Moreover, commenter (0793-PBPA) mentions that EPA has historically concluded that both routine maintenance and an increase in production rate of an existing facility (assuming no capital expenditure) are not modifications. The commenter writes, that's presumably why EPA limited wellsite modifications under NSPS OOOOa (for fugitive emissions purposes) to when a new well is drilled at an existing well site and to when a well at an existing well site is hydraulically fractured or refractured. The commenter underscores the point that these are fundamentally different than liquids unloading, which does not involve any change and instead is a routine part of initiating flow in the well production process, but rather akin to the removal of a clog.

According to the commenter (0831-AXPC), there are a number of methods an operator may use based on the engineering needs of the well, and an operator may even need to adjust the method being used over the course of the same day. Nevertheless, the commenter reiterates the point that not all methods for liquids unloading involve the venting of emissions or cause the affected facility to increase its potential to emit.

Commenter (0935-Colorado Oil and Gas Association (COGA)) asserts that EPA's reasoning to treat each unloading event as a modification that makes a well an affected facility subject to the NSPS, on the grounds that each unloading event should be seen as an operational change, is incorrect, because it conflates intermittent activities with operational changes. The commenter explains that oil and gas operations (like other industries) involve numerous intermittent activities – bypassing production to an atmospheric tank is analogous to opening a separator dump valve, starting or stopping an engine, resuming operations after a temporary shut in for maintenance, or any number of intermittent activities. The commenter contends that these activities do not constitute a modification of the facility, and neither does an unloading event.

Commenters (0564-Arkansas Independent Producers and Royalty Owners (AIPRO), 0808-American Petroleum Institute (API)) question what constitutes a “facility modification” and what is triggered by a modification; arguing that the three proposed modifications – *i.e.*, centralized production facilities (CPFs), tanks/tank batteries, and liquids unloading, in the rule do not meet the definition of a modification to a location, because they are activities at a location and not physical changes to the facilities.

Commenter (0564-AIPRO) writes that the action of liquids unloading at a facility is part of the normal operations of the facility and does not constitute a physical change to the method of operations.

Response I-12-2: Based on comments received on the November 2021 Proposal, the December 2022 Supplemental Proposal for NSPS OOOOb specifies that a modification to an existing well

occurs when the definition of modification in 40 CFR 60.14 is met, including when an existing well undergoes hydraulic fracturing or re-fracturing. The final rule maintains what was proposed in the December 2022 Supplemental Proposal. See discussion in sections IV.F.1, IV.F.3.a.i, IV.F.3.a.ii, and IV.F.3.a.iii of the December 2022 Supplemental Proposal preamble related to what EPA proposed as constituting a well affected facility/designated facility, as well as EPA's request for comments regarding operational scenarios that would constitute a modification for liquids unloading operations.<sup>2</sup> See Section 6.4.1 (Applicability) of Volume II of this RTC for comments and responses on the December 2022 Supplemental Proposal on the definition of a well affected/designated facility and what constitutes a modification under the NSPS OOOOb for liquids unloading operations. Lastly, see sections X.F.1 and 3 of the preamble to the final rule which details EPA's final standards related to well affected facilities/designated facilities and what constitutes a modification for liquids unloading operations.

Comment: Commenter (0763-Texas Commission on Environmental Quality (TCEQ) and Railroad Commission (RRC)) suggests that adding well liquid unloading as a new affected facility creates a situation where companies may need to register and certify operations to demonstrate compliance at sites that were not previously subject to TCEQ registration requirements. According to the commenter, establishing the activity as a trigger for affected facility status creates a scenario where many existing sites that are not subject to NSPS OOOOa or new NSPS OOOOb requirements will become applicable to the NSPS. The commenter adds that the November 2021 Proposal also defines every well unloading operation as a "modification;" however, this does not seem to line up with the legally defined definition of a "modification" under NSPS as a "change in operation." This will create unintended consequences where modification can trigger review under the prevention of significant deterioration (PSD) program.

Response I-12-3: Based on comments received on the November 2021 Proposal, the December 2022 Supplemental Proposal for NSPS OOOOb specifies that a modification to an existing well occurs when the definition of modification in 40 CFR 60.14 is met, including when an existing well undergoes hydraulic fracturing or re-fracturing. See discussion in sections IV.F.1, IV.F.3.a.i, IV.F.3.a.ii, and IV.F.3.a.iii of the December 2022 Supplemental Proposal preamble related to what EPA proposed as constituting a well affected facility/designated facility, as well as EPA's request for comments regarding operational scenarios that would constitute a modification for liquids unloading operations.<sup>3</sup> Please also see Section 6.4.1 (Applicability) of Volume II of this RTC for comments and responses on the December 2022 Supplemental Proposal on the definition of a well affected/designated facility and what constitutes a modification under the NSPS OOOOb for liquids unloading operations. Lastly, see sections X.F.1 and 3 of the preamble to the final rule which details EPA's final standards related to well affected facilities/designated facilities and what constitutes a modification for liquids unloading operations.

#### 12.1.1.2 Legal Considerations

Comment: Commenter (0831-AXPC) expresses concern that adopting the approach in the November 2021 Proposal—that a liquids unloading event per se represents a modification of the

---

<sup>2</sup> 87 FR 74781-74782.

<sup>3</sup> 87 FR 74781-74782.

affected facility—is not in keeping with the statute. The commenter asserts that the CAA provides that a source undergoes “modification” when it is subject to “any physical change in, or change in the method of operation of, a stationary source which increases the amount of any air pollutant emitted by such source or which results in the emission of any air pollutant not previously emitted.” [CAA section 111(a)(4), 42 U.S.C. § 7411(a)(4)] While the commenter supports the use of best management practices (BMPs) as a work practice standard to minimize the methane emissions associated with vented liquids unloading events with some clarifications, an approach under which each unloading event constitutes a modification is in conflict with the statute because liquids unloading is not, per se, either a physical change to the source or a change in its method of operation, nor does it necessarily increase the source’s emissions.

Similarly, commenter (0808-API) contends that the November 2021 proposed definition for liquids unloading poses a legal issue, because liquids unloading is necessary at many wells to achieve the production potential of the given resource. As such, the commenter contends that liquids unloading is part of normal operations for the well and therefore, does not constitute a physical or operational change to that well. Additionally, the commenter argues that because the regulatory definition of “modification” measures an emission increase in terms of the short-term potential to emit of the affected facility, it cannot be said that liquids unloading results in an emissions increase.

Commenter (0808-API) acknowledges that the D.C. Circuit has held that the definition of “modification” should be construed expansively. [*New York v. EPA*, 443 F. 3d 880, 886-7 (D.C. Cir. 2006)]. However, the commenter asserts that the court recognized that even though the term “modification” is broad, it “cannot bring an activity that is never considered a ‘physical change’ in the ordinary usage within the ambit of new source review (NSR),” which the commenter maintains is the case here, with liquids unloading.

Response I-12-4: Based on comments received on the November 2021 Proposal, the December 2022 Supplemental Proposal for NSPS OOOOb proposed that a modification to an existing well occurs when the definition of modification in 40 CFR 60.14 is met, including when an existing well undergoes hydraulic fracturing or re-fracturing. See discussion in sections IV.F.1, IV.F.3.a.i, IV.F.3.a.ii, and IV.F.3.a.iii of the December 2022 Supplemental Proposal preamble related to what EPA proposed as constituting a well affected facility/designated facility, as well as EPA’s request for comments regarding operational scenarios that would constitute a modification for liquids unloading operations.<sup>4</sup> Please also see Section 6.4.1 (Applicability) of Volume II of this RTC for comments and responses on the December 2022 Supplemental Proposal on the definition of a well affected/designated facility and what constitutes a modification under the NSPS OOOOb for liquids unloading operations. Lastly, see sections X.F.1 and 3 of the preamble to the final rule which details EPA’s final standards related to well affected facilities/designated facilities and what constitutes a modification for liquids unloading operations.

#### 12.1.1.3 Other

Comment: Commenter (0749-Petroleum Association of Wyoming (PAW)) underscores that EPA has not proposed a time component. The commenter asks, “[w]hat if a blowdown event only

---

<sup>4</sup> 87 FR 74781-74782.

lasts for 2 minutes, or 60 seconds? Would the same requirements apply as an event that lasts for a longer duration?”

Response I-12-5: The November 2021 Proposal and December 2022 Supplemental Proposal purposefully did not propose a time component for what constitutes a gas well liquids unloading event. The final rule requires owners or operators to minimize or eliminate emissions from liquids unloading operations. Where any venting to the atmosphere occurs as a result of liquids unloading activities, an owner or operator of a well affected/designated facility must employ BMPs to minimize emissions to the maximum extent possible.

### ***12.1.2 Affected Facility Definition***

Comment: Several commenters (0599-MSA, 0727-OSEE/ODEQ, 0743-Western Energy Alliance (WEA), 0763-TCEQ/RRC, 0777-Ascent Resources, LLC (Ascent), 0808-API, 0935-COGA) support the adoption of the November 2021 proposed affected facility Option 2 definition.

Commenter (0831-AXPC) requests that EPA clarify in Option 2 that its liquids unloading requirements would apply specifically to gas wells utilizing venting liquids unloading techniques.

Commenter (0777-Ascent) states that EPA should pursue only Option 2, which would limit the affected facility to those well liquids unloading operations that have associated venting, and thus have emissions to control – a more-appropriate way to define the affected facility for purposes of the proposed rule, according to the commenter. The commenter writes, [if] the purpose of the November 2021 Proposal is to control the emissions associated with well liquids unloading operations, then under Option 2, liquids unloading with no associated emissions would not be impacted by the rule, and thus should not be included in the scope of “affected facility.”

Commenter (0763-TCEQ/RRC) writes, if well liquid unloading is included, they recommend that only those facilities not designed to eliminate venting be considered affected facilities [Option 2], as facilities that have eliminated venting to the atmosphere are not significant sources of methane emissions.

Commenters (0743-WEA, 0808-API) state that, contingent on clarification that liquids unloading requirements are specific to liquids unloading of gas wells that vent emissions to atmosphere, the commenters support EPA’s proposed Option 2. The commenters specifically request (along with commenter 0911-North Dakota Petroleum Council (NDPC)) that EPA clarify within its proposed rule that liquids unloading requirements are *only* applicable to gas wells that vent emissions to atmosphere –consistent with the Technical Support Document (TSD) for liquids unloading. Commenter (0808-API) adds that it was EPA's intent to limit the affected facility for liquids unloading to gas wells only, because EPA's process description in the TSD for liquids unloading mentions only gas wells.

In a similar comment, commenter (0911-NDPC) requests clarification as to if well liquids unloading operations only apply to gas wells as described in 40 CFR 98. Furthermore, the

commenter believes that the EPA should only focus regulations on the liquids unloading operations that result in the venting of natural gas.

Commenter (0935-COGA) states that limiting the rule's applicability to well liquids unloading events with emissions to atmosphere [Option 2] is consistent with the EPA's November 2021 Proposal to limit the applicability of its pneumatic controller standards to each continuous bleed natural gas driven pneumatic controller "that vents to the atmosphere" and to each intermittent bleed controller that "is designed to only release natural gas to the atmosphere as part of the actuation cycle." [86 FR 63202]

Commenter (0599-MSD) supports Option 2 solely for gas wells that vent. According to the commenter, reporting for wells that do not vent is burdensome, with no emission benefit, and too broad in scope. The commenter recommends that [under Option 2], an affected facility be defined as every well that undergoes liquids unloading using a method that vents; adding that wells that utilize non-venting methods would not be affected facilities that are subject to the NSPS OOOOb.

Similarly, several commenters (0599-MSD, 0743-WEA, 0749-PAW, 0935-COGA) specifically oppose the adoption of the November 2021 proposed affected facility Option 1 definition.

Commenter (0749-PAW) writes that non-venting liquids unloading wells should not be affected facilities.

Commenter (0743-WEA) contends that liquids unloading activities and techniques do not contribute in any significant way to methane emissions, and therefore, there is no justification for them to be subject to recordkeeping and reporting requirements as affected facilities. Consistent with this reasoning, the commenter asserts that Option 1 is not technically feasible. According to the commenter, this approach should limit the required recordkeeping and reporting requirements, such as to not duplicate the reporting made by operators under EPA's Greenhouse Gas Reporting Program (GHGRP) Rule, Subpart W.

Commenter (0599-MSD) believes that Option 1 should be eliminated from the proposed rule; arguing nearly all wells experience liquid unloading. The commenter worries that the application of the proposed Option 1 definition would therefore apply to almost all wells, even wells that are still producing naturally without any added artificial lift technology. The commenter contends that this would be an unreasonable recordkeeping request.

Commenter (0935-COGA) argues that the definition of an affected facility for well liquid should not include wells that unload liquids using only non-emitting techniques, as contemplated in EPA's Option 1. [86 FR, 63179 and 63210]. The commenter contends that this definition would unnecessarily regulate facilities with activities that do not emit and implementing this definition would be difficult for routine activities such as plunger lift actuations and the use of soaps, surfactants, velocity strings, or other methods that allow liquids to flow from the well without emissions. The commenter suggests that EPA only regulate activities that cause emissions to atmosphere [Option 2]. As support, the commenter briefly discusses the state of Colorado and their choice, when adopting regulations in response to local conditions, not to regulate non-

emitting events. Moreover, the commenter adds that EPA's Option 1 would require recordkeeping and reporting for no purpose.

Response I-12-6: In the December 2022 Supplemental Proposal, rather than including three separate definitions for well affected facilities (as initially proposed in the November 2021 Proposal) for (1) oil wells with associated gas, (2) gas wells that undergo liquids unloading, and (3) wells that undergo completions, the EPA proposed a single definition for a well affected facility, which was defined as a single well, in the proposed NSPS OOOOb. See discussion in sections IV.F.1, IV.F.3.a.i, IV.F.3.a.ii, and IV.F.3.a.iii of the December 2022 Supplemental Proposal preamble related to what EPA proposed as constituting a well affected facility/designated facility, as well as EPA's request for comments regarding operational scenarios that would constitute a modification for liquids unloading operations.<sup>5</sup> See also Section 6.4.1 (Applicability) of Volume II of this RTC for comments and responses on the December 2022 Supplemental Proposal on the proposed definition of a well affected/designated facility and what constitutes a modification under the NSPS OOOOb for liquids unloading operations. Lastly, see sections X.F.1 and 3 of the preamble to the final rule which details EPA's final standards related to well affected facilities/designated facilities and what constitutes a modification for liquids unloading operations.

In response to the commenter that requested that the EPA clarify in the rule that its liquids unloading requirements apply specifically to "gas wells" utilizing venting liquids unloading techniques. The EPA agrees and confirms that the final rule requirements apply to "gas wells" that unload liquids.

With regards to the commenter that requests that EPA limit recordkeeping and reporting to only liquids unloading activities and techniques that vent emissions and to not duplicate the reporting made by operators under EPA's Greenhouse Gas Reporting Program (GHGRP) Rule, Subpart W, see responses to comments provided in section 12.5 of this Chapter, and section X.F.1 and 3 of the preamble to the final rule which details EPA's final liquids unloading operation standards and associated recordkeeping and reporting requirements.

Comment: Commenters (0391-KBIC, 0605-Muscogee (Creek) Nation, 0781-NTAA, 0833-Ute EPD, 0844-Environmental Defense Fund (EDF) *et al.*) support minimizing emissions from liquids unloading and the adoption of the Option 1 affected facility definition that defines every well that undergoes liquids unloading as an affected facility.

Commenter (0775/0776-Air Pollution Control Division, Colorado Department of Public Health and Environment (CDPHE)) supports EPA's November 2021 proposed Option 1 affected facility definition as preferable from an administrative tracking perspective and an emissions perspective. The commenter states that unloading activities that use technology designed to eliminate venting, such as plunger lift, sometimes do vent to the atmosphere. Furthermore, the commenter maintains that, under the November 2021 proposed Option 2 definition, a well that uses a plunger lift (that sometimes limits venting but not always) would potentially not be an

---

<sup>5</sup> 87 FR 74781-74782.

