenter (2359-Competitive Enterprise Institute and Heritage Foundation) states that EPA’s proposal is not reasonable, and that an unreasonable regulation may be challenged as arbitrary and capricious. The commenter notes that EPA asserts that its climate-benefit calculations are not a factor influencing regulatory stringency. “However, we emphasize that the monetized benefits analysis is entirely distinct from the statutory [best system of emission reduction] BSER determinations proposed herein and is presented solely for the purposes of complying with [Executive Order] EO 12866”<sup>1</sup>. The commenter states that the disclaimer does not shield the proposal from litigation risk. The commenter states that EO 12866 itself serves a more basic rule of reason. The commenter notes that the Supreme Court stated in its review of the Mercury Air Toxics Standards (MATS) rule in *Michigan v. EPA*: “One would not say that it is even rational, never mind ‘appropriate’, to impose billions of dollars in economic costs in return for a few dollars in health or environmental benefits...No regulation is ‘appropriate’ if it does significantly more harm than good.”<sup>2</sup>

Response II-21-1: The EPA has responded to this comment in section VIII (Overview of Control and Control Costs) of the final rule preamble.

### 21.2 Executive Order 13132: Federalism

Comment: Commenter (2257-Michigan Oil and Gas Association (MOGA)) is concerned with the issue of Federalism and how funding will be allocated. The commenter agrees with the West Virginia Department of Environmental Protection January 14, 2022, response letter Docket ID. No. EPA-HQ-OAR-2021-0317, and questions how the EPA will appropriate funding for individual states to acquire staff, training, equipment, etc. required to monitor, collect, inspect, review, and enforce future emission guidelines (EG) proposed in EG OOOOc.

The commenter (2257-MOGA) requests that EPA be transparent regarding how funding will be appropriated and how funding is going to be allocated so that state agencies, oil and gas producers and taxpaying citizens are informed prior to consideration of proposed regulations. The commenter’s primary concern is the potential for associated costs from unfunded federal programs imposed on state agencies via “federalism” that might be passed on to oil and gas producers in each state. The commenter requests that EPA explain or provide certainties that state agencies will not solicit funding from oil and gas producers to implement unfunded federal regulations. The commenter believes that the need for these clarifications and certainties is of paramount importance since the EPA did not consider these costs when estimating their cost-

---

<sup>1</sup> 87 FR 74843. BSER stands for “best system of emission reduction.” Clean Air Act section 111 performance standards are to reflect the degree of emission limitation achievable by the best system of emission reduction, taking into consideration cost, energy requirements, and non-air environmental impacts.

<sup>2</sup> *Michigan v. EPA*, 576 U.S. 743, 752 (2015), <https://supreme.justia.com/cases/federal/us/576/14-46/case.pdf>.

benefit analysis, including the financial cost feasibility analysis and justification of producer cost reduction burden per unit of methane or other emission constituents.

Commenter (2403-Petroleum Alliance of Oklahoma (PAO)) contends that there are significant Federalism issues with the December 2022 Supplemental Proposal. The commenter notes that EPA did not lessen the requirements on states as compared to the November 2021 Proposal, but stated that it updated, strengthened, and/or expanded the November 2021 Proposal for methane emissions from existing designated facilities that states would have to implement. Under its analysis of Executive Order 13132: Federalism, EPA states, “These actions will not have substantial direct effects on the states as defined in the Executive Order, on the relationship between the Federal Government and the States, or on the distribution of power and responsibilities among the various levels of government.”

However, the commenter (2403-PAO) states that Oklahoma provided comments to EPA on its November 2021 Proposal, where it states that, “[t]he most concerning issue presented by the proposed rule is the vast amount of state resources that will be required to implement the rule and the absence of any additional funding to states to account for the extreme increase in workload.” The commenter reports that Oklahoma goes on to state that the number of oil and gas permitted facilities would go from approximately 10,000 to over 200,000. The commenter asserts that there is a clear disconnect between EPA’s analysis and what states communicated to EPA.

Commenters (2219-WOGCC, 2227-Western Energy Alliance (WEA), 2237-North Dakota Industrial Commission (NDIC) and North Dakota Department of Environmental Quality (NDDEQ), 2254-Permian Basin Petroleum Association (PBPA), 2258-Marcellus Shale Coalition (MSC), 2353-CrownQuest Operating, LLC (CrownQuest)) assert that the December 2022 Supplemental Proposal has substantial direct effects on states, conflicts with state law, and fails to apply cooperative federalism principles.

Commenter (2219-WOGCC) recommends that EPA complete the required federalism evaluation appropriately. The commenter asserts that EPA requiring well plugging plans, financial assurance for well plugging, and notice of transfer of owner or operator is a significant change in the relationship between the federal government and states. The commenter notes that states consider a variety of criteria when determining appropriate well plugging plans and financial assurance. The commenter questions what happens in the future when a state requires certain procedures in a plugging plan that EPA would not approve. The commenter questions whether EPA will overrule a state on a process EPA does not even have authority over. The commenter believes this is a clear change in the distribution of power and responsibilities and the relationship between the federal government and the states.

Commenter (2258-MSC) asserts that states are neither subjects of nor created by the federal government. While federal laws duly enacted by the U.S. Congress are applicable to the states, the state has historically been the primary regulator of the activities within its borders. With respect to oil and gas activity and its regulation, intended to protect both the environment and public health, the commenter states that Pennsylvania has a mature regulatory regimen that adequately addresses most if not all the criteria that EPA seeks to promulgate. The commenter

asserts that in some areas, such as well closure plans, the Agency clearly seeks to expand its historic role of oil and gas oversight under the guise of air quality. The commenter states that this extension is tenuous at best and not justified by any demonstration that the various states are not already adequately addressing the underlying issue or equipped with the necessary statutory authority to do so if warranted.

The commenter (2258-MS) believes that, in abandoning the long-held and successful principle of cooperative federalism, the Agency seeks to impose a one-size-fits-all regulatory framework upon the states themselves, negating the states' authority to design different but equally effective regulatory programs. According to the commenter, the EPA imposes unnecessary, burdensome, and duplicative requirements upon not only industry, but the states themselves. It creates significant uncertainty and perpetuates confusion upon the industry as to what standards it is to meet; applicable to what date; and achieved within what timeframe. In doing so, the commenter believes that EPA wastes valuable and limited government resources, while also significantly raising the overall cost of doing business for operators with little, if any, commensurate environmental benefit for their citizens.

Commenter (2227-WEA) believes that the proposed rules reflect a broad-brush, one-size-fits all approach and do not account for significant regional challenges and differentiators that occur in distinctive parts of the U.S., particularly in the Rocky Mountain West with its wide-open and topographically difficult expanses and extreme weather conditions. In addition, contrary to EPA's assertion in the *Federal Register* notice, the commenter states that federalism implications from the proposed rules do exist and they will substantially and directly affect states and their relationship with the federal government. A prime example of this, according to the commenter, is designation of an oil well with associated gas as an affected facility, which is duplicative and conflicts with the existing regulation of flaring by various state oil and gas commissions.

Commenter (2237-NDIC/NDDEQ) states that the December 2022 Supplemental Proposal substantially intrudes on North Dakota's authority to implement and enforce its own methane emissions control program. The commenter asserts that the nearly four decades of Clean Air Act (CAA) reporting by the commenter clearly demonstrate the responsible operation and consistent success of North Dakota's programs.

Commenter (3845-ND Congress) asserts that EPA's proposed rule conflicts with core principles of federalism and states' rights by undermining state regulatory programs implemented by the North Dakota Industrial Commission ("NDIC") and North Dakota Department of Environmental Quality ("NDDEQ"). The commenter reports that the NDIC has already reduced flaring significantly via implementation and enforcement of gas capture goals. As of April 2023, statewide gas capture in North Dakota was 95 percent. The NDIC also has a robust program covering plugging and abandonment of oil and gas wells. The commenter notes that the EPA's proposed additional restrictions on flaring and well closure requirements fly in the face of the NDIC's efforts and authority. The commenter provides that the NDDEQ investigates and enforces violations of North Dakota's air regulations, including enforcement of federal regulations delegated to North Dakota under the CAA. The commenter adds that the NDDEQ has effectively implemented this delegated authority for decades. Yet, the commenter asserts that the EPA's proposed super-emitter response program would deputize third parties to encroach on

NDDEQ's delegated authority. The commenter believes that responding to third parties, likely with limited experience, will undermine NDDEQ's existing investigative process and create unnecessary churn for the agency. To add to this issue, the commenter states that the EPA has released no guidance on how it expects states to implement the super-emitter response program, raising additional concerns with the scope and degree of NDDEQ's oversight in this process. Commenter (2254-PBPA) states that the proposed NSPS OOOOb conflicts with and overrides states' oil and gas regulations. With respect to oil wells with associated gas, the commenter notes that EPA's position on flaring overlaps with existing state regulations that already prohibit or limit flaring under appropriate circumstances, that are enforced by agencies with relatively more on-the-ground knowledge than EPA, and that reflect states' interests in conserving their own resources.<sup>3</sup> Further, the commenter states that EPA's proposed well closure plan overlaps with existing state regulations that already address well closure and financial assurance.<sup>4</sup>

The commenter (2254-PBPA) provides that EPA admitted in its November 2021 Proposal that "[t]he proposed EG OOOOc may have federalism implications because development of State plans may entail many hours of staff time to develop and coordinate programs for compliance with the proposed rule, as well as time to work with State legislatures as appropriate, and develop a plan submittal."<sup>5</sup> The commenter states that EPA has not explained its new (opposite) view in the December 2022 Supplemental Proposal.

In addition, out of respect for cooperative federalism and each state's on-the-ground expertise, the commenter (2254-PBPA) requests that EPA allow states to adopt existing source performance standards (ESPS) that take a different form of numerical standards than the "presumptive" numerical standards that EPA has proposed as long as States can demonstrate equivalency.<sup>6</sup> The commenter notes that CAA 111(d) only requires EPA to "establish a procedure" under which each state can submit ESPS plans,<sup>7</sup> as opposed to requiring EPA to establish "presumptive" numerical standards. The commenter believes it is misguided to predetermine that states cannot demonstrate equivalency, whether on a source category or programmatic level, because an overly prescriptive approach would eliminate flexibility needed to make adjustments to accommodate advancements in technology and operational practices.

Commenter (2353-CrownQuest) asserts that the December 2022 Supplemental Proposal conflicts with state law and fails to apply cooperative federalism principles. The commenter believes that the rules are a broad one-size-fits all approach, and do not allow for state variances. The commenter states that EPA insists on treating all minor oil and gas emission sites as major emitting sites. The proposed rule justifies an emissions reduction based on the total onshore oil and gas production category rather than the intended source segment per the CAA.

An example of this misguided approach, the commenter (2353-CrownQuest) notes that EPA reclassifying multiple wellhead production sites as "facilities" because they are not remote like single wellheads are. The commenter reports that operators monitor a multi-wellhead site for the

---

<sup>3</sup> See, e.g., 16 Tex. Admin. Code §3.32 (Railroad Commission of Texas gas release requirements).

<sup>4</sup> See, e.g., 16 Tex. Admin. Code §3.14 (Railroad Commission of Texas plugging requirements).

<sup>5</sup> 86 Fed. Reg. 63,110, 63,261 (Nov. 15, 2021).

<sup>6</sup> 87 Fed. Reg. at 74,706 (referring to presumptive standards in EG OOOOc).

<sup>7</sup> 42 U.S.C. §7411(d)(1).

same time as a single-wellhead site. The commenter notes that EPA swapped the term “remote,” which described the location and disconnection of these sites, with “centralized.” This change indicates that multi-wellhead sites are now a facility rather than the discrete, remote, and low-emission sites they are. The commenter notes that nothing changes with wellheads if there are one or multiple on a site – they remain remote and seldom visited. The commenter asserts that it is a misinterpretation to conflate that these are now “sites” by adding a few extra pieces. The commenter contends that EPA cherry-picks studies to show leak rates in addition to their estimation of over half a million new sites to EPA regulation. The commenter highlights in their comment letter that the modeling approach that EPA takes makes no sense other than to apply a one size fits all approach to make it easier for the EPA to track.

The commenter (2353-CrownQuest) notes that EPA developed these rules over a multiyear period and has produced over 2,000 pages for the proposed rule. The commenter contends that the rule text, with 180 pages of proposed regulation, is not concise nor an exact technical specification for industries to follow. Instead, the commenter believes that the rule is mainly broad generalities. The commenter notes an example is the annual report for each regulated item that explains how the operator complied with these broad rules. Instead of what they believe are burdensome, expensive, and convoluted rules, they assert that EPA should embrace the changes the industry already has made in collaborative BSER. The commenter adds that the EPA’s overview references a 2005 level, which the commenter believes shows their bias for their predetermined plan instead of the tremendous work and methods the oil and gas industry has undertaken to reduce methane emissions from 1990 to 2020.

Another example highlighted by the commenter (2353-CrownQuest) is the requirement that states implement EG OOOOc standards within 18 months. The commenter states that EPA spent over two years developing, according to them, a restrictive yet unspecific rule and passed on the hard regional work and analysis. The commenter believes it is dishonest to overtly state a rule this restrictive that specifically keeps states from varying from the proposed rule.

Response II-21-2: To the issue of EPA appropriating funding for individual states to fulfill the state’s duty to implement subpart OOOOc EG, the EPA does not appropriate funding as the commenter suggests. The U.S. Congress authorizes and appropriates funds to EPA that are disbursed through EPA to the various states in support of their authorized and delegated duties of environmental protection. The amount of funding is not set or determined by EPA. Funds given to states by Congress through EPA are provided based on many factors including anticipated needs on the part of states to fulfill their role in protecting the environment in many capacities such as those cited by the commenter. In sum, EPA provides all the eligible funds it can as authorized and appropriated by Congress for that purpose.

One commenter requested that EPA explain or provide certainties that state agencies will not solicit funding from oil and gas producers to implement unfunded federal regulations. The EPA can offer no such assurance or certainty. States operate environmental protection programs under state authorities that do include the power of taxation, user fees, and other means of generating revenue for the purpose of operating state programs, including those programs that protect the environment. While the U.S. Congress does authorize and appropriate funding through EPA for state environmental programs, states are expected to provide their own funding for the protection

of the environment from the constituents they serve. Those funds are in turn authorized for collection by the legislative and executive authorities in those states. EPA has absolutely no ability to influence those deliberations beyond the normal channels of communication between EPA and the state environmental protection agencies in our shared mission to protect the environment and human health.

EPA cannot comment on the accuracy of the estimate of the commenter that the state will be required to issue permits for an additional 190,000 affected facilities without additional information in support of such an assertion. In response the EPA points out that the NSPS OOOOc EG does not require that states issue facility-specific permits to affected facilities under OOOOc EG. Many states employ different administrative means such as general permits, permits by rule, and approved SIPs to regulate affected facilities under the NSPS. The state is expected to submit plans under section 111(d) to designate facilities subject to OOOOc EG with the intent to ensure compliance with the EPA EG or equivalent standards developed by the state. As stated in response to other commenters' concerns about adequate funding, the EPA provides all the funds authorized and appropriated from the U.S. Congress for that purpose to the state agencies, to be combined with the funds appropriated and authorized by their state governments, to protect human health and the environment.

The EPA disagrees with the premise of the comment asking "what happens in the future when a state requires certain procedures in a plugging plan that EPA would not approve." The commenter continues by asking whether EPA "will overrule a state on a process EPA does not even have authority over." The EPA has independent authority to enforce subparts OOOOb under the Act. If a state fails to act under 111(d) such that EPA ultimately promulgates a federal plan implementing OOOOc EG, EPA would then have authority under the Act to implement and enforce the provisions for wells that permanently shut down that require capping or plugging under OOOOc. In the alternative, states may submit their 111(d) plans for approval by EPA. EPA would approve plans under 111(d) that meet the minimum requirements of OOOOc EG. In the scenario provided by the commenter that EPA and a state could disagree about whether a provision of a state 111(d) plan meets those minimum requirements, EPA and the state agency would engage in rule and comment rulemaking to arrive at a conclusion subject to administrative and judicial review. There is nothing new, novel, or different about such a process than that envisioned by the Congress as expressed in the Act.

Contrary to the assertion of the commenter "that in some areas, such as well closure plans, the Agency clearly seeks to expand its historic role of oil and gas oversight under the guise of air quality," the EPA is within its authority to add affected sources to a standard where the emissions profile of such sources indicate regulation is appropriate. Abandoned wells leaking VOC, HAP, and methane are a well-documented source of emissions across the United States, notwithstanding the success of some states to address the issue. EPA is within its authority under the Act and section 111 to add to the list of affected regulated facilities those emission points that emit the same pollutants as other affected facility emission points, in this case leaking abandoned wells.

Contrary to the assertion of the commenter that EPA is "...in abandoning the long-held and successful principle of cooperative federalism..." the EPA believes that section 111(d) is the

embodiment of cooperative federalism envisioned by Congress. The EPA has fulfilled its duty to provide federal guidelines in the form of duly promulgated subpart OOOOc EG under the Act's section 111(d) as Amended in 1990, which in turn calls the state to create and adopt a single or series of state standards subject to review, approval and consent of the state government that create the equivalent level of protection for their constituents, improving protection for the environment and human health. The NSPS has fulfilled this role dating back to the original Clean Air Act of 1970<sup>8</sup> and its subsequent reauthorizations over the following 53 years.

One commenter referenced the EPA addition of associated gas as a regulated emission point. Like the example of abandoned leaking wells, section 111(b) provides the authority for EPA to regulate additional points of emissions of regulated pollutants where the Administrator determines it may contribute significantly to air pollution which causes or contributes to the endangerment of public health or welfare. Emissions of associated gas are not substantively different than any other emission point regulated by the NSPS affected facilities regulated thus far under OOOO or OOOOa. While the various states may have standards applicable to these sources, that does not mean that all states have done so, or that all states have done so effectively. The foundation of the Act and sections 111(b) and (d) are to assure all states and their citizens the level of protection for human health and the environment to which they are entitled by law.

Response II-21-3: As explained in section X.C and XI.C of the final rule preamble, EPA has finalized the Super Emitter Program as primarily a compliance assurance program with EPA in a centralized role to certify third-parties, receiving and reviewing data from these third, and then notifying owner or operators if the data received from the third party is accurate and reasonable, The final rule no longer permits third party's from notifying owner or operators directly.

EPA disagrees with the commenter asserting that the EPA's proposed super-emitter response program would deputize third parties to encroach on NDDEQ's delegated authority. See the response to comment II-14-4 where EPA explains the limited obligations that the super-emitter initiative places on operators, which does not include responding to reports from deputized third parties. See response to comment II-14-5 on the role that EPA has assigned itself for implementing the program so that "unnecessary churn" is unlikely. The Super Emitter Program is being finalized primarily as a compliance assurance program and is not an enforcement program. In response to the comment that EPA has released no guidance on how it expects states to implement the super-emitter response program, raising additional concerns with the scope and degree of NDDEQ's oversight in this process, EPA is developing a centralized reporting portal to handle receive super emitter reports. The final rule, as described in Section X.C.4 of the preamble has universal reporting requirements which all affected owner or operators who receive a notification must submit. While this information will be submitted to the EPA, the system will be designed to make the data available to all stakeholders, including the state, local, and tribal authority.

See Chapter 6 in response to EPA standards regulating associated gas. As explained in Response II-6-52 and II-6-54, EPA reviewed state standards to arrive at the final promulgated standards for

---

<sup>8</sup> PUBLIC LAW 91-604-DEC. 31, 1970.

associated gas and has established similar provisions for allowing flaring under exigent circumstances and certain recurring events that require flaring.

With respect to the comment on the implications for federalism in the NSPS and section 111(d), EPA directs the commenter's attention to the discussion explaining our change of viewpoint beginning at 87 FR 74812.

EPA agrees that the process provided for under section 111(d) with respect to state plans to implement OOOOc does allow for flexibility to address sources with state standards equivalent to the presumptive standards in OOOOc EG. In addition, under certain circumstances and with adequate demonstration that it is appropriate, a state can prescribe a standard to a subcategory of sources that are subject to a less stringent standard when considering its remaining useful life.

The EPA disagrees that the NSPS treats all minor oil and gas emission sites as major emitting sites. The NSPS applies to affected facilities regardless of whether they are located at major sources for criteria or HAP emissions. Subpart OOOOb and OOOOc EG are based on the same authority of the Act as Amended in 1990 and does not in any way violate state law.

EPA disagrees with the comment with respect to the difference between a well site with one well and associated equipment, and a well site with multiple wells on a single well pad also with associated equipment. As explained in the supplemental proposal, EPA analysis for leaking and fugitive emission monitoring is based on the data from leak and fugitive emissions from affected facility components. As the commenter knows, more well heads require more components and bring with them the greater probability of leaks and fugitive emissions. EPA has attempted to balance the need for periodic monitoring with the data underlying the probabilities of leaks and fugitive emissions, rather than prescribe a single high frequency of monitoring that ignores the variation in well sites, the very policy that the commenter asserts that EPA is pursuing. The remote or central location of a well site is not indicative of the equipment counts found on well pads, and therefore not predictive of leak and fugitive emission rates.

The EPA is embracing the changes the industry has made in most of this final rule with respect to advancing technology for methane abatement. For example, the EPA fugitive inspection program using OGI and the super-emitter program have been developing with the emerging technology since the promulgation of subpart OOOOa in 2016 (81 FR 35824). EPA published a specific request for information to gather additional data on emerging technology (81 FR 46670) for methane abatement. Technologies for which we received data or information are now entering the market and may be used to meet the requirements of subparts OOOOb and OOOOc EG.<sup>9</sup>

EPA responds to the comment that EPA has passed on the "hard regional work..." to the states for execution under OOOOc EG by reiterating our duty and authority to implement the NSPS under section 111 of the Act as Amended, which creates the framework for cooperative federalism in protecting human health and the environment.

<sup>9</sup> See EPA Docket ID EPA-HQ-OAR-2016-0346.

## **21.3 Executive Order 13175: Consultation and Coordination with Indian Tribal Governments**

Comment: Several commenters (2163-EOS, 2177-Southern Ute Indian Tribe (Southern Ute), 2181-Ute Indian Tribe of the Uintah and Ouray Reservation (Ute Indian Tribe), 2303-National Tribal Air Association (NTAA), 2331-Mandan, Hidatsa and Arikara (MHA) Nation) request that EPA expand Tribal consultation and coordination. The commenters present policies and standards that EPA must follow to ensure Tribal sovereignty and self-determination. Examples of some of the specific comments provided are included in the following paragraphs.

Commenter (2163-EOS) asserts the proposed rule should be principles based and ensure that Tribal Nations have a voice in the development of resources within their territories.

Commenter (2303-NTAA) urges EPA to consult directly with Tribes on a government-to-government basis and asserts that the EPA must evaluate the industry's and proposed rule's unique impact to Tribes. The commenter states that public listening sessions and training webinars are helpful but not sufficient.

The commenter (2303-NTAA) agrees with EPA's recognition that national standards and guidelines are needed to reduce methane and other harmful pollutants from new and existing sources in the oil and natural gas industry. The commenter states that significant oil and natural gas sources are on and near Tribal lands, and methane, volatile organic compound (VOC), and hazardous air pollutant (HAP) emissions from the oil and natural gas industry negatively impact Tribal communities. The commenter asserts that each Tribe's unique circumstances must be evaluated. Additionally, oil and natural gas development can provide important revenue for Tribes, making strong, cost-effective national requirements and standards even more important.

The commenter (2303-NTAA) states environmental justice concerns may apply to many American Indian/Alaska Native communities, and the commenter urges EPA to properly address environmental justice concerns. That concern for environmental justice, however, cannot replace government-to-government consultation with Tribes. The commenter states that Tribes are sovereign nations with self-determination and cannot be treated the same as environmental justice communities. The commenter asserts that EPA must consult directly with Tribes on a government-to-government basis and must evaluate the industry's and proposed rule's impacts to Tribes.

The commenter (2303-NTAA) notes that on January 26, 2021, President Biden issued a Memorandum on Tribal Consultation and Strengthening Nation-to-Nation Relationships committing to honoring Tribal sovereignty and including Tribal voices in policy deliberation that affects Tribal communities. The commenter urges EPA to take this commitment seriously in finalizing and implementing regulations for the oil and natural gas industry.

Commenters (2177-Southern Ute, 2181-Ute Indian Tribe) request that EPA defer to the standards set in the United Nations Declaration on the Rights of Indigenous Peoples (UNDRIP) and employ the concept of Free, Prior, and Informed Consent (FPIC). The commenters note that the UNDRIP sets the bare minimum standards of tribal consultation, including treaty

acknowledgement and tribal sovereignty, and FPIC is vital for the engagement of meaningful consultation. The commenters add that these two standards require tribal approval for all rules implemented on their lands and tribal oversight on any program proposed.

The commenters (2177-Southern Ute, 2181-Ute Indian Tribe) request consultation and approval prior to any rule that will directly affect their lands. If the rule is finalized prior to tribal approval, the commenters request tribal exemptions to any section of the proposed rule that affects tribal nations, and deferral to tribal implementation plans and tribal authority.

The commenters (2177-Southern Ute, 2181-Ute Indian Tribe) note that the proposed rule states that “[t]he EPA notes that this supplemental proposal does not directly impose specific requirements on designated facilities, including those located in Indian country. Before developing any standards for sources on tribal land, the EPA would consult with leaders from affected tribes.” However, the commenters assert that operators on tribal lands will be affected by these proposed standards and state that there are no tribal exemptions.

Commenter (2331-MHA Nation) asserts that the December 2022 Supplemental Proposal must reflect EPA’s Federal Trust Obligations and Acknowledge Tribal treaty rights and include direct engagement with Tribes. As the commenter notes that they provided in their previous comments, in promulgating regulations aimed at protecting human health and the environment that apply to oil and gas development on tribal lands, EPA must still consider its trust responsibility to individual tribes and whether its regulations will have implications for specific tribal treaty rights.<sup>10</sup> The commenter adds that EPA has expressly “recognize[d] the right of tribes as sovereign governments to self-determination and acknowledge[d] the federal government’s trust responsibility to tribes.”<sup>11</sup> The commenter states that this responsibility requires engaging with tribes on an individual basis to understand how a forthcoming rulemaking will implicate development of tribal trust resources and rights protected by treaties. As the EPA looks to finalize and implement the supplemental proposal, the commenter encourages EPA to continue to engage with tribes on a government-to-government basis to uphold its trust responsibility and ensure its final regulations do not infringe on tribal treaty rights.

Commenter (2331-MHA Nation) requests that EPA work with Tribes to support and facilitate achieving Treatment as a State (TAS). As noted previously, the commenter asserts that the TAS process is burdensome and does not facilitate development of tribally led and administered CAA programs.<sup>12</sup> As a result, the commenter states that the TAS process is underutilized and tribes continue to rely on federal plans despite expressing interest in developing their own tribal clean air requirements.<sup>13</sup> The commenter has expressed to EPA its interest in pursuing TAS to develop its own standards for the oil and gas industry. However, it is unlikely the commenter will have developed the resources and expertise required to achieve TAS to submit its own EG in

---

<sup>10</sup> See Comment submitted by Mandan, Hidatsa and Arikara (MHA) Nation, at 1-2, Docket ID No. EPA-HQ-OAR-2021-0317-0794.

<sup>11</sup> See *id.* at 2; see also U.S. Environmental Protection Agency, Memorandum from EPA Administrator Michael S. Regan, to all EPA Employees, regarding “Reaffirmation of the U.S. Environmental Protection Agency’s Indian Policy”, at 1 (Sept. 30, 2021), Scanned Document (epa.gov).

<sup>12</sup> Comment submitted by Mandan, Hidatsa and Arikara (MHA) Nation, at 3-4, Docket ID No. EPA-HQ-OAR-2021-0317-0794.

<sup>13</sup> *Id.*

compliance with the timeline proposed under the December 2022 Supplemental Proposal. The commenter expresses that, like many other tribes, it will be forced to rely on a federal plan until TAS requirements are met.

In addition to presenting tribes with the option of submitting EG, the commenter (2331-MHA Nation) requests that EPA actively work with tribes to provide access to the funding and technical assistance required for tribes to apply for TAS to develop these plans, including working with tribes to develop technical expertise and acquire equipment necessary to monitor and gather data on oil and gas emissions sources in Indian country. The commenter understands that the Inflation Reduction Act (IRA) allocated funds to EPA to provide grants and support to tribes and states with monitoring and reducing air emissions (including methane emissions from the oil and gas sector), CAA research and development, and climate pollution reduction, among other programs and initiatives.<sup>14</sup> To the extent these funds and other EPA programs could support tribes in developing the knowledge and expertise required to successfully apply for TAS to implement EG under this proposal, the commenter encourages EPA staff to work with tribes to provide technical assistance and identify those funding sources early on in the grant application process so that tribes can take advantage of those opportunities and move toward establishing their own clean air programs. The commenter believes that providing the option to develop EG without connecting tribes to the resources and support required to do so does little to support tribes in exercising their sovereignty to develop clean air regulations aimed at protecting health and welfare in Indian country.

Response II-21-4: As discussed in section XVII.F (Executive Order 13175: Consultation and Coordination with Indian Tribal Governments) of the final rule preamble, Tribal consultations were completed after the November 2021 Proposal at the request of the Northern Arapahoe Tribe, MHA Nation, and Eastern Shoshone Tribe.<sup>15</sup> Additional tribal consultation was completed at the request of MHA Nation and an informational meeting was held with the Ute Tribe after the December 2022 Supplemental Proposal.<sup>16</sup> Consistent with previous actions affecting the Crude Oil and Natural Gas source category, the EPA understands there is continued significant tribal interest because of the growth of the oil and natural gas production in Indian country. In accordance with the EPA Policy on Consultation and Coordination with Indian Tribes, the EPA will continue to engage in consultation with tribal officials as these rules become implemented.

As stated in the November 2021 Proposal, the EPA found that 112 unique tribal lands are located within 50 miles of an affected oil and natural gas source, and 32 tribes have one or more oil or natural gas sources on their lands. The while many of the affected and designated facilities impacted by final NSPS and EG on tribal lands are owned by private entities, some tribes also own affected and or designated facilities. There would be tribal implications associated with this rulemaking in the case where a unit is owned by a tribal government or in the case of the NSPS, a tribal government is given delegated authority to enforce the rulemaking. Tribes are not required to develop plans to implement the EG under CAA section 111(d) for designated existing

---

<sup>14</sup> The White House, Building a Clean Energy Economy: A Guidebook to the Inflation Reduction Act's Investment in Clean Energy and Climate Action (Jan. 2023) <https://www.whitehouse.gov/wp-content/uploads/2022/12/Inflation-Reduction-Act-Guidebook.pdf>.

<sup>15</sup> See Memorandum in EPA-HQ-OAR-2021-0317.

<sup>16</sup> See Memorandum in EPA-HQ-OAR-2021-0317.

sources. The EPA notes that this final rule does not directly impose specific requirements on designated facilities, including those located in Indian country. Before developing any standards for sources on tribal land, the EPA would consult with leaders from affected tribes.

See also, Volume I, Chapter 6 (Environmental Justice (EJ) Implications and Stakeholder Outreach), subsection 6.1.2 (Native American Environmental Justice Impacts ), Responses I-6-2 through I-6-4, for EPA's response to comments on EPA's EJ analyses.

Comment: Commenter (2241-Utah Department of Natural Resources (UDNR)) provides details of successful voluntary efforts to show that using incentives and allowing industry and state and tribal governments self-regulation is the most successful approach.

The commenter (2241-UDNR) mentions the Western States and Tribal Nations Natural Gas Initiative (WSTN) voluntary initiative. The WSTN was established in 2021 through a memorandum of understanding signed by state and tribal governments including the Utah Office of Energy Development, the Wyoming Energy Authority, the Ute Indian Tribe of the Uintah and Ouray Reservation, the Secretariat of Economic Development of Baja California Mexico, the Colorado counties of Garfield, Mesa, Moffat, and Rio Blanco, and the New Mexico Energy, Minerals, and Natural Resources Department, and the Jicarilla Apache Nation.<sup>17</sup> The commenter notes that the WSTN is taking a proactive approach to addressing Rural Economic Development, Tribal Self Determination, Climate Change, carbon Net Zero.<sup>18</sup>

In December 2022, the commenter (2241-UDNR) reports that the WSTN held its West Coast Liquefied Natural Gas Export Forum at Colorado Mesa University in Grand Junction, Colorado.<sup>19</sup> During this forum, various natural gas related topics were raised and discussed including the fact that Rocky Mountain natural producers are leading the way in decarbonizing natural gas production,<sup>20</sup> partly through the WSTN's efforts. The commenter notes that more importantly, the forum discussed tribal perspectives on energy production on tribal lands, with top leaders representing the Navajo Nation, the Crow Tribe of Indians and their member nations the Ute Indian Tribe, the Southern Ute Indian Tribe and the Jicarilla Apache Nation.<sup>21</sup> The commenter notes that, according to the forum report, "all five tribes have energy development interests and shared their concern that the use of their sovereign land is hampered by the 'paternal approach,' as one panelist put it, taken by the federal government bureaucracy. Panelists questioned the commitment to genuine tribal consultation, and urged immediate reform to layers of red tape that means tribes must follow Bureau of Indian Affairs and Environmental Protection Agency rules even to build roads on their reservation, let alone develop energy

<sup>20</sup> Id.

<sup>21</sup> Id.

resources.”<sup>22</sup> The commenter believes that this paternal approach identified by these tribal leaders echoes the state’s sentiment that the current proposed rule will simply add on more government oversight, regulatory burden, and other increased “paternalistic” factors where they are not needed.

Response II-21-5: EPA responds to the comment by reiterating our duty and authority to implement the NSPS under section 111 of the Act as Amended, which creates the framework for cooperative federalism in protecting human health and the environment. We also direct the commenter to EPA’s discussion of federalism and it relates to this NSPS at 87 FR 74812.

See also Responses II-21-2 and II-21-3 of this Chapter.

Comment: Commenter (2392-Earthjustice *et al.*) states that Tribal communities are specifically vulnerable to climate-driven impacts on cultural practices and access to traditional lands. The commenter reports that both the United Nations Educational, Scientific, and Cultural Organization (UNESCO) and the Intergovernmental Panel on Climate Change (IPCC) recognize that “climate change represents one of the greatest threats to culture and heritage.”<sup>23</sup> This is particularly true for tribal communities, as “the consequences of observed and projected climate change have and will undermine indigenous ways of life that have persisted for thousands of years.”<sup>24</sup> The commenter notes that while some indigenous resource managers “believe their cultures already possess sufficient knowledge to respond to climate variation and change,” the loss of traditional knowledge may undercut tribal community resilience to climate change.<sup>25</sup>

Although a great diversity exists amongst tribal communities and cultural practices across the U.S., the commenter (2392-Earthjustice *et al.*) asserts that many indigenous cultures entail a unique connection to, and relationship with, the natural environment. Research demonstrates that impacts of climate change, including increased frequency of wildfires, higher temperatures, and extreme changes to local ecosystems “will affect the quantity and quality of the resources tribes depend upon to perpetuate their cultures and livelihoods.”<sup>26</sup> For example, the Yurok Tribe in northern California culturally identify as “great fisherman” and rely upon ney-puy, the Yurok word for salmon, harvested from the Klamath River for food.<sup>27</sup> In recent years climate-driven hot weather and drought conditions have warmed the river’s water giving rise to parasites that have

<sup>27</sup> The Yurok Tribe, Our History (last visited Feb. 3, 2023), <https://www.yuroktribe.org/our-history>.

depleted salmon stocks to dangerously low levels.<sup>28</sup>

Moreover, the commenter (2392-Earthjustice *et al.*) states that climate change now threatens to accelerate indigenous displacement. Indigenous communities in the U.S. have already been dispossessed of nearly 99 percent of their historical land base.<sup>29</sup> Centuries of colonialism in the U.S. forced many tribes off their ancestral homelands and onto reservations, such as with the MHA Nation and the Garrison Dam project (discussed above). These land losses will only continue as climate change progresses. The commenter reports that in Alaska, at least 31 native communities “face imminent climate displacement from flooding and erosion.”<sup>30</sup> The village of Newtok initiated complete relocation in 2019 due to shoreline erosion from thawing permafrost and storm surge.<sup>31</sup> Likewise in Louisiana, the commenter reports that land subsidence worsened by climate-accelerated sea-level rise forced the Biloxi-Chitimacha-Choctaw to abandon their coastline territories.<sup>32</sup>

Response II-21-6: We interpret the comment as support for our proposal and supplemental proposal; as such, no response is required.

## **21.4 Executive Order 12898: Federal Actions to Address Environmental Justice in Minority Populations and Low-Income Populations**

Comment: Commenters (2163-EOS, 2257-MOGA, 2355-Constellation Energy Corporation (CEC), 2392-Earthjustice *et al.*) request robust engagement with vulnerable communities, and clearly defined engagement requirements.

Commenter (2392-Earthjustice *et al.*) recognizes that EPA’s obligation to identify and address environmental justice concerns is rooted in Executive Orders, implementing agency guidance, and public pronouncements of the Biden Administration. Collectively, the commenter states that these legal and policy documents articulate a two-fold obligation.

The commenter (2392-Earthjustice *et al.*) asserts that first, EPA must analyze the substantive impacts of proposed regulations on disproportionately impacted communities. Second, EPA must guarantee procedural justice by ensuring that disadvantaged communities have access to

decision-making processes and that community feedback can and does influence the agency's final decisions.

Commenter (2163-EOS) argues the proposed rule should be principles-based and needs to require timely and equitable engagement for stakeholders and communities most affected by and/or vulnerable to impacts. They add that rules need to address and improve public health and safety and environmental justice. The commenter adds that methane emissions reduction is important from an environmental justice perspective. The commenter notes that poor and marginalized (including indigenous) communities are expected to incur disproportionately high negative impacts of climate change and that they are least equipped to absorb those impacts. They contend that this could exacerbate existing inequities and add another layer of investment risk. They add that methane leaks and flaring can be accompanied by toxic and particulate matter with deleterious local health impacts.

Commenter (2355-CEC) urges EPA to include strong environmental justice measures in the final rule to protect disadvantages and overburdened communities. The commenter encourages EPA to finalize the new provisions requiring states to include certification and evidence of meaningful engagement in their state plans. The commenter agrees that a state be required to provide a list of pertinent stakeholders, summary of engagement and stakeholder input in their plan submittal. The commenter agrees that EPA must evaluate states' demonstrations regarding meaningful engagement and that a lack of these elements are grounds for EPA to find the submission incomplete or to disapprove the plan. Finally, the commenter agrees with EPA's proposed definitions of "meaningful engagement" and "pertinent stakeholder."

Commenter (2257-MOGA) implores EPA to outline its explicit intention, direction and limitations when encouraging community engagement related to oil and gas production related facilities. The commenters primary concern is safety. Michigan's oil and gas industry employees are arguably the most highly skilled, trained, insured and safety-oriented workforce in the United States. The commenter urges EPA to clearly define its proposed "community engagement" intent and provide specific restrictions and associated guidelines to prevent injuries.

Response II-21-7: The EPA, in the development of the final NSPS OOOOb and EG OOOOc rules, engaged with communities most affected by, and vulnerable to, adverse climate and air quality impacts from oil and gas operations. The EPA also conducted an EJ assessment for this action. The documentation for this assessment is contained in section 4 of the *Regulatory Impact Analysis for the Proposed Standards of Performance for New, Reconstructed, and Modified Sources and Emissions Guidelines for Existing Sources: Oil and Natural Gas Sector Climate Review* prepared for the November 2021 Proposal,<sup>33</sup> in section 4 of the *Regulatory Impact Analysis of the Supplemental Proposal for the Standards of Performance for New, Reconstructed, and Modified Sources and Emissions Guidelines for Existing Sources: Oil and Natural Gas Sector Climate Review* prepared for the December 2022 Supplemental Proposal,<sup>34</sup> and in section 4 of the *Regulatory Impact Analysis for the Standards of Performance for New, Reconstructed, and Modified Sources and Emissions Guidelines for Existing Sources: Oil and Natural Gas Sector Climate Review* prepared for this action. See section XVII.J (Executive

---

<sup>33</sup> See Document ID No. EPA-HQ-OAR-2021-0317-0173.

<sup>34</sup> See Document ID No. EPA-HQ-OAR-2021-0317-1566.

Order 12898: Federal Actions to Address Environmental Justice in Minority Populations and Low-Income Populations and Executive Order 14096: Revitalizing our Nation's Commitment to Environmental Justice for All) of the final rule preamble for a summary of EPA's environmental justice assessment conducted in support of this final rulemaking.

Please also see section VII (Summary of Engagement with Pertinent Stakeholders) of the final rule preamble for a summary of engagement with pertinent stakeholders, including, but not limited to, industry, small businesses, tribal nations, and communities most affected by, and vulnerable to, the impacts of the rule. For example, the EPA hosted a two-part webinar training specifically targeted toward both communities with EJ concerns and tribal nations on November 16 and 17, 2021. The purpose of this training event was for the EPA to facilitate stakeholder panel discussions and to provide background information and an overview of the November 2021 Proposal, as well as information on how to effectively engage in the regulatory process. Subsequently, on November 14, 2022, the EPA hosted a call for environmental groups and EJ communities; on November 17, 2022, the EPA held a webinar for both members of tribal nations and communities; and on November 30, 2022, the EPA held a training for Tribal Environmental Professionals.

In response to comments that EPA include new provisions requiring states to include certification and evidence of meaningful engagement in their state plans, see discussion in section XIII.C.6 (Meaningful engagement) of the final rule preamble. In the November 2021 Proposal and December 2022 Supplemental Proposal, the EPA proposed and solicited comment on a requirement that states perform early outreach and meaningful engagement with pertinent stakeholders during the development process of their state plans pursuant to EG 0000c. The EPA is not finalizing the provision for meaningful engagement in this rulemaking. Rather, since similar revisions to subpart Ba are now final and are therefore applicable to the EG 0000c, state plans must be submitted according to the provisions in 40 CFR 60.23a(i) which requires states to document in their plan submittals how they provided meaningful engagement with the pertinent stakeholders. Specifically, subpart Ba requires as part of completeness criteria in 40 CFR 60.27a(g) that states must submit, with the plan or revision, documentation of meaningful engagement including a list of identified pertinent stakeholders and/or their representatives, a summary of the engagement conducted, a summary of stakeholder input received, and a description of how stakeholder input was considered in the development of the plan or plan revisions.

Comment: Commenter (2257-MOGA) expresses concern with the proposed exemptions of Bureau of Land Management (BLM) properties from requirements applied to private land wells and facilities. The commenter questions why EPA provides an exemption on BLM lands that leads to increased emissions on underserved communities if the intent is to reduce emissions and protect underserved communities. The commenter believes that this is a double standard for emission reduction regulations when applied to current and future proposed NSPS and Environmental Justice initiatives. The exemption of emissions on BLM lands allows thief hatches to be opened to accurately measure production, to ensure the federal government is able to accurately assess production for consideration of royalty payments without operational pressures pushing storage tank volumes downward. The commenter states that this exemption is not consistent with the EPA and Biden Administration's intent to reduce or eliminate fugitive

emissions, nor does this rule adhere to or facilitate the administration's Environmental Justice initiative for under-served communities which includes tribal lands. The commenter notes that these practices are not permissible for producers on private land and would violate current and future NSPS regulations in addition to proposed future EPA Emission Guidelines for existing facilities.

Response II-21-8: The EPA does not agree with the premise of the comment with respect to EPA rules as they apply to operators on federal land under BLM oversight. The NSPS is a federal rule authorized under the Clean Air Act as Amended in 1990 and governs air emissions at oil and gas operations under this NSPS subpart OOOOb and OOOOc EG. There is no exemption to these rules for operators on federal lands. The rules are applied and enforced by EPA and BLM for lands under federal jurisdiction, and there is no explicit exemption for operators on BLM lands. BLM's standards align with EPA standards. Where there is the potential to conflict, BLM generally tries to minimize regulatory overlap. Where EPA has adopted requirements that are at least as effective as and would potentially overlap with the provisions of BLM rules, the BLM rules provide a means for operators to comply with the EPA requirements in lieu of the BLM requirements. EPA also notes that EPA rules are not a substitute for independent BLM waste reduction regulations. The EPA rules do not fulfill the BLM's statutory responsibility to reduce waste of public resources.

## **21.5 General Comments on Statutory and Executive Reviews**

Comment: Commenter (2219-WOGCC) asserts that EPA has not appropriately evaluated statutory and executive order reviews. The commenter states that this rule imposes significant burdens on local, small businesses, likely forcing insolvency on many of them. The commenter believes that the insolvency of these companies will result in loss of employment, royalties and taxes in local communities and the state.

Response II-21-9: The EPA disagrees with the comment that EPA has not appropriately evaluated the burden on local and small business. In response to comments on the analyses conducted at proposal, see Volume I, Response I-20-22 in Chapter 20 (Emissions and Regulatory Impacts), subsection 20.2.5 (Economic Impacts), on economic impacts and impacts to production. See also Volume I, Chapter 20 (Emissions and Regulatory Impacts), subsection 20.2.7 (Impact on Small Business), Response I-20-27, for a full discussion of small business impacts. Based on comments received on the November 2021 proposal and December 2022 Supplemental Proposal, the EPA further revised the RIA. EPA directs that commenter to the final RIA sections 4.4.6.2 for the result of the modeling that was performed to estimate the impact of the final rule on such entities.

## **Chapter 22. Appendix K**

The following sections provide a summary of comments received on EPA's proposed protocol for the use of OGI in the determination of leaks as Appendix K.

### **22.1 General Support and Opposition for Appendix K**

#### ***22.1.1 Unnecessary Changes***

Comment: One commenter (2196) argued that EPA designed the Appendix K protocol to determine the presence and location of leaks and not for the Quantitative Optical Gas Imaging (QOGI) process of direct measurement of emission rates from sources. The commenter further stated that changes in the supplemental proposal are devoted to the measurement function and are not necessary for an OGI LDAR program.

Response II-22-1: Although Appendix K is not designed for quantitative OGI, EPA disagrees that the changes made the December 2022 Supplemental Proposal were geared toward QGI cameras or to the measurement function of QOGI cameras. The changes made in the December 2022 Supplemental Proposal were made in response to comments received on the November 2021 Proposal and are applicable to cameras used in qualitatively determining the presence of leaks.

#### ***22.1.2 Unnecessary Performance Assurances***

Comment: Two commenters (2366, 2483) stated that the protocol's performance assurances are excessive and can be supplanted by demonstrating a properly working infrared camera application.

Response II-22-2: EPA disagrees with that the included performance assurances are unnecessary. While EPA agrees that it is important that an OGI camera operator be able to show that the infrared camera is working properly, how an operator is trained and uses the camera in the field is critical to finding leaks with an OGI camera. Therefore, it is necessary for OGI camera operators to prove initial and continued competency with an OGI camera to ensure that the operator can find leaks.

#### ***22.1.3 Support for Scope of Appendix K***

Comment: One commenter (2305) acknowledged and supported the removal of the requirement to use Appendix K for OGI surveys in the Transmission and Gathering & Boosting sectors.

Response II-22-3: EPA acknowledges the commenter's support.

#### ***22.1.4 Support for Use of Appendix K in Subparts Beyond NSPS 0000b***

Comment: One commenter (2428) recommended that EPA amend 40 CFR part 63 subpart CC such that the use of OGI technology and Appendix K are allowed as an alternative to Method 21 for petroleum refineries. Approval as an alternative would reduce both industry and Agency

resources associated with the preparation and approval of Alternative Method of Emission Limitation or Alternative Monitoring requests to allow OGI. The commenter expressed preference for an amended subpart CC over the currently available leak detection and repair (LDAR) Alternative Work Practice (AWP) in the General Provisions of part 60 and part 63. The commenter further stated that other part 60 and 63 standards should also be modified to make Appendix K an option for industry sectors beyond refineries.

Response II-22-4: This comment on updating subparts other than NSPS OOOO, NSPS OOOOa, NSPS OOOOb, and EG OOOOc is outside the scope of this rulemaking.

## **22.2 Definitions and Terminology**

### ***22.2.1 OGI Camera Operator***

Comment: Some commenters (2446, 2535) requested that EPA consider adding a definition for “OGI camera operator/camera operator/trained OGI camera operator” as “a camera operator that does not yet meet the definition of a ‘Senior OGI camera operator’ but has completed the training specified in section 10.”

Response II-22-5: EPA is adding a definition of “OGI camera operator” to Appendix K, which is defined as someone who has completed the training required in section 10 of Appendix K and has passed the final survey test. Additionally, EPA notes that a senior OGI camera operator is a subcategory of OGI camera operator.

### ***22.2.2 Senior OGI Camera Operator***

Comment: One commenter (2177) requested that EPA clarify the duration in the definition of “survey hours” and whether this aligns with “dwell time” or “monitoring survey” hours. The commenter similarly requested that EPA clarify “at least 2 hours” in section 10.2.2.4.

Response II-22-6: EPA has added a definition of “survey hours” to Appendix K. A survey hour is the accumulation of 60 minutes of conducting a survey with an OGI camera. Rest breaks are not included in a survey hour. The 60 minutes do not need to be consecutive to constitute a survey hour. EPA is also clarifying that the final test in section 10.2.2.4 must consist of 2 survey hours.

EPA notes that the version of Appendix K in the December 2022 Supplemental Proposal did not use the terminology “monitoring survey hours”. Dwell time is the time spent looking at a particular scene before moving to the next scene. Dwell time is active survey time and would count towards a survey hour.

### ***22.2.3 Delta Temperature (delta-T)***

Comment: One commenter (2196) contends that the assumption outlined in section 3.0 that emission process gas temperature is equal to ambient air temperature is not an acceptable practice. The commenter noted that in the field the emitted process gas is commonly a different temperature than ambient and asked that the last sentence of this definition be deleted.

Response II-22-7: EPA disagrees with the commenter. Gases cool rapidly upon expansion when released and approach ambient temperature close to the release point. This is also why cloudy days tend to pose more difficulty than sunny days, as the cloud temperature profile will be closer to ambient than that of the unobstructed sky.

## **22.3 OGI Camera Specifications**

### ***22.3.1 Camera Configurations for Initial Certification***

Comment: One commenter (2421) requested that section 6.1.2 be expanded to require an indication of the configuration mode used to test the technology. This detail would encourage conformity between manufacturer and the testing facility. Specifically, if a technology provider tests in an enhanced imaging mode for compliance with 6.1.2 but operators use the technology in a less sensitive mode, the technology could easily miss intended leaks due to inappropriate application in the field.

Response II-22-8: EPA acknowledges the commenter's concern regarding initial specification testing. However, we do not consider it necessary to add this level of specificity to Appendix K to allow for future technology development flexibility. Development of the operating envelope will prevent an OGI camera operator from using a mode that cannot meet the specified sensitivity requirements.

Comment: One commenter (2399) recommended that section 6.1.2 be revised to expand the detectable viewing distance of 17 grams per hour of methane emissions beyond two meters. An advantage of OGI cameras is that it reduces the need to elevate monitoring personnel by two meters or more to monitor "difficult to monitor" components.

Response II-22-9: EPA notes the intent of section 6.1.2 is to set a standard bar that all OGI cameras must achieve, not to restrict all OGI surveys to two meters viewing distance. Section 6.1.2 is an initial demonstration of capability of an OGI camera model. Section 8, development of the operating envelope, is used to determine the maximum distance for viewing components under specific field conditions.

### ***22.3.2 Detection Limits***

Comment: One commenter (2421) agreed with the new minimum detection level of butane as 5 g/hr but questioned the level of detection for propane. The commenter stated that the foundation of Appendix K and optical gas imaging as a technology is based on the response factors (RF), per Section 6.1.1 and Annex 1 of Appendix K. Therefore, the commenter states that propane (a compound with a RF of 1.000) should not have a detection threshold higher than methane (a compound with a RF of 0.297). The commenter recommended that propane have a minimum detection level similar to butane, 5 g/hr, since it is also over 3.3 times more absorptive for the defined technology in the spectral range of the technology, and the commenter suggested that all references to the minimum detection threshold of propane in section 8 also be changed to 5 g/hr.

Another commenter (2428) questioned why a lower mass rate criteria was selected for butane when the response factor for butane and propane are almost identical. The commenter stated that this seems inconsistent with the language in section 1.2, which allows for the average response factor approach with respect to propane.

Response II-22-10: See discussion in section XIV.A.2 of the preamble to the final rule which details EPA's final standards related to OGI camera detection limits.

### ***22.3.3 Equipment Needed for Certification Testing***

Comment: One commenter (2465) objected to the accuracy requirements of ancillary meteorology equipment used for the initial verification test. The commenter specifically objected to sections 6.2.6.2 and 6.2.6.3, which require an accuracy of 1.0 mbar or less with a resolution of 0.1 mbar for ambient pressure measurement and an accuracy 0.2 m/s and a minimum range of 0.1 to 20 m/s for wind speed measurement. The commenter stated that if the measurement frequency is once every hour as described in section 6.2.6, the change in time is much larger than the accuracy. The commenter requested an accuracy of 5.0 mbar with a resolution of 1.0 mbar for ambient pressure measurement and an accuracy of 1.0 m/s and a minimum range of 0.1 to 20 m/s for wind speed.

Response II-22-11: EPA agrees with the commenter and has implemented the requested changes.

Comment: One commenter (2196) requested that EPA remove the wind direction and humidity requirements of sections 6.2.6.4 and 6.2.6.5.

Response II-22-12: EPA disagrees with the commenter. Wind direction and humidity are critical measurements, and as such, we are maintaining the requirement to monitor these requirements as part of the initial camera model demonstration.

### ***22.3.4 Sensitivity Requirement***

Comment: Two commenters (2366, 2483) notes that EPA revised the Scope section of Appendix K to apply more broadly, but for transmission and storage applications, the added complexity of including propane and butane is not warranted because those constituents are present at low levels (<1%) and the majority of the gas (>90%) is methane. The commenters further stated that the method should provide for a sector-specific performance test verification gas composition and analyte flowrate.

Response II-22-13: In the December 2022 Supplemental Proposal, EPA only required the use of Appendix K for OGI surveys at gas processing plants. Sections of gas processing plants contain appreciable amounts of volatile organic compounds (VOC), and as such, it is important that an OGI camera used for leak inspection at these sources be able to identify VOC leaks. Therefore, EPA disagrees with the commenter that adding a specification for butane or propane is unwarranted for OGI cameras used on these sources. For upstream oil and gas sources other than gas processing plants, EPA is not requiring the use of Appendix K.

EPA also notes that sector-specific performance requirements can be considered on a regulation specific basis when EPA revised a subpart to reference Appendix K. Such sector-specific performance requirements would be defined in the referencing subpart and not in Appendix K.

## 22.4 Operator Training

### 22.4.1 General Opposition on Training Requirements

Comment: Several commenters (2177, 2220, 2248, 2366, 2483) indicated that the training requirements are excessive and too burdensome. One commenter (2366) stated that the initial training, refresher training, quarterly audits, and documentation requirements are unnecessary, unsupported, and too burdensome to implement for a simple leak screening method. Another commenter (2421) objected to EPA's reliance on a single field study<sup>1</sup> to develop the "onerous" training requirements and asserted that EPA should provide additional data to support the requirements.

Response II-22-14: EPA disagrees that the training requirements are excessive. Additionally, EPA notes that the training requirements were not based on the cited study but were developed based on the outcome of the Appendix K workshop held in November 2020 and were further refined based on the comments received on the November 2021 Proposal. Proper training is critical for the development of an OGI camera operator's ability to detect leaks and continuing audits are necessary to assess continued proficiency. This is similar to EPA Method 9, which requires opacity observers to recertify every 6 months.

Comment: Some commenters (2286, 2429) expressed concern that there may be very few experts available to oversee training. One commenter (2286) stated that due to the level of credentials and experience required, there may be a shortage of expertise, especially for natural gas processing plants who may currently comply with the requirements of NSPS OOOO and OOOOa. These plants would have to revise their LDAR programs and would need to complete initial and ongoing inspections. Another commenter (2429) stated that the burden of the requirements may make it more difficult to hire, train, and retain inspectors in the field.

Response II-22-15: Based on the grandfathering provisions that were added to the December 2022 Supplemental Proposal, EPA believes that there should not be a shortage of senior OGI camera operators. However, we note that gas processing plants can continue to use EPA Method 21 if they do not wish to update their LDAR programs. EPA anticipates those OGI camera operators who initially qualify as senior OGI camera operators will be interested in conducting training and auditing initially because some of the time spent training and auditing OGI camera operators also counts towards their time requirements to maintain their senior OGI camera operator designation under Appendix K.

---

<sup>1</sup> The commenter Zimmerle, D., Vaughn, T., Bell, C., Bennett, K., Deshmukh, P., Thoma, E. (2020). Detection Limits of Optical Gas Imaging for Natural Gas Leak Detection in Realistic Controlled Conditions. *Environ. Sci. Technol.* 54(18), 11506 – 11514. <https://doi.org/10.1021/acs.est.0c01285>.

### ***22.4.2 Recertification Requirements***

Comment: One commenter (2177) stated that the retraining and classroom requirements in section 10.5 are arbitrarily stringent; the commenter suggested that an OGI operator with previous experience should only be required to attend a refresher training if they have not conducted monitoring within the last 12 months.

Response II-22-16: EPA notes that in the December 2022 Supplemental Proposal, the recertification requirements in section 10.5 were changed to require retraining instead of the full initial training. EPA contends that it is reasonable to require an operator who has not recently conducted a survey to attend a refresher training and that the retraining is equivalent to a refresher training.

### ***22.4.3 Initial Training Requirements for Experienced Camera Operators***

Comment: One commenter (2177) asked EPA to clarify the requirements in section 10.6.2 to indicate whether the “40 hours of experience” required of OGI camera operators is intended to align with “dwell time” or “monitoring survey” time.

Response II-22-17: The 40 hours of experience refers to 40 survey hours. A survey hour is defined as 60 minutes of active survey time. Dwell time is the time spent looking at a particular scene before moving to the next scene. Dwell time is active survey time and is, therefore, inherently a part of the monitoring survey time.

### ***22.4.4 Classroom Training Requirements***

Comment: Some commenters (2139, 2421) recommended that EPA clarify the standards for OGI classroom instruction. One commenter (2421) noted that Appendix K does not describe who is qualified to conduct classroom training; the commenter urged that this should not be senior OGI camera operators, whose level of expertise is needed in the field, but by someone with previously experience in classroom training. Commenter (2139) requested that EPA define additional requirements for an OGI instructor, including (1) 2 years minimum experience developing or delivering content (including the topics in sections 10.2.1.1 through 10.2.1.8); (2) certification to a minimum of Infrared Thermographer Level II with recertification every 2 years; (3) 100 hours of career instructional classroom experience including 20 hours within the last 12 months; and (4) an option to “grandfather” requirements for OGI instructors that already meet the requirements of (1) through (3).

Response II-22-18: EPA disagrees with the commenters and is not including additional requirements for qualifying OGI instructors. EPA recognizes that there are OGI camera operators or other personnel that are qualified to conduct classroom training on the basic operation of OGI cameras other than those that meet the qualifications outlined by the commenters, and we do not want to restrict the capability of owners and operators to use those personnel. EPA does note that a senior OGI camera operator may give or develop the classroom training, but the classroom training is not required to be developed or given by a senior OGI camera operator.

Comment: One commenter (2139) provided specific comments on the duration of classroom instruction on specific topics. The commenter noted that there is no definition of the total required number of hours of classroom instruction, no requirement for number of hours for each element listed in sections 10.2.1.1 through 10.2.1.8, no identification of a method of instruction, and no requirements for testing or proof of classroom training comprehension. The commenter recommended that EPA require a minimum of 16 hours of classroom instruction covering the topics in sections 10.2.1.1 through 10.2.1.8, a minimum of 8 hours each for Basic Science and Camera Operation and Image Interpretation, Regulations, and Documentation, and a minimum pass score of 80 percent (consistent with ASNT SNT-TC-1A (2022)<sup>2</sup>). Commenters (2139, 2248) also requested that EPA clarify that the instruction may be led in-person within a classroom or instructor led online and that EPA specifically provide a definition of “classroom.”

Response II-22-19: EPA has not prescribed a minimum time for the initial training. It is more important that the training cover the required topics than for the training to last a set amount of time. Additionally, EPA is not requiring a final test for the classroom training. While the classroom training is important, we consider the final field test, which incorporates the information learned in the classroom, to be the true assessment of an OGI camera operator’s abilities. Requiring one final test at the end of training strikes a balance between the burden of initial training and the necessity of ensuring that OGI camera operators are adequately trained.

EPA notes that in the December 2022 Supplemental Proposal, section 10.2.1 of Appendix K stated that classroom training can be at a physical location or online, which addresses the commenters’ concerns, and we do not believe an actual definition of classroom training is necessary. The online training does not need to be live, as long as the trainee has access to all of the materials, the training covers the required subjects, and the trainee has access to the trainer for any questions that they may have on topics covered in the training.

Comment: One commenter (2129) requested that the biennial refresher training be shorter than the initial training, and recommended the refresher training included a minimum time of 2 hours that could be performed in a classroom or online.

Response II-22-20: EPA has not prescribed a minimum time for the biennial refresher training. It is more important that the training cover the required topics than for the training to last a set amount of time. EPA notes that both the initial and the biennial refresher training can be conducted in-person or online.

#### ***22.4.5 Initial Field Training***

Comment: Several commenters (2177, 2196, 2428) remarked on the duration of the training requirements in section 10.2.2. One commenter (2177) stated the requirements would take an entire week or possibly longer if there are multiple trainees. The commenter stated that mandating a minimum of 3 survey hours for observation, a minimum of 12 side-by-side survey

---

<sup>2</sup> The American Society for Nondestructive Testing recommended practice number SNT-TC-1A: “Personnel Qualification and Certification in Nondestructive Testing.” Available at <https://www.asnt.org/MajorSiteSections/Standards/SNT-TC-1A.aspx> on July 11, 2023.

hours, 15 supervised survey hours, and 2 survey hours for testing is unnecessarily burdensome, noting that EPA's requirements don't account for the actual hours that would be needed due to fatigue limitations. The commenter suggested that a total of four supervised hours should be sufficient, with a minimum of 30 minutes of survey time for the final test. Another commenter (2428) requested that EPA avoid specific hourly requirements for each training phase; the commenter attested that it would be more appropriate to specify a total of 30 hours of field survey hours which includes direct observation, side-by-side, and independent surveys, without prescriptive hours. The commenter stated that this flexibility would allow instruction to be tailored to trainee needs, and as long as the 30 hours of training surveys includes an appropriate number of components to be surveyed (e.g., 300) and a final monitoring survey test, it should be sufficient.

A third commenter (2196), referring to the November 2021 proposed duration requirements of section 10.2.2 which were provided by number of site surveys (subsequently repropose as hours in the December 2022 Supplemental Proposal), provided estimates of the duration required in terms of days, citing the differences in facility operations and sizes. The commenter estimated that the trainee observation period should take approximately 2 days, the side-by-side comparative survey should take 5 days, and the independent trainee survey with senior OGI camera operator oversight should take 5 days. The commenter recommended the number of days be added to the training program as an option in lieu of number of sites.

Response II-22-21: EPA disagrees that the initial field training requirements are unnecessarily burdensome. Proper training is critical for the development of an OGI camera operator's ability to detect leaks. Four hours of supervised monitoring is not enough training for an average OGI camera operator to be proficient in finding leaks. The training requirements were developed based on the outcome of the Appendix K workshop held in November 2020 and were further refined based on the comments received on the November 2021 Proposal.

EPA also disagrees that the number of survey hours should not be broken into the three different levels. There is merit for all trainees to conduct surveys in each of the three levels, progressing from observation to independent monitoring. While EPA understands that training needs to be tailored to individual trainees, we note that the survey hours specified at each level are a minimum requirement. Trainers are highly encouraged to increase the time spent at any level where it is deemed to be appropriate for an individual trainee.

In regards to providing the requirements in survey days in lieu of number of sites, the change that was made in the December 2022 Supplemental Proposal to make the requirement in terms of survey hours instead of number of sites should provide the flexibility requested by the commenter.

Comment: One commenter (2177) stated that the repeat test in section 10.2.2.5 if a trainee doesn't pass the monitoring survey test is unnecessary and should remain optional.

Response II-22-22: EPA disagrees with the commenter. It is important that an OGI camera operator have a demonstrated ability to locate leaks with an OGI camera prior to conducting surveys that will be used to demonstrate compliance with leak detection programs.

#### ***22.4.6 Performance Audits for Camera Operators***

Comment: One commenter (2177) objected to the duration of the performance audit requirements of sections 10.4.1.1 (comparative monitoring) and 10.4.2 (video review), each of which require 2 hours of survey footage. The commenter expressed that a survey of a simple facility may only require a few minutes due to a minimal number of components. The commenter suggested that the comparative monitoring should only require the senior OGI camera operator to survey the same site without a specific duration. The commenter further pointed out that the requirements of section 10.4.2 conflict with the leak monitoring requirements of 9.7 and 9.7.1, one of which states no footage is required for non-leaking components and the latter which allows recording a photo in lieu of a video. The commenter urged that the time requirements of 10.4.2.1 should be removed as it may be impossible to compile 2 hours of video every quarter due to lack of actual leaks, which would likely incentivize a camera operator to dedicate more time to recording longer videos of found leaks and less time identifying unknown leaks.

Response II-22-23: EPA disagrees with the commenter that there is a conflict between the auditing requirements and the allowance in section 9.7 to only record images of leaks. There is nothing in section 9.7 that would preclude a camera operator from recording non-leaking components or an entire survey, as long as they record the leaking components. Additionally, the two-hour requirement for the performance audit can be accomplished via comparative monitoring or unedited video review, so if the audit is done via comparative monitoring, there is no requirement to record the whole two-hour audit.

Additionally, EPA notes that the two-hour video review should not be composed of video footage of only leaks. Instead, the camera operator being audited should record 120 minutes of actual survey time (not just leaks) so that the survey technique is evident to the reviewer. If the sites being surveyed are such that multiple sites are needed to accumulate 120 minutes of OGI survey process footage, then multiple videos containing unedited and uncut video recording of each complete site survey are allowed to be submitted to the senior OGI camera operator for review.

Comment: Several commenters (2177, 2258, 2483) opposed the quarterly frequency of the performance audits. Commenters (2217, 2258) suggested that the audit requirements should be conducted annually. Some commenters (2428, 2177) responded to the EPA's request for input on a reduced performance audit frequency for certain operators. One commenter (2428) noted that in the initial stages of OGI monitoring implementation, more frequent performance audits are key in ensuring technician efficacy, however, technician monitoring proficiency will increase quickly over time with monitoring and survey experience. Commenters (2177, 2428) asserted that for technicians who consistently have satisfactory performance audits, it is appropriate to extend the interval between audits for those technicians. A commenter (2177) recommended that OGI camera operators who demonstrate continuing proficiency and accuracy (e.g., operators who do not have significant deficiencies during two consecutive performance audits) should have reduced performance audit frequencies. Another commenter (2428) recommended that EPA adopt a "skip period" approach, as follows: for technicians who pass four consecutive quarterly performance audits, the audit interval should be extended to semiannual, for technicians who pass two consecutive semiannual performance audits, the audit interval should be extended to

annual. The commenter noted that if a technician does not pass a semiannual or annual audit or does not conduct a monitoring survey during the previous 12 months per section 10.5 of Appendix K, then quarterly performance audits should be restarted.

Response II-22-24: EPA understands the concerns raised by the commenter and agrees that experienced OGI camera operators should not need to undergo a quarterly performance audit. While EPA considers a performance-based (or “skip period”) approach a valid option, we are concerned that implementing this type of approach would be complicated for compliance and recordkeeping purposes. As such, EPA has determined that the best path forward is to maintain a uniform performance audit frequency for all OGI camera operators, but to reduce the performance audit frequency to semiannual, which is the same frequency as the recertification requirements of EPA Method 9. This decision will also reduce burden and operational challenges associated with locating senior OGI camera operators, especially for small businesses.

Comment: One commenter (2362) questioned why the performance audit would allow OGI operators to miss up to 10 percent of leaks in the final field test and performance audits and objected that EPA has not rationally explained these requirements. The commenter asserted that 10 percent missed leaks could lead to large fugitive emissions of VOCs and methane and would not constitute BSER.

Response II-22-25: EPA notes that this change was made in response to comments received on the November 2021 Proposal and was discussed in the December 2022 Supplemental Proposal.<sup>3</sup> If less than 10 leaks are found by a senior OGI camera operator during a field test or performance audit, the trainee or auditee would need to find all the leaks to pass. However, in situations where there are numerous leaks, EPA decided it was appropriate to allow a “pass” percentage. This acknowledges the fact that OGI is a subjective technique, and that it is difficult for two people to always see the exact same thing, even when both operators are trained. A slight change in conditions or vantage point can affect the operator’s ability to view leaks. While EPA expects camera operators to adjust as necessary to see leaks, it is important to acknowledge there may be instances where one operator will miss a leak seen by another operator. We also note that it is entirely possible that the trainee or auditee may find more leaks than the senior OGI camera operator. The importance of the OGI camera operator’s technique is why we are maintaining performance audits for all operators, even experienced operators.

Comment: One commenter (2177) objected to the retraining requirements of 10.4.3.2 through 10.4.3.4; the commenter stressed that these requirements would force a company to dedicate at least two full time employees for almost a full week (each requiring more than an entire workday with no breaks, and more for testing and travel time) solely to retrain a single camera operator.

Response II-22-26: EPA notes that retraining requires 18 hours of survey time (16 of training, 2 of testing). Even adding in time for rest breaks, this equates to less than a work week. While we understand the commenter’s concern regarding the time commitment, it is essential that OGI

---

<sup>3</sup> 87 FR 74838 (December 6, 2022).

camera operators be able to find leaks on a routine basis. If the operator is unable to pass a performance audit, there is no assurance that the operator is finding leaks during routine surveys.

#### ***22.4.7 Senior OGI Camera Operators***

Comment: One commenter (2220) expressed concern regarding the definition of senior OGI camera operator. The commenter was concerned that state agencies would be required to redirect staff resources and potentially encounter higher travel costs to meet the requirements outlined in Appendix K, which would potentially inhibit an agency's ability to meet other compliance obligations.

Response II-22-27: Personnel in federal, state, and local government agencies performing oversight duties are not required to meet the requirements outlined in Appendix K. The rigor of Appendix K is intended to ensure that owners or operators (or their contractors) conducting leak surveys are properly trained and conduct surveys in a manner to minimize the incidence of not finding leaks that are present. The occurrence of false leaks with an OGI camera is a much less likely scenario and can easily be guarded against by a general understanding of interferences that can occur during an OGI survey. Therefore, the only issue that arises from agency personnel not being trained to the rigor of Appendix K is that the agency personnel may not find all of the leaks that are present at the site, although they should be able to find the largest leaks with a basic level of OGI training.