“affected facility” and, according to the commenter, the times that it does vent would go unrecorded.

Commenter (0844-EDF *et al.*) supports Option 1 of EPA’s November 2021 Proposal, because it is essential that records be kept of liquids unloading events so that the Agency, the public, and operators understand when and why liquids unloading could not be conducted with zero emissions. The commenter briefly defines Option 1 – specifically, how the Agency proposes to define the affected facility as every well that undergoes liquids unloading, meaning that wells utilizing a non-emitting method for liquids unloading would be affected facilities and subject to certain reporting and recordkeeping requirements. The commenter contends that this is a critical requirement to ensure that operators do not claim to conduct liquids unloading events with zero emission techniques, when in reality venting is occurring. The commenter points out that as EPA has recognized, “under some circumstances venting could occur when a selected liquids unloading method that is designed to not vent to the atmosphere is not properly applied (*e.g.*, a technology malfunction or operator error).”<sup>6</sup> The commenter continues to write that in some cases, the malfunction or error could be so great that it results in venting 100 percent of the gas intended to be captured. Because of this, the commenter insists that EPA require recordkeeping so it is aware of these events and overall emissions, and to build an understanding of what causes these errors and how they can be prevented. The commenter believes that the EPA should therefore finalize Option 1 and require operators to maintain records of the number of unloading events that occur, the method used, and any venting that occurred.

Response I-12-7: In the December 2022 Supplemental Proposal, rather than including three separate definitions for well affected facilities (as initially proposed in the November 2021 Proposal) for (1) oil wells with associated gas, (2) gas wells that undergo liquids unloading, and (3) wells that undergo completions, the EPA proposed a single definition for a well affected facility, which was defined as a single well, in the proposed NSPS OOOOb. See discussion in sections IV.F.1, IV.F.3.a.i, IV.F.3.a.ii, and IV.F.3.a.iii of the December 2022 Supplemental Proposal preamble related to what EPA proposed as constituting a well affected facility/designated facility, as well as EPA’s request for comments regarding operational scenarios that would constitute a modification for liquids unloading operations.<sup>7</sup> See Section 6.4.1 (Applicability) of Volume II of this RTC for comments and responses on the December 2022 Supplemental Proposal on the proposed definition of a well affected/designated facility and what constitutes a modification under the NSPS OOOOb for liquids unloading operations. Lastly, see sections X.F.1 and 3 of the preamble to the final rule which details EPA’s final standards related to well affected facilities/designated facilities and what constitutes a modification for liquids unloading operations.

Comment: Commenters (0599-MSA, 0814-Independent Petroleum Association of America (IPAA) *et al.*, 0831-AXPC) request that EPA focus requirements on liquid unloading events resulting in venting and not the “design” of the liquid unloading method. The “design” of the methods, venting or non-venting, according to the commenter (0599-MSA), is not relevant. The commenter writes that the current GHGRP Rule (*i.e.*, 40 CFR 98 Subpart W) reporting

---

<sup>6</sup> 86 FR 63179, November 15, 2021.

<sup>7</sup> 87 FR 74781-74782.

elements, (*i.e.*, gas wells that vent) should be maintained as the basis for a liquid unloading affected facility.

The commenters (0599-MS, 0814-IPAA *et al.*, 0831-AXPC) go on to explain that the design of a well's liquids unloading strategy often can give rise to multiple possible outcomes depending on various factors that can change daily, *e.g.*, operating temperatures and pressures, reservoir behavior, gathering and compression systems, offset well effects. Any attempt to define affected facilities based on whether a well is "designed" to vent during unloading or not, according to the commenters, is problematic because both design possibilities may and often do exist concurrently at a given well. The commenters state that all wells will eventually require liquids unloading at multiple points over the course of their operations, although one cannot necessarily predict when or how many times over the life of the well, nor will it be the same for every well. Similarly, the commenters note that the methods used to unload liquids throughout the life of the well will change depending on the conditions of the well. A method that was, at one point, according to the commenters, successful in routing the well stream to a separator with no venting may eventually cease to successfully unload liquids due to changes in well conditions. The commenters add that the ostensible "design" method is therefore not an accurate predictor of whether unloading activities at a given well will or will not result in unloading during a given point in the well's life. The commenters conclude that framing the rule in terms of a well's "design" in this regard is not relevant and will only lead to confusion, and they recommend that EPA only require reporting of the events that result in venting from a given well, without labeling a well as "designed" to unload without venting.

Commenter (0831-AXPC) maintains that any extension of this requirement to existing sources would be inappropriate based on the clear focus of CAA 111(d)'s text, structure, and purpose on allowing states to consider the particular characteristics of a source over the course of its operations or remaining life. The commenter notes, however, that even solely in terms of the Administrator's new-source authority, a standard would not be "adequately demonstrated" and/or "achievable" if it did not account for the manner in which sources actually operate in the course of production.

Additionally, the commenter (0831-AXPC) claims that the use of wells' designed unloading methods and whether the methods are designed to vent or not, as the basis for determining an affected facility would create significant ambiguity, and recommends, overall, that the EPA should propose (in the supplemental proposal) a standard that requires reporting of unloading events that actually result in venting—not one, as in the November 2021 Proposal, that bases applicability around a source's and/or its unloading events' "design." The commenter recalls, under the Option 2, an affected facility would be defined as every well that undergoes liquids unloading using a method that is not designed to eliminate venting (*i.e.*, that results in emissions to the atmosphere).

Response I-12-8: In the December 2022 Supplemental Proposal, rather than including three separate definitions for well affected facilities (as initially proposed in the November 2021 Proposal) for (1) oil wells with associated gas, (2) gas wells that undergo liquids unloading, and (3) wells that undergo completions, the EPA proposed a single definition for a well affected facility, which was defined as a single well, in the proposed NSPS OOOOb. See discussion in

sections IV.F.1, IV.F.3.a.i, IV.F.3.a.ii, and IV.F.3.a.iii of the December 2022 Supplemental Proposal preamble related to what EPA proposed as constituting a well affected facility/designated facility, as well as EPA's request for comments regarding operational scenarios that would constitute a modification for liquids unloading operations.<sup>8,9</sup> See Section 6.4.1 (Applicability) of Volume II of this RTC for comments and responses on the December 2022 Supplemental Proposal on the proposed definition of a well affected/designated facility and what constitutes a modification under the NSPS OOOOb for liquids unloading operations. Lastly, see sections X.F.1 and 3 of the preamble to the final rule which details EPA's final standards related to well affected facilities/designated facilities and what constitutes a modification for liquids unloading operations.

In response to the commenter that maintains that any extension of this requirement to existing sources would be inappropriate based on the clear focus of CAA 111(d)'s text, structure, and purpose on allowing states to consider the particular characteristics of a source over the course of its operations or remaining life. BMPs to minimize or eliminate methane emissions are both "adequately demonstrated" and "achievable". See section XIII.C.3 of the final rule preamble for a discussion on state plans submitted in accordance with emission guidelines that include provisions for remaining useful life and other factors (RULOF). State plans submitted in accordance with these EG that include provisions for RULOF must comply with the subpart Ba general RULOF provisions in 40 CFR 60.24a. For informational purposes, the EPA has summarized the RULOF provisions that have been finalized in the subpart Ba rulemaking, which is separate and distinct from this action in section XIII.C.3 of the final rule preamble.

## **12.2 Proposed BSER**

### ***12.2.1 Proposed Well Liquids Unloading Requirements***

Comment: Commenter (0444-Damascus Citizens for Sustainability (DCS)) supports EPA's November 2021 Proposal to limit emissions by reducing emissions from maintenance activities, like liquids unloading. Similarly, commenter (0789-Pennsylvania Department of Environmental Protection (PDEP)) asks that EPA consider regulating natural gas emissions from well liquids unloading operations.

Response I-12-9: Commenters are supportive of requirements to limit/regulate emissions from well liquids unloading operations. Please see sections X.F.1 and 3 of the preamble to the final rule which details EPA's final standards related to well affected facilities/designated facilities and liquids unloading requirements.

Comment: Commenter (1341-Pennsylvania Grade Crude Oil Coalition (PGCC) *et al.*) asserts that it is unreasonable for EPA to regulate well liquids unloading operations as a modification under NSPS OOOOb. The commenter states that it is unaware of any existing technology that would enable them to control emissions associated with the different methods of liquids unloading, all of which, the commenter reports only occur intermittently for short periods of time. The commenter asserts that the proposed requirements incorrectly assume that technology

---

<sup>8</sup> 87 FR 74781-74782.

<sup>9</sup> 87 FR 74781-74782.

exists that would allow for any emissions generated during such events to be controlled. According to the commenter, section 111 of the CAA prohibits the Agency from imposing new emission control requirements when there is no control technology available.

Commenter (1341-PGCC *et al.*) notes that although EPA's November 2021 Proposal suggests that "well liquids unloading" events in which emissions are "eliminated" may not be covered under proposed NSPS OOOOb, this potential exemption is of little value to the commenter's members (*i.e.*, conventional producers). The commenter writes that their members use tube swabbing, rabbits (plunger lifts), casing swabbing, and other methods as part of routine maintenance, including liquids unloading, on their wells, and contends that these events are very different from the "intermittent, high-emitting" events that EPA wants to regulate.

Response I-12-10: See discussion in sections IV.F.1, IV.F.3.a.i, IV.F.3.a.ii, and IV.F.3.a.iii of the December 2022 Supplemental Proposal preamble related to EPA's proposed standard of performance: perform well liquids unloading with zero methane or VOC emissions. The BSER proposed was to employ techniques or technologies that eliminate methane and VOC emissions. Where it was technically infeasible or not safe to meet the zero emissions standard, the proposal required that owners and operators employ BMPs to minimize methane and VOC emissions during well liquids unloading operations to the maximum extent possible.<sup>10</sup> See section 6.4.2 (Proposed BSER) of Volume II of this RTC for comments and responses on the December 2022 Supplemental Proposal on the proposed zero emission standard for liquids unloading operations. Lastly, see sections X.F.1 and 3 of the preamble to the final rule which details EPA's final standards related to well affected facilities/designated facilities.

With regards to the commenter that notes that they are unaware of any existing technology that would allow them to control emissions associated with the different methods of liquids unloading, the EPA assumes that the commenter is referring to add-on control technologies. While there are some owners and operators that report that they route emissions from liquids unloading events that vent emissions to an enclosed combustor or flare, the EPA recognizes that this is not a common practice. However, there are some gas well liquids unloading techniques that are currently employed that vent minimally or eliminate venting to the atmosphere.<sup>11</sup>

In response to commenter that indicated that their members use liquids unloading techniques as part of routine maintenance that are very different from the "intermittent, high-emitting" events that EPA wants to regulate, the final rule requires that owners or operators minimize or eliminate emissions of methane and VOC emissions to the atmosphere from all liquids unloading events. If liquids unloading technologies/techniques, where employed, vent emissions to the atmosphere, the EPA wants to ensure that BMPs are followed to minimize or eliminate emissions to the maximum extent possible.

Comment: Commenter (1341-PGCC *et al.*) expresses frustration that EPA ignored or failed to address several key recommendations offered by small entity representatives, including the recommendation to *not* propose liquids unloading requirements. The commenter maintains that a best management practice written into a regulation, particularly one that is very "site-specific,"

---

<sup>10</sup> 87 FR 74781-74782.

<sup>11</sup> See discussion in section XII.D.e of November 2021 Proposal preamble. 86 FR 63211.

will not provide small entities clear instructions and [will] lead to confusion and significant risk of unwarranted enforcement actions. The commenter references the “Panel Report”.<sup>12</sup>

Response I-12-11: See discussion in sections IV.F.1, IV.F.3.a.i, IV.F.3.a.ii, and IV.F.3.a.iii of the December 2022 Supplemental Proposal preamble related to what EPA proposed as constituting a well affected facility/designated facility, and proposed liquids unloading operation requirements.<sup>13</sup> The BSER proposed was to employ techniques or technologies that eliminate methane and VOC emissions. Where it was technically infeasible or not safe to meet the zero emissions standard, the proposal required that owners and operators employ BMPs to minimize methane and VOC emissions during well liquids unloading operations to the maximum extent possible.<sup>14</sup>

Based on the December 2022 Supplemental Proposal, BMP plans, meeting minimum criteria, were required to be developed by owners and operators. For unloading operations that use technologies or techniques that are not zero-emitting, an owner or operator was p develop, maintain, and follow a BMP plan to minimize venting of methane and VOC emissions to the maximum extent possible from each gas well liquids unloading operation. This BMP must meet the following minimum criteria:

(1) Include steps that create a differential pressure to minimize the need to vent a well to unload liquids,

(2) Include steps to reduce wellbore pressure as much as possible prior to opening the well to the atmosphere,

(3) Unload liquids through the separator where feasible, and

(4) Close all wellhead vents to the atmosphere and return the well to production as soon as practicable.

While the December 2022 supplemental proposal included BMP minimum criteria, the proposed standards and presumptive standards did not specify rigid requirements for an owner or operator to follow and small entities would have flexibility on the specific elements and steps included in their BMPs based on their operations and technologies and techniques employed. The BMP plan minimum criteria proposed in the December 2022 Supplemental Proposal have been maintained in the final rule.

See section 6.4.2 (Proposed BSER) of Volume II of this RTC for comments and responses on the December 2022 Supplemental Proposal on the proposed zero emission standard for liquids unloading operations. Lastly, see sections X.F.1 and 3 of the preamble to the final rule which

<sup>12</sup> Final Report of the Small Business Advocacy Review Panel on EPA's Planned Proposed Rule Emission Standards for New, Reconstructed, and Modified Sources in the Oil and Natural Gas Sector, Document ID No. EPA-HQ-OAR-2021- 0317-0074 (Sept. 2021) (Panel Report).

<sup>13</sup> 87 FR 74781-74782.

<sup>14</sup> 87 FR 74781-74782.

details EPA's final standards related to well affected facilities/designated facilities and liquids unloading requirements.

Comment: Commenter (1341-PGCC *et al.*) maintains that the November 2021 proposed requirements to regulate liquids unloading operations are, at large, unnecessary due to infrequency and low-emitting nature of these events of well liquids unloading events, particularly at the wells of the commenter's members and would cause more environmental harm than benefit. According to the commenter, any requirement to control emissions during these infrequent events would be cost-prohibitive. The commenter underscores the point that recovery units would require electricity, which, the commenter writes, is unavailable at tens of thousands of conventional well sites in Pennsylvania and New York. The commenter continues to note that the cost of delivering electricity to these remote conventional well sites would be exorbitant and excessive. Consequently, vapor recovery using a generator for power would likely result in a net increase in emissions at the well sites of the Conventional Groups' commenter's members.

In a similar remark, commenter (1341-PGCC *et al.*) urges EPA to withdraw all aspects of the November 2021 Proposal purporting to regulate "well liquids unloading" at conventional oil and gas well sites in Pennsylvania and New York; arguing that the commenter's members should be allowed to continue to perform necessary maintenance and use stimulation techniques without the prospect of installing currently unavailable emissions controls. The commenter contends that forcing their members to pay for customized control systems and operate such systems during routine maintenance and stimulation on a well would be economically devastating and likely would lead to premature well shut ins.

Response I-12-12: See discussion in sections IV.F.1, IV.F.3.a.i, IV.F.3.a.ii, and IV.F.3.a.iii of the December 2022 Supplemental Proposal preamble related to what EPA proposed as constituting a well affected facility/designated facility, and proposed liquids unloading operation requirements.<sup>15</sup>

For commenters that state that liquids unloading should not be regulated due to the cost of delivering electricity or the use of a generator and that the application of the proposed standards would result in premature shut-ins for conventional groups, the EPA has not finalized its December 2022 Supplemental Proposal to require owners and operators to employ techniques or technologies that eliminate methane and VOC emissions, unless it was technically infeasible or not safe to meet the zero emissions standard.