Comment: Two commenters (2220, 2399) expressed concern about a potential lack of qualified senior OGI camera operators. One commenter (2220) stated that the number of qualified senior OGI camera operators is limited based on the requirements of Appendix K and the process of achieving such a qualification. Another commenter (2399) appreciated that the December 2022 Supplemental Proposal considered comments on the November 2021 Proposal and revised the senior OGI camera operator requirements. However, the commenter urged EPA to make further revisions, due to concerns with respect to the scarcity of operators that could qualify as senior OGI camera operators. The commenter stated that the requirements hinder midstream industry in-house personnel from qualifying as senior OGI camera operators. Additionally, because there is work that only senior OGI camera operators can perform, and initially there will be a small number of qualified operators available, senior OGI camera operators are likely to be very costly, if they are available at all. The commenter further stated that even with the revised requirements, it will likely take years to qualify enough senior OGI camera operators to meet regulated industries' training, auditing, and survey needs.

Response II-22-28: EPA acknowledges the commenters' concern. We have made allowances for operators to initially use previous training and experience to alleviate the issues surrounding the lack of senior OGI camera operators. Because an operator can qualify as a senior OGI camera operator after 1400 hours of survey experience (less than one year of full-time surveying), we expect the pool of qualified senior OGI camera operators to greatly increase within a year of promulgation of Appendix K. This should lead to both an increase in availability and a decrease in cost of senior OGI camera operators.

## **22.5 Operating Envelope**

### ***22.5.1 Industry Support***

Comment: One commenter (2428) supported the development of operating envelopes, stating that the “use of pre-defined operating envelopes through testing as prescribed in section 8.0 of Appendix K is a highly useful and pragmatic methodology to determine detection capability and restrictions for monitoring surveys.”

Response II-22-29: The EPA acknowledges the commenter’s support.

### ***22.5.2 Daily Field Checks Instead of Operating Envelopes***

Comment: One commenter (2305) stated the operating envelope is overly complicated and that daily field checks ensure the camera operator can identify fugitive emissions and set a maximum viewing distance. The commenter suggested that a change in weather that could significantly alter the viewing distance (e.g., large temperature changes of 10 degrees or significant wind changes), could trigger a retest to ensure the viewing distance set point is still adequate to identify fugitive emissions. Another commenter (2428) stated that technicians should already be trained in recognition of factors which would impact the leak detection capability, and that this is already adequately addressed in section 9.2.3. The commenter stated that if conditions are significantly different, then the technicians should switch to another operating envelope or conduct another distance check verification.

The commenter (2428) maintained that most OGI camera manufacturers plan to have completed the development of the operating envelopes after Appendix K is promulgated but urged that a daily or site-specific distance check should remain an option. The commenter acknowledged that there may be times when OGI camera operators will be using an OGI camera that does not yet have any established operating envelopes either because the camera OEM has yet to publish operating envelopes once Appendix K is promulgated, the OGI camera is new to market, or monitoring conditions for a specific survey or site are unique regarding the pre-defined operating envelopes and the camera operator may want to ensure that the delta-T and viewing distance are appropriately set.

Response II-22-30: See discussion in section XIV.A.3 of the preamble to the final rule which details EPA’s final standards related to daily field checks in lieu of an operating envelope.

### ***22.5.3 Configuration Concerns***

Comment: One commenter (2399) reiterated the comments they provided in response to the November 2021 Proposal regarding the camera performance criteria in proposed section 8 of Appendix K. The commenter states the requirements are not suitable for surveying locations in the remote or rural areas where gas plants often operate. The commenter also stated that the initial performance verification requirements under Appendix K section 6.1.2 conflict with the requirement to establish operating envelopes detailed in sections 8.3 and 8.4. The commenter also noted that requirements in sections 8.3 and 8.4 instruct the establishment of operating

envelopes for potentially hundreds of different configurations. Because each configuration requires time to establish and test, the commenter argued that these requirements bog down operators and discourage the use of OGI cameras.

Response II-22-31: EPA disagrees with the commenter that section 6.1.2 conflicts with sections 8.3 and 8.4 of Appendix K. The intent of section 6.1.2 is to set a standard bar that all OGI cameras must achieve and is an initial demonstration of the capability of an OGI camera model. Section 8 is used to determine the different field conditions (distance, wind speed, and delta-T) under which a trained observer should be able to identify leaks.

Development of operating envelopes is likely to occur well in advance of a planned survey. Additionally, as the operating envelope is specific to a camera model, it is unlikely that each owner or operator would have to develop their own operating envelopes, unless there is a site-specific reason to do so. As such, EPA does not agree that operators will be bogged down with establishing operating envelopes.

Comment: One commenter (2421) argued the terminology of “all potential configurations” in section 8.3 is too vague to cover realistic testing situations and recommended a word change to “common field use configurations.” The commenter appealed for clarity regarding camera alternate color palettes and high sensitivity mode and whether these configurations require a defined operating envelope.

Response II-22-32: EPA understands the commenter’s concern, but does not agree with the change in terminology, as common field configuration is a more vague term than what is currently in Appendix K. EPA is not defining a list of configurations that must be tested for an operating envelope, because we do not want to inadvertently exclude any potential future OGI camera from Appendix K by being overly prescriptive in the listing of configurations. Instead, as noted in the December 2022 Supplemental Proposal, we are requiring testing for operating envelopes in all potential configurations that could impact the detection limit. If a configuration does not impact the detection limit, there should be documentation to support that assertion. If a particular configuration will not be used in the field to conduct surveys, an operating envelope is not needed for that configuration.

For alternate color palettes, the camera operator (with or without help from the camera manufacturer) needs to determine whether the change in color palette affects the detection limit. A high sensitivity mode would be expected to affect the detection limit.

#### ***22.5.4 Observers***

Comment: Commenters (2535, 2446) requested that the language in section 8.5.3 be clarified. Commenter questioned whether each location is required to have 4 trained OGI camera operators.

Response II-22-33: Development of the operating envelopes is likely to occur well in advance of a planned survey. Additionally, as the operating envelope is specific to a camera model, it is unlikely that each owner or operator would have to develop their own operating envelopes.

Therefore, EPA does not anticipate that it will be necessary for every site to have 4 OGI camera operators.

If a facility has a situation that requires a unique operating envelop to be developed, then it is expected that this process will occur with enough time to gather a panel of four observers either at a testing location or at the facility location. EPA notes that the observers are not required to be senior OGI camera operators. Additionally, the observers do not have to be trained in accordance with Appendix K, although we caution that use of an observer who is not trained in accordance with Appendix K may result in reduced operating envelopes because an untrained observer is likely to see less leaks.

## **22.6 Conducting OGI Surveys**

### ***22.6.1 delta-T Monitoring***

Comment: In lieu of verifying the delta-T check function in section 9.1.4 of Appendix K, one commenter (2465) suggested a daily image check with a butane lighter or propane cylinder (which is already required in section 9.1.3) under fixed conditions to reduce the burden of Appendix K. Another commenter (2196) claimed that sections 9.1.4, 9.2.1, and 9.2.2 are unnecessary and should be deleted, maintaining that virtually any background provides a delta-T.

Response II-22-34: EPA notes that verifying the operation of the delta-T check function is only applicable for those cameras that include that function and for those OGI camera operators who will use the function to maintain a minimum delta-T.

Regarding the removal of sections 9.1.4, 9.2.1, and 9.2.2, EPA disagrees and notes that there are many backgrounds where the temperature is nearly the same as the gas, and as such, would not provide an adequate delta-T for monitoring.

Comment: Two commenters (2421, 2428) responded to EPA's request on ways that an OGI camera operator can ensure an adequate delta-T exists during monitoring surveys for cameras that do not have a built-in delta-T check function. One commenter (2428) stated that a technician should use the camera's function to display the temperature of the equipment or background behind the component being surveyed for leaks. If the ambient temperature is known, then it is a simple step to add/subtract the background to determine delta-T. Another commenter (2421) claimed that the comprehensive training, required by Appendix K, should ensure operators will retain an adequate delta-T. The commenter also noted that High Sensitivity Mode increases the sensitivity of the technology to a degree that the delta-T is less relevant.

Response II-22-35: EPA acknowledges the information provided by the commenters. EPA agrees monitoring background temperature and ambient temperature can be used to ensure the camera operator maintains an adequate delta-T.

### ***22.6.2 Dwell Time***

Comment: Commenters (2177, 2258, 2421, 2428, 2196) suggest that dwell time requirements be removed. Commenters felt that the dwell time requirements are overly restrictive and dwell time should be left to the discretion of the operator. These commenters argued that trained operators and the Appendix K protocol, which includes certification requirements and audit requirements, are adequate to demonstrate that operators are capable and qualified to detect leaks without dwell time requirements. One commenter (2248) suggested that dwell time as a concept is more appropriate for Method 21, where the search is focused on an invisible leak. Another commenter (2483) stated that the proposed viewing requirements would increase survey time approximately four-fold.

Commenters (2305, 2421) were critical of the proposed requirement that a component must be imaged from at least two different angles, and the OGI camera operator must dwell on each angle for a minimum of 2 seconds per component in the field of view. Commenters (2366, 2483) were also critical of the proposed allowance for reduction of the dwell time for complex scenes based on the monitoring area and number of components according to Table 14-1 of Appendix K. These commenters argued that dwell times and angles are unnecessary, burdensome, and impractical to implement.

Some commenters provided suggestions for alternative dwell times, noting that dwell times should be based on scenes since operators are focused on looking for movement in a scene when conducting surveys. One commenter (2305) suggested that a minimum of 3 seconds per scene would be appropriate, while another commenter (2421) recommended a maximum dwell time of 5 seconds per angle of view for scenes with multiple components. A third commenter (2428) suggested that scenes be differentiated according to the number of components being imaged and viewing distance. The commenter stated that an example of a “simple” scene would be a scene of 20-25 components viewed from a distance of 15-25 feet. The commenter stated that this approach offers a high probability of leak detection by a technician and limiting the number of components to 25 in a simple scene means a technician is likely to have great discernment or granularity of the image which improves the ability to detect a leak.

Response II-22-36: See discussion in section XIV.A.1 of the preamble to the final rule which details EPA’s final standards related to dwell time.

Comment: One commenter (2399) stated the concept of establishing a minimum dwell time does not take full advantage of the ability to make OGI the preferred leak detection option at a gas plant. The commenter cited technical literature which tracked scan speed on the unit level (well head, separator, tank) and not on the individual component level.<sup>4</sup> The commenter further stated that an advantage of using OGI cameras under Subpart OOOOa is that individual component counts are not necessary, but under Appendix K, a component driven time requirement disregards a camera operator’s experience and significantly diminishes the benefits of using an OGI camera.

---

<sup>4</sup> The commenter cited Zimmerele, et al., Detection Limits of Optical Gas Imaging for Natural Gas Leak Detection in Realistic Controlled Conditions, Environ. Sci. Technol. 2020, 54 (18), 11506-11514.

Response II-22-37: In the final version of Appendix K, EPA has updated the dwell time requirement to implement the concept of a simple scene. See discussion in section XIV.A.1 of the preamble to the final rule which details EPA's final standards related to dwell time.

EPA notes that even though Appendix K does take component counts into consideration, it does not require documentation of these component counts to the degree that a Method 21 based leak detection program does. However, EPA maintains that it is still necessary for owners and operators, as well as OGI camera operators, to know all the components regulated by a leak detection program and where all the components are located, as it is important to confirm that each component has been appropriately viewed using the OGI camera.

### ***22.6.3 Rest Breaks***

Comment: Commenters (2196, 2305, 2366, 2399, 2428, 2483) contended that rest break intervals should not be defined by Appendix K, and the requirement in Appendix K is unsupported and arbitrary. One commenter (2428) stated that OSHA already has appropriate guidelines for ergonomics in the workplace which include eye strain.

Commenters (2305, 2399, 2428) argued that camera operators do not look through their cameras for periods longer than 1-2 minutes at a time before the camera is put down so the operator can see their surroundings and walk to the next viewing location. Another commenter (2348) argued that the break duration should be empirically determined, include dwell time, and should be adjusted to consider environmental conditions. Another commenter (2196) reported that it is natural for a technician to take natural breaks after completing one unit or area and before switching to another or after switching levels or after a climb. Further, bodily functions (including hydration & heat relief) and bathroom breaks interrupt sampling and in aggregate are longer than the Appendix K prescribed times.

One commenter (2399) agreed that operators generally need breaks to avoid eye and mental fatigue but suggested that if Appendix K defines a rest break, it should be a 30-minute break after every two hours of monitoring because operators frequently receive breaks while walking through midstream facilities, which typically have a lower density of components. The commenter further noted that this will allow the OGI camera operator to develop a monitoring rhythm and more effectively survey larger facilities.

Response II-22-38: EPA disagrees that a mandated rest break is unsupported and arbitrary. The language for rest breaks that was put into the November 2021 Proposal was derived from EPA Method 9, which is another visual observation method. EPA determined it was appropriate to add a similar requirement for Appendix K because both mental and eye fatigue are known issues that occur with prolonged viewing of components with an OGI camera. Such fatigue may be a safety hazard, and it may also prevent the OGI camera operator from finding leaks that are present.

EPA acknowledges natural breaks will occur at regular intervals when an OGI camera operator moves between process units or process levels and notes that rest breaks are only required if these natural breaks do not occur frequently enough such that the OGI camera operator is

continuously surveying for more than 30 minutes. EPA encourages OGI camera operators to take longer or more frequent rest breaks as needed to reduce the incidence of fatigue.

#### **22.6.4 Monitoring Regulated Components**

Comment: One commenter (2428) stated that while the revised language provided for the monitoring survey methodology affords additional flexibility, the methodology remains limited to three options without any ability for a site to propose an alternative. The commenter (2428) requested that EPA add language which allows a site to use another methodology as long as it meets the intent and capabilities of the ones currently identified; the commenter contended that a site could propose an alternative to their delegated authority prior to use.

Response II-22-39: EPA is not currently aware of another approach that would effectively ensure an owner or operator monitors all components regulated by a referencing subpart. If an owner or operator develops a new methodology that can achieve this goal, the owner or operator may submit a request for alternative monitoring procedures under 40 CFR 60.13(i) or 40 CFR 63.8(f), as applicable. Additionally, when Appendix K is applied to a specific subpart through a rulemaking, commenters may request that additional methodologies be added for use of Appendix K in that subpart.

### **22.7 Records and Reporting**

#### **22.7.1 Burden**

Comment: One commenter (2248) agreed with clearly stating the recordkeeping requirements within the protocol. However, commenters (2366, 2248, 2196) stated that the recordkeeping requirements are unnecessary and burdensome. One commenter (2196) expressed the opinion that, as written, the method contains “too many compliance traps” due to the recordkeeping burden; the commenter urged that if finalized as is, industry would likely revert to using EPA Method 21 due to this burden.

Response II-22-40: EPA disagrees with commenters. The recordkeeping outlined in Appendix K is necessary to ensure compliance with the various requirements of the protocol, including the training requirements and the conditions under which surveys must be conducted. In the December 2022 Supplemental Proposal, EPA updated the recordkeeping requirements to indicate certain records only need to be available to an owner and operator and made available to a delegated agency upon request.

If an owner or operator wishes to use EPA Method 21 due to recordkeeping associated with Appendix K, use of EPA Method 21 remains an option in NSPS OOOOb and EG OOOOc, which are the only subparts that currently include the use of Appendix K.

Comment: One commenter (2399) pointed to section 9.3.2 of Appendix K as an example of burdensome requirements, noting it would require significant time and effort to “develop visual cues (e.g., tags, streamers, or color-coded pipes) to ensure that all regulated components were monitored.” The commenter notes that establishing a new set of component tags throughout gas plants (and keeping them updated over time) offers no advantage over EPA Method 21 and

discourages OGI camera use. Another commenter (2177) objected to the requirement in section 9.7.2 of Appendix K to tag equipment; the commenter asserted that tagging equipment is not necessary and sometimes not physically or safely possible. The commenter stated a photo of the leaking component and description should be sufficient. The commenter proposed revised text for section 9.7.2 as follows: “Identification of the component associated with each leak must be recorded and stored with the OGI survey records.”

Response II-22-41: EPA notes that section 9.3.2 is one of three options for ensuring all regulated components are monitored. The other options include developing route maps or maps with designated observation points and GPS route tracing. Owners and operators are allowed to choose the option that works best for their site, and as such, we do not anticipate that all owners and operators will be developing visual cues for monitoring components.

The requirement to tag a component for repair is only applicable if the repair cannot be made immediately. A photograph of the component may not be enough to identify the component if there are multiple components in the vicinity of the leak. EPA notes that tagging components is a requirement in most leak detection programs and provides an easy way for a technician to locate the correct component in the field. As such, we are retaining the requirement to tag components that cannot be immediately repaired at the time of inspection.

### ***22.7.2 Video Records***

Comment: Several commenters (2177, 2428, 2446, 2483, 2535) questioned the video and photo capture requirements in sections 9.7, 9.7.1 and 9.7.2 of Appendix K. Commenters (2177, 2428, 2446, 2535) noted that section 9.7 states that no footage is required for non-leaking components and allows the use of a photo versus a video, while section 9.7.1 requires a full video of the monitoring survey and must document the monitoring results for each piece of equipment. Commenters (2325, 2446) suggested revising section 9.7 as follows: “The site must have a procedure for documenting fugitive emissions or leaks found during the monitoring survey according to 9.7.1 or 9.7.2, one of the following approaches. If no emissions are found, no recorded footage is required to demonstrate that the component was not leaking.” Another commenter (2428) stated the full video language should be deleted or revised to clearly state that the full continuous video is an alternative to maintaining leak imagery only. Yet another commenter (2258) expressed concern that the requirement for a full, uninterrupted video could present challenges due to limitations in storage space and the need to charge and change camera batteries; the commenter requested clarification on whether multiple videos would be accepted for a single survey.

One commenter (2177) supported the use of a single photograph for identifying leaking components as sufficient, but urged that some leaks may not be identifiable as a single photo frame depending on the camera configuration used; the commenter proposed that EPA adjust 9.7.1 to focus the text on the leaking component and revise the text to “..or photograph that depicts the component associated with the leak”.

Commenters (2366, 2483) stated that the proposed Appendix K remains inconsistent with the quality criteria in Method 21 and recordkeeping requirements in other methods and LDAR

programs (e.g., short video clip or photograph that depicts the leak and the component associated with the leak.).

Response II-22-42: In the November 2021 Proposal, EPA required a 10-second video clip for each leaking component. Based upon comments on that proposal, in the December 2022 Supplemental Proposal, we changed the recordkeeping to allow a short video clip or photograph to be kept for each leaking component. We also allowed owners and operators to keep a recording of the entire survey instead of individual video clips. However, we realize based on the comments we received in response to the December 2022 Supplemental Proposal that our intent was not clear and that commenters read the revised text to mean that videos of the entire survey were a requirement. To alleviate this confusion, in the final Appendix K, we have largely reverted the text to its origin November 2021 Proposal form but have retained the allowance for photographs to document leaks. Additionally, we have added a sentence to section 9.7.1 of Appendix K that states that a recording of the full survey suffices for the requirement to take individual videos of leaking components.

EPA acknowledges that the requirement to keep video clips or photographs is different from other LDAR programs. However, LDAR is generally performed using EPA Method 21, and during an inspection, the operator documents the EPA Method 21 reading when a leaking component is found. Taking a photograph of a visual OGI image is analogous to documenting the instrument reading when using EPA Method 21.

### ***22.7.3 Quality Assurance Verification Video***

Comment: Commenters (2421, 2428, 2258) reiterated objections to the requirement to include a 5-minute quality assurance verification video in the monitoring plan. Commenters (2421, 2258) urged that the requirement is overly burdensome, unnecessary, and has not been required for previous regulations for similar applications. The commenters (2421, 2258, 2428) explained that this requirement would require extensive data storage for operators and would present challenges in managing this data, without a clearly added benefit. Commenters (2421, 2428) requested the QA verification video requirement be deleted entirely. One commenter (2421) requested that EPA either require training as described in section 10 or require daily QA verification, not both. The commenter remarked that if the EPA requires training, it should honor the operator as trained after completion of the required steps and eliminate any daily QA process. Another commenter (2258) suggested the duration of the video should be based on the completion of required QA verification tasks (i.e., the time to complete all elements described in section 9.1) in lieu of an arbitrary amount of time.

Response II-22-43: EPA considers the requirement for a daily QA video a reasonable alternative to requiring full survey videos. While we agree that it is not necessary to keep a full video of a monitoring survey, it is important to be able to assess each OGI camera operator's technique when reviewing survey records, as the ability to find leaks that are present is dependent on the camera operator's technique. The daily QA video allows someone who is not present for the survey to determine whether an OGI camera operator uses proper technique on a day-to-day basis. This documentation is especially important for a delegated agency to have available in

their review of OGI survey records and to assess whether Appendix K is being properly implemented.

EPA does not consider a 5-minute video clip cost prohibitive, even if the video clip is taken daily. The average size of a 5-minute OGI video clip is approximately 600 megabytes. If a clip is taken each business day of the year, this will equate to approximately 156 gigabytes of data. Cloud storage of files generally runs in the range of \$5-\$10 for a terabyte of storage.

Regarding the suggestion to change the duration of this video requirement, EPA disagrees with the commenter. The intent of the QA video is to evaluate the OGI camera operator's survey process, not to document that the QA verification tasks in section 9.1 of Appendix K have been completed. As such, we are retaining the length of the QA video as 5 minutes.

#### ***22.7.4 Documentation of Ambient Weather Changes***

Comment: One commenter (2366) stated that a requirement to record the weather conditions (ambient temperature, wind speed, relative humidity, and sky conditions) every 2 hours is arbitrary and unsupported. Another commenter (2483) requested that EPA remove requirements related to reporting weather conditions.

Response II-22-44: The EPA disagrees with the commenters and has retained the requirement in Appendix K to record weather conditions at regular intervals. EPA notes that the weather conditions are a relevant component of how a survey is conducted. Wind speed and temperature are directly related to how an OGI camera operator uses the camera's operating envelope, and as such, an operator needs to be always aware of these parameters and any changes in these parameters. Sky conditions are important to understanding the types of backgrounds that may be present during the survey, which is related to the OGI camera operator's ability to find a suitable delta-T. Understanding the conditions of a survey are crucial to anyone who is reviewing the results of a survey, as well as to the person conducting the survey.

## **22.8 Response Factors and Annex 1**

### ***22.8.1 Calculated Response Factors***

Comment: One commenter (2767) noted that the response factors based on the peer reviewed paper by Zeng et al.,<sup>5</sup> need to be calculated using log base 10, not natural log as was used, because the calculations use log base 10 absorption coefficient data.

Response II-22-45: EPA has evaluated the information provided by the commenter and agrees that the response factors should have been calculated using a log base 10 approach. We have revised the response factors we used in developing the detection limits in Appendix K. The

---

<sup>5</sup> Zeng, Y., Morris, J., Sanders, A., Mutyala, S., & Zeng, C. (2017). Methods to determine response factors for infrared gas imagers used as quantitative measurement devices. *Journal of the Air & Waste Management Association*, 67(11), 1180-1191.

Appendix K Technical Support Document has been revised using the recalculated response factors.

Comment: One commenter (2767) noted that all relevant compounds (alkanes, alkenes, benzene, toluene, xylene, ethylbenzene) have a response factor of at least 0.25 at 10,000 ppm-m for all known possible filters between 3.2 and 3.5  $\mu\text{m}$ , and as such, there is no need for recalculating or measuring the response factor values for any relevant compound if the spectral range of the bandpass filter of OGI camera is at 3.2-3.4  $\mu\text{m}$ .

Response II-22-46: EPA has purposely made Appendix K openly generic. While we acknowledge that most commercially available midwave infrared OGI cameras on the market today with a high quality 3.2-3.4  $\mu\text{m}$  filter should easily be able to prove that relevant alkanes, alkenes, and aromatics have appropriate response factors, Appendix K is written for OGI cameras of the future as well as those on the market today. It's important that we guarantee the filters on these cameras continue to retain appropriate responses to these chemicals. Therefore, we are retaining the response factor criteria.

### ***22.8.2 Annex 1 Should be a Stand-alone Method***

Comment: Commenters (2366, 2483) observed that Annex 1 contains a detailed method and procedure for determining a response factor. Both commenters argued that Annex 1 should be separated from the OGI method, and published as a stand-alone method (e.g., for the purpose of reference for subsequent optical/remote sensing technology methods) or as an appendage to Appendix K.

Response II-22-47: EPA disagrees with the commenters. If EPA develops additional optical or remote sensing technology methods that would benefit from Appendix K Annex 1, we may update Appendix K to remove Annex 1 at that time. Currently, because there is a link between Appendix K and Annex 1 and Annex 1 only applies to Appendix K, it is prudent that the two pieces remain together.

### ***22.8.3 Pixel Count for Each Measurement Area***

Comment: One commenter (2457) noted that section 1.1.2 of Annex 1 to Appendix K states that there will be three different areas representing the reference cell, gas cell, and the raw blackbody surface and that these three areas should be uniform and avoid the edges of the inner wall of the reference cell and the gas cell. The commenter further noted that the pixel count for each area was proposed to be at a minimum of 1% of the total pixels of the detector, which the commenter calculated to be a 32 x 24 pixel region. Given that the active surface area of a typical blackbody is small (about 10 x 10 inches), the commenter recommended reducing the minimum size of the three uniform measurement areas from 1% to 0.5%. The commenter stated that this reduction will still provide a sufficient area for each of the three measurements.

Response II-22-48: EPA agrees with the commenter and has implemented this change.

#### **22.8.4 Measurement Data Set**

Comment: One commenter (2457) noted that section 1.1.3 of Annex 1 to Appendix K requires a minimum of 31 measurements, which is assumed to take 31 seconds for a 1 Hz device. The commenter explained that common OGI cameras have a frame rate much higher than 1 Hz, e.g., 30 Hz. The commenter stated that in such a case, only 1 second of data would need to be collected, and this duration may be too short to get a stable and representative reading. The commenter contended that it would be better to specify a minimum of 30 seconds data collection or 30 independent measurements, whichever requires more time.

Response II-22-49: EPA agrees with the commenter that 1 second is too short of a period to get a stable and representative reading. We have revised the requirement in paragraph 1.1.3 of Annex 1 to require a measurement data set of 1,000 data points. Based on the information provided by the commenter, this should take just over 30 seconds for most common OGI cameras, which is consistent with what we originally intended.

#### **22.8.5 Error with the Response Factor Equation**

Comment: One commenter (2457) stated that the response factor equation contained in paragraph 6.2 of Annex 1 to Appendix K is incorrect and should be:

$$RF = \frac{[I_{Blackbody} - (I_{Compound\ of\ Interest} - I_{Gas\ Cell})]}{[I_{Blackbody} - (I_{Reference\ Compound} - I_{Reference\ Cell})]}$$

Where “ $I_{Blackbody}$ ” is the average of the IR radiance pixel area for the blackbody surface over the measurement set.

Response II-22-50: EPA has updated the equation in Annex 1 as suggested by the commenter.

#### **22.8.6 Alternative to Annex 1**

Comment: One commenter (2767) was concerned about the wide use of response factors, including in section 1.2. The commenter stated that the response factor requirement is very specific to a spectral range of a current common bandpass filter (i.e., 3.2 to 3.5 micrometers) and is relative to a camera’s sensitivity to propane. The commenter noted that a response factor is not a measure of absolute response sensitivity of an OGI camera, and therefore it should not be presented as such. The commenter further stated that because response factor criteria is manufacturer specific it should not appear in the protocol.

proposed an alternative method to Annex 1. The commenter stated that the response factor is a ratio of compound specific responses of the target gas to an arbitrary reference gas and maintained that measuring an absolute response criterion is a better method to measure the sensitivity of an OGI camera. The commenter recommended using what they call the compound specific response (CSR). The CSR is determined using the CSR function provided:

$$CSR[CL] = \int_{\lambda_1}^{\lambda_2} [(1 - 10^{-\alpha(\lambda)CL}) \cdot t(\lambda)] d\lambda$$

Where:

- $t(\lambda)$  – bandpass filter transmission as a function of wavelength (between  $\lambda_1$  and  $\lambda_2$ )
- $\alpha(\lambda)$  – absorption coefficient spectrum in  $\text{ppm}^{-1}\text{m}^{-1}$  measured in base-10 absorbance

The commenter (2767) proposed a simplified protocol where an average  $\Delta I$  (or camera response between background radiance and gas plume radiance) threshold determines in what  $\Delta T$  cut-off conditions the camera can be used. For example, the requirement could mandate that only OGI cameras that have an average factor of 5 difference in response between the gas radiance and the blackbody background radiance at a  $\Delta T$  of  $\pm 2$  K are applicable.

Response II-22-51: EPA continues to believe that specifying a response factor threshold in Appendix K is necessary for ensuring that a camera can see the compounds that are included in the emissions stream and for verifying that a camera meets a minimum performance threshold. However, EPA acknowledges the method provided by the commenter could be a valid alternative to Annex 1 of Appendix K. EPA needs additional time and information to fully evaluate this alternative and develop it into a complete protocol. Furthermore, EPA is concerned with finalizing this alternative without first providing notice and taking comment on it. EPA notes that we will continue to review the information provided by the commenter, and if appropriate, Appendix K will be amended in a future rulemaking to incorporate the alternative, possibly as Annex 2 of Appendix K.

## 22.9 Other Comments

### 22.9.1 General Comments

Comment: Several commenters (2248, 2535, 2399) generally supported the revised changes to Appendix K, but some commenters (2535, 2483) had concerns with the appendix as drafted and felt that significant edits were still necessary. Specifically, one commenter (2483) asserted that EPA retained onerous training, certification, and other test method requirements, including initial training, refresher training, quarterly two-hour performance audits, and other documentation requirements that should be revised.

Other commenters (2248, 2399) urged that the appendix is drafted in a way that would discourage its use over Method 21 monitoring, especially at natural gas processing plants. One commenter (2399) stated that Appendix K "is overly rigid with respect to everything from dwell times to break times, robbing it of any improved efficiencies over Method 21."

Response II-22-52: EPA disagrees with the commenters that Appendix K does not provide improved efficiencies over EPA Method 21. An OGI survey using Appendix K can provide reduced monitoring times because multiple components can be viewed simultaneously, operators do not need to physically move in between all components, and operators may not need to climb ladders to reach components. An OGI survey also provides advantages of increased safety

because personnel can view components from a distance and may not need to be elevated to view components. These advantages alone may lead an owner or operator to opt to perform monitoring surveys with OGI instead of EPA Method 21.

EPA acknowledges that there are extensive training and auditing requirements in Appendix K because operator training is critical to developing the ability to see leaks with an OGI camera. We have continued to make strategic edits to these training requirements, such as reducing the audit frequency to semiannual from quarterly but maintain that a robust training and auditing program is necessary to ensure operators are able to see leaks that are present.

Comment: One commenter (2483) requested that EPA continue to adopt the revised draft protocol submitted by the Appendix K workgroup and continue to engage with the workgroup. The commenter asserted that the workgroup members, which include a diverse team of experts who have previously supported OGI research, development, and demonstration, are able to provide recommendations that would ensure that OGI and other remote sensing technologies remain viable.

Response II-22-53: Throughout the development of Appendix K, EPA has continued to engage with stakeholders. Prior to proposing Appendix K, EPA held an OGI workshop that was open to the public. Input from that workshop was used to develop the version of Appendix K that was included in the November 2021 Proposal. Based on input received during the comment period from various stakeholders, we revised Appendix K in the December 2022 Supplemental Proposal. We have made further revisions in the final version of Appendix K based on the comments we received from stakeholder on the December 2022 Supplemental Proposal.

Comment: Several commenters (2196, 2248) asserted that EPA should remove specific sections of Appendix K. One commenter (2248) stated that EPA should remove section 5.0 of Appendix K; the commenter stated that the requirements are not appropriate to include in the protocol, noting that safety conditions are extensively regulated by other agencies under robust regulatory frameworks, and additionally, each company has its own required and voluntary safety programs to address site-specific safety conditions.

Response II-22-54 EPA notes that Appendix K is formatted similarly to the test methods in parts 60, 61, and 63. These test methods generally contain a section on safety similar to the one in Appendix K. Section 5.0 of Appendix K is not meant to be all encompassing, and owners, operators and users of Appendix K should continue to adhere to other regulatory requirements on safety, as well as their own voluntary safety programs. Section 5.0 of Appendix K is only intended to make users generally aware of the types of hazardous they may encounter will using the protocol.

### ***22.9.2 Burden and Cost***

Comment: A couple of commenters (2366, 2483) expressed concern that the requirements of Appendix K remain too costly or burdensome and maintained that EPA failed to consider feedback on the initial proposal in the supplemental that would have streamlined some requirements that were burdensome. Commenters (2366, 2483) urged that although the

December 2022 Supplemental Proposal indicates that Appendix K only applies to the processing segment, the final version of the method will likely be adopted, or at least relied upon, by state agencies because it will be the only standalone method for OGI, and therefore could add unwarranted burden to operators in other segments.

One commenter (2366) suggested that EPA conduct a cost benefit analysis. Another commenter (2483) noted that EPA did not include the costs for Appendix K in its OOOOb and OOOOc analysis and should do so. The commenter stressed that if the burdensome criteria of Appendix K is used as precedent for other methods, implementation of new and developing technologies will be hindered.

Response II-22-55: EPA disagrees with the commenters. EPA made substantial changes between the November 2021 Proposal and December 2022 Supplemental Proposal that reduced the burden of implementing Appendix K. EPA has continued to streamline the requirements of Appendix K based on feedback received from commenters on the December 2022 Supplemental Proposal. EPA cannot stop delegated authorities from requiring the use of Appendix K on their own, but we have clearly stated that Appendix K only applies where a subpart references it.

EPA is not conducting a cost benefit analysis for Appendix K because on its own Appendix K does not apply to any sector. Each sector is different regarding the types and number of components that must be monitored, as well as the frequency of monitoring. Therefore, it isn't possible to do a one-size-fits-all type of cost benefit analysis for Appendix K. This is why cost benefit analyses are performed for individual subparts during rulemakings.

EPA notes that all technologies are different, and each technology will require analysis of necessary quality assurance requirements to ensure adequate implementation. Some technologies rely less on operator experience or involvement, and in that instance, training of operators is likely to either not be necessary or to be greatly reduced. EPA is committed to reviewing new technologies and creating pathways for their use.

Comment: One commenter (2220) expressed concern that the requirements of Appendix K remain too costly or burdensome and that the requirements would impose a massive workload and strain on both operators and state agencies. The commenter was concerned that state agencies would need to hire additional full-time employees and incur additional training, equipment, and other associated costs not considered in the proposal. The commenter estimated costs for initial training to certify staff in operating OGI cameras would initially be roughly \$80,000 to \$100,000, and the cost of purchasing and regularly maintaining necessary OGI equipment to comply with the requirements is estimated at \$1.3 million.

The commenter further noted there would be costs to operators to hire qualified third-party contractors to perform some of the OGI fugitive emissions monitoring, which may be infeasible for some smaller operators. The commenter stated that the requirements could result in potential adverse economic impacts, as the cost associated with monitoring surveys outlined in Appendix K would impose expenses on small operators that exceed their revenues. The commenter was also concerned that the requirements in Appendix K would require operators to dedicate more time and resources to performing OGI inspections, which could consume available resources that

would otherwise be dedicated to performing ongoing compliance duties, such as making repairs. Based on this information the commenter contended that the increased burden had no significant environmental outcome and surmised that contractor costs will escalate from current levels due to the increased demand.

Response II-22-56: Personnel in federal, state, and local government agencies performing oversight duties are not required to meet the requirements outlined in Appendix K. The rigor of Appendix K is intended to ensure that owners or operators (or their contractors) conducting leak surveys are properly trained and conduct surveys in a manner to minimize the incidence of not finding leaks that are present. The occurrence of false leaks with an OGI camera is a much less likely scenario and can easily be guarded against by a general understanding of interferences that can occur during an OGI survey. Therefore, the only issue that arises from agency personnel not being trained to the rigor of Appendix K is that the agency personnel may not find all of the leaks that are present at the site, although they should be able to find the largest leaks with a basic level of OGI training. As such, the requirements outlined in Appendix K should cause no burden for federal, state, and local government agencies.

EPA acknowledges that there are costs associated with implementing any leak detection program, whether leak detection monitoring is conducted with OGI or EPA Method 21. A cost analysis is conducted for each rulemaking where a leak detection program is implemented. EPA generally considers the cost of in-plant personnel and third-party contractors, as well as the frequency for conducting the monitoring. EPA notes that Appendix K is only required for OGI surveys at natural gas processing plants in NSPS OOOOb and EG OOOOc. Additionally, EPA has provided owners and operators the option to use EPA Method 21 for these sources if the owner or operator wishes to do so. As such, owners and operators can choose to implement the program that works best for their site.

EPA disagrees that Appendix K provides no significant environmental outcome or that it takes time away from performing other duties, such as repairs. Generally, OGI surveys, even surveys conducted using Appendix K, can be performed more quickly than a monitoring event with EPA Method 21, and as such, the owner or operator reduces the amount of time spent monitoring and has more time to conduct maintenance and repair. Additionally, because technique and training are paramount to an OGI camera operator finding leaks where they exist, the requirements outlined in Appendix K ensure that more leaks will be found, thereby reducing emissions to the environment and creating a positive environmental impact.

## **22.10 Incorporations by reference**

In some cases, commenters incorporated by reference all or part of a comment letter submitted by another commenter. Rather than repeat the associated comment excerpts for each commenter, the EPA has listed the comment excerpt only once and provided a list of all the commenters who otherwise incorporated the comments by reference in the table below.

## Chapter 23. Miscellaneous Other Comments

### 23.1 General Support-Opposition to Proposed Action

#### *23.1.1 General Support for the Rule and Reduction of Emissions from Oil and Natural Gas Sources*

Comment: Commenters (1611-ELPC, 1620-EEN, 1633-NRDC, 1642-PJSN, 1644-YECA, 1647-Physicians for Social Responsibility Pennsylvania, 1648- 1651-CJM, 1659-CRP-PA Chapter, 1900-Private Citizen, 2036-NPCA, 2152-CALSTRS, 2163-EOS Federated Hermes, 2164-NA Management, 2166-ODNR, 2209-PLS, 2212-UCS, 2242-SGI, 2244-NK, 2245-Private Citizen, 2248-NDPC, 2249-NACAA, 2256-MLBO, 2271-Private Citizen, 2293-SH, 2296-NMED, 2299-NEI Investments, 2302-Texas State Representatives, 2303-NTAA, 2329-Sierra Club LSC, 2356-Earthworks et al, 2364-CE4K, 2396-Shell, 2420-WHPCA, 2422-WLN, 2425-TCS, 2429-WOC, 2434-Private Citizen, 2441-HAWC, 2456-Private Citizen, 2499-Ohio Conservative Energy Forum, 2627-BCIMC, 2628-Private Citizen, 2697-STAM, 2766-1000 Grandmothers, 2883-Congress, 3001-Great Old Broads for Wilderness, 3083-Private Citizen, 3335-Private Citizen, 3389-Private Citizen, 3399-Private Citizen, 3486-Private Citizen, 3602-Fort Berthold Protectors of Water and Earth Rights, 3585-Vote Solar, 3621-Private Citizen, 3653-Private Citizen, 3660-Private Citizen, 3705-Breathe Easy Susquehanna County, 2796-Chicago Area Peace Action, 3507-Save the Sound, 3611-Private Citizen, 3733-350 Bay Area Action, 3775-Mothers and Others for Clean Air, 3794-Parents for a Safer Environment, Others) support EPA curbing methane, volatile organic compound (VOC), and hazardous air pollutant (HAP) emissions from the oil and gas sector in order to address climate change mitigation goals and environmental/ecological/public health. Commenters request that the EPA push for the strongest, most comprehensive methane rules possible to protect the peoples' health from all sources of oil and gas methane pollution, to slow down the degradation of our environment and minimize harm to future generations. Many of these commenters requested that EPA further strengthen requirements (e.g., ban or limit flaring, strengthen abandoned well requirements). Several commenters specifically note that they support the EPA's proposal to establish emissions guidelines (EG) for existing oil and natural gas infrastructure because regulating existing sources will drive the largest portion of emissions reduction.

Commenter (2249-NACAA) provides that the supplemental proposal expands the November 2021 proposal to address numerous additional sources through performance standards and guidelines. The commenter generally supports these expansions within the proposed rule, which would eliminate important loopholes and provide more complete and consistent protections. These technical considerations include the articulation of standards for liquids unloading operations, pneumatic pumps, and dry seal compressors.

Commenter (2396-Shell) supports the EPA's efforts to establish rigorous performance standards for reducing methane emissions from new and existing facilities within all segments of the oil and gas sector. Commenter (2256-Mille Lacs Band of Ojibwe) notes that within their air shed but not within their treaty-ceded territories is a liquified natural gas (LNG) storage facility that tempers the availability of natural gas in their local natural gas transmission network. By

eliminating any fugitive emissions from facilities such as this one, they note that it will also help further the U.S. climate change mitigation goals.

Several commenters (1651-CJM, 1655-AAP, 2036-NPCA, 2037-Climate Action CA, 2209-PLS, 2212-UCS, 2302-Texas State Representatives, 2313-Private Citizen, 2335-Private Citizen, 2441-HAWC, Others) specifically state that given methane's prodigious short-term climate forcing power and contribution to climate change, reducing methane emissions deserves the most prompt and aggressive approach possible.

Commenter (2185-NY CRF) asks EPA to require methane reductions that are consistent with pathways to achieve net zero greenhouse gas (GHG) emissions by mid-century, such as the International Energy Agency (IEA) Net Zero Emissions by 2050 Scenario, which requires methane emissions from fossil fuel operations to fall by around 75 percent between 2020 and 2030.<sup>1</sup>

Commenter (1648-PA Audubon) states that reducing methane emissions is the fastest, easiest, and cheapest thing we can do to immediately slow the pace of climate change. Additionally, they state that we need the strongest possible supplemental methane rule to protect the health of humans, our feathered bird friends, and all other living beings on our planet. The commenter urges the EPA to enact the strongest possible methane safeguards and quickly finalize them.

Commenter (2164-NA Management) notes that establishing comprehensive and durable federal methane regulations will set a baseline for performance across the industry, which will provide long-term regulatory certainty and help to mitigate climate and transition-related risks for investors. Commenter (2163-EOS Federated Hermes) states without cutting methane significantly and rapidly, staying under 1.5-degrees C will not be possible, and 2-degrees C is increasingly out of reach. They provide that a recent Intergovernmental Panel on Climate Change (IPCC) report<sup>2</sup> points to potentially catastrophically high economic and societal costs of unmitigated warming, identifies methane pollution as one of the key drivers of climate change and underscores the urgent need for protective action to reduce methane emissions significantly. This disruption would pose systemwide threats to company financial performance, investors, and their beneficiaries, including retirees from all walks of life.

Commenter (2462-Private Citizen) provides two examples that show the broad consensus on the need to reduce methane emissions.

- (1) International Monetary Fund analysts<sup>3</sup> write in 2022 “Methane Emissions Must Fall for World to Hit Temperature Targets”.
- (2) Thousands of climate scientists, e.g., Schaeffer (2019)<sup>4</sup>: “Earlier cuts [in methane] mitigate climate feedbacks and avoid climate tipping points. Methane mitigation is

---

<sup>2</sup> IPCC Sixth Assessment Report [<https://www.ipcc.ch/report/ar6/wg1/>].

<sup>3</sup> Black et al. 2022. <https://www.imf.org/en/Blogs/Articles/2022/11/02/methane-emissions-must-fall-for-world-to-hit-temperature-targets>.

<sup>4</sup> Schaeffer. 2019. On the Causes and Consequences of Recent Trends in Atmospheric Methane <https://doi.org/10.1007/s40641-019-00140-z>. Published online: 22 August 2019 Current Climate Change Reports (2019) 5:259–274.

therefore of higher importance for the Representative Concentration Pathways (RCPs) that target a lower global temperature increase, such as RCP-2.6. Even under the most optimistic scenarios for future political and economic developments, as exemplified by the Shared Socioeconomic Pathway 1 (SSP1), methane cuts have to be regulated through policies.”

Some commenters specifically point to the adverse effects of climate change as support for reducing methane emissions. Examples of some of the specific comments provided are included in the following paragraphs.

*Rising Temperatures.* Commenter (2392-Earthjustice et al) states research shows that rising temperatures will alter the chemical and physical interactions that contribute to air pollution such as particulate matter and ground-level ozone. Prolonged warm seasons are projected to increase the number of days with poor air quality, in part due to increased risk of wildfires and windblown dust events. The resulting increased exposure to air pollutants is likely to have “significant respiratory and cardiovascular health effects.”

Commenter (2392-Earthjustice et al) states rising global temperatures are projected to increase heat-related illnesses and deaths. Increased exposure to higher temperatures impacts the human body’s ability to regulate internal temperatures, and exacerbates pre-existing conditions, such as cerebral, respiratory, and cardiovascular diseases. The commenter notes that latine, low-income, and black populations are respectively 1%, 11%, and 41% more likely to live in areas with the highest projected increases in extreme-temperature related deaths. One broad study found that Black mothers are disproportionately exposed to the overlapping risks of extreme heat and air pollution, putting them at greater risk of adverse pregnancy outcomes.

Commenter (2392-Earthjustice et al) states climate-driven increases in the frequency and intensity of extreme heat is expected to impact labor sectors where employees work outside and where employees work inside but without access to air conditioning. Vulnerable weather-exposed industries include agriculture, forestry, fishing and hunting, mining, construction, manufacturing, and transportation and utilities. As temperatures rise to unsafe levels, workers in these industries may see their hours reduced or be unable to work at all.

*Extreme Weather Events.* Several commenters (2036-NPCA, 2215-WVRC et al, 2420-WHPCA, 2441-HAWC ) point to extreme weather events due to rising temperatures occurring at greater frequency, fueled by climate change, like record flooding and wildfires, longer and more intense allergy seasons, increased risk from water-borne and vector-borne diseases such as Lyme Disease, and worsening air quality.

Commenter (2441-HAWC) provides that wildfires have displaced communities and disrupted critical infrastructure. Wildfires have put additional pressure on public health and emergency response resources which have already been strained thin under the pandemic. Wildfires also contribute to particulate pollution and air pollution levels where it was unsafe to exercise or even walk outside.

Commenter (1648-PA Audubon) notes birds and amphibians are the most threatened by global warming and climate change. About 90 percent of some bird populations have already declined due to climate change. The National Audubon Society states that climate change is today's biggest threat to birds. Climate change has caused advanced spring migration, changes in birds' habitats, higher possibility of disease transmission, earlier egg-laying time, less food availability, and a decline in the bird population.

Other commenters provide comments on local air quality concerns. Commenter (2296-NMED) notes that several ozone monitors in New Mexico show that air quality is approaching or exceeding the 2015 ozone national ambient air quality standards (NAAQS). The commenter provides that the Sunland Park area in southern New Mexico is currently designated as in nonattainment of the 2015 ozone NAAQS, with an additional seven counties in the state monitoring ozone concentrations at or above 95 percent of the standard. Monitored ozone concentrations increased throughout New Mexico over the last several years, including both of New Mexico's oil and natural gas producing regions in the San Juan and Permian Basins. According to the EPA's latest National Emissions Inventory (NEI) (EPA, 2014 NEI version II), over 80 percent of the emissions in these areas are from oil and natural gas sources. The commenter adds that the Carlsbad ozone air monitor (AQS ID # 35-015-1005) in the Permian Basin, which is an area of rapid growth in oil production, serves as a prime example of the air pollution problems facing New Mexico. The design value for ozone at this monitor has elevated from 68 ppb in 2016 to 78 parts per billion (ppb) in 2020. The commenter states that the 2021 data show some of the highest monitored ozone concentrations recorded in the past decade, indicating this upward trend will continue throughout the state.

To improve air quality in these areas, the commenter (2296-NMED) reports that they developed the Ozone Attainment Initiative (OAI) and joined the EPA's Ozone Advance program. As part of the OAI, the commenter is currently researching options for control measures for all source sectors. The EPA's proposed rule is fundamental to reducing emissions from the oil and gas sector. Without these important reductions, according to the commenter, additional counties in New Mexico and other states may exceed the 2015 ozone NAAQS, resulting in additional nonattainment area designations and nonattainment permitting requirements. Recent photochemical modeling indicates that interstate transport contributes to high ozone concentrations in New Mexico. As a result, New Mexico faces nonattainment designations and increased nonattainment permitting requirements, while many states contributing to these exceedances have taken no action to address their contributions. According to the commenter, this further emphasizes the need for strong, federally enforceable emissions standards for the oil and natural gas sector to ensure fair and equitable requirements in basins that span state lines.

Response II-23-1: These comments are supportive comments; as such, no response is required. While these commenters generally support the development of the NSPS OOOOb and EG OOOOc rules, they urge EPA to do more to reduce methane and VOC emissions from the oil and natural gas industry. As discussed in section II.A (Purpose of the Regulatory Actions) of the final rule preamble, the final rulemaking takes a significant step forward in mitigating climate-destabilizing pollution and protecting human health by reducing GHG and VOC emissions from the oil and natural gas industry, specifically the Crude Oil and Natural Gas source category. These mitigations are based on proven, cost-effective technologies already required by prior

EPA regulations or states' regulations or deployed by industry leaders to reduce this dangerous pollution. The final rules will also encourage the deployment of innovative technologies that currently exist to rapidly and cost-effectively detect and reduce methane pollution and promote further innovation that is already under way to find even more efficient and effective ways to mitigate this pollution. Because methane is the main component of natural gas, the rules also result in more saleable product. The oil and natural gas industry is the United States' largest industrial emitter of methane. Human emissions of methane, a potent GHG, are responsible for about one third of the warming due to well-mixed GHGs, the second most important human warming agent after carbon dioxide. The EPA is finalizing the actions described in the preamble to the final rule in accordance with its legal obligations and authorities following a review directed by EO 13990, "Protecting Public Health and the Environment and Restoring Science to Tackle the Climate Crisis," issued on January 20, 2021.

Comment: Commenter (2147-Private Citizen), while supporting the rule, suggests that the evidence shows that lack of enforcement allows the oil and gas industry to keep emitting. <https://www.hcn.org/articles/energy-industry-new-mexicos-new-pollution-rules-leave-oil-and-gas-operators-to-police-themselves>. The commenter asserts that new methane rules without strong enforcement mechanisms are ineffectual. The commenter adds that self-reporting by the industry is also a big problem and provides the following on the issue: <https://www.hcn.org/articles/energy-industry-new-mexicos-new-pollution-rules-leave-oil-and-gas-operators-to-police-themselves>.

The commenter (2147-Private Citizen) explains that they believe that there is a disconnect between the rule-making process, the subsequent implementation and enforcement process, and the profound and immediate impacts of methane emissions. The commenter asserts that enforcement mechanisms for non-compliance must be swift and effective.

Response II-23-2: A similar comment regarding the need for enforcement was also provided on the November 2021 Proposal, see Volume I, Chapter 23 (Miscellaneous Other Comments), subsection 23.15 (Enforcement), Response I-23-64 for response to this comment.

### ***23.1.2 United States Responsibility to Reduce Emissions***

Comment: Commenters (1659-CRP, 2461-CRS, 2501-OS) state that given that the U.S. is one of the largest global emitters of methane, the U.S. has the opportunity and responsibility to devise effective strategies for a rapid and sustained reduction in methane emissions, to limit near-term warming, improve air quality, and help mitigate the worst outcomes of climate change.

Commenter (2163-EOS Federated Hermes) states the rule would progress the U.S. climate leadership at COP27 in Sharm El-Sheikh, Egypt including via the Joint Declaration from Energy Importers and Exporters<sup>5</sup>, Egypt, that builds on the commitment to push for methane reduction

---

<sup>5</sup> Joint declaration from energy importers and exporters on reducing GHG emissions from fossil fuels [ <https://www.state.gov/joint-declaration-from-energy-importers-and-exporters-on-reducing-greenhouse-gas-emissions-from-fossil-fuels/> (note: link no longer works)].

through The Global Methane Pledge which would support the 1.5-degrees C goal in a collective effort to reduce global methane emissions at least 30 percent by 2030.<sup>6</sup>

Response II-23-3: See Response II-23-1 of this Chapter.

Comment: Commenter (2396-Shell) states one of the key regulatory elements is the establishment of rigorous performance standards that strive to achieve an ambitious methane intensity performance level for the upstream segments of the oil and gas supply chain. Although the exact numeric value would depend on a variety of factors, including the availability of accurate measurement data, the commenter believes that performance standard should most likely be in the range of 0.20 percent based on the benchmark set by the upstream industry under the Oil and Gas Climate Initiative (OGCI). The commenter provides that another key element of the methane regulatory program should be the establishment of robust monitoring, reporting, and verification (MRV) protocols aligned with the Oil and Gas Methane Partnership's Methane Emissions Reporting Framework 2.0 (OGMP 2.0) across the full natural gas value chain. A third and final element states by the commenter is the development of a flexible implementation framework that allows for the conversion of EPA's final methane performance standards set for each affected facility and emitting activity into an overall methane intensity standard for each of the upstream segments of oil and natural gas source category that are to be regulated by the EPA regulations.

Commenter (2396-Shell) is urging adoption of these three key elements to ensure proper alignment of the U.S. regulatory framework with methane regulatory programs of other countries, such as those in the European Union. The commenter contends that this alignment is necessary to demonstrate that the U.S. will meet its commitment to reduce methane emissions through the Global Methane Pledge that President Biden announced last November in COP26. In addition, they add that it will be critically important for demonstrating regulatory equivalence between methane regulatory programs in the U.S. and other countries to support and facilitate the efficient flow of liquid natural gas exports from the U.S. to the European Union and other countries.

Response II-23-4: A similar comment was provided by this commenter on the November 2021 Proposal, see Volume I, Chapter 23 (Miscellaneous Other Comments), subsection 23.11 (Other Recommendations for Reducing Impacts from Methane Emissions), Response I-23-58 for response to this comment.

### ***23.1.3 General Opposition to the Rule***

#### ***23.1.3.1 General Opposition to Rule as Proposed***

Comment: Commenter (2292-WV AG et al) states that reducing methane emissions is a noble goal that industry stakeholders have already been working toward. The oil sector, for instance, reduced methane missions relative to production by 60 percent between 2011 and 2020. See Tackling Methane Emissions, AM. PETROLEUM INST., <http://bit.ly/3l65lsP> (last visited Feb. 3, 2023). They add that other reduction efforts, like the Oil & Gas Methane Partnership 2.0 and

---

<sup>6</sup> Global Methane Pledge [<https://www.ccacoalition.org/en/resources/global-methane-pledge>].

the Texas Methane & Flaring Coalition, are underway. However, the commenter contends that admirable environmental goals do not justify what they believe would be crushing to the American energy sector. They assert that top-down, heavy-handed governmental control is not the way to achieve the right balance between energy needs and environmental concerns—rather, they believe that American ingenuity and innovation, fostered by private initiative and state leadership should be the avenue to provide solutions. The commenter believes that the December 2022 supplemental proposal leaves little room for that. The commenter recommends that the agency abandon the proposal.

Commenter (2322-AR DEQ) states that the proposed rule creates a regulatory framework that conflicts with the current regulatory authorization enacted by the Clean Air Act (CAA) and corresponding Arkansas law. They note that, due to the complexity of this proposal, the unintended consequences for small businesses and families, the conflict of laws created by this proposal, and the significant changes to the original proposal presented by EPA in the December 2022 supplemental proposal, they urge EPA to withdraw the proposed rule. The commenter suggests that, if EPA moves forward, EPA reconsider what they believe are problematic and onerous requirements for states and oil and gas operators included in the proposed rule.

Commenters (2227-WEA, 2241-UDNR) encourage EPA to continue to evaluate the provisions discussed within the proposed rules, so that ultimately when the rules are published, it can fully allow for the intricacies and nuance required to effectively regulate industries as complex as the upstream and midstream oil and natural gas segments. The commenters contend that the EPA’s summary of potential rule provisions lacks flexibility and consideration for several factors that will make compliance impractical, if not technically infeasible, and in some cases may result in an overall increase in total GHG emissions.

Response II-23-5: In response to the claim that the proposals would be “crushing” to the American energy sector, the EPA disagrees. See responses to comments in Volume II, Chapter 20 (Impacts of the Proposed Rule), section 20.3.3 (Energy Impacts) for EPA’s response to other comments received that express concern over the impacts of the proposal on energy production and costs.

See also sections XVI.C (What are the cost impacts?) and D (What are the economic impacts?) of the final rule preamble where the EPA presents a summary of the results of the cost and economic impact and distributional analyses conducted.

The EPA disagrees with the request and basis provided by commenters for withdrawing/abandoning the NSPS OOOOb and EG OOOOc rules. The EPA considered, however, these and other comments when revising the NSPS OOOOb and EG OOOOc regulatory text proposed with the December 2022 Supplemental Proposal, including some of the nuances (*e.g.*, allowing for alternative standards) brought up and supported by the comments on the proposals. See section X of the final rule preamble for a summary of the final NSPS OOOOb and EG OOOOc requirements.

### 23.1.3.2 Do Not Support Application of a One-Size Fits All Approach

Comment: Commenter (2257-MOGA) does not support application of the EPA’s “one-size-fits-all” approach to all oil and gas-producing states. The approach proposed by the EPA does not allow for operational flexibility by producers to accommodate uncontrolled variabilities like difficult ambient weather and annual weather patterns. Specifically, the commenter states that the EPA’s approach will adversely affect states like Michigan and prevent small businesses from competing on an equal and level playing field in a free-market economy because of its geographic location. The commenter believes the EPA has not considered all operational, market and industry variables when developing the current proposed regulations. The EPA must re-evaluate and develop emission reduction regulations that are flexible, practical and allow equal and fair competition within the marketplace.

Commenter (2168-INOGA) states EPA has recognized that the regulations are complex and has taken some steps to simplify the regulations. The commenter supports the concept of simplifying the regulation, but also believes that a “one size fits all” approach is not appropriate either. The commenter has engaged with EPA multiple times in the past and will continue to advocate for our members to have EPA promulgate common sense and cost-effective regulations that cover their operations.

Response II-23-6: Please see discussion of state flexibilities and response to comments section XIII.C.2 of the final preamble.

With regards to the commenter not supporting the application of the EPA’s “one-size-fits-all” approach to all oil and gas-producing states, similar comments were received on the November 2021 Proposal, see Volume I, Chapter 23 (Miscellaneous Other Comments), section 23.17 (One-Size Fits All Approach) for EPA’s responses to those comments.

## **23.2 Environmental Justice Concerns**

### ***23.2.1 Climate Change and Air Quality Impacts on EJ Communities***

Comment: Commenters (1651-CJM, 1665-EEN, 2163-EOS at Federated Hermes, 2184-SRCA, 2215-WVRC et al, 2242-Seventh Generation Interfaith, 2250-NRPE et al, 2271-Private Citizen, 2278-Springfield NAACP, 2287-ICCR, 2289-Galilee Baptists, 2325-Aclima, 2334-Liveable Arlington, 2352-Environment Texas, 2364-CleanEarth4Kids, 2394-Earthworks, 2420-WHPCA, 2422-WLN, 2424-AYS, 2429-WOC, 2441-HAWC, 2461-CRS, 2462-Private Citizen, 2466-Private Citizen, 2627-BC Investment Management, 2766-1000 Grandmothers, Others) express concern that methane is a primary driver of climate change that has impacts on communities of color and the most vulnerable, including children and pregnant mothers. Several of the commenters generally agree that due to its high effect and relatively low atmospheric lifespan, it is imperative that the EPA address methane pollution by putting in place a robust methane pollution standard for new and existing oil and gas operations. The commenters generally assert that a strong standard can help protect communities, especially communities of color and tribal communities, which disproportionately suffer from the effects of climate change and air pollution (e.g., ozone pollution).

Commenter (2184-SRCA) asserts that there is a direct line between rapid climate change and environmental injustice. The commenter argues that infrastructure impacts places of historic discrimination (formerly enslaved, Indigenous, Appalachian descendants living where their ancestors created communities under harsh discrimination). The commenter notes that these populations have low carbon footprints, but the highest proportion of environmental health hazards. The commenter suggests that, if wealthy, privileged communities had been equally targeted to lose their lands under eminent domain seizures or having polluters build in their neighborhoods — the U.S. would be on a par with countries approaching 100 percent renewable energy.

Commenters (1651-CJM, 2250-NRPE et al, 2278-Springfield NAACP, 2289-Galilee Baptists, 2334-Liveable Arlington) express that EPA’s December 2022 supplemental rule standards to regulate methane pollution from the oil and natural gas sector, the largest industrial source of methane, is a welcome improvement but they do not believe that the rule goes far enough. Commenter (2278-Springfield NAACP) states this is especially true for black communities impacted by climate change and air pollution.

Response II-23-7: While these commenters generally support the development of the NSPS OOOOb and EG OOOOc rules, they urge EPA to do more to reduce methane and VOC emissions from the oil and natural gas industry to reduce impacts on vulnerable communities. As discussed in section II.A (Purpose of the Regulatory Actions) of the final rule preamble, the final rulemaking takes a significant step forward in mitigating climate-destabilizing pollution and protecting human health by reducing GHG and VOC emissions from the oil and natural gas industry, specifically the Crude Oil and Natural Gas source category. These mitigations are based on proven, cost-effective technologies already required by prior EPA regulations or states’ regulations or deployed by industry leaders to reduce this dangerous pollution. The final rules will also encourage the deployment of innovative technologies that currently exist to rapidly and cost-effectively detect and reduce methane pollution and promote further innovation that is already under way to find even more efficient and effective ways to mitigate this pollution. Because methane is the main component of natural gas, the rules also result in more saleable product. The oil and natural gas industry is the United States’ largest industrial emitter of methane. Human emissions of methane, a potent GHG, are responsible for about one third of the warming due to well-mixed GHGs, the second most important human warming agent after carbon dioxide. The EPA is finalizing the actions described in the preamble to the final rule in accordance with its legal obligations and authorities following a review directed by EO 13990, “Protecting Public Health and the Environment and Restoring Science to Tackle the Climate Crisis,” issued on January 20, 2021.

See also section XVI.F (What analyses of environmental justice did we conduct ?) of the final rule preamble for a summary of the environmental justice analyses we conducted in support of the final rules, including environmental justice and the impacts of climate change, impacts of climate change on indigenous communities, and environmental justice impacts of ozone exposure due to oil and natural gas VOC impacts.

Comment: Several commenters (1665-EEN, 2392-Earthjustice et al) indicate that research shows that living in close proximity—i.e., within one mile or less—of an oil and gas facility increases

health risks associated with oil and gas pollution, like cardiovascular disease, respiratory disease, and cancer, increase with proximity to these facilities. Commenter (2441-HAWC) notes one study by the Colorado Department of Public Health and Environment found that those living within 500 feet of a wellsite were at greater risk of cancer and those living within 2000 feet of a wellsite were at greater risk for adverse health impacts. Commenter (2394-Earthworks) reports that a half mile “threat radius” distance from an oil and gas facility is a very conservative estimate of the area within which elevated levels of toxic pollution are seen, and the distance within which adverse health impacts have most clearly been correlated with the presence of oil and gas facilities. Commenter (2364-CleanEarth4Kids.org) asserts that the EPA must take action to protect all Americans and especially the 17.6 million people who live within 1 mile of at least one active oil/gas well.

Commenter (2236-PSR-Pennsylvania) stresses that the harmful effects fracking has on the public health of our communities are detrimental. They assert that it is essential to place emphasis on those living nearby oil and gas operations— where methane emissions can increase risk of heart disease, lung disease, asthma, infertility for men and women, cancers (such as acute lymphatic leukemia and ewing sarcoma), eczema, and reduced life longevity in comparison to those that do not live within a close proximity to an oil and gas site.<sup>7</sup>

Several comments were received specifically highlighting regional concerns. A summary of some of those concerns are provided in the following bullets:

- Commenter (2422-WLN) states that poor air quality and environmental degradation on and near tribal lands in the San Juan Basin of New Mexico and Colorado and across the U.S. West contributes to public health crises.
- Commenter (2236-PSR) states almost 1.5 million Pennsylvanians live or work within a half mile of an active oil or gas well and are being denied this right. These individuals and their communities are exposed to methane emissions from fracking which has a significant impact on their health.
- Commenter (2466-Private Citizen) notes that she has spoken to dozens of Pennsylvania families and property owners who have had their quality of life, their property, their health, and their drinking water ruined by the Marcellus shale industry. Last year, she reports that the Public Herald, an online investigative journalism site, uncovered that since 2004, Pennsylvania residents have complained to the Pennsylvania Department of Environmental Protection (DEP) over 10,000 times about water, health issues, and other harms caused by the oil and gas industry.
- Commenter (2392-Earthjustice et al) states it is well documented that dangerous air emissions from oil and gas operations harm the health of people living and working near oil and gas production areas.<sup>8</sup> In large oil and gas production states, significant numbers of residents are heavily impacted by these health harms. For instance, 5 million people in

---

<sup>7</sup> Compendium published by PSR and Concerned Health Professionals of New York with Scientific, Medical, and Media Findings Demonstrating Risks and Harms of oil and gas drilling.

<sup>8</sup> Id. at 7, 9 (citing Lisa McKenzie et al., Ambient Nonmethane Hydrocarbon Levels Along Colorado’s Northern Front Range: Acute and Chronic Health Risks, 52 Env’t Sci. & Tech. 4414, 4414 (2018), <https://pubmed.ncbi.nlm.nih.gov/29584423/>[hereinafter “McKenzie et al., Nonmethane Hydrocarbon Levels Along the Front Range”]).

Texas, 3 million people in Ohio, 1.9 million people in Pennsylvania, and nearly a half-million people in Colorado live within just one mile of an oil or gas well.<sup>9</sup>

- Commenter (2394-Earthworks) adds the Oil and Gas Threat Map<sup>10</sup> shows 17.2 million people living within a half mile radius of oil and gas extraction, processing, or compressor stations. That includes 3.1 million at-risk students in more than 12,000 schools suffering 750,000 asthma attacks and 500,000 lost school days per year. This is an increase of 4.7 million people at risk since the last time the commenter updated their analysis in 2017.
- Commenter (1665-EEN) adds of the 3.1 million American children attending school within 0.5 radius of oil/gas facilities, Pennsylvania has at least 310,896 kids facing this hazard.<sup>11</sup> This makes addressing fugitive and leaking methane from both existing and leaking oil/gas facilities a moral responsibility.
- Commenter (2334-Liveable Arlington) states Arlington is a city of about 400,000 people in an area of 99 square miles on top of the Barnett shale. They have close to 400 methane gas wells using hydraulic fracturing in 52 drill sites, and the numbers are growing rapidly. The standard setback of 300 feet is measured from the wellhead to the main building of the protected use. That translates to gas wells right next door to daycares, homes, medical offices.
- Commenter (2334-Liveable Arlington) states 5.3 million Texans live within half a mile of an oil and gas site (the threat radius). In Tarrant County where their organization is based, close to 1 million out of 2.1 million residents live less than half a mile from fracking sites — the largest number of any county in America.
- Commenter (2334-Liveable Arlington) adds in EPA Region 6, almost 9 million people live within the threat radius of oil and gas development — more than half of the 17.3 million similarly impacted nationwide.
- Commenter (2501-Orion Strategies) reports that West Virginia is one of the top energy-producing states. West Virginia is home to many low-producing well sites that go unchecked and across our beautiful state, more than 50% of West Virginians live close to a well site. They note that the adoption of the proposed rule would ensure that all well sites, including high-polluting and low-producing wells, are properly monitored for emissions. As such, West Virginia is in drastic need of commonsense inspection standards for oil and gas wells to protect our communities.
- Commenter (2215-WVRC et al) asserts that Appalachians and West Virginians are especially at risk due to the many active and abandoned oil and gas wells in the region. Over half of West Virginians live within a mile of an active oil and gas well, and there are approximately 6,500 abandoned and orphaned wells in the state leaking methane. Low-producing oil and gas wells are responsible for half of all well-site methane pollution in the country, and Appalachia has the highest quantity of these sites nationwide with over 180,000 wells. The most populated county in West Virginia, Kanawha County, has 3,303 of these polluting wells – the highest number of low-producing wells in a single county. It is clear that pollution from the oil and gas sector is a pressing issue in

---

<sup>9</sup> Jeremy Proville et al., The Demographic Characteristics of Populations Living Near Oil and Gas Wells in the USA, 44 *Population and Env't* 1, 10 (2022), <https://link.springer.com/article/10.1007/s11111-022-00403-2> [hereinafter “Proville et al, Demographics Near Oil and Gas Wells”].

<sup>10</sup> The Oil and Gas Threat Map, <https://oilandgasthreatmap.com/>.

<sup>11</sup> <https://oilandgasthreatmap.com/>.

West Virginia, and the supplemental proposal to reduce this harmful pollution represents much-needed action to alleviate the burden felt by West Virginians from extractive industry.

- Commenter (2215-WVRC et al) states the high concentration of active and abandoned oil and gas wells in West Virginia exacerbates the public health crisis that already exists in West Virginia. West Virginia ranks highest in the nation for prevalence of heart attack and coronary heart disease, has the second highest cancer mortality rate, and is among the worst ranked for chronic respiratory disease. As one of the oldest populations in the nation, West Virginians are particularly vulnerable to negative health outcomes from these pollutants.

Response II-23-8: See Response II-23-7 of this Chapter.

### ***23.2.2 Water Quality***

Comment: Commenter (2392-Earthjustice et al) states although the December 2022 supplemental proposal does not cover water quality, a robust environmental justice analysis must address cumulative impacts incorporating cross-media effects on disproportionately impacted communities. In the context of oil and gas infrastructure and pollution, a discussion of associated water quality impacts provides crucial context for understanding cumulative impacts, including in addition to the adverse air quality impacts discussed above. The commenters note that EPA did not consider water quality impacts of oil and gas development in its Regulatory Impacts Analysis (RIA), but they consider this analysis informative for the purpose of analyzing disparate impacts associated with oil and gas infrastructure and pollution.

Commenter (2392-Earthjustice et al) continues, the extraction of oil and gas has been linked with adverse impacts on water quality. Ample evidence connects fracking with groundwater contamination.<sup>12</sup> Fracking also negatively impacts surface waters. The commenter notes that a recent study identified a correlation between newly drilled wells and salt concentrations in surface waters and noted that concentrations were highest in the aftermath of hydraulically fracturing an oil formation.<sup>13</sup> Because salt compounds are commonly found in water coming from newly fracked wells, these findings raise concerns that more dangerous substances, such as toxic chemicals used in oil and gas extraction, could also be reaching surface waters. The commenter adds that the EPA has also identified evidence that the discharge of inadequately treated fracking wastewater has contaminated surface and drinking water resources.<sup>14</sup> Outside of

---

<sup>12</sup> Gayathri Vaidyanathan, Fracking Can Contaminate Drinking Water, Sci. Am. (Apr. 4, 2016), <https://www.scientificamerican.com/article/fracking-can-contaminate-drinking-water>; Dominic C. DiGiulio and Robert B. Jackson, Impact to Underground Sources of Drinking Water and Domestic Wells from Production Well Stimulation and Completion Practices in the Pavillion, Wyoming, Field, 50 Env't Sci. & Tech. 4524, 4524-36 (2016), <https://pubs.acs.org/doi/abs/10.1021/acs.est.5b04970>.

<sup>13</sup> Pietro Bonetti et al., Large-Sample Evidence on the Impact of Unconventional Oil and Gas Development on Surface Waters, 373 Sci. 896, 896 (2021), <https://pubmed.ncbi.nlm.nih.gov/34413233/>.

<sup>14</sup> U.S. Env't Prot. Agency, Hydraulic Fracturing for Oil and Gas: Impacts from the Hydraulic Fracturing Water Cycle on Drinking Water Resources in the United States: Executive Summary at 1-2 (2016), <https://cfpub.epa.gov/ncea/hfstudy/recordisplay.cfm?deid=332990>.

the context of fracking, the commenter reports that stormwater runoff from oil and gas well pads has been found to introduce contaminants into nearby surface waters.<sup>15</sup>

Commenter (2392-Earthjustice et al) argues the disparate impacts of water quality degradation resulting from oil and gas extraction are acutely experienced by Black, Latine, tribal, and rural and low-income communities. In south Texas, the commenter states that researchers found evidence that areas with more than 80 percent population of color were twice as likely to live near fracking wastewater disposal wells than areas with less than 20 percent population of color.<sup>16</sup> Of the 217,624 people of color living less than three miles from a disposal well in southern Texas, 83.3 percent were Latine and 13.8 percent were Black.<sup>17</sup> A separate study analyzing the siting of fracking wells in the Marcellus shale region of Pennsylvania found evidence for income disparities in well siting.<sup>18</sup> The commenter adds that tribal communities have also faced unique threats to water quality from oil and gas infrastructure. For example, the Dakota Access Pipeline, which transports oil extracted from the Bakken oil fields in North Dakota, threatens water quality, and disturbs sacred sites of the Standing Rock Sioux tribe.<sup>19</sup>

Response II-23-9: With regards to comment that, “although the December 2022 supplemental proposal does not cover water quality, a robust environmental justice analysis must address cumulative impacts incorporating cross-media effects on disproportionately impacted communities”, the commenter is correct that water quality does not fall under the scope of the final rulemaking.

See also section XVI.F (What analyses of environmental justice did we conduct ?) of the final rule preamble for a summary of the environmental justice analyses we conducted in support of the final rules, including environmental justice and the impacts of climate change, impacts of climate change on indigenous communities, and environmental justice impacts of ozone exposure due to oil and natural gas VOC impacts.

### ***23.2.3 Vulnerable Communities***

Comment: Below are specific comments received on vulnerable communities affected by oil and natural gas infrastructure and the air quality and climate change effects of emissions of methane, criteria pollutants (e.g., VOC, NOx), and HAP.

---

*Black, Latine, Native American and Low-Income Populations.* Commenters (2392-Earthjustice et al, 2420-WHPCA) note disparate air quality health impacts result from the siting of oil and gas operations and infrastructure. Disproportionately large numbers of people living near oil and gas wells across the U.S. are from low-income communities and communities of color.<sup>20</sup> Commenter (2392-Earthjustice et al) goes further, of the nearly 18 million people in the U.S. that live within one mile of an active oil or gas well, 3.3 million are Latine, 3 million live below the poverty line, 1.8 million are black, and 500,000 are Native American.<sup>21</sup> Research additionally shows that populations of color, and in particular black populations, are disproportionately more likely than other demographics to live near fracking wells.<sup>22</sup> The cumulative impacts associated with well siting are also acutely experienced in Latine and black communities, as baseline air quality is, on average, more polluted in these communities. A 2014 study found that majority Hispanic neighborhoods were exposed to greater and more dangerous concentrations of nitrogen oxides (NOx) and particulate matter than majority white neighborhoods in the same cities.<sup>23</sup> Likewise, Black communities are exposed to 1.54 times the amount of particulate matter than the overall population.<sup>24</sup>

Commenter (2392-Earthjustice et al) also notes that multiple studies show that Latine and low-income populations are disproportionately vulnerable to climate-related air quality health impacts. With 2°C of warming, the commenter reports that an EPA study found that Latine and low-income populations are respectively 10 percent and 15 percent more likely than others to live in areas projected to have the highest climate-driven increases in childhood asthma.<sup>25</sup> Similarly, a 2021 of the Denver Metro-North Front Range ozone nonattainment area found that, when accounting for the effect of climate change on ozone trends, ozone levels are expected to increase the most in urban majority Latine and low-income communities.<sup>26</sup>

Commenter (2392-Earthjustice et al) adds that black, Latine, tribal, and rural and low-income communities are also disparately vulnerable to the adverse economic impacts of weather-exposed labor markets. Assuming 2°C of warming, Latine populations are 43% more likely than non-Latine populations to live in areas with the highest projected labor hour losses in weather-exposed industries. Low-income populations, American Indian and Native Alaska, and Black

communities are respectively 25 percent, 37 percent, and 23 percent more likely to live in these weather-impacted areas.

Commenter (2334-Liveable Arlington) states the health and economic costs of fracking is disproportionately borne by communities of color. In their very diverse community, they assert that fracking is an environmental justice issue.

Commenter (2364-CleanEarth4Kids.org) adds this is a racial, social, climate and environmental justice issue as urban fossil fuel drilling takes place in predominantly low-income communities of color.<sup>27</sup> The commenter reports that air pollution can trigger asthma attacks and black children have a 500 percent higher death rate from asthma compared with white children.<sup>28</sup> They note that there is a social cost of fossil fuels, a price that is being paid by low-income and people of color.

Commenter (2289-Galilee Baptist Church) notes that over one million African Americans live in counties that face a cancer risk above the EPA's level of concern from toxics emitted by natural gas facilities.

Commenters (2278-Springfield NAACP, 2289-Galilee Baptists) inform that more than 1 million people of African descent live within a half-mile of an existing natural gas facility, leaving these communities exposed to the toxic air pollution from methane gas. Commenters (2278-Springfield NAACP, 2289-Galilee Baptists, 2325-Aclima) state that the result of this exposure is increased cancer, reproductive and respiratory problems. Commenter (2289-Galilee Baptists) reports that illnesses contribute to missed work and school days. They note that methane pollution also contributes to climate change, which hits black communities first and worst in the form of flooding, heat waves and severe weather. The commenter provides that the African American community is disproportionately impacted because of historical and ongoing systemic racism, which has placed the commenters' communities adjacent to polluting industries.

Commenters (2303-NTAA, 2697-STA) state the emissions from oil and natural gas sources not only contribute to climate impacts, but seriously burden the health of nearby tribal communities. Ozone-forming VOCs and HAPs like benzene are emitted alongside methane. Inhalation of these dangerous pollutants can lead to irreversible lung damage, asthma attacks, and cancer, and Tribal communities already suffer from these illnesses at disproportionate rates. In this rulemaking, the commenter urges EPA to look at the environmental justice implications of the proposed action and seek to advance equity for all.

Commenter (2422-WLN) states that poor air quality caused by oil and gas pollution disproportionately impacts tribal communities. Environmental degradation on and near tribal lands in the San Juan Basin of New Mexico and Colorado and across the U.S. West contributes to public health crises.

Commenter (2353-CrownQuest) notes that the EPA points out the disproportionate benefit expected by these rules to indigenous peoples but also admits this rule will not apply to tribes in the U.S. as that is outside their authority bounds. According to the commenter, this rule is not a

---

<sup>27</sup> <https://www.fractracker.org/2020/12/people-and-production/>.

<sup>28</sup> <https://www.epa.gov/children/childrens-environmental-health-facts>.

serious attempt to help any American. Otherwise, they believe that tribes would already be instituting these and other regulations on oil and gas activity on their lands.

*Children.* Commenter (1665-Evangelical Environmental Network) notes studies have shown that smog, VOCs, and air toxics have a disproportionate impact upon life in the womb. The commenter provides that research by Dr. Shaina L. Stacy and others at the University of Pittsburgh found close proximity to unconventional gas wells in Butler County, PA is associated with babies born with lower birthweight.<sup>29</sup> Dr. Lisa M. McKenzie with the Colorado School of Public Health published peer reviewed research that links birth defects to methane production.<sup>30</sup> They add that research by Casey J.A., et al (2019) further describes that living within a half-mile radius of natural gas development leads to increased brain, spine, or spinal cord birth defects.<sup>31</sup>

Commenter (2253-Our Children's Trust) asserts that giving equal protection to children under law means treating them differently than adults. They explain that children are unique physiologically, emotionally, behaviorally, and generationally, including their average life longevity as compared to adults, and due to their lack of political and economic power and their dependency on adults.

Commenter (2253-Our Children's Trust) notes that EPA has highlighted children's heightened likelihood of suffering climate change-induced harms. For example, "[c]hildren's bodies are developing physically, which can make them more vulnerable to climate-related hazards like heat and poor air quality. They also breathe at a faster rate, increasing their exposure to dangerous air pollutants"<sup>32</sup> In addition, they add that the EPA has broadly recognized both the particular vulnerability of children to environmental harm and the importance of incorporating their interests and protection into its policy:

Childhood is a life stage experienced by everyone, and exposure to contaminants during early life is a key consideration in the assessment of how environmental impacts shape human health over the course of a lifetime.

Commenter (2253-Our Children's Trust) adds children also have unique behaviors such as breast feeding, crawling and hand-to-mouth activity that may contribute to increased exposure. Children eat more food, drink more water, and breathe more air in proportion to their body size as compared to adults, and the variety of the foods they consume is more limited. As children are still growing and developing, they do not respond to toxic substances in the same way as adults.

<sup>32</sup> Climate Change and Children's Health, <https://www.epa.gov/climateimpacts/climate-change-and-childrens-health> (last visited Feb 1, 2023).

For instance, they explain that their blood-brain barrier and metabolic processes are less mature. The timing of exposure to chemicals and other contaminants is critical in protecting human health. They note that the same dose of a chemical during different periods of development can have very different consequences.

Commenter (2253-Our Children's Trust) stresses that children who live in highly exposed or underserved communities may have reduced biological resilience and ability to recover from exposure to environmental hazards. With new threats and worsening conditions resulting from climate change, the EPA has a greater responsibility to provide children with heightened focus, assessment, and safeguards to protect their health.”<sup>33</sup>

Commenter (2253-Our Children's Trust) adds that climate change is causing a public health emergency that is already adversely impacting the physical and mental health of American children through, among other impacts, extreme weather events, rising temperatures and increased heat exposure, decreased air quality, altered infectious disease patterns, and food and water insecurity.<sup>34</sup> They provide that children are uniquely vulnerable to climate change impacts because of their developing bodies, higher exposure to air, food, and water per unit body weight, unique behavior patterns, dependence on caregivers, political powerlessness, and longevity on the planet.<sup>35</sup> The protection of constitutional rights of children, by following the science, is of the utmost importance and must be incorporated in all relevant EPA rulemaking and policies.

Commenter (2253-Our Children's Trust) states that they represent twenty-one youth plaintiffs, including eleven Black, Brown, and Indigenous youth, in the constitutional climate lawsuit, *Juliana v. United States*, in which the Administrator, in his official capacity, and EPA are defendants. This case asserts that, through the government's past and ongoing affirmative actions that cause climate change, it has violated the youngest generation's constitutional rights to life, liberty, property, and equal protection of the law, as well as failed to protect essential public trust resources. In this litigation, federal courts have affirmed “that the federal government has long promoted fossil fuel use despite knowing that it can cause catastrophic climate change”<sup>36</sup> and “has long understood the risks of fossil fuel use and increasing carbon dioxide emissions”.<sup>37</sup> The Ninth Circuit Court of Appeals found that there was evidence showing that the federal government was a substantial factor in causing the youth's constitutional injuries because “[a] significant portion of [GHG] emissions occur in this country; the United States accounted for over 25% of worldwide emissions from 1850 to 2012, and currently accounts for about 15 [percent].”<sup>38</sup> According to the commenter, without immediate effective action, our children and

<sup>38</sup> *Juliana v. United States*, 947 F.3d 1159, 1169 (9th Cir. 2020).

future generations will continue to suffer injury with long-lasting and potentially irreversible consequences.<sup>39</sup> They assert that these judicially-recognized facts should guide EPA's policies and practices so they can identify, and alter, those policies that exacerbate American youth's existing climate change injuries.

Commenter (2253-Our Children's Trust) adds under the 5<sup>th</sup> Amendment to the U.S. Constitution, the government is restrained from engaging in conduct that infringes upon fundamental rights to life, liberty, and property, and equal protection of the law, all of which includes a climate system that sustains human life and liberty. Under the Public Trust Doctrine, embedded in our Constitution and other founding documents, and in the very sovereignty of our Nation, U.S. residents (both present and future, i.e., posterity) have a right to access and use crucial natural resources, like air and water. The U.S. government, and its executive agencies, have fiduciary duties as trustees to manage, protect, and prevent substantial impairment to our country's vital natural resources which the government holds in trust for present and future generations.<sup>40</sup>

Commenter (2335-Private Citizen) adds recent studies have revealed the danger of living near fracking sites, most likely because of exposure to the methane gas and other GHG emitted from these sites. The commenter notes that a recent Smithsonian Magazine article discussed a study published by Environmental Health Perspective that showed a greatly increased risk of acute lymphocytic leukemia (ALL) in children and infants who live near fracking wells. They add that children near the wells were twice as likely to develop ALL as in the general child population, and babies born to pregnant women living near the wells had nearly 3 times the incidence of ALL.<sup>41</sup>

Commenter (2334-Liveable Arlington) reports that Tarrant County, has the highest rate of childhood asthma in the state and in the country. They note that almost one in five children have asthma. It also has the highest rate of birth defects recorded since 2007 of similar counties in Texas. The commenter adds that the Dallas Fort Worth region has not met federal ground level ozone standards in 30 years. They state that Barnett shale emissions contribute greatly to that.

More than 30,000 Arlington children go to public school within half a mile of wells, according to an analysis by Reveal from The Center for Investigative Reporting and up to 7600 attend private daycares within that radius. Eighty-five percent of the public-school students are children of color, and more than two-thirds live in poverty. Altogether, more than half of Arlington's public schools and day care facilities are within a half-mile of

---

Note that many researchers use the temperature targets set during the Paris Accord as a point of reference, not as a sanctioning of those levels of average planetary heating. See above as to why a 1.5°C target (hotter than today) is not lawful.

<sup>40</sup> *Juliana v. United States*, 217 F. Supp. 3d 1224, 1254 (D. Or. 2016).

<sup>41</sup> Smithsonian Magazine, "Children Living Near Fracking Sites Have an Increased Risk for Leukemia, Study Says" by Will Sullivan, August 25, 2022.

active gas production. Eight-day care centers are within 600 feet, the standard setback in Arlington.

Another commenter (2334-Liveable Arlington) similarly reports that a study from Yale University published in *Environmental Health Perspectives*, shows that childhood leukemia risks can triple in children from ages 2-7 who are exposed in utero, or after birth, to fracking emissions from distances as far away as 6,500 feet. The note that, in Arlington the setback is a mere 600 feet. The commenter provides examples where setback waivers were granted reducing the distance even further:

- Ten percent of the population in a 1,320 feet radius around the Truman site is made up of children under 5, where they would face a significantly higher cancer risk. They add that the Kookan Educational Center is a mere 2,200 feet away.
- Total Energies drilled and fracked 7 wells next door to 2 Arlington daycares in 2020-21 where they exerted great pressure on the city and succeeded in diluting a proposal to marginally expand daycare setbacks. Their openly stated reason — they wanted to drill more gas wells 280 feet from yet another preschool playground. When the city instituted a new rule requiring the use of electric rigs when drilling next to protected uses, Total Energies ignored that rule and continued operations with an emitting diesel-powered rig. The commenter states that they went undetected until their group turned them in. The commenter notes that they were allowed to continue work after a shutdown of a few weeks, and no fines were levied.

Response II-23-10: See Response II-23-7 of this Chapter.

#### ***23.2.4 Enforcement and Community Support to Mitigate Harm***

Comment: Commenters (2250-NRPE et al, 2278-NAACP Springfield, 2289-Galilee Baptists) request that the rule include ways for communities to access data and technology so that they can protect their homes and workplaces from methane pollution.

Response II-23-11: The scope of the rulemaking includes the regulation of oil and natural gas emissions sources of methane. See also Response II-23-7 of this Chapter.

With regards to data, methane emissions information is reported under the GHGRP. The GHGRP requires reporting of GHG data and other relevant information from large GHG emission sources, fuel and industrial gas suppliers, and CO<sub>2</sub> injection sites in the United States. Approximately 8,000 facilities are required to report their emissions annually, and the reported data are made available to the public in October of each year.

See also section X.C (Super Emitter Program) of the final rule preamble for a summary of the final standards for the Super Emitter Program. This program is designed to provide a transparent, reliable, and efficient mechanism by which the EPA will provide owners and operators with timely notifications of super-emitter emissions data collected by the EPA-certified third parties using the EPA-approved remote sensing technologies (e.g., satellites). Where such an event is attributable to a source regulated under CAA section 111 (NSPS OOOO, OOOOa, or OOOOb,

or a state or Federal plan implementing EG OOOOc), the responsible owner or operator will take action in accordance with the applicable regulation.

Comment: Commenter (2184-PSRCA) urges EPA to ensure the enforcement of all federal laws that address environmental justice when locating methane emitting facilities (fracked gas well drilling sites, compressor stations, and pipelines, gas power plants, and liquid natural gas (LNG) facilities; mega-landfills). Despite National Environmental Policy Act (NEPA), Department of Transportation (DOT), and Clean Air and Water Act provisions to protect these historically discriminated populations from further burdens of methane and other toxic air & water pollution, they assert that these sites continue to negatively impact environmental justice communities.

Response II-23-12: Similar comments regarding the need for enforcement of federal laws were also provided on the November 2021 Proposal, see Volume I, Chapter 23 (Miscellaneous Other Comments), subsection 23.15 (Enforcement), Response I-23-64, for response to this comment.

Comment: Commenter (2203-Ceres) recommends, considering the strong public health, environmental and climate interests served by this rulemaking, that any final rule and implementation strategy rely principally on ongoing and careful monitoring and rigorous enforcement, rather than voluntary compliance by the regulated entities.

Response II-23-13: See Response II-23-7 of this Chapter.

Comment: Commenter (2334-Liveable Arlington) states Arlington is going through another fracking boom in the Barnett shale. According to the commenter, French energy giant Total Energy and others plan to drill more than 100 new gas wells here, more than 20 in Arlington alone in the last 6 months. According to the commenter, they are doing it very callously, with horrific media reports of air pollution, sick neighbors, and in one recent instance an entire neighborhood being sprayed with “produced water.”

Commenter (2334-Liveable Arlington) continues that Arlington approved 6 new fracked methane gas wells at the Truman site behind closed doors without notifying residents or holding a public hearing because of a prior drilling permit. The site is surrounded by a large apartment complex, 2 mobile home communities, and many homes. It is located about 1,000 feet from the AISD Athletics Center and about 1,250 feet from the AISD Center for Visual and Performing Arts.

Commenter (2334-Liveable Arlington) adds according to EPA’s EJ Screening tool, in a 1,320-foot radius around the site, 83% of the residents are people of color, 54% do not have a high school diploma, 67% are low income, 46% are linguistically isolated, and 10% of the residents are children under 5.<sup>42</sup> According to our EPA EJ Screen analysis, the community around Truman is already:

- In the highest percentile for Air Toxics Cancer Risk (95-100<sup>th</sup> percentile).

---

<sup>42</sup> See the table accompanying this letter.

- In the 80-90<sup>th</sup> percentile for the Air Toxics Respiratory Hazards Index.

The commenter (2334-Liveable Arlington) argues that the permitting of 6 new gas wells will compound all the existing pollution, health, and economic burdens this neighborhood already faces, making this an egregious case of environmental injustice. Since the initial permit was issued more than 10 years ago, they note that hundreds of peer reviewed published research studies have linked fracking to serious health impacts.

The commenter (2334-Liveable Arlington) adds that, in 2020, the city council denied Total Energy a permit to drill behind a preschool at the AC360 site where all the enrolled children are black and Latino because of environmental justice concerns. Total Energy reapplied last year and won a reversal of the NO vote after putting intense pressure on the city council to ignore city permitting rules. Soon after, the commenter reports that, while drill site workers were opening tank hatches at the site, preschool staff in the playground became ill. A Texas Commission of Environmental Quality (TCEQ) investigation found nothing, however, a week later staffers once again got sick during another operation. As the city was getting ready to approve more gas wells at the site, the commenter's group had to file an emergency lawsuit to get the permit denied.

Commenter (2334-Liveable Arlington) expresses concern that there is no air monitoring done by the TCEQ, the state agency charged with air quality permits and regulation, or by the city of Arlington. Releases, venting of methane and dangerous toxics go on unreported, next to large numbers of children. The commenter asks the EPA to refer to this Optical Gas Imaging (OGI) video of compressor station pollution at the DWG site in Arlington:

<https://www.youtube.com/watch?v=DQILTIDvmH4>. Despite years of citizen and watchdog complaints to TCEQ, the commenter complains that no improvements have occurred. The commenter notes that there is a high school across the street, and many other schools within a half mile of this site.

Response II-23-14: The EPA acknowledges the commenter's concerns. As discussed in section II.A (Purpose of the Regulatory Actions) of the final rule preamble, the final rulemaking takes a significant step forward in mitigating climate-destabilizing pollution and protecting human health by reducing GHG and VOC emissions from the oil and natural gas industry, specifically the Crude Oil and Natural Gas source category. These mitigations are based on proven, cost-effective technologies already required by prior EPA regulations or states' regulations or deployed by industry leaders to reduce this dangerous pollution. The final rules will also encourage the deployment of innovative technologies that currently exist to rapidly and cost-effectively detect and reduce methane pollution and promote further innovation that is already under way to find even more efficient and effective ways to mitigate this pollution. Because methane is the main component of natural gas, the rules also result in more saleable product. The oil and natural gas industry is the United States' largest industrial emitter of methane. Human emissions of methane, a potent GHG, are responsible for about one third of the warming due to well-mixed GHGs, the second most important human warming agent after carbon dioxide. The EPA is finalizing the actions described in the preamble to the final rule in accordance with its legal obligations and authorities following a review directed by EO 13990, "Protecting Public Health and the Environment and Restoring Science to Tackle the Climate Crisis," issued on January 20, 2021.

See also section XVI.F (What analyses of environmental justice did we conduct ?) of the final rule preamble for a summary of the environmental justice analyses we conducted in support of the final rules, including environmental justice and the impacts of climate change, impacts of climate change on indigenous communities, and environmental justice impacts of ozone exposure due to oil and natural gas VOC impacts.

See also Volume I, Chapter 23 (Miscellaneous Other Comments), subsection 23.15 (Enforcement), Response I-23-64, for a response to comments provided on the November 2021 Proposal regarding the need for enforcement of federal laws.

## **23.3 Performance of Existing and Previous Emissions Mitigation Programs**

### ***23.3.1 Previous Oil and Natural Gas Sector Federal Rule Performance***

Comment: Commenter (2168-INOGA) inquires whether the prior rule makings have been successful at reducing emissions, as claimed during the development of the regulation? Further, they ask, if EPA's rules failed to meet the advertised expectations, why is this current rule being promulgated? The commenter believes that the EPA should be required to show the data from prior rule makings, illustrating the expected emissions reductions and the actual emissions reductions prior to promulgating more significant regulations on the oil and gas industry. The commenter asks whether the actual performance data justify the actions, or is the intent of this rulemaking to increase the compliance burdens (i.e., operating costs) on the oil and gas industry?

Response II-23-15: In response to the commenter who inquires whether prior rulemakings have been successful at reducing emissions, while the previous rulemakings have been successful at reducing emissions, greater emissions reductions of VOC and methane emissions are needed. As discussed in the final rule preamble, these final actions stem from the EPA's authority and obligation under CAA section 111 to directly regulate categories of new stationary sources that cause or contribute to endangerment from air pollution and to promulgate EG for states to follow in regulating existing sources (designated facilities) in the source category. See section II (Executive Summary), subsections A (Summary of the Major Provisions of this Regulatory Action) and B (Purpose of the Regulatory Actions), and section IV (Statutory Background and History) of the final rule preamble for support for the development of the NSPS OOOOb standards and EG OOOOc presumptive standards.

In response to the comment as to whether the intent of this rulemaking is to increase compliance burden on the industry, see responses to comments in Volume II, Chapter 20 (Impacts of the Proposed Rule), section 20.3.3 (Energy Impacts) for EPA's response to other comments received that express concern over the impacts of the proposal on energy production and costs. See also sections XVI.C (What are the cost impacts?) and D (What are the economic impacts?) of the final rule preamble where the EPA presents a summary of the results of the cost and economic impact and distributional analyses conducted.

### ***23.3.2 EPA Voluntary Programs***

Comment: Commenters (2308-NSWA, 2320-APGA) support EPA's voluntary, incentive-based program known as the Methane Challenge. The commenter provides that it's a partnership between EPA and oil and gas companies to bring greater transparency and accountability to methane emission reduction.

Commenter (2308-NSWA) also supports EPA's Natural Gas STAR program. Citing the EPA's website:

Natural Gas STAR Program provides a framework for Partner companies with U.S. oil and gas operations to implement methane reducing technologies and practices and document their voluntary emission reduction activities. By joining the Program, Partner companies commit to evaluate and implement cost-effective methane emission reduction opportunities and communicate and share that information across their corporation and with the Natural Gas STAR Program.

The commenter (2308-NSWA) suggests that the program's accomplishments speak for itself. The commenter cites the EPA's website:

Each year, Partners submit annual reports documenting their previous year's methane emission reduction activities. Since the inception of the Program, as of late 2021, Partners have eliminated 1.72 trillion cubic feet (Tcf) of methane emissions by implementing 153 cost-effective technologies and practices.

Response II-23-16: These comments are supportive comments; as such, no response is required.

### ***23.3.3 Oil and Gas Company Emissions Mitigation Efforts***

Comment: Commenter (2248-NDPC) states that given the many advancements in the oil and natural gas industry (e.g., equipment, drilling, completions, processing, technologies for sampling and analysis, and for controlling emissions) in the last decade alone, the commenter suggests that the EPA commission objective technical studies to explore and understand the 2023 oil and natural gas industry and not rely on technical documents written in the 1980s and 1990s.

Commenter (2179-KIOGA) states that the small businesses that make up the independent oil and natural gas industry recognize the importance of environmentally sound regulations to manage industry emissions, including methane. The commenter supports voluntary efforts by industry to reduce methane emissions. The commenter reports that their members are making constant improvements to the technology being used in the field to reduce, measure and report on emissions. The commenter states that they will continue to work with the Biden Administration as it considers initiatives to reduce methane and other GHG emissions.

Commenter (2172-KOGA) disputes that the oil and natural gas sector is the largest industrial emitter of methane as the EPA states. The commenter states that EPA's own data shows the reduction in methane and VOC emissions over time, with (post-2016) and without (pre-2016)

regulations imposed by EPA and that the data tables in prior rule makings do not support the EPA's claim that the oil and natural gas sector is the largest industrial emitter of methane. The commenter provides that data collected from the EPA's website shows that "waste" is the largest industrial emitter of methane in the U.S. (2021 data). The commenter notes that using the database provided by the EPA and filtering for only methane emissions, the "waste" category emits almost 93 million metric tons of CO<sub>2</sub>e verses the petroleum and natural gas systems segment at less than 71 million metric tons of CO<sub>2</sub>e. Reference: <https://ghgdata.epa.gov/ghgp/main.do>.

The commenter (2172-KOGA) also provides that, according to the Global Methane Initiative (GMI), the oil and natural gas sector is not the largest industrial emitter (See Figure 1 (of their comment letter): Emissions by Sector in million metric tons of carbon dioxide equivalent (MMTCO<sub>2</sub>e)). [Table 1 of their comment letter lists sources of methane emissions, where "waste" is listed as a greater contributor to methane emissions than the oil and natural gas sector. However, no values are shown. (See Reference: <https://www.globalmethane.org/methane-emissions-data.aspx>).]

Commenter (2163-EOS Federated Hermes) states many oil and gas companies have already demonstrated the feasibility of substantially reducing methane emissions using existing technologies at a reasonable cost. The commenter reports that members of the Oil and Gas Climate Initiative (OGMP) 2.0, including a range of large and small, publicly-traded and privately-owned companies such as ConocoPhillips, Occidental Petroleum, EQT, Devon, Pioneer, EOG, Diversified Energy, PDC, Crescent Energy, Civitas, Jonah Energy, TRP, as well as Cheniere<sup>43</sup>, Shell, BP, Equinor, Total Energies, Repsol, Eni, Petrobras, and non-signatories such as Chevron, Exxon and many others, have voluntarily committed to reducing the collective average methane intensity of aggregated upstream oil and gas operations to well below 0.20 percent by 2025.<sup>44</sup> However, methane emissions of many U.S. companies are much higher than 0.20 percent and only one third of all U.S. operators currently have plans to reduce methane and flaring emissions.<sup>45</sup> The commenter supports strong regulations to provide accessibility to emissions reductions technologies and accelerate industry-wide methane reduction. They suggest that strong regulations will benefit companies, the economy, the country, and the financial system.

Commenter (2308-NSWA) states that they support the efforts of the Environmental Partnership, which is an oil-and-gas-companies-led effort that focuses on solutions that are technically feasible, commercially proven, and will result in significant methane emission reductions. The commenter provides that efforts are focused on addressing blowdowns, venting, leak detection and repair (LDR), and liquids unloading.

<sup>43</sup> Partners-OGM Partnership [<https://www.ogmpartnership.com/partners>].

<sup>44</sup> An Investor's Guide to the Oil and Gas Methane Partnership 2.0. [<https://www.globalmethane.org/resources/details.aspx?resourceid=5197#:~:text=An%20Investor%E2%80%99s%20Guide%20to%20the%20Oil%20and%20Gas,guidance%20to%20investors%20on%20the%20OGMP%E2%80%99s%20reporting%20framework>].

<sup>45</sup> Dallas Fed Energy Survey [<https://www.dallasfed.org/research/surveys/des/2021/2104.aspx>].

Similarly, commenter (2241-UDNR) states that the oil and gas industry is already making strides to reduce gas emissions voluntarily. For example, the American Petroleum Institute (API) has formed “The Environmental Partnership,” which, as of 2021, represents 100 companies that make up more than 70 percent of the U.S. onshore oil and natural gas industry, reflecting the growing commitment to driving innovation, sharing best practices, and increasing transparency to reduce methane emissions in every major U.S. basin. In 2021, the commenter reports that the Environmental Partnership continued to make progress across all six environmental performance programs – including reducing flaring, replacing gas-driven pneumatic controllers with low- or zero-emitting devices, and reducing leak occurrence rates to 0.05 percent among the nearly 100,000 sites surveyed.

According to the 2022 Annual Report of the API’s Environmental Partnership the 100 participating oil and natural gas companies, the commenter (2241-UDNR) provides that in efforts to detect and repair leaks in the year 2021 alone, combined to do more than 345 million component inspections, conduct more than 460,000 leak detection surveys at over 90,000 sites and found a leak occurrence rate of only 0.05 percent. The commenter adds that the same companies replaced or removed from service over 22,400 gas-driven pneumatic controllers and installed over 4,500 zero-emission pneumatic controllers at new sites. More than 1,700 high-bleed pneumatic controllers were replaced, retrofitted, or removed from service and 60 of the 100 companies participating in this partnership no longer have high bleed pneumatic controllers in their operations. During 2021, the companies monitored more than 39,000 manual liquids unloading events and emission reduction practices were implemented during more than 7,800 pipeline blowdowns. Rod packing changes were made on over 3,200 reciprocating compressors and emissions reduction practices utilized on more than 1,500 compressor sites. Data from 2018 to 2021 industry efforts are even more impressive: More than 700 million component inspections were performed; 1.2 million leak detection surveys conducted; more than 51,000 gas-driven controllers replaced; and more than 10,000 zero-emission pneumatic controllers were installed.

The commenter (2241-UDNR) adds that companies participating in the API’s Environmental Partnership program have also been doing their part to reduce the flaring of natural gas. Since the launch of the flare management program in 2020, the Partnership has advanced best practices to reduce flare volumes, promote the beneficial use of associated gas and improve flare reliability and efficiency when flaring is necessary. To track progress, participants in the program annually report data to calculate flare intensity, a measurement of flare volumes relative to production. The annual report reviews flaring trends and reduction efforts and participants collaborate to share information on flare management programs that includes best practices and utilization of innovative technologies to reduce flaring intensity. The commenter reports that there was a 40 percent increase in the number of participating companies in the flare management program in 2021. These companies represent 62 percent and 40 percent of total U.S. oil and natural gas production, respectively. Including new company participants, the commenter reports that there was a 45 percent reduction in flare intensity and a 26 percent reduction in total flare volumes from the previous year.

In addition to the successes of the API’s Environmental Partnership, the commenter (2241-UDNR) notes that another program worth pointing out is the Utah Petroleum Association’s “Latch the Hatch” program that has voluntary commitments from several operators in Utah to

aggressively detect and mitigate leaks from wells and production facilities. The commenter reports that the results of last year's efforts were reported at the November 2022 Uinta Basin Oil and Gas Collaborative Meeting held in Duchesne, Utah. A video recording of that meeting was made and can be viewed on YouTube at the following link:

<https://www.youtube.com/watch?v=yRpGwrnsMpo>. The commenter states that a panel discussion of companies participating in "Latch the Hatch" can be viewed at time point 1:48:42, and they emphasize that the reported results are impressive.

Response II-23-17: The EPA applauds the effort and results that the oil and natural gas industry have achieved.

### ***23.3.4 State Agencies***

Comment: Commenter (2329-Sierra Club LSC) reports that their main environmental agency, the Texas Commission on Environmental Quality (TCEQ), does not generally require leak detection and repair (LDAR) for most permits, and generally only regulates VOC emissions in nonattainment areas. The commenter provides that an estimated 5 percent of permits in the analysis currently are requiring LDAR for oil and gas operations, meaning 95 percent are not. While they recently updated standards on VOCs in non-attainment issues, the commenter states that they fall far short of protecting communities, and do not include real methane standards for issues like leaking storage tanks. That is why they believe the proposal is so important.

Commenter (2329-Sierra Club LSC) adds, as can be seen from comments filed by the TCEQ and Texas Railroad Commission, there is opposition from the state agencies to the new proposed rule. Thus, the commenter states they will need help not only in implementing a strong protective rule, but oversight in its eventual implementation. The commenter requests that the EPA work with Texas agencies and industry to make sure that the rules are clear and that the timelines can be implemented. The commenter contends that, although there will be opposition (political) they need EPA's help to overcome that opposition and they are counting on the EPA to assure the job gets done.

Commenter (2334-Liveable Arlington) states that they need better protections to safeguard themselves, their families, and future generations. They contend that their local government and the state of Texas and the TCEQ have failed them. They assert that the rules and monitoring systems required for urban drilling in places like Arlington and its neighboring cities in the Barnett shale must be stringent, with severe penalties for non-compliance. Given what global fossil fuel giants, their city and state, subject their children to every day, the commenter asked for the following when methane rules were proposed last year by the EPA:

1. 24-hour air monitoring at the fenceline for new and existing wells and drilling infrastructure like compressor stations within 1500 feet of homes, schools, preschools, daycares, and medical centers. When air monitors show elevated levels of HAP, it should automatically trigger LDAR.
2. Immediate deployment of the best available emissions control technology.
3. Monthly Leak Detection and Repair for all new and existing wells.

4. End the wasteful and dangerous practice of the routine flaring (lit and unlit) of natural gas at oil and gas facilities.
5. Creating emissions monitoring programs with community involvement and data reported in real time.

Response II-23-18: See Response II-23-14 of this Chapter. In response to comments that the EPA should end wasteful flaring, the EPA, as a result of information provided through the public comment process, is finalizing revisions to the proposed requirements to limit routine flaring of associated gas. During the comment period, the EPA received extensive information regarding the availability and cost-effectiveness of alternatives to routine flaring, state-level requirements to limit or prohibit routine flaring, and commitments that owners and operators have already made voluntarily to phase out routine flaring in the near future. Based on this information and the EPA's updated BSER analysis, the EPA is finalizing requirements to prohibit routine flaring of associated gas from newly constructed wells that are developed after the effective date of the final rule.

Comment: Commenter (2401-State of Wyoming) believes Wyoming has successfully balanced conservation and exploitation of its minerals and is the best suited to be the environmental regulator. They report that they are leaders in regulating emissions from oil and gas facilities across the state. Wyoming's regulations are tried and tested and represent the most efficient process for protecting our environment. Specific to this proposed rule, Wyoming's DEQ and WOGCC are charged with preventing the waste of oil and gas and have authority over drilling, flaring, operations, production, and permitting. Wyoming has an extensive monitoring and inspection program for all oil and gas wells. While not specifically addressed in this proposal, the commenter states that it is important to note that Wyoming has been dedicated to the plugging and abandonment program for orphan wells, where Wyoming leads the nation. Even without the recent influx of federal funding, they report that all their known remaining orphan wells will be plugged in the near future.

Response II-23-19: The EPA acknowledges and commends Wyoming in their dedication to the plugging and abandonment program for orphan wells.

## **23.4 Public Comment Period/Scope**

### ***23.4.1 Public Comment Period Adequacy (i.e., Request for Extension, Inadequate Time Provided)***

Comment: Several commenters (1663-WVOAG, 1673-WEA, 1583-ODEQ, 1586-NACAA, 1587-DGCC, 1588-API, 1589-PCPBC, 1592-UPA, 1590-AXPC, 1591-GPAMA, 1594-BH, 1595-PW, 1604-PAE, 2200-NUEO, 1612-NDPC, 1619-IPANM, 2020- Mississippi Department of Environmental Quality (MDEQ), 2220-WDEQ, 2227-WEA, 2237-ICND, 2238-SOOGA, 2246-IPAA, 2257-MOGA, 2294-OOGA, 2297-Petro-Vest, 2321-AED, 2322-ADEE, 2330-KDAQ, 2437-MEC) state that the timeframe for comment was inadequate, citing several reasons for why they believe a longer comment period was warranted:

- The supplemental proposal comment period includes three major holiday periods.
- The proposed rule is one of the most complex and expansive regulatory programs the EPA has ever proposed.
- The proposed rule included over 500 pages with an additional 400 pages of regulatory impact analysis and 150 pages in *Federal Register*.
- Vagueness over the intention and focus of proposed actions and regulations made providing adequate comment and response a daunting task given the short response time.
- Far reaching impacts on the industry as well as tribal, state, and local authorities
- The proposed regulation will cover roughly 700,000 sources not previously subject to air quality regulations with an extremely high number of sources in certain states.
- December 2022 supplemental proposal, when finalized, will set in motion the process of controlling approximately 700,000 to one million sources, with a large majority of which have not been previous controls.
- A disproportionate effect on states, with few states have significant impact of number of sources.
- Several hundred pages of the supplemental proposal and supporting documents identifies key changes from the November 2021 proposal.
- The first look at the supplemental proposal was in mid-November 2022, and the supplemental regulations were not published in the *Federal Register* until December 6, 2022.
- Supporting documentation such as RIA and regulatory text not provided with original proposal.
- The proposal is well beyond the EPAs appropriate statutory authority and usurps the role of the states.
- The proposed rule affects a very large number of stakeholders.
- There are at least 142 areas/topics for which the EPA is soliciting comment.
- The regulatory and administrative burden on state authorities and small business across the country is significant.
- States have limited resources for review and analysis of such a large and far-reaching proposal.
- The proposal has potential repercussions on the state's approach to permitting, compliance monitoring, regulatory enforcement, and emissions inventory reporting.
- The rule poses an extraordinary challenge to the states and tribes' air program budget and resources as it will require legal interpretation, evaluation of state regulations and effect of state energy needs, analysis and potentially modeling of impacted sources, evaluation of emission inventories, consultation with stakeholders, and examination of compliance and enforcement needs.
- The new calendar year is a critical time in many states and for natural gas operators to compile, analyze and then report emissions data regulatory agencies.
- The EPA has not suggested that these changes are an emergency necessity, and no statutory mandate or court order would make it one.
- Neither the EPA nor any other party would be prejudiced by an extension
- There have been problems with documentation provided in the docket.
- The proposal includes requirements for a new Super Emitter Response Program. The commenters contend it will take additional time and effort to develop a better estimate of the cost of control and monitoring using a more accurate statistical approach than what the EPA

appears to have addressed in this proposal; in addition to assessing remaining useful life and other factors for the Program. The commenters contend that program alone warrants an extension of the comment period.

- Commenters state that the EPA is forcing an arbitrary and unwarranted rulemaking timeline while providing no justification for not extending the comment period.
- The EPA must provide for real and substantive review of the proposed regulations to prevent unfairness in the process and what they believe would be a pre-ordained sham result.
- The commenters note the proposal requirements and comment period overlap with many other interrelated regulatory actions:
  - Implementing regulations for Section 111(d) of the Clean Air Act.
  - An important revision to the definition of “Waters of the United States” under the Clean Water Act.
  - The EPA’s Request for Information on the Inflation Reduction Act (IRA) Methane Emissions Reduction Program (MERP).
  - Bureau of Land Management (BLM) Waste Prevention, Production Subject to Royalties, and Resource Conservation rule.
  - Federal Implementation Plan for Oil and Natural Gas Sources on the Uintah and Ouray Indian Reservation (U&O FIP).
  - State actions such as Pennsylvania’s new regulatory scheme regarding volatile organic compounds (VOC) for existing unconventional natural gas sources, to be published and take effect on December 10, 2022.

Commenter (2401-State of Wyoming) is concerned that EPA largely ignored the comments that were submitted by the Wyoming Department of Environmental Quality (WDEQ) on January 31, 2022, and has not engaged in meaningful dialog with Wyoming state agencies. The commenter calls to attention, for example, that DEQ submitted a 30-day comment period extension request for the supplemental proposal on December 14, 2022. EPA never responded to WDEQ’s request. Furthermore, they add that the State of Wyoming was never consulted during the development of the December 2022 supplemental proposal — The commenter understands that many other states have expressed this same concern.

Commenter (2257- MOGA) states that more time was necessary to address the concerns and comments of the participating Small Entity Representatives (SERs) submitted on July 13, 2021, and following the initial Small Business Advocacy Review (SBAR) panel discussion. The commenter’s small businesses do not have sufficient staff dedicated to understanding the proposed rules and regulations.

Another commenter (1590-AXPC) notes that the EPA has often granted extended timeframes to allow for more thorough public comment. For example, for the original NSPS OOOO proposal in 2011, the commenter provides that EPA extended the comment period to 90 days, and in one of the few similar examples of the EPA also proposing existing source guidelines under CAA section 111(d) (the Clean Power Plan (CPP)), the EPA first proposed 120 days of public comment and later extended public comment to nearly six months.

Commenter (2246-IPAA) states that the EPA is proposing to change regulations as they pertain to the oil and gas industry specifically while simultaneously proposing to make changes more

generically for CAA section 111(d) at 40 CFR, Part 60, subpart Ba. While the potential for “moving the goal posts” for states is great, the commenter believes that the EPA was unwilling to grant states and stakeholders even an additional two weeks to comment and coordinate the close of the comment period on two rulemakings that are clearly related and intertwined. The commenter continues that the EPA’s response to stakeholder’s request for additional time was very much akin to a parent’s response to a child questioning the parent’s directive (i.e., “because I said so”). While the commenter believes that may be an acceptable response from parent to child, the commenter questions whether such a decision, in and of itself, is not arbitrary and capricious.

Several commenters specifically request that the EPA extend the comment period as follows:

- Several commenters (1586-NACAA, 1599-WDEQ, 1600-AAPCA, 1623-PDEP, 2237-ICND, 2310-MDEQ) requests at least a 30-day extension.
- Several commenters (1583-ODEQ, 1588-API, 1590-AXPC, 1591-GPAMA, 1592-UPA, 1593-PAO, 1601-TCEQ, 1602-TRRC, 1604-PA, 1606-UIT 1614-AOGA, 1630-INGAA, 1645-OOGA, 1663-WVOAG, 1673-WEA, 2020-MDEQ, 2220-WDEQ, 2225-WSARC, 2227-WEA, 2257- MOGA, 2288-NDDEQ) request not less than a 60-day extension to the comment period. Specifically, the States of West Virginia, Alabama, Alaska, Arkansas, Georgia, Idaho, Indiana, Kentucky, Louisiana, Mississippi, Montana, Nebraska, North Dakota, Ohio, Oklahoma, South Carolina, Tennessee, Texas, Utah, and Wyoming request a 60-day comment period extension.
- Several commenters (1582-MSD, 1587-DGCC, 1589-PCPBC, 1594-BH, 1595-PWE, 1612-NDPC, 1619-IPANM, 2322-ADEE) request a 90-day extension of the comment period.
- Several commenters (1598-KEEC, 2170-WGOC, 2204-LIP, 2211-LER, 2223-TAEP) request an unspecified extension of the comment period.

Commenter (2403-PAO) states they (and many other entities) requested a 60-day comment period extension as they believed the 60-day comment period was unreasonable for such a complex and lengthy rulemaking. In response to the EPA’s November 2021 proposal, they requested that the EPA’s forthcoming proposed supplemental rule provide at least a 120-day comment period. That did not occur. The commenter requests that EPA provide rationale and justification for limiting the comment period to 60-days.

Response II-23-20: The EPA did not grant an extension to the comment period on the December 2022 Supplemental Proposal.

Comment: Commenter (2294-OOGA) states that it is their understanding that the EPA, in recent conversations with other national and regional industry trade groups, has indicated that it will consider comments submitted after the February 13, 2023, deadline. The commenter urges the EPA to do so, but questions why the U.S. EPA would not do so formally via publishing a notice of an extended comment period. Notwithstanding, the commenter notes that if the EPA considers any comments submitted after the February 13, 2023, deadline, it must consider all comments submitted after the deadline. With that, to the extent that IPAA, AXPC or API submit comments after the February 13, 2023, deadline, the commenter supports, adopts, and incorporates by reference those comments herein.

Response II-23-21: The EPA considered all comments after the February 13, 2023, deadline up until September 20, 2023. While the EPA was not intent on doing this, some of the information obtained after the comment period closed as an outgrowth of meetings with stakeholders was accommodated and we therefore reviewed all late comments up until the date stated above.

Comment: Several commenters (1590-AXPC, 2248-NDPC, 2428-API, 2248-NDPC) specifically state that they were unable to provide a complete set of comments due to the time comment period time constraints. Commenter (2248-NDPC) notes that they are unable to submit comments for centrifugal compressors and sweetening units. According to commenter (2428-API), much of the information the EPA requested, as well as additional information that the commenter wanted to provide, is not included in their submitted comments due to what they believe are arbitrary and unnecessarily imposed timing constraints of the comment period for the December 2022 supplemental proposal.

Commenter (2248-NDPC) states that based on the extent of the proposals and the haste at which it is being pushed through the system, their comments have been necessarily limited in scope and detail. The commenter requests that for future rulemakings that the EPA be more proactive in their industry engagement so they can be better prepared before publishing proposed rules, and not be bundled with multiple proposed regulatory actions to give the public and regulated industry the time to participate efficiently and effectively. The commenter notes that publishing proposed actions not yet defined, along with a solicitation for the feedback on the addition of regulated sources, creates regulatory and financial uncertainty for the regulated community. The commenter asserts that silence by the commenter on any part of this proposal should not be interpreted as agreement or support. According to the commenter, time constraints and the complex nature of these rules have impacted their ability to respond to every piece of this proposal.

Response II-23-22: In response to commenters that state that they were unable to provide a complete set of comments due to comment period time constraints, the public also had access to pre-publication versions of the preamble and regulatory text for the December 2022 Supplemental Proposal on EPA's website.

The EPA has also engaged with pertinent stakeholders regarding their concerns throughout the rulemaking process. Stakeholders have included, but are not limited to, industry, small businesses, tribal nations, and communities most affected by, and vulnerable to, the impacts of the rule. See discussion section VII (Summary of Engagement with Pertinent Stakeholders) in the final rule preamble.

Comment: Commenter (1665-EEN) and its pro-life community have been pursuing methane reduction from the oil and gas sector since 2015. The commenter states that children having been waiting long enough under the clouds of toxins, VOC's and methane that threatened their health and lives. According to the commenter, there is no need to further delay action, and they strongly oppose any attempt to extend the comment period past the February 13, 2023, deadline. According to the commenter, extending the deadline would be an immoral affront to our children and an injustice to all Americans. The commenter recommends that, following the close of the comment period, EPA must act quickly to consider all public comments, strengthen the final rule

beyond the provisions in the supplemental proposal and promulgate a final rule under CAA section 111 by early summer 2023.

Response II-23-23: The EPA did not grant an extension to the comment period on the December 2022 Supplemental Proposal.

#### ***23.4.2 Scope of Public Comments Submitted Under the December 2022 Supplemental Proposal***

Comment: Commenters (2308-NSWA, 2446-IPAA) state that the EPA indicates in the proposed rule that it “is not reopening for comment any aspect described in the November 2021 proposal that the EPA is not proposing to substantively address or update in this supplemental proposal.” The commenters state that they believe this is peculiar – if not contrary to the Administrative Procedure Act (APA). Furthermore, they add that no legal basis or justification for taking such a position is provided.

The commenters (2308-NSWA, 2446-IPAA) question whether the EPA has the legal authority to pick and choose what aspects of the November 15, 2021, publication to “reopen” for comment. The commenters contend that the appropriateness/legality of such position is even more in question when no regulatory language was provided in the original “proposal.” They inquire: How is it not arbitrary and capricious for the EPA to tell stakeholders what portions of a “proposal” is or is not open for comment?

Commenter (2446-IPAA) suggests that the EPA cannot have it both ways. If the EPA maintains its position that it has the authority/ability to choose what portions of a “proposal” are reopened for comment, then the commenter believes that the EPA should be precluded from responding to comments provided on the original “proposal” that were not addressed in a response to comment document placed in the docket prior to or concurrent with the supplemental proposal or addressed in the supplemental proposal preamble. The commenter states that various legal and technical arguments were raised by them and other trade associations, and certain states. In the December 2022 supplemental proposal, the EPA has elected to address some of the comments and has failed to address others while also indicating only certain issues would be open for additional comment during the limited 60-day comment period on the December 2022 supplemental proposal.

Response II-23-24: The EPA has considered and is responding to all timely comments received on the November 2021 and December 2022 proposals addressing the proposed requirements from both notices.

### **23.5 Public Hearing Allotted Time**

Comment: Commenters (1608-LA, 1681-PC50) request additional time be allotted at public hearings. According to the commenters, by December 14, 2022, at noon, all the slots for January 10, 11, and 12, 2023, were full. The commenters state that with almost 3 weeks left in the registration period, many people will find they have missed the opportunity to comment. While they understand that there is more time for written comments, they state that many people are

unable to navigate the websites for the EPA or Regulations.gov and find written comments difficult.

Response II-23-25: The EPA held a virtual public hearing January 10, 2023, through January 12, 2023, to provide the public the opportunity to present comments and information on the Agency's proposed updates to NSPS and EGs to reduce methane and other harmful pollution from the oil and natural gas industry. It is worth noting that the virtual public hearing was originally scheduled as a two-day hearing but due to the public's overwhelming interest, EPA extended the hearing an additional day. Over the course of three days, nearly 300 speakers (roughly 100 speakers per day), from members of the public either representing themselves or speaking on the behalf of one or more organization or agency, provided oral testimony.

Over 517,400 public comments were received on the December 2022 Supplemental Proposal. The EPA Docket Center consolidated mass mail campaigns, form letters and petitions into single DCNs, resulting in over 2,200 posted comments. Each of these comments were reviewed and significant comments relevant to this action have been considered – *i.e.*, comments not considered are duplicates, and comments withdrawn or unrelated/non-applicable to the December 2022 Supplemental Proposal.

## **23.6 Regulatory Text**

Comment: Commenters (2168- INOGA, 2172-KOGA) state that regulatory text must be provided for review and comment prior to actions being required by the oil and gas industry. The commenters note that the December 2022 supplemental proposal is like the November 2021 proposal, with only preamble text released. The commenters contend that the regulated community does not know what the real, or full extent of the regulation will be until the regulatory text has been released. The comments provided on the December 2022 supplemental proposal are based on their understanding of how the regulation will impact their businesses, only based upon reading the preamble and not reading regulatory text that will be used to consider compliance and for enforcement hearings. The commenters believe that the regulatory text should be released for the regulated community to review and provide comment prior to actions being required by the oil and gas industry. They add that they view this release of the preamble as another Advanced Notice of Proposed Rule Making, where EPA is collecting comments in preparation for releasing the formal regulatory code for review and comment by industry.

Response II-23-26: The EPA released proposed regulatory text with the December 2022 supplemental proposal, reflecting the proposed new subparts NSPS OOOOb and EG OOOOc, as well as the proposed Appendix K. The December 2022 supplemental proposal preamble directed the public to memoranda to the docket for each subpart that could be found at Docket ID No. EPA-HQ-OAR-2021-0317, and which supplemented the redline versions of NSPS OOOO and NSPS OOOOa provided in the November 2021 proposal (Docket ID Nos. EPA-HQ-OAR-2021-0317-0095 and EPA-HQ-OAR-2021-0317-0097). The EPA also posted the proposed regulatory text to the EPA's website at <https://www.epa.gov/controlling-air-pollution-oil-and-natural-gas-industry/epa-proposes-new-source-performance> (for NSPS OOOO, NSPS OOOOa, and Appendix K), and at <https://www.epa.gov/controlling-air-pollution-oil-and-natural-gas->

industry/epa-issues-supplemental-proposal-reduce (for NSPS OOOOb, EG OOOOc, and revised Appendix K).

The commenter makes a vague assertion that the regulatory text should be released for the regulated community to review and provide comment prior to actions being required by the oil and gas industry, but the commenter does not claim any actual difficulty in finding or commenting on the proposed rule language. The EPA's approach was not prejudicial to the commenter or any member of the public. The notice of proposed rulemaking clearly explained the proposed changes to the NSPS regulations and the proposed EG. In addition, as stated in the notice, the EPA publicly provided in the rulemaking docket and on EPA's website a memorandum with the redline strikeout version of subparts containing the edits to the CFR that would be necessary to incorporate the proposed changes.

The proposals met all APA and CAA notice-and-comment requirements. Nothing in the APA or the CAA, requires EPA to publish proposed rule text in the *Federal Register*. The requirement to publish a "notice of proposed rulemaking" is not a requirement to publish "proposed rule text." CAA section 307(d)(3) specifies the required elements of a "notice of proposed rulemaking," and "proposed rule text" is not a required element. The elements that are required to be included in the notice of proposed rulemaking (a "statement of basis and purpose," "a summary of . . . the major legal interpretations and policy considerations underlying the proposed rule, etc.") were included in the proposed rulemakings.

The APA does not require publication of proposed rule text in the *Federal Register* either. Section 553(b)(3) of the APA provides that a notice of proposed rulemaking shall include "either the terms or substance of the proposed rule or a description of the subjects and issues involved." Thus, the APA clearly provides flexibility to describe the "subjects and issues involved" as an alternative to inclusion of the "terms or substance" of the proposed rule. See also *Rybachek v. EPA*, 904 F.2d 1276, 1287 (9th Cir. 1990) (EPA's failure to propose in advance the actual wording of a regulation does not make the regulation invalid where EPA's discussion of the regulatory provisions "clearly describe[s] 'the subjects and issues involved.'").

Although in the past the EPA has at times published proposed amendatory regulatory text, the EPA's practice has varied. See, e.g., Hazardous Air Pollutants: Proposed Regulations Governing Constructed, Reconstructed or Modified Major Sources, 59 FR 15504 (April 1, 1994) ("The proposed regulatory text is not included in the Federal Register notice, but is available in Docket No. A-91-64 or by request from the EPA contact persons designated earlier in this note. The proposed regulatory language is also available on the Technology Transfer Network (TTN), of EPA's electronic bulletin boards."); Federal Standards for Marine Tank Vessel Loading and Unloading Operations and National Emission Standards for Hazardous Air Pollutants for Marine Tank Vessel Loading and Unloading Operations, 59 FR 25004 (May 13, 1994) ("The proposed regulatory text and other materials related to this rulemaking are available for review in the docket."). Even when we do include the proposed text in the Federal Register, we often include a redline version of proposed regulations in the docket for rulemakings to assist the public in understanding the proposed regulatory changes. In our experience, stakeholders find the redline version far more useful than the proposed amendatory language in the format required by the Office of the Federal Register. Although appropriate for the task of revising the CFR, this

language can be difficult to assess without the accompanying full regulatory text. Given this, and given that we rarely receive comments on the proposed amendatory language or on proposed regulatory language at all, we determined that for rulemakings such as these, it would be more efficient to take the approach here of making both easily accessible but not including the proposed amendatory text in the notice.

Comment: Commenter (2257-MOGA) states that the proposed regulations published by the EPA on December 6, 2022, did not offer a specific regulatory framework or text. Small business entities with minimal staff and limited resources need direct, well-defined, and easily understood proposed regulations to evaluate for impacts and provide meaningful comment. Further, the commenter states that the approximately 500 pages in the current proposed regulations combined with reference to NSPS OOOO, NSPS OOOOa, the Methane Rollback NSPS OOOOa, the initial NSPS OOOOa, NSPS OOOOb and EG OOOOc proposal and references to an unpublished “presumptive standard” to be proposed in 2023 overwhelmed the majority of the commenter’s constituents and made proposed regulations very unclear and not easily understood. The commenter states that that clear definition between what specifically was being proposed, when juxtaposed to past regulations and unpublished future regulations, made the immediate understanding of proposed impacts to many small business’ nebulas unattainable. According to the commenter, many of their members questioned the EPA’s direction and asked whether the EPA had intended the proposed regulations to be an “Advanced Notification of Future Rule-Making” since the EPA was soliciting numerous responses to questions, while simultaneously proposing non-specific and what they believe were unclear future regulations. The commenter suggests that this lack of clarity and confusing language significantly prevented many of the commenter’s constituents from fully understanding the proposed regulations and prevented meaningful and substantive comments on the potential short-term and long-term implications of proposed regulations that will affect small and very small businesses.

The commenter (2257-MOGA) adds that they support the comments made by the Independent Petroleum Association of America (IPAA) regarding issues of regulatory framework. The commenter recommends the EPA provide clear, well-defined, and easily understood proposed regulations that can be understood by all businesses, including small and very small businesses without environmental and legal staff. They recommend regulations include clear definitions of major equipment, calculation methodologies with samples, well-defined source definitions aligned with the 1979 CAA, and clarification of exemptions.

Response II-23-27: The December 2022 Supplemental Proposal regulatory text for the NSPS OOOOb, EG OOOOc and Appendix K was accessible via EPA’s website for this action and the EPA Docket established for this rulemaking.<sup>46,47</sup> See also Response II-23-26 of this Chapter.

Comment: Commenter (2220-WDEQ) states that the EPA issued the December 2022 supplemental proposal in the *Federal Register* as a roughly 150-page document containing no regulatory text. They acknowledge that the regulatory documents associated with the

---

<sup>46</sup> <https://www.epa.gov/controlling-air-pollution-oil-and-natural-gas-industry/epa-issues-supplemental-proposal-reduce#Additional>.

<sup>47</sup> For the proposed NSPS OOOOb regulatory text, see Docket ID Number EPA-HQ-OAR-2021-0317-1551; for the proposed EG OOOOc regulatory text, see Docket Number EPA-HQ-OAR-2021-0317-1552.

supplemental proposal (NSPS OOOOb, EG OOOOc, Appendix K) were included as attachments to the December 2022 supplemental proposal but expressed that viewing the regulatory documents required that the general public navigate through EPA’s website, or sort through an abundance of additional documents related to the December 2022 supplemental proposal on the docket, to access. The commenter contends that this is a misleading practice that severely lacks any form of transparency, and dramatically underrepresents the size of the proposed regulations (which consists of a total of more than 750 pages in length counting the preamble) and the time and resources to review them. Furthermore, the commenter expresses that the EPA has placed the onus on the general public to gather all the associated attachments rather than including them as one body of proposed text. The commenter notes that the EPA has undertaken this non-transparency practice recently with other proposed rules. The commenter considers this to be an inappropriate and exclusionary practice that is inconsistent with EPA’s own principles of meaningful engagement required under the December 2022 supplemental proposal.

Response II-23-28: See Response II-23-26 of this Chapter.

Comment: Commenter (2237-ICND) states that the EPA failed to provide fair notice of the December 2022 supplemental proposal’s rule text because the proposal did not contain proposed regulatory text. The commenter therefore believes that the December 2022 supplemental proposal is deficient, departing from the long-established practice of publishing the proposed regulatory text in the *Federal Register* notice and instead burying it in the administrative record. The commenter contends that this combination of actions raises substantial “fair notice” concerns. They add that it is also inconsistent with EPA’s commitment to EJ and transparency since many communities will not find it easy or customary to pore through the administrative record. According to the commenter, whatever formalistic legal arguments EPA might make that it has complied with the APA public notice requirements, it is indisputable that burying proposed regulatory text in the administrative record is neither transparent, nor does it promote or enable broad and diverse public participation.

Response II-23-29: See Response II-23-26 of this Chapter.

## **23.7 Meaningful Engagement with Industry**

Comment: Commenters (2223-TAEP, 2254-PBPA) state that for the proposed NSPS and EG, the EPA is relying on its previous work on methane — namely 40 CFR, Part 60, subpart OOOOa, the NSPS for VOC and methane emissions from the oil and natural gas sector (referred to as the “2016 Methane Rule”). The commenter recommends that before the EPA finalizes any methane regulation, that it works in partnership with the domestic oil and gas industry – especially small and mid-sized producers — toward a path that ensures the best way to reduce global emissions while encouraging and maintaining innovation. The commenter recommends that such work should focus on flexible partnership-based approach to identifying advanced environmental technological approaches to exploration and production activities – a more effective means to a better environment rather than a heavy regulatory “one size fits all” mandate.

Response II-23-30: See section VII (Summary of Engagement with Pertinent Stakeholders) of the final rule preamble for EPA’s extensive outreach with the public, states, tribal nations, and a

broad range of pertinent stakeholders in order to gather information from a variety of viewpoints. Throughout the rulemaking process the EPA has met individually with hundreds of industry representatives, non-governmental organizations (NGOs), technology vendors, academics, data companies, and others.<sup>48</sup>

## **23.8 Emissions Control Vendor Information**

Several commenters provide information to the EPA on their emissions control technologies that they advocate could be used by oil and natural gas facilities to mitigate VOC and or methane emissions. Technologies highlighted by commenters are highlighted below.

### ***23.8.1 Digital Flare Mitigation Technology***

Comment: Commenter (2175-Crusoe Energy) responds to EPA’s solicitation that “additional information on potential emerging technologies that provide uses for the associated gas in a beneficial manner other than routing to a sales line, using as a fuel, or reinjecting the gas.” The commenter believes that Crusoe’s digital flare mitigation (DFM) is just such a technology. The commenter provides that their DFM technology harnesses stranded and wasted energy resources to power advanced computing systems or for use onsite by operators and has reliably demonstrated its ability to exceed the BSER standard of 95 percent methane reduction—representing the type of emerging technology that should be considered a beneficial use for oil and gas operators to comply with the standards of performance for oil wells with associated gas. More details about their DFM technology and its applications are included as Appendix A to their comment letter.

The commenter (2175-Crusoe Energy) adds that their generators exceed the BSER standard requiring control devices to achieve at least 95 percent reduction in methane and VOCs, emissions, with a calculated combustion efficiency averaging 99.9 percent in 2022, determined from stack tests conducted at least annually to meet 40 CFR Part 60 Subpart JJJJ requirements. By comparison, the commenter notes that the latest research from the University of Michigan found that observed destruction removal efficiency of open flares was on average only 91.1 percent. In other words, they state that about 9 percent of the methane directed to a flare escapes to the atmosphere compared to 0.1 percent with DFM. Based on these numbers, the commenter states that their DFM technology prevented an estimated 2,700 metric tons of methane from escaping into the atmosphere. Because methane has a 20-year global warming potential (GWP)—82.5 times that of carbon—their 2021 methane emissions reductions translated to over 220,000 metric tons of CO<sub>2</sub>e (mtCO<sub>2</sub>e) emissions avoided. In total, they report that their currently deployed fleet of DFM systems have the capacity to reduce an estimated 800,000 mtCO<sub>2</sub>e per year, comparable to removing approximately 170,000 cars from the road for a year. Since the company was founded in 2018, the commenter notes that their company has prevented over 4 billion cubic feet of gas from being flared. They note that their DFM technology offers oil producers an economic, operationally practical, and usually cost-free alternative to natural gas flaring, harnessing stranded and wasted energy for productive use. They add that they have robust in-house logistics, supply chain, engineering, and operations capabilities, which enable

---

<sup>48</sup> See various stakeholder meeting memoranda reflected in EPA’s Docket ID No. EPA-HQ-OAR-2021-0317.

them to deploy and commission DFM systems within one week and operate them with the highest environmental and safety standards.

The commenter (2175-Crusoe Energy) reports that their DFM systems are deployed directly to the oil wellsite to convert the stranded gas, which would otherwise be wasted and flared, into electricity that is used to power modular data centers. These data centers support computer-intensive applications, including Crusoe Cloud, a company cloud computing platform for high performance computing (HPC), computational biology, artificial intelligence, 3-dimensional rendering and other HPC workloads, and cryptocurrency transaction processing (“mining”). They state that it can also be used to generate electricity that can be used onsite by operators, which can be particularly beneficial at remote locations where electricity might not otherwise be available. In many circumstances, the commenter notes that their company purchases the associated gas from the operator for a nominal fee and covers the costs associated with delivering the equipment to the site. As a result, in many situations, the commenter states that operators who do not otherwise have access to sales lines are able to reduce their methane emissions without incurring significant additional costs.

The commenter (2175-Crusoe Energy) continues to report that their methane mitigation solution is also modular and highly scalable. They explain that DFM systems can manage gas volumes as low as 300,000 cubic feet per day, with no functional maximum. The commenter provides that their company has worked with operators of all sizes to deploy DFM systems that range from generators with a capacity of 2MW (consuming 300,000 cubic feet of flared gas per day) to a turbine with a capacity of 15MW (that can utilize over 2 million cubic feet of flared gas per day). In areas with multiple flaring well pads, the commenter provides that they have developed a system of centralized delivery points to increase efficiency and reliability. Further, they report that they can provide long-term services allowing operators to continue developing the acreage. As wells decline or have access to gas gathering, the commenter states that their company can decrease modules to adjust to the total gas supply.

Commenter (2175-Crusoe Energy) states that EPA noted in its proposal that it is soliciting comments on more specific technologies that have been proven to be viable in the field to utilize associated gas and avoid venting or flaring. The commenter responds that their Crusoe [Digital Flare Mitigation] DFM system is just such a proven technology. The commenter reports that their DFM technology is already commercially available and has proven to be scalable and reliable. Currently, they report that they have over 120 mobile data centers deployed across oil fields in Colorado, North Dakota, and Montana, with continued expansion planned domestically, and soon, internationally. They add that their DFM systems are designed to run year-round and to comfortably operate in temperatures from –20°F to 100°F, while warm weather units can comfortably operate up to 105°F. The commenter notes that they have successfully operated below and above this temperature range by deploying precautions and operational protocols that minimize outages. They further add that their generators are contained in metal enclosures, which have louvers and fans for summer months, and building heaters or oil and water heating systems that automatically turn on if the unit goes down in the winter, so they can be restarted.

Commenter (2175-Crusoe Energy) further reports that their company’s warm weather systems, designed to operate in hotter regions like Texas, are not enclosed but do have canopies over the

electrical equipment, rain louvers over the engine air intake, and air filters to combat sand and dirt. In the summer, they note that they can reduce the load on the engine if it is running hot or shut off individual computing units that are at risk of overheating. They explain that they mitigate such risks as much as they can through ensuring proper louver positions on our data centers and making sure the box filters are clean. They add that they also have video monitoring in most locations so we can adjust louvers and respond quickly before issues arise. They further add that they also have software that automatically notifies mechanics or mining technicians, who provide 24/7 on call support and response to problems. Through July 25, 2022, they report that their uptime exceeded 98 percent, excluding storms, low gas (where operators did not provide the DFM technology with enough gas to operate), and planned maintenance. The commenter states that their company's DFM technology also has a proven track record of operational safety. Over the past two years, they add that they have recorded over 500,000 man-hours worked without a recordable injury to an employee or contractor.

The commenter (2175-Crusoe Energy) goes on to report that their company's DFM technology also provides additional GHG reduction benefits for oil producers, upstream operators, and the public. Due to the lower combustion efficiency of open flares and the leakage of highly potent methane into the atmosphere, the emissions associated with the gas that would have been flared in the absence of their technology/support would be nearly 70 percent higher than their accounted Scope 1 emissions. Additionally, they add that had the same computing assets been powered by connecting them to the grid rather than using flared gas, those assets would have generated an additional 85,000 mtCO<sub>2e</sub> emissions based on the U.S. grid average. By explicitly including DFM or similar technologies as listed beneficial uses that can qualify in meeting BSER in any final rule, the commenter believes that the EPA can help to further reduce methane emissions while generating positive social benefits and without causing operators to incur additional costs.

The commenter (2175-Crusoe Energy) further reports that their company recently completed a full accounting of the company's 2021 emissions using the GHG Protocol's Corporate Accounting and Reporting Standard. In 2021, they found that their technology/support reduced flaring by nearly 1.7 billion cubic feet of natural gas. In addition, they also calculated its "avoided emissions," sometimes referred to as Scope 4, to paint a more complete picture of the company's positive and negative GHG impacts, using one common definition for Scope 4 as "GHG emissions impact of a product relative to the situation where that product does not exist." In their company's case, this meant comparing the emissions from using their DFM systems to the emissions that would have resulted from the flaring of natural gas in its absence.

In sum, the commenter (2175-Crusoe Energy) concludes that their company's DFM technology has proven to be a win for both industry and the environment, and they respectfully submit that this is exactly the kind of emerging technology EPA's regulations should allow for and encourage.

Response II-23-31: The EPA appreciates the information provided by the commenter on their DFM technology.

### ***23.8.2 Advanced Catalytic Technology***

Comment: Commenter (1603-Thermon) explains that their company is a U.S. based global supplier of industrial heating equipment. They explain that they have recently developed a new product that is designed specifically for methane abatement using advanced catalytic technology. They provide that this new device is ideally suited for use with processing vented methane into water vapor and carbon dioxide at conversion rates of 90 to 98 percent. The commenter adds that the device is designed to run continuously and indefinitely without an electrical power source, and since the device operates at a low temperature, it does not produce NOx.

Response II-23-32: The EPA appreciates the information provided by the commenter on their use of advanced catalytic technology designed specifically for methane abatement.

### ***23.8.3 Instrument Air Package Information***

Comment: Commenter (1609-Qnergy) reports that, with respect to the size of compressors and generators, their company provides instrument air packages with rocking piston compressors that are as small as 1 horsepower (HP). The commenter adds that their 5 HP compressors (both scroll and screw) are driven by the PG5650 (5.6 kW Stirling generator). Further, they note that their company released triplet packages of more than 16 kilowatts (kW) (3 x PG5650) to power large compressors.

Response II-23-33: The EPA appreciates the information provided by the commenter on their instrument air packages.