See Chapter 6, section 6.4.2 (Proposed BSER) of Volume II of this RTC (RTC) Document for comments and EPA's responses to comments on the December 2022 Supplemental Proposal. See also section X.F.1 and 3 of the preamble to the final rule for details on EPA's final standards and XI.F.1 and 3 for the basis for any changes made from the December 2022 Supplemental Proposal and final rule related to liquids unloading as an outgrowth of significant comments.

Comment: Commenters (0599-MS, 0814-IPAA *et al.*, 0831-AXPC) acknowledge that the routing of emissions back to a sales line is possible but not always practical and creates secondary emissions. The commenters note that one operator uses mobile gas lift compressors

---

<sup>15</sup> 87 FR 74781-74782.

(MGLC) to unload wells to minimize venting emissions. According to the commenters, the estimated cost for routing unloading emissions to the sales line using mobile gas lift wellsite compressors for one operator is \$280K/year. The commenters note that the equipment size, layout, spacing requirements (Fire Class/Divisions), and cost would make it difficult to justify for use on marginal or remote wells; adding that the secondary emissions from the model 3406 gas powered compressor are approximately 4 tons/event carbon dioxide equivalent (CO<sub>2</sub>e).

Response I-12-13: See discussion in sections IV.F.1, IV.F.3.a.i, IV.F.3.a.ii, and IV.F.3.a.iii of the December 2022 Supplemental Proposal preamble related to what EPA proposed as constituting a well affected facility/designated facility, and proposed liquids unloading operation requirements.<sup>16</sup> The EPA has not finalized its December 2022 Supplemental Proposal to require owners and operators to employ techniques or technologies that eliminate methane and VOC emissions, unless it was technically infeasible or not safe to meet the zero emissions standard. See Chapter 6, section 6.4.2 (Proposed BSER) of Volume II of this RTC Document for comments and EPA's responses to comments on the December 2022 Supplemental Proposal. See also sections X.F.1 and 3 of the preamble to the final rule for details on EPA's final standards and sections XI.F.1 and 3 of the preamble to the final rule for the basis for any changes made from the December 2022 Supplemental Proposal and final rule related to liquids unloading as an outgrowth of significant comments.

Comment: Commenters (0599-MS, 0814-IPAA *et al.*, 0831-AXPC) believe that venting should be permitted and that BMPs should be followed to minimize any associated emissions. The commenters note that nearly all non-venting liquids unloading events are done against a surface back pressure that is greater than atmospheric pressure. The commenters add that even small amounts of back pressure, such as unit increases in psi, could dispositively determine whether an unloading attempt is successful or not. The commenters explain that many wells will not unload against surface back pressure and therefore require venting to the atmosphere. The commenters caution that due to the variable nature of liquids unloading operations, attempts to contain the surging fluids and gases becomes a very difficult design problem. Specifically, the commenters note that engineering equations are not available to accurately estimate the pressure affects as the fluid stream reaches the surface equipment, and therefore, having a totally closed system without the ability to vent to the atmosphere, in many cases creates a safety concern – *i.e.*, potential bursting of tanks. To prevent this or similar events, the commenters maintain that surface equipment would need to be designed with safety factors that would result in significantly overrated and oversized equipment with the associated excessive cost – a solution which the commenters deem impractical, particularly for low producing wells.

The commenters (0599-MS, 0814-IPAA *et al.*, 0831-AXPC) add that much of the surface equipment needed for the separation of gas from liquids requires a threshold operating pressure and a flow regime that is not significantly sporadic. To be able to measure and control unloading emissions, the commenters contend that this separation – which is often not practical unless tanks that can vent to accumulate the sporadic flow stream are used which allow for liquid/gas gravity separation over time – would need to be completed. According to the commenters, the use of compressed nitrogen to unload wells is common practice, especially when a well does not have the ability to use produced gas – *e.g.*, a single well on a location, an exploration type well

---

<sup>16</sup> 87 FR 74781-74782.

without any gathering infrastructure. The commenter explains that since the unloading gas stream will be a mixture of the injected nitrogen and formation gas the gas will have too high a nitrogen content to put in a sales line or to burn efficiently via a flare. Until the mixture can go to beneficial use, the commenters note that some venting may be necessary. The commenters emphasize that these operations make all attempts to minimize this venting, typically with a recirculation system.

Moreover, the commenters (0599-MS, 0814-IPAA *et al.*, 0831-AXPC) note that in certain basins/formations, a temporary shut-in to build pressure does not build enough delta between bottomhole pressure and surface pressure to overcome the production impediment caused by liquid holdup; therefore, unloading to a low-pressure system is required.

According to the commenters (0599-MS, 0814-IPAA *et al.*, 0831-AXPC), even in circumstances where a non-venting solution may be possible, the amount of equipment, additional artificial lift engines, and associated secondary emissions, often makes it an obviously poor choice. The commenters also note that location size can also prevent the installation of any such equipment, particularly when there is not adequate and prudent spacing between wellheads and other potential ignition sources and fired equipment such as compressor exhaust and flares. The commenters agree that production engineers are professional problem solvers, and they should be empowered to come up with the best solutions, as discussed in the preceding comments.

Furthermore, the commenters (0599-MS, 0814-IPAA *et al.*, 0831-AXPC) recommend that production engineers attempt to capture methane emissions and put them into the sales line when practical. The commenters state that during plunger lift, gas lift assist, soap assist, venturi system lift, swabbing, and many other forms of liquids unloading, gas is often captured and routed to sales or to a control device (*e.g.*, flare, compression input, heaters, generators). The commenters maintain that this is in line with EPA's observation that "[s]electing a particular method to meet a particular well's unloading needs must be based on a production engineering decision that is designed to remove the barriers to production." [86 FR 63,211] While the commenters recognize that in many cases there are ways to achieve this with going to sales or a control device, they also acknowledge that when an operator can no longer do so, they still need to be able to vent. The commenters write, there are many Gas STAR partner reported opportunities (PROs) that address the cost side of these solutions that are highly variable.

Response I-12-14: The EPA appreciates the feedback and information provided by commenters. See discussion in sections IV.F.1, IV.F.3.a.i, IV.F.3.a.ii, and IV.F.3.a.iii of the December 2022 Supplemental Proposal preamble related to what EPA proposed as constituting a well affected facility/designated facility, and proposed liquids unloading operation requirements.<sup>17</sup> The EPA has not finalized its December 2022 proposal to require owners and operators to employ techniques or technologies that eliminate methane and VOC emissions, unless it was technically infeasible or not safe to meet the zero emissions standard. See Chapter 6, section 6.4.2 (Proposed BSER) of Volume II of this RTC Document for comments and EPA's responses to comments on the December 2022 Supplemental Proposal. See also sections X.F.1 and 3 of the preamble to the final rule for details on EPA's final standards and sections XI.F.1 and 3 of the preamble to the

---

<sup>17</sup> 87 FR 74781-74782.

final rule for the basis for any changes made from the December 2022 supplemental proposal and final rule related to liquids unloading as an outgrowth of significant comments.

Comment: Commenter (0808-API) argues that non-emitting control measures under the November 2021 Proposal are work practices and EPA should correct its terminology in the Final Rule. The commenter writes that as a practical matter, the term “zero-emissions” is apt because the object of proposed standards, including liquid unloading standards that require owners or operators to perform liquids unloading with zero methane or volatile organic compound (VOC) emissions, is to eliminate methane and VOC emissions from the affected facility. But as a legal matter, the commenter claims that the term “zero-emissions” is imprecise and in error because proposed standards (for liquid unloading and pneumatic controllers) impose equipment or work practice obligations and do not impose a numeric emissions limitation of zero.

According to the commenter, the legal distinction is important because a fully compliant pneumatic controller or liquids unloading event may still have incidental VOC and methane emissions. The commenter acknowledges that no piece of equipment or work practice is perfect – even if implemented according to best practices. With that understanding, the commenter writes, the term “zero-emissions” expresses an idealized outcome that is belied by reality. The commenter continues, a zero-emissions numeric standard would unreasonably cause incidental emissions to be a violation of the standard. EPA should correct its terminology in the Final Rule by stating that non-emitting control measures under this rule are work practices.

Response I-12-15: See discussion in sections IV.F.1, IV.F.3.a.i, IV.F.3.a.ii, and IV.F.3.a.iii of the December 2022 Supplemental Proposal preamble related to what EPA proposed as constituting a well affected facility/designated facility, and proposed liquids unloading operation requirements.<sup>18</sup> The EPA has not finalized its December 2022 proposal to require owners and operators to employ techniques or technologies that eliminate methane and VOC emissions, unless it was technically infeasible or not safe to meet the zero emissions standard. See Chapter 6, section 6.4.2 (Proposed BSER, subsection 6.4.2.2 Zero Emission Standard) of Volume II of this RTC Document for EPA’s responses to comments on the December 2022 Supplemental Proposal. See also sections X.F.1 and 3 of the preamble to the final rule for details on EPA’s final standards and presumptive standards and sections XI.F.1 and 3 of the preamble to the final rule for the basis for any changes made from the December 2022 supplemental proposal and final rule related to liquids unloading as an outgrowth of significant comments.

### ***12.2.2 Liquids Unloading BSER Analysis***

Comment: Commenter (1341-PGCC *et al.*) claims that EPA’s assumed emissions from “well liquids unloading” events does not include the relatively unique operations at the wells operated by the commenter’s conventional members – the study that is the sole basis for EPA’s estimates evaluated 107 wells, with 11 wells in the Appalachian region, none of which are configured like the wells owned and operated by the commenter’s members – and therefore, the commenter states that the EPA cannot regulate well liquids unloading events at the wells of the commenter’s members.

---

<sup>18</sup> 87 FR 74781-74782.

Response I-12-16: See discussion in sections IV.F.1, IV.F.3.a.i, IV.F.3.a.ii, and IV.F.3.a.iii of the December 2022 Supplemental Proposal preamble related to what EPA proposed as constituting a well affected facility/designated facility, and proposed liquids unloading operation requirements.<sup>19</sup> While the December 2022 supplemental proposal included BMP minimum criteria, the proposed standards and presumptive standards did not specify rigid requirements for an owner or operator to follow and small entities would have flexibility on the specific elements and steps included in their BMPs based on their operations and technologies and techniques employed. The BMP plan minimum criteria proposed in the December 2022 Supplemental Proposal have been maintained in the final rule.

Implementing the BMPs proposed in the December 2022 Supplemental Proposal and maintained in the final rule to minimize or eliminate VOC and methane emissions from gas well liquids unloading events constitutes requirements that every well affected/designated facility can implement.

Comment: Commenters (0599-MS, 0814-IPAA *et al.*, 0831-AXPC) contend that the BSER analysis for velocity strings was incomplete and generally not applicable to a wide variety of unloading challenges – *e.g.*, fields where the potential for frac hits exists during normal prudent field development. In these cases, the commenters note that a significant amount of water will result in legacy offset wells and velocity strings will make the recovery and de-liquification of these wells extremely difficult or impossible as the tubing conduit, with reduced diameter, would create significant friction and back pressure. The commenters add that velocity strings also are very difficult to unload and swabbing, and plunger options are either reduced or eliminated due to the small diameter. Furthermore, the commenters note that velocity string sizing requirements change with time requiring replacement and they are therefore not considered permanent solutions for liquid unloading. The commenters state that the increased emissions and costs were not considered in the BSER analysis.

Response I-12-17: See discussion in sections IV.F.1, IV.F.3.a.i, IV.F.3.a.ii, and IV.F.3.a.iii of the December 2022 Supplemental Proposal preamble related to what EPA proposed as constituting a well affected facility/designated facility, and proposed liquids unloading operation requirements.<sup>20</sup> The EPA has not finalized its December 2022 proposal to require owners and operators to employ techniques or technologies that eliminate methane and VOC emissions, unless it was technically infeasible or not safe to meet the zero emissions standard. See Chapter 6, section 6.4.2 (Proposed BSER, subsection 6.4.2.2 Zero Emission Standard) of Volume II of this RTC Document for comments and EPA’s responses to comments on the December 2022 Supplemental Proposal. See also sections X.F.1 and 3 of the preamble to the final rule for details on EPA’s final standards and sections XI.F.1 and 3 of the preamble to the final rule for the basis for any changes made from the December 2022 supplemental proposal and final rule related to liquids unloading as an outgrowth of significant comments.

Zero-emitting technologies and techniques are encouraged but are not required under the final rule. Nonetheless, the EPA acknowledges the commenter’s position regarding the analysis provided for velocity strings in the November 2021 proposal did not BSER analysis and that

---

<sup>19</sup> 87 FR 74781-74782.

<sup>20</sup> 87 FR 74781-74782.

velocity strings generally not applicable to a wide variety of unloading challenges. Nonetheless, the EPA acknowledged in the November 2021 proposal BSER analysis that there are several techniques owners and operators can choose from to unload liquids, including manual unloading, velocity tubing or velocity strings, beam or rod pumps, electric submergence pumps, intermittent unloading, gas lift (e.g., use of a plunger lift), foam agents, wellhead compression, and routing the gas to a sales line or back to a process.

Comment: Commenters (0599-MSD, 0814-IPAA *et al.*, 0831-AXPC) question the methodology that was employed by EPA to establish cost reasonableness. Specifically, the commenters note that EPA's analysis, when establishing \$/tons of emission reduction in establishing reasonableness, does not include data on emission reductions. The Agency acknowledged that establishing an emission reduction that would be achievable by event is difficult as baseline level of management practices and emissions varies significantly. The commenters state that the \$/ton reduction is then calculated from the baseline level based on hypothetical emission reduction values of 10 percent, 25 percent, and 50 percent. The commenters emphasize that these are hypothetical values and therefore, questionable as representing reduction per event. Additionally, the commenters note that baseline emissions are a crucial factor in calculating the tonnage of reduction; yet EPA lacks transparency in providing justification for the baseline emissions applied in the calculation of cost effectiveness. As such, the commenters question EPA's cost-effectiveness of the "Non-Emitting Evaluation" option. To establish the cost-effectiveness for existing sources (*i.e.*, wells already equipped with "non-venting" technology such as plunger lift), the commenters note that EPA's BSER analysis is based on 2015 -2019 liquid unloading data from Subpart W, and the data shows 98 percent of "with plunger" wells are those equipped with automated plunger, for which, EPA cannot establish an emission reduction baseline; hence, the analysis is based on the remaining 2 percent of the well population representing manual liquid unloading operations. The commenters question the representation of this analysis since 98 percent of actual wells are equipped with automated plunger system from which EPA cannot establish actual reduction.

Response I-12-18: See discussion in sections IV.F.1, IV.F.3.a.i, IV.F.3.a.ii, and IV.F.3.a.iii of the December 2022 Supplemental Proposal preamble related to what EPA proposed as constituting a well affected facility/designated facility, and proposed liquids unloading operation requirements.<sup>21</sup> The EPA has not finalized its December 2022 proposal to require owners and operators to employ techniques or technologies that eliminate methane and VOC emissions, unless it was technically infeasible or not safe to meet the zero emissions standard. See also sections X.F.1 and 3 of the preamble to the final rule for details on EPA's final standards and sections XI.F.1 and 3 of the preamble to the final rule for the basis for any changes made from the December 2022 supplemental proposal and final rule related to liquids unloading as an outgrowth of significant comments.

In response to commenters that express that the BMP analyses based on hypothetical emission reduction per event values of 10 percent, 25 percent, and 50 percent is questionable. As the commenter noted, the Agency acknowledged that establishing an emission reduction that would be achievable by event is difficult as baseline level of management practices and emissions varies significantly. No one, however, disputes that BMPs, when implemented, during gas well

---

<sup>21</sup> 87 FR 74781-74782.

liquids unloading events that vent, would reduce vented emissions as a result of an owner or operator being required to follow a BMP plan to minimize or eliminate emissions to the maximum extent possible.