### ***23.8.4 Pneumatic Electronic Controller Technology***

Comment: Commenter (2290-WedgeRock) notes that there is no mention of utilizing engineered gear technology to mitigate methane emissions. The commenter provides that high-efficiency worm and planetary gears can be coupled with an electric operator to provide more efficient controller. The commenter explains that high-efficiency gears can assist in helping motor operators achieve performance requirements such as speed of operation while reducing power required to operate the electric controller. According to the commenter, reducing power requirements in these applications make solar powered solutions more viable and cost effective.

The commenter (2290-WedgeRock) states that some commenters argue that emergency shutdown devices (ESDs) must be excluded from the affected facility definition due to functional needs. The commenter notes that they point to issues with electric and air-driven pneumatic controllers not being able to be operated in sufficient time to protect life and property. The commenter explains that the use of spring return gears coupled with electric operators provide a fail-safe electro-mechanical device that is an extremely reliable emergency shut-down device that does not utilize natural gas and therefore has an emission rate of zero. When coupled together, they add that an electric controller and a spring-return gear create a failsafe electric controllers can provide a robust solution to using natural gas-driven controllers in ESD situations. Upon a command to close the ESD valve, springs can be set to drive the valve to the emergency position in less time than natural gas-driven pneumatic controllers. According to the

commenter, the use of spring-return gears makes the use of electric operators much more viable in ESD situations and should be considered when discussing BSER.

The commenter (2290-WedgeRock) goes on to explain that spring return gear operators can also be used as stand-alone devices to create a manual-reset ESD. The gear utilizes a high-efficiency planetary gear that requires minimal turns to set in the ready mode and in an ESD situation, the spring is released and operates the valve. Spring-return gears can operate automatically as an ESD on loss of power, loss of pressure, or overpressure situations. This manual reset ESD can be activated utilizing a pressure transmitter and a solar powered remote controller in areas where power is not available or not reliable. A small solar system can power the transmitter, the remote operated controller, and wireless communications for the affected site. The Spring-return gears can also be activated by a low voltage signal from an operator's control room when an upset condition is identified or from a solar powered pressure transmitter with battery backup system. The commenter states that an operator can then inspect the area, take corrective action, and utilize the handwheel to reset the ESD once the situation is returned to normal. The commenter provides that, since both these options do not use natural gas, there would be no need for quarterly inspections, thereby minimizing maintenance costs.

To conclude, the commenter (2290-WedgeRock) suggests that the use of high-efficiency and spring-return gear operators should be considered as a technically feasible option. As noted, the commenter states that when a high-efficiency worm or planetary gear is coupled with an electric controller, the package can allow for reduced power consumption, making the use of solar powered electric controllers more reliable. The commenter adds that the use of spring return gears, when used alone can provide a manual-reset ESD that is extremely reliable. When a spring-return gear is coupled with a motor operator, the commenter notes that it can provide a failsafe electromechanical device that can be used to operate an emergency shutdown valve.

Response II-23-34: The EPA appreciates the information provided by the commenter on their high-efficiency spring return technology.

## **23.9 Performance-Based Compliance Alternative**

Comment: Commenter (2452-Hess) states that the EPA is soliciting comment on the potential use of intensity or production in the development of action levels, including appropriate thresholds for setting such action levels on both a short-term and long-term basis.”<sup>49</sup> The commenter believes that performance-based approaches offer opportunities to achieve emissions reductions that are equal to or greater than the reductions achievable by more prescriptive requirements, such as those included in the December 2022 supplemental proposal. Accordingly, the commenter requests that the EPA allow performance-based approaches as an alternative to demonstrate compliance with methane emissions reductions and provides further support for their request in the following paragraphs.

*Industry led efforts support performance-based standards.* The commenter (2452-Hess) reports that they are a founding member of the ONE Future Coalition – the exact type of industry-led

---

<sup>49</sup> Id. at 74744.

effort the EPA referenced in its solicitation of comments. ONE Future is a group of companies from the natural gas industry focused on reducing methane emissions across the natural gas value chain. ONE Future adopts a performance-based approach to emissions reduction, focusing on the outcome – emissions reductions – rather than on specific technical or operational controls. The goal of ONE Future is to voluntarily lower methane emissions to less than 1 percent of gross methane production across the U.S. value chain by 2025. Peer reviewed analyses indicate that a leak/loss rate of 1 percent or less across the U.S. natural gas value chain provides immediate GHG reduction benefits. ONE Future believes that by orienting our activities toward this specific and measurable outcome, companies can achieve a sustained focus on identifying the opportunities for emissions abatement that yield the greatest benefit for the least cost. It grants individual companies the flexibility to choose precisely how they can most cost-effectively and efficiently achieve their goal, which could include deploying an innovative technology, modifying a work practice, or in some cases, replacing a high-emitting asset with a low-emitting asset.

The commenter (2452-Hess) states that the EPA has endorsed the ONE Future Coalition’s efforts through its Methane Challenge Program. Companies that join the Methane Challenge Program can choose one of two commitment options – the Best Management Practice Commitment Option or the ONE Future Intensity Commitment Option. The ONE Future Coalition’s approach remains an effective means of emissions reductions and The EPA should continue to endorse it through this rulemaking. In support of our GHG emissions and flaring intensity reduction targets, the commenter tracks and monitors air emissions at each of our assets and undertakes a variety of emissions reduction initiatives.<sup>50</sup> Based on this experience, the commenter believes that regulations that mandate the adoption of specific technologies, practices, and procedures for all facilities or operations of a certain type are less effective and efficient than performance-based approaches. Prescriptive requirements may not be effective in every operational situation, as conditions can vary between producing fields (e.g., Permian Basin versus Bakken) and individual well sites. In addition, prescriptive requirements can quickly become outdated with rapid improvements in emissions control technology or oil and gas production equipment or methods. In contrast, performance-based standards facilitate innovation and use of alternative technologies and allow operators to create bespoke solutions to their specific site conditions, which may include use of alternative technologies, while still allowing for similar or greater emissions reductions.

*States have successfully adopted performance-based standards that have measurably improved air quality and are driving future improvements.* Commenter (2452-Hess) provides that performance-based approaches for emissions reductions have already been successfully

---

<sup>50</sup> Currently, the commenter reports that they are evaluating, piloting or implementing the following emissions reduction opportunities: optimizing gas infrastructure, which includes additional compression capacity and gathering lines; installing oil coolers to stabilize oil and reduce tank gas flashing to flare; reinjecting natural gas liquids into the product line at compressor stations; replacing gas assisted flares with more efficient air assist flares; diverting compressor station blowdown from flares to station inlet; optimizing pipe heat trace design to lower power consumption; using grid electricity, which we mitigate through the purchase of Renewable Energy Credits, to power onshore drilling and completions activity; examining alternatives to wellhead flaring, such as utilizing natural gas for onsite power generation or conversion to liquified natural gas; examining purchase power options to supply Hess’ electricity needs through renewable or carbon neutral energy, thereby offsetting or eliminating our Scope 2 GHG emissions; and using advanced data analytics and machine learning to optimize fuel gas consumption.

implemented in oil and gas producing states. For example, the North Dakota Industrial Commission’s Order No. 24665, issued in 2014, established gas capture goals that imposed progressively higher capture requirements for associated gas. This requirement resulted in a rapid expansion of infrastructure and operational improvements leading to significant reductions in flared gas. In addition, they report that Colorado recently established a “Greenhouse Gas Intensity Program for the Oil and Natural Gas upstream Segment.”<sup>51</sup> This program requires operators to reduce preproduction and production emissions, with progressively more stringent intensity targets beginning in 2025. Gas capture goals and intensity-based programs like those adopted at the state level drive improvement while allowing flexibility for operators to implement appropriate solutions for their unique situations.

*Federal laws and regulations support use of performance-based approaches.* In addition to state initiatives, the commenter (2452-Hess) states that performance-based approaches to emissions reductions have been endorsed at the federal level. The bipartisan Inflation Reduction Act of 2022 (IRA) established a Methane Emissions Reduction Program (MERP) that requires the EPA to collect a “waste emissions charge” from owners or operators of certain facilities subject to 40 CFR Part 98 Subpart W (Subpart W) that exceed an applicable waste emissions threshold. For petroleum and natural gas production, the methane charge applies to emissions that exceed either “A) 0.20 percent of the natural gas sent to sale from such facility; or B) 10 metric tons of methane per million barrels of oil sent to sale from such facility, if such facility sent no natural gas to sale.”

Notably, the commenter (2452-Hess) explains that the IRA includes an exemption for an applicable facility subject to and in compliance with “methane emissions requirements pursuant to subsections (b) and (d) of section 111 [of the Clean Air Act]” if the EPA Administrator determines that such standards are in effect and compliance “will result in equivalent or greater emissions reductions as would be achieved by the proposed rule of the Administrator entitled ‘Standards of Performance for New, Reconstructed, and Modified Sources and Emission Guidelines for Existing Sources: Oil and Natural Gas Sector Climate Review’ (86 Fed. Reg. 63110 (November 15, 2021)), if such rule had been finalized and implemented.” The IRA’s explicit connection to emissions reductions from the proposed rule that preceded the December 2022 supplemental proposal demonstrates the suitability of similar performance-based approaches in the December 2022 supplemental proposal. Specifically, the reference shows that Congress has focused on the resulting emissions reductions and not the mechanism to achieve the reductions. The commenter believes that the EPA should do the same here.

Further, the commenter (2452-Hess) states that the existing EPA regulations establish a logical framework from which to measure performance-based improvements. Subpart W provides a ready-made system for tracking and measuring emissions against prior years. Similar to the integration of Subpart W into the IRA’s MERP, the commenter suggests that the EPA could use Subpart W data to guide performance-based standards for the December 2022 supplemental proposal.

Response II-23-35: The EPA appreciates the commenter’s recommendation. However, creating the recommended framework to measure performance-based improvements is not supported by

---

<sup>51</sup> See 5 C.C.R. § 1001-26(IV). 5 See 42 U.S.C. § 7436(f).

CAA sections 111(b) and 111(d), which is the basis for the NSPS OOOOb standards and EG OOOOc presumptive standards. See sections IV (Statutory Background and Regulatory History) and V (Legal Basis for the Final Rule Scope) of the final rule preamble for the basis and scope of the final NSPS OOOOb and EG OOOOc rules.

As noted by the commenter, however, CAA section 136(c) directs the Administrator of the EPA to “impose and collect a charge on methane emissions that exceed an applicable waste emissions threshold under subsection (f) from an owner or operator of an applicable facility that reports more than 25,000 metric tons of carbon dioxide equivalent (CO<sub>2</sub> Eq.) of GHG emitted per year pursuant to subpart W of part 98 of title 40 (40 CFR part 98), regardless of the reporting threshold under that subpart” (hereinafter, waste emissions charge). An “applicable facility” is defined under CAA section 136(d) to include nine specific industry segments as defined in GHGRP subpart W. Pursuant to CAA section 136(g), the waste emissions charge “shall be imposed and collected beginning with respect to emissions reported for calendar year 2024 and for each year thereafter.” See section VI.C (Methane Emissions Reduction Program) of the final rule preamble for additional discussion on the Methane Emissions Reduction Program, including the section 136(f) exemption from the waste emissions charge for applicable facilities that meet certain criteria.

## **23.10 Alternative Technical Measurement and Verification Protocols and Testing Laboratories**

### ***23.10.1 Technology Neutral Protocol to Measurement and Verification***

Comment: Commenter (2426-Veritas) notes that their approach (*i.e.*, Veritas) is a standardized, science-based, technology neutral, measurement and verification-informed methane emission measurement approach to calculating and reporting methane emissions. The commenter reports that their initiative was launched in 2021 by GTI Energy. They state that their approach provides specific technical protocols for each segment of the natural gas industry (production, gathering and boosting, processing, transmission and storage, distribution, and LNG) to measure methane emissions in a consistent, credible, and comparable way. The commenter further provides that their technology-neutral protocols formulate a comprehensive toolbox of methodologies designed to accelerate methane emissions reductions.

The commenter (2426-Veritas) reports that the first versions of the protocols are being made publicly available February 14, 2023, at: <https://veritas.gti.energy>.

The commenter (2426-Veritas) explains that the Veritas technical protocols consist of:

- *Methane Emissions Intensity:* Defines what methane intensities should look like for each segment of the natural gas supply chain.
- *Measurement:* Describes how to take measurements to inform emission inventories, by segment.
- *Reconciliation:* Reconciles emission-factor or baseline inventories with actual measurements, by segment.
- *Value Chain Summation:* Adds multiple segments to reach a total emissions intensity.

- *Assurance*: Provides guidance for verifying an emissions inventory, company documentation requirements, and third-party auditing

The commenter (2426-Veritas) asserts that Veritas is unique in that it is entirely committed to broadening access to the most effective technical processes and technologies that are currently available to reduce methane emissions, in hopes of giving industry a hands-on blueprint of how to implement methane mitigation initiatives successfully and yield credible results.

The commenter (2426-Veritas) informs that GTI Energy will publish and maintain these protocols as open-source, technical tools that can be deployed and operationalized by different stakeholders around the world.

Response II-23-36: The EPA appreciates the commenter's provided information on their standardized, science-based, technology neutral, measurement and verification-informed methane emission measurement approach to calculating and reporting methane emissions.

Development of emission inventories are outside the scope of the final rulemaking and this document.

### ***23.10.2 Biogenic Carbon Content Testing***

Comment: Commenter (2169-Beta Analytic) submitted information on developing technology for the EPA to consider with regards to the proposed approval process for technologies for alternative periodic screening. The commenter believes that, particularly important is that while existing methane detection technologies only identify the presence of emissions, the method they provide for EPA's consideration would have the potential to identify their source through isotopic characterization. Specifically, their recommendation is that the EPA consider the potential for biogenic carbon content testing using isotopic concentrations to play a role in methane emissions detection and create a regulatory pathway for its use.

The commenter (2169-Beta Analytic) notes that their testing laboratory was among the originators of the American Society for Testing and Materials (ASTM) D6866 biobased/biogenic testing standard using carbon-14 to distinguish renewable carbon sources from petroleum sources in solids, liquids, and gases. They inform that renewable testing started in 2003 at the request of U.S. Department of Agriculture (USDA) representatives who were interested in Beta's Carbon-14 capabilities for their USDA BioPreferred® Program ([www.biopreferred.gov](http://www.biopreferred.gov)). Carbon-14 third party testing is now standardized in a wide range of international standards including ASTM D6866, European Committee for Standardization (CEN) 16137, European Standard (EN) 16640, ISO 16620, International Organization for Standardization (ISO) 19984, British Standard (BS) EN ISO 21644:2021, ISO 13833 and EN 16785. The commenter reports that they continue to be involved in ASTM D6866 revisions.

The commenter (2169-Beta Analytic) recommends Carbon-14 testing as the preferred method for determining the biogenic carbon content of methane emissions under the EPA's proposal to reduce pollution from oil and natural gas operations. Their recommendations to the EPA

following this proposal to reduce pollution from the oil and natural gas industry to fight the climate crisis and protect public health are as follows:

- (1) Consider the potential for isotopic identification to play a key role in methane tracking and remediation in the near future based on Beta Analytics' six-month Phase I SBIR Grant timeline, with the intention to apply for a two-year extension (Phase II) thereafter.
- (2) Expand upon the proposed survey matrices for alternative periodic screening to incorporate isotopic concentration testing, as Beta's methodology will be fundamentally different from existing processes that use sample concentration practices.
- (3) Include baseline testing of atmospheric gases so that isotopic changes over time can be determined, differentiated, and remediation strategies identified.
- (4) Include periodic isotopic performance testing of oil and NG emissions that is conducted by an ISO/International Electrotechnical Commission (IEC) 17025:2017 accredited testing laboratory.
- (5) Research how emissions reduction equivalency achieved with isotopic concentration testing could be compared to OGI.

The commenter (2169-Beta Analytic) adds that isotopic characterization of methane emissions may lead to new remediation strategies to combat increasing global methane concentration. The commenter believes that ASTM D6866 testing is crucial for the EPA's goal of fighting the climate crisis and protecting public health by reducing pollution from major methane emitters, oil and natural gas.

Commenter (2169-Beta Analytic) emphasizes support for Carbon-14 measurements done by commercial third-party testing as being robust, consistent, and with quantifiable accuracy/precision of the carbon-14 amount under ASTM D6866 method B. They provide that EN 16785 is the only standard that allows a variant of the Mass Balance (MB) method of 'carbon counting' under EN 16785-2. EN 16785-1 requires that the biocarbon fraction be determined by the carbon-14 method.

In ASTM D6866 method B, the commenter (2169-Beta Analytic) explains that the carbon-14 result is provided as a single numerical result of carbon-14 activity, with graphical representation that is easily understood by regulators, policy makers, corporate officers, and more importantly, the public. The commenter believes that the overwhelming advantage of carbon-14 is that it is an independent and standardized laboratory measurement of any carbon containing substance that produces highly accurate and precise values. In that regard, they add that it can stand alone as a quantitative indicator of the presence of renewable vs. petroleum feedstocks. When carbon-14 test results are challenged, the commenter explains that samples can be rapidly remeasured to verify the original reported values (unlike mass balance).

The commenter (2169-Beta Analytic) suggests that MB lacks robust and transparent methods of validation for mixing, balancing, and tracking carbon that translates to a real credit-based system. The U.S. Department of Agriculture BioPreferred program discovered early on that misbranding could undermine not only regulatory, but more importantly, consumer confidence, which was also pointed out in a 2021 panel on the assessment of mass balancing accounting method for polymers working by the National Institute of Standards and Technology (NIST). They also determined that some brand owners might find the MB approach too complex. When the 2021 NIST panel was asked in a single work to describe mass balancing accounting for polymers, the six descriptive words were: complex, critical, necessary, confusing, ugly, and certifiable. [Note: Additional support for the use of Carbon-14 measurements over MB methods is provided in the commenter's letter.]

The commenter (2169-Beta Analytic) concludes by noting that, to ensure the highest level of quality, laboratories performing testing under the USDA BioPreferred Program by ASTM D6866, require that the laboratory be accredited to ISO/IEC 17025:2017 testing standard. The commenter states that this accreditation is unbiased, third party verified, and annually audited by the accreditation body. According to the commenter, it is unique to laboratories that not only have a quality management program that is conformant to the ISO 9001:2008 standard, but more importantly, have demonstrated to an outside third-party laboratory accreditation body that they have the technical competency necessary to consistently deliver technically valid test results. ISO/IEC 17025:2017 accredited testing laboratory results are universally recognized and accepted by all governmental, regulatory bodies and laboratories.

Response II-23-37: The EPA appreciates the commenter's provided information on biogenic carbon content testing conducted at their laboratory.

### ***23.10.3 Synergistic Measurement Requirements Across EPA's Regulatory Program***

Comment: Commenter (2350-CEI) recommends that the EPA consider synergistic measurement requirements for operators to comply with across the EPA's regulatory program. The commenter notes that several EPA regulatory initiatives related to the oil and natural gas sector are in development in addition to this proposed rulemaking, including the requirements for the GHGRP under Subpart W and the implementation of the IRA methane fee and MERP. The commenter explains that evolving measurement technologies offer the EPA the opportunity to harmonize the methodologies used to satisfy both GHGRP and NSPS OOOO requirements, along with upcoming requirements for the implementation of the methane fee. Approved technologies, according to the commenter, and the conditions around their deployment such as survey frequency and probability of detection, should be consistent between the different regulatory programs.

The commenter (2350-CEI) provides that creating a like-to-like comparison between facilities or operators in an evolving environment of measurement technologies is challenging. They explain that measurements from advanced technologies must be carefully interpreted so that their spatial and temporal scales align with those of the reporting program. Different technologies have different spatial and temporal characteristics, along with varying probabilities of detection and uncertainty. Therefore, qualified experts familiar with how to accurately measure and quantify

GHG emissions from oil and gas facilities are essential when developing empirical data. The commenter recommends that the EPA utilize modeling tools and public empirical datasets compiled by credible third-party experts.

The commenter (2350-CEI) states that they are a founding sponsor of one such organization: the Energy Emissions Modeling and Data Lab<sup>52</sup> (EEMDL), which was launched in January 2023 by the University of Texas at Austin in partnership with Colorado State University and the Colorado School of Mines. The commenter provides that EEMDL is developing transparent models and datasets for accurate GHG emissions accounting across global oil and gas supply chains. EEMDL has three strategic approaches: (1) develop community models and tools for GHG emissions assessments, (2) make timely and high-resolution emissions datasets that are publicly available, and (3) create educational and training materials to enable the widespread use of EEMDL's models and data. The commenter suggests that modeling tools, such as those EEMDL is developing, may help the EPA account for the different spatial and temporal scales of available measurement technologies, and support operators as they prepare annual GHGRP inventories based on empirical data. The commenter believes that EEMDL's datasets may be robust enough to help the EPA conduct a robustness check on its bottom-up inventory, and even be used to prepare dynamic, empirical emission factors based on the previous year's measurement data from industry.

Response II-23-38: While not within the scope of this rulemaking, the EPA appreciates the commenter's provided information on their recommendation that the EPA consider synergistic measurement requirements for operators to comply with across the EPA's regulatory program.

### **23.11 Low-Emissions Design/Methane Destruction Methods**

Comment: Commenter (2213-Occidental) appreciates EPA adopting an equipment-based approach for determining the fugitive emissions monitoring frequency in lieu of the baseline emissions approach. The commenter notes that this framework incentivizes low-emission designs and aligns with their company's low-emissions designs for new oil and gas facilities.

The commenter (2213-Occidental) provides that their designs for new oil and gas facilities in the Permian and DJ Basins use pipelines instead of trucks to transport oil to a central processing facility, eliminating the need for oil storage near wells. According to the commenter, these tankless designs reduce both the volume of oil and gas on-site and the amount of potentially emitting equipment. They also report that they use instrument air to operate the pneumatic devices at these facilities. The commenter reports that these innovative facility designs decrease our environmental footprint by reducing emissions, dust, noise, and truck traffic.

Complementing their low-emissions design, the commenter (2213-Occidental) reports that these facilities are also less susceptible to leaks and fugitive emissions due to automation and measurement systems. They state that their automation and measurement systems are used in many locations to continuously monitor the performance of their wells and facilities. The commenter adds that it monitors key processes, process variables (such as temperature, pressure,

---

<sup>52</sup> Information regarding EEMDL can be accessed at <https://www.eemdl.utexas.edu/>.

and flow rate), and equipment components in real-time or near-time that alert our operators to a potential issue, allowing them to take swift action. They provide that automation and measurement systems also enable them to trend equipment performance and plan for maintenance and replacement.

Response II-23-39: The EPA commends the commenter for their implementation of low-emissions designs that are less susceptible to leaks and fugitive emissions due to automation and measurement systems. The EPA also agrees that finalizing an equipment-based approach for fugitives that is based on the specific equipment that is located at the well site does complement their low-emissions design approach.

Comment: Commenter (2184-PSR Climate Ambassador) states that because methane capture technologies are most often faulty and imperfect, [it is] best for the EPA to give technical guidance to corporations planning to build new gas transmission pipelines or LNG facilities to create new business plans to create renewable energy sources instead. The commenter requests that the EPA perfect their public relations to guide all new energy infrastructure and new facilities on how to use renewable energy sources.

Response II-23-40: Providing technical guidance to corporations planning to build new gas transmission pipelines or LNG facilities to create new business plans to create renewable energy sources instead is not within the scope of this rulemaking; as such, no response is required.

Comment: Commenter (2407-MA) requests the EPA take the potential emergence of methane removal methods into account by indicating in its current rulemaking that it will assist in their research and development and review the results frequently, with a view toward adding approved methane emissions destruction methods to the list of Best Systems of Emissions Reduction (BSER) (the standard required under CAA section 111 as soon as possible). The commenter provides a list of current and proposed research projects for methane removal technologies in an attachment to their comment letter (e.g., zeolites and catalysis, photocatalysis, generation of Cl atoms (one-carbon molecules), generation of hydroxyl radicals by photolysis and generation of ultraviolet (UV)-B/UV-C, and oxygen atoms, methanotroph-based methane removal or mitigation).

Response II-23-41: The EPA appreciates the information the commenter provided on current and proposed research projects for methane removal technologies.

## **23.12 Units of Measure**

Comment: Several commenters (2168- INOGA, 2172 KOGA, 2200-NuEO, 2257-MOGA and 2211-LER) state that that the EPA should use the language of the industry to clearly communicate objects and standards. Specifically, the commenters note the mixed use of imperial units (i.e., 6 tons per year and metric units (kilograms (kg)/hour(hr))).

Commenter (2257-MOGA) notes their constituents commented on the lack of understanding of kg/hr and requested the EPA use scf/hr and ppm which is the standard language and vernacular of the industry. The commenters state that the EPA should standardize on either imperial units or

metric units. According to commenters, mixing the units between imperial and metric is going to create errors for operators that do not have the capability to convert between the two. If the EPA desires to use metric units, it is recommended that a calculator should be available, when the final regulation is released, to be able to convert between imperial and metric units.

Response II-23-42: The EPA acknowledges the commenter's request. The EPA generally uses imperial and not metric units, but often has to convert supporting data that is in metric units.

### **23.13 NSPS OOOO and NSPS OOOOa Changes**

Comment: Commenter (2326-AXPC) remains supportive of EPA, in keeping the efficiencies in 40 CFR subpart OOOOa, that EPA intends to retain, as reflected in the December 2022 supplemental proposal. The commenter states that these efficiencies reduce unnecessary burden without negative environmental impacts – thus increasing the cost-effectiveness of the NSPS OOOOa rulemaking.

Response II-23-43: These comments are supportive comments; as such, no response is required.

### **23.14 Administrative Record – Early Input on Methane Regulation**

Comment: Commenter (2355-CEC) requests that all contents of regulatory docket ID No. EPA-HQ-OAR-2021-0295 should be part of the record for docket ID No. EPA-HQ-OAR-2021-0317. The commenter notes that the EPA opened a docket for stakeholders to submit early input on issues informing the original proposal, and that docket was assigned Docket ID No. EPA-HQ-OAR-2021-0295. According to the original proposal, the contents of Docket ID No. EPA-HQ-OAR-2021-0295 are not automatically part of the original proposal rulemaking record, and for information submitted to that docket to be considered in the Original Proposal and Supplemental Proposal rulemaking, it must be resubmitted to Docket ID No. EPA-HQ-OAR-2021-0317. That approach risks excluding information and material that informed EPA's Proposal from the administrative record. Instead, the commenter believes that all contents of Docket ID No. EPA-HQ-OAR-2021-0295 should be automatically incorporated into and considered part of the rulemaking docket for the November 2021 original proposal and December 2022 supplemental proposal, Docket ID No. EPA-HQ-OAR-2021-0317.

Response II-23-44: The EPA has included in the docket for this action all information upon which the Administrator relied for the proposed and final actions, as well as all comments received on the proposed rulemakings, consistent with the requirements of CAA section 307(d).

With regards to the request that the contents of non-rulemaking Docket ID No. EPA-HQ-OAR-2021-0295 be included in the rulemaking Docket ID No. EPA-HQ-OAR-2021-0317, the EPA has not granted that request. The EPA opened the non-rulemaking docket (Docket ID No. EPA-HQ-OAR-2021-0295) for public input on the Agency's efforts to reduce emissions of methane and other air pollutants from new and existing sources in the oil and natural gas sector in order to further the Administration's policies as described in Executive Order 13990, "Protecting Public Health and the Environment and Restoring Science to Tackle the Climate Crisis." The goal of this non-rulemaking docket and other public engagement efforts was to gather perspectives from

a broad group of stakeholders for the oil and natural gas sector, including individuals and communities that experience disproportionate adverse health and environmental impacts as a result of oil and natural gas operations.

### **23.15 TSD Citation — Cost Impacts of Revising Control Device Efficiency Standards to 98 Percent**

Comment: Commenter (2362-EIP et al) notes that Chapter 7 of the TSD includes a link to the “...updated chapters and spreadsheets for the planned Seventh Edition...” of EPA’s Air Pollution Cost Control Manual. However, the commenter states that the link is broken, which means the document cited is not available to the public.

Response II-23-45: The EPA Air Pollution Control Cost Manual, upon a simple search at: <https://www.epa.gov/economic-and-cost-analysis-air-pollution-regulations/cost-reports-and-guidance-air-pollution#cost%20manual>. There was a missing hyphen between cost and analysis. See also Docket ID EPA-HQ-OAR-2021-0317-0050 (U.S. Environmental Protection Agency (EPA). 2002. EPA Air Pollution Control Cost Manual. Sixth Edition. EPA/452/B-02-001. Updated Chapters 1 and 2. 2017-2019). The November 2021 Proposal Technical Support Document (TSD) Air Pollution Control Cost Estimation Spreadsheets for Elevated Flares (April 2019) can be found at Docket ID EPA-HQ-OAR-2021-0317-0039. The December 2022 Supplemental Proposal TSD (EPA-HQ-OAR-2021-0317-1578), Chapter 7, Air Pollution Control Cost Estimation EPA Flare Cost Excel Sheets can be found at Docket ID EPA-HQ-OAR-2021-0317-1621.

### **23.16 Other CAA Program Considerations**

#### ***23.16.1 Regulation of Existing Sources in Metropolitan Areas Under CAA Section 112***

Comment: Commenter (2307-Climate Action et al) encourages EPA to regulate existing oil and gas sources using CAA section 112 in metropolitan areas. The commenter believes that that will allow much prompter control requirements, without the long spans allowed for states and tribes to submit plans, and another period during which EPA reviews such plans as well as eliminates the ability of states or tribes to exempt certain facilities.

Response II-23-46: This comment regarding the regulation of existing oil and gas sources using CAA section 112 is outside the scope of this rulemaking; as such, no response is required.

#### ***23.16.2 Consistency with International Methane Emission Reduction Programs***

Comment: Commenter (2396-Shell) provides technical input on the EPA’s methane performance standards and related regulatory requirements in the proposed rule through various associations and groups of which the commenter and its affiliates across the globe hold memberships. As a result, the focus of their comments here is on several overarching elements that they believe should be included in the EPA’s methane regulatory program being developed under CAA section 111. The commenter suggests that the EPA’s full development and inclusion of the elements they outline below is necessary to ensure proper alignment of the U.S. regulatory

framework with methane regulatory programs of other countries, including those countries within the European Union. In particular, the commenter asserts that this alignment is critically important for demonstrating regulatory equivalence between the U.S. and the European Union (as well as other countries) – which, in turn, can best support and facilitate the efficient flow of LNG exports from the U.S. to those other countries.

The commenter (2396-Shell) provides key background information that informs their position on how proper alignment of the EPA’s methane regulatory framework can best be achieved with the ambitious methane regulatory programs being established by other countries. In particular, their comments briefly discuss global trends on LNG trading and relevant natural gas regulatory developments in the European Union that should inform the EPA’s development of the U.S. methane regulatory program under section 111 of the CAA. A review of these relevant international trends and regulatory developments is followed by a discussion of the three key elements that the EPA should include in the U.S. methane regulatory program to promote efficient flow of LNG exports from the U.S. to the European Union and other countries. As discussed below, these key regulatory elements include the establishment of—

- Rigorous performance standards that strive to achieve an ambitious and stringent methane intensity performance standard (such as an intensity level in the range of 0.20 percent as determined based on best available measurement data) for the upstream segments of the natural gas supply chain;
- Robust monitoring, reporting and verification (MRV) protocols aligned with the OGMP 2.0; and
- Flexible implementation framework that allows for the conversion of the EPA’s final methane performance standards for each upstream segment of the supply chain into an overall methane intensity standard.

*Global trends on LNG trading and recent regulatory developments in the European Union.* As one of the world’s largest global traders in LNG, the commenter (2396-Shell) recognizes that how the European Union regulates methane emissions from upstream natural gas operations has implications for the workability of the global market. According to the commenter, these implications are potentially of great importance to U.S. LNG exports and U.S. natural gas producers that sell LNG for export. Notably, global LNG demand continues to grow each year (even during the outbreak of the covid pandemic) and is projected to increase from 360 million tons per year in 2020 to 700 million tons per year by 2040. Furthermore, the commenter notes that the U.S. is the world’s fastest growing LNG exporter with ten new LNG export projects coming online in 2020 and with total LNG exports projected to increase by 188 percent from 50 million tons per year in 2020 to 144 million tons per year in 2040.

The commenter (2396-Shell) provides that the European Union is a key market for import of natural gas from the U.S. and other countries. As a result, the European Union’s decisions on methane regulations (specifically the potential adoption of methane intensity standard) could have significant ramifications for U.S. exports of natural gas into the European Union.

The commenter (2396-Shell) notes that the European Commission recently issued last December its legislative proposal to reduce methane emissions from the energy sector. Although not yet

finalized, that legislative proposal includes a prerogative for the Commission to amend the legislative proposals to impose more stringent measures on natural gas importers by 2025 once better global methane emission data are available, including targets. The European Parliament has been calling for the introduction of such targets and is expected to request their inclusion in the final legislation prior to 2025. For example, an intensity performance standard of 0.20 percent could apply to the upstream segment of the natural gas supply chain from wellhead to point of sale.

Given that the European Union imports from the U.S. and other countries over 80 percent of its natural gas, the commenter (2396-Shell) reports that it is anticipated that if the legislation is amended to introduce a methane intensity standard for all gas consumed in the EU, the European Union will apply such a standard to natural gas (including LNG) that is imported from all foreign countries. To assure that the imported natural gas meets this methane intensity standard, the importers of the natural gas may be subject to a proportional financial penalty for the portion of their natural gas volumes that exceeds the applicable methane intensity standard. This financial penalty could be imposed as a methane fee or other GHG-related tax or fee. In addition, according to the current legislative proposal, the European Union member states are mandated to impose a penalty on natural gas imported from those countries without a robust MRV system in place. The commenter states that the penalty can be based on an assigned default emission intensity value that conservatively accounts for the potential methane emissions attributable to the production, processing, and shipment of that imported natural gas.

By contrast, the commenter (2396-Shell) explains that no financial penalties are likely to be imposed on natural gas imported from those countries that have methane regulations that are at least equivalent to the methane intensity standards and MRV protocols to be established by the European Union. In such cases, oil and gas producers, LNG traders, and shippers would not have to add another layer of verification to prove that their natural gas meets the European Union intensity standard. Without such equivalence – if the European Union proceeds with an emissions intensity standard – demonstrating compliance with that standard for upstream emissions could potentially put U.S. LNG exports at a competitive disadvantage because the only possible way to avoid financial penalties would be through costly and potentially unworkable added MRV schemes that could require tracing natural gas molecules from individual producers along complex natural gas delivery chains.

*EPA's proposed NSPS OOOOb and EG OOOOc methane control requirements.* Commenter (2396-Shell) believes that the proposed methane control requirements for new and existing oil and natural gas sources generally reflect best available control measures that are generally aligned with any methane intensity target considered by the European Union in the future for the upstream segment of the natural gas supply chain in the U.S.

*Robust MRV protocols modeled after OGMP 2.0 for demonstrating compliance and determining methane emission intensity across the natural gas supply chain.* The commenter (2396-Shell) believes that the regulatory framework authorized under CAA provides the EPA and states with considerable latitude to establish credible and reliable protocols for determining compliance with methane intensity standards. One such option is OGMP 2.0, which establishes a greatly improved set of MRV protocols that have been under development since 2019 by the United

Nations Environment Program (UNEP) and the Climate and Clean Air Coalition (CCAC) in partnership with the European Union Commission, the Environmental Defense Fund, and major industry players. The commenter explains that these MRV protocols focus on establishing best-practices for quantifying methane emissions from all segments of the oil and gas sector where material quantities of methane emissions can be released. OGMP 2.0 effectively increases the accuracy and granularity of methane emission monitoring, reporting, and verification for oil and gas assets.

In the recently proposed methane legislation, the commenter (2396-Shell) notes that the European Union uses the OGMP 2.0 as the basis for its mandatory MRV protocols under methane regulatory program that it now has under development. The commenter believes that OGMP 2.0 sets a necessary new standard for credible and transparent methane emissions reporting, while recognizing the outstanding technological, commercial, and cost challenges to improved emissions reporting. In the current legislative proposal, these MRV protocols would likely also apply to all imports of natural gas into the European Union, including LNG and pipeline natural gas imported from other countries. Adoption of the OGMP2.0 protocols by natural gas/LNG exporters into the European Union and natural gas producers in the country of origin, satisfies MRV data transparency requirements in the European Union methane legislation.

For these reasons, the commenter (2396-Shell) urges the EPA to develop robust MRV protocols for demonstrating compliance with the methane emissions standards and determining methane emission intensity across the natural gas value chain. In so doing, the EPA should work to ensure that MRV protocols being developed for the U.S. regulatory program are fully consistent and generally equivalent to the version of OGMP 2.0 now being developed for use in the European Union. This equivalence will provide a simple mechanism for demonstrating that LNG from the U.S. meets the performance standards that could be established in the future for importing LNG into the European Union.

*Methodology for converting performance standards into methane emission intensity standards.*

A third and final element put forth by the commenter (2396-Shell) is the development of a flexible implementation framework that allows for the conversion of the EPA's final methane performance standards for each affected facility and emitting activity into a methane intensity standard for all segments of oil and natural gas source category. The commenter explains that intensity targets are an effective means of managing methane emissions in the upstream natural gas supply chain and once applied to each segment of the natural gas supply chain, have the advantage of stimulating methane emissions reductions in every segment of the chain. Instead of just focusing on only certain specific types of sources for achieving the mandated methane reductions, an intensity standard would provide the most flexible and efficient way for companies to achieve methane reductions. According to the commenter, this approach will ensure all methane sources are managed and allow companies to focus its control efforts on those sources that are most impactful and effective way to reduce methane emissions.

Furthermore, the commenter (2396-Shell) believes that the establishment of an intensity standard could greatly simplify the process for demonstrating the regulatory equivalence of LNG imported from the U.S. into the European Union. The commenter asserts that the best way to

position U.S. gas exports to the European Union is based on regulatory equivalence between the trading blocks. This eliminates the formidable technical challenges with tracing gas molecules from individual producers along complex gas delivery chains. According to the commenter, such a framework for demonstrating accommodate equivalency could help to preserve U.S. competitiveness and export opportunity.

The commenter (2396-Shell) provides a regulatory analysis in Appendix B<sup>53</sup> of their comment letter that includes an explanation of the legal authority and discretion accorded to the EPA and states for implementing the methane performance standards established under section 111 of the CAA. As discussed in Appendix B of their comment letter, they believe that this authority allows for the conversion and implementation of methane performance standards into equivalent methane intensity standards.

Response II-23-47: Similar comments were provided by this commenter on the November 2021 Proposal, see Volume I, Chapter 23 (Miscellaneous Other Comments), subsection 23.11 (Other Recommendations for Reducing Impacts from Methane Emissions), Response I-23-58 for response to this comment.

### ***23.16.3 Presumptive Minimum Fee Program Required Under Title V of the CAA***

Comment: Commenter (2222-WDNR) recommends that EPA review the assumptions (established and unchanged since 1993) on which the current presumptive minimum fee program required under Title V of the CAA is based, given the changes over time to the emissions profiles of regulated sources. The commenter asserts that the review needs to include an analysis of the reduction in actual emissions at Part 70 sources even as the complexity of work and the number federal requirements has increased.

Response II-23-48: The current presumptive minimum fee program required under title V of the CAA is out of scope of this rulemaking; as such, no response is required.

Comment: Commenter (3380-Private Citizen) asserts that Michigan's Oil and Gas Industry does not warrant the new regulations on existing emission sources that are covered under the EPA's proposed EG OOOOc. The commenter provides that, during 2021 Michigan (1) had 15,748 active oil and gas wells (10,362 gas and 5,386 oil); (2) total annual production was 4,400,000 barrels oil and 71,800,000 thousand cubic feet (Mcf) natural gas; (3) the average production for oil wells was 2.24 barrels of oil per day (BOPD) and for gas wells 20 thousand cubic feet per day (Mcf); and (4) there were only 25 producing properties making over 100 BOPD and 32 gas production properties delivering over 1,000 Mcfd. The commenter contends that assessing fees for natural gas emissions on pumping oil wells that are only active for a couple hours per day is excessive and fees associated would likely make a significant number of wells uneconomic. Likewise for gas wells, a significant number are operated on vacuum compression, so emissions are not feasible on wellheads and gathering lines. The commenter notes that they understand the need to reduce natural gas emissions but they believe that assessing fees must focus on large

---

<sup>53</sup> Appendix B of the commenter's letter is entitled "EPA and State Authority to Convert EPA'S Final Methane Performance Standards to Intensity Standards", 3 pages.

emitters. Lastly, the commenter suggests that EPA should have production rate minimums similar to marginal wells such as a minimum of 10 BOPD or of 50 Mcfd.

Response II-23-49: In response to the commenter stating that the Michigan Oil and Gas Industry does not warrant new regulations on existing emissions sources that are covered under the EPA's proposed EG OOOOc, see section VIII.C (Establishing Standards of Performance in State Plans) of the final rule preamble for a discussion of the requirements under section 111(d) that a state plan's standards of performance reflect the presumptive standard.

The commenter states that they believe that fees should be focused on large emitters and recommended that production rate minimums be applied where only rates above the production rate would be assessed for fees. The current fee program required under title V of the CAA (which we believe that the commenter is referring to) is out of scope of this rulemaking; as such, no response is required.

If, however, the commenter is referring to a waste emissions charge via the implementation of CAA section 136, that it was outside of the scope of this rulemaking. CAA section 136(c) directs the Administrator of the EPA to "impose and collect a charge on methane emissions that exceed an applicable waste emissions threshold under subsection (f) from an owner or operator of an applicable facility that reports more than 25,000 metric tons of carbon dioxide equivalent (CO<sub>2</sub> Eq.) of GHG emitted per year pursuant to subpart W of part 98 of title 40 (40 CFR part 98), regardless of the reporting threshold under that subpart" (hereinafter, waste emissions charge). An "applicable facility" is defined under CAA section 136(d) to include nine specific industry segments as defined in GHGRP subpart W. Pursuant to CAA section 136(g), the waste emissions charge "shall be imposed and collected beginning with respect to emissions reported for calendar year 2024 and for each year thereafter." See section VI.C (Methane Emissions Reduction Program) of the final rule preamble for additional discussion on the Methane Emissions Reduction Program, including the section 136(f) exemption from the waste emissions charge for applicable facilities that meet certain criteria.

## **23.17 Inconsistency with Other Federal Requirements**

Comment: Commenter (2257-MOGA) states that several small-entity oil and gas producers in the State of Michigan have asked the EPA why the Mineral Leasing Act and updates to the BLM regulations highlight waste prevention including, limiting gas flaring, leak detection, reduced venting and gas capture when Michigan's small business operators are being asked to open tank hatches daily to "strap" the oil level in each tank containing oil produced from BLM property. For those readers who are not lease operators, geologists and/or engineers engaged in the daily production of oil and gas, they report that when a thief hatch is open, all working, standing, and breathing losses (including methane and VOCs) are vented from the system. The commenter understands the frustration of Michigan's producers and the great financial and impractical operational burden additional regulations will place on already diminishing production, but BLM required daily venting of methane and VOCs from the entire tank system and vapor recovery piping to ascertain production within ¼ of an inch, while simultaneously imposing leak detection of possible leaks is hypocritical and completely invalidates the cost benefit analysis of methane and VOC emissions reduction.

Response II-23-50: This comment on BLM requirements is outside the scope of this rulemaking; as such, no response is required.

Comment: Commenter (2257-MOGA) questions EPA’s narrative and rhetoric regarding the dangers of methane to “climate change” when simultaneously proposing regulations regarding methane sources that are not linear to the EPA narrative of the dangers of methane to human health and the environment. As noted in their January 17, 2023, letter requesting a public comment extension from 20 state Attorney Generals, the EPA had published concurrent revisions to both the December 6, 2022, proposed NSPS OOOO(b) and EG OOOO(c) and “Waters of the United States”. The commenter notes that the EPA’s press release on December 30, 2022, indicated that the final “Waters of the United States” was necessary to “protect people’s health” by expanding the definition of “Water of the United States” to “upstream water resources”. The commenter questions the EPA’s logic regarding expanding protection of the “Waters of the United States” and associated wetlands while simultaneously explaining the harmful effects of methane on climate change.

The commenter (2257-MOGA) reports that wetlands emit almost twice the amount of methane to the environment than estimated oil and natural gas production emissions. Many of the commenter’s constituents question whether it is appropriate for the EPA to propose regulations for the protection of wetlands likely resulting in the creation and protection of additional wetlands when the EPA has gone to great lengths to explain the detrimental effects of methane on human health and the environment. The commenter’s members are concerned with this logic and feel the EPA is “picking and choosing” logic and data to support an anti-oil and gas narrative.

Response II-23-51: See discussions in sections IV (Statutory Background and Regulatory History) and V (Legal Basis for the Final Rule Scope) of the final rule preamble for the basis and scope of the final NSPS OOOOb and EG OOOOc rules.

With regards to the final “Waters of the United States” definition, this comment is out of scope of this rulemaking, as such, no response is required.

Comment: Commenter (2293-Private Citizen) states that in Utah, the proposed Uinta Basin Railway (UBR) would facilitate expansion of oil extraction in an area already non-compliant with CAA pollution standards. The commenter explains that the UBR’s anticipated 3-4-fold increase of oil production, transportation, and ultimately combustion would increase—not decrease—U.S. GHG emissions locally, regionally, and globally. Nevertheless, the commenter states that the U.S. Surface Transportation Board (STB) and the U.S. Forest Service have green-lighted the 85-mile long UBR, granting the permit and right of way requested by district and interlocal agency officials aligned with the fossil fuel industries.

The commenter (2293-Private Citizen) adds that the STB and Forest Service environmental reviews failed to comprehensively address VOC-and methane- generated ozone formation and related health impacts in the Uinta Basin and downwind in Colorado. They report that they failed to address likely SC-GHG impacts to the region and beyond. According to the commenter, the STB and the Forest Service disingenuously pretended that the only impacts needing focus were

those directly occurring within the immediate UBR project area. [Note that Uinta is sometimes spelled Uintah.]

Additionally, the commenter (2293-Private Citizen) provides that the Uinta Basin oil industry has a second proposed project in-the-works to get more waxy crude oil transported to domestic and foreign markets. The U.S. BLM will have to decide whether to permit construction of what's been dubbed a "hydrocarbon highway" through Gate Canyon, so that a fleet of oil tankers can proceed through Nine Mile Canyon to the Union Pacific railhead. Nine Mile Canyon is a world-class prehistoric art and artifacts gallery. With BLM approval for Gate Canyon and the STB-Forest Service go-aheads for UBR, Uinta Basin oil and gas businesses would have three transit corridors to expand oil production and exports. The commenter asks how this "squares" with President Biden's COP27 pledge?

According to a 2021 University of Utah report in the journal *Nature*, the commenter (2293-Private Citizen) reports that 6-8 percent of methane extracted in the Uinta Basin is escaping into the atmosphere.<sup>54</sup> Methane is a precursor to tropospheric (ground level) ozone formation and is a potent climate change gas. The commenter notes that a Univ. of Utah report notes that uncaptured Uinta Basin methane emissions are among the highest in the U.S. The commenter includes graphic evidence of how bad the ozone pollution has been recently in Duchesne County, located in the Uinta Basin. The Basin is currently home to over 10,000 wells...a number expected to increase if the UBR and the hydrocarbon highway are constructed.

Response II-23-52: The Uinta Basin Railway (UBR) expansion of oil extraction approved by the U.S. Surface Transportation Board (STB) and the U.S. Forest Service and BLM approval for Gate Canyon is out of scope of this rulemaking; as such, no response is required.

## **23.18 Misunderstanding of GHG Physics**

Comment: Commenter (2300-SEPP) argues EPA's regulations against GHGs demonstrate the ignorance of physical science by the Federal government. The commenter states that starting in 1859, using early spectroscopy, John Tyndall developed a series of laboratory experiments to explain why the earth was sufficiently warm to sustain complex life, given its distance from the sun. He realized that certain atmospheric gases are transparent to incoming radiation from the sun but inhibit the loss of heat. Tyndall named these gases GHGs and recognized that by far the most important one is water vapor.

Commenter (2300-SEPP) states that in effort to explain other issues such as Ice Ages, some scientists misinterpreted the work of Tyndall including the noted chemist Svante Arrhenius who, in 1896, proposed a relationship between carbon dioxide concentrations and temperatures that the commenter contends were false. The commenter notes that the EPA has used this paper to defend its views on the warming influence of carbon dioxide and other GHGs even though Arrhenius refuted his earlier work in 1906.

---

<sup>54</sup> [www.nature.com/articles/s41598-021-01721-5](https://www.nature.com/articles/s41598-021-01721-5).

The commenter (2300-SEPP) reports that we now have over 150 years of laboratory experiments backed by over 50 years of atmospheric observations that show the characteristics of GHGs. What the EPA does not recognize is:

- For an average temperature of 296 K (22.85C, 73.1F) the earth emits infrared radiation in the range from 0 to about 2000 nanometers, as defined by Planck's law. Earth's strongest emissions are from about 400 to 800 nanometers. Calculations of GHG interference with other electromagnetic radiation beyond 2000 nanometers have little meaning.
- GHGs interfere with infrared radiation in specific wavelengths (frequencies). For example, carbon dioxide interferes strongly with infrared radiation in the 500 to 800 nanometer range.
- The warming effect is non-linear. No simple mathematical ratio can correctly compare two GHGs such as carbon dioxide and methane.
- The greenhouse effect is self-limiting. For example, the influence of both carbon dioxide and water vapor are logarithmic, meaning that the rate of temperature increase declines as the concentration increases.
- Both carbon dioxide and water vapor are strongly saturated. Just like a sponge saturated with water, the carbon dioxide and water vapor cannot interfere with significantly more infrared energy emitted by the earth in that wavelength (frequency), and it passes through to space. Adding more of that GHG has little effect on temperatures.
- The interference capability of a specific GHG may be virtually eliminated by another GHG. For example, the wavelengths (frequencies) in which methane interferes with infrared radiation are already covered by water vapor, the dominant GHG. This joint interference renders the influence of additional methane minuscule.

Commenter (2300-SEPP) adds that the peer reviewed fifty-year old HITRAN database is based on over 150 years of laboratory measurements under ideal conditions. Atmosphere measurements of pressure and temperature from weather balloons provide the data to modify the cross-sections of laboratory measurements in calculable ways. The commenter contends that these corrections are needed to understand what is really occurring in the atmosphere, going far beyond laboratory measurements, much less speculation.

Commenter (2300-SEPP) states Atomic, Molecular, and Optical (AMO) physicists have made their careers on understanding how matter interacts with electromagnetic radiation, including infrared radiation emitted by all bodies in space, including the earth. Distinguished AMO physicists William van Wijngaarden, University of York, and William Happer, emeritus of Princeton, have used the HITRAN database to write a series of papers on the interaction of GHGs on the earth's thermal (infrared) radiation.

Commenter (2300-SEPP) concludes in so doing, these physicists have summed a wealth of physical evidence that has been ignored by the EPA and by many scientists for decades. The commenter asserts that physical evidence trumps any speculation or theories. According to the commenter, it is past time for the EPA to evaluate physical evidence, not its pet theories. Until it

has done so, the commenter believes that any of EPA's additional regulations on methane such as this one, or other GHGs are based on speculation, not science.

Response II-23-53: These comments are not within the scope of this rulemaking; as such, no response is required.

With regards to reference to article by Wijngaarden and Happer, see Volume I, Chapter 20 (Emissions and Regulatory Impacts), section 20.2.2 (Global Warming Potential (GWP) of Methane, Response I-208.

Methane is a powerful greenhouse gas. Methane is 28 times as potent as CO<sub>2</sub> over a 100-year time frame, and historical emissions of methane have contributed about a third of today's warming. Methane also contributes to increases in global tropospheric ozone levels, which damages human health and ecosystems. This action will contribute to reductions in methane emissions. See section III.A.1 (Climate change impacts from GHG emissions) of the final rule preamble for a discussion on the climate change impacts from GHG emissions.

### **23.19 Reports and Studies Submitted to EPA**

Comment: Several commenters provide studies/reports for EPA to consider. Examples of some of those studies/reports provided by commenters follow.

Commenter (3605-Private Citizen) provides a cite to a preprint paper that discusses first results from the use of measurement informed inventories at midstream facilities. The commenter suggests that in the current supplemental proposal, the proposed regulatory structure for advanced monitoring solutions appears to be driven primarily by observations from the production sector. They assert that the challenges in the midstream sector are substantially different and that the provided work provides a first look at how next-generation methods can accelerate methane mitigation:

Brown, et al., Informing methane emissions inventories using facility aerial measurements at midstream natural gas facilities;  
<https://chemrxiv.org/engage/chemrxiv/article-details/63e6b8aafcfc27a31f8ec5b9>

Another commenter (3812-Earthworks) submitted a report titled "Certified Disaster: How Project Canary & Gas Certification are Misleading Markets & Governments." Oil Change International and Earthworks. April, 2023. This report examines the gas certification market, specifically one of the current industry leaders, Project Canary. Commenter (3816-EDF) submitted a study published in Environmental Research: Health by BU, UNC, and EDF researchers examining the health impacts of U.S. oil and gas production. The study assesses the air quality and human health impacts of ozone, fine particulate matter, and nitrogen dioxide from the oil and gas sector in the U.S. in 2016 and finds that this air pollution from the sector in 2016 resulted in 7,500 excess deaths and \$77 billion in total health impacts, in addition to the climate impacts of methane emissions from the sector.

Response II-23-54: The EPA appreciates the information provided by the commenters. See also section III (Air Emissions from the Crude Oil and Natural Gas Sector and Public Health and Welfare) of the final rule preamble for a discussion of climate change impacts from GHG emissions, and the impacts from VOC and sulfur dioxide (SO<sub>2</sub>) emissions.

## **23.20 Legal Challenges**

Comment: Commenter (3848- Native Village of Kotzebue) questions the implications of the June 2022 *West Virginia vs EPA* SCOTUS decision for CAA Sections 111(b) and 111(d) standards, in addition to the related history and current status of the 2015 Clean Power Plan (CPP) and the 2019 Affordable Clean Energy (ACE) rule, how does this Supplemental Proposal substantively address the clear Congressional authority requirement now put in place by the SCOTUS?

The commenter (3848- Native Village of Kotzebue) suggests that the Agency would be better off trying to get specific language passed by Congress, instead of continuing to try and implement Agency rulemaking, with regards to issues specifically related to air pollution from major stationary sources, including the oil and gas production sector. The commenter wonders what EPA's strategy will be to successfully implement a new Rule all the way past legal challenges.

Response II-23-55: The EPA provided its statutory authority for this action in sections IV (Statutory Background and Regulatory History) and V (Legal Basis for Final Rule Scope) of the final rule preamble.

## **23.21 Out of Scope Comments**

Comment: Commenter (2382-Mappingyouuniverse) submitted a policy memo. The executive summary of the memo states that the NSPS are a part of the regulation on the methane released by the oil and gas industry with a history that traces back to the Obama administration. In order to prevent politically unstable conditions that would repeal the policy for the third time, the EPA should reconsider hiring practices and using existing staff to advance data analysis efforts and expanding administrative capacity across the agency to aid in implementation of the NSPS. Public managers should be concerned with innovation in the interest of their own workloads and the efficiency of the work between industry and environmental agencies. The policy memo provides recommendations for EPA to consider.

Response II-23-56: The commenter's policy memo and its suggestions are out of scope of this rulemaking; as such, no response is required.

Comment: Commenter (1900-Private Citizen) expresses that they understand the need to control fugitive methane leaks, in order to control climate change. However, the commenter provides that noise related to a compressor station operation is also a problem. They provide that their neighborhood of 50-80 homes fits the description of what the EPA calls as an impacted community, and they are bearing the brunt of the environmental and health effects of a compressor and noise impacts. The commenter reports that many of their neighbors (the stakeholders) do not understand how a compressor station was built with so few of them

knowing about it. Upon researching this, the commenter found that a tiny legal announcement was made in a small newspaper called the Brooke Review, in December of 2019; public comments went on through January of 2020. With the holidays, and the beginnings of COVID-19, few of us were aware that this compressor station was being built, and that it would be so noisy, and that it would flare and emit VOCs into their quiet rural neighborhood. The four major complaints the commenter has regarding the compressor station impacting their community and noise regulation include:

- There was a poor method of notification to neighborhood that a natural gas compressor would become our new neighbor before it was constructed.
- There was no explanation or rationale provided to them as to how a natural gas compressor site is selected. The site selected is 600-700 feet from established neighborhoods, but the sound and emissions carry much further.
- There is no ambient, real time air monitoring available to neighbors now that the compressor is built and online.
- Why has the regulation of noise been ignored?

Response II-23-57: Noise pollution is out of scope of this rulemaking; as such, no response is required.

## Appendix A. Comments on Updated Social Cost of Greenhouse Gases Estimates

EPA identified public comment submissions received in the rule docket as containing content related to EPA's updated estimates of the social cost of greenhouse gases (SC-GHG) that were used in sensitivity analysis in the Supplemental Proposed Rule RIA and were described in the accompanying Supplementary Material for the RIA, titled *External Review Draft: Report on the Social Cost of Greenhouse Gases: Estimates Incorporating Recent Scientific Advances*. In this Appendix EPA provides a summary and responses to this set of public comments.

Throughout this Appendix, we refer to EPA's *External Review Draft: Report on the Social Cost of Greenhouse Gases: Estimates Incorporating Recent Scientific Advances* as the "Draft Report" and the finalized version of this report as the "Final Report". The SC-GHG estimates developed in the 2022 Draft Report are referred to as the "EPA SC-GHG estimates", and the 2021 Interim IWG recommended SC-GHG estimates are referred to as the "IWG SC-GHG estimates".

### A.1 General Comments and Use of SC-GHG Estimates in Policy Analysis

Comment: Many commenters (2349-RFF, 2398-Policy Integrity NYU, 2246-NRDC, 2194-S. Dietz et al., 2315-NYSDEC, 2397-Climate Alliance, 2433-EDF, 2208-CCES et al., 3174-Climate Science et al., 2212-UCS, 2355-Constellation, 2343-Policy Integrity NYU, 2315-NYSDEC, 2183-M. Freeman et al., 2433-EDF, 3658- PolicyInteractive, 2410-CA AG et al., 2464-Heal and Bressler, 2343-Policy Integrity NYU, 2364-CleanEarth4Kids, 3183-Climate Committee, 2231-R. Sohn, 2293-S. Holmes, 2313-M. Plevin-Foust) express overall support for EPA's Draft Report of The Social Cost of Greenhouse Gases: Estimates Incorporating Recent Scientific Advances.

Several commenters (2433-EDF, 2293-S. Holmes, 2313-M. Plevin-Foust, 3658-PolicyInteractive, 2253-OCT, 2364-CleanEarth4Kids) highlight the urgent need for strong climate policies and urge EPA to take action.

Commenters (2349-RFF, 2208-CCES et al., 2398-Policy Integrity NYU, 2246-NRDC, 2343-Policy Integrity NYU, 2355-Constellation) laud EPA for developing a robust integrated assessment model and affirm that EPA followed the recommendations provided by the National Academies of Science, Engineering, and Medicine (NASEM). Commenters (2349-RFF, 2208-CCES et al., 2246-NRDC, 2397-Climate Alliance, 2315-NYDEC, 3183-Climate Committee) assert that EPA's Supplemental Proposal is consistent with the latest available science. Several commenters state that EPA's SC-GHG estimates are a significant improvement over prior values that have been used (2349-RFF, 2194-S. Dietz et al., 2397-Climate Alliance, 2208-CCES et al., 3174-Climate Science et al., 3183-Climate Committee, 2343-Policy Integrity NYU, 2398-Policy Integrity NYU).

Commenter (2349-RFF) states that "The EPA report is fully responsive to all of the NASEM's near-term recommendations" and "The EPA report's updated SC-GHG estimates are the best available SC-GHG estimates, consistent with the best available science, and should therefore replace the interim estimates reported by the Interagency Working Group in February 2021."

Commenter (2208-CCES et al.) notes that EPA’s SC-GHG estimates represent the first comprehensive update in a decade, and during that time, the scientific community has developed an improved understanding of the economics of greenhouse gas emissions. The commenter affirms that the “Draft Report comprehensively incorporates this new research and updates the social cost of greenhouse gases consistent with the best available science and economics” and “closely applies the 2017 recommendations of the National Academies of Sciences, Engineering, and Medicine.” The commenter further notes that independent valuations of the SC-GHG closely resemble the estimates from EPA’s Draft Report. The commenter notes that “Numerous foreign countries including Germany, France, and the United Kingdom also apply similar or higher valuations for the social cost of greenhouse gases” and “experts widely agree that the Working Group’s climate-damage estimates are far too low.”

Commenter (2398-PolicyIntegrity NYU) states that the Draft Report follows the roadmap provided by the National Academies of Sciences. The commenter further notes that “EPA deserves credit for developing a state-of-the-art modular integrated assessment model consistent with the suggestions of the National Academy of Sciences.” The commenter notes that EPA’s estimates are a significant improvement over the climate-damage valuations developed by the IWG and that there is a “widespread economic consensus that those Working Group values represent lower-bound estimates.”

Commenter (2246-NRDC) states that the EPA Draft Report’s update of the SC-GHG “is grounded in up-to-date science and economics” and “accurately implements necessary updates recommended by the National Academies of Sciences (NAS).”

Commenter (2194-Dietz et al.) self-identifies as academic researchers who study the social cost of greenhouse gas emissions, and from that perspective, offer congratulations to the EPA team “on their excellent work that follows many of the recent advances in climate economics.” The commenter states that the EPA Draft Report “represents a significant advance and update on earlier social cost of greenhouse gas numbers put forward by the Interagency Working Group.”

Commenter (2397-Climate Alliance) applauds EPA for its improvement over the IWG’s interim estimates, which the commenter argues are outdated and significantly underestimate the costs of climate damages. The commenter further states that EPA’s SC-GHG estimates use the latest science, appropriate discounting, and account for global damages.

Commenter (2183-M. Freeman et al.) states that the central numerical value of the social cost of carbon as well as the use of a central real social discount rate around a value of approximately 2% have strong independent support from the academic literature. The commenter cites their own independent research<sup>1,2</sup> and another study<sup>3</sup> that similarly document a higher SCC over the last decade than what is reported by the IWG interim estimates.

---

<sup>1</sup> Hänsel, M.C., Drupp, M.A., Johansson, D.J., Nesje, F., Azar, C., Freeman, M.C., Groom, B. and Sterner, T., 2020. Climate economics support for the UN climate targets. *Nature Climate Change*, 10(8), pp.781-789.

<sup>2</sup> Nesje, F., Drupp, M., Freeman, M. and Groom, B., 2022. Philosophers reinforce economists' support for UN climate targets but disagree on why.

<sup>3</sup> Tol, R.S., 2021. Estimates of the social cost of carbon have increased over time. *arXiv preprint arXiv:2105.03656*.

Commenter (3174-Climate Science et al.) states that “there is little question but that the EPA social cost of carbon estimate is more representative of reality than its progenitors, given its incorporation of numerous recommendations for more accurate modeling stemming from the expert community.”

Commenter (2343-Policy Integrity NYU) states that EPA’s Draft Report “faithfully implements the roadmap laid out in 2017 by the National Academies of Sciences, and, while it represents a significant increase over the climate-damage valuations from the IWG, that increase is consistent with the widespread economic consensus, including the IWG’s own repeated recognition that its valuations are underestimates.”

Commenter (2355-Constellation) supports EPA’s work on the SC-GHG while the IWG’s work continues and highlights that underestimates of the SC-GHG would result in market disincentives for investments in cleaner energy. The commenter notes “[a]s a critical member of the IWG, EPA is an agency with technical and economic expertise that makes it well-suited to establish a social cost of greenhouse gases. EPA’s external review draft of its report on the social costs of greenhouse gases providing updated estimates based on the most recent scientific advances is a valuable resource that – together with the public comments EPA receives on it – should inform the continued work of the IWG.”

Response A-1-1: EPA thanks the commenters for their supportive comments. EPA believes that the Final Report represents the latest available science and follows the recommendations of the National Academies of Science, Engineering, and Medicine. EPA acknowledges the comments received expressing general support for EPA’s draft report and SC-GHG estimation methodology. Some of these commenters had additional recommendations for improvement in specific aspects of the estimation methodology and process; we address these in other sections of this Appendix.

Comment: Commenters (2315-NYSDEC, 2397-Climate Alliance, 2212-UCS, 2349-RFF, 2246-NRDC, 2398-Policy Integrity NYU, 3658-PolicyInteractive, 2355-Constellation) express support for EPA’s update on SC-GHG estimates and for use of these estimates in policy analysis. Commenters (2398-Policy Integrity NYU, 2246-NRDC, 2355-Constellation) express support for regular updates to the SC-GHG.

Commenter (2315-NYSDEC) “recommends that EPA issue cost values for all Greenhouse Gas emissions (GHGs) and, at the very least, for those GHGs reported to the greenhouse gas reporting program. This work will help states undertake action on these GHGs and avoid the redundant use of public funds to conduct such work.”

Commenter (2397-Climate Alliance) identifies themselves as a bipartisan coalition of governors representing 60 percent of the U.S. economy and 55 percent of the U.S. population and commits to considering the environmental and societal impacts of GHG emissions in their climate action efforts. The commenter expresses the need to account for the true cost of climate damages in policymaking. The commenter states that many members have already included estimates of the SC-GHG in their policymaking and urge EPA to ensure that the final IWG estimates are at least as strong as those presented in EPA’s Draft Report. The commenter notes that “[p]roperly

accounting for the societal costs of a changing climate is key to crafting effective state and federal policies and achieving our shared net-zero climate goals.”

Commenter (2212-UCS) commends EPA for taking “an important and necessary step” in issuing the Draft Report and incorporating its findings as a sensitivity in the supplementary RIA. The commenter notes that “while EPA makes clear that the rulemaking is not predicated on these supplemental [SC-GHG] values, the rulemaking as a whole benefits from their incorporation to provide fuller context for the potential impact of this rule.” The commenter argues that while there is an ongoing IWG process to standardize SC-GHG values, EPA should incorporate its understanding of updates in science, economics, and best practice given the potential relevance of the issue to the rulemaking.

Commenter (2246-NRDC) states that “EPA should adopt the Draft Report’s social cost of greenhouse gas (SC-GHG) estimates because they accurately reflect current scientific and economic consensus.” The commenter further argues that EPA’s modular approach makes it easier to make future updates to the SC-GHG to incorporate advances in science and economics, which the commenter recommends should occur regularly, at least every five years.

Commenter (2398-Policy Integrity NYU) added that EPA’s SC-GHG model is a “powerful tool” which has uses to policymakers beyond calculating the social costs of GHG emissions. The commenter suggests that EPA calculate the total cost of climate damages, as this would provide policymakers and the public with the scale of benefits of various global greenhouse gas emission targets and inform them about the scale of climate action necessary and/or justifiable. The commenter further argues that EPA should update its analysis at least every five years to “benefit of responding to evolving research with the need for a thorough and predictable process” as advised by the National Academy of Science.

Commenters (2355-Constellation, 2343-Policy Integrity NYU) state that it is appropriate for the Supplemental Proposal’s RIA to consider EPA’s social cost of methane sensitivity analysis, as it addresses NASEM recommendations. Commenter (2355-Constellation) “encourage[s] coordination among agencies for consistent application of a social cost of greenhouse gases to provide certainty to the regulated community, avoid confusion, and ensure that all federal regulations reflect the benefits of climate change mitigation.”

Commenter (2293-S. Holmes) states that “[a] key to meeting national goals is establishing a Social Cost of GHGs framework that is based on scientifically sound, real-world values.” The commenter expresses concern towards federal actions that have potentially undermined President Biden’s commitment to climate change action, such as the proposed Uinta Basin Railway. The commenter argues that environmental reviews conducted by other federal agencies failed to consider the SC-GHG impacts of the Uinta Basin Railway and therefore recommends that the administration standardize climate change action across federal agencies.

Response A-1-2: EPA acknowledges the comments received expressing general support for EPA’s SC-GHG estimates and the associated estimation methodology. Some of these commenters had additional recommendations for improvement in specific aspects of the estimation methodology and process; we address these in other sections of this Appendix.

Comment: Several commenters (2208-CCES et al., 2194-S. Dietz et al., 3658-PolicyInteractive, 2246-NRDC, 2313-M. Plevin-Foust, 2253-OCT, 2398-Policy Integrity NYU, 3183-Climate Committee), while providing overall support for EPA’s Report on the Social Cost of Greenhouse Gases, emphasize that EPA’s SC-GHG values remain an underestimate of the true cost of climate damages. Commenters (2208-CCES et al., 2194- S. Dietz et al., 3658-PolicyInteractive, 3183-Climate Committee) offer recommendations to improve EPA’s analysis or bolster EPA’s justification in a number of areas, discussed in more detail in the sections that follow.

Commenter (2208-CCES et al.) states that while the Draft Report is praised for incorporating the latest research and recommendations, the commenter believes that EPA still underestimates the true costs of climate change. The commenter states that EPA can expand the discussion of precedent for consideration of climate damages on a global scale to further bolster support for this geographic perspective. The commenter emphasizes that the federal government has historically viewed its climate-damage valuations as low, and the current EPA valuations are an improvement on earlier figures.

Commenter (2194-S. Dietz et al.) urges EPA to make further improvements to its SC-GHG particularly by including their recent peer-reviewed research on incorporating tipping points in SC-GHG estimation<sup>4</sup> and offer suggestions for how EPA can do this. The commenter argues that without doing so, the direct consequences for policy are an underestimate of the SC-GHG and mitigation policies that are too lax.

While expressing support for EPA’s SCC estimates, commenter (3658-PolicyInteractive) explains: the baseline for damage costs is likely overly conservative due to omitted damages; there is increased urgency to find policy solutions for the breakdown of Earth’s ecological support system; cultural behaviors are driven by monetary incentives, rather than reducing CO2 emissions; and EPA’s estimates are within and towards the lower end of the range of SCC estimates identified in literature from the past 2 years.<sup>5,6,7,8</sup>

Commenter (2246-NRDC) notes that Table 3.2.1 of the Draft Report does not include a majority of the foreseeable impacts of climate change and specifically highlight three omitted damages “that if accounted for would result in an even higher SC-GHG: wildfire related damages which are especially significant within the United States’ borders, and the environmental and ecosystem services damages due to increasing GHG emissions.”

While expressing the need for swift climate action, several commenters (2313-M. Plevin-Foust, 2253-OCT) argue that the SC-GHG estimates are underestimates and do not go far enough to protect children and intergenerational equity (2253-OCT) or international equity (2313-M. Plevin-Foust). The commenters recommend revising the estimates with greater emphasis on these issues. Commenter (2313-M. Plevin-Foust) supports an even higher SCC, noting that it would result in climate stability and global security, improve public health, preserve our economy, and influence other nations to adopt the SCC.

Commenter (2398-Policy Integrity NYU) states that EPA appropriately emphasizes that the SC-GHG estimates are likely underestimates of the true marginal damages of GHG pollution. The commenter highlights numerous omitted damages and argues that the near-term discount rates should be adjusted downward.

Commenter (3183-Climate Committee) notes the improvements in EPA's SC-GHG estimates but argues that it is likely an underestimate of the value that should be used in policy.