Comment: Commenter (0808-API) is concerned that EPA has not asserted an adequate legal basis for the November 2021 proposed emissions standards that allow for “technical feasibility” exceptions. The commenter proclaims that the fact that EPA needed to allow for technical infeasibility exceptions to the proposed non-emitting standards indicates that the non-emitting standards are not permissible under section 111 of the CAA. According to the commenter, a “standard of performance” must reflect the degree of emissions limitation “achievable” through application of the best system of emissions reduction that EPA finds to be “adequately demonstrated.” CAA section 111(a)(1). The November 2021 proposed non-emitting standards do not meet this requirement for two reasons: First, EPA has not demonstrated that techniques that eliminate emissions from liquids unloading events are “demonstrated in practice” for purposes of designating such techniques as BSER, and second, the proposed non-emitting standards of performance are legally questionable because they are not “achievable,” as demonstrated by the need to establish exceptions to make the standard sufficiently practicable. Foremost, the commenter acknowledges that that non-emitting liquids unloading techniques can be used in some circumstances and that associated gas can be routed to a sales line in some situations, but the need to create exceptions under both standards shows that non-emitting techniques are not demonstrated in practice for the full range of regulated activities and circumstances. The commenter argues that EPA needs to seek to avoid the obligation to show that non-emitting techniques are demonstrated in practice by creating exceptions for situations where non-emitting techniques are not demonstrated in practice. According to the commenter, this incorrectly relieves EPA of the burden of promulgating achievable standards in the first instance and improperly defers infeasibility determinations to the time when the rule is implemented and enforced rather than when the rule is promulgated – *i.e.*, puts the burden on affected facilities to prove to EPA that they qualify for the exceptions. An approach ultimately not supported by the commenter. The commenter provides that the court (*i.e.*, *Essex Chemical Corp. v. Ruckelshaus*) confirmed that, given adequate justification, EPA may set technology-forcing standards of performance under CAA section 111. However, the commenter stresses that this does not support EPA’s November 2021 Proposal to determine that non-emitting techniques are “adequately demonstrated” as it is clear that there are a significant number of potentially affected facilities will not be able to meet the non-emitting standards. The commenter urges EPA in the upcoming supplemental proposal to provide a better explanation of how setting presumptively applicable non-emitting standards with a case-by-case “off ramp” satisfies these statutory requirements – BSER to be “adequately demonstrated” and standards of performance to be “achievable.”

Response I-12-19: See discussion in sections IV.F.1, IV.F.3.a.i, IV.F.3.a.ii, and IV.F.3.a.iii of the December 2022 Supplemental Proposal preamble related to what EPA proposed as constituting a well affected facility/designated facility, and proposed liquids unloading operation requirements.<sup>22</sup> The EPA has not finalized its December 2022 proposal to require owners and operators to employ techniques or technologies that eliminate methane and VOC emissions, unless it was technically infeasible or not safe to meet the zero emissions standard. See also

---

<sup>22</sup> 87 FR 74781-74782.

sections X.F.1 and 3 of the preamble to the final rule for details on EPA's final standards and sections XI.F.1 and 3 of the preamble to the final rule for the basis for any changes made from the December 2022 supplemental proposal and final rule related to liquids unloading as an outgrowth of significant comments.

Comment: Commenters (0831-AXPC, 0599-MSC, 0814-IPAA *et al.*) believe that enclosed combustion devices and thermal oxidizers should be considered as control options.

Commenters (0599-MSC, 0831-AXPC, 0814-IPAA *et al.*) claim that EPA reports and peer reviews on the technical and cost feasibility of using a flare to control vented emissions from liquids unloading events, indicate that a flare cannot be used in all situations. As an example, the commenters reference a peer review<sup>23</sup> which states, "[t]he flowing characteristics during venting operations inhibit the design of flare equipment." During the unloading operation, initial gas flow rate and pressure are high and decline rapidly over a short period of time. Flare design (tip diameter) is based on flow rate and design criteria can be found in Radian Corporation/EPA 1995 Report – Chapter 7 on Flares<sup>24</sup>. In addition, the commenters note that the sporadic nature of liquid unloading venting operations would require either a continuous pilot or electronic igniter, and the design cost associated with the requirements needed for this type of flow would be cost prohibitive. Additional information for flare applicability in this context is available in EPA Gas Star PRO Fact Sheets No. 904 "Install Flares" and No. 903 "Install Electronic Flare Ignition Devices".

While the commenters (0599-MSC, 0831-AXPC, 0814-IPAA *et al.*) recognize that EPA's decision to not to consider a flare as a control option for unloading events could be justified with respect to some operational scenarios, the commenters maintain that there are opportunities to use flares in many cases, and these cases are likely the ones that offer the biggest opportunity for methane emission reductions. To illustrate, the commenters write, consider the methods of liquids unloading that use an artificial lift engine, *e.g.*, gas lifting the fluids with compressed gas. In this example, the commenters note that the well still may require a very low surface pressure to effectively remove the liquids and the quantity of produced gas could be significant before it can be directed to sales or recirculated into a gas compressor intake; concluding that a flare as a control device in this situation would be technically feasible and likely result in a safer operation. The commenters suggest that flares should be considered as a control option in this rulemaking, and an unloading event controlled with a flare should be considered as non-venting liquids unloading.

Response I-12-20: See discussion in sections IV.F.1, IV.F.3.a.i, IV.F.3.a.ii, and IV.F.3.a.iii of the December 2022 Supplemental Proposal preamble related to what EPA proposed as constituting a well affected facility/designated facility, and proposed liquids unloading operation requirements.<sup>25</sup> The EPA has not finalized its December 2022 proposal to require owners and operators to employ techniques or technologies that eliminate methane and VOC emissions,

<sup>23</sup> Jim Bolander, P.E., Senior Vice President, Southwestern Energy (SWN). Review Submitted: April 2014. Pg. 8

<sup>24</sup> Chapter 7 FLARES: Diana K. Stone, Susan K. Lynch, Richard F. Pandullo, Radian Corporation Research Triangle Park, NC 27709, Office of Air Quality Planning and Standards U.S. Environmental Protection Agency, Research Triangle Park, NC 27711, December 1995.

<sup>25</sup> 87 FR 74781-74782.

unless it was technically infeasible or not safe to meet the zero emissions standard. See Chapter 6, section 6.4.2 (Proposed BSER, subsection 6.4.2.2 Zero Emission Standard) of Volume II of this RTC Document for comments and EPA's responses to comments on the December 2022 Supplemental Proposal. See also sections X.F.1 and 3 of the preamble to the final rule for details on EPA's final standards and sections XI.F.1 and 3 of the preamble to the final rule for the basis for any changes made from the December 2022 supplemental proposal and final rule related to liquids unloading as an outgrowth of significant comments. Under the final rule/presumptive standards, owners or operators are also allowed the option to comply with the GHG and VOC standards by reducing methane and VOC emissions from each gas well liquids unloading event by 95 percent by routing emissions to a control device via a closed vent system (CVS). The emissions reduction that would be achieved by this option could be greater than or equal to what could be achieved through the implementation of BMPs.

Comment: Commenters (0599-MS, 0814-IPAA *et al.*, 0831-AXPC) offer several examples that would not allow liquids unloading to be performed without venting. Foremost the commenters write that production engineers should be empowered to make the best production decision, and when they decide venting is required, it should be considered technically necessary. According to the commenters, many wells need to unload to an atmospheric tank for unloading to be successful; sporadic unloading is difficult to model and the selection of surface equipment that does not vent creates safety concerns; separation equipment requires threshold operating pressures and perform poorly under sporadic flow; the use of compressed nitrogen to unload wells often requires some venting; high surface producing pressures can result from gathering and compressor system maintenance or unplanned upsets. The commenters explain that wells often cannot unload against these higher surface pressures; and locations are often too small to accommodate the significant amount of equipment which would be necessary for non-venting liquids unloading.

Response I-12-21: See discussion in sections IV.F.1, IV.F.3.a.i, IV.F.3.a.ii, and IV.F.3.a.iii of the December 2022 Supplemental Proposal preamble related to what EPA proposed as constituting a well affected facility/designated facility, and proposed liquids unloading operation requirements.<sup>26</sup> The EPA has not finalized its December 2022 proposal to require owners and operators to employ techniques or technologies that eliminate methane and VOC emissions, unless it was technically infeasible or not safe to meet the zero emissions standard. See Chapter 6, section 6.4.2 (Proposed BSER, subsection 6.4.2.2 Zero Emission Standard) of Volume II of this RTC Document for comments and EPA's responses to comments on the December 2022 Supplemental Proposal. See also sections X.F.1 and 3 of the preamble to the final rule for details on EPA's final standards and sections XI.F.1 and 3 of the preamble to the final rule for the basis for any changes made from the December 2022 supplemental proposal and final rule related to liquids unloading as an outgrowth of significant comments.

### ***12.2.3 Zero Emissions Standard***

Comment: Commenter (0777-Ascent) argues that EPA should replace the infeasible "zero emissions" standard with a requirement that affected well liquids unloading operations minimize emissions through BMPs. The commenter states that they have significant experience using a

---

<sup>26</sup> 87 FR 74781-74782.

variety of practices to safely and effectively minimize the emissions associated with gas well liquids unloading but worry that those practices would not satisfy EPA's contemplated "zero emissions" requirement. According to the commenter, there are many reasons why liquids may accumulate in a wellbore and require liquid unloading, some of which are due to external factors not in the control of the well operator. The commenter states that the November 2021 proposed standard would necessitate a detailed review and discussion of infeasibility for each event with no benefit to emissions.

The commenter (0777-Ascent) recommends that, rather than establish a "zero emissions" standard with an exception for unloading with minimized emissions when zero-emissions unloading is technically infeasible, EPA propose the use of BMPs to minimize methane and VOC emissions during liquids unloading events to the extent possible as the standard itself. The commenter warns that the program contemplated by EPA sets an impossible compliance bar, and further reiterates that a proposed standard to develop and use BMPs to minimize methane and VOC emissions during liquids unloading events to the extent possible will achieve the same emissions reductions while eliminating the unnecessary burdens associated with demonstrating that zero-emissions unloading is infeasible.

Moreover, the commenter (0777-Ascent) suggests that EPA use the API Environmental Partnership Program materials<sup>27</sup> to help define a program for what qualifies as BMPs for minimizing the VOC and methane emissions associated with well liquids unloading.

Response I-12-22: See discussion in sections IV.F.1, IV.F.3.a.i, IV.F.3.a.ii, and IV.F.3.a.iii of the December 2022 Supplemental Proposal preamble related to what EPA proposed as constituting a well affected facility/designated facility, and proposed liquids unloading operation requirements.<sup>28</sup> The EPA has not finalized its December 2022 proposal to require owners and operators to employ techniques or technologies that eliminate methane and VOC emissions, unless it was technically infeasible or not safe to meet the zero emissions standard. See Chapter 6, section 6.4.2 (Proposed BSER, subsection 6.4.2.2 Zero Emission Standard) of Volume II of this RTC Document for comments and EPA's responses to comments on the December 2022 Supplemental Proposal. See also sections X.F.1 and 3 of the preamble to the final rule for details on EPA's final standards and sections XI.F.1 and 3 of the preamble to the final rule for the basis for any changes made from the December 2022 supplemental proposal and final rule related to liquids unloading as an outgrowth of significant comments.

Comment: Commenter (0808-API) suggests that the November 2021 proposed BSER may not consider/include exceptions that are deemed or determined to be technically infeasible, because BSER must be technically feasible for the source category. The commenter provides a brief overview of the proposed standard under NSPS OOOOb that requires owners or operators to perform liquids unloading with zero methane or VOC emissions." [86 Fed. Reg. at 63179] The commenter mentions that the proposed standard is based on a determination that non-emitting techniques constitute BSER for these sources. At the same time, the commenter points out that

---

<sup>27</sup> <https://apitep02.wpengine.com/what-were-doing/manual-liquids-removal/>.

<sup>28</sup> 87 FR 74781-74782.

EPA acknowledges that non-emitting techniques are not always feasible or safe and provide alternative standards to cover those situations.

In general, the commenter (0808-API) supports this approach as a practical matter and agrees that non-emitting measures and methods should be used where they are technically feasible and cost effective. The commenter highlights that the EPA rightly understands that non-emitting approaches are not always practicable and that imposing an absolute requirement would constitute an unwarranted prohibition on necessary operations, such as liquids unloading, in many situations. With that in mind, the commenter believes that the proposed alternative measures are a common-sense solution.

Response I-12-23: See discussion in sections IV.F.1, IV.F.3.a.i, IV.F.3.a.ii, and IV.F.3.a.iii of the December 2022 Supplemental Proposal preamble related to what EPA proposed as constituting a well affected facility/designated facility, and proposed liquids unloading operation requirements.<sup>29</sup> The EPA has not finalized its December 2022 proposal to require owners and operators to employ techniques or technologies that eliminate methane and VOC emissions, unless it was technically infeasible or not safe to meet the zero emissions standard. See Chapter 6, section 6.4.2 (Proposed BSER, subsection 6.4.2.2 Zero Emission Standard) of Volume II of this RTC Document for comments and EPA's responses to comments on the December 2022 Supplemental Proposal. See also sections X.F.1 and 3 of the preamble to the final rule for details on EPA's final standards and sections XI.F.1 and 3 of the preamble to the final rule for the basis for any changes made from the December 2022 supplemental proposal and final rule related to liquids unloading as an outgrowth of significant comments.

Comment: Commenter (0844-EDF *et al.*) supports EPA finalizing a standard of zero emissions for liquids unloading events and should consider affected facilities any site that undergoes liquids unloading. The commenter suggests EPA require rigorous documentation of all liquids unloading events and clear best practices that must be followed in limited situations in which liquids unloading cannot be conducted with zero emissions.

Specifically, the commenter (0844-EDF *et al.*) writes that EPA should limit permissible circumstances when liquids unloading can be conducted without zero emissions and require rigorous documentation of why venting had to occur. The commenter notes that EPA has proposed to allow venting if "it is technically infeasible or not safe to perform liquids unloading with zero emissions," in which case EPA proposes "to require that an owner or operator establish and follow [BMPs] to minimize methane and VOC emissions during liquids unloading events to the extent possible."<sup>30</sup> According to the commenter, EPA does not intend to "dictate all of the specific practices that must be included," but rather "would specify minimum acceptance criteria required for the types and nature of the practices."<sup>31</sup> The commenter maintains that this is too nebulous and is likely to result in regular venting, followed by operators checking off a handful of best practices. The commenter recommends that EPA clearly define best practices, list them in

---

<sup>29</sup> 87 FR 74781-74782.

<sup>30</sup> 86 FR 63,179.

<sup>31</sup> *Id.*

hierarchical order, and require operators to follow the practices or otherwise provide rigorous documentation as to why they could not do so.

Response I-12-24: See discussion in sections IV.F.1, IV.F.3.a.i, IV.F.3.a.ii, and IV.F.3.a.iii of the December 2022 Supplemental Proposal preamble related to what EPA proposed as constituting a well affected facility/designated facility, and proposed liquids unloading operation requirements.

<sup>32</sup> The EPA has not finalized its December 2022 proposal to require owners and operators to employ techniques or technologies that eliminate methane and VOC emissions, unless it was technically infeasible or not safe to meet the zero emissions standard. See Chapter 6, section 6.4.2 (Proposed BSER, subsection 6.4.2.2 Zero Emission Standard and subsection 6.4.2.4 Best Management Practices (BMPs)) of Volume II of this RTC Document for comments and EPA's responses to comments on the December 2022 Supplemental Proposal. See also sections X.F.1 and 3 of the preamble to the final rule for details on EPA's final standards and sections XI.F.1 and 3 of the preamble to the final rule for the basis for any changes made from the December 2022 supplemental proposal and final rule related to liquids unloading as an outgrowth of significant comments.

See section XI.F.3.b of the final rule preamble discusses the final rule recordkeeping and reporting requirements that apply to gas well liquids unloading events that vent to the atmosphere.

#### ***12.2.4 Best Management Practices***

Comment: Commenter (0810-Petroleum Alliance of Oklahoma (Petroleum Alliance-OK)) states that there are a variety of liquids unloading processes (*e.g.*, blowing a gas well down to a tank, swabbing a cased hole, and artificial lift), which are often tailored to the best production methods for the well. The commenter contends that EPA should not dictate production methods to producers. The commenter adds that many of their members participate in The Environmental Partnership whereby participants commit to monitor the manual unloading process onsite or in close proximity and close all wellhead vents to the atmosphere as soon as practicable. Overall, the commenter supports and encourages EPA to allow the use of these best management practices for this operation.

Commenters (0599-MS, 0831-AXPC) agree with EPA's observation, at 86 Fed. Reg. 63,180, "that there may be reasons that a non-venting method is infeasible for a particular well, and the proposed rule would allow for the use of BMPs to reduce the emissions to the maximum extent possible for such cases."

Similarly, commenter (0599-MS) supports the use of BMPs when venting is required for liquid unloading activities – as proposed for unloading technologies or techniques that result in venting to the atmosphere – *i.e.*, implement BMPs to ensure that venting is minimized and maintain BMPs as records, and record instances when they were not followed. Additionally, the commenter supports liquid unloading BMPs that empower production engineers to direct

---

<sup>32</sup> 87 FR 74781-74782.

unloading activities without technical justification and that are aimed at daily operational venting minimization.

Commenter (0831-AXPC) believes that it is crucial to allow flexibility for liquids unloading operations and appreciates that EPA acknowledges this.

Commenter (0743-WEA) is supportive, in general, of developing BMPs to be applied to liquids unloading; however, the commenter stresses doing so in such a way that avoids duplication of reporting efforts and unnecessary requirements.

Commenter (0808-API) generally supports a work practice standard built around the BMP approach described by EPA in the November 2021 Proposal. More specifically, the commenter supports EPA in allowing flexibility for operators to manage and operate their wells based on the engineering needs of the well. As a point of clarification, the commenter notes that the November 2021 Proposal characterizes several techniques as non-venting techniques. According to the commenter, some of the solutions discussed may minimize emissions from unloading, but not fully eliminate them.

Response I-12-25: See discussion in sections IV.F.1, IV.F.3.a.i, IV.F.3.a.ii, and IV.F.3.a.iii, and IV.F.3.b of the December 2022 Supplemental Proposal preamble related to what EPA proposed as constituting a well affected facility/designated facility, and proposed liquids unloading operation requirements.<sup>33</sup> The EPA has not finalized its December 2022 proposal to require owners and operators to employ techniques or technologies that eliminate methane and VOC emissions, unless it was technically infeasible or not safe to meet the zero emissions standard. See Chapter 6, section 6.4.2 (Proposed BSER, subsection 6.4.2.2 Zero Emission Standard and subsection 6.4.2.4 Best Management Practices (BMPs)) of Volume II of this RTC Document for EPA's responses to comments on the December 2022 Supplemental Proposal. See also sections X.F.1 and 3 of the preamble to the final rule for details on EPA's final standards and sections XI.F.1 and 3 of the preamble to the final rule for the basis for any changes made from the December 2022 supplemental proposal and final rule related to liquids unloading as an outgrowth of significant comments.

Comment: Commenters (0599-MS, 0831-AXPC, 0814-IPAA *et al.*) emphasize that automation reduces the safety risk of exposing personnel to hazardous atmospheres. The commenters agree with EPA's observation, at 86 Fed. Reg. 63,213, that "there may be safety and technical reasons why venting to the atmosphere is necessary to unload liquids." In addition, the commenters also agree that "it is possible that a well production engineer has already explored non-venting options and determined that there was no feasible option due to its specific characteristics and conditions."

Specifically, commenters (0599-MS, 0814-IPAA *et al.*) object to BMPs that include a requirement for the direct measurement of vented emissions and/or an operator to be in close proximity to the unloading activities when the use of automation equipment, remote sensors, and other surveillance technologies are used, as they would be a safety concern. The commenters state that an emission quantification hierarchy of direct measurement, engineering equations,

---

<sup>33</sup> 87 FR 74781-74782.

and emission factors will for almost all sources result in the most accurate emission values; however, engineering challenges, economic criteria, and safety considerations will result in the optimal selection on a case-by-case basis. The commenters underscore the point that there are safety concerns regarding direct measurement of venting emissions; adding that National Institute for Occupational Safety and Health- Occupational Safety and Health Administration (NIOSH-OSHA) have issued a Hazard Alert<sup>34</sup> – a supplement to the OSHA Alliance Tank Hazard Alert released in 2015 [National Service, Transmission, Exploration & Production Safety (STEPS) Network 2015], which describes the safety and health hazards when workers manually gauge or sample fluids from production, flowback, or other tanks. The commenters add that this alert also describes ways to protect workers by eliminating or reducing exposures to hazardous atmospheres, and actions employers should take to ensure that workers are properly aware of the hazards and protected from exposure to hydrocarbon gases and vapors. According to the commenters, although there are many cases of direct measurement being performed on methane emissions many of them are done in a controlled experimental environment. The commenters note that, in reality, workers need to use extreme caution whenever working around hydrocarbon emissions and many of the direct measurement techniques used and suggested (see 3CCAC Appendix A: Conducting Emission Surveys, Including Emission Detection, and quantification equipment, which include turbine meters, vane anemometers, hotwire anemometers) actually expose workers to these emissions and therefore should be avoided.

Response I-12-26: The final rule does not require direct measurement of vented emissions from liquids unloading events, however, implementing BMPs to minimize or eliminate emissions does require owners or operators ensure that steps outlined in their BMP are properly implemented to minimize venting to the maximum extent possible, which can be by automated or manual means.

See discussion in sections IV.F.1, IV.F.3.a.i, IV.F.3.a.ii, IV.F.3.a.iii, and IV.F.3.b of the December 2022 Supplemental Proposal preamble related to what EPA proposed as constituting a well affected facility/designated facility, and proposed liquids unloading operation requirements.

<sup>35</sup> The EPA has not finalized its December 2022 proposal to require owners and operators to employ techniques or technologies that eliminate methane and VOC emissions, unless it was technically infeasible or not safe to meet the zero emissions standard. See Chapter 6, section 6.4.2 (Proposed BSER, subsection 6.4.2.2 Zero Emission Standard and subsection 6.4.2.4 Best Management Practices (BMPs)) of Volume II of this RTC Document for EPA’s responses to comments on the December 2022 Supplemental Proposal. See also sections X.F.1 and 3 of the preamble to the final rule for details on EPA’s final standards and sections XI.F.1 and 3 of the preamble to the final rule for the basis for any changes made from the December 2022 supplemental proposal and final rule related to liquids unloading as an outgrowth of significant comments.

Comment: Commenter (0777-Ascent) argues that EPA should not use NSPS OOOOb and EG OOOOc to establish a prescribed set of practices or steps that limit an owner or operator’s flexibility in designing and implementing BMPs to minimize emissions from well liquids unloading. The commenter insists that operators should have flexibility to design their BMPs in a

---

<sup>34</sup> Health and Safety Risks for Workers Involved in Manual. Tank Gauging and Sampling at Oil and Gas Extraction Sites. <https://www.osha.gov/sites/default/files/publications/OSHA3843.pdf>.

<sup>35</sup> 87 FR 74781-74782.

way that best fits their operations while maintaining the goal of minimizing emissions during the unloading event.

Commenters (0743-WEA, 0808-API) affirm EPA's decision to allow flexibility for liquids unloading operations – a complex topic that has historically been difficult to address from a regulatory perspective (as noted by commenter 0808-API) and support EPA in providing criteria for consideration for inclusion in an operator's BMP. According to the commenters, techniques used for liquids unloading are certainly not a one-size-fits-all application. The commenters add that techniques used for liquids unloading are certainly not a one-size-fits-all application. According to the commenter, while certain technique(s) may reduce emissions from one well source, those same techniques, if used on a well with differing characteristics, may result in an increase in emissions. Consequently, the commenter (0743-WEA) asks that EPA work with industry to select already developed BMPs to apply to liquids unloading operations.

Commenters (0599-MSD, 0814-IPAA *et al.*, 0831-AXPC) agree with EPA's observation that "[s]electing a particular method to meet a particular well's unloading needs must be based on a production engineering decision that is designed to remove the barriers to production" [86 FR 217, 63211]. The commenters maintain that describing clearly where a well stream is directed via a process flow diagram and explanation is not in most cases a trivial explanation. According to the commenters, many well sites, especially sites with multiple wells, have a complex surface piping system for equipping the site with the various liquid unloading activities that could result, (e.g., gas injection, recirculation of produced gas in wellsite compression, vapor recovery unit (VRU) control options, combustors, oxidizers, multiple use of separators and tanks often manifolded together, soap and chemical delivery systems).

The commenters (0599-MSD, 0814-IPAA *et al.*) note that many member companies employ the Best Practice Implementation Principle, as defined in the API's *The Environmental Partnership Program for Manual Liquids Unloading: Operators*. The commenters add that although companies are committed to monitoring the manual unloading process and close all wellhead vents to atmosphere, it is important to point out that the definition of Manual Liquids Unloading is "an operation undertaken by an operator to temporarily divert the flow from the well to an atmospheric vent without assistance of automated equipment", and the definition of Monitored: "operator on-site or in close proximity and able to close atmospheric vent as soon as practicable to minimize the gas vented to atmosphere." The commenters state that the use of automation is a very important point in this BMP formulation, and the use of remote sensors, mechanically activated devices, positive closure and seal indicators, camera technology, and associated surveillance and alarming can greatly enhance the effectiveness of optimal liquid unloading and in many cases is more effective than relying on personnel to be on site. Therefore, the commenters contend that BMPs should not require having a person onsite during the liquids unloading event to expeditiously end the venting when the liquids have been removed (as suggested), but rather BMPs should encourage the continued use and expansion of use of automation technologies that are scalable and economic.

Commenter (0831-AXPC) acknowledges that the process footprint during a liquids unloading event can change throughout the life of the well depending on well conditions. According to the commenter, describing clearly where a well stream is directed via a process flow diagram and

explanation is often a complex and burdensome task that would ultimately not yield value in this context. Moreover, the commenter reports that the direct measurement of vented emissions is not always possible and runs a serious risk of exposing personnel to hazardous atmospheres. The commenter reminds EPA that NIOSH-OSHA have issued a Hazard Alert associated with working around open top tanks,<sup>36</sup> and generally recommend protecting workers by eliminating or reducing exposures to hazardous atmospheres.

Commenter (0924-U.S. Small Business Administration (SBA)) suggests that when EPA drafts implementing rule text, that EPA include deference to the BMP developed for that operation reflecting production engineering decisions. The commenter further suggests that EPA provide enforcement assurance that following a written BMP is sufficient to comply with the NSPS, and that methane emissions from liquids unloading operations cannot be used in of itself to show a violation of the NSPS.

Commenters (0599-MS, 0814-IPAA *et al.*) object to BMPs with any prescriptive requirement for using any specific unloading technology – like the requirement to try a plunger lift, or attempt the use of an artificial lift engine, both of which, the commenters write, can be found in the New Mexico draft language, as they would be too prescriptive in nature and would potentially impact the production engineer’s best design decisions.

Commenters (0599-MS, 0831-AXPC, 0814-IPAA *et al.*) recommend that EPA consider common elements (found within New Mexico [NM], Pennsylvania [PA], and Colorado [CO] state approved BMPs), which are non-prescriptive and allow for operators to employ their expertise in the selection of appropriate liquids unloading practices, in determining the minimum BMP element requirements. According to the commenters the commonality or consistencies of these elements reflects recognized and common practices that are proven. One such common practice, identified by the commenters, is to require monitoring during a liquid unloading event via the presence of an operator on-site or in close proximity. According to the commenters the application of remote monitoring via sensor technology may also be employed as feasible.

Commenters (0599-MS, 0814-IPAA *et al.*, 0831-AXPC) support BMPs that:

- Require an operator at the wellsite or in close proximity unless the use of automation equipment, remote sensors, and other surveillance technologies are used.
- Require the operator to report when the BMPs have not been followed.
- Allow for the use of flaring as a control option.
- Allow for routing emissions to a sales line or back to a process.

Commenters (0743-WEA, 0808-API) supports the language that EPA includes in the November 2021 proposal preamble:

...following specific steps that create a differential pressure to minimize the need to vent a well to unload liquids and reducing wellbore pressure as much as possible prior to

---

<sup>36</sup> Health and Safety Risks for Workers Involved in Manual. Tank Gauging and Sampling at Oil and Gas Extraction Sites. <https://www.osha.gov/sites/default/files/publications/OSHA3843.pdf>.

opening to atmosphere via storage tank, unloading through the separator where feasible, and requiring an operator to remain on-site throughout the unloading, and/or closure of all well head vents to the atmosphere and return of the well to production as soon as practicable.

Commenter (0743-WEA) maintains that this language, if applied as criteria for an operator's BMPs, would provide for emissions minimization across all types of liquids unloading events without prescribing certain technologies.

Response I-12-27: See discussion in sections IV.F.1, IV.F.3.a.i, IV.F.3.a.ii, IV.F.3.a.iii, and IV.F.3.b<sup>37</sup> of the December 2022 Supplemental Proposal preamble related to what EPA proposed as constituting a well affected facility/designated facility, and proposed liquids unloading operation requirements.<sup>38</sup> The EPA has not finalized its December 2022 proposal to require owners and operators to employ techniques or technologies that eliminate methane and VOC emissions, unless it was technically infeasible or not safe to meet the zero emissions standard. See Chapter 6, section 6.4.2 (Proposed BSER, subsection 6.4.2.2 Zero Emission Standard and subsection 6.4.2.4 Best Management Practices (BMPs)) of Volume II of this RTC Document for EPA's responses to comments on the December 2022 Supplemental Proposal. See also sections X.F.1 and 3 of the preamble to the final rule for details on EPA's final standards and sections XI.F.1 and 3 of the preamble to the final rule for the basis for any changes made from the December 2022 supplemental proposal and final rule related to liquids unloading as an outgrowth of significant comments.

With regards to comments that BMPs should not include a requirement for direct measurement of vented emissions, the final rule does not require direct measurement of vented emissions from liquids unloading events. See Response I-12-26 of this Chapter.

With regards to the commenter that requests that EPA allow the use of flaring as an emissions control option. Under the final standards under NSPS OOOOb and presumptive standards under EG OOOOc, based on these and other comments, owners or operators are allowed the option to comply with the GHG and VOC standards by reducing methane and VOC emissions from each gas well liquids unloading event by 95 percent by routing emissions to a control device via a CVS, which can include a flare.

Comment: Commenter (0756-Baker Hughes) believes that BMPs should include technologies that reduce the frequency of events as a means of reducing overall emissions; noting (along with commenter (0729-Energy Workforce & Technology Council (EWTC))) that there are significant opportunities to reduce emissions associated with liquids unloading despite the diversity of circumstances and technologies involved. According to the commenters, one means of facilitating reductions in methane emissions generated by liquids unloading is to deploy advanced methods that reduce the frequency of unloading events. To illustrate, the commenters mention technologies offered to improve production efficiency.

---

<sup>37</sup> 87 FR 74781-74782.

<sup>38</sup> 87 FR 74781-74782.

Additionally, commenter (0729-EWTC) writes there are artificial lift solutions that use advanced analytics and “smart” edge technology to boost production and reduce associated methane emissions from oil and gas wells.

According to commenter (0756-Baker Hughes), Vine Energy recently signed a contract to deploy its artificial lift solution, Productionlink™ Edge, across 100 natural gas wells in Louisiana's Haynesville Shale.