Response A-1-3: The EPA thanks the commenters for their comments. EPA believes the methodological updates implemented in the Final Report represent a major step forward in bringing SC-GHG estimates closer to the frontier of climate science and economics and address near-term updating recommendations from the National Academies' (2017). Nevertheless, EPA acknowledges that the SC-GHG estimates presented in the Report still have several limitations, as would be expected for any modeling exercise that covers such a broad scope of scientific and economic issues across a complex global landscape. The EPA has expanded the discussion in the Final Report of the numerous categories of damages that are not currently quantified and other model limitations that lead the EPA to conclude that the resulting SC-GHG estimates likely underestimate the marginal damages from GHG pollution. The EPA will continue to review developments in the literature, including more robust methodologies for estimating the magnitude of the various direct and indirect damages from GHG emissions, and look for opportunities to further improve SC-GHG estimation going forward. Some of these commenters had additional recommendations for improvement in specific aspects of the estimation methodology and process; we address these in other sections of this Appendix.

Comment: Commenter (2239-A.Fraas et al.) notes the progress made by EPA's External Review Draft, but recommends that EPA provide more clarity about the implications of the methodology choices and transparency in the representation of SC-GHG estimates, especially in light of differing opinions on how to appropriately address fundamental uncertainties involved in developing damage estimates. The commenter notes, for example, the daunting nature of this calculation has caused some researchers to argue for abandoning the SCC altogether and instead use alternative approaches that examine the cost-effectiveness of different policies.

Response A-1-4: EPA has provided increased clarity and transparency in the Final Report by expanding the discussion of the methodology underlying each component, or module, of the SC-GHG estimation process and the associated uncertainties. EPA has also added a new Appendix in the Final Report to summarize the treatment of uncertainty in each module. Responses to more detailed comments from this commenter are provided in the sections below.

Comment: Commenters (2220-WDEQ, 2401-Gov Mark Gordon, 2339-INGAA, 2413-CEI/HF, 2428-API, 2218-TCEQ and RRC) raise concerns over the inherent uncertainties in EPA’s analysis.

Commenters (2220-WDEQ, 2401-Gov Mark Gordon, 2339-INGAA) raise concerns about EPA’s calculations, specifically regarding the usage of Integrated Assessment Models (IAMs). The commenters argue that IAM-based analyses lack precision and can produce results that align with desired outcomes as the key inputs can be arbitrarily chosen.

Commenter (2413-CEI/HF) argues that “SC-GHG estimates are too speculative, and too easily manipulated for political purposes, to inform regulatory decisions.”

Commenter (2428-API) argues that the SC-GHG estimates have limited utility beyond their original intended application in cost-benefit analysis due to its significant uncertainty and malleability. The commenter highlights the wide range of uncertainty and variability associated in the SC-GHG estimates, particularly for methane and carbon dioxide. Overall, the commenter questions the broader applicability and reliability of SC-GHG estimates, emphasizes the uncertainty surrounding them, and suggests that their use be limited to cost-benefit analysis.

Commenter (2218-TCEQ and RRC) argues that EPA’s SC-GHG estimates “unjustifiably inflates the climate benefits of the proposed regulatory scheme.” The commenter notes that “The ‘benefit’ of avoided climate change cost or damages because of the assumed international methane emission reductions is unquantifiable and uncertain. Yet, the cost of compliance by both oil and gas owner/operators and states is real and immediate.” The commenter further expresses concern that EPA’s sensitivity analysis denotes that benefits from the proposed regulations would not be realized during the 2023-2035 timeframe.

Response A-1-5: All policy analysis involves uncertainty. The EPA acknowledges uncertainty in SC-GHG estimation but disagrees that the uncertainty is so great as to undermine use of SC-GHG estimates in analysis, including in the RIA for this final rule. The uncertainty in the SC-GHG estimates applied in the Final RIA is fully acknowledged and comprehensively discussed in the Final RIA, Final SC-GHG Report, and supporting academic literature. The presence of uncertainty is not a reason to exclude the best available estimates of quantified/monetized benefits, as long as it is appropriately characterized. Rather, good economic analysis, consistent with OMB Circular A-4, requires that agencies use the best available scientific, technical, and economic information to derive the best estimates of costs and benefits that they can, and then communicate to the public the limitations and uncertainties of the analyses. This is what the EPA has attempted to do in developing and discussing the updated SC-GHG estimates presented in the Final Report and applied in the Final RIA for this rulemaking.

Taken together, the methodologies adopted in EPA’s updated SC-GHG estimates allow for a more holistic treatment of uncertainty than in past estimates used by the EPA. The updates incorporate a quantitative consideration of uncertainty into all modules and use a Monte Carlo approach that captures the compounding uncertainties across modules. EPA has expanded and clarified the discussion of uncertainty throughout the Final Report, including a new Appendix A.8 and Table A.8.1 summarizing EPA's methodology for the treatment of uncertainty. EPA has

also discussed a variety of sensitivities and uncertainties in the review of the literature and in the presentation of the multiple modeling approaches in the report, including the three damage modules.

EPA addresses comments related to the time horizon of analysis within responses in Section A.2 below.

Comment: Commenters (2361-EPRI, 2227-W. Energy Alliance) provide criticism of EPA's External Review Draft and challenge the applicability of EPA's SC-GHG estimates in policy. Commenters (2428-API, 2339-INGAA, 2327-AK DEC) highlight the lack of clarity in how EPA's SC-GHG will be used.

Commenter (2361-EPRI) states that EPA's SC-GHG estimates "are not yet scientifically reliable and robust for policy use" and that the report does not satisfy the recommendations of the NASEM.

Commenter (2227-W. Energy Alliance) notes that EPA made subjective decisions in the SC-GHG estimation process that could lead to controversy (e.g., focusing on global impacts, relying on long-term economic forecasting, emphasizing risk management over potentially innovative risk-taking) and over-relies on one indicator (SCC) as a surrogate for more comprehensive policymaking inputs. The commenter argues that due to these factors, particularly reliance on SCC as an economic indicator of future CO<sub>2</sub> emission damages, it is unlikely the use of SCC will be stable through future administrations. The commenter further states that the SC-CO<sub>2</sub> should not be used in isolation when considering environmental or public policies. The commenter concludes that EPA should not use the SCC in isolation when establishing environmental, energy, or national security policy. While discussing EPA's comparison to the 2021 interim SC-CH<sub>4</sub> estimates, the commenter also claims EPA's summary to be misleading because "it is the result of using a different range of discount rates in the tables being compared". The commenter states that EPA should conduct its SC-CH<sub>4</sub> analysis more transparently.

Commenter (2339-INGAA) supports actions to reduce GHG emissions but expresses serious concerns regarding the use of the SC-GHG estimates. The commenter argues that the SC-GHG estimates are highly speculative, policy-laden, and ultimately non-scientific. The commenter argues that EPA's decisions to issue its own SC-GHG analysis, which differs substantially from the IWG's and produces much higher estimates, creates unnecessary and harmful regulatory uncertainty for industry. The commenter argues that at a minimum, SC-GHG estimates must be reached through a process that minimizes regulatory uncertainty. The commenter urges EPA to rescind its Draft Report and cease employing its different SC-GHG figures in its decision-making.

Commenter (2254-PBPA) notes that agencies that were not required to use the IWG's SCC estimates and refused to use them because of the lack of consensus on discount rate, the failure of the tool to measure actual incremental impacts of a project on the environment, and the lack of standards to determine "significant" monetized values for NEPA purposes.

Commenters (2428-API, 2339-INGAA) add that it is impossible to determine why EPA drafted the report or how it intends to use it (such as for cost-benefit analyses). Commenter (2428-API) remarks that it is unclear what EPA's Draft Report is and how its SC-GHG estimates should be used. The commenter clarifies that EPA's estimates cannot be used in sensitivity analyses as it does not achieve either of EPA's purposes for conducting a sensitivity analysis and is therefore, not suitable for use. Those purposes being either to compute the effects of altering inputs on resulting outputs of a model, or to study how uncertainty in model outputs can be correctly apportioned to various sources of uncertainty in the inputs of the model.

Commenter (2327-AK DEC) expresses concerns for relying on a calculation of the social cost of carbon that is currently being challenged in court by various states in the case of *Louisiana vs. Biden*. The commenter points out that the rulemaking fails to discuss the ongoing litigation, which is significant because it directly related to the justification for the entire rule. This comment suggests that the rulemaking process may be incomplete or inadequate in considering important legal issues and current legal challenges.

Response A-1-6: The EPA disagrees that there is a lack of clarity in the intended purpose of the report or EPA's intended use of the SC-GHG estimates in regulatory analysis. The EPA also disagrees with the assertion that the scientific basis for the SC-GHG estimates is not sufficient to support their use in regulatory analysis. Since 2008, the EPA has used estimates of the SC-GHG in analyses of regulatory actions that affect GHG emissions. In the EPA's regulatory analyses the Agency strives to use the best available science. Over time, the EPA has updated the SC-GHG estimates it uses in regulatory analysis to reflect improvements in the science. The Final Report presents a set of SC-GHG estimates that incorporates numerous methodological updates that address the near-term recommendations of the National Academies and reflect the state of the science on estimating the climate change damages associated with marginal changes in GHG emissions. The updated estimates are used in the Final RIA to monetize changes in GHG emissions expected to result from the rulemaking in the same fashion that previous estimates of the SC-GHG have been applied by the EPA since 2008.

The EPA disagrees with the commenters that suggested that the use of the SC-GHG estimates in a sensitivity did not achieve the agencies intended purpose for the sensitivity analysis. The purpose of the sensitivity analysis was to consider how the estimated climate benefits would change based on updated estimates of the SC-GHG that incorporate important methodological updates that address the near-term recommendations of the National Academies and new science. The sensitivity analysis was able to achieve that purpose.

Comments related to the process by which the SC-GHG estimates were developed are discussed in more detail and responded to in Section A.7 below. Regarding the comment about the case of *Louisiana vs. Biden*, EPA notes that this case and a companion case, *Missouri v. Biden*, have been dismissed by the courts for lack of party standing. *See Louisiana v. Biden*, 64 F.4th 674 (5th Cir. 2023); *Missouri v. Biden*, 52 F.4th 362 (8th Cir. 2022) *cert. denied*, --- S.Ct. ---, 2023 WL 6558409 (Mem) (Oct. 10, 2023).

EPA disagrees with the commenter's (EPRI) assertion that the updated SC-GHG estimates have not addressed the National Academies' recommendations. EPA discusses how the

methodological updates in each module address the National Academies' recommendations throughout Section 2 of the Final Report and summarizes this information in Section 5 of the Final Report. EPA responds to this commenter's specific comments about each module in the remaining sections of this Appendix.

Comment: Commenters (2220-WDEQ, 2339-INGAA, 2450- Williams Companies, Inc., 2353-CrownQuest Op) argue that EPA's report does not properly value the social benefits of energy and instead focuses solely on the costs of emissions. Commenter (2220-WDEQ) mentions the \$372,000,000 oil and natural gas brought to Wyoming in the form of severance taxes for fiscal year 2021. Additionally, the commenter mentions the direct and indirect employment benefits and wages associated with the oil and natural gas industry. The commenter further states that EPA is using a flawed methodology that dramatically overstates the societal benefits while significantly underestimating the costs to states and regulated entities to implement the rule.

Commenter (2339-INGAA) argues that EPA's cost-benefit analysis is one-sided in that it calculates the global costs of GHG emissions over a centuries-long time horizon but fails to calculate the societal benefits of energy over the same period. The commenter notes that the Shared Socioeconomic Pathways research, which EPA discusses but does not use, states that a Fossil-fueled Development pathway is projected to lead to global Gross Domestic Product (GDP) nearly twice as high as a Sustainability pathway that reduces fossil fuel use.

Similarly, commenter (2450-Williams Companies, Inc.) argues that EPA fails to calculate the social benefits of energy, which the commenter states, includes the long-term effects on GDP and economic growth rates, bringing households out of energy poverty, and reducing the use of harmful cooking gas.

Commenter (2353-CrownQuest Op) criticizes the EPA report stating, "Never does the report consider the benefits hydrocarbon production provides to our society."

Response A-1-7: A rule that affects GHG emissions may also affect the production or consumption of goods and services, in which case it could create costs and benefits for businesses and households that either produce or use those goods and services. These costs and benefits are important to include in an analysis of the rule's impacts but are not the result of changes in GHG emissions from the rule and therefore, it would be inappropriate to try and include them in the SC-GHG used to value changes in GHG emissions. In other words, the SC-GHG is not a measure of social welfare from the consumption of goods and services whose production results in GHG emissions, nor is it intended to capture other positive or negative externalities associated with the production of those goods and services. Similarly, the SC-GHG is not intended to capture the benefits or costs to society from the production and consumption of goods and services associated with regulatory compliance, or the impacts from changes in other emissions that may also occur as a result of regulatory compliance. The SC-GHG is just one component of a larger analysis that includes consideration of other potential relevant impacts of a policy, including the social costs of compliance, labor market changes, and changes in emissions of other pollutants, as appropriate for the specific analysis.

## A.2 Socioeconomic and Emissions Module

Comment: Several commenters provide supportive statements specific to the use of the Resources for the Future Socioeconomic and Emissions Projections (RFF-SPs; Rennert et al. 2022a<sup>9</sup>) in the socioeconomic and emissions module of the EPA’s draft update.

Commenter (2349-RFF) expresses support for EPA’s socioeconomic module, highlights its utility, and argues that it addresses the recommendations of the National Academies of Science, Engineering, and Medicine. The commenter states that the long-run socioeconomic projections used in the EPA Report combine expert judgement and statistical information, can account for future policies and dependencies between variables, and provide the associated uncertainty bounds of socioeconomic projections. The commenter notes that the methodology is published in a peer-reviewed study.<sup>10</sup>

Commenter (2246-NRDC) applauds the EPA’s draft update for being “grounded in up-to-date science and economics” that “appropriately applies recommendations made by the [National Academies] to update both how the SC-GHG analysis is conducted and key parameters.” The commenter emphasizes that the modular approach enables better consistency, transparency, and the representation of uncertainty and probability ranges for estimates of the SC-GHG” and “enables timely updates... as new scientific literature becomes available.” With regard to the socioeconomic module, the commenter states that the usage of RFF-SPs provides three advantages to the status quo. First, the commenter notes that the RFF-SPs can be regularly updated to reflect the changing conditions and changes in expert predictions of economic growth, and the probabilities assigned to different outcomes can be re-weighted accordingly. Second, the commenter highlights that the RFF-SPs predict economic growth through 2300, which enables a more accurate estimation of economic damages through that timeframe. Third, the commenter states that the RFF SPs link discount rates to expected economic growth and thus enable accounting for economic growth uncertainty in how future damages are discounted.

Response A-2-1: The EPA thanks the commenters for their supportive comments regarding the modular approach and the use of the RFF-SPs in the socioeconomic and emissions module.

Comment: Commenter (2398-Policy Integrity NYU) credits EPA with developing a state-of-the-art modular integrated assessment model consistent with the recommendations of the National Academies. The commenter encourages EPA to use its model to also calculate SC-GHG estimates and the total cost of climate change using socioeconomic and emissions projections for each of the Shared Socioeconomic Pathways (SSPs), which the commenter states, spans the likely emission space. The commenter notes that this information is not needed for regulatory

---

<sup>9</sup> Rennert, K., Prest, B.C., Pizer, W.A., Newell, R.G., Anthoff, D., Kingdon, C., Rennels, L., Cooke, R., Raftery, A.E., Ševčíková, H. and Errickson, F., 2022. The social cost of carbon: advances in long-term probabilistic projections of population, GDP, emissions, and discount rates. *Brookings Papers on Economic Activity*, 2021(2), pp.223-305.

<sup>10</sup> Rennert, K., Prest, B.C., Pizer, W.A., Newell, R.G., Anthoff, D., Kingdon, C., Rennels, L., Cooke, R., Raftery, A.E., Ševčíková, H. and Errickson, F., 2022. The social cost of carbon: advances in long-term probabilistic projections of population, GDP, emissions, and discount rates. *Brookings Papers on Economic Activity*, 2021(2), pp.223-305.

cost-benefit analysis, but that these values would demonstrate the scale of benefits of various global greenhouse gas emission targets, which “could inform public and policymaker opinion of the scale of climate action necessary and/or justifiable.”

Response A-2-2: The EPA Draft SC-GHG Report discusses the SSPs, recognizes the use of these deterministic socioeconomic projections in the IPCC report and other applications, and presents a direct comparison of the RFF-SPs to the SSPs. EPA has expanded this discussion and presentation in the Final Report. The discussion explains that while the SSPs generally fall within or near the range of the RFF-SP probabilistic projections, they are limited in providing a comparison to the full RFF-SP distribution. The SSPs were intentionally developed to reflect a range of reasonably likely scenarios corresponding to different storylines rather than a more comprehensive range of plausible scenarios like the RFF-SPs. The SSPs were also only developed to provide projections out to 2100 and, as shown in the Final Report, long term SSP-based projections are sensitive to the post-2100 extrapolation method used. The SSPs were intentionally developed without probabilities attached to them, making them less suitable for addressing uncertainty. SSP-based projections of economic growth, for example, vary depending on which of the three available alternative interpretations of the SSPs (from the IIASA, OECD, or PIK economic growth model) is selected from the SSP database. The SSP developers explicitly note that the provided “‘illustrative’ SSP should not be interpreted as the central or representative case...It is recommended to use the GDP projections by all teams to test the sensitivity of the results due to different GDP assumptions.”<sup>11</sup> Therefore, any estimates of the SC-GHG for each SSP ignore the significant role of socioeconomic uncertainty in the estimates of the SC-GHG. EPA, however, notes that if such illustrative estimates are of interest to the commenter, the GIVE model does allow users to estimate climate damages using a given deterministic SSP-based socioeconomic scenario and emission scenario, and single post-2100 extrapolation method, as an input to the model (<https://github.com/rffscghg/MimiGIVE.jl>). However, the use of such a deterministic growth and emissions trajectory prevents the representation of significant uncertainties in both the damages and discounting module which was recommended by the National Academies (2017).<sup>12</sup> Therefore, EPA disagrees with the commenter and believes that an SSP-based SC-GHG calculation would be of limited additional value in informing policymakers and the public of the scale of benefits associated with GHG emission reductions.

Comment: Commenter (2239-A. Fraas et al.) highlights the significant uncertainty in projections of economic growth through the year 2300 and notes that certain assumptions of exogenous growth, exogenous preferences, and utility function stability become more tenuous in longer time

---

<sup>11</sup> Keywan Riahi, Detlef P. van Vuuren, Elmar Kriegler, Jae Edmonds, Brian C. O'Neill, Shinichiro Fujimori, Nico Bauer, Katherine Calvin, Rob Dellink, Oliver Fricko, Wolfgang Lutz, Alexander Popp, Jesus Crespo Cuaresma, Samir KC, Marian Leimbach, Leiwen Jiang, Tom Kram, Shilpa Rao, Johannes Emmerling, Kristie Ebi, Tomoko Hasegawa, Petr Havlík, Florian Humpenöder, Lara Aleluia Da Silva, Steve Smith, Elke Stehfest, Valentina Bosetti, Jiyong Eom, David Gernaat, Toshihiko Masui, Joeri Rogelj, Jessica Streffer, Laurent Drouet, Volker Krey, Gunnar Luderer, Mathijs Harmsen, Kiyoshi Takahashi, Lavinia Baumstark, Jonathan C. Doelman, Mikiko Kainuma, Zbigniew Klimont, Giacomo Marangoni, Hermann Lotze-Campen, Michael Obersteiner, Andrzej Tabeau, Massimo Tavoni. frames. The commenter recommends that EPA temporally disaggregate the distributional effects of the SC-GHG estimates into three groupings: the present to 2100; from 2101 to 2200; and from 2201 to 2300. The commenter argues that it is appropriate for the public, who is bearing the cost of the regulatory actions, to see how the benefits of climate policies are distributed among generations. The commenter states that the assumptions underlying the modeling are not sufficiently justified, including the distribution of uncertainty around input parameters, such as population size, economic growth, discount rates, and surface temperatures. Given the input uncertainties that EPA documents, the commenter believes that it is not credible to present SC-GHGs as point estimates for the years beyond 2030, and EPA should instead present them as distributions.

Response A-2-3: Thank you for the comments. EPA has added information in the Final Report to aid the reader in understanding the temporal evolution of the discounted marginal damages. A temporal disaggregation of discounted marginal damages from CO<sub>2</sub> emissions is provided in Extended Data Fig. 2 in Rennert et al. (2022b)<sup>13</sup> for the Greenhouse Gas Impact Value Estimator (GIVE) model. This figure shows the contribution of discounted damages in each year to the SC-CO<sub>2</sub>. The figure also includes the distribution of the discounted damages. The point estimates provided in the report are the certainty equivalent SC-GHG as defined in Section 2.5 of the report and is consistent with the consumption capital asset pricing model. The SC-GHG is calculated from a distribution of discounted marginal damages. This distribution is provided in the Final Report (in Section 3.1 for CO<sub>2</sub> and in the Appendix for methane and nitrous oxide). EPA has also substantially expanded the discussion of the development of the RFF-SPs in Section 2.1 of the Final Report to include a more detailed explanation of the methods used, the sources of uncertainty and the plausibility of socioeconomic projections. Further, EPA has introduced a supplementary Table A.8.1 in Appendix A.8. that provides a concise summary of the treatment of uncertainty in each module, including the socioeconomic and emissions module. EPA notes that these details were available in public documents through the provided citations and EPA has simply added some of the details provided in the references to the report itself.

Comment: Commenters (2361-EPRI, 2344-IER, 2227-W. Energy Alliance, 2428-API) provided feedback on the socioeconomic and emissions module, emphasizing the importance of clarity, consistency, and coherence. The commenters stated that additional module documentation and methodological details are necessary for full assessment. The commenters noted that EPA's socioeconomic module contains potentially implausible socioeconomic projections or is not appropriately modeling GHG reduction policies.

Commenter (2361-EPRI) argues that EPA's socioeconomic and emissions module does not fully satisfy the recommendations put forth by the National Academies of Sciences, Engineering, and Medicine (NASEM) with respect to transparency, scientific basis, and treatment of uncertainty. The commenter states that the socioeconomic module documentation should be enhanced to allow for a full evaluation of the methodology, including a further justification of model parameters, and a consideration of the broader academic literature (e.g., scenarios used in IPCC

work (Clarke et al. 2014<sup>14</sup>, Huppmann et al. 2018<sup>15</sup>, Byers et al. 2022<sup>16</sup>), IEA (2021<sup>17</sup>, 2019<sup>18</sup>), Morris et al. (2022)<sup>19</sup>, and Rose et al. forthcoming<sup>20</sup>). Similarly, the commenter argues that the Rennert et al. (2022b)<sup>21</sup> paper that EPA relies on lacks the internal consistency, coherency, and transparency regarding the expert elicitation process and the absence of details necessary for evaluating and understanding the projections and probabilities assigned to future policies. The commenter further emphasizes the importance of including socioeconomic structural details, such as population composition, as well as structural transition uncertainty in the projections. The commenter highlights deep uncertainties related to economic development that is independent from climate policy, as well as uncertainties stemming from climate policy design.

Commenter (2361-EPRI) expresses support for additional methodological details and results to facilitate a full assessment. Specifically, the commenter suggests that the socioeconomic module documentation should add the following information: 1) all module methodological details, an assessment and comparison to the literature, and further justification of assumptions, 2) implemented equations and parameters, 3) presentation and evaluation of the quantitative relationship between population, economic growth, and emissions projections, 4) a greater discussion and justification for the implied/assumed/modeled evolution of the structure of global and regional economies, populations, and climate policies (country ambition, timing, and design) from the present until 2300, and (5) the addition of minimum and maximum values to all figures. The commenter cites the need for socioeconomic projections to be integrated into the damages and discounting modules and for discussions regarding how the socioeconomic projections affect societal vulnerability, adaptation, and net economic damages and discounting.

The commenter also emphasizes the need to revise module documentation to clearly communicate the connections and relationships between different modules. Furthermore, the commenter states that EPA has chosen to constrain its module choices to what others have already done in the peer reviewed literature, which causes issue in terms of robustness and inconsistencies (from combining pieces from different studies). Lastly, the commenter states that there is clearly more information available than what is currently being considered in the methodology and encourages EPA to utilize a larger number of academic studies.

Commenter (2361-EPRI) states that emissions projections used by EPA are an implausible socioeconomic pathway, especially for the post-2100 projection assumptions. Furthermore, the commenter states that pathways should be assessed for their plausibility, and pathways with negligible plausibility of occurrence should be removed. An example of this is the EPA projection that greenhouse gas emissions will peak this decade. According to the commenter, this is extremely unlikely given historical trends, so the results with emissions peaking this decade or earlier should be removed. In general, the commenter asserts a preference for assessing the plausibility or likelihood of each pathway actually occurring and focusing on the pathways that are more likely or more probable to occur. The commenter asserts that some of the key assumptions used in the Rennert et al. (2022b) analysis, including the assumption that global economic growth rates will decline after 2100, require additional justification.

Commenter (2227-W. Energy Alliance) finds the *Nature* article<sup>22</sup> (cited by EPA)'s conclusion that CO<sub>2</sub> emissions will continue through 2300 inconsistent with the Paris Climate Agreement. To that end, the commenter expresses confusion at EPA's use of the 2300 GHG timeline, in comparison to the administration's commitment to limiting climate change through the Agreement. The commenter expresses support for EPA's assumption that CO<sub>2</sub> emissions will not reach net zero by 2300 and recommends that EPA estimate SCC in time horizons where greenhouse gas emissions (including CO<sub>2</sub> and methane CH<sub>4</sub>) reach net zero by 2100, 2200, and 2300, to allow for comparison of costs and benefits associated with different levels of GHG-reducing policies.

Commenter (2428-API) argues that EPA should explain why its global emissions projection does not reflect globally coordinated action, given that this is a key rationale for the use of global SC-GHG estimates. The commenter asks that EPA provide documentation related to the RFF paper upon which EPA's modeling relies, including how and why certain experts were chosen to assist in forecasting, how RFF selected experts from nominee pool, as well as documentation of RFF survey methodologies and results.

Commenter (2344-IER) states that EPA's "science fiction time horizons are inappropriate." The commenter provides quotes from the EPA report summarizing the post-2100 extrapolations used in the IWG's socioeconomic scenarios and then argues that EPA does not properly justify its projections of the world's energy system into the 2200s. The commenter describes alternative

projections from Star Trek, in which significant technological discoveries are made, and states that even though Star Trek is a fictional show, EPA does not justify believing its projections over Star Trek's.

Response A-2-4: EPA appreciates the commenters' statements that estimations should be developed through cogent modulation and methodologies, the rationale for which ought to be made available for public review. To address the commenters' request for additional documentation, EPA substantially expanded the discussion in Section 2.1 of the Final Report describing the development of the RFF-SPs, to include a more detailed discussion of the methods used, the sources of uncertainty and the plausibility of socioeconomic projections. Further, EPA has introduced a supplementary Table A.8.1 in Appendix A.8. that provides a concise summary of the treatment of uncertainty in each module, including the socioeconomic and emissions module. EPA notes that these details were available in public documents through the provided citations and EPA has simply added some of the details provided in the references to the report itself. Additional details on the development of the RFF-SPs including the expert elicitation process, methodological details, an assessment and comparison to the literature, implemented equations and parameters, quantitative relationships are provided in Rennert et al. (2022a)<sup>23</sup>, including in the online appendix to Rennert et al. (2022a)<sup>24</sup>, and the relevant journal articles (Müller et al. 2022<sup>25</sup>, Raftery and Ševčíková 2023<sup>26</sup>).

EPA acknowledges commenters' concern about the challenges involved in assessing long term socioeconomic projections. Likewise, the National Academies recognized that their recommendations for the socioeconomic module "may entail projecting GDP, population and emissions two to three centuries into the future, which presents a significant challenge" (National Academies 2017, p. 90)<sup>27</sup>. To meet this challenge, the National Academies recommended the reliance on statistical methods to project historical data combined with elicitation of expert judgement to produce probabilistic projections and that good scientific practices be followed, including with respect to transparency, scientific basis, treatment of uncertainty and that methods be consistent with the available peer-reviewed literature. As described in the Final Report, the RFF-SPs used in the socioeconomic module underlying EPA's updated SC-GHG estimates are consistent with the National Academies' recommendations. They were developed using a mix of statistical and expert elicitation techniques to capture uncertainty in a single probabilistic approach, taking into account the likelihood of future emissions mitigation policies and

technological developments, and provide the level of disaggregation necessary for damage calculations. Unlike other sources of projections, they provide inputs for estimation out to 2300 without the need for EPA to make post-2100 extrapolation assumptions. The EPA disagrees with the commenter's description that Rennert et al. (2022a) "assume" that global economic growth rates decline after 2100 and that this needs more justification. The RFF-SP probabilistic economic growth projections are based on Müller et al.'s (2022) statistical model combined with the results of a formal expert elicitation of 10 leading macroeconomics and growth economists, conducted individually. As part of the elicitation, the experts first quantified their uncertainty for a set of calibration questions, the results of which were used to performance-weight the experts in the final combination. Experts demonstrated a high level of statistical accuracy on the calibration questions. The elicitation focused on quantifying uncertainty for a representative frontier of economic growth in OECD countries for four years (2050, 2100, 2200, 2300). In general, the experts tended to agree with each other that median economic growth would slow between 2050 and 2300. Where experts tended to disagree was on the amount of uncertainty in future projections. However, 9 out of 10 of the experts estimated an uncertainty range that was narrower than the Müller et al. (2022) projections.

EPA disagrees with the commenter's (2361-EPRI) suggestion that EPA should selectively remove "arguably implausible" pathways from the peer-reviewed RFF-SP probabilistic projections. EPA has no scientific rationale for ignoring parts of the peer reviewed published projections or adjusting the distributions on an ad hoc basis. The economic growth and population projections comport with very-long term historical relationships and were developed by leading experts in their respective fields. The EPA disagrees with the commenter that projections of CO<sub>2</sub> emissions peaking this decade should be removed from the analysis as implausible. The probabilistic emissions projections should represent the full distribution of possible outcomes. Following the National Academies' recommendations, RFF designed the survey in a way that asked the experts to incorporate the expected evolution of future policy in their responses. As presented in Rennert et al. (2022a), under the median economic growth trajectory, the combined results of the experts' responses suggested a probability of approximately 50% that emissions would decline by 2050 from today's levels (see Figure 7 in Rennert et al. 2022a). The commenter's assertion that there is no probability that emissions will peak this decade is not consistent with other emissions projections. Since 2021, the International Energy Agency annual outlook has projected that CO<sub>2</sub> emissions could peak this decade based on the stated policies scenario (IEA 2021<sup>28</sup>, 2022<sup>29</sup>, 2023<sup>30</sup>). EPA agrees with the commenter that assigning a likelihood to the pathways is preferable. By using a probabilistic approach, the estimates that EPA utilizes assigns the likelihood of each pathway occurring.

EPA thanks the commenter (2361-EPRI) for providing citations for additional information to consider for the socioeconomic module. Some of the citations are to information that has already been discussed and presented in the report, such as the SSP scenarios used in IPCC Assessment Reports. The commenter also suggested that EPA consider other population projections, such as those developed by the United Nations (UN). The population projections in the RFF-SPs are an extension of the methodology used for the UN population projections. The EPA has expanded

<sup>29</sup> IEA (2022), *World Energy Outlook 2022*, IEA, Paris <https://www.iea.org/reports/world-energy-outlook-2022>

<sup>30</sup> IEA (2023), *World Energy Outlook 2023*, IEA, Paris <https://www.iea.org/reports/world-energy-outlook-2023>

the discussion in Section 2.1 of the Final Report to provide details on the consistency of the RFF-SP population projections to the UN population projections that end in 2100. The EPA has also expanded the discussion of existing socioeconomic projections developed using MIT's Emissions Prediction and Policy Analysis (EPPA) Model to now also reference updated probabilistic socioeconomic projections based on the EPPA model (Moore et al. 2022)<sup>31</sup>. EPA looks forward to reviewing the forthcoming EPRI-MIT socioeconomic work (Rose et al. forthcoming)<sup>32</sup> mentioned by the commenter when it is available. The EPA will continue to follow these and other advances in the published literature on long term socioeconomic projections and look for opportunities to incorporate peer reviewed methodological advances that address the National Academies longer term recommendations for this module in future updates of the SC-GHG estimates.

One commenter expressed confusion about the RFF-SPs projection of emissions through 2300 in comparison to the GHG mitigation commitments under the Paris Agreement. As described in the SC-GHG Report, under the RFF-SPs, GHG emissions are projected using expert elicitation techniques. Within the survey questions posed, the experts were asked to incorporate their views about changes in technology, fuel use, and other conditions, including the expected evolution of future policies (such as those made under the Paris Agreement). In Section 2.1 of the Final Report, EPA has expanded the discussion of the methods used to develop the RFF-SP emission projections, including what the experts reported regarding the factors they considered under different economic growth scenarios. For example, to support the high-end emissions, it was common for experts to state that low economic growth could lead countries to revisit emission reduction pledges. Additional details on experts' rationales regarding changes in fossil fuel and process-related CO<sub>2</sub> emissions, natural CO<sub>2</sub> stocks, negative emissions technologies, and CH<sub>4</sub> and N<sub>2</sub>O emissions in the context of the Paris Climate Agreement are available in Rennert et al. (2022a) and the accompanying online appendix.

Regarding the comment about appropriate time horizons, it is unclear why the commenter referenced the post-2100 extrapolation methods developed by the IWG in 2010 for the socioeconomic projections underlying the IWG recommended SC-GHG estimates. The socioeconomic module used in EPA's update SC-GHG analysis relies on the RFF-SPs (Rennert et al. 2022a). As described in the Report, the RFF-SPs are a set of probabilistic projections of population, GDP, and GHG emissions (CO<sub>2</sub>, CH<sub>4</sub>, and N<sub>2</sub>O) to 2300. Consistent with the National Academies' recommendation, the RFF-SPs were developed using a mix of statistical and expert elicitation techniques to capture uncertainty in a single probabilistic approach, taking into account the likelihood of future emissions mitigation policies and technological developments, and unlike other sources of projections, they provide inputs for estimation out to 2300 without further extrapolation assumptions. This is a suitable time horizon consistent with

---

<sup>31</sup> Moore, F.C., Lacasse, K., Mach, K.J., Shin, Y.A., Gross, L.J. and Beckage, B., 2022. Determinants of emissions pathways in the coupled climate–social system. *Nature*, 603(7899), pp.103-111.

<sup>32</sup> Rose, SK, J Morris, A Gurgel, forthcoming. Quantifying uncertainty in global and sub-global socioeconomic and greenhouse gas emissions futures.

the National Academies' recommendation<sup>33</sup> and OMB Circular A-4 (2003) guidance<sup>34</sup>, since in the modeling conducted for this report 2300 is far enough in the future to capture the majority of discounted climate damages. See Section 2.1 and 3 of the Final Report for more discussion.

Comment: Commenters (2413-CEI/HF, 2227-W. Energy Alliance) highlight the need for EPA to elucidate the disparities in CO<sub>2</sub> emissions between revised and prior assessments.

Commenter (2413-CEI/HF) notes that EPA's External Review Draft projects that CO<sub>2</sub> emissions in 2300 will be less than one third of what the IWG analysis predicts, however, EPA's resulting SCC estimates in 2080 are 3 to 4 times higher than the IWG estimates. The commenter criticizes EPA for not discussing this "paradox" and remarks that the change in the central discount rate is undoubtedly a factor in this dichotomy. The commenter additionally requests that EPA produce charts to compare IWG and RFF-SP emission projects for CH<sub>4</sub> and N<sub>2</sub>O emissions.

Commenter (2227-W. Energy Alliance) similarly recommends that EPA should explain in the RIA that the cumulative CO<sub>2</sub> emissions used in the revised SC-CO<sub>2</sub> estimates are based on cumulative CO<sub>2</sub> emissions that are significantly lower than cumulative CO<sub>2</sub> emissions values used in previous SC-CO<sub>2</sub> estimates, with further explanations as to why cumulative CO<sub>2</sub> emissions are only about 28% of the emission values used in past SC-CO<sub>2</sub> estimates, but the estimates SC-CO<sub>2</sub> (using a comparable 3% discount rate) is now 57% larger (\$80/tCO<sub>2</sub> versus \$51/tCO<sub>2</sub>).

Response A-2-5: EPA has expanded the discussion of the relative contribution of several modelling changes in Section 4.1 of the Final Report. As explained in the Report, the increases in the SC-GHG estimates relative to the IWG recommended interim estimates are due to the combined effect of the methodological updates, some of which are integrated in a way that makes a complete decomposition of the incremental contribution of each change difficult. For example, a comparison of SC-GHG estimates based on a constant 3% discount rate with results based on a 2% near-term Ramsey discount rate reflects the combined effect of using a lower near-term rate and the shift from a constant to a dynamic discounting approach that accounts for any correlation between climate change damages and economic growth through the use of probabilistic RFF-SPs growth projections. A re-estimation of the IWG recommended interim estimates using lower constant discount rates finds that the SC-CO<sub>2</sub> increases from \$51/mtCO<sub>2</sub> to \$121/mtCO<sub>2</sub> for 2020 emissions when shifting from a constant 3% to a constant 2% discount rate (NYSDEC 2022)<sup>35</sup>. This illustrates that the combined effect of shifting to a dynamic discount rate approach together with the socioeconomic, climate, and damage module updates accounts for the additional 60% increase in the SC-CO<sub>2</sub> to \$190/mtCO<sub>2</sub> for 2020 emissions.

---

<sup>33</sup> The National Academies (2017) recommended that socioeconomic scenarios used to estimate the SC-GHG should: "extend far enough in the future to provide inputs for estimation of the vast majority of discounted climate damages".

<sup>34</sup> Regarding the analytic time horizon for regulatory benefit-cost analysis, OMB Circular A-4 (2003) advises "The ending point should be far enough in the future to encompass all the significant benefits and costs likely to result from the rule" (OMB 2003). OMB Circular A-4 (2023) similarly advises "The ending point for your analysis should be far enough in the future to encompass, to the extent feasible, all the important benefits and costs likely to result from all regulatory alternatives being assessed" (OMB 2023).

<sup>35</sup> New York State Department of Environmental Conservation (NYSDEC), 2022. Establishing a Value of Carbon: Guidelines for Use by State Agencies. [https://www.dec.ny.gov/docs/administration\\_pdf/vocguid22.pdf](https://www.dec.ny.gov/docs/administration_pdf/vocguid22.pdf).

This does not imply that each update influences the SC-GHG in the same direction. For example, ignoring the correlation between climate change damages and economic growth – as is the case with a constant discount rate approach – can lead to overestimating the SC-GHG if there is a positive correlation between economic growth and marginal damages (Newell, Pizer, Prest 2022)<sup>36</sup>. In the case of methane, the IWG interim SC-CH<sub>4</sub> estimate under a 2% constant discount rate (\$2,700/mtCH<sub>4</sub> for 2020 emissions (NYSDEC 2022)) exceeds the fully updated SC-CH<sub>4</sub> estimate under a 2% near-term Ramsey discount rate. The Report also discusses additional comparative analysis from Rennert et al. (2022b)<sup>37</sup> that illustrates to the extent possible the incremental impact of some of the updates in the GIVE model, relative to a recent version of the DICE model.

In response to the commenter’s request, additional figures have been included in Appendix A.6 of the Report presenting the net annual global emissions of CO<sub>2</sub>, CH<sub>4</sub>, and N<sub>2</sub>O under the RFF-SPs and the IWG’s EMF-22 based emissions scenarios from 1900 to 2300.

### A.3 Climate Module

Comment: Among the commenters expressing strong support for EPA’s draft update, several commenters provided comments specific to the climate module (2208-CCES et al., 2246-NRDC, 3174-Climate Science et al., 2194-S. Dietz et al., 2398-Policy Integrity NYU).

Commenter (2208-CCES et al.) supports EPA’s Draft Report for closely following the 2017 roadmap provided by the National Academies of Sciences regarding the social cost of greenhouse gases. The commenter noted that the National Academies recommended that the climate module “reflect current scientific understanding of the relationships between greenhouse gas emissions, concentrations, radiative forcing, and global mean surface temperature change” and specifically endorsed the FaIR model that EPA adopted as satisfying those criteria.

Commenters (2246-NRDC, 2398-Policy Integrity NYU) state that the EPA’s climate module is consistent with NASEM’s recommendations. More specifically, commenter (2446-NRDC) states that EPA appropriately applies recommendations made by the NASEM to update both how the SC-GHG analysis is conducted and key input parameters. With respect to the climate module, the commenter states that EPA’s climate module applies the “latest scientific consensus on the relationship between carbon emissions and temperature and sea-level rise.” The commenter applauds the Draft Report’s use of the FaIR model for its more robust representation of uncertainties and projections. The commenter states that the FaIR model methodology results in “ranges of emissions and temperature increase [that] better represent uncertainties in emissions projections, physical carbon cycle uncertainty, and physical climate uncertainty (all of which are built into FaIR) than the status quo.”

Some commenters (3174-Climate Science et al., 2194-S. Dietz et al., 2398-Policy Integrity NYU), while expressing general support for EPA’s efforts to improve estimates of the SC-GHG, discuss areas in which the climate module does not yet fully capture various climate dynamics and potential tipping points. These commenters emphasize that by not modeling the effect of tipping points, the resulting SC-GHG values will be an underestimate of the true cost of GHG emissions.

Commenter (3174-Climate Science et al.), while providing support for EPA’s improved SC-GHG estimates, notes that several key omissions lead to a “gross underestimation” and argues that this is an “especially egregious failing.” In particular, the commenter notes EPA’s admission that it has not included (or partially included) the impact of extreme weather events, temperature and precipitation extremes, ocean acidification, non-linear sea level rise, damages to ecosystems, and the effect of climate change on migration, displacement, labor productivity, and national security, among many other categories of omitted damages. The commenter cites recent peer-reviewed scientific research that highlights the dangers of 2 degree C warming.<sup>38</sup>

---

<sup>38</sup> Hansen, J., Sato, M., Hearty, P., Ruedy, R., Kelley, M., Masson-Delmotte, V., Russell, G., Tselioudis, G., Cao, J., Rignot, E., Velicogna, I., Tormey, B., Donovan, B., Kandiano, E., von Schuckmann, K., Kharecha, P., Legrande, A. N., Bauer, M., and Lo, K.-W.: Ice melt, sea level rise and superstorms: evidence from paleoclimate data, climate modeling, and modern observations that 2 °C global warming could be dangerous, *Atmos. Chem. Phys.*, 16, 3761–3812, <https://doi.org/10.5194/acp-16-3761-2016>, 2016.

Commenter (2194-S. Dietz et al.) congratulates EPA “on their excellent work that follows many of the recent advances in climate economics” but notes that quantification of the effect of tipping points in the climate system on the SC-GHG is possible. The commenter recommends that EPA directly incorporate elements of their recently published research on eight tipping points<sup>39</sup> into the climate module rather than including only a qualitative discussion of it. Specifically, the commenter recommends incorporating the modules from their Model for Economic Tipping point Analysis (META) model that represent several tipping points: the dieback of the Amazon rainforest, the Indian summer monsoon (ISM) variability, the weakening of the Atlantic Meridional Overturning Circulation (AMOC), the surface albedo feedback, and the permafrost carbon feedback. The commenter states that they would be happy to advise EPA on suitable parameter settings for running META. The commenter acknowledges three caveats related to missing impact avenues in two of these tipping points: 1) the weakening of the Atlantic meridional overturning circulation, which has only been considered as having beneficial temperature impacts, but would also change precipitation patterns, potentially leading to increased damages; 2) aspects beyond additional carbon release resulting from the Amazon dieback, such as loss of biodiversity or ecosystem services, are missing from economic literature, underestimating damages stemming from the dieback; and 3) some interactions between tipping points do not rely upon direct modelling of geophysical impacts, but rather quantified expert judgements. The commenters note that their modules for other tipping points are either already implicitly accounted for in the GIVE model (i.e., disintegration of both the Greenland and West Antarctic ice sheets) or should only be used in sensitivity analysis due to remaining uncertainties (e.g., the release of ocean methane hydrates). The commenter further states that by omitting tipping points from the analysis will thereby underestimate the true SC-GHG, and the resulting policies relying on these estimates will not be stringent enough.

Similarly, commenter (2398-Policy Integrity NYU) agrees that tipping points should be included. Specifically, the commenter notes that EPA’s climate-economic module “lacks a singular tipping point used in the Working Group’s damage models, which directly impacts human welfare through lost consumption.” Such a singular tipping point representation in the damage models can represent the various “environmental tipping points triggered by climate change more generally.” Additionally, the commenter states that EPA excludes other tipping points that were not included in the Working Group’s models but should be included in EPA’s model – such as social tipping points, interactions resulting from runaway climate change due to the melting of methane hydrates and permafrost and diebacks of the Amazon and boreal forests, and the impact of society on emissions through feedback effects. The commenter recommends that EPA adopt the Dietz et al. (2021)<sup>40</sup> “modeling strategy into the modular IAM,” but commenter notes, “the resulting damage valuations would likely still represent an underestimate due to missing tipping points and connections, as well as omitted non-market impacts.” Alternatively, the commenter suggests adopting a reduced-form estimates of the damages from tipping points based on Dietz et al.’s results, rather than explicitly modeling each tipping point

---

<sup>39</sup> Dietz, Simon, James Rising, Thomas Stoerk, and Gernot Wagner (2021): “Economic impacts of tipping points in the climate system,” *Proceedings of the National Academy of Sciences*, 118 (34) e2103081118.

<sup>40</sup> Dietz, Simon, James Rising, Thomas Stoerk, and Gernot Wagner (2021): “Economic impacts of tipping points in the climate system,” *Proceedings of the National Academy of Sciences*, 118 (34) e2103081118.

and their interconnectedness (This latter recommendation for an alternative approximation approach is discussed in the Damages Module section of comments below).

Commenter (2227-W. Energy Alliance) presents a divergent view on the topic of climate tipping points. The commenter commends EPA for not incorporating tipping points in the draft estimates and recommends the Agency cite the Dietz et al. (2021)<sup>41</sup> paper *in support of* this decision and note their relatively low impact on SC-CO<sub>2</sub> estimates. The commenter interprets the study results to suggest that climate tipping points, such as disintegration of the West Antarctic and Greenland Ice Sheets, do not result in significantly higher SC-CO<sub>2</sub> estimates. The commenter argues that the paper implies that some tipping points, such as the Atlantic Meridional Overturning Circulation, could actually mitigate climate impacts of warming temperatures. Similarly, the commenter expresses support for EPA's exclusion of extreme weather impacts from the model, writes that this decision is consistent with Lomborg (2020),<sup>42</sup> who the commenter argues "provides significant detail explaining that extreme weather events are not increasing due to climate change, but instead demonstrates that increasing costs and impacts from extreme weather are due to the increasing human population and development footprint primarily in coastal regions around the world." The commenter also notes that the *Nature*<sup>43</sup> article cited by EPA and Lomborg (2020)<sup>44</sup> share opinions on sea level rise, as EPA assigns only a small fraction of the SCC to sea level rise costs, and Lomborg agrees that the significantly increased annual coastal flooding costs associated with sea level rise will be managed through adaptive measures. To this point, the commenter recommends EPA cite Lomborg (2020).

Response A-3-1: EPA appreciates the commenters' feedback on the climate module. The FaIR model, developed by researchers at Oxford University, is one of the most widely used reduced complexity models used to generate projections of global temperature change, is open source, and was highlighted by the National Academies as a model that satisfies their recommendations for a near-term update of the climate module in SC-GHG estimation. However, EPA agrees that the climate module omits some potentially large-scale Earth system feedback effects (e.g., from tipping elements or 'tipping points') and that recent studies have started to make progress on incorporating more tipping points in the estimation of SC-GHG. In particular, Dietz et al. (2021)<sup>45</sup> have advanced the quantification of tipping elements to explicitly account for several important temperature feedbacks within the climate system. The EPA has expanded the discussion of Dietz et al. (2021) and their results in Section 3.2 of the Report to acknowledge significant advancements made in this area. The EPA will continue to follow progress in this line of research and look for opportunities to better reflect tipping elements and other Earth system

<sup>44</sup> Lomborg, B., 2020. Welfare in the 21st century: Increasing development, reducing inequality, the impact of climate change, and the cost of climate policies. *Technological Forecasting and Social Change*, 156, p.119981.

<sup>45</sup> Dietz, Simon, James Rising, Thomas Stoerk, and Gernot Wagner (2021): "Economic impacts of tipping points in the climate system," *Proceedings of the National Academy of Sciences*, 118 (34) e2103081118.

feedback effects and to account for non-climate mediated GHG effects in future updates of the SC-GHG estimates. Throughout the report, EPA has expanded discussion about how the presented SC-GHG estimates likely underestimate the marginal damages from greenhouse gas pollution. EPA has especially expanded discussion in Section 3.2 "Omitted Damages and Other Modeling Limitations" including remarks and references on tipping elements.

EPA disagrees with commenter (2227-W. Energy Alliance) that the Dietz et al. (2021) results *support* the exclusion of tipping points in the climate module. As discussed in the Final Report, under their main specification Dietz et al. (2021) estimate that the inclusion of eight individual tipping points into the analysis increases the SC-CO<sub>2</sub> by approximately 25 percent. The authors additionally state that the distribution of these effects is highly right skewed, noting a 10 percent chance that the SC-CO<sub>2</sub> more than doubles. EPA does not agree with commenter's interpretation that these effects are insignificant. The authors further acknowledge, in both their published study and in their comments in this rulemaking summarized above, that research is still needed to incorporate other physical impacts from these feedbacks, such as precipitation and ecosystem impacts associated with passing a tipping point. For example, the authors note in their comment letter (2194-S. Dietz et al.) that a key missing damage channel related to the AMOC slowdown relates to changed precipitation patterns, which scientists believe would lead to additional rather than lowered damages (Liu et al. 2017)<sup>46</sup>.

The EPA also disagrees with commenter's (2227-W. Energy Alliance) recommendation to cite Lomborg (2020) as in agreement with the *Nature*<sup>47</sup> article cited in EPA's Report. EPA clarifies that the exclusion of extreme weather impacts in the SC-GHG estimates presented in EPA's Report is an omission due to data and modeling limitations in the ability to explicitly represent these impacts in both the climate module and the damages module used for SC-GHG estimation, not an explicit choice to exclude the potential impacts of extreme events due to insufficient scientific consensus about these events being impacted by climate change. Regarding historical trends, the IPCC AR6 chapter on extreme events states that, "Evidence of observed changes in extremes and their attribution to human influence (including greenhouse gas and aerosol emissions and land-use changes) has strengthened since AR5, in particular for extreme precipitation, droughts, tropical cyclones and compound extremes (including dry/hot events and fire weather)." Regarding future changes, the IPCC stated that "even relatively small incremental increases in global warming (+0.5°C) cause statistically significant changes in extremes on the global scale and for large regions (high confidence). In particular, this is the case for temperature extremes (very likely), the intensification of heavy precipitation (high confidence) including that associated with tropical cyclones (medium confidence), and the worsening of droughts in some regions (high confidence)."<sup>48</sup> Finally, EPA agrees with the commenter that explicit treatment of

adaptation is important for estimating the damages from climate change, including in the category of sea level rise impacts. We have expanded the discussion of the adaptation assumptions in the Report, including the optimistic assumptions of the implementation of optimal, lowest-cost adaptation strategies with respect to sea level rise damages and highlight this as an important area for future research.

Comment: Commenter (2361-EPRI) provides several recommendations pertaining to the climate module. First, the commenter recommends that EPA revise the module to fully address NASEM recommendations, including undertaking NASEM performance tests. The commenter states “the module documentation should be enhanced to satisfy the transparency, scientific basis, and uncertainty consideration recommendations (NASEM Recommendation 2-2). The documentation should assess the literature they are using, provide methodological details, equations, and parameters, provide additional detailed results, and justify the methodological choices in that literature and associated with its integration into EPA’s overall framework, as well as justify detailed results. In addition, the module should provide spatially disaggregated climate information (and account for uncertainties) and evaluate climate model performance with respect to the specific experiments NASEM (2017) recommended (NASEM Recommendations 4-1, 4-2, and 4-5).”<sup>49</sup>

Second, the commenter argues that EPA should expand evaluation and comparison to justify the approach and better account for uncertainty. The commenter offers specific improvements for EPA’s temperature modeling, including expanding its comparison of the central tendencies of FaIR to MAGICC and Hector to include distributional comparisons and comparisons to other reduced complexity models, such as MIT Earth System Model; and representing the low end of the IPCC AR6 climate sensitivity distribution. The commenter disputes the plausibility of EPA’s temperature projection of as high as almost 8 degrees Celsius in 2300 as shown in Figure 2.2.2, stating, “Society is likely to respond and manage the climate before then.” The commenter argues that a pathway plausibility assessment would help to rule out such outcomes from consideration or assign even lower probabilities to them.

Third, the commenter recommends endogenizing non-GHG radiative forcing to address the current fixed forcing assumption’s inconsistency with the broad range of projected futures and to capture non-GHG forcing uncertainty in temperature projections. Finally, the commenter argues that EPA needs to provide additional methodological details and results pertaining to all the climate module recommendations above to facilitate a full assessment.

The commenter also encourages EPA to revisit the large emissions pulse size used to calculate the SC-GHG estimates and to discuss and assess non-linearity and choice justification. The commenter states that since the pulse sizes used for computing the social costs of methane and

---

*Change 2021: The Physical Science Basis. Contribution of Working Group I to the Sixth Assessment Report of the Intergovernmental Panel on Climate Change* [Masson-Delmotte, V., P. Zhai, A. Zhou (eds.)]. Cambridge University Press.  
[https://www.ipcc.ch/report/ar6/wg1/downloads/report/IPCC\\_AR6\\_WGI\\_Chapter11.pdf](https://www.ipcc.ch/report/ar6/wg1/downloads/report/IPCC_AR6_WGI_Chapter11.pdf)

<sup>49</sup> National Academies of Sciences, Engineering, and Medicine. 2017. *Valuing Climate Damages: Updating Estimation of the Social Cost of Carbon Dioxide*. Washington, DC: The National Academies Press.  
<https://doi.org/10.17226/24651>.

nitrous oxide are currently unclear, greater transparency is needed on the size of the pulses used and the justification for implementing a large pulse. The commenter asks EPA to discuss “potential bias given non-linearities in both the climate and damage modules from deriving an average per ton SC-GHG result from implementing a large pulse.”

Response A-3-2: EPA disagrees that the climate module needs revision in order to fully address the NASEM near-term recommendations. FaIR 1.6.2 is a fitting model to serve as the basis for an updated climate module to address NASEM recommendations. In fact, NASEM specifically highlighted FaIR as a model which addressed their criteria: see the first paragraph of the section in Chapter 4 entitled, “An Illustrative Simple Earth System Model.”<sup>50</sup> FaIR is open source, and therefore meets NASEM recommendations for transparency. FaIR’s uncertainty calibration to IPCC assessed values of climate sensitivity and other parameters are documented in the SC-GHG report, and the IPCC also relied on FaIR for its own uncertainty analysis (see the IPCC AR6 WGI assessment in the Supplementary Information for Chapter 7).<sup>51</sup> With regard to the production of spatially disaggregated climate information, the NASEM Recommendation 4-5 begins, “To the extent needed by the damages module, the Interagency Working Group should use disaggregation methods...”. As described in Section 2.3 of the Report, all three of the approaches to damage function estimation use only GMST as an input to the global damage module. But as detailed in Section 2.3 of EPA’s Report (and further discussed in Section 3.2), the underlying damage studies incorporate various resolutions of regional climate, and therefore, it is not necessary for the climate module itself to produce such regionally disaggregated data. EPA has updated and added figures and surrounding discussion in Section 3.2 exploring modeling of regional population, temperature, sea level, and precipitation projections.

The commenter’s second recommendation is that EPA expand its evaluation and comparison to other climate models. The commenter highlights alleged differences between FaIR and MAGICC to justify this recommendation, claiming that MAGICC is a warmer model and providing a figure (the commenter’s Figure 5) to show comparisons between MAGICC and FaIR. The commenter claims that the source of Figure 5 is the IPCC database. However, this Figure is inconsistent with Table 7.SM.4 from the IPCC.<sup>52</sup> Since the commenter does not provide a more complete citation than “Source: IPCC database”, EPA is unable to determine more about this inconsistency. In Section 2.2 of the Report, EPA has expanded the discussion of the Reduced Complexity Model Intercomparison Project (RCMIP)<sup>53</sup> (Nicholls et al. 2020),<sup>54</sup>

Reduced Complexity Model Intercomparison Project Phase 1:

which compares all three models (FaIR, MAGICC, and Hector) against the Earth system models used by the IPCC.

The commenter also suggests that the temperature change scenarios in Figure 2.2.2 reaching almost 8°C in 2300 should be assigned lower probabilities or ruled out. EPA notes that the report methodology already does reflect the lower probability of the highest-temperature outcomes. In particular, Figure 2.2.2 is shaded to illustrate percentile ranges, and 8°C falls outside of the illustrated 1st to 99th percentile range. As discussed in EPA's Report, the distribution of projected global mean surface temperature in Figure 2.2.2 reflects uncertainty in both emissions and physical climate processes that are consistent with the latest projections coming out of the Sixth Assessment Report (IPCC 2021a)<sup>55</sup>.

The commenter further suggests that the reason for ruling out or lowering the probability weights of high-temperature outcomes is that "Society is likely to respond and manage the climate before then." EPA disagrees with ad hoc adjustments to the methodology, such as "ruling out" particular socioeconomic or climate scenarios based on heuristic judgements of "implausibility." The highest temperature scenarios are represented with lower probability as indicated by the percentile shading in EPA's report Figure 2.2.2, which is based upon the underlying draws of emissions scenarios and climate parameters. As detailed in EPA's Report, the RFF-SP emissions scenarios are based upon expert elicitations, taking into account the likelihood of future emissions mitigation policies and technological developments EPA has no scientific rationale for ignoring parts of the peer reviewed published emissions projections or adjusting the distributions on an ad hoc basis. In addition, as discussed in the Report, EPA's modeling does not yet account for many feedback effects, such as the impact of climate change damages on future emissions. The National Academies (2017) identified explicitly accounting for feedbacks between the damages and climate modules to the socioeconomic module as an important longer-term goal in the SC-GHG estimation process. EPA will continue to follow advances in the literature on this topic, consistent with the National Academies' recommendations regarding continued improvements. Such future research could further explore the likelihood of additional mitigation policy in the scenarios with the most adverse outcomes.

Regarding the commenter's recommendation to endogenize non-GHG radiative forcing in order to better reflect non-GHG forcing uncertainty in the temperature projections, EPA acknowledges that aerosol emissions uncertainty is not currently represented in the modeling and has introduced a discussion of the potential to further explore aerosols in Section 2 of the Final Report. However, while aerosol radiative forcing uncertainty is a large contributor to historical forcing uncertainty, recent research suggests it may not contribute as much to future uncertainty. A recent submitted paper, Sarofim et al. (2023),<sup>56</sup> used the "silicone" methodology to fill in

---

introduction and evaluation of global-mean temperature response. *Geoscientific Model Development*, 13(11), pp.5175-5190.

<sup>55</sup> Intergovernmental Panel on Climate Change (IPCC). 2021a. *Climate Change 2021: The Physical Science Basis. Contribution of Working Group I to the Sixth Assessment Report of the Intergovernmental Panel on Climate Change* [Masson-Delmotte, V., P. Zhai, A. Pirani, S.L. Connors, C. Péan, S. Berger, N. Caud, Y. Chen, L. Goldfarb, M.I. Gomis, M. Huang, K. Leitzell, E. Lonnoy, J.B.R. Matthews, T.K. Maycock, T. Waterfield, O. Yelekçi, R. Yu, and B. Zhou (eds.)]. <sup>56</sup> Sarofim, M., Smith, C., Malek, P., McDuffie, E., Hartin, C., & Lay, C. (2023). How high is high enough? A multi-million-member ensemble analysis of future climate scenarios and their relevance.

aerosols and minor GHGs for the RFF-SPs and find that there is a very modest impact as a result of including these substances because most of the underlying literature scenarios have similar reductions in far-future emissions of these substances. Similarly, Figure SPM-4<sup>57</sup> shows that in each of the five SSP scenarios, CO<sub>2</sub> uncertainty is the largest contributor to future climate uncertainty. EPA will continue to follow advances in the literature on these topics, consistent with the National Academies' recommendations regarding continued improvements.

Regarding the commenter's request for additional documentation and assessments, EPA disagrees with the commenter's suggestion that the discussion of methodology and results in the Draft Report was insufficient to facilitate a full assessment. Section 2.1 provides a detailed description of the climate module, including how the FaIR model compares to other reduced complexity climate models and IPCC assessments, and how it addressed the National Academies near term recommendations. In the Final Report, EPA has added discussion of additional details noted by the commenter, such as an explanation of how FaIR has a number of uncertain parameters that are chosen to be compatible with each other. The EPA has also added a new Appendix in the Final Report to summarize the treatment of uncertainty in each module, including the climate module. EPA notes again that FaIR 1.6.2 is open-source, and the parameter set is available online. The method used to generate the FaIR parameter ensemble yields a joint distribution of all parameters such that they are consistent with the historical observations and future model data against which the parameter set was calibrated. The full list of uncertain parameters and their quintile values for the FAIR v1.6.2 climate model is available in Supplementary Information Table 3 in Rennert et al. (2022).<sup>58</sup> Finally, in the Final Report, EPA has expanded the explanation of the emission pulse sizes used for the SC-GHG estimation. As discussed in Section 2, the pulse sizes used for the model runs were selected to be the smallest size that the climate system model will reasonably represent and where the damage functions are responding on the margin.

Comment: Commenter (2344-IER) argues that it is more important for regulatory impact analysis to describe temperature and sea level impact of the rule than to estimate SC-GHG as the latter is "abstract concept and one influenced by the technology we may or may not have when Captain James T. Kirk is born on March 22, 2233." The commenter recommends that EPA present the temperature and sea level rise impacts of the rule anywhere EPA reports the SC-GHG.

Response A-3-3: EPA disagrees that it is more important for RIAs to explain the temperature and sea level impact of a regulation than to report a monetized measure of the value of those physical changes to society. First, uncertainty about future technology is not a reason to favor reporting

---

<sup>57</sup> Figure SPM.4 in IPCC, 2021: Summary for Policymakers. In: Climate Change 2021: The Physical Science Basis. physical impacts on temperature and sea level over monetized benefits to society that are calculated using SC-GHG estimates. The characteristics of future technologies will affect the SC-GHG through many of the same channels as they would affect future temperatures and sea levels. For example, future technologies will determine the emissions-intensity of the future economy. Second, a monetary measure of climate impacts provides a more comprehensive way to inform the public and policymakers of the climate benefits or disbenefits expected from a proposed action and its alternatives. Presenting the climate impacts of a proposed rule in only physical units (e.g., fractions of a degree of temperature change or centimeters of sea level rise) does not disclose or explain when and how society will be affected by those physical changes. EPA and OMB guidance recommends that an agency provide an assessment of the potential costs and benefits of all economically significant regulatory actions, and that this assessment include a monetization of benefits and costs to the extent feasible. The SC-GHG provides an aggregated measure of affected individuals' willingness to pay for reduced climate change impacts associated with policy actions that reduce GHG emissions and is, therefore, the theoretically appropriate value to use when conducting benefit-cost analyses of policies that affect GHG emissions.

## A.4 Damage Module

Comment: Commenters (2208-CCES et al., 2349-RFF, 2397-U.S. Climate Alliance, 2246-NRDC) provide supportive comments specific to the methodology that EPA employs in its damage module.

Commenter (2397-U.S. Climate Alliance) applauds EPA’s inclusion and utilization of updated estimated values for the SC-GHG in the Draft Report, expressing that they were informed by the latest science and will properly account for the societal costs of climate damages when crafting effective state and federal policies. Similarly, commenter (2208-CCES et al.) states that EPA’s methodology and damage valuations are consistent with those applied by a range of expert independent researchers. The commenter states that the Draft Report faithfully implements recommendations laid out by the National Academies of Sciences for updating the social cost of greenhouse gases and applies the latest available science to its estimates.<sup>59</sup> Specifically, the damage module addresses the need to “draw on recent scientific literature” and “extend far enough in the future” to capture all key climate impacts.

Commenter (2349-RFF) endorses EPA’s use of the Greenhouse Gas Impact Value Estimator, or GIVE model, a product of RFF and the University of California, Berkeley’s Social Cost of Carbon Initiative, highlighting its comprehensive nature. The commenter explains how the GIVE model modularizes and updates each of the four modules of SCC estimation and provides peer-reviewed scientific literature bolstering the various components of the model: (1) Long-run socioeconomic projections,<sup>60</sup> (2) Improved climate model,<sup>61,62,63</sup> (3) Updated damage functions,<sup>64,65,66</sup> and (4) Economic discounting.<sup>67</sup> The commenter concludes with the central estimates of SC-CO<sub>2</sub> or SC-CH<sub>4</sub> from the GIVE model and explains its critical usage in the EPA report, along with supplementation from the damage functions from the Data-Driven Spatial

Climate Model by the Climate Impact Lab and an aggregate damage function developed in Howard and Sterner (2017).<sup>68</sup>

Commenter (2246-NRDC) expresses support for the use of three different methodologies to convert climate impacts into economic damages, including a meta-analysis of existing literature, that “taken together provide a more expansive view of the economic harms of climate change.”

Response A-4-1: EPA thanks the commenters for supportive comments on the damage module.

Comment: Multiple commenters (2208-CCES et al., 2398-Policy Integrity NYU, 2246-NRDC) expressed overall support of EPA’s damage module and recommend updating the damage functions as estimates become available, including adding feedback effects between modules when possible. Commenters (2410-CA AG et al., 2246-NRDC, 2398-Policy Integrity NYU, 2208-CCES et al., 2293-S.Holmes) underscore the importance of addressing omitted impact categories, and commenters (2398-Policy Integrity NYU, 2208-CCES et al.) state that these omitted damages result in conservative estimates of the SC-GHG.

Commenter (2410-CA AG et al.) encourages the modeling of wildfire health impacts and loss of culturally and historically significant assets. While EPA’s Draft Report lists wildfire damages and other damage categories as unquantified or partially quantified, it does not “evaluate their significance” or “indicate... which non-quantified effects are most important and why.” The commenter states that adding this kind of analysis, as called for in OMB Circular A-4 (2003), would greatly enhance the informative value of all future discussions of SC-GHG. The commenter specifies the importance of two specific unquantified damages: (1) health impacts from wildfires and (2) the loss of culturally and historically significant assets. The commenter highlights a study by the Union of Concerned Scientists that identified many historic sites and landmarks at risk from climate change.<sup>69</sup> The commenter recommends that EPA discuss significant omitted damages, including damages from wildfire, and damages to culturally and historically important resources, whenever EPA refers to the SC-GHG in rulemaking.

Commenter (2246-NRDC) also lists several omitted damages and the impact their omission has on EPA’s analysis. The commenter states that because health-related impacts are not monetized, EPA’s report is missing a substantial cost, and health-related damages linked to climate events should be included in future revisions of the SC-GHG. Similarly, the commenter states that omitting damages from climate change-induced wildfires, including market losses, non-market losses, and mortality costs, also biases the SC-GHG estimates downwards. Lastly, the commenter remarks that omitted environmental damages such as biodiversity impacts will have significant effects and recommends prioritizing their inclusion in the future.

<sup>68</sup> Howard, P. H., & Sterner, T. Few and not so far between: a meta-analysis of climate damage estimates. *Environmental and Resource Economics*, (2017) 68(1), 197-225.

<sup>69</sup> Union of Concerned Scientists, *National Landmarks at Risk: How Rising Seas, Floods, and Wildfires Are Threatening the United States’ Most Cherished Historic Sites*, at 4–32, 36–40, 44 (2014).

Commenter (2398-Policy Integrity NYU) encourages EPA to more strongly emphasize that omitted impacts bias the damage estimates downwards and to take steps to address these omissions. The commenter notes that although EPA properly characterizes its climate-damage valuations as underestimates, it can do more to emphasize the point and take steps to address it. For one, the commenter states that the 2017 Howard and Sterner<sup>70</sup> damage function does not account for the “increased value of non-market goods and services due to their growing relative scarcity from climate and non-climate factors” and argues that this is another reason to further lower the discount rate as a way to implicitly account for relative prices. The commenter goes on to say that if EPA elects not to decrease the rate of discount rates for this reason, then the Agency should at least recognize discounting as an additional reason that the SC-GHG values presented in EPA’s report underestimate climate damages. The commenter recommends that EPA augment the impact specific damage functions (from DSCIM and GIVE) as relevant published studies become available. The commenter also suggests that as part of the damage function update process, EPA should conduct its own regular literature reviews to address omitted impacts using relevant published studies. As an example, the commenter recommends EPA use benefit-transfer methods to add the representation of labor productivity damages from DSCIM into the GIVE and Howard and Sterner based damage functions “in order to avoid excluding empirically established impacts. Then, when labor productivity is successfully addressed by one of the other two damage functions, EPA can adopt this alternative estimate, so as to benefit from independence in damage estimates.” The commenter also encourages EPA to incorporate tipping points into the damage function and provides examples of some methods to do so. Within this discussion, the commenter highlights that the recent Dietz et al (2021)<sup>71</sup> “analysis represents the most sophisticated analysis in the literature capturing multiple explicit tipping points, and is the ideal strategy that the EPA should adopt to integrate those damages into its valuations, as it avoids stylized representations of tipping points and their consequences.” As noted above, the commenter suggests that an alternative to explicitly modeling multiple tipping points and their interactions could be to adopt a reduced-form estimates of the damages from tipping points based on Dietz et al.’s results. The commenter acknowledges, however, that “this approach is less desirable than explicit modeling, as it is reliant on other modeling assumptions made by the authors that may be inconsistent with EPA’s model.” The commenter emphasizes that modeling omitted tipping points “would be a critical step toward the National Academies long-term goal of modeling feedback effects between the various IAM modules.” Regarding other omitted impacts, that commenter highlights several that should be included based on the availability of published studies with sufficient detail and the magnitude of potential impact, such as environmental services and biodiversity; air pollution due to rising heat, methane converting to ozone, and wildfires; inland flooding; and freshwater availability.

Additionally, commenter (2398-Policy Integrity NYU) provided comments on the specification of the Howard and Sterner based damage function used in the damage module. The commenter states that EPA “appropriately selects the Howard and Sterner (2017)<sup>72</sup> damage function, as it is

---

<sup>70</sup> Howard, P. H., & Sterner, T. (2017). Few and not so far between: a meta-analysis of climate damage estimates. *Environmental and Resource Economics*, 68(1), 197-225.

<sup>71</sup> Dietz, S., van der Ploeg, F., Rezai, A. and Venmans, F., 2021a. Are economists getting climate dynamics right and does it matter? *Journal of the Association of Environmental and Resource Economists*, 8(5), pp.895-921.