Both commenters (0729-EWTC, 0756-Baker Hughes) acknowledge, this follows a three-month joint pilot project in Haynesville Shale using the artificial lift solution across 10 wells, during which Vine Energy's gas production increased by 5 percent and well unloading events decreased by 94 percent.<sup>39</sup>

Response I-12-28: The EPA appreciates the commenters' information on artificial lift/technology solutions to reduce venting of methane and VOC emissions from gas well liquids unloading events. See discussion in sections IV.F.1, IV.F.3.a.i, IV.F.3.a.ii, IV.F.3.a.iii, and IV.F.3.b<sup>40</sup> of the December 2022 Supplemental Proposal preamble related to what EPA proposed as constituting a well affected facility/designated facility, and proposed liquids unloading operation requirements.<sup>41</sup> The EPA has not finalized its December 2022 proposal to require owners and operators to employ techniques or technologies that eliminate methane and VOC emissions, unless it was technically infeasible or not safe to meet the zero emissions standard. See Chapter 6, section 6.4.2 (Proposed BSER, subsection 6.4.2.2 Zero Emission Standard and subsection 6.4.2.4 Best Management Practices (BMPs)) of Volume II of this RTC Document for EPA's responses to comments on the December 2022 Supplemental Proposal. See also sections X.F.1 and 3 of the preamble to the final rule for details on EPA's final standards and sections XI.F.1 and 3 of the preamble to the final rule for the basis for any changes made from the December 2022 supplemental proposal and final rule related to liquids unloading as an outgrowth of significant comments.

Comment: Commenters (0599-MSA, 0814-IPAA *et al.*, 0831-AXPC, 0924-SBA) recommend that, for states where a BMP governing liquid unloading event is required under the states' regulations (*e.g.*, permit requirements), BMPs be deemed sufficient and satisfy the requirements of NSPS. Commenter (0831-AXPC) writes, that Congress designed NSR to be at least as stringent as the NSPS program, see CAA section 169(3) (defining Best Available Control Technology, the standard applicable under NSR, as an emissions limit that “[i]n no event” shall result in more emissions than those allowed under any applicable standard under 111). Therefore, the commenter recommends that a source's NSR-derived requirements for an activity be deemed to satisfy the requirements of the NSPS. According to the commenter, doing otherwise would contradict the statute and impose unnecessary duplicative regulations for no additional emissions benefit, and would be doubly inappropriate under the state-planning process under CAA 111(d), given the strong and explicit textual commitment to federalism and state flexibility in that subsection's text and structure. The commenter suggests that EPA allow states

---

<sup>39</sup> <https://www.bakerhughes.com/company/news/vine-energy-deploys-baker-hughess-advanced-analytics-enhance-gas-production-and>

<sup>40</sup> 87 FR 74781-74782.

<sup>41</sup> 87 FR 74781-74782.

to incorporate into their state plans under new EG OOOOc their NSR provisions for sources' liquids unloading events. The commenter contends that, to do otherwise would violate the cooperative federalist design of not one but two portions of the statute: CAA 111(d) and the states' NSR programs as incorporated in their State Implementation Plans under CAA 110.

Response I-12-29: See section XIII.C.3 of the final rule preamble for a discussion on state plans submitted in accordance with EGs that include provisions for remaining useful life and other factors (RULOF). State plans submitted in accordance with these EG that include provisions for RULOF must comply with the subpart Ba general RULOF provisions in 40 CFR 60.24a. For informational purposes, the EPA has summarized the RULOF provisions that have been finalized in the subpart Ba rulemaking, which is separate and distinct from this action in section XIII.C.3 of the final rule preamble.

### ***12.2.5 Other Requirements – Legacy Wells***

Comment: Commenter (0585-KOGA) recommends that a threshold of four (4) liquid unloading events per year be permitted before a singular well becomes an affected facility. According to the commenter, the additional compliance requirements could be the difference in eliminating or maintaining a large group of existing gas wells; or reducing the remaining life of many wells. The commenter expresses concern that wells that would have otherwise been considered exempt because they vent only a small amount of methane during a “liquid unloading” event that may only occur once a year or once every five years would become affected facilities and have to comply with NSPS OOOOb requirements of fugitive emission surveys and records submission for EPA.

The commenter (0585-KOGA) reports that there are a large number of “legacy” gas wells in the Appalachian Basin, comprised of just a wellhead that EPA rightly is proposing to exempt from EG OOOOc requirements. The commenter states that, as EPA notes, a significant number of these legacy wells with low pressure and low flow develop fluid buildup issues. In order to keep producing gas the fluid needs to be removed from the wellbore. The commenter explains that the fluid removal typically needs to be completed as frequently as once or twice per year and as infrequently as once every few years. The commenter adds that during these “unloading” operations a portion of the volume of gas in the wellbore is vented along with any additional production. The commenter states that the volume of this vented gas from the shallow wells operating at pressures well under 100 psi is less than 25,000 Standard Cubic Feet. Therefore, the commenter contends that even if liquid unloading events occurred 4 times a year, the total volume vented would be well under the 3 tons per year threshold proposed by EPA for exemption, and the 4 tons per year threshold recommended by the commenter.

The commenter (0585-KOGA) provides the following example: A typical Kentucky gas well is 1,500 feet deep and constructed with 6.25-inch internal diameter casing. The well has a volume of 320 cubic feet (6.25-inch diameter = 0.26 feet radius, volume =  $\text{Pi} \times r^2 \times h$ , volume =  $\text{Pi} \times (0.26 \text{ ft})^2 \times 1,500 \text{ ft} = 320 \text{ ft}^3$ ). At 50 psi that gas volume is 1,134 cubic feet (at standard conditions). Assuming the composition is 80 percent methane, the commenter writes, the methane emissions from the well casing is 31.8 pounds per event. According to the commenter,

if the well has an open flow of 40,000 cubic feet per day, the production is 10,000 ft<sup>3</sup>/day during the 6 hours required to remove the accumulated liquids. Approximately 11,000 ft<sup>3</sup> of gas is vented (10,000 ft<sup>3</sup> + 1,134 ft<sup>3</sup>), of which, the commenter notes, 80 percent is methane or 8,900 cubic feet of methane. The density of methane is 0.035 pounds/ft<sup>3</sup>. 8,900 ft<sup>3</sup> x 0.035 pounds/ft<sup>3</sup> = 311 pounds of methane vented per unloading event. The commenter concludes that the proposed well could complete 19 unloading events during a year before exceeding EPA's 3 tons per year threshold – the emissions rate is primarily driven by the production rate of the well, not the physical size of the wellbore.

Response I-12-30: See discussion in sections IV.F.1, IV.F.3.a.i, IV.F.3.a.ii, IV.F.3.a.iii, and IV.F.3.b<sup>42</sup> of the December 2022 Supplemental Proposal preamble related to what EPA proposed as constituting a well affected facility/designated facility, and proposed liquids unloading operation requirements.<sup>43</sup> The EPA has not finalized its December 2022 proposal to require owners and operators to employ techniques or technologies that eliminate methane and VOC emissions, unless it was technically infeasible or not safe to meet the zero emissions standard. See Chapter 6, section 6.4.2 (Proposed BSER, subsection 6.4.2.2 Zero Emission Standard and subsection 6.4.2.4 Best Management Practices (BMPs)) of Volume II of this RTC Document for EPA's responses to comments on the December 2022 Supplemental Proposal. See also sections X.F.1 and 3 of the preamble to the final rule for details on EPA's final standards and sections XI.F.1 and 3 of the preamble to the final rule for the basis for any changes made from the December 2022 supplemental proposal and final rule related to liquids unloading as an outgrowth of significant comments.

## 12.3 Liquids Unloading Definition

Comment: Commenter (0808-API) recommends that EPA clearly define liquids unloading within NSPS OOOOb. The commenter explains that other well maintenance and workover activities may occur on a well, and these activities are distinctly different, require different equipment and operation, and are reported differently in federal and state greenhouse gas inventories from well liquids unloading. To address this clarification, the commenter offers the following definition for "Liquids Unloading":

*Liquids Unloading* means the removal of accumulated liquids from the wellbore that reduce or stop natural gas production from natural gas wells. Routine well maintenance activities, including workovers, swabbing, coil tubing cleanouts, or any other activity that requires a rig or other machinery are not considered liquids unloading.

Response I-12-31: The EPA received a similar comment on the December 2022 Supplemental Proposal from this commenter. EPA's response to this commenter's proposed changes to the December 2022 Supplemental Proposal liquids unloading definition is provided at Volume II of this RTC, see section 6.4.3 of Chapter 6 (Response II-6-102). See final definition of "liquids unloading" at 40 CFR 60.5430b.

<sup>42</sup> 87 FR 74781-74782.

<sup>43</sup> 87 FR 74781-74782.

## 12.4 Direct Measurements of Gas Volume

Comment: Commenter (0776-CDPHE) contends that EPA's estimation method in the Greenhouse Gas Reporting Program, Subpart W, 40 CFR Part 98 (GHGRP), does not reliably calculate the volume of gas emitted during a well liquids unloading or maintenance activity. Accordingly, the commenter reports that they would require operators to use more direct measurements of this volume in their calculations.

Response I-12-32: The final rule requirements do not require that owners or operators measure/calculate or report liquid unloading vented emissions as required under GHGRP 40 CFR Part 98 Subpart W (subpart W) using Equations W-7, W-8, or W-9 of 40 CFR 98.233(f). The EPA streamlined recordkeeping and reporting requirements in the final rule to include the minimum required records and reports to ensure compliance with the final standards/presumptive standards. These streamlined requirements exclude requiring owners and operators having to measure/calculate or report liquid unloading vented emissions which are being reported under subpart W. See sections X.F.1 and 3 of the preamble to the final rule which details EPA's final standards related to well affected facilities/designated facilities and liquids unloading requirements.

## 12.5 Recordkeeping and Reporting Requirements

Comment: Commenter (0599-MSD) requests that EPA not consider record keeping and reporting requirements for non-venting liquid unloading events, but instead, consider existing data as reported under Subpart W to account for liquid unloading events resulting in vented emissions. The commenter maintains that it is not warranted to maintain records for non-venting events, and the lack of a framework for what constitutes a non-venting event renders it impractical or not possible to qualify or quantify a non-venting event. To illustrate, the commenter provides that the period of time when a well equipped with a plunger system sends the well stream directly to a separator with no vented emissions would qualify as a non-venting period. The commenter states that it is unclear how liquid unloading events during this period would be quantified (*e.g.*, a count of plunger cycles that successfully lift liquids and unload).

Commenter (0749-PAW) notes that non-vented liquids unloading reporting requirements are not feasible due to the nature of those events and administratively burdensome with no net gain in emission reductions. The commenter adds that liquids unloading will inevitably happen to every well at some point in its lifetime. By considering a liquid unloading event a modification, the commenter maintains that all well site facilities would become affected, and this would lead to an administrative burden with reporting and leak detection and repair (LDAR) monitoring while not reducing emissions.

Response I-12-33: The EPA streamlined recordkeeping and reporting requirements in the December 2022 Supplemental Proposal and final rule to include the minimum required records and reports to ensure compliance with the proposed and final standards/presumptive standards.

See discussion in sections IV.F.1, IV.F.3.a.i, IV.F.3.a.ii, and IV.F.3.a.iii of the December 2022 Supplemental Proposal preamble related to what EPA proposed as constituting a well affected

facility/designated facility, and proposed liquids unloading operation requirements.<sup>44</sup> Please also see sections X.F.1 and 3 of the preamble to the final rule which details EPA's final standards related to well affected facilities/designated facilities and liquids unloading requirements, including the final recordkeeping and reporting requirements.

Comment: Commenters (0599-MS, 0749-PAW, 0814-IPAA *et al.*, 0831-AXPC) note that, for reporting of liquid unloading events that result in vented emissions, EPA currently requires reporting of liquid unloading vented emissions under GHGRP 40 CFR Part 98 Subpart W (subpart W) using Equations W-7, W-8, or W-9 of §98.233(f). The commenters suggest that the current reporting methodology options are adequate and urge EPA to consider existing data reported under this Subpart W and not impart additional unnecessary reporting requirements. Commenter (0749-PAW) stresses that any additional reporting requirements would be duplicative and burdensome with no resulting emission reductions.

Commenter (0808-API) contends that the November 2021 Proposal Option 1, as written, would generate a significant amount of administrative burden by requiring operators to track all unloading events, including unloading events that are automated (on artificial lift or pump jacks), as well as those that do not vent any emissions to the atmosphere. The commenter notes that operators already report the number of liquids unloading events to EPA under the GHGRP. According to the commenter, several of the proposed reporting requirements/information – *e.g.*, the number of liquids unloading events in an annual report, are duplicative of other EPA reporting requirements.

Commenter (0831-AXPC) contends that the November 2021 Proposal Option 2 approach (which would apply to gas wells venting to the atmosphere) is consistent with EPA emission reporting requirements under the Greenhouse Gas Reporting Program at 40 CFR Part 98, where Calculation Methodology 1 states “. . . where gas wells are vented to the atmosphere to expel liquids accumulated in the tubing . . .” The commenter recommends that EPA utilize the existing required reporting for liquids unloading under Subpart W, and that EPA not impose additional reporting requirements.<sup>45,46</sup> The commenter recommends protecting workers by eliminating or reducing exposures to hazardous atmospheres and believes that EPA's GHGRP is adequate for liquids unloading reporting and quantification.

Response I-12-34: The EPA streamlined recordkeeping and reporting requirements in the December 2022 Supplemental Proposal and final rule to include the minimum required records and reports to ensure compliance with the proposed and final standards/presumptive standards. The final rule recordkeeping and reporting requirements do not require that owners or operators measure/calculate or report liquid unloading vented emissions as required under GHGRP 40 CFR Part 98 Subpart W (subpart W) using Equations W-7, W-8, or W-9 of 40 CFR 98.233(f).

---

<sup>44</sup> 87 FR 74781-74782.

<sup>45</sup> For reporting of liquids unloading events that result in vented emissions, the EPA currently requires reporting of liquids unloading vented emissions under GHGRP 40 CFR Part 98 Subpart W using Equations W-7, W-8, or W-9 of §98.233(f).

<sup>46</sup> Health and Safety Risks for Workers Involved in Manual. Tank Gauging and Sampling at Oil and Gas Extraction Sites. <https://www.osha.gov/sites/default/files/publications/OSHA3843.pdf>.

See discussion in sections IV.F.1, IV.F.3.a.i, IV.F.3.a.ii, and IV.F.3.a.iii of the December 2022 Supplemental Proposal preamble related to what EPA proposed as constituting a well affected facility/designated facility, and proposed liquids unloading operation requirements.<sup>47</sup> Please also see sections X.F.1 and 3 of the preamble to the final rule which details EPA's final standards related to well affected facilities/designated facilities and liquids unloading requirements, including the final recordkeeping and reporting requirements.

Comment: Commenters (0599-MS, 0814-IPAA *et al.*, 0831-AXPC) object to BMPs with any of the following requirements as they would be a record keeping and reporting burden with no direct emission reduction benefit:

- Technical justification for the unloading methodologies employed.
- Process flow explanation and or diagrams of unloading activities.
- Historical account of all activities associated with attempts to unload wells. (0599-MS, 0814-IPAA *et al.*)
- Direct measurement of vented emissions. (0831-AXPC)

Response I-12-35: While the final rules (*i.e.*, NSPS OOOOb and EG OOOOc) require that BMPs be implemented to minimize or eliminate methane and/or VOC for well affected/designated facilities that vent to the atmosphere, none of the requirements that commenters objected to were included in the final monitoring, recordkeeping and reporting requirements. The EPA streamlined recordkeeping and reporting requirements in the final rule to include the minimum required records and reports to ensure compliance with the final standards/presumptive standards.

See discussion in sections IV.F.1, IV.F.3.a.i, IV.F.3.a.ii, and IV.F.3.a.iii of the December 2022 Supplemental Proposal preamble related to what EPA proposed as constituting a well affected facility/designated facility, and proposed liquids unloading operation requirements.<sup>48</sup> Please also see sections X.F.1 and 3 of the preamble to the final rule which details EPA's final standards related to well affected facilities/designated facilities and liquids unloading requirements, including the final recordkeeping and reporting requirements.

## 12.6 Other Comments

### 12.6.1 Maintenance Activities – Recordkeeping and Reporting Requirements

Comment: Commenter (0727-OSEE/ODEQ) expresses concern about maintenance activities that require a well be opened for servicing. 86 Fed. Reg. 63119. Specifically, the commenter asks, “[i]f a well is opened for servicing, would those interventions be subject to reporting and/or recordkeeping? If so, what requirements would be applicable?”

Response I-12-36: The commenter did not provide sufficient context regarding “servicing” for the EPA to respond to. However, the EPA acknowledges that there may be a need for

---

<sup>47</sup> 87 FR 74781-74782.

<sup>48</sup> 87 FR 74781-74782.

applicability rule clarity and considered these and other comments requesting clarifications when developing the December 2022 Supplemental Proposal regulatory text. If servicing the well is because an owner or operator is unloading liquid and the well is a well affected facility/designated facility, that activity would be subject to requirements under NSPS OOOOb and EG OOOOc. Minimal recordkeeping and reporting requirements apply when liquids unloading technologies and techniques employed do not result in venting to the atmosphere. For events that vent to the atmosphere, BMPs to minimize or eliminate emissions are required to be followed in addition to meeting the associated records and reports.

See discussion in sections IV.F.1, IV.F.3.a.i, IV.F.3.a.ii, and IV.F.3.a.iii of the December 2022 Supplemental Proposal preamble related to what EPA proposed as constituting a well affected facility/designated facility, and proposed liquids unloading operation requirements.<sup>49</sup> Please also see sections X.F.1 and 3 of the preamble to the final rule which details EPA's final standards related to well affected facilities/designated facilities and liquids unloading requirements.

### ***12.6.2 Existing State Requirements***

Comment: Commenter (0776-CDPHE) provides a brief history of the state of Colorado's adopted and later expanded requirements that operators use BMPs to reduce emissions from well liquids unloading and other downhole well maintenance activities, and asks that EPA consider these regulations, particularly standards deemed more stringent – *i.e.*, Colorado's standards on plunger lifts and capture or control of emissions from well liquids unloading and well swabbing activities, once an applicability threshold is met or exceeded. The commenter recognizes that not all methods of liquids unloading lead to emissions to the atmosphere and stresses the fact that Colorado's regulations focus on those liquids unloading activities that do result in the emissions of natural gas. When plunger lifts are used, the commenter notes that under Colorado regulations, smart automation is used to monitor wellhead parameters – tubing and casing pressure, flow rate, and plunger travel time to “optimize plunger operations,” further reducing emissions.

To combat environmental injustice, the commenter (0776-CDPHE) states that Colorado's regulations require/apply a more stringent threshold to well unloading activities occurring in those areas. The commenter writes, the applicability thresholds are based on how frequently wells associated with a well production facility are unloaded or swabbed with emissions to the atmosphere. The commenter adds that they agree with EPA's determination that it may not be feasible in all circumstances to capture or control emissions. The commenter notes that Colorado's regulations do provide an exemption from control where an operator demonstrates to the commenter that control is not technically feasible.

Response I-12-37: The EPA, in the development of the proposed and final requirements for liquids unloading operations, reviewed existing state (including Colorado) and federal regulations and industry voluntary programs that govern liquids unloading activities, in addition to comments received on the proposals. The final standards/presumptive standards reflect many of the elements of regulations and voluntary programs reviewed. See discussion in sections IV.F.1, IV.F.3.a.i, IV.F.3.a.ii, and IV.F.3.a.iii of the December 2022 Supplemental Proposal

## Chapter 13. Centrifugal Compressors

### 13.1 General Support/Opposition for Proposed Centrifugal Compressor Requirements

Comment: Several commenters (0605-Muscogee (Creek) Nation, 0781-National Tribal Air Association (NTAA), 0391-Keweenaw Bay Indian Community (KBIC)) support the November 2021 proposed requirement to reduce emissions from wet seal degassing systems by 95 percent for existing sources, consistent with the proposed New Source Performance Standards (NSPS).

Conversely, commenter (1375-Kinder Morgan) states that if EPA maintains the November 2021 Proposal to control emissions from existing (as of 2021) wet seals by 95 percent, operators would more than likely be forced to replace wet seals with dry seals due to retrofit technical feasibility issues and costs that would be incurred. The commenter contends that this could have the unintended consequence of increasing emissions, because of the potential for dry seals to emit more pollutants than certain wet seals systems and the embodied energy needed to produce new equipment to replace well-functioning existing equipment. The commenter contends that EPA acknowledges that replacing wet seals with dry seals is an unreasonable outcome.

Response I-13-1: In response to comments received on the November 2021 Proposal, EPA proposed a different regulatory approach for this particular (wet seal centrifugal compressor) affected/designated facility in the December 2022 Supplemental Proposal. For details, please see discussion in sections IV.G.1.b and IV.G.2.b of the December 2022 Supplemental Proposal preamble.<sup>1</sup> Please also see section X.G.1 and X.G.2 of the preamble to the final rule which details EPA's final centrifugal compressor NSPS OOOOb and EG OOOOc standards/presumptive standards.

Comment: Commenter (0785-John Crane Inc.) supports conversion of oil seals and support systems for selected installations to a dry gas seal. The commenter states that the oil seals would be replaced by dry gas seals utilizing narrow section design (Aura narrow section), which minimizes compressor cavity modification requirements. The commenter notes that gas panel support systems would also be designed for the installations. In general, the commenter states that leaks are reduced typically by 90 percent.

Response I-13-2: In response to comments received on the November 2021 Proposal, EPA proposed a different regulatory approach for centrifugal compressor affected/designated facilities in the December 2022 Supplemental Proposal. For details, please see discussion in sections IV.G.1.b and IV.G.2.b of the December 2022 Supplemental Proposal preamble.<sup>2</sup> Please also see section X.G.1 and X.G.2 of the preamble to the final rule which details EPA's final centrifugal compressor NSPS OOOOb and EG OOOOc standards/presumptive standards. If an owner or operator of a centrifugal compressor equipped with a wet seal converts their oil seal to a dry gas seal, they would be required to meet the final NSPS OOOOb standards and EG OOOOc

---

<sup>1</sup> 87 FR 74791-92, December 6, 2022.

<sup>2</sup> 87 FR 74791-92.

presumptive standards for centrifugal compressors equipped with dry seals, however, the conversion from a wet seal to a dry seal would be allowed under the final rule.

## 13.2 Applicability/Exemptions

Comment: Commenter (0808-American Petroleum Institute (API)) recommends that EPA include special consideration for compressors on the Alaskan North Slope (ANS). Specific issues noted by the commenter include:

- On the ANS there is not a market for natural gas sales.
- Most of the gas that is produced with the oil is separated and then compressed (using large wet seal compressors) to be reinjected back down hole for conservation and enhanced oil recovery.
- The wet seal compressors on the ANS were installed from the mid-1970s to the mid-1980s, when the oil fields there began to be produced.
- Wet seal centrifugal compressors located on the ANS were originally designed and installed with a seal oil degassing system that captures most of the gas by volume then routes that gas to a flare.

The commenter (0808-API) explains that the ANS system design is simple. Rather than routing the sour seal oil directly to a degassing drum/tank (which vents to atmosphere), the sour seal oil is first routed to the sour seal oil traps. In these traps, most of the gas breaks out of the oil while remaining at a high enough pressure that it can enter the low-pressure flare header line. The gas that breaks out in these traps is routed to the flare, not vented. The sour seal oil is only then sent to the degassing drum/tank, where any remaining entrained gas breaks out and is vented to atmosphere. The commenter's comment letter includes a figure that depicts this process.

In 2010, the commenter (0808-API) provides that EPA's Natural Gas Star program<sup>3,4</sup>, in conjunction with British Petroleum (BP), conducted an analysis of this wet seal degassing system design on the ANS at the Central Compressor Station. This analysis, according to the commenter, concluded that the sour seal oil degassing design employed on the ANS has greater than 99 percent emission control. The commenter states that this level of emission control is equivalent to a dry gas seal system.

Commenter (0808-API) suggests that, since dry gas seal systems are not subject to the November 2021 Proposal (due to their low leak rate), and the ANS wet seal degassing system design has demonstrated equivalence to dry gas seal systems, wet seal degassing designs employing sour seal oil traps should also not be subject to the rule. The commenter asserts that the two systems are equivalent from a venting perspective and should receive similar treatment under the regulations.

---

<sup>3</sup> <https://www.epa.gov/sites/production/files/2016-04/documents/smith.pdf>.

<sup>4</sup> <https://www.epa.gov/sites/default/files/2016-06/documents/capturemethanefromcentrifugalcompressionsealoiddegassing.pdf>.

Response I-13-3: In response to comments received on the November 2021 Proposal, EPA proposed a different regulatory approach for particular centrifugal compressor affected/designated facilities in the December 2022 Supplemental Proposal. For details, please see discussion in sections IV.G.1.b and IV.G.2.b of the December 2022 Supplemental Proposal preamble.<sup>5</sup>

The EPA received a similar comment on the December 2022 Supplemental Proposal regarding the ANS wet seal degassing systems being unable, based on technical and cost feasibility issues, to meet the proposed BSER for existing and modified sources. They also provided information supporting their position that the ANS wet seal degassing systems used are inherently low-emitting. EPA's response to this comment is provided at X.G.2.f (Wet Seal Compressors Equipped with a Seal Oil Gas Separation System Utilized on the Alaska North Slope (ANS)) of the final rule preamble.

Comment: Commenters (0465-Jordan Development Company, LLC (JDC), 0946-Michigan Oil and Gas Association (MOGA)) request that EPA listen to the small business industry segment before creating a technically and financially infeasible "one-size-fits-all" approach to regulations based on generalized production modeling and special interest groups. The commenters recommend that EPA continue the exemption of both centrifugal and reciprocal compressors "located at a well site, or an adjacent well site and servicing more than one well site, is not an affected facility" as provided in both NSPS OOOO and OOOOa. According to the commenters, well operators visit and service these wells and associated compressors daily to inspect for proper operation, leaks and to conduct maintenance and repairs activities. Any necessary repairs are implemented as soon as possible to avoid product loss and to maximize profit returns. If EPA wishes to propose monitoring for well site compressors, the commenters recommend EPA allow the more feasible and cost-effective monthly auditory, visual, and olfactory (AVO) inspection and documentation, similar to the requirements allowed under 40 CFR 60.5416a.

Response I-13-4: With regards to comments requesting that EPA listen to the small business industry segment before creating a technically and financially infeasible "one-size-fits-all" approach to regulations based on generalized production modeling and special interest groups, see comment response to similar comments in Volume I, Chapter 23, section 23.17 (One-Size Fits All Approach), Response I-23-70.

In response to comments received on the November 2021 Proposal, EPA proposed a different regulatory approach for centrifugal compressor (and reciprocating compressor) affected/designated facilities in the December 2022 Supplemental Proposal. For details, please see discussion in sections IV.G.1 (for NSPS OOOOb) and IV.G.2 (for EG OOOOc) of the December 2022 Supplemental Proposal preamble.<sup>6</sup> The applicability of compressor standards to centralized production facilities does not extend to single well sites. See section XI.G.5 of the final rule preamble regarding the applicability of requirements to compressors located at centralized production facilities.

---

<sup>5</sup> 87 FR 74791-74792.

<sup>6</sup> 87 FR 74783-92.

Comment: Commenter (1375-Kinder Morgan) believes that compressors in the transmission segment should be treated similar to the compressors located at well sites. The commenter notes that the wet seal proposal applies the existing BSER currently applicable to wet seals under NSPS OOOO and OOOOa to additional affected facilities. The commenter states that this is because EPA relies exclusively on the BSER analysis it undertook for wet seal compressors in the 2015/2016 NSPS OOOOa rulemaking to propose the same controls for the proposed NSPS OOOOb and EG OOOOc. The commenter further notes that EPA excluded centrifugal compressor wet seals located at well sites from the prior rules because there are a small number of wet seals at well sites, and the cost of controlling emissions would not be cost-effective, and EPA carried this conclusion forward in the proposed NSPS OOOOb. According to the commenter the type of controls that would be used on a well site would be the same or similar to those used at a transmission compressor station and that based on the low leak rates and minimal emissions documented (through measurement) from its wet seal centrifugal compressor systems, wet seals in the transmission segment are more similarly situated to those at well sites.

Response I-13-5: In response to comments received on the November 2021 Proposal, EPA proposed a different regulatory approach for centrifugal compressor affected/designated facilities in the December 2022 Supplemental Proposal. For details, please see discussion in sections IV.G.1 (for NSPS OOOOb) and IV.G.2 (for EG OOOOc) of the December 2022 Supplemental Proposal preamble.<sup>7</sup> For comments and responses to comments on the December 2022 Supplemental Proposal, see Volume II, Chapter 10 (Centrifugal Compressors) and section XI.G of the final rule preamble.

Comment: Commenter (0808-API) requests that EPA clarify the applicability of compressor standards to well sites. The commenter states that the definition proposed for central production facility may extend applicability to compressors located at well sites, which have historically been exempt from the compressor standards. As EPA states they have not updated their cost analyses with new information with respect to well sites, the commenters believe that extending applicability to well sites was not EPA's intent.

Commenter (0923-Lambda Energy Resources LLC (Lambda)) urges EPA to keep the current compressor exemptions shown in both subparts NSPS OOOO and OOOOa stating compressors "located at a well site, or an adjacent well site and servicing more than one well site, is not an affected facility."

Response I-13-6: The applicability of compressor standards to centralized production facilities does not extend to single well sites. See section XI.G.5 of the final rule preamble regarding the applicability of requirements to compressors located at centralized production facilities.

---

<sup>7</sup> 87 FR 74783-92.

## 13.3 BSER Analysis

### *13.3.1 Proposed Wet Seal Centrifugal Compressor Standards*

Comment: Commenters (1375-Kinder Morgan, 0415/1391-Interstate Natural Gas Association of America (INGAA)) state that the November 2021 proposed 95 percent reduction standard is unclear insofar as there is no indication of what value or baseline to which the reduction is to be measured against. The commenter note that the baseline was not identified in development of NSPS OOOO and NSPS OOOOa or in the proposed NSPS OOOOb and the issue was not materially raised by commenters in prior NSPS rulemakings either because the BSER for wet seals did not apply to the transmission segment (NSPS OOOO) or the BSER only theoretically applied to the transmission segment (NSPS OOOOa) because no new wet seals were installed after 2015. A requirement to reduce emissions with an unknown baseline by 95 percent is a wholly different requirement, and the commenters respectfully submits that such proposal is arbitrary and ripe for compliance concerns. The commenters request additional clarity and technical analysis to understand whether and to what extent a 95 percent emissions reduction requirement can and will be achieved, either through control or routing to process.

Response I-13-7: In response to comments received on the November 2021 Proposal, EPA proposed a different regulatory approach for centrifugal compressor affected/designated facilities in the December 2022 Supplemental Proposal. For details, please see discussion in sections IV.G.1 (for NSPS OOOOb) and IV.G.2 (for EG OOOOc) of the December 2022 Supplemental Proposal preamble.<sup>8</sup> For EPA's response to comments on the December 2022 Supplemental Proposal, see Volume II, Chapter 10 (Centrifugal Compressors) and section XI.G of the final rule preamble.

Comment: Commenter (1375-Kinder Morgan) notes that EPA is proposing to require "emissions" be reduced by 95 percent without considering that air, not containing either volatile organic compounds (VOCs) or methane, inherently constitutes part of the emissions stream from wet seals. The commenter states that EPA has conducted no analysis to determine the amount of air contained in potential emissions from wet seals. While the commenter does not have precise data on the amount of air contained in emissions from wet seals, they note that they continue to evaluate this issue. One vendor to the commenter, Solar Turbines, Inc. ("Solar"), has concluded that the emissions from its units are "mostly engine air." According to the Solar analyses, "it is likely that the[ ] flow data represent mostly engine air and that the actual methane emissions are much lower." The commenter contends that, so long as EPA fails to account for the levels of air contained in emissions from wet seals, the 95 percent reduction standard will not only be inaccurate, but it will remain unclear because, as currently written, the standard requires that operators reduce emissions that contain "mostly engine air." Without defining the way in which baseline emissions should be measured or prescribing a method for determining the amount of pollutants contained within overall emissions from wet seals, the commenter asserts that EPA's requirement is impossible to meet.

---

<sup>8</sup> 87 FR 74783-74792.