<sup>72</sup> Howard, P.H. and Sterner, T., 2017. Few and not so far between: a meta-analysis of climate damage estimates. *Environmental and Resource Economics*, 68(1), pp.197-225.

the most up-to-date meta-regression estimate of global damage estimates for the Agency's purposes."<sup>73</sup> The commenter notes that EPA offers compelling reasons for this selection and applies it in an appropriate manner, but recommends that EPA also consider applying an alternative specification of the damage function from Howard and Sterner "rather than relating solely on their most conservative estimate." The commenter recommends that EPA adjust its selection to account for additional information in Howard and Sterner (2022)<sup>74</sup> to reflect updated information, including potential changes to the central estimate of non-catastrophic damages and its variance. Specifically, the commenter recommends that EPA consider using an alternative damage estimate that excludes damage estimates corresponding to temperature increase above 4 degrees Celsius, as the standard errors for estimates increase at that level, making damage estimates highly uncertain and speculative. The commenter highlights the need for EPA to (1) update the underlying dataset of Howard and Sterner as new global damage studies become available and (2) adopt the most up-to-date methodologies.

Commenter (2313-M. Plevin-Foust) describes the link between climate change and security, suggesting that the consequences of climate change, such as resources scarcity and climate migrants, can exacerbate global instability. The commenter's claim is bolstered by the fact that the Pentagon has ranked the climate emergency as the greatest threat to peace and global stability, as increased drought and hunger has the potential to lead to more wars and threats to democracies worldwide. The commenter states that the hotter and more unlivable the global South becomes, the more of the world and especially the U.S. will be overwhelmed with climate refugees. The commenter suggests that considering a higher social cost of carbon can help prevent the worst outcomes from occurring, keeping the U.S. safer as a result. The commenter suggests that modelling of physical impacts should include dangerous weather, smoke caused by forest fires, drought, species extinction, and pest-borne disease.

Commenter (2293-S. Holmes) discusses the ozone related health effects from methane emissions, notes the absence of tropospheric ozone figures in the SC-GHG Report's Table 3.2.1, and states that the Supplemental RIA did not monetize the ozone health effects from the methane emissions reductions expected from the proposed rule. The commenter acknowledged that the discussion of recent estimates from the literature that find ozone-related mortality benefits of CH<sub>4</sub> emissions reductions "to be \$800 to \$1,800 per metric ton of methane emissions" is useful, but "what would be more helpful at the state level, though, would be a set of clearly prescribed methane and other social cost of greenhouse gas cost valuations that can readily be applied to energy and environmental policy making and utility regulation."

Commenter (2208-CCES et al.) emphasizes that EPA's updated estimates exclude certain key climate damages and urges the agency to integrate reliable quantifications of these impacts as they emerge. The commenter states that EPA's updated social-cost valuations offer a reasoned approach to assessing climate impacts. The commenter acknowledges that EPA notes the existence of omitted climate damages within its Draft Report and correctly emphasizes in the Draft Update that its valuations likely undervalue the marginal damages from greenhouse gas

---

<sup>73</sup> Howard, P. H., & Sterner, T. Few and not so far between: a meta-analysis of climate damage estimates. *Environmental and Resource Economics*, (2017) 68(1), 197-225.

<sup>74</sup> Peter H. Howard & Thomas Sterner, *Between Two Worlds: Methodological and Subjective Differences in Climate Impact Meta-Analyses* 12, 19 (Resources for the Future Working Paper 22-10, 2022).

pollution and emphasizes the damages and limitations that contribute to this potential undervaluation in a dedicated section of the report. The commenter also stresses that the Draft Report excludes numerous expected climate impacts, including diseases, ecosystem services, water impacts, and national security effects, among others. The commenter mentions that there are efforts outside EPA to quantify omitted impacts and suggests that EPA should integrate these quantifications once available. The commenter also highlights that while certain impacts can be valued economically, others that are harder to measure might always remain underestimated.

Response A-4-2: EPA thanks the commenters for the helpful suggestions regarding omitted damage categories. Consistent with OMB Circular A-4 guidance (2003 and 2023), the EPA acknowledges and discusses the numerous categories of climate impacts and associated damages that are either not yet incorporated in the SC-GHG analysis or only partially incorporated. These omissions are listed in Table 3.2.1, and the EPA has further expanded the discussion of omitted damages in the Final Report (e.g., in Section 3.2). This includes additional discussion of the damages from wildfire and highlighting the omission of damages to culturally and historically important resources, as requested by one commenter. One advantage of the modular framework recommended by the National Academies and adopted in the updated SC-GHG estimation is that future research on new or alternative damage functions can be incorporated into the damage module in a relatively straightforward way as they become available. The EPA will continue to review developments in the literature, including more robust methodologies for estimating the magnitude of the various damages from climate impacts and explore ways to better inform the public of the full range of GHG impacts.

EPA appreciates the comments made by commenter (2398-Policy Integrity NYU) regarding the choice of specification of the Howard and Sterner (2017) meta-analysis. As discussed in the Report, EPA focuses on a specification that includes estimates across the full range of temperature changes considered in the underlying studies, rather than specifications that are constrained to studies using lower temperatures and, then, extrapolate them to estimate damages at higher temperatures, because this approach is more consistent with the share of the projected temperature anomaly distribution exceeding 4°C and the temporal distribution of discounted damages over the course of the modeling period. EPA has further clarified in the Final Report that this choice of specification likely underestimates the benefits of GHG abatement. EPA has also expanded the discussion in the Final Report to recognize the updated Howard and Sterner (2022) working paper and other emerging meta-regression studies incorporating more recent global damage estimates. EPA will continue to follow the published literature in this area as the Agency looks for opportunities to improve damage functions in future updates of the SC-GHG.

One commenter highlighted that tropospheric ozone related benefits of CH<sub>4</sub> emissions reductions expected from the rule were not monetized in the Supplemental Proposal RIA. EPA notes that this impact is listed in Table 3.2.1 of the Report as ‘not yet incorporated’ in the updated SC-CH<sub>4</sub> estimates. EPA has expanded the discussion of this important omitted damage category in both the Report and in the final RIA. The Report and final RIA discusses the results of a newly published study by McDuffie et al. (2023),<sup>75</sup> who present recent estimates of the health risks

---

<sup>75</sup> McDuffie, E.E., Sarofim, M.C., Raich, W., Jackson, M., Roman, H., Seltzer, K., Henderson, B.H., Shindell, D.T., Collins, M., Anderton, J. Barr, S., and Fann, N., 2023. The Social Cost of Ozone-Related Mortality Impacts From Methane Emissions. *Earth's Future*, 11(9), p.e2023EF003853.

associated with the methane-ozone impact mechanism. The authors use the same socioeconomic projections, mortality risk valuation, and discounting approach described in the Report and find the monetized increase in respiratory-related human mortality risk from the ozone produced from methane emissions in 2020 to be \$1,800 per ton of CH<sub>4</sub>. EPA will continue to look for opportunities to incorporate the ozone related impacts of CH<sub>4</sub> emissions in future updates to the SC-CH<sub>4</sub>.

EPA responds to the comments about further lowering the discount rate in part as a way to proxy for omitted damages in the Discounting Section of comments below.

Comment: Commenter (2361-EPRI) emphasizes the need for enhanced documentation of the module methodology to meet all the NASEM near-term recommendations. Specifically, commenter recommends that EPA provide discussion, assessment, and justification for differences in results across damage modules, sectoral SC-GHG distribution results, and results for other discount rates and years. The commenter cites issues of damage estimate comparability discussed by the IPCC WGII 2021 report<sup>76</sup> and the National Academies (2017). The commenter states that all NASEM recommendations should be followed, and inconsistencies and incoherent connections between modules should be resolved.

The commenter states that different methodologies (statistical, structural, and meta-analyses) have been used in the damages module, and that these methodological differences raise questions about whether the results are comparable and can be readily combined and treated as alternatives or instead should be viewed as different lines of evidence that need to be formally integrated with one informing and/or constraining the other. The commenter argues that DSCIM is based on statistical analyses, while GIVE is derived from structural analyses. The commenter adds that EPA should discuss the methodologies as presented in the literature of the models they are using, including DSCIM, and explain why agricultural impacts are a small part of DSCIM results, as compared to GIVE. The commenter recommends that EPA assess and discuss the methodological details in the literature that they are using.

The commenter recommends that EPA's damage module should consider more of the available literature to accurately estimate damages and account for uncertainty. The commenter states that EPA currently considers only a small fraction of the existing literature, despite "relevant alternatives globally and for individual damages categories." The commenter mentions that current sectoral damage approaches (DCSIM and GIVE) do not consider potential interactions between damage categories, which potentially lead to comparability issues in the damage module. The commenter presents figures showing examples of alternative global damage estimates from the literature, (e.g., Burke et al. 2015<sup>77</sup>) and some alternatives for individual damage categories (e.g., health damage estimates from a Bressler et al. study lacking a full

reference and crop yield damage estimates developed from Nelson et al. (2014)).<sup>78</sup> The commenter also states that EPA should “more fully incorporate current scientific knowledge to account for reasonable alternatives, reconcile lines of evidence, and improve uncertainty representation” and that models as well as their implementation should be consistent with the current body of scientific literature. The commenter also suggests including 1) equations, parameters, and examples regarding cross-module linkages and integration; 2) other assumptions, input data, equations, parameter values, uncertainty specifications from the literature used, and sources; and 3) additional intermediate and final results to enhance transparency. In addition, the commenter notes that any documentation should be self-contained. Additionally, the commenter highlights issues regarding spatial resolution, adaptation responses, statistical uncertainty, and integration with the socioeconomic module requiring transparent and explicit documentation. The commenter suggests that details are missing regarding how global and regional projections of GDP, population, global temperature, and sea level rise are integrated into each damage sector. The commenter recommends that EPA provide explicit descriptions and assessment of the variations in adaptation represented across damage modules and sectors, as well as a disaggregated total and incremental damage projection results by module and over time to improve transparency and facilitate assessment.

Commenter emphasizes the need for enhanced documentation of the module methodology to meet all the NASEM near-term recommendations. Specifically, commenter recommends that EPA provide discussion, assessment, and justification for differences in results across damage modules, sectoral SC-GHG distribution results, and results for other discount rates and years. The commenter cites issues of damage estimate comparability discussed by the IPCC WGII 2021 report<sup>79</sup> and the National Academies (2017). The commenter states that all NASEM recommendations should be followed, and inconsistencies and incoherent connections between modules should be resolved.

The commenter recommends presenting damage results without socioeconomic, climate, and SLR uncertainty in order to determine the damage-specific response and uncertainty representations. The commenter also suggests including detailed undiscounted damage results over time by country and category per projection and adding a discussion of consistency across the damage modules.

Response A-4-3: EPA thanks the commenter for their review of the damages module but disagrees with the commenter’s suggestion that the NASEM (2017) near-term recommendations have not been met. Section 5 and Table 5.1 in the Final Report describe how the methodology

satisfies the NASEM near-term recommendations for this module. EPA disagrees that we do not address the “comparability” issue as mentioned by the commenter. Specifically, the NASEM (2017) report states: “The differences in methodologies and in scope create challenges for users trying to synthesize understanding of impacts or damages. For instance, structural and empirical methods are fundamentally different from one another and, as a consequence, they produce results that may not be directly comparable. These comparability and scope issues need to be addressed in some way when developing damage functions.” EPA provides a thorough discussion of combining different lines of evidence in Section 4.1 of the Report. As outlined in the Report, EPA set out to reflect the state of current understanding of climate damages in the published literature and, therefore, EPA believes the damage module reflects that there are different approaches to damage function estimation which result in different estimates. In response to the NASEM recommendation to update existing damage functions to reflect recent scientific literature, EPA adopted a suite of three updated damage functions (GIVE, DSCIM, and a meta-analysis), which together represent the major scientific lines of evidence on the economic impacts of climate change that are available, capture uncertainty, and, in the cases of GIVE and DSCIM, provide transparent bottom-up modeling that map Earth system changes to damages. The models’ spatially explicit and impact-specific modeling of relevant processes allows for improved understanding and transparency about mechanisms through which climate impacts are occurring and how each damage component contributes to the overall results, consistent with the NASEM recommendations. The damage functions in the GIVE model offer a direct implementation of the NASEM near-term recommendation to develop updated sectoral damage functions that are based on recently published work and reflective of the current state of knowledge about damages in each sector. Specifically, the National Academies noted that “[t]he literature on agriculture, mortality, coastal damages, and energy demand provide immediate opportunities to update the [models]” (National Academies 2017, p. 199), which are the four damage categories currently in GIVE. The EPA Report transparently describes each approach and state of the damage function literature (e.g., Section 2.3) and provides a clear, well-reasoned explanation for how these different lines of evidence were incorporated into the damage module (see e.g., Section 4.1).

EPA notes that development of more formal integration approaches to account for structural uncertainty across damage functions is an opportunity for improvement in future updates. One approach to integrating different lines of evidence would be at the stage of model estimation (e.g., structural uncertainty across damage modules). However, currently DSCIM is a stand-alone model with a spatial resolution of over 25k impact regions and requires complex estimation and large capacity computing power. Therefore, this type of integration with the other damage modules is not currently feasible as each independent model was created by independent research teams and include a single characterization of each impact category that was identified by the research teams as the best available for inclusion in each of the models. However, statistical uncertainty in impacts is accounted for parametrically in each of the impact categories when statistical uncertainty was available. Regarding differences in the DSCIM and GIVE agriculture damages, EPA has documented the differences between the two agricultural studies underlying each of the models in Tables 2.3.1 (DSCIM) and Table 2.3.2 (GIVE). Moreover, the differences in damages are the combined result of all the methodological differences between the DSCIM and GIVE models as described in Sections 2.3.1 and 2.3.2.

To provide additional transparency and understanding of how statistical uncertainty is incorporated within each of the damage modules, EPA has added Appendix A.8, along with Table A.8.1, that documents how uncertainty is addressed and captured within, and across, modules. Regarding interactions between the impact categories, EPA recognizes in the Report that the models do not yet account for potential interactions between them. This is explicitly discussed in Section 3.2 and outlined in Table 3.2.1 as an area for future development.

Regarding the commenter's request for documentation on the differences and similarities in adaptation responses across the damage modules, EPA notes that Section 3.2 of the Final Report contains a thorough documentation of the damage module and the methodological details of the damage categories included in DSCIM and GIVE. The methods used in the underlying studies are also summarized in Table 2.3.1 (DSCIM) and Table 2.3.2 (GIVE), including how they account for adaptation.

Regarding the commenter's suggestion to isolate the damage-specific uncertainty, EPA notes for the commenter that the inputs to the damage modules include uncertainties carried through from both the socioeconomic and climate modules, which compounds with the parametric uncertainty in the damage modules. Isolating the damage-specific uncertainty to the results as recommended by commenter would, in part, require choosing central sets of parameters for the upstream socioeconomic and climate modules to use as the baseline settings from which to interrogate damage function uncertainty. Because many of these inputs are probabilistic in nature (e.g., the RFF-SPs), this is not feasible within the current modeling framework and parameterization. The socioeconomic module uncertainty is represented as 10,000 equally-likely socioeconomic projections with no central setting or draw. Similarly, the jointly sampled parameter draws for the climate module do not have a central case.

To ensure transparency and to accommodate interest in alternative specifications and sensitivities, EPA has provided all source code, data, and documentation such that anyone in the public can access, freely, the necessary tools to explore the models. This is available, as listed in the Report and on EPA's SC-GHG website, at [github.com/USEPA/scghg](https://github.com/USEPA/scghg).

Comment: Some commenters (2231-R. Sohn, 2313-M. Plevin-Foust, 2246-NRDC, 2227-W. Energy Alliance, 3603-T. Lent) submitted comments pertaining to the "value of statistical life" (VSL) estimates used to value marginal mortality risk changes in the damages module.

Commenters (2231-R. Sohn, 2313-M. Plevin-Foust) express overall support for EPA's Supplemental Proposal but argue that it is morally indefensible to ultimately use different VSL values for citizens of different countries that result from adjusting VSL values using countries' per-capita GDP. Commenter (2313 Plevin-Foust) states that the importance and invaluableness of human life reinforces EPA's efforts to calculate the SCC. The commenters urge EPA to monetize changes in marginal mortality risk changes projected to occur in other countries using the same VSL values assigned to Americans even if such a change doubles the resulting SC-CO<sub>2</sub>. Commenter (2313-M. Plevin-Foust) argues that it is in the United States' best interest to do so for climate stability, global influence and security, and economic and health reasons. The commenter also notes that the social cost of carbon adopted by the U.S. will also likely be used by Canada and other nations.

Commenter (2246-NRDC) acknowledges that “economic theory indicates that to satisfy Kaldor-Hicks criterion WTP to VRR [value for mortality risk reduction] need to reflect the actual views of the target population”, “recognizes that the VRR should scale with per capita GDP to some extent”, and that the “scaling approach correctly implies that as nations grow wealthier in the future, their WTP for VRR would increase”. However, the commenter is concerned that it is unlikely that the assumed income elasticity of 1.0 is appropriate for VRR across all levels of GDP, and the commenter argues that “Developing a VRR for other nations is an ethical and political issue as well as an economic one. Assigning a very low VRR to the citizens of other nations politically signals a lack of concern for their health”. The commenter presents three feasible potential alternatives to EPA’s current approach: (1) using an equity-weighted approach to estimating SC-GHG, as described by Cromar et al.<sup>80</sup>; (2) applying a lower bound VRR for less affluent countries, such that if the benefits transfer approach used in the Draft Report results in a VRR less than the preset lower bound then the VRR would default to that lower bound; or (3) applying one U.S. VRR and one globally weighted VRR that “wouldn’t discriminate between the VRR of nations by GDP per capita”. The commenter notes that they are unaware of an existing method for setting the lower bound value under option 2, hence “EPA would have to work with experts to make a policy judgement to develop this value.”

Commenter (2227-W. Energy Alliance) argues for additional scrutiny of using the same approach for carcinogenic risk to assess climate change-related mortality risk. The commenter notes “WTP values used in the revised SC-CO<sub>2</sub> estimates are based on cancer risk reduction that one might be a beneficiary of in one’s own lifetime. EPA has now applied that concept to climate change risk reduction that are more likely to impacts non-U.S. citizens well outside the range of a current adult’s life span.” The commenter further notes the heterogeneity in risk aversion throughout the population. The commenter encourages EPA to further explain what value was used for the Statistical Value of a Life and the WTP values in the revised SC-CO<sub>2</sub> estimates.

Commenter (3603-T. Lent) objects to the use of VSL, suggesting that the formulation used by EPA in the Draft Report disproportionately values the lives of higher-income populations. The commenter argues that this leads to a perverse outcome in which “the current VSL formulation puts a higher value on lives of populations in which the individuals are statistically more likely to do more damage if they live longer”. As an alternative, the commenter recommends the agency evaluate the social costs of regulatory actions in terms of predicted life extension benefits. Commenter (2339-INGAA) argues that damage calculations erroneously seek to translate non-market effects, particularly human health impacts, or mortality risks, into dollar amounts. The commenter asserts that such quantification is a non-scientific value judgment.

Response A-4-4: In Appendix A.7 of the Report, EPA has provided a thorough discussion of the methodology underlying the estimates of willingness to pay for mortality risk changes – a number inaptly termed the “Value of Statistical Life” (VSL) – that are applied in the SC-GHG estimation process. As explained in OMB Circular A-4 (2003), “these terms refer to the measurement of willingness to pay for reductions in only small risks of premature death. They have no application to an identifiable individual or to very large reductions in individual risks.

---

<sup>80</sup> Kevin Cromar, Peter Howard, Valeri N. Vásquez, David Anthoff, Health Impacts of Climate Change as Contained in Economic Models Estimating the Social Cost of Carbon Dioxide (2021); <https://agupubs.onlinelibrary.wiley.com/doi/full/10.1029/2021GH000405>.

They do not suggest that any individual's life can be expressed in monetary terms” (OMB 2003). Circular A-4 (2023) contains similar guidance (OMB 2023).

As discussed in Appendix A.7, the benefits transfer approach used for monetizing expected marginal mortality risk changes occurring in other countries based on a positive income elasticity is consistent with the approach used in the default version of the damage functions and published studies used in the report, other academic literature, advice given to the IWG by experts, and other prominent domestic and international guidance documents that speak to international mortality risk reduction valuation. EPA disagrees with the commenters who recommend that the Agency develop a new alternative benefits transfer approach. Assigning a uniform VSL globally based on the global average would value the marginal mortality risk changes to residents of lower income countries higher than their willingness to pay and value mortality risk changes to higher income countries less than their willingness to pay. Using a globally uniform VSL approach based on the global average would also lead to inconsistencies for climate-driven U.S. mortality risk changes and how EPA values U.S. mortality risks from other causes in benefit-cost analysis (BCA). An implicit weighted social welfare function is also present in one commenter’s suggestion of a potential approach that sets a lower bound VSL for less affluent countries. Indeed, the commenter acknowledges that they are unaware of an existing method for setting such a lower bound value and hence the Agency would have to “make a policy judgement” to develop this value.

EPA disagrees with the commenters who object to the use of any monetized measure of the value of mortality risk reductions, or other non-market effects, on the grounds that it is a “non-scientific value judgment.” As explained in Appendix A.7 of the Report, for damage categories that involve non-market impacts (commodities or services not traded in the market, like changes in mortality risks) there is no readily observed price information and there are challenges in capturing the value of something as precious as changes in life expectancy. However, economists have developed a robust literature to infer values for these non-market commodities using methods that are consistent with the theoretical underpinnings of EPA’s BCA. EPA has relied on estimates from the published literature to monetize changes in mortality risks expected from policy options in regulatory BCA since the 1980s. For more discussion of the development of this methodology, see Appendix A.7 of the Final Report and EPA’s Guidelines for Preparing Economic Analyses.<sup>81</sup>

Comment: Two commenters (2464-Heal and Bressler, 2428-API) argue that using PPP-adjusted VSL estimates is not compatible with the Kaldor Hicks criterion.

Commenter (2464-G. Heal and D. Bressler) applaud the EPA for their “excellent work” and commend the Agency for making numerous significant improvements in the updated SC-GHG estimates compared to the IWG SC-GHG estimates. Then, among a “few constructive criticisms”, the commenter argues that an assertion made in the Draft Report about current EPA BCA practice being consistent with the Kaldor-Hicks potential compensation principle is incorrect. The commenter highlights two key points of contention: 1) the valuation of premature mortality risk changes in EPA RIAs and 2) the use of purchasing power parity (PPP)-adjusted

---

<sup>81</sup> U.S. Environmental Protection Agency (EPA), 2010. Guidelines for Preparing Economic Analyses. EPA-240-R-10-001. <https://www.epa.gov/environmental-economics/guidelines-preparing-economic-analyses>

income in the development of the SC-GHG estimates. Regarding the first point, the commenter states that EPA's practice of assigning a single uniform value to monetize mortality risk changes to U.S. populations is inconsistent with the Kaldor-Hicks principle, and results in the BCA being closer to welfare weighting than a Kaldor-Hicks consistent BCA. Regarding the second point, the commenter argues that the use of PPP-adjusted dollars undermines the potential compensation principle and recommends that the benefits and costs be measured in a number representing an actual unit of exchange over which transfers can occur, such as money at market exchange rates. The commenter suggests that EPA use a Negishi-Weighted social welfare function instead of strictly adhering to the Kaldor-Hicks potential compensation test, as the use of the social welfare functions is argued to better represent observed preferences.

Commenter (2428-API) questions EPA's usage of PPP-based projections in the SC-GHG framework. Referencing a study,<sup>82</sup> the commenter argues that using PPP is incompatible with a pure Kaldor-Hicks approach. Specifically, the authors provide an example in which a regulation would generate net costs when analyzed in PPP-adjusted dollars but would generate net benefits when analyzed using market exchange rates. The commenter urges EPA to explain how using PPP-adjusted dollars aligns with the federal government's overall approach to cost-benefit analysis and suggests that EPA should clarify its rationale and address any potential inconsistencies with the established principles of cost-benefit analysis.

Response A-4-5: EPA understands the concerns about using PPP-adjusted income in the development of the SC-GHG estimates, but there is no clear consensus in the economic literature on whether the market exchange rate or PPP should be used to adjust the GDP value. The choice involves a tradeoff between consistency with the potential compensation test of the Kaldor-Hicks criterion and reflecting the actual preferences in the country under consideration. Using the PPP takes into account the different price levels and different baskets of goods consumed across countries, and it more accurately describes relative standards of living across countries. PPP adjustment is also the standard approach in the literature (Hammitt and Robinson 2011<sup>83</sup>, Nordhaus 2017a<sup>84</sup>, 2017b<sup>85</sup>, Robinson, et al. 2019a<sup>86</sup>) and it is the same approach used in the damage function estimates in GIVE and DSCIM. EPA believes that this is currently the best practice for benefit transfer of VSL estimates, but we recognize that this is an approximation. EPA has added discussion of this issue in Appendix A.7 of the Final Report.

Comment: A few commenters (2227-W. Energy Alliance, 2445-J.K. Davis, 2428-API) opined on the damage functions used for particular impact categories (such as agriculture) and the degree to which the damage estimates could be considered “conservative”.

Commenter (2227-W. Energy Alliance) recommends that EPA revisit their damage functions, which suggest adverse agricultural impacts associated with higher temperatures, to accurately reflect the agricultural benefits some warming can have on crops. The commenter states that historical damage functions indicate that a certain degree of warming benefits certain types of agriculture, yet the damage function used by EPA suggests otherwise. The commenter also highlights the potential for significant adaptation through agricultural science and crop engineering. Furthermore, the commenter advises EPA to acknowledge the significant increase in agricultural damage in the revised global SC-CO<sub>2</sub> estimates due to the new agricultural damage function used in the GIVE model. The commenter recommends that EPA addresses the uncertainty and lack of clarity associated with the damage function used in the *Nature*<sup>87</sup> article. The commenter also argues that EPA's conclusion that the new SC-CO<sub>2</sub> estimates are an underestimation of future climate change impacts is not well-supported. As support for this assertion, the commenter notes that the GIVE damage function used by EPA indicates that climate change impacts to U.S. citizens are lower than those impacts suggested by a global SC-CO<sub>2</sub> value and are almost entirely a result from the contribution of the Temperature Mortality damage function. The commenter also states that Temperature Mortality has not been a significant factor in estimating SC-CO<sub>2</sub> in the past, but now constitutes half of the latest estimates, warranting further scrutiny and verification.

Commenter (2445-J.K. Davis) similarly expressed concerns that EPA's SC-GHG draft report does not sufficiently account for the potential benefits of greenhouse gases, such as enhanced photosynthesis from increased CO<sub>2</sub> levels and that cold weather deaths would decrease.

Commenter (2428-API) expresses that EPA should provide more support for its claim that its damage estimates are conservative due to non-quantified damages and other model limitations, because these assertions could potentially bias the IWG's process. Furthermore, the SC-GHG estimate of marginal damages in the report is likely to be an underestimation because there are multiple categories of damages that are not represented in the report. The commenter asserts that EPA should list and explain the range of possible options and how the Agency's approach represents the conservative choices reflected in the report. The commenter emphasizes that mortality-related impacts are significant in two sectoral damage functions. The commenter cites a research paper<sup>88</sup> and an IPCC report<sup>89</sup> that suggest the temperature-mortality response function differs by age, particular among individuals over the age of sixty-five. To account for such differences, the commenter recommends that EPA impart heterogeneity across age brackets when the agency conducts analyses. The commenter adds that the temperature-mortality function will likely change for a given location depending on adaptation measures. The commenter

<sup>89</sup> Rose, S, D Diaz, T Carleton, L Drouet, C Guivarch, A Méjean, F Piontek, 2022. Estimating Global Economic Impacts from Climate Change. In *Climate Change 2022: Climate Impacts, Adaptation, and Vulnerability. Contribution of Working Group II to the Sixth Assessment Report of the IPCC*, Chapter 16.

recommends future projections of the temperature-mortality function to account for potential adaptation to temperature change, considering various factors such as regional climate and socioeconomic status, to improve estimations. The commenter is critical of EPA's SC-GHG model because it uses damage functions at the subnational and/or sectoral level, but there is no discussion explaining why other damage functions, particularly those produced by structural economy-wide models, were excluded. The commenter calls for EPA to identify all possible damage function approaches and discuss their relative merits and shortcomings to provide stakeholders with a clear understanding of the selected approach. The commenter also calls for clear and apparent justification from EPA for the significant increase in the new SC-CO<sub>2</sub> estimates.

Response A-4-6: EPA has included a thorough discussion of the impact categories underlying each of the damage modules in section 2.3.1 for DSCIM and 2.3.2 for GIVE. These outline the net impacts estimated for categories such as the agricultural sector. As mentioned in the Report, the “The agriculture damage function component of GIVE follows Moore et al. (2017)<sup>90</sup>. It is derived using (1) a meta-analysis of over 1,000 published temperature-yield response estimates from 55 unique studies, and (2) an open-source computable general equilibrium (CGE) model that estimates the welfare consequences (as equivalent variation) of climate-induced productivity changes, accounting for adjustments in agricultural markets including trade patterns, consumption, and production. The productivity changes (for maize, rice, wheat, and soybeans) are based on biophysical crop impacts documented in the literature. Productivity impacts include both within-crop adaptations (e.g., varietal and planting date changes) as well as CO<sub>2</sub> fertilization using estimates of the size of these effects from the meta-analysis.” That is, the concerns raised by the commenter are fully addressed in the study underlying the agriculture damage function in GIVE.

With respect to the assertion that EPA has overestimated damages, EPA has documented many reasons for the SC-GHG estimates are likely to be a partial accounting of climate change impacts and likely underestimate the marginal benefits of GHG abatement (e.g., see Section 3.2). Additionally, regarding GIVE model-based results, Rennert et al. (2022b)<sup>91</sup> “expect that, in total, the future inclusion of additional damage sectors and tipping elements is likely to raise the estimates of the SC-CO<sub>2</sub>, and that therefore the estimates from the present study are likely best viewed as conservative.” EPA notes for the commenter that while all the near-term NAS recommendations have been met, Section 3.2 provides a thorough discussion of opportunities for future improvements. For example, although the damage functions applied in this report offer an improved accounting of adaptation and its costs, the modeled estimates employ optimistic assumptions about adaptation decisions in the estimation of coastal damages in GIVE and DSCIM.

<sup>90</sup> Moore, F.C., Baldos, U., Hertel, T., and D.B. Diaz., 2017. New science of climate change impacts on agriculture implies higher social cost of carbon. *Nature Communications*, 8(1), pp.1-9.

<sup>91</sup> Rennert, K., Errickson, F., Prest, B.C., Rennels, L., Newell, R., Pizer, W., Kingdon, C., Wingenroth, J., Cooke, R., Parthum, B., Smith, D., Cromar, K., Diaz, D., Moore, F., Müller, U., Plevin, R., Raftery, A., Ševčíková, H., Sheets, H., Stock, J., Tan, T., Watson, M., Wong, T., and Anthoff, D., 2022b. Comprehensive evidence implies a higher social cost of CO<sub>2</sub>. *Nature*. 610(7933), 687-692

The damage functions capture multiple net damage pathways that can be broadly divided into market and non-market pathways. Some net economic damages are experienced through markets, such as changes in net agricultural productivity, net energy expenditures, and property damage from increased flood risk. Examples of net damages experienced through the nonmarket pathways include changes in net mortality rates and changes in ecosystem services, including those provided by biodiversity.

Comment: Commenter (2417-Save LBI) argues that it is incorrect to present a permanent dollar social benefit based on a project's carbon emission reduction when it comes to sea level rise. The commenter suggests that EPA should not use the cost per ton numbers to quantify the environmental benefit of such projects. The commenter recommends that EPA make several revisions, including explaining the time delays between emission reductions and actual sea level rise reductions, creating a new carbon cost factor without the sea level rise element for cost-benefit analyses, and clarifying how the model's dollar benefit can be attributed to a state.

Response A-4-7: EPA would like to clarify for the commenter that the SC-GHG, as estimated in the Report, does, in fact, account for complex dynamics of environmental and socioeconomic conditions. Moreover, "The SC-GHG is the monetary value of the future stream of net damages associated with adding one ton of that GHG to the atmosphere in a given year" (Executive Summary of the Report). To estimate the SC-GHG for a given year  $t$ , the models are run twice – first as a baseline using exogenous trajectories of GHG emissions, and second with an additional pulse of GHG emissions in year  $t$ . After recalculating the temperature effects and damages expected in all years beyond  $t$  resulting from the adjusted path of emissions, the streams of marginal damages (i.e., the difference in damages in every year  $t + n$  between the baseline and adjusted model) are discounted to a present value in the discounting module. In this way, the model is capturing the value of having less sea level rise in year  $t + 1$ ,  $t + 2$ , and so on, relative to a world without the additional ton of GHG emissions. Regarding the appropriate use of the SC-GHG in benefit-cost analyses and accounting for global impacts, EPA refers the commenter to Section 1.3 and Section 4.2 of the Report.

## A.5 Discounting Module

Comment: Several commenters (2208-CCES et al., 2246-NRDC, 2410-CA AG et al., 2397-Climate Alliance, 3658-PolicyInteractive, 2349-RFF, 2398-Policy Integrity NYU, 2183-M. Freeman et al.) provided supportive feedback on the discounting module used in EPA's External Review Draft.

Commenters express support for EPA's updated discounting methodologies, particularly the transition to lower near-term discount rates than used in previous SC-GHG estimates. Commenters (2349-RFF, 2398-Policy Integrity NYU, 2183-M. Freeman et al.) affirm that EPA's discounting methodology and choice of near-term rates used have broad support from the academic literature.

Commenter (2208-CCES et al.) states that EPA uses an appropriate range of discount rates and encourages EPA to provide further justification of its discounting approach through regulatory practices and precedents, including EPA's past decisions on ozone protection<sup>92</sup> and the Clean Air Mercury Rule.<sup>93</sup> The commenter suggests that EPA emphasize its prior recommendation under the George W. Bush administration<sup>94</sup> of using lower discount rates for assessing climate damages. The commenter highlights the strong support of EPA's declining discounting rate approach in the economics literature. The commenter also notes that OMB's Circular A-4 (2003) guidance to intergenerational discounting offers strong support for EPA's declining-rate approach and explicitly endorses the use of lower discount rates for long-term effects such as climate change.

Commenter (2246-NRDC) notes the improvements regarding EPA's use of dynamic discount rates and argues that it is better able to address uncertainty in future economic growth. The commenter remarks that the Ramsey formula accounts for the fact that consumption discount rates would change based on changing economic conditions (lower discount rates are applied when economic growth is lower and vice versa). The commenter also states that EPA's choice of discount rates (1.5%, 2%, and 2.5%) are appropriate but argues that these values are conservative. The commenter further highlights other improvements to the discounting module including the incorporation of the relationship between discount rates and economic growth. Similarly, commenter (2410-CA AG et al.) applauds EPA's Draft Report and the use of dynamic discount rates with near-term rates of 1.5%, 2%, and 2.5% and argue that the 1.5% rate is most appropriate.

Commenter (2397-Climate Alliance) agrees that EPA's discounting methodology uses an appropriate range of discount rates. Similarly, commenter (3658-PolicyInteractive) expresses

Reg. 8136, 8162–63 (Feb. 11, 1993); Protection of Stratospheric Ozone; Refrigerant Recycling; Substitute Refrigerants, 69 Fed. Reg. 11946, 11975 (Mar. 12, 2004).

<sup>93</sup> Standards of Performance for New and Existing Stationary Sources: Electric Utility Steam Generating Units, 70 Fed. Reg. 28,606, 28,642 (May 18, 2005). This rule was later vacated by the D.C. Circuit on grounds unrelated to the discount rate. *New Jersey v. EPA*, 517 F.3d 574 (D.C. Cir. 2008).

<sup>94</sup> Regulating Greenhouse Gas Emissions Under the Clean Air Act, 73 Fed. Reg. 44,354, 44,416, 44,446 (July 30, 2008); Technical Support Document on Benefits of Reducing GHG Emissions (2008).

support for EPA's SC-GHG estimates and states that the discount rate should be no higher than 2.5 percent, citing the February 2021 IWG TSD.<sup>95</sup>

Commenter (2349-RFF) supports EPA's updated dynamic discounting approach and particularly endorses the change in the central discount rate from 3% to 2%. The commenter notes that the updated discounting methodology is well-supported by peer-reviewed economic literature and essential for capturing risk accurately. The commenter affirms that the shadow price of capital (SPC) approach is the correct and "analytically preferred method" for addressing concerns that regulatory costs may displace investment. The commenter discourages the use of a 7% discount rate based on investment returns. The commenter cites recent research<sup>96,97,98</sup> which demonstrates that the use of the 7 percent rate is "generally deeply flawed, especially when impacts are long-lived, such as in the case of climate change." The commenter urges analysts to adopt the SPC approach as laid out in recent literature.

Commenter (2398-Policy Integrity NYU) states that "both discount rate experts and climate experts consistently select a central discount rate of 2% (or lower when considering relative prices) as appropriate in inter-generational contexts, including in the climate context."

Commenter (2183-M. Freeman et al.) focuses their comment primarily on the dynamic discounting approach that EPA employed and states that the discounting methods used to calculate the SCC, including the central real social discount rate of approximately 2%, have strong independent support from the academic literature.

Response A-5-1: Thank you for the supportive comments.

Comment: Commenters (2208-CCES et al., 2398-Policy Integrity NYU) acknowledge the improvements in EPA's discounting methodology and advocate for further reductions in discount rates. The commenters argue that omitted damages result in a discount rate schedule that is biased upward. The commenters also note that consideration of relative prices of non-market goods support a lower discount rate.

Commenter (2208-CCES et al.) acknowledges that in the Draft Update, EPA has applied a reasonable range of discount rates which align with economic evidence, theory, and consensus. Despite the strengths recognized, the commenter highlights that the short-term discount rates used by EPA in the Draft Report are conservative, suggesting that evidence supports a range of 0.5% to 2.5% with a central estimate of approximately 1.5%. The commenter additionally addresses the connection between omitted impacts and the discount rate and suggests that unaccounted-for damages not only directly lead to an underestimation of the SC-GHG but also

---

<sup>97</sup> Pizer, W.A. A Shadow-Price-of-Capital Approach to Harmonize Discounting for Greenhouse Gases in Broader Benefit-Cost Analyses. (2021). [https://media.rff.org/documents/OMB-2021-0006-0059\\_attachment\\_1.pdf](https://media.rff.org/documents/OMB-2021-0006-0059_attachment_1.pdf)

<sup>98</sup> Newell, R. G., Pizer, W. A. & Prest, B. C. The Shadow Price of Capital: Accounting for Capital Displacement in Benefit-Cost Analysis. *Resources for the Future*

indirectly via the discount rate through an overestimated economic growth rate. The commenter emphasizes that omitted impacts can affect the SC-CO<sub>2</sub> due to their influence on the variability of per-capita consumption growth rate and suggests a potential solution would be to adopt a lower discount rate range. The commenter recommended that if EPA does not decrease its range of discount rates, as recommended above, it should at least incorporate the arguments from that section into its dedicated discussion of reasons that the Draft Update's climate-damage valuations are likely underestimates.

Commenter (2398-Policy Integrity NYU) also urges EPA take steps to address omitted impacts, such as lowering the discount rates or noting that discounting contributes to underestimating damages. The commenter offers a mathematical argument that the presence of omitted damages not only results in an underestimate of the SC-GHG itself but additionally results in the use of an upwardly biased discount rate that works to indirectly lower estimates of the SC-GHG through the discounting methodology.

Commenters (2208-CCES et al., 2398-Policy Integrity NYU) urge EPA to consider relative prices of non-market goods in the discounting module. Commenter (2208-CCES et al.) notes that “[t]his is important, as damage functions have historically failed to account for the increased value of non-market goods and services due to their growing relative scarcity from climate and non-climate factors”. The commenters note that the experts surveyed in Drupp et al. (2018)<sup>99</sup> that explicitly accounted for relative prices supported a lower discount rate in the range of 0% to 2% with a central estimate of 1%. The commenter notes that “[r]elative prices can be implicitly captured by adjusting the social discount rate downward”.

Response A-5-2: As described in detail in the report, EPA assessed numerous lines of evidence calibrating the discount rate module including, historical real rates of returns, empirical studies of equilibrium real interest rates, future projections of real interest rates, and surveys of economists and technical experts. While singular lines of evidence may point to slightly higher or lower rates, looking across this wide body of evidence, EPA finds broad support for a near-term discount rate in the range of 1.5% to 2.5% with a central focus on 2.0%. Furthermore, as described in detail in the report, EPA finds broad support in the economic literature and in the National Academies recommendations for using the Ramsey formula to endogenize a dynamic discount rate schedule consistent the other modules used to estimate the SC-GHG.

EPA appreciates that, in some cases, if omitted damages were able to be included in the model, the endogenously determined risk adjusted discount rate schedule could be lower than what is currently included in the modeling. However, this result depends on the nature of the omitted damages and the correlation with economic growth. Since the quantitative effect on the dynamic discount rate schedule will depend on the specifics of the omitted damages, making precise exogenous adjustments to the discount rate to account for these effects would be challenging. Similarly, EPA appreciates the point that willingness to pay for non-market goods can vary over time as preferences and their availability changes. The damages module accounts for changes in willingness to pay overtime as preferences change based on key factors, such as income. However, EPA does not currently find sufficient support for calibrating specific quantitative

---

<sup>99</sup> Drupp, M.A., Freeman, M.C., Groom, B. and Nesje, F., 2018. Discounting disentangled. *American Economic Journal: Economic Policy*, 10(4), pp.109-134.

adjustments to the discount rate to account for potentially omitted factors like changes in the relative scarcity of non-market goods over time. However, EPA looks forward to advances in the scientific literature of climate change that will allow for increased inclusion of currently omitted damages and improve the characterization of changes in willingness to pay over time, at which point, any impact on the dynamic discount rate schedule can be appropriately accounted for endogenously within the modeling framework. This approach will ensure that the impacts on the discount rate are consistent with the best available evidence on damages and consistent with the other components of the modeling.

Comment: Commenters (2253-OCT, 2208-CCES et al., 2410-CA AG et al.) acknowledge the significant improvements in EPA’s discounting methodology and advocate for further reductions in discount rates due to concerns regarding intergenerational equity.

Commenters (2253-OCT) acknowledges the improvements made by EPA’s Draft Report regarding the choice of lower near-term discount rates. The commenter argues that the use of discount rates (1.5%, 2%, and 2.5%) in the SC-GHG Report undervalues the benefits of climate action for children and future generations. The commenters suggest eliminating all estimates derived from these “constitutionally and ethically indefensible” discount rates. The commenter instead argues for incorporating discount rates that account for intergenerational equity and requiring the Agency to use constitutionally compliant discount rates of zero or near-zero percent. The commenter also raises concerns about equating personal and societal level consumption behavior preferences.

Commenter (2208-CCES et al.) notes that EPA’s approach to discounting resonates with the Working Group’s prior acknowledgment that rates of “2 percent and lower are warranted for intergenerational impacts.” The commenter highlights that Circular A-4 (2003)’s recommendation for additional analysis using a lower but positive discount rate for impacts with intergenerational effects. The commenter argues that relying solely on market-based data for discount rates ignores intergenerational equity.

Commenter (2410-CA AG et al.) applauds EPA for its use of near-term discount rates (1.5%, 2%, and 2.5%). The commenter cites research that support a long-term discount rate of no higher than 2 percent.<sup>100,101,102</sup> The commenter further advocates for the use of the estimates with a 1.5 percent discount rate because these estimates have a near-zero pure rate of time preference and

<sup>102</sup> Att. 36, Council of Economic Advisers, Discounting for Public Policy: Theory and Recent Evidence on the Merits of

Updating the Discount Rate, Issue Brief, at 3 (Jan. 2017), available at [https://obamawhitehouse.archives.gov/sites/default/files/page/files/201701\\_cea\\_discounting\\_issue\\_brief.pdf](https://obamawhitehouse.archives.gov/sites/default/files/page/files/201701_cea_discounting_issue_brief.pdf). 176 EPA-HQ-O

echoes EPA's statement that Ramsey (1928)<sup>103</sup> argued that it is ethically indefensible to apply a positive pure rate of time preference when considering intergenerational contexts.

Response A-5-3: EPA notes that the 1.5%, 2%, and 2.5% rates used in the report, and to which the commenters refer, are the near-term discount rates. EPA did not use a constant discount rate over the modeling time horizon and therefore the near-term discount rates do not reflect the discount rates used for intergenerational impacts. The discount rate in future years is determined by the Ramsey formula consistent with economic theory and socioeconomic scenarios used in the modeling. As noted in the report, the Ramsey formula describes the consumption discount rate as a function that explicitly reflects: (1) preferences for utility in one period relative to utility in a later period (called the "pure rate of time preference"); and (2) the value of additional consumption as income changes. With respect to the pure rate of time preference, the calibrated values used by EPA (0.01%, 0.20%, and 0.46%), and presented in Table 2.4.2, are within the ranges of value used in peer-reviewed literature. The vast majority of papers in the climate change literature adopt values in the range of 0% to 2% per year, with most studies in the lower end of the range (IPCC 2014a<sup>104</sup>). The selection of rates on the lower end of that range tend to emerge from ethical concerns. Some have argued that to use any value other than 0 would unjustly discriminate against future generations (e.g., Arrow et al. 1995<sup>105</sup>, Stern 2006<sup>106</sup>). When Drupp et al. (2018)<sup>107</sup> surveyed economists about the most appropriate values for the pure rate of time preference the experts' responses had a median (mean) value of 0.5 (1.1) percent, and a mode value of 0. However, even under the case of intergenerational neutrality, a small positive pure rate of time preference may be appropriate to account for the probability of unforeseen cataclysmic events (Stern 2006).<sup>108</sup> Furthermore, it has been argued that very small values could be associated with an unreasonable rate of optimal savings (Arrow et al. 1995). As such, EPA finds that its calibrated values are within the range of values used in the peer reviewed literature, including those that are based on a prescriptive approach, and that no further adjustment to the pure rate of time preference is warranted. The second component of the Ramsey formula accounts for the value of additional consumption as income changes. This component of the discount rate specification explicitly accounts for intergenerational equity by ensuring that the relative impact of damages accounts for difference in economic wellbeing. The central parameter in defining this effect within the Ramsey formula is the elasticity of marginal utility with respect to consumption. As discussed in the report, the calibrated values of this parameter used by EPA are also within the ranges of values used in the peer-reviewed literature.

<sup>108</sup> Stern (2006) assumes a pure rate of time preference of 0.1%. This reflects a 91% probability of the human race surviving 100 years.

Comment: Commenters (2398-Policy Integrity NYU, 2183-M. Freeman et al.) express overall support for updates made to EPA’s discounting methodology but seek clarifications and highlight potential areas of improvement.

Commenter (2398-Policy Integrity NYU) requests that EPA clearly specify its extended Ramsey equation and the underlying parameters and argues that “[t]his transparency will enable the public, including other federal and state agencies, to better understand the assumptions underlying the certainty-equivalent social cost of greenhouse gases.” The commenter further argues that a lack of understanding may prevent other entities from adopting these estimates and apply them to contexts with different risk profiles. The commenter notes that Figure 2.4.1 in EPA’s Draft Report “shows only the ‘certainty-equivalent risk-free discount rate’, omitting the risk premium term, implies that EPA never displays the explicit discount rate in full”. The commenter requests that EPA provide the implicit climate beta schedule and the risk premium parameter/value and explain the derivation of these values.

Commenter (2183-M. Freeman et al.) provides general support for EPA’s discounting methodology but presents some technical recommendations. The commenter notes that Newell, Pizer, and Prest (2022)<sup>109</sup> present the same Ramsey equation as equation 2.4.1 in the EPA report and observe that uncertainty in economic growth implies that the discount rate is also a random variable. The commenter states that there are two equivalent ways to express the SCC: 1) one in which the expectation is first taken over time and has the interpretation of dynamic discounting, and 2) one in which the expectation is first taken over simulation and has the interpretation of risk-adjusted discounting. The commenter elaborates that describing the discount rate as used in the Draft Report’s equation 2.4.1 as a “dynamic discounting environment” is potentially misleading and suggests that EPA refer to this approach as “risk-adjusted”. The commenter’s rationale is that it is difficult to place policy interpretations on the simulation-specific values,  $SCC_s$ , generated from taking the expectation over time first. The commenter notes that  $SCC_s$  only has the interpretation of a simulation-specific SCC under highly restricted assumptions regarding how growth uncertainty is resolved. Instead,  $SCC_s$  represents “a perfect hindsight value that EPA wishes, at time  $t = T$ , that it had enacted at time  $t = 0$  contingent on state  $s$  being the actual path the economy takes”. The commenter argues that this is inconsistent with how growth uncertainty resolves under the stochastic process of Müller, Stock, and Watson (2022).<sup>110</sup> The commenter further notes that summary statistics other than the mean of the SCC and the discount rate therefore require further explanation in the EPA report. The commenter argues that these values are real numbers and not stochastic variables and do not have 95% confidence intervals or other summary statistics associated with stochastic variables. The commenter notes that EPA correctly focuses on the mean estimate of the SCC and recommends that EPA further clarify the purpose and interpretation of other summary statistics presented in the report (e.g., median, 95<sup>th</sup> percentile). The commenter recommends that EPA focus on a single central estimate for the SCC and clarify the purpose of presenting the SCC estimates based on short-term rates of 1.5% and 2.5%.

<sup>109</sup> Newell, R.G., Pizer, W.A. and Prest, B.C., 2022. A discounting rule for the social cost of carbon. *Journal of the Association of Environmental and Resource Economists*, 9(5), pp.1017-1046.

<sup>110</sup> Müller, U.K., Stock, J.H. and Watson, M.W., 2022. An econometric model of international growth dynamics for long-horizon forecasting. *Review of Economics and Statistics*, 104(5), pp.857-876.

Commenter (2183-M. Freeman et al.) also presents concerns related to the calibration of the Ramsey parameters. The commenter notes that they are unaware of previous research that demonstrates that the three models that EPA uses in its analysis (Ramsey (1928)<sup>111</sup>, Bauer and Rudebusch (2023)<sup>112</sup>, and Müller, Stock, and Watson (2022)<sup>113</sup>) are theoretically consistent with each other. Therefore, the commenter argues that EPA would benefit from giving reassurance to the theoretical consistency of estimating parameters ( $\rho$  and  $\eta$ ) using these three models as inputs.

Response A-5-4: EPA agrees with commenter (2398-Policy Integrity NYU) that transparency is important, and in the Report, EPA has provided highly detailed information regarding the process for calibrating the discount rate and the resulting discount rate schedule. Each of the 10,000 draws in the Monte Carlo simulation has a dynamic discount rate schedule based on the calibrated Ramsey parameters and the annual growth rate for that trial. Figure 2.4.1 in the Report presents percentiles and means of the distribution of this dynamic discount rate. This summarizes the actual 10,000 discount rate schedules used by EPA to discount marginal damages. The certainty-equivalent discount rate presented in Figure 2.4.1 in the Report is the single, time-averaged discount rate that produces the same discount factor for any given year as the expectation of the distribution of stochastic discount factors used in the modeling. An alternative approach suggested by the commentor (2183-M. Freeman et al.) would be to use a risk-adjusted rate to discount the marginal damages across all Monte Carlo trials. The commentor noted that these two approaches are numerically equivalent in terms of estimating the SC-GHG. However, this alternative approach would require accounting for the correlation between marginal damages and consumption growth (Prest 2023)<sup>114</sup>. Therefore, EPA chose to discount the marginal damages for each trial separately using the trial-specific discount rate schedule based on the Ramsey equation. Figure 2.4.1 presents the rates used by EPA, and Figure 3.1.1 presents the distribution of the discounted marginal damages per metric ton of CO<sub>2</sub> for 2030 emissions. To provide further transparency, EPA has provided the implied climate beta for three damage modules separately and for all damage modules combined in Appendix A.4 of the Final Report. Providing the risk premia for the three models is more difficult, primarily because the discounting in DSCIM is conducted in a high-computing environment, but Prest (2023)<sup>115</sup> calculates the risk premia for the GIVE damage module, which is also provided in Appendix A.4.

EPA understands the perspective of commenter (2183-M. Freeman et al.) but prefers the use of “dynamic discounting” to draw a clear distinction between the discounting approach used in this report and the constant discounting approach used in previous estimates of the SC-GHG used by EPA. However, EPA has included additional details on the discounting methodology in

Appendix A.4 of the final report to highlight that the discounting approach used also accounts for consumption risk as the commenter describes.

EPA appreciates the concern about interpreting the simulation-specific values,  $SCC_s$ , and correctly characterizing the distributions shown in the report. While EPA believes that characterizing the uncertainty surrounding the SC-GHG estimates is important, the title of Figure 3.1.1 and other figures in the appendix have been changed to “Distribution of the Discounted Marginal Damages” to clarify the information being presented is distinct from a distribution of SC-GHG estimates.

In calibrating the Ramsey parameters, EPA followed the peer-reviewed work of Newell et al. (2022)<sup>116</sup>, which uses the empirical work of Bauer and Rudebusch (2023)<sup>117</sup> and Müller, Stock, and Watson (2022)<sup>118</sup> in a single framework to calibrate the parameters. In their peer-reviewed work, Rennert et al. (2022a<sup>119</sup>, 2022b<sup>120</sup>) apply these calibrated parameters to the Ramsey formula for estimating the SC-GHG using the RFF-SPs and EPA applies a consistent approach in its modeling. As noted in EPA’s SC-GHG Report, the Ramsey formula, while widely used in the economics literature and based on economic theory, is an approximation to highly complex real-world processes. As such, using empirical data to calibrate the parameters of the model can result in some approximation error as is always the case with structural economic models that seek to distill the economic connections that are of first order importance but are unable to represent every detail of the economy. EPA will continue to follow the literature on discounting and best practices for calibrating approaches to empirical data.

Comment: Commenters (2398-Policy Integrity NYU, 2183-M. Freeman et al., 2208-CCES et al) provide suggestions for addressing new research on the climate beta.

Commenter (2398-Policy Integrity NYU) discusses the implications for the omission of climate damage categories and tipping points for EPA’s discounting methodology. Specifically, the commenter argues that these omissions greatly decrease the per-capita consumption variance and therefore, produces an overly strong correlation between global GDP and climate damages. The commenter argues that this leads to a climate beta that is too high. In addition, the commenter argues that if climate damages impact economic growth, then this would result in lower the climate beta. The commenter urges EPA to give a more thorough discussion of the climate beta and illustrate that the insurance premium can be split into two terms (insurance and scale effects)

following Lemoine (2021).<sup>121</sup> The commenter argues that this may reduce the debate over the climate beta because these two independent effects are commonly confounded.

The commenter (2398-Policy Integrity NYU) also suggests that EPA conduct a sensitivity analysis over the climate beta and set the central value equal to zero but notes that this may be challenging given EPA's modular approach. The commenter notes considerable uncertainties around the value of the climate beta and argues that the climate beta is considerably lower than one. The commenter cites research<sup>122</sup> which shows that experts generally prefer lower discount rates for climate projects potentially because climate projects are viewed as less risky than infrastructure investments. The commenter further argues that it is a "strong possibility that EPA's implicit estimate of the climate beta exceeds the actual climate beta in the real world". The commenter argues that the continued use of the consumption-based Capital Asset Pricing Model (CCAPM) ensures that the impact of this potential bias is limited. Lastly, the commenter provides a mathematical argument that the value of the climate beta can theoretically be either positive or negative.

Commenter (2183-M. Freeman et al.) argues that implied climate beta assumed by EPA's model is close to one due to the fact that per-capita consumption growth is broadly proportional to the monetized flow of damages. The commenter recommends setting the beta value to zero, on the basis that empirical evidence is only beginning to emerge and that the value of one used by EPA is at the high end of the range in recent academic findings. The commenter cites recent research<sup>123,124</sup> that offer support for a default assumption that project risk is independent of future economic growth. The commenter notes that correlation structure between economic growth and damages in EPA's report is typical of other Integrated Assessment Models and questions whether this correlation structure reflects the best available empirical evidence. The commenter argues that revising the estimate of the climate beta will have an unclear effect on the SCC. Finally, the commenter reiterates that "the strongest argument for climate change mitigation may rely on the prevention of tipping points or other climate-related catastrophes" and that "such benefits are not captured by the near linear relationship between damages and growth in the EPA report, or where risk premia are calculated using covariances in equation 2.5.2".

Commenter (2208-CCES et al.) explains that omitted impacts reduce consumption growth variability and strengthen the correlation between global GDP and climate damages (increasing the "climate beta"). The commenter also states that including environmental and social tipping points decreases the climate beta by introducing non-linearities into the climate-economic system. A suggested solution is to consider a lower discount rate range.

Response A-5-5: In EPA's modeling, the climate beta is not a choice variable that analysts specify exogenously. EPA's modular approach, based on the recommendations of the National

Academies, uses the state-of-the-science information on socioeconomic, climate change, damages, discounting, and uncertainty, where feasible, to estimate the SC-GHG in a consistent manner. This process ensures that any risk adjustment to the SC-GHG estimates is internally consistent and based on the scientific information available. Therefore, there is no need to exogenously specify a climate beta value using estimates from the literature or other heuristic arguments as recommended by some public commenters.

For transparency and clarity in the assumptions used in the SC-GHG estimation, EPA updated the Report with a discussion of the climate beta in Appendix A.4 and the reported the climate beta implied by the discounting approach. EPA agrees that the incorporation of risk adjustments in estimates of the SC-GHG is an important area for new research, acknowledges the arguments made by the commenters that a climate beta of one is on the high end of values noted in some recent studies, and will follow this research closely in further iterations of the SC-GHG. EPA appreciates the citations from the commenters which highlight the discussion in the literature over the sign and magnitude of the climate beta. The limitations highlighted in Appendix A.4 present key gaps in the current literature and opportunities for further study. EPA will continue to follow the scientific literature on tipping points, omitted damages, and adaptation and plans to incorporate advances into future SC-GHG estimates, as feasible and appropriate. As such advances allow for more effects to be directly incorporated into the SC-GHG modeling, the endogenous risk adjustments will reflect the impact of those updates on the variance of consumption and the value of the climate beta implicit in the estimates.

Comment: Commenters (2253-OCT, 2311-Heal et al., 2183-M. Freeman et al.) question EPA's focus on a descriptive approach to discounting. An opposing view is presented by commenter (2339-INGAA), who argues that EPA's discounting approach relies on normative and unscientific judgements.

Commenter (2253-OCT) argues that "descriptive methodologies incorporate faulty assumptions that are unlikely to hold in a climate-ravaged world as well as implicit value judgments that indefensibly ignore fundamental considerations of intergenerational equity and children's fundamental rights."

Commenter (2311-Heal et al.) suggests that the selection of discount rates is a "social choice problem" and argues that an ideal approach to discounting is unlikely to exist due to irreconcilable differences in views. The commenter proposes addressing the ethical questions associated with discounting directly rather than relying on a simplistic empirical analysis. The commenter argues that EPA's purely descriptive approach is needlessly limited and notes that much of the considerations for intergenerational discounting are normative in nature.

Commenter (2183-M. Freeman et al.) argues that the positive approach to discounting in the report may leave the methods open to scrutiny and suggest that the intergenerational discount rate should balance positive and normative considerations. The commenter also states that the "EPA report would benefit from giving reassurance that the ways in which the risk premium is implicitly determined through the dynamic discounting approach is consistent with its broader positive philosophy of discounting." The commenter discusses the equity premium puzzle and notes that financial market risk premia would be underestimated when using the CCAPM. The

commenter notes “if the climate beta is indeed almost one, then CCAPM estimates are much lower than the values that would be derived from a purely positive estimate of the climate risk premium.” Therefore, the commenter argues that the “theoretical framework for estimating the risk premium, together with future proposed extensions, are more naturally interpreted as being normative.” Commenter (2183-M. Freeman et al.) shares their subjective opinion that using a high market-inferred risk premium in the intergenerational context is inappropriate but notes that they take a more neutral stance of positive vs. normative considerations. The commenter further notes that the Ramsey formula was developed under a normative framework, which does not change even if the parameters are calibrated using positive approaches. The commenter argues that the EPA Report would benefit from providing reassurance regarding the internal theoretical consistency of estimating positive parameters from Equation 5 in Newell, Pizer, Prest (2022).<sup>125</sup>

A divergent view is presented by commenter (2339-INGAA). The commenter argues that EPA’s discounting approach is unscientific and relies on normative assumptions. The commenter cites Fleurbaey et al. (2019)<sup>126</sup>, which argues that there are ethical decisions regarding the use of a utilitarian social welfare function and the conclusion that societal values can be determined by individual behavior, and the National Academies Report<sup>127</sup>, which states that the Ramsey parameters are not observable and require an ethical judgement.

Response A-5-6: Regardless of the theoretical approach used to derive the discount rate(s), there remain inherent conceptual and practical difficulties of adequately capturing consumption trade-offs over many decades or even centuries. While EPA relies on the descriptive approach for selecting specific discount rates based on observed preferences for temporal tradeoffs of consumption, the EPA is aware of the normative dimensions of both the debate over discounting in the intergenerational context and the consequences of selecting one discount rate over another. However, the EPA’s analysis relies primarily on the descriptive approach to inform the choice of a discount rate for SC-GHG estimation, consistent with the rationale outlined in IWG TSDs (e.g., IWG 2010<sup>128</sup>, 2021<sup>129</sup>) and EPA’s economic analysis guidelines (EPA 2010)<sup>130</sup>. With a recognition of its limitations, the IWG found this approach to be the most defensible and transparent given its consistency with both the standard contemporary theoretical foundations of benefit-cost analysis and the approach recommended by OMB’s existing guidance. In implementing this approach, EPA calibrates the  $\rho$  and  $\eta$  parameters of the Ramsey formula

following the Newell et al. (2022) calibration approach, as applied in Rennert et al. (2022a, 2022b). Under this approach, the parameters are calibrated such that (1) the decline in the certainty-equivalent discount rate path matches the latest empirical evidence on interest rate uncertainty estimated by Bauer and Rudebusch (2020<sup>131</sup>, 2023<sup>132</sup>) and (2) the average of the certainty-equivalent discount rate over the first decade matches a near-term consumption rate of interest based on multiple lines of evidence as to the near-term consumptions interest rate. This approach is consistent with the National Academies (2017) recommendation that the parameters in the Ramsey formula be chosen in a manner “consistent with theory and evidence and that produce certainty-equivalent discount rates consistent, over the next several decades, with consumption rates of interest.” The calibrated Ramsey parameters are also within the ranges of values of  $\rho$  and  $\eta$  used in the peer-reviewed literature, including many studies that state their parameter choices are based on prescriptive reasoning.

EPA appreciates the comments regarding the equity premium puzzle and the limitations of the CCAPM framework. However, the approach used within the CCAPM framework is conducted in a positive fashion. As commenter (2183-M. Freeman et al.) noted, the risk premium is implicitly determined through the dynamic discounting approach, and this approach is consistent with standard discounting approaches (Cochrane 2005<sup>133</sup> Asset Pricing).

Comment: Commenter (2239-A. Fraas et al.) presents concerns over EPA’s use of a declining certainty-equivalent discount rate and argues that this generates intertemporal inconsistencies.

Commenter (2239-A. Fraas et al.) argues that “it is unwise to completely abandon constant discounting and rely entirely on benefit estimates that assume a declining rate.” The commenter notes that while the use of declining discount rates is accepted, some use of constant discounting could avoid temporal inconsistencies. The commenter states that within-generation and intergenerational inconsistencies have the potential to arise when a declining discount rate is employed over extended periods of time and references Viscusi (2022)<sup>134</sup>. The commenter argues that this is because such a rate reflects the present generation’s perspective, potentially misrepresenting the preferences and priorities of future generations. The commenter argues that future generations will likely live longer, and a declining discount rate would place a greater weight on benefits in the latter part of the generation. The commenter highlights that “the future generations may prefer a different trajectory of benefits that is more front-loaded within that generation” and cautions against underestimating benefits early in life for future generations. The commenter refers to similar reasoning presented by Birdsall and Steer (1993)<sup>135</sup> and Wildavsky (1988).<sup>136</sup> The commenter states that EPA should not only rely on benefit estimates that assume a declining rate, as some analyses should maintain a constant discount rate. The commenter notes

that EPA does not discuss the implications of increases in longevity for the applicability of the Ramsey rule.

Response A-5-7: The use of the Ramsey formula provides internal consistency within the modeling between the socio-economic scenarios and the discount rate. With uncertainty in the per capita consumption growth rate, the Ramsey discount rate becomes a dynamic parameter within the modeling framework that reflects how uncertainty about future conditions has implications for how future impacts are valued. Gollier (2014)<sup>137</sup> showed that when there is uncertainty in future consumption growth, the distribution of discount rates defined by the Ramsey formula will have a certainty-equivalent risk-free discount rate path that declines over time, under standard assumptions about individual preferences. As noted by the commenter, use of a dynamic discount based on the Ramsey formula is consistent with accepted practice in the economics literature. The declining certainty-equivalent discount rate implied by the Ramsey formula is also consistent with the empirical literature on discount rates under uncertainty (e.g., Newell and Pizer 2003<sup>138</sup>, Bauer and Rudebusch 2023<sup>139</sup>). Therefore, use of a constant discount rate would be inconsistent with the empirical literature on discount rates under uncertainty and would fail to provide internal consistency within the modeling between socio-economic scenarios and the discount rate as recommended by the National Academies and has been applied extensive in the economics literature estimating the SC-GHG.

EPA recognizes that in some implementations a declining discount rate could imply an intertemporal inconsistency in the preferences of society if consumption growth were modeled deterministically or if a declining discount rate schedule were specified exogenously. However, EPA models consumption growth stochastically, and the declining certainty equivalent discount rate used in the EPA Report is generated endogenously using the Ramsey formula. In the Monte Carlo analysis, scenarios with high consumption growth are discounted at a higher rate than scenarios with lower consumption growth. Because of the non-linearity of the discount factor, the lower discount rate will have a greater impact on the certainty equivalent rate as time increases, leading to the declining certainty equivalent rate. As detailed in the report, this is consistent with the empirical literature and best practices for estimating the SC-GHG. Furthermore, this approach does not lead to temporal inconsistencies in preferences because the calibrated Ramsey parameters ( $\eta$  and  $\rho$ ), which reflect social preferences, are held constant. While EPA acknowledges that transferring these calibrated estimates into the future may result in an approximation error with respect to the preferences of future generations, the Agency is unaware of any peer-reviewed scientific studies that attempt to forecast changes in the Ramsey parameters due to changes in life expectancy.

Comment: Two commenters (2239-A. Fraas et al., 2344-IER) question the applicability of the Ramsey rule. Commenter (2239-A. Fraas et al.) raises concerns about the applicability of the Ramsey rule because health improvements, particularly improvements in longevity, may be as

---

<sup>138</sup> Newell, R.G. and Pizer, W.A., 2003. Discounting the distant future: how much do uncertain rates increase valuations? *Journal of environmental economics and management*, 46(1), pp.52-71.

<sup>139</sup> Bauer, M.D. and Rudebusch, G.D., 2023. The Rising Cost of Climate Change: Evidence from the Bond Market. *The Review of Economics and Statistics*, 105(5), pp.1255-1270.

valuable as consumption gains and cites several research papers<sup>140,141</sup> to support this. The commenter also argues that “[t]he rapidly changing composition of consumption over time itself raises utility, a fact ignored in the Ramsey formulation”. The commenter argues that the Ramsey formula is based on an outdated view of economic growth and cites research on human capital generation.<sup>142,143</sup> The commenter argues that EPA needs to address the broader question of how endogenous growth, improvements in health and longevity, and increasing consumption efficiency over time affect the choice of the social discount rate for climate control policy before committing to the use of the Ramsey formula.

Commenter (2344-IER) expresses that the Ramsey equation is a “logically flawed approach” because several inputs into the Ramsey equation are not observable, including the pure rate of time preference and the income elasticity of utility, and aggregating these values presents serious conceptional and practical hurdles. The commenter argues that the use of Ramsey-derived rates allows EPA to choose parameter values that do not fit the investment and savings levels observed in the real world. The commenter questions the use of the Ramsey formula since return to capital are observable and show higher rates than rates produced by Ramsey calculations, which the commenter suggests may mean the Ramsey-derived rates are not optimal. The commenter states that even if EPA’s calculation is mathematically optimal, it does not reflect real world economic scenarios. The commenter states “[u]nless this Ramsey optimality holds across all investments, it is not optimal to use this calculated rate for discounting.”

Commenter (2428-API) argues that EPA’s divergence from a constant 3 percent consumption rate of discounting is inconsistent with current OMB guidance and that EPA should refrain from alternate approaches until the 2023 proposed revisions of Circular A-4 are finalized.

Response A-5-8: The use of the Ramsey formula provides internal consistency within the modeling between the socio-economic scenarios and the discount rate. As noted in report, the Ramsey formula is widely used in the peer reviewed literature and is consistent with the National Academies’ (2017) recommendations on discounting, where they highlighted its internal consistency as an important feature. It is an important improvement over the use of a constant discount rate and incorporates links between the modules used for this estimate. However, as noted in the Final Report, the Ramsey formula, while widely used in the economics literature, is an approximation to highly complex real-world processes. EPA understands that non-market factors such as health and longevity may evolve over time in ways that could affect preferences for intertemporal tradeoffs in ways that are not currently included in the modeling. The EPA will continue to follow the literature on discounting and alternative specification that can incorporate additional characteristics, as feasible and appropriate.

EPA further notes that, while this RTC was being drafted, OMB finalized its updates to Circular A-4. The updated Circular A-4 (2023) guidelines clarify that agencies may develop economic

models in which the evolution of the discount rates is endogenous, which is precisely the approach EPA has developed here.

Comment: Commenters (2398-Policy Integrity NYU, 2339- A. Fraas et al., 2428-API) question the Treasury security rates used to calibrate the near-term discount rates. Commenter (2398-Policy Integrity NYU) contends that an analysis of recent Treasury returns supports a lower near-term discount rate than is used in EPA’s Draft Report. Conversely, commenter (2339-A. Fraas et al.) argues that EPA’s calibration of discount rates to Treasury notes is likely to bias downward the proposed consumption discount rate. Commenter (2428-API) questions whether there is a structural break in Treasury rates, and commenter (2361-EPRI) argues that analyzing short-run investments over recent decades is impractical in the context of climate change.

Commenter (2398-Policy Integrity NYU) suggests that EPA’s Draft Update discount rate range is too high and offers evidence suggesting an improved range of 0.5% to 2.5% with a central rate of 1.5%. The commenter argues that the academic literature is in support of EPA’s claim of a structural break in Treasury yields occurring in the early 1990s. The commenter notes that EPA’s focus on the 30-year period after this structural break supports a discount rate ranging from 1.5 to 2 percent, with an average rate of 1.7 percent. The commenter further states that recent research (Bauer & Rudebusch, 2023)<sup>144</sup> suggests a continued downward trend in Treasury yields and a real interest rate of 1 percent or less in the 2010s. Given this research, and EPA’s claim of prioritizing the 30-year time period, the commenter argues that is unclear why EPA presents the 1.5 rate on equal footing as the 2.5 rate. The commenter states that even a conservative interpretation of Bauer & Rudebusch (2023)<sup>145</sup> supports a discount rate range of 0.5 to 2.5 percent with a central rate between 1.0 and 1.5 percent.

Commenter (2339-A. Fraas et al.) argues that given the long forecasting time horizon of EPA’s analysis, interest rate behavior in recent decades is not necessarily more relevant than interest rates in earlier periods. The commenter notes that “there is no discussion of the effect of the remarkable monetary policy pursued by the Federal Reserve over the last several decades, which have kept interest rates on Treasuries artificially low, or that fiscal policy is now becoming more expansionary.” The commenter further argues that only a small percentage of consumers own Treasury securities, leading to a segmentation of the capital market and a range of markets for consumption smoothing.<sup>146</sup> The commenter notes that EPA acknowledges this on page 59 of the Draft Report. The commenter further notes that several studies<sup>147, 148, 149</sup> document higher marginal rates of time preference. The commenter discusses the energy efficiency paradox and

<sup>149</sup> Warner, J.T. and Pleeter, S., 2001. The personal discount rate: Evidence from military downsizing programs. *American Economic Review*, 91(1), pp.33-53.

argues that the private market does not pursue energy efficiency options that EPA's benefit-costs analysis find optimal potentially due to higher discount rates of the population and cites Gillingham and Palmer (2014)<sup>150</sup> and Helfand and Dorsey-Palmateer (2015).<sup>151</sup>

Commenter (2428-API) urges EPA to provide more justification for the "claim that long-term structural breaks in the interest rate imply lower interest rates in the future" and cites a working paper<sup>152</sup> that disputes the notion of structural breaks. The commenter also asks that EPA explain how near-term interest rates from the last 30 years can fully inform the choice of an appropriate discount rate for the SC-GHG, given the projection horizon of 300 years.

Commenter (2361-EPRI) states that "[c]omparing to 10-year Treasury or other relatively short run observed investment rates over the last few decades, or even fifty years, is impractical given the century long GHG investments being modeled and multi-century SC-GHG modeling horizon." The commenter advocates for benchmarking to investments that are longer than 10 years which have a centuries-long time series. The commenter notes that 3% represents the long-run real interest rates for social security from 1870 to 2005 and argues that this is the appropriate benchmark given the long-time horizon and that it reflects the long-run trade-offs in consumption.

Response A-5-9: EPA recognizes that a range of empirical evidence suggestive of a downward secular trend in interest rates and therefore, does place a greater focus on the range of mean interest rate estimates from 1991-2020. However, the range of near-term discount rates used in the report are based on multiple lines of evidence, including historical real rates of returns, empirical studies of equilibrium real interest rates, future projections of real interest rates, empirical evidence of long-run discount rates implied by real estate markets, and surveys of economists and technical experts. Looking across this wide body of evidence, EPA finds broad support for a near-term discount rate in the range of 1.5% to 2.5% with a central focus on 2.0%.

As commenters note, one line of evidence considered by EPA includes the average real rate of return on 10-year Treasury Securities. EPA finds support in economics literature for using returns on 10-year Treasury Securities as a risk-free measure of intertemporal tradeoffs appropriate for calibrating discount rates (e.g., Newell and Pizer 2003<sup>153</sup>, Bauer and Rudebusch 2023<sup>154</sup>). In addition, EPA notes that the average real rate of return on 10-year Treasury securities has formed the basis for OMB's Circular A-4 (2003) guidance on consumption

discount rates.<sup>155</sup> One specific line of evidence considered by EPA includes the average rate of return over the past 30 years. While highly informative EPA did not select the near-term discount rate based solely on this one line of evidence. In addition, EPA considered the average real rate of return on 10-year Treasury Securities over a longer period going back to the early 1970s in addition to empirical literature that considered equilibrium real interest rates on government securities. Using a time series of 10-Year Treasury securities, Bauer and Rudebusch (2023) estimate a current equilibrium real interest rates of 1.3, 1.9, and 2.4 percent, the lower estimate from the author’s univariate unobserved-components (UC) model. In their online appendix, Bauer and Rudebusch (2023) also consider a longer 220-year time series of real return to government securities and find a similar range of equilibrium real interest rates (1.5, 2.3, and 3.0 percent). Furthermore, the interest rate on the 30-year Treasury bond, which is also informative of long-run social time preferences and is likely less influenced by short-run monetary policy interest rate fluctuations, is on average only 0.5 to 0.7 percentage points higher than the interest rate on 10-year bond. But across these lines of evidence there is a consistent finding of a downward secular trend in real interests over time. In addition, EPA considered long-term forecasts of future real interest rates conducted by the U.S. Congressional Budget Office and the Social Security Administration, with the latter going out to 2100. EPA also considered long-run discount rates implied by real estate markets. As discussed in the Final Report, Giglio et al. (2015)<sup>156</sup> find that the discount rate for 100-year real estate claims is 2.6%. The authors argue that since real estate is a risky asset, this value provides an upper bound for the long-run risk-free rate of interest (Giglio et al. 2015, Giglio et al. 2021<sup>157</sup>). Finally, EPA also considered recent surveys of economists and technical experts on the appropriate discount rate, which EPA found to be consistent with the empirical evidence.

Comment: Commenters (2428-API, 2361-EPRI, 2239-A. Fraas et al.) question the RFF-SP economic growth projections and the implications for EPA’s discounting module.

Commenter (2428-API) urges EPA to state and explain how it calculates the near-term real growth rate of consumption per capita ( $g_t$ ). The commenter notes that “to recover the Ramsey parameters, a near-term consumption per capita growth rate of around 1.45 percent would seemingly be needed.” However, the commenter remarks that EPA notes that the average global per capita growth rates have been closer to 2% in recent decades. Additionally, in discussing the calibration of the Ramsey parameters, the commenter requests that EPA clarify how it estimates the near-term consumption growth rate “net of baseline climate change damages” beyond what is offered in Appendix 3 of EPA’s Draft Report.

---

<sup>155</sup> OMB’s Circular A-4 (2023) guidance on consumption discount rates likewise was based on the average real rate of return on 10-year Treasury marketable securities (OMB 2023). OMB noted that such securities are widely held through, for example, pension fund investments, and reflect the market price at which individuals can make nearly risk-free loans. OMB Circular No. A-4: Explanation and Response to Public Input (2023), <https://www.whitehouse.gov/wp-content/uploads/2023/11/CircularA-4Explanation.pdf>.

<sup>156</sup> Giglio, S., Maggiori, M. and Stroebel, J., 2015. Very long-run discount rates. *The Quarterly Journal of Economics*, 130(1), pp.1-53.

<sup>157</sup> Giglio, S., Maggiori, M., Rao, K., Stroebel, J. and Weber, A., 2021. Climate change and long-run discount rates: Evidence from real estate. *The Review of Financial Studies*, 34(8), pp.3527-3571.

Commenter (2361-EPRI) recommends that EPA remove the feature netting out damages from economic growth. The commenter argues that “[i]f damages are changing the projected economic growth rates, then the resulting discount rate is no longer consistent with assumed growth and the required equilibrium condition that insures that deferred consumption is sufficient for projected growth no longer holds.” The commenter argues that EPA’s approach is inconsistent with the discussion on page 49 of the EPA Draft Report in which EPA explains why damages specifications that include the effect of climate damages on economic growth were not chosen. The commenter further argues that this approach is inconsistent with the use of consumption near-term target interest rates. The commenter argues for an assumed economic growth rate of 1.9% to 2% for a global calibration.

The commenter (2361-EPRI) questions the assumption that the savings rate is fixed (and thus GDP and consumption growth are identical) and presents historical data that illustrates that world and regional savings rates change over time and vary by region. The commenter notes that EPA’s fixed savings rate assumption should be revised, as it has significant implications for EPA’s discounting growth rates. The commenter notes significant variation in regional historical growth rates and argues that EPA should use regional discounting for consistency with projected regional growth rates. Commenter (2428-API) similarly argues that EPA should explain the rationale for using the same discount rate for all regions and notes that the economic growth rate varies across regions. The commenter states that “EPA should discuss how the SC-GHG estimates would change if the savings rate varied at the national or regional given historical trends.”

Commenter (2239-A. Fraas et al.) remarks that the assumptions underlying the calibration EPA’s social discount rates are not well justified and that the growth process used in the Ramsey formula are unclear in the EPA Report. The commenter notes an important category of uncertainty – the possibility of major economic disruptions, such as economic depressions, wars, financial crises, and pandemics that are unrelated to climate change. The commenter cites previous research<sup>158,159,160</sup> on this topic as well as a paper<sup>161</sup> that suggests adding a risk premium to account for this category of uncertainty. As an alternative, the commenter argues that it is possible to model these events explicitly by incorporating a perturbation (a sharp decline) in the growth rate following by a higher-than-average growth rate which returns the economy back to the average rate of growth. The commenter states that the effect of this perturbation would carry through the discount rate and damage estimates and should reflect the past and expected future frequencies of catastrophic economic disruptions. The commenter states that one of the reasons why they believe EPA’s Draft Report understates the consumption discount rate is that “uncertainties about the growth rate and the possibility of catastrophic damages suggest

additional risk premia that are not reflected in the statistical process that generates the growth forecasts.”

Response A-5-10: EPA calibrates the Ramsey parameters following the approach detailed by Newell, Pizer, and Prest (2022).<sup>162</sup> In this approach, the near-term certainty equivalent discount rate, that is the average over the first 10 years, is calibrated to be consistent with the near-term target discount rate. Because the calculation of the certainty equivalent discount rate is a non-linear operation, this is not the same as using the average near-term growth rate to calibrate the Ramsey parameters. Therefore, one cannot back out the exact average near-term growth rate in the RFF-SPs using the near-term target discount rate and the calibrated Ramsey parameters as suggested by one commenter.

The near-term per-capita economic growth rate used in the calibration procedure is from the RFF-SPs as described in detail in the draft and final report. There is heterogeneity in the growth rates over time as shown in Figure 2.1.2. In the Final Report, EPA has clarified that the average economic growth per capita in the set of RFF-SPs used in the modeling ranges is around 1.4% in the initial years.

As stated in the Report, when using the Ramsey formula to estimate the SC-GHG, the per capita consumption growth rate,  $g_t$  is calculated net of baseline climate change damages. More specifically, in a given run, the economic growth rate per capita used in the Ramsey formula for the purposes of discounting is calculated by subtracting baseline climate damages per capita, as estimated by the damage modules described in Section 2.3, from the economic output per capita in the RFF-SPs and taking the growth rate. Regarding the netting of climate damages from economic growth when applying the Ramsey formula, Kelleher and Wagner (2019)<sup>163</sup> explain that the correct approach is to subtract the baseline climate damages from the economic growth rate, as these damages drive a wedge between output and consumption growth for which one should account.

EPA recognizes that savings rates change over time and vary by region but has used a constant savings rate as an approximation in applying the Ramsey formula, consistent with the literature. EPA acknowledges the commenters recommendation with regard to regional implementation of the Ramsey formula for discounting. The National Academies (2017) noted that damages could be aggregated across regions and discounted globally or discounted regionally and then aggregated, but using region-specific discount rates would requires Ramsey parameters calibrated for each region. EPA is not aware of peer-reviewed economic studies that have developed an approach to calibrating the Ramsey parameters at a country or region level using empirical evidence consistent with the National Academies’ (2017) recommendations. The Agency will continue to follow the scientific literature on probabilistic socioeconomic scenarios and potential regional calibration of Ramsey parameters.

---

<sup>162</sup> Newell, R.G., Pizer, W.A. and Prest, B.C., 2022. A discounting rule for the social cost of carbon. *Journal of the Association of Environmental and Resource Economists*, 9(5), pp.1017-1046.

<sup>163</sup> Paul Kelleher, J. and Wagner, G., 2019. Ramsey discounting calls for subtracting climate damages from economic growth rates. *Applied Economics Letters*, 26(1), pp.79-82.

EPA understands that the probabilistic RFF-SPs may not incorporate all sources of economic uncertainty going forward; however, they will be representative of historical sources economic variation. The economic projections in the report are based on long-run growth dynamics from a model fit to historic data from 1900 – 2017 (Müller Stock, and Watson, 2022).<sup>164</sup> The period included major economic disruptions such as economic depressions, wars, financial crises, and pandemics. The economic projections represent estimates of long-run growth and not high frequency events such as business cycles or other short-lived impacts. The model allows for persistent excursions for the common global growth factor with reversion to the mean over the very long-run. These excursions are carried through the discount rate and damage module. The socioeconomic projections include many draws with negative growth rates in some years, which implicitly includes scenarios of major economic disruptions (see Figure 2.1.2 in the report).

Comment: Commenter (2428-API) questions whether EPA’s discount rates and parameters conform to surveys of experts cited in the Draft Report. Commenter (2183-M. Freeman et al.) suggests an alternative approach for calibrating the Ramsey parameters. Commenter (2361-EPRI) provides suggestions for Ramsey parameter calibration and additional module documentation.

Commenter (2428-API) notes that the calibrated Ramsey parameter,  $\rho$ , is lower than those found in Drupp et al. (2018)<sup>165</sup>. The commenter also references a passage from the EPA Draft Report which notes that small values of  $\rho$  could be associated with unreasonable optimal savings rates particularly with  $\eta$  around one. The commenter argues that such results call into question the choice of near-term discount rates and suggests that EPA should select the Ramey parameters and allow the near-term discount rates to be determined by the Ramsey formula.

Commenter (2183-M. Freeman et al.) suggests that the calibration of  $\rho$  and  $\eta$  are not reflective of the actual market rates for at least a decade prior to when the report was written. The commenter suggests a potential alternative: “fixing the short-end of the term structure to the market rate at the time the report was written, the long rate to the Bauer and Rudebusch (2023)<sup>166</sup> [estimates], and then applying a term structure for intermediate dates.”

Commenter (2361-EPRI) approves of EPA adopting a dynamic discounting approach following the NASEM recommendations but questions the calibration of the near-term discount rates. The commenter argues that the  $\rho$  parameter should be positive and that the  $\eta$  parameter should be greater than one. Citing Stern (2006)<sup>167</sup> and Nordhaus (2006)<sup>168</sup>, the commenter argues that  $\rho$  values of 0.1% have been controversial as this suggests that consumers are indifferent between current and future consumption and states that this critique would certainly apply to EPA’s

---

<sup>168</sup> Nordhaus, WD, 2006. “The Stern Review on the Economics of Climate Change,” November, p.6.

choice of 0.01% for  $\rho$ . The commenter further argues that an  $\eta$  less than 1.5 implies a very large savings rate of 67% and cites Arrow (1999).<sup>169</sup>

Commenter (2361-EPRI) expresses that the discounting module's documentation requires explicitly stated calibration and calculation details of every aspect of the discounting approach instead of relying on the literature cited for essential details. Specifically, the commenter notes that "details are needed on the specific lines of evidence regarding observed rates, use of the probabilistic socioeconomic scenarios in the calibration, and assumptions and constraints during calibration."

Response A-5-11: EPA calibrates the parameters of the Ramsey formula following the approach of Newell et al. (2022), as applied in Rennert et al. (2022a, 2022b). Under this approach, the parameters are calibrated such that (1) the decline in the certainty-equivalent discount rate path matches the latest empirical evidence on interest rate uncertainty estimated by Bauer and Rudebusch (2023) and (2) the average of the certainty-equivalent discount rate over the first decade matches a near-term consumption rate of interest based on multiple lines of evidence as to the near-term consumptions interest rate. This approach is consistent with the National Academies (2017) recommendation that the parameters in the Ramsey formula be chosen in a manner "consistent with theory and evidence and that produce certainty-equivalent discount rates consistent, over the next several decades, with consumption rates of interest." This approach provides an empirical basis for calibrating the Ramsey parameters and results in values that are within the ranges used in the peer-reviewed literature (see Table 6-1 in NASEM 2017<sup>170</sup>). The calibrated values are also consistent with those recommended by recent surveys. The values for  $\eta$  and  $\rho$  in Table 2.4.2 of the report are consistent with the range of central tendency estimates reported in Drupp et al. (2018).<sup>171</sup> EPA finds this data driven approach to calibrating the Ramsey parameters more appropriate than selecting values of the Ramsey parameters that potentially inconsistent with observed interest rates.

As highlighted by commenter (2183-M. Freeman et al.), the average real rate of return on the 10-year Treasury bond is sensitive to the time period analyzed and the measures of inflation expectations used. This is, in part, why EPA considered multiple lines of evidence when calibrating the near-term discount rate. It is also why EPA finds that fixing the short-end of the term structure to a single measure of a market rate at the time the estimates are developed will introduce additional uncertainty and is inappropriate.

EPA notes that the report, appendices, citations contained therein, and the online repository of replication source code provide specific details on the discounting approach including, calibration, lines of evidence regarding observed rates, and use of the probabilistic socioeconomic scenarios in the calibration.

<sup>171</sup> Drupp, M.A., Freeman, M.C., Groom, B. and Nesje, F., 2018. Discounting disentangled. *American Economic Journal: Economic Policy*, 10(4), pp.109-34.

Comment: Commenters (2413-CEI/HF, 2339-INGAA, 2361-EPRI, 2445- J. Davis, 2428-API, 2344-IER, 2239-A. Fraas) raise concerns regarding the near-term discount rates used in EPA’s Draft Report and argue that the discount rate range should be higher. Commenters (2239- A. Fraas et al., 2361-EPRI) question whether regulatory compliance will also displace capital investment. Commenters (2428-API, 2344-IER, 2339-INGAA) state that EPA’s approach is inconsistent with OMB Circular A-4 (2003).

Commenter (2361-EPRI) states that near-term target rates should be 3-5%. The commenter argues that the 3% rate is consistent with very long-run consumption tradeoffs and presents an analysis of government real interest rates for social security from Girola (2005)<sup>172</sup>. The commenter notes that the 5% value is consistent with long-run private investment trade-offs and cites several research papers<sup>173,174,175</sup>. The commenter notes that consumption trade-off “do not appear to be what is modeled in the damage calculations”, instead, “the damage categories appear to be computing changes in private investment, aggregate consumption, or trade-offs with utility”, which the commenter argues, appear to be consistent with trade-offs at the macroeconomic level.

Commenter (2239-A. Fraas) argues that the discount rate range used in the draft guideline understates the consumption discount rate. The commenter notes the small response rate in the surveys of economic experts cited by EPA and also notes that the means of discount rate responses for certain groups of experts are above EPA’s upper end near-term target rate. The commenter further argues that the low consumer discount rates are not appropriate for evaluating regulations that displace corporate investment. The commenter states that it seems likely that EPA climate regulations will impact both consumption and investment. The commenter argues that a key rationale for using the opportunity cost of capital in regulatory analysis is that it ensures that there are no other uses of investment capital that could result in a Pareto improvement. The commenter notes that this logic applies both intra- and inter-generationally and cites several research papers<sup>176,177,178,179,180,181</sup>.

<sup>181</sup> Weyant, J.P., 2008. A critique of the Stern Review's mitigation cost analyses and integrated assessment. *Review of Environmental Economics and Policy*, 2(1), pp.77-93.

The commenter (2239-A. Fraas) notes that Li and Pizer (2021)<sup>182</sup> estimate the shadow price of capital and find that it is only in the long run that the social discount rate declines to the consumption rate. The commenter emphasizes that “the target discount rates used to start off the temporal discount rate path should not be based on a consumption rate, as is suggested in the EPA-ERD, when regulatory compliance displaces capital investment.” The commenter states that both the shadow price of capital approach and EPA’s approach require an estimate of the opportunity cost of capital, which the commenter argues, is remarkably stable at 7 percent.

Commenter (2445-J.K. Davis) contends that EPA should use a 7% discount rate, in line with traditionally accepted norms, to evaluate the future impacts of proposed regulations. The commenter suggests that EPA employed a 3% rate and has amplified the perceived cost of greenhouse gases without adequate scientific justification.

Commenter (2227- W. Energy Alliance) notes that EPA uses lower discount rates than have been historically used in the SC-GHG report. The commenter further notes that the choice of discount rate can be manipulated to arrive at the SC-GHG that is desired. The commenter recommends that EPA conduct a coherent analysis using a range of discount rates to address the continued controversy surrounding discount rates.

Commenter (2344-IER) argues that EPA has chosen to “willfully ignore and mischaracterize the requirements of Circular A-4” by omitting estimates using a 7 percent discount rate. The commenter emphasizes that OMB Circular A-4 (2003) allows for sensitivity analyses with lower discount rates for contexts with intergenerational impacts “in addition to calculating net benefits using discount rates of 3 and 7 percent.” The commenter states that “To have a robust set of alternative scenarios, EPA has to include a scenario with a 7 percent discount rate.”

The commenter (2344-IER) further argues that low intergenerational discount rates are inappropriate. The commenter states that discounting and discount rates “are not tools for weighing the relative value of people’s welfare in different time periods, instead, they are tools for ranking different investments” and argues that discounting at the 2 percent rate is therefore not more equitable to future generations than discounting at the 7 percent rate. The commenter argues that it is likely future generations will be much wealthier and better equipped to overcome climate change than people today. Therefore, the commenter suggests EPA inequitably reduces the welfare of disadvantaged people today in order to benefit the future wealthy.

Commenter (2339-INGAA) states that EPA acknowledges the arguments for lower discount rates but ignores the countervailing arguments for higher discount rates, which the commenter argues is one-sided. The commenter argues that “[u]sing a 7% discount rate, consistent with Circular A-4, is entirely defensible on grounds that society should evaluate costly investments in GHG emissions reductions by comparing them to the foregone returns on a same-sized investment elsewhere,” and cites Kreutzer (2016)<sup>183</sup>. The commenter further argues that “intergenerational equity considerations provide a strong rationale for using higher discount

---

<sup>182</sup> Li, Q. and Pizer, W.A., 2021. Use of the consumption discount rate for public policy over the distant future. *Journal of Environmental Economics and Management*, 107, p.102428.

<sup>183</sup> David Kreutzer, Discounting Climate Costs, Heritage Found. (June 16, 2016), <https://tinyurl.com/ys9e9ay6>.

rates, on grounds that money/utility should not be transferred to the comparatively wealthy (i.e., future generations) at the expense of the comparatively poor (i.e., the current generation).”

Commenter (2361-EPRI) questions the discount rate on the basis of potential inconsistencies between benefits and costs in analyses using the SC-GHG estimates given differences in how climate benefits are discounted compared to regulatory compliance costs.

Response A-5-12: The discount rates used in the Report on the SC-GHG are consistent with the guidelines in OMB Circular A-4 (2003).<sup>184</sup> The Circular states that “the analytically preferred method of handling temporal differences between benefits and costs is to adjust all the benefits and costs to reflect their value in equivalent units of consumption and to discount them at the rate consumers and savers would normally use in discounting future consumption benefits” (OMB 2003).<sup>185</sup> Because the damage estimates developed for use in the SC-GHG are estimated in consumption-equivalent terms, the application of this 2003 OMB guidance is to use the consumption discount rate to calculate the SC-GHG.<sup>186</sup> Circular A-4 also notes that “[s]pecial ethical considerations arise when comparing benefits and costs across generations” and advises consideration of lower but positive discount rates (OMB 2003).<sup>187</sup>

In 2010 and in every update to the social cost of greenhouse gases, the IWG maintained that the consumption rate of interest is the correct discounting concept to use when the future damages from climate change that are estimated in consumption-equivalent units. The National Academies (2017)<sup>188</sup> similarly stated that when discounting damages measured as consumption equivalents, as is the case in EPA’s damage estimates, the consumption rate of interest is the appropriate concept. Furthermore, the National Academies (2017) recommended that the IWG “choose parameters for the Ramsey formula that are consistent with theory and evidence and that produce certainty-equivalent discount rates consistent, over the next several decades, with consumption rates of interest.”

As detailed in the report, and above, EPA examined multiple lines of evidence when selecting the near-term target consumption interest rates for calibrating the Ramsey formula. EPA considered historical real rates of returns, empirical studies of equilibrium real interest rates, future projections of real interest rates, and surveys of economists and technical experts. EPA recognizes that there are strengths and limitations associated with each of these lines of evidence, which emphasizes the importance of considering multiple lines. Looking across this wide body

---

<sup>184</sup> Office of Management and Budget (OMB). 2003. *Circular A-4, Regulatory Analysis*. OMB. [https://obamawhitehouse.archives.gov/omb/circulars\\_a004\\_a-4/](https://obamawhitehouse.archives.gov/omb/circulars_a004_a-4/)

<sup>185</sup> Similarly, OMB’s Circular A-4 (2023) points out that “The analytically preferred method of handling temporal differences between benefits and costs is to adjust all the benefits and costs to reflect their value in equivalent units of consumption before discounting them” (OMB 2023).

<sup>186</sup> The same guidance is provided for in Circular A-4 (2023) (OMB 2023).

<sup>187</sup> Circular A-4 (2023) (OMB 2023) likewise recognized special ethical considerations in the intergenerational discounting context. It also recognized long-term uncertainty in the discount rate when recommending consideration of discount rates below the near-term social rate of time preference when a rule has important intergenerational benefits or costs.

<sup>188</sup> National Academies of Sciences, Engineering, and Medicine (National Academies). 2017. *Valuing Climate Damages: Updating Estimation of the Social Cost of Carbon Dioxide*. National Academies Press.

of evidence, EPA finds broad support for a near-term consumption interest rates in the range of 1.5% to 2.5% with a central focus on 2.0%.

Multiple commenters point to the potential for the cost of regulatory requirements to displace of capital investment as cause for using a higher discount rate when estimating the SC-GHG. EPA is aware that because of market distortions, such as taxes on capital income, the overall social burden is greater in the case where investment is displaced relative to consumption. As noted in OMB Circular A-4 (2003 and 2023), the theoretically correct approach to addressing this issue would be to convert the impacts of displaced capital investment into consumption equivalents using the shadow price of capital (SPC) and then discount them at the consumption interest rate. As detailed in Appendix A.2 of the report, using the social opportunity cost of capital to discount the marginal damages when estimating the SC-GHG would not be an appropriate process for incorporating additional costs associated with displace capital investment into regulatory analysis. Instead, any potential effects on capital investment should be address directly, using the SPC approach as recommended by Circular A-4 (2003).<sup>189</sup> Li and Pizer (2021)<sup>190</sup> show that when impacts are borne over a long-time horizon, as is the case with climate change, using an ad hoc upward adjustment to the discount rate to account for capital displacement can result in significant analytical errors relative to the SPC approach. Therefore, EPA uses a consumption interest rate to discount when estimating the SC-GHG, consistent with the recommendations of the National Academies (2017).

Comment: The commenters (2227- W. Energy Alliance, 2339-INGAA) request that EPA clarify to what extent the choice of lower near-term discount rates is responsible for the difference between EPA's External Review Draft SC-CO<sub>2</sub> and the previous 2021 IWG SC-CO<sub>2</sub>.

Commenter (2227-W. Energy Alliance) criticizes the comparison of new SC-CO<sub>2</sub> estimates to the existing estimates without acknowledging the difference in discount rates.

Commenter (2339-INGAA) argues that EPA should disclose how much of the difference in SC-GHG values between the Draft Report and the IWG interim estimates are attributable to a lower discount rate. The commenter argues that the EPA Report follows closely the methodology of Rennert et al. (2022b)<sup>191</sup>, and in this paper, the authors show a substantial decline in the SCC estimates due to a shift in the discount rate from 3 to 2 percent.

Response A-5-13: The increases in the SC-GHG estimates are due to the combined effect of the methodological updates described in Section 2 of the report, some of which are integrated in a way that makes a complete decomposition of the incremental contribution of each change difficult for all three damage functions used in the damage module. For example, a comparison of SC-GHG estimates based on a constant 3% discount rate with results based on a 2% near-term Ramsey discount rate reflects the combined effect of using of a lower near-term rate and the shift

---

<sup>189</sup> Circular A-4 (2023) provides additional discussion on implementing this approach.

<sup>190</sup> Li, Q. and Pizer, W.A., 2021. Use of the consumption discount rate for public policy over the distant future. *Journal of Environmental Economics and Management*, 107, p.102428.

<sup>191</sup> Rennert, K., Errickson, F., Prest, B.C., Rennels, L., Newell, R., Pizer, W., Kingdon, C., Wingenroth, J., Cooke, R., Parthum, B., Smith, D., Cromar, K., Diaz, D., Moore, F., Müller, U., Plevin, R., Raftery, A., Ševčíková, H., Sheets, H., Stock, J., Tan, T., Watson, M., Wong, T., and Anthoff, D., 2022b. Comprehensive evidence implies a higher social cost of CO<sub>2</sub>. *Nature*. 610(7933), 687-692

from a constant to a dynamic discounting approach that accounts for the possible correlations between climate change damages and economic growth through the use of probabilistic RFF-SPs growth projections. A re-estimation of the IWG recommended interim estimates using lower constant discount rates finds that the SC-CO<sub>2</sub> increases from \$51/mtCO<sub>2</sub> to \$121/mtCO<sub>2</sub> for 2020 emissions when shifting from a constant 3% to a constant 2% discount rate (NYSDEC 2022). This illustrates that the combined effect of shifting to a dynamic discount rate approach together with the socioeconomic, climate, and damage module updates accounts for the additional 60% increase in the SC-CO<sub>2</sub> to \$190/mtCO<sub>2</sub> for 2020 emissions presented in Table 4.1.1 of the report. This does not imply that each update influences the SC-GHG in the same direction. For example, ignoring the correlation between climate change damages and economic growth – as is the case with a constant discount rate approach – can lead to overestimating the SC-GHG if there is a positive correlation between economic growth and marginal damages. See, for example, Newell et al. (2022) and Rennert et al. (2022b) for an illustration of this potential. Table 1 in Rennert et al. (2022b) also provides an analysis that illustrates the incremental impact of some of the other updates in the GIVE model, relative to a recent version of the DICE model. For example, the authors find that the use of the GIVE damage functions increases the SC-CO<sub>2</sub> by 36% (from \$59/tCO<sub>2</sub> to \$80/tCO<sub>2</sub> for 2020 emissions), relative to a model run that uses the updated FaIR-based climate modelling, the RFF-SP socioeconomic module, and the Ramsey discounting approach reflecting a 3% near-term discount rate but retains the DICE-2016R damage function. In the case of methane, the IWG interim SC-CH<sub>4</sub> estimate under a 2% constant discount rate (\$2,700/mtCH<sub>4</sub> for 2020 emissions (NYSDEC 2022)<sup>192</sup>) exceeds the fully updated SC-CH<sub>4</sub> estimate under a 2% near-term Ramsey discount rate presented in Table 4.1.1 of the report.<sup>193</sup>

## A.6 Global Focus in SC-GHG Estimates

Comment: Commenters (2397-Climate Alliance, 2398-Policy Integrity NYU, 2246-NRDC, 2208-CCES et al., 2281-CCES et al., 2410-CA AG et al., 3174-Climate Science et al., 2313-M. Plevin-Faust,) express support for the consideration of global damages in EPA’s Draft Report on the SC-GHG. The commenters make numerous arguments in favor of considering global damages. Commenters (2398-Policy Integrity NYU, 2208-CCES et al.) contend that EPA’s consideration of global climate damages is both economically sound and consistent with previous approaches, including those developed under the George W. Bush administration. The same commenters highlight OMB Circular A-4 (2003)’s recommendation for agencies to report effects beyond the borders of the United States and note that agencies regularly consider costs and benefits to foreign entities in their decision-making. The commenters (2398-Policy Integrity NYU, 2208, 2281-CCES et al.) provide examples of precedents that support extraterritorial effects, such as NEPA analyses and EPA’s past consideration in the context of stratospheric ozone regulation, and highlights court decisions that have upheld EPA’s authority to consider global impacts. Furthermore, the same commenters argue that across a wide range of contexts – including outside the climate context – agencies have justified rules on the importance of international reciprocity and cooperation.

Commenter (2398-Policy Integrity NYU) summarizes that EPA is acting rationally in accounting for climate impacts on a global basis, and that this method is consistent with historical examples of agency regulatory authority. The commenter encourages EPA to highlight this point as support for its global approach. Commenter (2398-Policy Integrity NYU) provides a thorough analysis of the historical and legal frameworks under which U.S. agencies, including EPA, have considered the transboundary environmental effects of domestic actions. The commenter highlights the National Environmental Policy Act (NEPA) as a fundamental piece of legislation that instructs agencies to recognize global environmental challenges and foster international cooperation, as stipulated by 42 USC section 4332.<sup>194</sup> Consistent with NEPA’s directives, U.S. agencies have, for over four decades, assessed the impacts of their actions that extend beyond national borders. Commenter (2398-Policy Integrity NYU) notes that NEPA instructs and in some cases requires agencies to consider transboundary impacts of environmental problems. The commenter further clarifies that courts have often upheld EPA’s authority to consider international cooperation when setting domestic pollution standards, including the U.S. Court of Appeals for the D.C. Circuit in *National Coalition Against the Misuse of Pesticides v. Thomas*.<sup>195</sup> The commenter provides several other examples of courts upholding EPA’s power to do so, as well as instances of other agencies regulating based on international cooperation in climate contexts and beyond (e.g., spillover effects in the case of the Department of Energy’s consideration of liquefied natural gas exports to nations with which the United States does not have a free trade agreement).

Further underlining the federal commitment to acknowledging the international ramifications of domestic actions, Commenter (2398-Policy Integrity NYU) cites the 1979 Executive Order 12114, which establishes procedures for agencies to consider environmental effects outside the

---

<sup>194</sup> 42 U.S.C. § 4332(2)(F)

<sup>195</sup> 815 F.2d 1579 (D.C. Cir. 1987).

U.S. territories.<sup>196</sup> The executive order emphasizes the importance of safeguarding the environment of the global commons, foreign nations, and globally significant ecological resources.<sup>197</sup> Building upon this, the Council on Environmental Quality in 1997 reinforced the necessity for agencies to analyze the foreseeable transboundary effects of proposed domestic actions in NEPA analyses.<sup>198</sup>

To further demonstrate the legal breadth and historical consideration of transboundary effects, the Commenter (2398-Policy Integrity NYU) references several court decisions. The commenter states that these judgements, such as the D.C. Circuit’s verdict in *Environmental Defense Fund v. Massey*,<sup>199,200</sup> and other court precedents like *Manitoba v. Salazar*<sup>201</sup> and *Backcountry Against Dumps v. U.S. Department of Energy*,<sup>202</sup> have emphasized the responsibility of agencies under NEPA to consider the foreseeable transboundary environmental effects of their actions. While there may be some inconsistencies in the case law about NEPA’s extraterritorial application,<sup>203,204</sup> the commenter finds the prevailing judicial sentiment to be aligned with the broader goal of NEPA – ensuring that federal agencies consider both domestic and global environmental implications of their actions, especially when these actions impact the global commons or the American environment.<sup>205</sup>

Commenter (2208, 2281-CCES et al.) expresses that EPA has appropriately focused on a global estimate of climate benefits, rejecting the temporary practice of the Trump administration of disregarding all climate effects that occur outside the physical borders of the United States. The commenter states that EPA should strengthen its justification by 1) emphasizing the concern for impacts of U.S. pollution on foreign welfare in the Clean Air Act and other sources of law, 2) further highlighting the significance of U.S. strategic interests and reciprocity, 3) further emphasizing the importance of extraterritorial impacts and spillovers, and 4) highlighting the inconsistency that would occur if the agency considered only domestic benefits while focusing on global costs.

**CAA:** The commenter (2281-CCES et al) notes that section 111 of the CAA, under which EPA issues the proposed rule, charges EPA with regulating “air pollution which may reasonably be anticipated to endanger public health or welfare,”<sup>206</sup> where “welfare” is defined to include “effects on . . . weather . . . and climate.”<sup>207</sup> When interpreting similar language in section 202 of the CAA, the Supreme Court found “there is nothing counterintuitive to the notion that EPA can curtail the emission of substances that are

putting the global climate out of kilter.”<sup>208</sup> And when industry challenged another EPA climate program under Title I of the CAA by arguing that the statute “was concerned about local, not global effects,” the U.S. Court of Appeals for the D.C. Circuit had “little trouble disposing of Industry Petitioners’ argument that the [CAA’s prevention of significant deterioration (PSD)] program is specifically focused solely on localized air pollution,” finding instead that the statute was “meant to address a much broader range of harms,” including “precisely the types of harms caused by greenhouse gases.”<sup>209</sup> The commenter also notes a recent law-review article that exhaustively reviewed the legislative history of the CAA’s definition of “welfare” and concluded that “when Congress included the ‘effects on . . . climate’ language in the statute, it understood that adverse climate effects could occur on a global scale.”<sup>210</sup> For instance, the commenter reports that Senator Caleb Boggs, a Republican from Delaware and ranking minority member of the Public Works Subcommittee on Air and Water Pollution, which was considering the CAA in 1970, entered a report into the record stating that air pollution “alters climate and may produce global changes in temperature.”<sup>211</sup> Senator Jennings Randolph of West Virginia likewise submitted a statement into the record explaining that U.S. air pollution could “produce unacceptable worldwide climate changes.”<sup>212</sup> According to the commenter, Congress’s clear concern for the effects of domestic pollution on the global climate—many more examples of which are discussed in this law-review article—demonstrates that a global perspective is appropriate, if not required, when EPA regulates under the CAA.

**National Environmental Policy Act (NEPA):** The commenter (2281-CCES et al) provides that NEPA broadly declares a national environmental policy and requires of all agencies that “to the fullest extent possible[,] the policies, regulations, and public laws of the United States shall be interpreted and administered in accordance with the policies set forth in this chapter,”<sup>213</sup> including the need to “recognize the worldwide and long-range character of environmental problems” and to “lend appropriate support” to help “maximize international cooperation.”<sup>214</sup> The commenter states that, especially because

<sup>211</sup> Id. at 32–33.

<sup>212</sup> Id. at 33.

<sup>213</sup> 42 U.S.C. § 4332(1)

<sup>214</sup> Id. § 4332(2)(F); see also *EDF v. Massey*, 986 F.2d 528, 536 (D.C. Cir. 1993) (“Section 102(2)(F) further supports the conclusion that Congress, when enacting NEPA, was concerned with worldwide as well as domestic problems facing the environment. . . . Compliance with one of the subsections can hardly be construed to relieve the agency from its duty to fulfill the obligations articulated in other subsections.”); *NRDC v. NRC*, 647 F.2d 1345, 1387 (D.C. Cir. 1981) (J. Robinson, concurring; J. Wilkey wrote for the Court, but there was no majority opinion) (concluding that even if a conflict with another statute prevents the agency from conducting an environmental impact statement, that “does not imply that NRC may ignore its other NEPA obligations,” including the “provision for multinational cooperation” and the “policy of the United States with respect to the ecological well-being of this planet”; rather, the agency “should remain cognizant of this responsibility”); *Greene County Planning Bd. v. Federal*

adopting a global perspective on climate damages will advance U.S. foreign policy goals, NEPA requires EPA to interpret all of its laws, including the CAA, in ways that recognize the worldwide character of environmental problems. As EPA recognizes in the Draft Update,<sup>215</sup> using global social cost of GHG estimates helps fulfill that requirement. Likewise, in a recent guidance document, the Council on Environmental Quality highlighted this very statutory language to conclude that “it is most appropriate for agencies to focus on [social cost of GHGs] estimates that capture global climate damages.”<sup>216</sup>

Additionally, the commenter notes that other key legal commitments compel this same conclusion. For instance, the United Nations Framework Convention on Climate Change—to which the United States is a party<sup>217</sup>—declares that national “policies and measures to deal with climate change should be cost-effective so as to ensure global benefits at the lowest possible cost.”<sup>218</sup> The Convention further commits parties to evaluating global climate effects in their policy decisions, by “employ[ing] appropriate methods, for example impact assessments . . . with a view to minimizing adverse effects on the economy, on public health and on the quality of the environment, of projects or measures undertaken by them to mitigate or adapt to climate change.”<sup>219</sup> According to the commenter, the unmistakable implication of the Convention is that parties—including the U.S.—must account for global economic, public health, and environmental effects in their impact assessments. In 2008, a group of U.S. senators—including then-Senator John Kerry, who helped ratify the framework convention on climate change—agreed with this interpretation of the treaty language, saying that “[u]pon signing this treaty, the United States committed itself to considering the global impacts of its greenhouse gas emissions.”<sup>220</sup>

Furthermore, the commenter adds that NEPA requires agencies to administer and interpret the nation’s law to “recognize the worldwide and long-range character of environmental problems” and to “lend appropriate support” to help “maximize

---

Power Comm’n, 455 F.2d 412, 424 (2d Cir. 1972) (“The Commission’s ‘hands-off’ attitude is even more startling in view of the explicit requirement in NEPA that the Commission ‘recognize the worldwide and long-range character of environmental problems’ and interpret its mandate under the Federal Power Act in accordance with the policies set forth in NEPA.”).

<sup>220</sup> Comment Letter from U.S. Sens. Feinstein, Snowe, Nelson, Cantwell, Sanders, Kerry, Durbin, Reed, Boxer, & Cardin to Mary Peters, Sec’y, U.S. Dep’t of Transp. on Proposed Rule for Average Fuel Economy Standards, Passenger Cars and Light Trucks; Model Years 2011 2015 (July 1, 2008).

international cooperation.”<sup>221</sup> Numerous court decisions—including one from the U.S. Court of Appeals for the D.C. Circuit—have held that reasonably foreseeable transboundary effects must appear in NEPA analyses.<sup>222</sup> And consistent with those decisions, agencies have assessed transboundary impacts under NEPA for over forty years under Executive Order 12,114, which instructs agencies to “take into consideration in making decisions” effects of their actions on the “environment of a foreign nation” and “the global commons.”<sup>223</sup> The commenter contends that EPA’s consideration of extraterritorial environmental impacts is consistent with decades of agency practice.

***Administrative Procedures Act (APA):*** The commenter (2281-CCES et al) provides that under the APA, it is arbitrary and capricious for agencies to “entirely fail[] to consider an important aspect of the problem”<sup>224</sup>—an obligation that a federal court held requires federal agencies to consider international climate impacts. Specifically, the commenter notes that a recent ruling from the U.S. Court for the Northern District of California struck down as arbitrary the Bureau of Land Management (BLM) rescission of the Waste Prevention Rule in part because the agency had abandoned the Working Group’s peer-reviewed, global estimates of the social cost of GHGs in favor of flawed estimates (the same estimates that EPA applied under the Trump administration) that looked narrowly at effects within the U.S. borders.<sup>225</sup> The Court found that the global values developed by the Working Group reflected “the best available science about monetizing the impacts of greenhouse gas emissions,”<sup>226</sup> whereas “focusing solely on domestic effects has been soundly rejected by economists as improper and unsupported by science.”<sup>227</sup> The Court reminded BLM that relevant executive orders, including Executive Order 12,866, require consideration of “all” costs and benefits, based on the “best reasonably obtainable scientific, technical, economic, and other information,” and concluded that “no[] . . . regulatory rules or orders require exclusion of global impacts.”<sup>228</sup>

***Executive Order 13990 and Other Rulemaking Efforts:*** Commenter (2281-CCES et al) provides that Executive Order 13990 (Protecting Public Health and the Environment and Restoring Science To Tackle the Climate Crisis (2021)) instructed agencies to “tak[e] global damages into account,” because “[d]oing so facilitates sound decision-making, recognizes the breadth of climate impacts, and support the international leadership of the United States on climate issues.”<sup>229</sup> This language again, according to the commenter, reinforces the instructions from NEPA that, whenever not precluded by statute from doing so, agencies should account for the environmental impacts of their actions on foreign nations and global commons.

**Historic Precedent:** The commenter (2281-CCES et al) notes that agencies have considered key effects on international reciprocity in their regulatory cost-benefit analyses and decision-making. The commenter describes EPA’s 1988 regulations to protect stratospheric ozone as best antecedent. The commenter provides that, in issuing those regulations, EPA recognized that it could “consider other countries’ willingness to take regulatory action” in “deciding whether and how to regulate.”<sup>230</sup> EPA also took “[c]onsideration of the international ramifications of United States action” into account when “analyzing the cost and feasibility of controls.”<sup>231</sup> And in its regulatory impact analysis (RIA), EPA modeled alternative regulatory stringency levels based on potential international participation rates and the influence that EPA regulation would have on reciprocal international actions.<sup>232</sup> The commenter states that by adopting a global approach to the social cost of GHGs, EPA therefore draws upon the approach that it took for stratospheric ozone under the Reagan administration.

The commenter (2281-CCES et al) adds that on several prior occasions—again outside the context of climate change—Courts have upheld EPA’s authority to consider effects on international reciprocity and cooperation due to domestic pollution standards. In one case, for instance, the D.C. Circuit upheld EPA’s decision to set an interim tolerance of 30 parts per billion (ppb) for the chemical ethylene dibromide under the Food, Drug, and Cosmetic Act (FDCA)—rather than ban the chemical altogether—after EPA concluded that a ban “could damage cooperative [food-safety] efforts,” reasoning that “[s]ince effective enforcement of food safety laws depends upon such cooperation, a ban might increase the risk that fruit and vegetables would enter the U.S. treated with unsafe levels of pesticides or infested with pests or diseases.”<sup>233</sup> The D.C. Circuit similarly upheld EPA’s consideration of international harmonization in setting nitrogen oxide (NOx) emissions standards for commercial aircraft gas turbine engines, after EPA issued a standard under the CAA to align U.S. standards with international standards.<sup>234</sup>

Additionally, commenter (2281-CCES et al) notes agencies have also considered transboundary spillover effects in making key decisions. As one example, when considering the “public interest” in the certification of natural gas exports under the Natural Gas Act,<sup>235</sup> the Department of Energy routinely “consider[s] international trade policy, foreign policy, and national security interests.”<sup>236</sup> As another example, the Food and Drug Administration also frequently considers international effects as part of its

regulatory decision-making, and has recognized that such costs are particularly relevant because “a portion of foreign costs could be passed on to domestic consumers.”<sup>237</sup>

Commenter (2281-CCES et al) states that Courts have confirmed that agencies may—and, in some cases, must—consider international spillover effects. In 2020, the U.S. Court of Appeals for the Ninth Circuit rejected a Bureau of Ocean Energy Management approval of an offshore oil drilling and production facility after the agency concluded that domestic extraction would not affect international fossil-fuel supply and consumption.<sup>238</sup> As the Court explained, because domestic production causes “foreign consumers [to] buy and consume more oil”—and because that consumption “can be translated into estimates of greenhouse gas emissions” that harms the U.S.—the agency had an obligation to consider those increased foreign emissions resulting from domestic action.<sup>239</sup> Two subsequent district court opinions similarly faulted Department of Interior analyses for omitting the effects of domestic production on foreign demand and consumption.<sup>240</sup> The commenter contends that the fact that Courts have required agencies to consider the spillover impacts from foreign GHG emissions provides strong support for EPA’s consideration of spillovers from domestic emissions.

Commenter (2246-NRDC) expresses support for basing the SC-GHG on global economic damage, due to the impact such damages will have on American assets abroad and the global nature of the U.S. economy. The commenter further argues for the adoption of the same global SC-GHG estimate among countries, noting that the alternative – i.e., “if each country accounts solely for the damage caused by its own emissions within its own geographic boundary” – then “in aggregate the severity of the global damage will be severely undercounted, and a global tragedy of the commons would lead to global climate degradation”. The commenter points to recent research for a mathematical proof of this hypothesis.<sup>241</sup> The commenter also points to recent research as providing a detailed justification of the importance of international reciprocity as a reason for adoption a global focus in SC-GHG estimation:

“They explain how other countries, including Canada, Sweden, Germany, and the United Kingdom, have strategically selected a global SC-GHG, that the United States has benefited from other countries’ policies to account for global damage from their own emissions, and, most importantly, they explain how the United States can foster an atmosphere of reciprocity by leading with a global SC-GHG. They explain how economic ‘models of strategic behavior and real-world experiments suggest the United States may be able to stimulate cooperative international action by leading by example;

A Theoretical Perspective 7–8 (Aug. 12, 2016), <https://cenrep.ncsu.edu/cenrep/wp-content/uploads/2015/07/Kotchenpaper.pdf> [<https://perma.cc/BH2A-7KGV>] (“The result is intuitive: the marginal benefit of emissions is equated across all countries and equal to the sum of the marginal damages of emissions. . . . That is, all countries must internalize the GSC-GHG [global SC-GHG], which then defines a unique level of Pareto optimal emissions for each country.”).

building trust, a reputation for equity, and a critical mass of initial actors; and promoting a tit-for-tat dynamic of mutually beneficial reciprocity between nations.”<sup>242</sup>

Finally, the commenter (2246-NRDC) suggests that a global SC-GHG estimate is consistent with the Clean Air Act because the Act compels EPA to act on emissions of air pollutants that “may reasonably be anticipated to endanger public health or welfare,” and welfare is expansively defined to include “effects on ... climate.” See, e.g., Clean Air Act §§ 202(a)(1) and 302(h). The commenter argues that since GHGs are air pollutants under the CAA and since the adverse effect of this pollution do not stop at U.S. borders, “there is thus no basis in the statute to limit the scope of “public health” and “welfare” to only those effects manifested inside the Nation’s borders. For these reasons, EPA would fail its legal duty to adequately consider danger to health and welfare if it were to circumscribe its analysis to domestic impacts only.”

Commenter (2410-CA AG et al.) argues that the consideration of global impacts of greenhouse gas emissions is fully within the authority of federal agencies. The commenter cites an example of the consideration of global benefits being upheld in court<sup>243</sup> as well as an example of where the failure to do so was ruled an error in *California v. Bernhardt*, in which the Court noted that “focusing solely on domestic effects has been soundly rejected by economists as improper and unsupported by science.”<sup>244</sup>

Response A-6-1: EPA thanks commenters for their supportive comments and numerous recommendations. EPA has expanded the explanation of why the Agency focuses on SC-CH<sub>4</sub> estimates that provide a global measure of the monetized benefits from CH<sub>4</sub> emission reductions in the final RIA.

Comment: Commenter (2239-Fraas et al.) states that they agree with EPA’s justification for using global SC-GHG estimates. In particular, the commenter states that global SC-GHG estimates “might help to promote future international cooperation and indicate the future scale of international cooperation that fighting climate change may require.” However, the commenter argues that providing both global and country estimates “will increase transparency about who receives the benefits, will foster policy discussions about fairness and equity, will furnish agencies with the flexibility to prepare analyses consistent with their statutory mandates, and will provide important distributional information to help in international negotiations.” The commenter states that presenting both a domestic and a global SCC increases transparency to Congress and U.S. citizens who will bear most of the cost of U.S. emissions reductions policies. The commenter also states that reporting both estimates may “reduce disruptive whipsawing of carbon policy analyses across administrations.”

The commenter (2239-Fraas et al.) further argues that EPA’s justification for only providing a subset of domestic damages is unpersuasive. The commenter argues that there is a rich set of environmental and economic data available in the U.S., and the commenter supports developing

regional damage estimates within the U.S. as the science improves further. The commenter argues that the inherent uncertainties in a domestic SCC is no greater than the uncertainties in producing a global SCC. The commenter states that a “scientific advisory panel to the EPA recommended soft-linking as an option for incorporating disaggregated spatial environmental information into EPA’s SAGE model (EPA, 2017).”<sup>245</sup> The commenter also argues that the development of a domestic SCC is a natural pre-requisite to being able to conduct environmental justice analyses as recommended by President Biden’s Modernizing Regulatory Review memorandum.<sup>246</sup>

Commenter (2239-Fraas et al.) lastly argues that the “exclusive focus on the global SCC also presumes that U.S. policymakers are indifferent about whether climate-control benefits occur in the U.S. versus elsewhere in the world.” The commenter argues that this view is inconsistent with the Clean Air Act and President Clinton’s 1993 Executive Order on Regulatory Planning and Review.<sup>247</sup> The commenter notes that international cooperation and reciprocity on climate change should be assessed by emissions reductions or binding agreements and not stated goals or pledges. The commenter cites evidence that shows that most countries fail to meet their 2015 Paris Agreement commitments,<sup>248</sup> which were not legally binding.

Response A-6-2: EPA thanks the commenter for their supportive statements about EPA’s justification for using global SC-GHG estimates. EPA agrees with the commenter that transparency and distributional analysis is important in EPA RIAs. EPA is continuously striving to improve its ability to present evidence on the possible distributional effects of climate change in our analyses. In this regard, the SC-GHG Report provides a discussion of the available evidence on the distribution of climate change impacts based on the results from the SC-GHG modeling and related published literature from U.S.-specific modeling efforts. This presentation is also included in the final RIA. Taken together, applying the U.S.-specific partial SC-CH<sub>4</sub> estimates derived from the multiple lines of evidence described in the RIA to the CH<sub>4</sub> emissions reduction expected under the final rule would yield substantial benefits. EPA will continue to review developments in the literature, including more robust methodologies for estimating the magnitude of the various damages to U.S. populations from climate impacts and reciprocal international mitigation activities, and explore ways to better inform the public of the full range of GHG impacts.

Similarly, EPA is continuously striving to improve its ability to present evidence on the possible effects of climate change in communities with environmental justice concerns. When assessing the environmental justice (EJ) impacts of climate change it is critical to consider not only the marginal impacts of the expected emissions reductions, as is measured by the SC-GHG, but also difference in baseline exposure to the impacts of climate change and interactions with other

<sup>248</sup> “Climate Commitments Not On Track to Meet Paris Agreement Goals” as NDC Synthesis Report is Published. United Nations. 2021. <https://unfccc.int/news/climate-commitments-not-on-track-to-meet-paris-agreement-goals-as-ndc-synthesis-report-is-published>

socioeconomic and environmental stressors. Furthermore, the framework of EJ analyses does not require monetization of damages as is necessary for inclusion with an estimate of the SC-GHG. Therefore, in the EJ assessment presented in the RIA, the EPA relies on many lines of evidence on the local and regional impacts of climate change and not only those lines of evidence that allow for monetization of the damages. Therefore, EPA disagrees that “that the development of a domestic SCC is a natural pre-requisite to being able to conduct environmental justice analyses” as the purpose and scope of such analyses differs from that of the SC-GHG.

Comment: Several other stakeholders disagree with EPA’s use of global estimates (2428-API, 2227-W. Energy Alliance, 2339-INGAA, 2237-NDIC, 2254-PBPA, 2445-J.K. Davis). Commenters (2237-NDIC, 2339-INGAA, 2428-API) argue that it is inconsistent to measure global benefits of GHG reductions against the domestic costs imposed by U.S. environmental regulations. Commenters (2339-INGAA, 2237-NDIC, 2429-API), argue that EPA’s focus on global estimates may conflict with the Clean Air Act, and commenter (2254-PBPA) argues that Circular A-4 requires EPA to focus on domestic effects of emissions reductions. Commenters (2227-W. Energy Alliance, 2339-INGAA, 2428-API) question whether presenting global estimates of the SC-GHG will engender international reciprocity and argue that countries may instead limit their efforts to reduce GHG emissions in response.

Commenter (2237-NDIC) notes that EPA must assess the Supplemental Proposal based only on domestic costs, as required by the CAA. The commenter writes that when considering the Supplemental Proposal based on solely domestic estimates of SC-GHG, the Proposal is not justified. The commenter also argues that EPA’s authority to advance Section 111 regulations under the CAA is not based in global climate benefits. Instead, Section 111 directs EPA to consider the quantity of air pollutant emission which each category will emit; the extent to which each pollutant may reasonably be anticipated to endanger public health or welfare; and the mobility and competitive nature of each such category of sources and the consequent need for nationally applicable new source standards of performance when putting forth standards for new sources. The commenter argues that this direction is clear in that analyses must be based on assumptions related to national, not global, impacts. In addition, the commenter remarks that EPA has not been authorized by Congress to impose national costs for the sake of global benefits.

Commenter (2237-NDIC) asserts that while E.O. 13990 may provide limited guidance on considering the SC-GHGs for public policy purposes, it cannot change or override the statutory requirements established by Congress in the Clean Air Act. The commenter questions the legality of the E.O. if it is interpreted as requiring the exclusion of separate domestic benefits calculations, which they claim violates the CAA. The commenter also criticizes EPA’s cost-benefit analysis for the Supplemental Proposal, claiming that it unfairly imposes costs solely on the U.S. public while claiming global benefits. They emphasize concerns regarding the use of an ideological global SC-GHG metric, which they argue fails to adequately consider the domestic SC-GHGs. The commenter adds that federal agency regulations have been overturned in the past for failing to justify not using *domestic* cost-benefit calculations, as in *Wyoming et al. v. DOI et al.*, 493 F. Supp. 1046.<sup>249</sup>

---

<sup>249</sup> 493 F. Supp. 3d 1046 (D. Wyo. 2020).

Commenter (2237-NDIC) criticizes EPA for calculating the domestic SC-GHG in previous benefit-cost analyses but refusing to use those calculations. The commenter highlights that EPA has developed and quantified domestic estimates of the SC-GHG in response to Executive Order 13783. The commenter mentions that benefit-cost analyses, including the one for the Oil and Natural Gas Technical Reconsideration and Policy Review, estimated the domestic SC-GHG to be in the range of \$1 to \$7 per metric ton of carbon dioxide. The commenter argues that even at the high end of the domestic range, the estimated climate benefits of the proposal significantly decrease, while the net burden on the U.S. public increases. The commenter concludes that the Supplemental Proposal is not justified when the domestic SC-GHG is appropriately considered to assess the costs faced by the U.S. public. The commenter argues that EPA should either use the existing domestic calculation or update it, rather than excluding the domestic social costs and relying on speculative global costs.

Commenter (2339-INGAA) expresses that EPA does not justify that the global effects would not be symmetrical to national effects, stating that while U.S. citizens are affected by international climate impacts, foreign citizens are also affected by U.S. domestic climate impacts. The commenter acknowledges that there is likely not perfect symmetry in this respect, but they offer it as a reasonable default assumption. The commenter argues that spillover effects are not a credible justification for the use of global SC-GHG figures. The commenter then disagrees with EPA's reciprocity reasons for a global focus because it is "merely hopeful speculation" and that "[i]f anything, it runs contrary to what rational choice would traditionally predict, i.e., that unilateral action to improve a commons will affirmatively encourage *free riding*, not reciprocity." To support this statement, the commenter cites a research paper<sup>250</sup> as "characterizing a free-riding response as "more probable" than reciprocity" and another study that states that "U.S. GHG policies could lead other countries to become more lax in their policy efforts, reducing U.S. benefits. This means that the implication for reciprocity could be negative."<sup>251</sup>

Commenter (2339-INGAA) argues that use of global SC-GHG estimates can lead to a biased cost-benefit analysis if it does not also consider the "social benefits of energy" over a similar geographic and temporal scope. The commenter writes that EPA's decision to present global estimates of the SC-GHG conflicts with historical standard benefit-cost practice on the part of federal rule makers generally and EPA specifically, noting that EPA in the past has not given equal weighting to citizens of other countries even in matters with cross-border effects (such as mercury or sulfur dioxide pollution). The commenter adds that EPA's decision to increase domestic damage figures due to DSCIM and GIVE's underestimation of domestic GHG mitigation benefits does not pass the "test of rationality in administrative decision-making." Lastly, the commenter suggests that the power to endorse use of global damages over domestic may be outside of EPA's authority, and that where Congress has issued judgement on the matter, EPA must follow it. To that end, the commenter argues that the CAA represents Congressional intent to prioritize domestic over global impacts, with its purpose of protecting and enhancing

---

<sup>250</sup> Masur, J. S., & Posner, E. A. (2011). Climate regulation and the limits of cost-benefit analysis. *Calif. L. Rev.*, 99, 1557.

<sup>251</sup> Gayer, T., & Viscusi, W. K. (2016). Determining the proper scope of climate change policy benefits in US regulatory analyses: Domestic versus global approaches. *Review of Environmental Economics and Policy*.

the quality of “the Nation’s” air resources. The commenter also suggests EPA’s use of global damages may be in violation of the major questions doctrine.

Commenter (2339-INGAA) further states that EPA’s focus on the complexity of disaggregating domestic and global effects does not justify their use of global estimates. The commenter states that domestic climate change damages are expected to represent a small percentage of global damages, remarking that estimates have ranged from 14-19% under the previous administration, to 5-12% under EPA’s current DSCIM and GIVE models depending on the emission and year. To that end, the commenter states that EPA’s reasoning for using global estimates is unsatisfactory.

Commenter (2428-API) refers to Section 115 and Title VI of the Clean Air Act (CAA) for characterizations of how to consider international effects of domestic air pollutant emissions. The commenter elaborates that such considerations are limited to 1) scenarios in which there is reciprocity, meaning the United States has the same rights to prevent or control air pollution in that country as given to the other country by Section 115, or 2) consideration of global impacts of ozone-depleting chemicals of concern. Accordingly, the commenter argues that these two characterizations represent the extent of international effects that can be considered when characterizing domestic damages. While expressing opposition to EPA’s consideration of global effects, the commenter suggests that total non-U.S. mortality damages are not a reasonable proxy for impacts on U.S. citizens living abroad. The commenter further argues that if EPA justifies the use of global SC-GHG estimates based on considerations of international reciprocity then EPA must explain why its global emissions projection does not reflect globally coordinated action. The commenter argues that EPA should consider and discuss “[r]easonable alternatives that maintain consistency between the geographic scope and the emissions trajectories.”

Commenter (2227-W. Energy Alliance) cites an article<sup>252</sup> that models individual countries’ “preferred” SCC relative to a theoretical global SCC using game theory and decision science. The commenter discusses that the author finds under this model, “to serve its national interests the United States would be rational to support an internal SCC that is about 75% of the [global SCC].” The commenter states that, while simplistic, the author’s modeling indicates that a country’s national interests do not necessarily align with a global SCC. The commenter concludes that “[p]erhaps there is a policy argument to be made for the United States to internalize a GSCC” but “*that is not a scientific decision but rather a policy choice*”, and even “if political consensus on a global SCC were achieved, which to date hasn’t happened, it would still be rational for there to be policy differences on the value used by U.S. policymakers when establishing U.S. climate, energy, and national defense policies. ...One can argue for [use of a global SCC], but EPA should not suggest its position is the only rational position or simply science based.” The commenter “emphasize that such an important topic as the SCC with such expansive societal implications deserves full public scrutiny and should not be buried in the rulemaking for one industrial sector.”

Commenter (2450-Williams Companies, Inc.) argues that EPA demonstrates an overreliance on global climate effects, which conflicts with proper statutory construction of the CAA. On the one

---

<sup>252</sup> “Which Social Cost of Carbon? A Theoretical Perspective,” M. Kotchen, Journal of the Association of Environmental and Resource Economists, volume 5, number 3, 2018.

hand, the commenter suggests that Section 111 is, at most, silent on whether global climate calculus is appropriate when developing emission controls. The commenter contends EPA has misconstrued such silence as a conferral of authority to broadly rely on global estimates when drafting standards that should otherwise be based on domestic considerations. For instance, the commenter states that a plain reading of CAA's language imparts a clear mandate on EPA to lead "reasonable Federal, State, and local government actions . . ."<sup>253</sup> In that capacity, the commenter adds, the agency's role is to act as "the primary regulator of *domestic* greenhouse emissions."<sup>254</sup> Consonantly, the commenter asserts that this domestic mandate is reinforced by OMB guidance under Circular A-4 (2003), which instructs agencies to "focus on the benefits and costs that accrue to citizens and residents of the United States" with only ancillary focus, if any focus at all, on international concerns.<sup>255</sup> According to the commenter, EPA's rationale for departing from the aforementioned precedent is based on 1) the revocation of Executive Order 13783 and 2) EPA's disagreement with the prior administration's reliance on what the agency claims are faulty domestic emissions calculi. The commenter asserts that neither of those justifications furnish EPA with the authority to enlarge the CAA and rely on global climate damages to the extent the agency did when it drafted this proposal.

Commenter (2254-PBPA) argues that OMB Circular A-4 (2003) bounds EPA to use domestic effects as the basis of the Agency's BCA. The commenter notes that contrary to Federal courts' instructions – which require EPA to separate global considerations from domestic – EPA relied on global effects in developing its estimates.

Commenter (2445-J.K. Davis) emphasizes that the primary objective of regulatory analysis should be to assess the impact on the United States, given the lawful territorial reach of a federal regulator. The commenter argues that EPA's expansion of its social cost analysis globally is neither legally nor logically justified and is an example of arbitrary agency action.

Response A-6-3: Some commenters argue that the EPA's use of global SC-GHG estimates – either the IWG recommended interim estimates or EPA's updated estimates – to monetize the climate benefits expected from this action is inappropriate because EPA is precluded from considering international climate impacts under the Clean Air Act (CAA). Other comments argue that EPA's focus on global SC-GHG estimates in the RIA is not well reasoned or is inconsistent with OMB guidance for regulatory analysis under E.O. 12866. EPA disagrees with both assertions and discusses each in turn.

First, EPA disagrees with commenters who stated that EPA has no authority to consider the international climate benefits of this action, taken pursuant to the Clean Air Act (CAA). As an initial matter, commenters misunderstand the basis for this action. As explained in Section XVI.E of the preamble, this action is justified under the EPA's record-based analysis of the statutory factors of CAA section 111, and the monetized benefits analysis is not used to justify this action. However, to the extent a reviewing court were to conclude, contrary to the EPA's express position, that the presentation of these monetized climate benefits in fact constitutes a

---

<sup>253</sup> 42 U.S.C. § 7401(c).

<sup>254</sup> *City of New York v. Chevron Corp.*, 993 F.3d 81, 99 (2d Cir. 2021) (emphasis added).

<sup>255</sup> OMB Circular A-4 (2003), Section E: Identifying and Measuring Benefits and Costs, available at [https://www.whitehouse.gov/wp-content/uploads/legacy\\_drupal\\_files/omb/circulars/A4/a-4.pdf](https://www.whitehouse.gov/wp-content/uploads/legacy_drupal_files/omb/circulars/A4/a-4.pdf)

reviewable portion of the record for this action, the EPA explains here in the alternative, that the consideration of global monetized benefits using SC-CH<sub>4</sub> estimates would be lawful under the CAA.

EPA notes that when the Agency is directed to consider costs under the CAA, it does not consider costs on a nationality basis but rather, typically, cost is considered at the facility or firm level without respect to which entity owns or operates the facility(s) or firm(s). Further, EPA's cost estimates in RIAs, including the cost estimates contained in the Final RIA for this rule, regularly do not differentiate between compliance costs expected to accrue to U.S. firms versus foreign interests.<sup>256</sup>

The Act as a whole does not have an exclusively domestic focus. It allows consideration of international effects where rulemakings have international consequences and does not narrowly focus only on harms occurring within U.S. borders. For example, in CAA section 115 and Title VI, Congress demonstrated its intent that EPA address transboundary effects of air pollution. Section 111 of the CAA charges EPA with regulating "air pollution which may reasonably be anticipated to endanger public health or welfare," and "welfare" is defined to include "effects on...weather...and climate."<sup>257</sup> Case law supports addressing global harms specifically under similar language in the CAA. For example, in *Massachusetts v. EPA*, 549 U.S. 497 (2007), the Court found that "there is nothing counterintuitive to the notion that EPA can curtail the emission of substances that are putting the global climate out of kilter." As another example, in *Coalition for Responsible Regulation v. EPA*, 684 F.3d 102, 120 (D.C. Cir. 2012), the Court held that the CAA's prevention of significant deterioration program was "meant to address a much broader range of harms," including "precisely the types of harms caused by greenhouse gases." Case law also more broadly supports the use of a global SC-GHG estimate when setting a national policy that will have global effects on climate change. For example, in *Zero Zone, Inc. v. Dep't of Energy*, 832 F.3d 654, 679 (7th Cir. 2016), the Court rejected a petitioner's challenge to DOE's use of a global, rather than domestic, social cost of carbon in setting a national efficiency standard under the Energy Policy and Conservation Act, holding that DOE had reasonably identified carbon pollution as "a global externality" and concluding that, because "national energy conservation has global effects, . . . those global effects are an appropriate consideration when looking at a national policy." Notably, when Congress defined "welfare" under the CAA to include "effects on...climate," Congress understood that adverse climate effects could occur on a global scale.<sup>258</sup> The global effects of GHG emissions are an important aspect of the problem, and it is appropriate, if not required, that if the use of SC-GHG is

---

<sup>256</sup> For example, in the RIA for the 2018 Proposed Reconsideration of the Oil and Natural Gas Sector Emission Standards for New, Reconstructed, and Modified Sources, the EPA acknowledged that some portion of regulatory costs will likely "accru[e] to entities outside U.S. borders" through foreign ownership, employment, or consumption (EPA 2018, p. 3-13). In general, a significant share of U.S. corporate debt and equities are foreign-owned, including in the oil and gas industry.

<sup>257</sup> 42 U.S.C. § 7602(h); *Massachusetts v. EPA*, 127 S. Ct. 1438, 1447 (2007).

<sup>258</sup> See Richard L. Revesz, Bostock and the End of the Climate Change Double Standard, 46 COLUM. J. ENV'T L. 1, 9 (2020) (detailing the extensive relevant legislative history, including that "[d]uring debate on the 1970 Amendments, which added the terms 'climate' and 'weather' to the definition of 'welfare,' Senator Boggs introduced into the record a White House Report stating that: 'Air pollution alters climate and may produce global changes in temperature. . . . [T]he addition of particulates and carbon dioxide in the atmosphere could have dramatic and long-term effects on world climate.' This evidences an affirmative awareness of the problem of global climate change at the time Congress added the words 'climate' and 'weather' to the definition of 'welfare.'").

considered a part of the administrative record for this action, that EPA assess global effects, i.e., global monetized benefits, in applying the SC-GHG.<sup>259</sup> The only way to protect health and welfare in the U.S. from climate change impacts is to address climate change on a global scale, because it is a global pollution problem. Harmonization of U.S. regulatory policy with international effort can, where consistent with domestic legal authority, be a valid consideration.<sup>260</sup>

Second, EPA disagrees with the comments suggesting that EPA's decision to use and focus attention on global SC-GHG estimates when monetizing the climate benefits in the RIA for this action was not well reasoned or inconsistent with OMB guidance for regulatory analysis under E.O. 12866. As summarized in this section and discussed in greater detail in the SC-GHG Report and Final Rule RIA, the EPA focuses on the global value of climate change impacts when analyzing policies that affect GHG emissions because of the distinctive global nature of the climate change problem.

Unlike many environmental problems where the causes and impacts are distributed more locally, GHG emissions are a global externality making climate change a true global challenge. GHG emissions contribute to damages around the world regardless of where they are emitted. Thus, international cooperation and reciprocity are essential to successfully addressing climate change, as the global nature of greenhouse gases means that a ton of GHGs emitted in any other country harms those in the U.S. just as much as a ton emitted within the territorial U.S. Assessing the benefits of U.S. GHG mitigation activities requires consideration of how those actions may affect mitigation activities by other countries, as those international mitigation actions will provide a benefit to U.S. citizens and residents by mitigating climate impacts that affect U.S.

---

<sup>259</sup> *Id.* The Federal government also regularly considers international effects in non-CAA contexts, including effects on international reciprocity. *See, e.g.* The National Environmental Policy Act (NEPA), which directs Federal agencies to recognize the worldwide and long-range character of environmental problems” and “maximize international cooperation.” *See* 42 U.S.C. 4321, 4331(a), (b)(1), and 4332(F). Notably, these relevant provisions in NEPA do not just apply narrowly to agencies’ productions of environmental impact statements; rather, agencies are much more broadly instructed “to the fullest extent possible[,] the policies, regulations, and public laws of the United States shall be interpreted and administered in accordance with the policies set forth in this chapter,” 42 U.S.C. 4332(1), including the need to “recognize the worldwide and long-range character of environmental problems.” 42 U.S.C. 4332(2)(F). In other words, NEPA supports agency interpretations of applicable laws in ways that recognize the worldwide character of environmental problems.

<sup>260</sup> Note that the United Nations Framework Convention on Climate Change—to which the United States is a party, S. Treaty Doc. No. 102-38; S. Exec. Rept. No. 102-55—declares that national “policies and measures to deal with climate change should be cost-effective so as to ensure global benefits at the lowest possible cost,” committing parties to consider the global benefits of their actions. U.N. Framework Convention on Climate Change art. 3(3), May 9, 1992, 1771 U.N.T.S. 107 (emphasis added); *see also id.* art. 3(1) (“The Parties should protect the climate system for the benefit of present and future generations of humankind, on the basis of equity and in accordance with their common but differentiated responsibilities and respective capabilities.”) (emphasis added); *id.* art. 4(2)(a) (committing developed countries to adopt policies that account for “the need for equitable and appropriate contributions by each of these Parties to the global effort”). *See also* Protection of Stratospheric Ozone, 53 Fed. Reg. 30,566, 30,569 (Aug. 12, 1988) (EPA may consider “the effect of United States action on other countries’ willingness to take regulatory action.”); *National Ass’n of Clean Air Agencies v. EPA*, 489 F.3d 1221 (D.C. Cir. 2007) (upholding EPA’s consideration of international harmonization in setting NOx emissions standards for commercial aircraft gas turbine engines, after EPA issued a standard under the Clean Air Act to align U.S. standards with international standards.)

citizens and residents. This is a classic public goods problem because each country's reductions benefit everyone else, and no country can be excluded from enjoying the benefits of other countries' reductions. The only way to achieve an efficient allocation of resources for emissions reduction on a global basis — and so benefit the U.S. and its citizens and residents — is for all countries to base their policies on global estimates of damages. If each country were to design policies to equate marginal damages with marginal abatement costs using only the damages inflicted on their own citizens and residents, the world would not achieve the socially optimal level of emissions; each country would be relatively worse off from the impact of foreign emissions.<sup>261</sup>

As discussed in the SC-GHG report, the EPA's focus on global SC-GHG estimates is consistent with a wide range of scientific and economic experts who have emphasized the issue of international cooperation and reciprocity as support for assessing global damages of GHG emission in domestic policy analysis. Using a global estimate of damages in U.S. analyses of regulatory actions allows the U.S. to continue to actively encourage other nations, including emerging major economies, to also assess global climate damages of their policies and to take steps to reduce emissions. For example, many countries and international institutions have already explicitly adapted the global SC-GHG estimates used by EPA in their domestic analyses (e.g., Canada, Israel) or developed their own estimates of global damages (e.g., Germany), and recently, there has been renewed interest by other countries to update their estimates since the draft release of the updated SC-GHG estimates presented in the December 2022 Supplemental Proposal RIA.<sup>262</sup> In addition, as discussed in the SC-GHG Report several studies have empirically investigated international GHG mitigation reciprocity, through both policy diffusion and technology diffusion effects.

A few commenters questioned whether presenting global estimates of the SC-GHG would engender international reciprocity and argue that countries may instead limit their efforts to reduce GHG emissions in response. EPA disagrees that such "free-riding" would be the more likely outcome and notes that recent research does not find support for a free-rider hypothesis in the context of climate policy. For example, Schmidt et al. (2022)<sup>263</sup>, using data on emission-weighted carbon prices while controlling for a variety of other potential explanatory variables, find that the evidence does not support the presence of free riding. EPA also notes that one commenter's quote from a study to substantiate the commenter's argument for free-riding omitted a key sentence from the study that ran counter to the commenter's claim. The authors of

---

<sup>261</sup> As one public commenter (in their comments to OMB on the Proposed Revisions to Circular A-4) explained: "...US greenhouse gas emissions account for about 12 percent of the global total. If all countries considered only the domestic effects of their greenhouse gas emissions, about 88 percent of climate change impacts on US citizens would be ignored. An analytic focus solely on direct impacts to the United States of US emissions, when generalized, therefore omits most of the total climate impacts the United States faces" (<https://www.rff.org/publications/testimony-and-public-comments/comments-on-the-proposed-revisions-to-circular-a-4/>).

<sup>262</sup> In April 2023, the government of Canada announced the publication of an interim update to their SC-GHG guidance, recommending SC-GHG estimates identical to the EPA's updated estimates presented in the December 2022 Supplemental Proposal RIA. The Canadian interim guidance will be used across all federal departments and agencies, with the values expected to be finalized by the end of the year. <https://www.canada.ca/en/environment-climate-change/services/climate-change/science-research-data/social-cost-ghg.html>.

<sup>263</sup> Schmidt, R.C., Drupp, M., Nesje, F. and Hoegen, H., 2022. Testing the free-rider hypothesis in climate policy. *arXiv preprint arXiv:2211.06209*.

the study stated “U.S. GHG policies could lead other countries to become more lax in their policy efforts, reducing U.S. benefits. This means that the implication for reciprocity could be negative. *Given ongoing international efforts, a more likely scenario is that the reciprocity value is positive* [emphasis added].”<sup>264</sup>

For all of these reasons, the EPA believes that a global metric is appropriate for assessing the climate benefits of avoided methane emissions in the final RIA. In addition, as emphasized in the National Academies (2017) recommendations, “[i]t is important to consider what constitutes a domestic impact in the case of a global pollutant that could have international implications that impact the United States.” The global nature of GHG pollution and its impacts means that U.S. interests are affected by climate change impacts through a multitude of pathways and these need to be considered when evaluating the benefits of GHG mitigation to U.S. citizens and residents. Examples of affected interests include, direct effects on U.S. citizens and assets located abroad, international trade, and tourism, and spillover pathways such as economic and political destabilization and global migration that can lead to adverse impacts on U.S. national security, public health, and humanitarian concerns. These impacts point to another dimension of the global nature of the climate change problem and are better captured within global measures of the social cost of greenhouse gases.

To summarize, in the case of this global pollutant, the assessment of global net damages of GHG emissions allows EPA to fully disclose and contextualize the net climate benefits of the CH<sub>4</sub> emission reductions expected from this final rule. This approach is the same as that taken in EPA regulatory analyses from 2009 through 2016 and since 2021. Contrary to some commenters’ assertions, it is also consistent with guidance in OMB Circular A-4 (2003) that states when a regulation is likely to have international effects, “these effects should be reported.”<sup>265</sup> Furthermore, given that it is in the U.S. interest to account for the global consequences of a global pollutant like CH<sub>4</sub>, EPA believes there is no inherent inconsistency in comparing monetized climate benefits based on global SC-CH<sub>4</sub> estimates to the estimated costs anticipated from a regulatory action in regulatory benefit-cost analysis. Importantly, EPA notes that the cost

---

<sup>264</sup> Gayer, T., & Viscusi, W. K. (2016). Determining the proper scope of climate change policy benefits in US regulatory analyses: Domestic versus global approaches. *Review of Environmental Economics and Policy*.

<sup>265</sup> While OMB Circular A-4 recommends that international effects be reported separately, the guidance also explains that “[d]ifferent regulations may call for different emphases in the analysis, depending on the nature and complexity of the regulatory issues.” Circular A-4 (2023) states that “In certain contexts, it may be particularly appropriate to include effects experienced by noncitizens residing abroad in your primary analysis. Such contexts include, for example, when:

- assessing effects on noncitizens residing abroad provides a useful proxy for effects on U.S. citizens and residents that are difficult to otherwise estimate;
- assessing effects on noncitizens residing abroad provides a useful proxy for effects on U.S. national interests that are not otherwise fully captured by effects experienced by particular U.S. citizens and residents (e.g., national security interests, diplomatic interests, etc.);
- regulating an externality on the basis of its global effects supports a cooperative international approach to the regulation of the externality by potentially inducing other countries to follow suit or maintain existing efforts; or
- international or domestic legal obligations require or support a global calculation of regulatory effects” (OMB 2023). See also footnote 12 of Circular A-4 (2023) (discussing the SC-GHG specifically).

estimates contained in EPA RIAs do not distinguish and segregate the share of compliance costs that accrue to foreign interests.<sup>266</sup>

Finally, the EPA disagrees with commenters who suggest that the EPA should focus on a metric of benefits resulting solely from changes in climate impacts occurring within U.S. borders (typically referred to as a “domestic” SC-GHG). As explained in the final RIA, the global models used in the SC-GHG modeling do not lend themselves to being disaggregated in a way that can provide comprehensive information about the distribution of the rule's climate benefits to citizens and residents of particular countries, or population groups across the globe and within the U.S. However, as EPA is continuously striving to improve the ability to present evidence on the possible distributional effects of climate change in our analyses, the SC-GHG Report provides a discussion of the available evidence on the distribution of climate change impacts based on the results from the SC-GHG modeling and related published literature from U.S.-specific modeling efforts (such as the FrEDI model described in the Final rule). This presentation is also included in the final RIA for this action. EPA notes that, contrary to some commenters’ claims, previous EPA RIAs – including the November 2021 Proposal RIA and the December 2022 Supplemental Proposal RIA – have also included a presentation of a rule’s climate benefits resulting from climate impacts occurring within the territorial United States to the extent that they were represented in the IWG’s SC-GHG modeling framework, along with an explanation of the inadequacy of such estimates in measuring damages to U.S. citizens and residents.

As discussed in the final RIA, taken together, applying the U.S.-specific partial SC-CH<sub>4</sub> estimates derived from the multiple lines of evidence described in the RIA to the CH<sub>4</sub> emissions reduction expected under the final rule would yield substantial climate benefits – even given the numerous explicitly omitted damage categories and other modeling limitations that make it likely that these estimates underestimate the benefits from CH<sub>4</sub> emission reductions. The EPA has expanded the discussion of omitted and partially modeled damage categories and other modeling limitations in the SC-GHG Report in response to public comments and peer reviewer recommendations. The EPA will also continue to review developments in the literature, including more robust methodologies for estimating the magnitude of the various damages to U.S. populations from climate impacts and reciprocal international mitigation activities, and explore ways to better inform the public of the full range of GHG impacts.

---

<sup>266</sup> For example, in the RIA for the 2018 Proposed Reconsideration of the Oil and Natural Gas Sector Emission Standards for New, Reconstructed, and Modified Sources, the EPA acknowledged that some portion of regulatory costs will likely “accru[e] to entities outside U.S. borders” through foreign ownership, employment, or consumption (EPA 2018, p. 3-13).

## A.7 Process of Developing SC-GHG Estimates

Comment: Commenters (2398-Policy Integrity NYU, 2246-NRDC) discuss the process for updating the SC-GHG estimates and request that updates be made regularly. The commenters urge EPA to update its integrated assessment model and corresponding SC-GHG estimates every 5 years, consistent with the National Academies (2017) recommendation, because this update cycle would appropriately balance the benefit of evolving research with the need for a regular process. The commenters further note that the damage functions could be updated more frequently as improvements become available.

Commenter (2355-Constellation) expressed support for the use of EPA's SC-CH<sub>4</sub> estimates in the Supplemental Proposal RIA and notes that “[a]s a critical member of the IWG, EPA is an agency with technical and economic expertise that makes it well-suited to establish a social cost of greenhouse gases.” The commenter recommends that the updated estimates inform the continued work of the IWG and “encourage[s] coordination among agencies for consistent application of a social cost of greenhouse gases to provide certainty to the regulated community, avoid confusion, and ensure that all federal regulations reflect the benefits of climate change mitigation.”

Response A-7-1: The EPA thanks the commenters for these recommendations. EPA is committed to making evidence-based decisions pertaining to the methodologies used in EPA analyses, guided by the best available science and input from the public and peer reviewers. Thus, as noted in previous EPA regulatory impact analyses and again in the RIA for this final rule, the EPA will continue to review developments in the scientific literature, including more robust methodologies for estimating the magnitude of the various direct and indirect damages from GHG emissions, and look for opportunities to further improve SC-GHG estimation going forward. The final SC-GHG report discusses areas where additional research is needed to model climate change impacts and associated damages that are not yet represented in the damages module and to address other longer-term recommendations from the National Academies. The EPA agrees with the commenters and the National Academies peer review panel that a 5-year updating cycle would appropriately balance the benefit of incorporating evolving research with the need for a regular process. Finally, the EPA continues to participate in the IWG's work under E.O. 13990. EPA's technical report along with the peer review of the report will be among the many technical inputs available to the IWG as it continues its work.

Comment: Some commenters raise concerns about the adequacy of the public comment opportunities offered on the SC-GHG estimates used in the Supplemental Proposal RIA.

Commenters (2227-W. Energy Alliance, 2237-NDIC, 2428-API, 2339-INGAA) express that, considering the complexity of the rulemaking, the comment period was not adequate for the public, regulated industry, or other interested parties to provide proper comment. Commenters (2237-NDIC, 2428-API) emphasize the importance of adhering to the review and comment provisions, including a sound interpretation of APA. Commenter (2237-NDIC) expresses that EPA's use of the IWG's values on a global scale without following the notice and comment provisions of the Administrative Procedure Act (APA) constitutes a violation. The commenter argues that “[a]ny action by the Executive Branch in setting binding values for the SC-GHG, that

were established pursuant to a legitimate delegation of authority from Congress, are subject to the requirements of the [APA]”.

Similarly, commenter (2254-PBPA) argues that the lack of an adequate public comment process as well as limited transparency undermines the APA. The commenter states that the use of the SCC “undermines the APA’s public notice requirement by hiding the true costs of this rule behind mischaracterized climate benefits that appear to vastly outweigh any costs. By creating a one-sided and thumb-on-the-scale cost benefit analysis, EPA has made it difficult for the public to understand the costs of its proposal.” Commenter (2227-W. Energy Alliance) states the length and complexities of the SC-GHG Report and SC-CH<sub>4</sub> estimates that affect many industries, it was inappropriate for the document to be buried in an appendix within another complex rulemaking that is targeted to one industry. Further, the commenter wonders why EPA attempted to calculate SCC in the rulemaking without a public engagement plan.

Commenter (2428-API) expresses appreciation for EPA’s willingness to accept comments on the SC-GHG Report as recommended by the National Academies and states that certain aspects of the process, such as EPA’s approach to taking public comment and committing to peer review, are consistent with the principles of President Biden’s Executive Orders. However, the commenter states that EPA should have engaged with interested stakeholders during its revisions to update the four modules in the SC-GHG Report instead of postponing public comment until each module was updated and the SC-GHG Report was drafted. Further, given the extensive new data and analysis reflected in the revised report, the commenter states the 69-day comment period was insufficient for soliciting detailed and comprehensive feedback from stakeholders. The commenter requests EPA provide a new and substantially longer comment period for the SC-GHG Report exclusively, and the estimates contained therein.

Similarly, commenter (2361-EPRI) suggests that after revisions are made to the draft SC-GHG methodology and documentation, a separate dedicated public comment period for the revised draft methodology, and a peer review appropriate for a regulatory methodology with significant implications, should occur. This will give “the public and scientific community confidence in the results and decisions they inform.” The commenter states that currently, how the public is engaged and how input will be used is unclear. The commenter recommends: establishing a clear public engagement process; opportunities to comment in all phases; opportunities for public input into the peer review process, and a definition between the public input and the peer review process.

Response A-7-2: EPA disagrees with the commenters’ assertions that EPA has provided insufficient public comment opportunities on either the IWG recommended interim SC-GHG estimates or on EPA’s draft updated SC-GHG values.

The interim SC-GHG estimates recommended by the IWG in February 2021 are the same as the values developed by the IWG prior to the group being disbanded in 2017, adjusted for inflation. Those estimates were subject to public comment in a dedicated OMB led public comment period in 2013 and in the context of dozens of EPA proposed rulemakings. For example, EPA solicited comment on the SC-CH<sub>4</sub> estimates when used in sensitivity analysis for the Proposed Rulemaking for Greenhouse Gas Emissions and Fuel Efficiency Standards for Medium- and

Heavy-Duty Engines and Vehicles–Phase 2 (EPA and DOT, 2015<sup>267</sup>), and again when the estimates were first used in the primary benefit-cost analysis for a number of proposed rulemakings in 2015 (EPA 2015a<sup>268</sup>, 2015b<sup>269</sup>). In addition, the public has had opportunity to comment on the interim IWG estimates following their use in EPA regulatory analyses for numerous proposed rulemakings published since the release of the February 2021 TSD, including in the November 2021 Proposal RIA and the December 2022 Supplemental Proposal RIA.

With respect to EPA’s draft updated SC-GHG estimates, the EPA identified 55 unique substantive public comment submissions to the docket that were relevant to the estimates presented in sensitivity analysis in the December 2022 Supplemental Proposal RIA and the External Review Draft of the SC-GHG Report that was provided as Supplementary Material to the RIA. The EPA is responding to these comments in this RTC. The EPA also conducted an external expert peer review of the External Review Draft of the SC-GHG Report consistent with the guidelines set forth in EPA’s Peer Review Handbook 4th Edition, 2015.<sup>270</sup> The public comments received on the Supplemental Proposal RIA were also available to the peer reviewers as they conducted their review. Several of the peer reviewers even cited public comments pertaining to the draft updated SC-GHG estimates in their recommendations. The EPA posted a recording of the public meeting of the peer review panel on the webpage and posted the final peer review report following its completion in May 2023.

Finally, the EPA disagrees that either the IWG interim SC-GHG estimates or the EPA’s draft updated SC-GHG values are themselves a final agency action under the APA. These figures are included in the final RIA for this particular action pursuant to the EPA’s responsibility under E.O. 12866 to provide monetized benefit-cost analysis for significant regulations.

Comment: Commenters (2428-API, 2445-J.K. Davis) argue that EPA’s development of SC-GHG estimates was not transparent.

Commenter (2428-API) states that there are different versions of the RIA in the rule docket and that aspects of the draft RIA – including discussion of the draft updated SC-GHG estimates and sensitivity analysis – “were deleted in their entirety without explanation shortly before the publication of the Proposed NSPS Revisions.” The commenter stated that “the version of the RIA that EPA posted on its website for public comment on November 11, 2022 contains the

<sup>270</sup> U.S. Environmental Protection Agency Peer Review Handbook 4th Edition. 2015. Science and Technology Policy Council U.S. Environmental Protection Agency. Washington, D.C. 20460 [https://www.epa.gov/sites/default/files/2020-08/documents/epa\\_peer\\_review\\_handbook\\_4th\\_edition.pdf](https://www.epa.gov/sites/default/files/2020-08/documents/epa_peer_review_handbook_4th_edition.pdf)

subsequently deleted discussion of the SC-GHG Report and Appendix B sensitivity analysis. Thus, EPA is presently soliciting comments on two strikingly different versions of the Draft RIA." The commenter argues that "the Agency's publication of two divergent Draft RIAs raises significant questions about the sufficiency of the notice-and-comment opportunity on the required E.O. 12866 analysis as well as the Proposed NSPS Revisions." The commenter urges EPA to provide access to the records including data and studies used in reaching EPA's conclusions, pursuant to the Clean Air Act (CAA). Specifically, the commenter requests that EPA identify the comments it received on individual EPA proposed rulemakings and the IWG's February 2021 TSD about the IWG's interim SC-GHG estimates that influenced aspects of the EPA's SC-GHG Report. The commenter also requests that more of the studies cited in the SC-GHG report be added to the docket, such as the documentation regarding the expert elicitation and forecasting that was a key part of RFF's modeling effort.

Similarly, commenter (2445-J.K. Davis) expresses the need for reproducibility as a necessary condition for transparency. The commenter (2445-J.K. Davis) suggests EPA should withdraw the report as it doesn't provide materials needed for an independent replication.

Response A-7-3: The EPA provided the public with extensive documentation supporting the draft updated SC-GHG estimates used in the sensitivity analysis in the December 2022 Supplemental Proposal RIA. In the rule docket, EPA provided copies of all studies and reports cited in the RIA, including references cited in the RIA Appendix that presented the sensitivity analysis. This included studies explaining the RFF modeling effort (e.g., Rennert et al. 2022a<sup>271</sup>, 2022b<sup>272</sup>) as requested by one commenter. In addition, the RIA pointed the reader to the dedicated EPA webpage (<https://www.epa.gov/environmental-economics/scghg>) for more information about the development of the estimates. The webpage provides instructions and computer code for the SC-GHG estimates presented in the Draft Report allowing for independent replication and providing additional information about the peer review process. Finally, the EPA disagrees with the commenter's assertion that EPA solicited public comment on two different versions of the Supplemental Proposal RIA. The EPA only takes comment on the final version of an RIA accompanying a proposed rule. As required by the Clean Air Act, EPA docketed documentation on all changes made to the rulemaking package during the interagency review process.

Comment: Some commenters (2428-API, 2399-GPA Midstream Association) argue that they have not received a response to previous comments they made regarding the IWG interim estimates.

Commenter (2428-API) claims that neither the IWG nor EPA responded to or meaningfully considered their comments on the IWG's interim SC-GHG estimates submitted to OMB in 2021,

---

<sup>271</sup> Rennert, K., Prest, B.C., Pizer, W.A., Newell, R.G., Anthoff, D., Kingdon, C., Rennels, L., Cooke, R., Raftery, A.E., Ševčíková, H. and Errickson, F., 2022a. The social cost of carbon: Advances in long-term probabilistic projections of population, GDP, emissions, and discount rates. *Brookings Papers on Economic Activity*. Fall 2021, pp.223-305.

<sup>272</sup> Rennert, K., Errickson, F., Prest, B.C., Rennels, L., Newell, R., Pizer, W., Kingdon, C., Wingenroth, J., Cooke, R., Parthum, B., Smith, D., Cromar, K., Diaz, D., Moore, F., Müller, U., Plevin, R., Raftery, A., Ševčíková, H., Sheets, H., Stock, J., Tan, T., Watson, M., Wong, T., and Anthoff, D., 2022b. Comprehensive evidence implies a higher social cost of CO<sub>2</sub>. *Nature*. 610(7933), 687-692.

in particular comments about “the selection of discount rates, the ability to reasonably forecast impacts on expansive time horizons, and the importance of providing domestic SC-GHG alongside global values”. The commenter argues that as a key member of the IWG, the EPA has an obligation to address the arguments raised before it, and since the subject of API’s 2021 comments are still present in the EPA’s SC-GHG report, “EPA plainly ignored API’s comments”. Lastly, the commenter states “while it remains unclear what the SC-GHG Report is or how EPA intends to use it, nowhere does EPA represent that the report is in draft form or that the Agency will revise the SC-GHG Report based on comments and data received”. The commenter claims that the Agency’s solicitation of comments at this point is not a sufficient allowance for public participation and engagement with stakeholders that the National Academies recommended.

Commenter (2399-GPA Midstream Associates) expresses that the Administration has not responded to comments submitted by the commenter and others that identified deficiencies in the IWG’s interim SC-CH<sub>4</sub> figures used to estimate projected climate and health benefits in the Supplemental Proposed Rule. which largely require further scientific study. The commenter states that until the peer review process is conducted and subject to public review and comment, it is inappropriate for EPA to consider the interim values to support its Supplemental Proposed Rule.

Response A-7-4: As discussed previously in this section, the interim SC-GHG estimates recommended by the IWG in February 2021 and used in the primary benefit-cost analysis in both the November 2021 Proposal RIA and the December 2022 Supplemental Proposal RIA are the same as the values developed by the IWG prior to the group being disbanded in 2017, adjusted for inflation. Those estimates were subject to public comment in a dedicated OMB led public comment period in 2013 and in the context of dozens of EPA proposed rulemakings that used the estimates. The EPA responded to the comments received within final rulemakings that used the estimates. For example, EPA responded to public comments on the SC-CH<sub>4</sub> estimates in Response to Comments on the 2016 Final Rulemaking for Greenhouse Gas Emissions and Fuel Efficiency Standards for Medium- and Heavy-Duty Engines and Vehicles–Phase 2,<sup>273</sup> the 2016 Final Rulemaking for Emission Standards for New and Modified Sources in the Oil and Natural Gas Sector, and the 2016 Final Rulemaking for Revisions to the Emission Guidelines for Existing Sources and Supplemental Proposed New Source Performance Standards in the Municipal Solid Waste Landfills Sector. In addition, EPA has responded to public comments received on the IWG estimates in final rulemakings published since the release of the February 2021 TSD, such as the December 2021 Final Rulemaking for Revised 2023 and Later Model Year Light-Duty Vehicle Greenhouse Gas Emission Standards.<sup>274</sup> In responding to previous comments, EPA has expressed disagreement with arguments made by commenters – for example, regarding discount rates, time horizons, and the global focus of the SC-GHG estimates - but has not ignored the comments EPA has received on the IWG estimates. To the extent that the comments on these topics were raised in this rulemaking proceeding, the Agency is providing responses on these issues here, consistent with its longstanding practice of addressing public comments on its RIA accompanying rulemaking actions.

<sup>274</sup> <https://nepis.epa.gov/Exe/ZyPDF.cgi?Dockey=P1013NRH.pdf>

Finally, contrary to one commenter's assertion that "nowhere does EPA represent that the report is in draft form", the EPA clearly labeled the report as an "external review draft" in the Supplemental Proposal Preamble, the Supplemental Proposal RIA (p. 189), and in the Supplementary Material to the RIA, which was titled "External Review Draft of the Report on the Social Cost of Greenhouse Gases: Estimates Incorporating Recent Scientific Advances". In the Supplemental Proposal Preamble, the EPA "invite[s] the public to comment on both the sensitivity analysis of the monetized climate benefits and the accompanying external review draft technical report that the EPA has prepared that explains the methodology underlying the newer set of SC-CH<sub>4</sub> estimates... The monetized climate benefits calculated using the SC-CH<sub>4</sub> are included in the benefit-cost analysis, and thus, as is generally the case with any analytical methods, data, or results associated with RIAs, the EPA welcomes the opportunity to continually improve its understanding through public input on these estimates."

Comment: Some commenters questioned the relationship between EPA's update and the IWG process under E.O. 13990.

Commenters (2301-U.S. Chamber of Commerce, 2428-API) express confusion about why EPA operated outside of the IWG process. Commenters (2339-INGAA, 2428-API, 2361-EPRI, 2237-NDIC, 2254-PBPA) argue that EPA acted in violation of Executive Order 13990. Commenter (2450-Williams Companies, Inc.) argues that EPA does not sufficiently explain "why the agency departed from the process set forth in EO 13990, why it felt compelled to act independently of the IWG, of which it is a member, or why the IWG's Interim Estimates were inadequate for this rulemaking analysis."

Commenters (2428-API, 2339-INGAA) highlight that EPA, despite being a member of the Interagency Working Group on the Social Cost of Greenhouse Gases, has developed its own agency-specific SC-GHG estimates in the SC-GHG Report. The commenters view this development as incompatible with the unified approach promised by the Biden administration and as contrary to E.O. 13990. The commenters emphasize that the IWG's development of a SC-GHG highlights the multiple areas of expertise needed to perform such calculations, which is not likely found in a single agency like EPA.

Commenter (2339-INGAA) suggests that EPA's use of its own SC-GHG estimates in regulatory analysis conflicts with E.O. 13990, deviates from the IWG process, and creates regulatory uncertainty for industry. Specifically, the commenter states that EPA violates the following components of E.O. 13990: (1) The IWG shall proceed by publishing interim SC-GHG figures within 30 days and final SC-GHG figures by January 2022, and (2) the IWG shall provide recommendations regarding "a process for reviewing and, as appropriate, updating" the SC-GHG estimates and the underlying methodologies on which they are based, and most critically, (3) that agencies shall use the IWG's interim SC-GHG estimates "when monetizing the value of changes in greenhouse gas emissions." The commenter states that EPA has acted contrary to those instructions by issuing and employing its own entirely different SC-GHG estimates. Specifically, the commenter believes that EPA is supposed to work as a member of the IWG, and not promulgate its own unilateral issuances in contradiction to the process contemplated in E.O. 13990. The commenter recommends that EPA ceases use of these SC-GHG estimates in decision making and revoke its Draft Report.

Commenter (2361-EPRI) raises concerns over EPA's issuance and use of its own new SC-GHG estimates being procedurally improper. Specifically, concerns involve violation of Executive Order 13990, undermining the purpose for which the IWG was established, and the creation of an unnecessary and harmful regulatory uncertainty for the industry.

Commenter (2428-API) expressed concern that, given that EPA's SC-GHG Report contains the most recent estimate of the SC-GHG provided by the federal government, other federal agencies may utilize the estimates in EPA's SC-GHG Report rather than the estimates in the IWG's 2021 Interim TSD. The commenter noted that although E.O. 13990 requires agencies use the IWG's values, EPA's lack of a clear statement of "what the SC-GHG Report is or how its estimates are to be used perpetuates a serious concern that EPA's values may be misapplied in a variety of different regulatory and administrative contexts."

Commenter (2301-U.S. Chamber of Commerce) expresses support for the appropriate consideration of GHG emissions as part of benefit-cost analyses under E.O. 12866 and reemphasizes their June 2021 comments to the IWG on the need for an open, transparent, and centralized IWG process and urges continued efforts to promote those values. The commenter noted that following the IWG's release of interim SC-GHG estimates and the accompanying Technical Support Document in February 2021, they were encouraged by planned updates to the IWG process, including additional public comment and peer review on the estimates, while also reserving judgment until further details are provided on the approach of the peer review. The commenter argues the agency's decision to include the External Review Draft in this rulemaking has now sowed confusion among interested parties about whether this represents an official update to the IWG SC-GHG, raises concerns as to the cohesiveness of the IWG, could potentially lead to delays in finalizing and implementing any final methane regulations, and hinders the credibility of the External Review Draft. The commenter argues that EPA's decision to release the External Review Draft independent of the IWG "may set a new precedent, whereby each agency under the IWG's umbrella will publish its own SC-GHG estimates, which would defeat the entire purpose of the uniform IWG process and foster nothing but continuing regulatory uncertainty." To remedy these concerns, the commenter recommends that EPA withdraw the External Review Draft and defer to the IWG for updating SC-GHG estimates under E.O. 13990.

Response A-7-5: EPA disagrees with the commenters' contention that it is procedurally improper for the Agency to develop updated SC-GHG estimates for use in RIA analysis. As an initial matter, commenters rely on an executive order that by its own terms creates no right or benefit enforceable against the U.S. government by any party. *See* E.O. 13990 sec. 8(c).

EPA is a member of the Interagency Working Group (IWG) that was reconstituted in 2021 under Executive Order (E.O.) 13990 and is in the process of developing a comprehensive update of its recommended SC-GHG estimates. In February 2021, the IWG recommended the interim use of the most recent SC-GHG estimates developed by the IWG prior to the group being disbanded in 2017, adjusted for inflation (IWG 2021). As discussed in the February 2021 TSD<sup>275</sup>, the IWG

---

<sup>275</sup> Interagency Working Group on Social Cost of Carbon (IWG). 2021 (February). *Technical Support Document: Social Cost of Carbon, Methane, and Nitrous Oxide: Interim Estimates under Executive Order 13990*. United States

concluded that these interim estimates reflected the immediate need to have SC-GHG estimates available for agencies to use in regulatory benefit-cost analyses and other applications until updated estimates that address the National Academies' recommendations are available. The IWG's February 2021 TSD recognized the limitations of the interim estimates and encouraged agencies to use their best judgment in, for example, considering lower discount rates.

The EPA is committed to making evidence-based decisions pertaining to the methodologies used in EPA analyses, guided by the best available science and input from the public and peer reviewers. Thus, as noted in previous EPA regulatory impact analyses and the Proposal RIA and Supplemental Proposal RIA for this action, while the EPA is participating in the IWG's work under E.O. 13990, the Agency is also continuously reviewing developments in the scientific literature, including more robust methodologies for estimating the magnitude of the various direct and indirect damages from GHG emissions, and looking for opportunities to further improve SC-GHG estimation going forward. EPA's development of updated SC-GHG estimates, and use of these estimates in sensitivity analysis in an RIA along with an external peer review and public comment process, is similar to the process by which SC-CH<sub>4</sub> estimates were first used in EPA RIAs. As explained in the SC-GHG Report, the EPA began using estimates of SC-CH<sub>4</sub> and SC-N<sub>2</sub>O from Marten et al. (2015)<sup>276</sup> in RIAs starting in 2015. The Marten et al. estimates were first applied in sensitivity analyses in RIAs of proposed rulemakings with CH<sub>4</sub> and N<sub>2</sub>O emission impacts.<sup>277</sup> Following the completion of an external peer review of the application of these estimates to federal regulatory analysis, the estimates were used in the main analysis of other rulemakings with CH<sub>4</sub> emissions impacts (see EPA 2015a<sup>278</sup>, 2015b<sup>279</sup>, 2016a<sup>280</sup>, 2016b<sup>281</sup>, and EPA and DOT (2016)<sup>282</sup> for a discussion of public comments received on the valuation of non-CO<sub>2</sub> GHG impacts in general and the use of the Marten et al. (2015) estimates). In August 2016, the IWG folded these SC-CH<sub>4</sub> and SC-N<sub>2</sub>O estimates into their SC-GHG

recommendations to agencies within an addendum to the IWG's TSD (IWG 2016a<sup>283</sup>, 2016b<sup>284</sup>). EPA's updated SC-GHG estimates and accompanying report will be among the many technical inputs available to the IWG as it continues its work.

The EPA disagrees that EPA's release of updated SC-GHG estimates within an EPA RIA will create regulatory uncertainty for industry and other stakeholders. As described above, the EPA provides notice and public comment opportunities on each proposed regulation and its accompanying analyses, including any use of the SC-GHG in benefit-cost analyses. Thus, regulated entities and other interested stakeholders can anticipate having the standard opportunities for public comment on any proposed rule for which any SC-GHG estimates are applied in an analysis either accompanying or supporting such rulemaking. In this instance, commenters, including those here, had the opportunity to comment on all aspects of the data and methodologies that inform the presentation of the SC-GHG values in the final RIA accompanying this action.

Comment: Commenters (2301-U.S. Chamber of Commerce, 2361-EPRI) criticize the EPA peer review process of its External Review Draft and argue that this process was insufficient.

Commenter (2361-EPRI) suggests that EPA's proposed peer review and overall scientific process is insufficient to develop scientifically robust and reliable estimates and insufficient for the public to have confidence in the outcome. The commenter suggests that EPA implement the following changes: (1) Revise the peer review candidate selection process to ensure full and unbiased coverage of the core scientific disciplines underpinning the SC-GHG, (2) Expand the peer review process to a scientific review process, (3) Submit the External Review Draft to a peer review panel of at least 14 appropriate panelists, including two experts per relevant core scientific discipline, (4) Conduct a peer review appropriate for regulatory methodology, which should seek to provide the public with confidence in the outcome, (5) Substantially increase opportunities for public engagement and input, and (6) Improve the overall scientific process for developing and using SC-GHG estimates. The commenter highlights a recent EPRI article that discusses the importance of these suggestions, particularly pertaining to appropriate peer review.<sup>285</sup> Specifically, the commenter suggests that EPA explicitly requests a peer review of the scientific reliability and robustness of the methodology and estimates, selects an appropriate peer review panel to carry out the review, requires consensus recommendations from the review panel, provides a transparent process with public input regarding the panel selection, and to revise the panel selection criteria for the needed core science expertise while avoiding conflicts of interests and following all existing peer review guidance.

<sup>284</sup> Interagency Working Group on the Social Cost of Greenhouse Gases (IWG). 2016b (August). *Addendum to Technical Support Document on Social Cost of Carbon for Regulatory Impact Analysis under Executive Order 12866: Application of the Methodology to Estimate the Social Cost of Methane and the Social Cost of Nitrous Oxide*. United States Government. [https://www.epa.gov/sites/default/files/2016-12/documents/addendum\\_to\\_sc-ghg\\_tsd\\_august\\_2016.pdf](https://www.epa.gov/sites/default/files/2016-12/documents/addendum_to_sc-ghg_tsd_august_2016.pdf)

<sup>285</sup> Rose, S, 2022. Putting science first in creating and using the social cost of carbon, The Hill, November 18, [thehill.com](https://thehill.com)

Commenter (2301-U.S. Chamber of Commerce) states that as EPA appeared to be taking lead in organizing the peer review process of the IWG's updated SC-GHG estimates on behalf of the IWG and the agencies, it was assumed that further iterations of the SC-GHG estimates would be published for peer review by the IWG directly under a separate OMB docket. The commenter adds that by releasing the External Review Draft as an appendix to the Methane Proposal, EPA has limited the public's awareness of this draft largely to those potentially subject to any finalized methane regulations, despite the fact that SC-GHG estimates will have a much broader impact. The commenter expresses concern that including the External Review Draft unnecessarily opens the Methane Proposal up to additional risk of legal challenges that could delay its implementation.

Response A-7-6: The EPA believes that conducting a transparent, high-quality external peer review of the updated SC-GHG estimates is important to ensure that the methodological updates adopted in EPA's SC-GHG Report are consistent with economic theory and reflect the latest science. The EPA disagrees with the commenters' assertions that the peer review of the SC-GHG Report was insufficient or that the process was unclear. EPA conducted the peer review of the draft SC-GHG Report consistent with the guidelines set forth in EPA's Peer Review Handbook 4th Edition, 2015.<sup>286</sup>

The peer review was independently managed by a contractor to EPA. The contractor reviewed the public nominations received in response to a 21-day call for peer reviewer nominations that ended on February 15, 2022 [federalregister.gov/d/2022-01387] to ensure they have the types of disciplinary expertise listed in the notice and used traditional techniques (e.g., a literature search) to identify additional qualified candidates in the disciplines described below. The contractor then developed a list of 14 candidate reviewers. EPA invited public comment on all 14 candidates. The 21-day comment period closed December 1, 2022. After review and consideration of public comments received on the candidates, the contractor selected the final panel of 7 experts in a manner consistent with EPA's Peer Review Handbook 4th Edition, 2015 (EPA/100/B-15/001), based on the following factors: (1) Demonstrated expertise through relevant peer-reviewed publications in one or more of the following areas: environmental economics, climate science, integrated assessment modeling, and benefit-cost analysis; (2) professional accomplishments and recognition by professional societies; (3) demonstrated ability to work constructively and effectively in a committee setting; (4) absence of conflicts of interest; (5) no appearance of partiality; (6) willingness to commit adequate time for a thorough review of the draft report, including preparation of individual written comments that will be made publicly available; and (7) availability to participate virtually in a public peer review meeting and to provide subsequent revised individual comments. The contractor then independently conducted a conflict of interest (COI) screening of the candidates and final selected reviewers to confirm that those listed have no COI in conducting this review. The contractor ensured that the peer reviewers did not participate in the development of the product being reviewed and are independent of EPA as required under OMB's Final Information Quality Guidelines for Peer Review (p. 38).

In addition to the two opportunities for comment during the peer review selection process as described above, the public was also invited to attend the meeting of the peer review panel on

---

<sup>286</sup> [https://www.epa.gov/sites/default/files/2020-08/documents/epa\\_peer\\_review\\_handbook\\_4th\\_edition.pdf](https://www.epa.gov/sites/default/files/2020-08/documents/epa_peer_review_handbook_4th_edition.pdf)

March 29, 2023. The EPA posted the charge questions on the EPA webpage and provided public notice of the peer reviewer meeting 3 weeks in advance. Since the public comment period on the Supplemental Proposal closed on February 13, 2023, the public comments received on the Supplemental Proposal were also available to the peer reviewers as they conducted their review. Some peer reviewers even cited public comments in their final report. The EPA posted a recording of the public meeting on the webpage and posted the final peer review report following its completion in May 2023.

The peer reviewers commended the agency on its development of this update, calling it a much-needed improvement in estimating the SC-GHG and a significant step towards addressing the National Academies' recommendations with defensible modeling choices based on current science. The peer reviewers provided numerous recommendations for refining the presentation and for future modeling improvements, especially with respect to climate change impacts and associated damages that are not currently included in the analysis. Additional discussion of omitted impacts and other updates have been incorporated into the SC-GHG Report to address peer reviewer recommendations. Complete information about the external peer review, including the peer reviewer selection process, the charge questions and final report with individual recommendations from peer reviewers, and the EPA's response to each recommendation is available at: <https://www.epa.gov/environmental-economics/scghg-td-peer-review>.

**COMMENTS NAME:** Mass Comment Campaign by Faculty from the University of Texas and Texas AM College Systems. (email)

In the U.S. oil and gas production is the largest industrial source of methane pollution. This pollution is accelerating the pace of climate change and harming the health of our families and communities — and it's only getting worse.

This issue hits close to home. The University of Texas is the fifth-largest oil producer in the state, with 10,000 oil wells in West Texas on land owned by the University. Unfortunately, these wells have been shown to consistently release harmful methane into the atmosphere with little regulation - in 2017, these wells flared as much as 5.2 billion cubic feet of natural gas. Despite University of Texas researchers publishing a number of studies on the dangers of flaring, and UT representatives speaking out against methane flaring, University Lands has failed to implement any substantial solutions. We now call upon the EPA to make certain that its potential new guidelines protect people and the planet from these toxic releases.

While EPA's proposed methane safeguards are an important step in the right direction, they do not go far enough, and must be strengthened in order to protect communities on the frontlines of oil and gas development, and confront the climate crisis head-on. The EPA must strengthen their proposed rule to protect public health and the climate, through a supplemental rulemaking or other action, in order to:

1. End the wasteful and dangerous practice of routine flaring at oil and gas facilities, as states like Colorado and New Mexico have done already.
2. Require regular monitoring at all smaller, high-polluting and leak-prone wells, and
3. Work to incorporate emission monitoring results generated by community groups and other third parties into its standards.

We cannot miss out on this opportunity to cut methane pollution, safeguard public health, and act on climate. That means strengthening your proposed rules to finalize the most comprehensive methane safeguards that finally reign in methane waste from oil and gas companies and hold polluters accountable.

Dear EPA Administrator Michael Regan,

I applaud the EPA for taking action to curb oil and gas methane pollution on behalf of the 12.5 million people living in our country who live near oil and gas drilling operations and all of us who face impacts from climate change. I specifically support federal methane standards for existing equipment and requiring zero-emitting pneumatic controllers at all new and existing sites. Thank you for also improving on the Obama Administration's oil and gas standards by, for example, including emission reduction requirements for liquids unloading events, regulating methane at storage tanks, and increasing the frequency of leak monitoring at many oil and gas wells.

However, I believe the EPA must go even further by increasing mandatory leak inspections to monthly for all wells and compressor stations and by eliminating the exemption from regular monitoring from those for wells that are calculated to emit below three tons per year of methane. We urge the EPA to further study advanced LDAR monitoring as one way of increasing the scope of its monitoring requirements.

In addition, flaring is a major nuisance and source of pollution for local communities near oil and gas operations. It must also be strictly limited so that operators can no longer flare associated gas at oil wells on a routine basis. I also urge the EPA to propose standards for abandoned or orphaned wells that require owners and operators to plug and control emissions from these sources, which are responsible for huge amounts of uncontrolled pollution.

Finally, I strongly support the EPA creating a community monitoring program. People who live near oil and gas operations are already documenting flaring, leaks, and other pollution that directly harms them. I support the EPA studying the relevant legal and technical considerations in order to establish an effective program where third-parties, citizen groups, and others could identify leaking equipment so as to ensure rapid repairs.

Thank you for the opportunity to comment.

**New Mexico. (web)**

We submitted our own organizational comment earlier today. Attached please find the petition we sent to members asking for their sign on. In just over a week, we received 631 signatures. New Mexico's own methane rules are divided between the Oil Conservation Commission, which already approved stringent rules on waste from venting and flaring, and the Environmental Improvement Board, which will announce its decision on leaks of ozone precursors later this year. Combined, the two rules make New Mexico a national leader in reducing methane emissions, an issue important to our members, many of whom live in the two major oil and gas basins in the state: the San Juan Basin in the northwest and the Permian Basin in the southeast and who regularly report their health impacts and the damage to the air, land and water in their region.

**Association. (web)**

Dear Administrator Regan:

As physicians, nurses, public health professionals and healthcare workers dedicated to providing our patients with a healthy future, we urge you to finalize comprehensive, loophole-free methane safeguards.

We thank the U.S. Environmental Protection Agency (EPA) for recognizing the threats posed by pollution from the oil and gas industry, and for proposing a rule to cut methane and other harmful pollutants from new and existing oil and gas operations. We urge EPA to strengthen and finalize the proposal into law without delay.

Climate change is a health emergency, and methane - a significant component of what is often referred to as "natural" gas - is a powerful climate pollutant. Methane is a dangerous greenhouse gas. Eighty-six times more potent than carbon dioxide, it is making our planet warmer, and public health is being harmed. To avoid catastrophic tipping points in the climate system, we must reduce greenhouse gases, including methane, dramatically and immediately. A recent report from the Lancet Medical Journal highlighted that without aggressive action to slash greenhouse gas pollution, the climate crisis will become the "defining narrative of human health." The proposed rule is a vital step forward in addressing these health threats, but must go further.

Stronger final rules will not only curb greenhouse gases, they will also result in immediate public health benefits by reducing volatile organic compounds, or VOCs. Some VOCs can cause cancer, affect the nervous system, or cause birth defects. In addition to being toxic, VOCs contribute to the formation of ground-level ozone pollution, which causes respiratory and cardiovascular harm, heart attacks and asthma attacks, stroke and early death. Ozone is also linked to premature birth, which with low birth weight is a leading cause of infant death. Communities living near oil and gas operations are especially at risk from these toxic emissions, and strong final standards are crucial to protect them.

We urge you to strengthen the proposed rule to reduce methane pollution from new and existing oil and gas operations by 65 percent of 2012 levels by 2025. This is an achievable target, and one that can be met using existing technologies, at low cost. We also urge you to strengthen requirements for smaller, low-producing wells require more frequent leak detection monitoring and repair; and put an end to the practice of routine flaring (burning of waste gas that results in harmful air pollution.) Requiring the oil and gas industry to take the most effective steps possible to prevent fugitive emissions of methane and other gases, and to capture those gases that do escape, will reduce climate pollution and result in direct health benefits in communities near oil and gas operations.

We urge EPA to strengthen and then quickly finalize requirements for new, reconstructed and modified oil and gas wells and equipment and standards for existing sources.

**COMMENTS NAME: Mass Comment Campaign submitted by member of Moms Clean Air Force. Sample attached (email)**

As a parent and member of Moms Clean Air Force, I'm deeply concerned with the health impacts of air pollution and climate change. That's why I was encouraged to learn that the EPA has proposed rules to cut methane and other harmful air pollutants from new and existing oil and gas operations.

This is an important first step to address the impacts of methane pollution. That's why I urge you to ensure that these rules are strong and comprehensive. They must cover all sources of oil and gas operations including smaller, leak-prone wells and limit routine flaring, both of which are outsized sources of methane emissions. Quickly and significantly reducing methane pollution is one of the best levers we have to slow the rate of climate change now, and it will help clean up the air to protect children's health.

Federal methane rules will establish vital protections for all children across the nation, especially for states that have failed to enact meaningful oil and gas methane protections at the state level.

Please ensure that the EPA passes comprehensive methane rules to protect our children's health and future.

**COMMENTS NAME: Mass Comment Campaign sponsored by National Religious Partnership for the Environment. (web)**

Dear Administrator Regan:

The proposed rules by the Environmental Protection Agency are an important step forward in undercutting the harms of methane pollution and addressing climate change. These standards can help protect communities, especially black communities, which are hit hard by climate change and air pollution.

With more than 1 million African-Americans living within a half-mile of an existing natural gas facility, methane pollution leaves these communities exposed to toxic air pollution, with negative health impacts including cancer, reproductive and respiratory problems.

These rules rightly regulate the oil and natural gas sector, the largest industrial source of methane, which is a potent climate pollutant 80 times more powerful than carbon dioxide. Reducing methane pollution can moderate the near-term impacts of climate change, which disproportionately affect low-wealth communities and communities of color. In study after study communities of color have been shown to disproportionately bear the burden of climate impacts. In the US, people of color have been found to be more vulnerable to heatwaves and extreme weather events, exasperating the systemic racism that is already suffered.

As Christians, we are called to care for God's creation and our communities, particularly the most vulnerable such as children, low-income families, and communities of color. Issuing national standards on methane will help care for these communities, including black communities, by protecting them from methane pollution and curbing climate change.

As Black Church leaders and lay leaders in Ohio, we the EPA to make methane pollution safeguards strong and work to protect all communities and in particular black communities.

**MAILER SECTOR: Other Advocacy Group**

**DOCKET NO.: [EPA-HQ-OAR-2021-0317-1431](#)**

**COMMENTS NAME: Mass Comment Campaign sponsored by Evangelical Environmental Network (EEN) (paper)**

Dear Administrator Regan:

On behalf of 133,242 pro-life Christians, I am honored to submit their supportive comments to the Environmental Protection Agency regarding the referenced proposed regulations.

*As pro-life Christians, we want the air we breathe to be safe for our children. But leaks in our oil/gas infrastructure spew toxic pollutants that put God's creation and our families - pregnant mothers and the unborn - in harm's way. Unborn children close to leaks are at higher risk of birth defects, and children attending school near leaks have higher rates of cancer and asthma.*

*That's why Christians are calling on the EPA to ensure that stronger regulations and inspections will cut this pollution from both existing and new leaks, particularly from low-producing wells. Our kids deserve better.*

We are thankful for EPA's proposed rules that will defend children's health. We are especially thankful that the new proposed standards are based on actual methane emissions instead of the amount of oil and gas production. Recent studies clearly prove that many smaller, leak-prone wells have disproportionately high emission rates of methane and associated gases.<sup>i</sup> Under the new emission-based rule, these methane superemitters will no longer slip through the cracks. Combined, the two standards will save \$6.6 - \$9.2 billion in avoided health costs and loss of life. While this indeed is good news, the proposed standards in the rule would be strengthened by incorporating the following:

- A ban on routine flaring except in emergency situations.
- Quarterly inspection via LDAR (Leak Detection and Repair) procedures of all wells with 2 tons per year (tpy) of methane emissions or greater. **(This recommendation is based on EPA's own conclusion in the proposed rule, which states: "...sites with total baseline methane emissions of 2 tpy, we conclude that regular monitoring at semiannual or quarterly frequencies would be cost-effective.")** Based on this conclusion that quarterly inspection of well sites with 2tpy emissions is cost-effective, we recommend that the 3-tpy-emissions threshold in the currently proposed standard be reduced to 2tpy-emissions and that the frequency of inspections be increased to quarterly.
- Sites below 2 tpy emission need to be inspected at least annually.
- Require a time limit on the need to replace all pneumatic valves and actuators.
- Develop a process for the incorporation of monitoring data from third-parties. The expanded monitoring may result in a major public health benefit.

- We look forward to secondary proposal due in Spring 2022 and hope that new methodologies for monitoring are approved and incorporated.

In the U.S., oil and gas production is the largest industrial source of methane pollution. Each year, the oil and gas industry releases 16 million metric tons of methane, and without immediate action, methane pollution from the industry will continue to skyrocket. We urge the EPA to promulgate these standards in the most expeditious fashion to defend our children and their future.

**COMMENTS NAME: Mass Comment Campaign by public representatives from the Commonwealth of Pennsylvania. (web)**

On behalf of the undersigned 59 public representatives from the Commonwealth of Pennsylvania, we write to you today in support of strong and comprehensive requirements to cut methane pollution from oil and gas operations. As the second largest producer of natural gas in the nation, and with significant numbers of both old and new well sites and infrastructure, our state is a prime example of why these strong standards are critical.

Methane, the principal component of natural gas, is over 80 times more potent than carbon dioxide over a 20-year time period. Recent studies found U.S. methane emissions levels to be 60% greater than currently estimated by the Environmental Protection Agency (EPA). Strange and severe weather events accelerated by climate change are already costing Pennsylvanians hundreds of millions of dollars, left people homeless, and flooded farmland.

In addition to methane, smog-forming volatile organic compounds (VOCs) and toxic hazardous air pollutants (HAPs), including cancer-causing agents such as benzene, are released by oil and gas operations. Smog is associated with 1.1 million summertime asthma attacks in children. This pollution contributes to the smog challenges across the state, especially in major metropolitan areas.

As elected officials, we are critically aware of the importance of protecting public health – both from a broader climate concern as well as considering local air quality and pollution impacts to our constituents and communities. This is a problem facing every resident of our state but especially frontline communities that must live with the oil and gas infrastructure and activity on a daily basis. The need for meaningful and inclusive standards is acute across Pennsylvania and

the benefits that can be achieved by strong rules that go far beyond emission reductions to real dollars that can be measured in the improved health of our children, families, friends, and neighbors.

We commend the EPA for proposing a rulemaking to reduce methane emissions at existing sites and facilities, as well as your consideration of a supplemental rulemaking to address leak detection and repair for smaller, leak-prone well sites. These well sites are found throughout our state, and their numbers are growing each and every year. It's important to note that low-producing wells are responsible for almost half of the methane pollution from oil and gas sources in Pennsylvania, or over half a million tons annually. According to the University of Cincinnati's Amy Townsend-Small, Ph.D., many wells that produce less than a barrel of oil per day leak into the atmosphere more than 100 percent of their reported gas production.

We appreciate the agency requiring an initial inspection but absent regular and frequent inspection requirements, these wells pose a considerable threat that – unless addressed fundamentally undermines the goals of this proposed rulemaking.

Thankfully, we have common sense solutions to reduce emissions that are cost-effective and will put people to work to find and fix leaks. Plus, reducing methane means less energy waste and more revenue to offset costs. That is a win for our environment and our economy.

We urge you to expeditiously develop and finalize comprehensive rules that cover all oil and gas well sites.

**Sample attached (web)**

I am writing in support of the EPA's proposed methane standard and to ask that the EPA take stronger action to reduce methane pollution. Over 12.5 million Americans live near enough to oil and gas drilling to be at risk for its health impacts, and methane is a major contributor to global warming as it is 86 times more potent of a greenhouse gas than carbon dioxide. Addressing Methane pollution is also an environmental justice issue. Oil and gas pollution disproportionately affects people of color, who have higher rates of health conditions associated with gas wells.

The long-overdue methane standards for existing oil and gas operations will help protect the health of communities harmed by oil and gas pollution and reduce the impact of methane pollution on climate change. Other provisions, including regulating methane from storage tanks and more frequent monitoring for methane leaks, will similarly have significant positive impacts on health and climate.

While we applaud the EPA for taking these important steps to regulate methane, the new rule does not go far enough to reduce methane pollution and allows for significant gaps in regulating emissions that will continue to expose people living near gas wells to severe health risks.

I urge the EPA to take stronger steps to reduce methane pollution by doing the following:

- Require monthly leak inspections at all wells and compressor stations and eliminate exemptions for smaller, high-polluting and leak-prone wells, including for wells that produce less than three tons per year of emissions.
- End routine flaring at oil and gas facilities, as states like Colorado and New Mexico have done already. Flaring is dangerous, wastes natural resources, and creates pollution that harms health and climate.
- Create a community monitoring program and incorporate community monitoring into the methane standard.
- Create standards for abandoned or orphaned wells that require owners and operators to plug and control emissions from these sources, which are responsible for huge amounts of uncontrolled pollution.

Strengthening the proposed methane rule is essential to protecting the health of communities suffering the impacts of oil and gas pollution and achieving the U.S.'s climate goals.

As a person of faith and conscience, I am writing to thank you for the recent rules on methane pollution from the oil and gas industry. The rules as proposed are an excellent start, but this critical moment of the climate crisis demands we do as much as possible immediately.

I am asking EPA to strengthen the proposed rule to end the wasteful and dangerous practice of routine flaring at oil and gas operations, as states like Colorado and New Mexico have done already. As I understand it, flareless completion is a reasonable alternative that may not even increase costs significantly.

([https://earthworks.org/issues/flareless\\_completions/#sthash.YKyufYb6.dpuf](https://earthworks.org/issues/flareless_completions/#sthash.YKyufYb6.dpuf))

I also ask EPA to require regular monitoring at all smaller, high-polluting and leak-prone wells.

All faith traditions share a sacred calling to care for the earth and to care for those who are most vulnerable in our communities. As a Unitarian Universalist minister, I lead a community with a deep commitment to respecting the interdependent web of which we are all a part. As a trained climate economist, I understand that our current practice of excessive emissions give us short-

term gains with a completely unaffordable long-term price tag.

Methane pollution causes deep and irreparable harm, polluting not only the land and the air, but also jeopardizing the health of children and those living in frontline communities.

Methane is a potent greenhouse gas and it's responsible for a quarter of the warming that we are experiencing today. We know that far too much is leaking from oil and gas operations and contributing to the climate crisis while wasting this resource and endangering public health. Our EPA must implement rules that will cut methane pollution from oil and gas operations 65 percent by 2025 while eliminating any loopholes around flaring and smaller wells that can contribute outsized methane pollution.

It is EPA's obligation and moral opportunity to protect all Americans from harmful methane pollution.

Thank you.

**COMMENTS NAME: Mass Comment Campaign sponsoring organization unknown.**

**Sample attached (web)**

Methane pollution is threatening our communities and wildlife by driving climate change.

In the U.S., oil and gas production is the largest industrial source of methane pollution. This pollution is accelerating the pace of climate change and harming the health of our families and cherished wildlife — and it's only getting worse. Thanks to the Environmental Protection Agency's new proposed rule, we now have an opportunity to restore regulations that rein in methane pollution.

The rule promises to cut methane emissions by 41 million tons. Because methane acts as a super-pollutant in the near-term, these reductions will help buy the U.S. time to continue working to solve the climate crisis and protect people and wildlife from unavoidable impacts. The rule also will reduce volatile organic compound (VOC) emissions by 12 million tons and hazardous air pollution by 480,000 tons, which will help prevent lung disease and asthma, smog, and premature death.

While EPA's proposed methane safeguards are an important step in the right direction, they do not go far enough, and must be strengthened in order to protect communities on the frontlines of oil and gas development, and confront the climate crisis head-on. EPA must strengthen their proposed rule to protect public health and the climate, through a supplemental rulemaking or other action, in order to:

1. End the wasteful and dangerous practice of routine flaring at oil and gas facilities, as states like Colorado and New Mexico have done already.
2. Require regular monitoring at all smaller, high-polluting and leak-prone wells, and work to incorporate emission monitoring results generated by community groups and other third parties into its standards.

We cannot miss out on this opportunity to cut methane pollution, safeguard public health and wildlife, and act on climate. That means strengthening the agency's proposed rules to finalize the most comprehensive methane safeguards that finally rein in methane emissions from oil and gas operations.

Thank you for your consideration.

Methane pollution from the oil and gas sector is accelerating the pace of climate change and harming the health of our families and communities across the country. That is why we are counting on the Environmental Protection Agency (EPA) to quickly finalize the strongest possible safeguards to cut methane and other harmful pollution from the oil and gas industry.

The updated draft rule improves upon or maintained many of the standards in the original draft rule released by EPA in 2021 identified by climate, public health, and environmental justice advocates like me, including by ensuring all wells are regularly and frequently inspected for leaks and that outdated pneumatic equipment is replaced with zero-emitting options. But there is more work to be done to ensure that communities like mine are protected.

EPA must do more to ensure that:

- Operators at wells capture associated gas and limit flaring of that gas in instances in which it is necessary for safety or maintenance reasons;
- Strengthen the standards to address emissions from storage tanks by making the standards applicable to more tanks; and
- Provide a clear pathway for participation in the Super Emitter Response Program by ensuring communities and citizens can access data and technologies to help reduce methane and other pollutants in the areas where we live and work.

My community is counting on your agency to quickly address these concerns, and to finalize strong, comprehensive new and existing source rules to cut methane pollution from the oil and gas sector before it's too late.

Thank you for your consideration.

**COMMENTS NAME:** Mass Comment Campaign sponsored by Evangelical Environmental Network (EEN). (web) (part 1)

As pro-life Christians, we want the air we breathe to be safe for our children. But leaks in our oil/gas infrastructure spew toxic pollutants that put God's creation and our families - pregnant mothers and the unborn - in harm's way. Unborn children close to leaks are at higher risk of birth defects, and children attending school near leaks have higher rates of cancer and asthma.

That's why Christians are calling on the EPA to ensure that stronger regulations and inspections included in EPA's Methane Supplemental Rule are never weakened. We want maximum protection for our children from pollution, particularly from low-producing wells.

We also call on EPA to make the rule stronger by:

- Limiting flaring except as needed for safety or maintenance.
- Including all storage tanks in the standard to reduce the leaks.
- Providing a clear way for communities to monitor and report large leaks from the oil and gas industry.

**MAILER SECTOR:** Non-profit, Public Health & Environmental Advocacy Group

**DOCKET NO.:** [EPA-HQ-OAR-2021-0317-2484](#)

**COMMENTS NAME:** Mass Comment Campaign sponsored by American Lung Association (ALA) et al. (web)

Dear Administrator Regan:

As representatives of regional, state and local health organizations and societies committed to patient care and public health, we support strong protections against environmental health harms. The U.S. Environmental Protection Agency (EPA) proposal to limit pollution from oil and gas operations is necessary to mitigate the immediate and long-term health risks resulting from the extraction, transportation and storage of oil and gas. We thank EPA for the updates made to the original proposal and urge the quick finalization of a strong rule no later than August 2023.

Protecting health, for our patients as well as practitioners and caregivers, is our top priority. But there is only so much that we and the institutions and constituents we represent can do at an individual level to protect health from outdoor air pollution. Enforceable rules to limit leaking of toxic air pollutants and climate pollutants like methane will immediately benefit public health in communities across the country and help stave off catastrophic effects of climate change.

Methane is a highly potent greenhouse gas that is accelerating climate change. Climate change poses threats to the ability of health professionals to help the public and deliver life sustaining care. It also increases the number of people who seek medical care or assistance by lengthening

allergy seasons, increasing vector borne illnesses and making air pollution worse. To truly realize a healthier future for all, we must drastically reduce the emissions that are perpetuating climate change.

A strong rule will also reduce the emissions of harmful pollutants that are released alongside methane at oil and gas sites. Volatile organic compounds (VOCs) include gases identified as hazardous air pollutants such as benzene, toluene and formaldehyde, among others. Benzene and formaldehyde are known human carcinogens. Ethylbenzene, another hazardous pollutant from oil and gas emissions, is a probable carcinogen. In addition to these dangers, VOCs also interact with other emissions in the presence of sunlight to form ground-level ozone pollution. Ozone, or smog, can worsen asthma, increase hospital visits, and contribute to low-birth weight (a leading cause of infant death) and premature death.

The updates made in this supplemental proposal strengthen the rule from EPA's original proposal in some areas – including advanced leak detection and repair standards, requiring zero emission pneumatic controllers and pumps and requiring the cleanup of more abandoned wells. We urge EPA to strengthen the proposal further by requiring operators of oil wells to better protect public health by limiting routine flaring of associated gas to safety or maintenance episodes. We also ask that EPA ensure the Super Emitter Response Program, which is designed to identify and address large leaks, includes clear and accessible pathways for communities and individuals to engage in holding polluters accountable.

As health organizations, we recognize the dangers of air and climate pollution and the benefits that will be experienced by all if the nation takes significant steps to reduce emissions and lessen the use of fossil fuels. This proposal by EPA to limit pollution from the oil and gas sector is needed to provide relief to communities that have been overburdened by dangerous pollution. We urge EPA to finalize the strongest possible rule by no later than August 2023.

**MAILER SECTOR:** Non-profit, Public Health & Environmental Advocacy Group

**DOCKET NO.:** [EPA-HQ-OAR-2021-0317-2488](https://www.epa.gov/epaospr/docket-0317-2488)

**COMMENTS NAME:** Mass Comment Campaign sponsored by Environment America, U.S. PIRG and Environmental Action. (web)

I applaud the EPA for proposing an updated methane rule that would curb significant sources of methane emissions. Still, the current draft of the rule contains loopholes that could allow unmitigated releases of methane to continue, especially through the practice of routine flaring and venting of methane directly into the atmosphere.

In November 2021, President Biden signed onto the Global Methane Pledge to reduce world methane emissions 30% below 2020 levels by 2030. That's a great first step toward healthier air and a more stable climate -- but we risk falling short if we don't address methane flaring and other practices that vent this pollutant directly into the atmosphere.

I urge you to make the final methane rule as strong as possible by including restrictions that phase out pollution from routine flaring.

**MAILER SECTOR:** Non-profit, Public Health & Environmental Advocacy Group

**COMMENTS NAME:** Mass Comment Campaign sponsored by Environment Texas Research and Policy Center. (web)

I support the proposed new protections aimed at cutting methane emissions, which is one of the worst global warming pollutants on the planet, in the oil and gas industry. The proposed safeguards would help reduce harmful air pollution, protecting both our climate, and our health. Although the proposal is strong, there are still improvements to be made. I urge the EPA to enact the strongest possible safeguards against methane pollution.

**MAILER SECTOR:** Non-profit, Public Health & Environmental Advocacy Group

**DOCKET NO.:** [EPA-HQ-OAR-2021-0317-2493](#)

**COMMENTS NAME:** Mass Comment Campaign sponsored by PennEnvironment Research and Policy Center. (web)

We, the undersigned, thank you for proposing strong air pollution standards for new and existing gas and oil infrastructure.

We appreciate that the proposed rule will help curb dangerous climate-warming emissions, reduce the release of pollutants known to worsen asthma and other respiratory diseases, and limit harmful smog pollution.

We are also extremely supportive of the fact that the proposal requires inspections at small wells that often have leak-prone equipment as well as the requirement that abandoned wells are subject to inspections until proper closure. These requirements will help protect the health of the more than a million Pennsylvanians living near wells sites.

We also appreciate the steps taken towards addressing super-emitters through a third-party monitoring program.

At the same time, we urge the U.S. Environmental Protection Agency to strengthen the rules by phasing out pollution from routine venting and flaring. We encourage you to push for the strongest possible methane rule to protect our health, tackle climate change, and build a safer and stronger commonwealth.

Cutting methane pollution from the oil and gas industry is the quickest, most cost-effective way to slow the rate of climate change happening now and protect community and wildlife health. That is why I support the Environmental Protection Agency's (EPA) proposed updated rule to cut methane and other harmful pollutants from oil and gas operations across the country. My community has waited too long for bold action to cut methane, and we need these protections now more than ever.

Reducing methane emissions is of the utmost importance for wildlife that continue to be negatively impacted by oil and gas development that fragments their habitat and puts additional strain on threatened species through accelerating climate change.

Cutting methane pollution will also have profound effects on millions of people across the U.S. experiencing record heat. Slowing today's unprecedented rate of warming can help avert our most acute climate risks, including megafires and extreme weather. New oil and gas sector pollution limits will also help prevent greater suffering from severe health impacts caused by smog and exposure to cancer-causing toxic emissions, a particular threat to communities of color and those living near facilities.

Now, the EPA must move quickly to enact solutions for pollution and finalize the strongest possible safeguards—such as eliminating pollution from flaring, requiring regular monitoring at smaller wells with leak-prone equipment, instituting community monitoring, and requiring zero-emitting pneumatic controllers and pumps.

Every day that passes without strong federal methane rules is a missed opportunity to reduce climate and air pollution from the oil and gas industry and protect the health and well-being of communities and wildlife across this country. We cannot continue to wait. We need the Biden administration to use all of its authority to enact strong solutions for pollution that protect our health, advance justice, and fight climate change.

Dear Environmental Protection Agency,

Earlier this month, environmental justice advocates and public health experts from around the country participated in a nationwide day of action to call on President Biden to cut methane pollution from the oil and gas industry.

This effort follows a proposal from EPA that would lead to a moderate reduction in methane leaks. The Biden administration has the chance to go further, but that's only going to happen if they hear from us now.

Oil and gas development has plagued vulnerable communities with methane pollution that pollutes the air, leaving residents at higher risk of cancer, asthma, and birth defects.

President Biden and EPA must strengthen new safeguards to further reduce methane pollution from the oil and gas industry, protect public health, and address the climate crisis. Half-measures won't do enough to protect frontline communities - the federal government must do more.

**MAILER SECTOR:** State / Local Government

As local and state elected officials from across Pennsylvania, Ohio and West Virginia, including the Appalachian region, we write today to support the proposed Environmental Protection Agency regulations to reduce methane pollution and waste from new and existing oil and gas operations and to support key measures to strengthen the standards before they become final.

As elected officials who collectively represent tens of thousands of constituents, we understand firsthand how important this issue is to our communities. For generations, Appalachia has been one of the largest producers of natural gas in our country, and with significant numbers of both old and new well infrastructure, our region will benefit substantially from reduced methane emissions.

Methane, which has more than 80 times the warming power of carbon dioxide over its first 20 years in the atmosphere, is released alongside dangerous pollution such as cancer-causing volatile organic compounds (VOCs) and air toxics like benzene. VOCs can also [worsen asthma and respiratory disease](#) and cause immune system damage and developmental problems in young

children. Methane also contributes to ground-level ozone, also known as smog, which worsens air quality and presents health risks across the state, especially in major metropolitan areas.

The oil and gas industry is one of the leading sources of methane pollution in the U.S., emitting roughly 16 million metric tons of methane every year. Pollution from small wells is an outsized problem too. In fact, while low-producing wells account for just 6% of production nationwide, these wells are responsible for 50% of methane emissions at oil and gas well sites. Here in Appalachia, these wells emit 1.2 million tons of methane annually.

In the Appalachian region, large percentages of the total population live within one mile of oil and gas wells. In West Virginia, more than half of the state's residents live near active wells (50.9%), the highest percentage in the nation, while more than a quarter (25.9%) of Ohioans and almost fifteen (15%) percent of Pennsylvanians.

Cutting methane pollution and waste from the oil and gas industry is the [quickest, most cost-effective way](#) to slow the rate of climate change happening now and protect communities and the environment from the worst effects of climate-forced extreme weather events.

The proposed rule is a significant step forward in achieving this goal, and we thank you for your steadfast leadership on this issue. Specifically, the updated draft rule improves upon the 2021 proposal by:

- Closing a loophole in the leak detection and repair (LDAR) standards. This change would require inspections with optical gas imaging cameras at all wells with equipment known to malfunction, such as tanks and flares.
- Moving away from the EPA's existing production-based LDAR requirements would require routine leak inspections at all wells, including low-producing wells that are responsible for half of all methane emissions nationwide.
- Strengthening the requirements for zero-emitting oil and gas equipment by including both pneumatic pumps and controllers.
- Creating a program to more quickly address super-emitters through third-party monitoring.
- Including inspections at abandoned wells until they are properly closed and ensuring that oil and gas companies submit a closure plan and conduct a post-closure survey of these wells to ensure they are not leaking.

However, there are three clear ways these protections must be strengthened:

- Limit flaring to instances where it is necessary for safety or maintenance reasons and require operators at wells to capture associated gas.
- Strengthen emission thresholds on storage tanks.

- Ensure that all communities and individuals can participate in the Super Emitter Response Program by providing a clear pathway for engagement and ensuring that approved monitoring technologies and data are accessible to all.

These issues must be addressed to protect communities affected by oil and gas operations, stop the needless waste of energy resources, and build a healthier, more resilient climate.

We look forward to working with you and your agency to speedily finalize these important standards and get them over the finish line to protect our climate, public health, and local economies.