Response I-13-8: The demonstration of 95 percent control is based on a mass emission rate reduction. To demonstrate 95 percent control, the owner or operator must demonstrate that the inlet mass emissions of VOC and methane have been reduced by at least 95 percent at the outlet. Because the calculation is mass-based and not volume-based, the addition of air does not matter in the calculation of percent control efficiency.

Comment: Commenters (1375-Kinder Morgan, 0415/1391-INGAA) state that EPA's estimate of technical feasibility and control costs for existing wet seal centrifugal compressors has not been applied or demonstrated in any real-world application of such controls. Further, the commenters contend that the impact of EPA retroactively applying the wet seal proposal to wet seals existing as of 2021 is significant. Commenter (1375-Kinder Morgan) notes that in total, they operate 197 wet gas seals, 98 of which are manufactured by Solar.<sup>9</sup> They add that all these units were installed prior to 1999, and most of them were installed in the 1980s. The commenter's remaining 99 wet seal centrifugal compressor units consist of 30 different models manufactured by 8 different manufacturers: Clark, Cooper Bessemer, DeLaval, Dresser Rand, Ingersoll-Rand, General Electric, Worthington, and Norwalk. The commenter reports that all these units were installed prior to 2000. They add that all their wet seal compressors were in operation prior to 2015 and after review of the commenter's records, they have confirmed that none of the wet seal centrifugal compressor affected facilities have been modified since 2015 to require control to 95 percent or to be replaced by dry seals. The commenter states that, when installing new units, since 2015, it is their practice to install dry seal centrifugal compressor systems, therefore, the 95 percent reduction standard has not been meaningfully applied by the commenter.

Commenter (1375-Kinder Morgan) states that, because BSER for wet seals may have been required by EPA in certain circumstances since the inception of NSPS OOOO, the same commenter conducted independent due diligence to understand how operators are effectively applying the existing 95 percent reduction requirements under NSPS OOOOa. The commenter engaged with multiple trade associations and other midstream operators, including operators of gathering and boosting compressor stations as well as natural gas processing plants. The commenter found that no midstream operator was able to share experience in effectively controlling or capturing a wet seal system by 95 percent.

Commenter (1375-Kinder Morgan) further states that EPA has not published any data or technical analysis describing the extent to which the current BSER for wet seals is implemented and cost-effective. Given the lack of application of what EPA suggests is BSER, the commenter states that it is apparent that EPA has not comprehensively evaluated the existing standard to determine whether it is an effective, reasonable, and cost-effective measure, and whether it should remain BSER for existing sources. The existing requirement in NSPS OOOOa appears to be largely theoretical because virtually all seals installed in the midstream and transmission segments since 2015 have been dry seals. This foundational issue of clarifying a 95 percent reduction requirement is a crucial one if EPA is to adopt a workable standard.

---

<sup>9</sup> Solar models operated by Kinder Morgan (the commenter) include: the Saturn, Centaur 40, Centaur 50, and Taurus 60.

Response I-13-9: In response to comments received on the November 2021 Proposal, EPA proposed a different regulatory approach for centrifugal compressor affected/designated facilities in the December 2022 Supplemental Proposal. For details, please see discussion in sections IV.G.1 (for NSPS OOOOb) and IV.G.2 (for EG OOOOc) of the December 2022 Supplemental Proposal preamble.<sup>10</sup> For EPA's response to comments on the December 2022 Supplemental Proposal, see Volume II, Chapter 10 (Centrifugal Compressors) and section XI.G of the final rule preamble.

Comment: Commenter (0415/1391-INGAA) states that to provide transparency for EPA's evaluation, EPA should include in the record of the supplemental notice a new Technical Support Document (TSD) (or technical memorandum) that presents EPA's analysis within one document rather than citing two previous TSDs, and that clearly and transparently states all assumptions associated with the calculations.

Response I-13-10: See EPA-HQ-OAR-2021-0317-1578 "2022 Supplemental Proposal Oil and Natural Gas Sector NSPS and EG Technical Support Document and Supporting Spreadsheets."

Comment: Commenter (0415/1391-INGAA) states EPA needs to reevaluate its BSER evaluation, for existing wet seal centrifugal compressors (the only kind that exists, actually, since no one is constructing new wet seal compressors). EPA should not rely on calculations that are not transparently provided in the record for the rulemaking, and EPA should not rely on current cost estimates for NSPS OOOOa proposed controls at existing wet seal compressors.

Response I-13-11: In response to comments received on the November 2021 Proposal, EPA proposed a different regulatory approach for centrifugal compressor affected/designated facilities in the December 2022 Supplemental Proposal. For details, please see discussion in sections IV.G.1 (for NSPS OOOOb) and IV.G.2 (for EG OOOOc) of the December 2022 Supplemental Proposal preamble.<sup>11</sup> For EPA's response to comments on the December 2022 Supplemental Proposal, see Volume II, Chapter 10 (Centrifugal Compressors) and section XI.G of the final rule preamble.

### ***13.3.2 Emissions***

Comment: Commenters (0415/1391-INGAA, 1375-Kinder Morgan) assert that actual wet seal centrifugal compressor baseline emissions are significantly lower than the emissions estimates that EPA used in the November 2021 Proposal's BSER analysis, and they recommend that EPA use updated emissions information reported under GHGRP subpart W. According to one commenter (0415/1391-INGAA), the emission factor for wet seal compressors for previous NSPS OOOO and NSPS OOOOa analyses is more than five times higher than the updated compressor emission factor, which EPA itself recognized and adopted in 2016.

The commenters (0415/1391-INGAA 1375-Kinder Morgan) note that a recent paper published by Pipeline Research Council International, Inc. (PRCI) provides a current best-estimate of

---

<sup>10</sup> 87 FR 74783-74792.

<sup>11</sup> 87 FR 74783-74792.

transmission and storage compressors emissions, to update emission estimates in the EPA Annual GHGRP inventory report, and to provide EPA with an analysis of measured compressor emissions for Subpart W.<sup>12</sup> The commenters provide that the paper compiled hundreds of measurements for wet seal compressor methane emissions between 2011 and 2016. The analysis found emissions from centrifugal units with wet seal systems were approximately 7,730 standard cubic feet (scf) of natural gas per day—vastly lower than historical estimates. The detailed results presented in the PRCI report show a composite wet seal compressor emission factor 85 percent lower than the inflated, circa 2010-2015 emission factor used by EPA in the TSD, with the emissions specific to the regulated source (degassing vent) over 90 percent lower.

Commenter (1375-Kinder Morgan) provides information on wet seal centrifugal compressor emissions for their equipment in the transmission segment and requests EPA to consider using it in any new BSER analysis. The commenter states that they conducted extensive analysis of its existing data to evaluate potential emissions from its wet seals and dry seals.<sup>13</sup> The commenter reviewed actual measurement data—leak rate, in standard cubic feet per minute (scfm)—from all of its wet and dry seal units, the data covering the period of 2017 through 2021. The data set is comprised of over 520 measured data points. According to the commenter, of its 197 wet seal units, the commenter has 223 measured data points for leak rate across 112 units. Where measured data for a particular unit was not available, the commenter calculated an average leak rate based on all documented measurements sourced from that particular model. If the commenter did not have measured data for a specific model, they conservatively applied the average of all measured data as the leak rate. For the latter, the commenter reports that this generic average was only applied to 10 wet seal units. A few critical summary points include the following:

- The average leak rate for all wet seal units was 0.46 scfm.
- The maximum measured leak rate was scfm, and the minimum leak rate was 0 scfm.
- Further parsing this data, 46 of the 112 wet seal units that were tested had a 5-year average of 0 scfm.
- Only 7 of the 112 wet seal units with measured data had one or more data points over 3 scfm over the last 5 years.
- Conservatively applying the maximum leak rate for each unit over the past 5 years, and assuming 8,760 hours of operation,<sup>14</sup> the total cubic feet of gas leaked for all 197 units is approximately 80,558 smcf for a single year, and the average is 409 smcf per unit.

---

<sup>12</sup> See T. McGrath et al., PRCI White Paper: Methane Emission Factors for Compressors in Natural Gas Transmission and Underground Storage based on Subpart W Measurement Data, at 47, Tbl. 4-1, Catalogue No. PR-312-18209-E01 (Oct. 17, 2019), available for purchase at <https://www.prci.org/Research/CompressorPumpStation/CPSPProjects/CPS-17-01A/142206/171289.aspx>.

<sup>13</sup> We refer the reader to Section VI of the comment letter for a summary of Kinder Morgan's measured data related to dry seals.

<sup>14</sup> Assuming 8,760 hours of operation is conservatively high. These wet seals will only have a leak rate when in operation, and they do not operate 8760 hours.

The commenter (1375-Kinder Morgan) states that they then applied the same methodology EPA applied in the November 2021 Proposal to determine the estimated tons-per-year (tpy) of VOC and methane, per unit:<sup>15</sup>

- Conservatively applying the max leak rate for each unit over the past 5 years, and assuming 8,760 hours of operation, for all 197 units the total methane emissions are estimated at 1,677 tpy, and 8.5 tpy methane per unit.<sup>16</sup>
- Conservatively applying the max leak rate for each unit over the past 5 years, and assuming 8,760 hours of operation, for all 197 units the total VOC emissions are estimated at 46 tpy, and 0.23 tpy VOC per unit.

Commenter (1375-Kinder Morgan) notes that EPA estimates indicate that the baseline uncontrolled emissions for each individual centrifugal wet seal compressor at transmission compressor stations to be 157 tpy methane and 4.3 tpy VOC. The commenter estimates that the baseline uncontrolled emissions for each of their companies' individual centrifugal wet seal compressors are 8.5 tpy methane and 0.41 tpy VOC, with an average leak rate of 0.46 scfm. Notably, the commenter states that most of the measured flow rates for wet seal compressors are lower than EPA's estimated flow rate for dry seal compressors of 6 scfm. In fact, of the commenter's 233 measured data points taken on wet seals across 112 units, only 2 units and a total of 4 data points were above 6 scfm. According to the commenter, these low emissions can be attributed to the companies' practice of maintaining its wet seals to the point that their emissions are comparable to or less than dry seals.

According to the commenter (1375-Kinder Morgan), the key points to takeaway are that: the commenters wet seals are a minimal source of methane emissions (based on conservative estimates<sup>17</sup>), and an insignificant source of VOC emissions, based on conservative estimates; reducing those values even further, let alone by 95 percent, would be cost prohibitive and potentially technically infeasible, particularly considering that much of the leak rate may be comprised of air, and not regulated pollutants; and finally, a well-maintained wet seal functions just as well if not better than a dry seal.

Response I-13-12: In response to comments received on the November 2021 Proposal, EPA re-evaluated the November 2021 BSER using GHGRP subpart W emissions information and

---

<sup>15</sup> 86 Fed. Reg. at 63,221 ("The wet-seal centrifugal compressor methane uncontrolled emission factors are based on the volumetric emission factors used for the GHGI, which were converted to a mass emission rate using a density of 41.63 pounds of methane per thousand cubic feet. The VOC emissions were calculated using the ratio of . . . 0.0277 pounds VOC per pound of methane for the transmission and storage segment.").

<sup>16</sup> These tpy calculations assume that the entire stream is emissions. However, as noted above, some significant percent of this stream could be merely *air* and not pollutants.

<sup>17</sup> The commenter (Kinder Morgan) recognizes that EPA also has public data submitted by the commenter and other operators regarding wet seals as a part of the GHGRP. The commenter submits that the data analysis that they summarize above is a better source of data (as compared to the Subpart W data points) for this particular analysis for the following reasons: The analysis above is more (1) comprehensive than the commenter's Subpart W data, as Subpart W includes reporting thresholds, which does not capture all of the commenter's wet seals; (2) accurate, because the commenter used measured data rather than application of an average factor; and (3) conservative, because the commenter applied a worst case scenario, assuming the highest measured leak rate at 8,760 hours of operation.

proposed a different regulatory approach for centrifugal compressor affected/designated facilities in the December 2022 Supplemental Proposal. For details, please see discussion in sections IV.G.1 (for NSPS OOOOb) and IV.G.2 (for EG OOOOc) of the December 2022 Supplemental Proposal preamble.<sup>18</sup> For EPA's response to comments on the December 2022 Supplemental Proposal, see Volume II, Chapter 10 (Centrifugal Compressors) and section XI.G of the final rule preamble.

### ***13.3.3 Cost and Cost Effectiveness***

Comment: Commenter (1375-Kinder Morgan) states that the BSER for wet seal centrifugal compressors in the transmission segment is a proposed regulatory approach for reduction of methane, with potentially only limited VOC co-benefits. The commenter indicates that they evaluated gas composition at five transmission compressor stations in support of this point. The data was gathered over a period of a year (July 2020 to July 2021) from gas chromatographs (GCs). The GCs continuously monitor the commenter's natural gas at all receipt points, some delivery points, and other key junctures along the transmission system. The GCs take approximately three samples every hour, which are then averaged to get one numerical block-hour average. The average VOC content evaluated was less than 1 percent and can be as low as 0.0206 percent.

Response I-13-13: In response to comments received on the November 2021 Proposal, EPA re-evaluated the November 2021 BSER for centrifugal compressor affected/designated facilities in the December 2022 Supplemental Proposal. For details, please see discussion in sections IV.G.1 (for NSPS OOOOb) and IV.G.2 (for EG OOOOc) of the December 2022 Supplemental Proposal preamble.<sup>19</sup> For EPA's response to comments on the December 2022 Supplemental Proposal, see Volume II, Chapter 10 (Centrifugal Compressors) and section XI.G of the final rule preamble.

Comment: Commenters (1375-Kinder Morgan, 0415/1391-INGAA) state that the costs used by EPA in the November 2021 Proposal's BSER analyses were not representative of actual costs, and that EPA had significantly underestimated the costs for the control options evaluated. The commenters note that in essence, EPA used figures it developed from previous, and historic rulemakings and updated those figures to account for inflation. However, according to the commenters the earlier figures are unreliable, not vetted by EPA, and clearly underestimate the costs associated with wet seal emissions control or capture.

The commenters (1375-Kinder Morgan, 0415/1391-INGAA) add that in developing NSPS OOOO, EPA found that the costs for the centrifugal compressor wet seal capture system and determined a system of this type, in which the seal oil degassing vents are routed to fuel gas, compressor suction or an existing flare would cost \$22,000. The commenters report that the estimated cost includes an intermediate pressure degassing drum, new piping, gas demister/filter and a pressure regulator for the fuel line. In 2016, EPA updated these costs. Where a facility already has a flare installed, EPA estimated capital costs to be \$23,252 for routing a wet seal

---

<sup>18</sup> 87 FR 74783-74792.

<sup>19</sup> 87 FR 74783-74792.

fluid degassing system to a process. To install a new control device, EPA estimated capital costs of \$71,783.

Commenters (1375-Kinder Morgan, 0415/1391-INGAA) state that in evaluating costs associated with the November 2021 Proposal for wet seals, EPA did not undertake new cost analysis necessary to confirm whether cost-estimates were accurate based on actual data; the agency simply adjusted values for inflation. The commenters found this approach highly problematic insofar that EPA's 2015 estimates are largely theoretical because BSER has not been applied under NSPS OOOOa for existing wet seal centrifugal compressors in the transmission segment. Further the commenters were concerned that EPA based its cost-benefit analysis on the 2010/2011 NSPS OOOO and 2016 NSPS OOOOa is not accurate since those analyses did not use the updated emissions factor for wet seal compressors, which is applied in the GHGRP. Commenter (0415/1391-INGAA) adds that, it appears that there are errors in the analysis, or EPA has included assumptions or calculation corrections that are not apparent or stated.

The commenters (1375-Kinder Morgan, 0415/1391-INGAA) contend that using inflated emissions factors overestimates the emissions as compared to the costs. One of the commenters (1375-Kinder Morgan) provided detailed cost information that they stated was more representative of actual costs for three combustion scenarios, the option to route to a process for control, and retrofit costs. [See sections 13.3.2.1 and 13.3.2.2 below]

Response I-13-14: In response to comments received on the November 2021 Proposal, EPA re-evaluated the November 2021 BSER for centrifugal compressor affected/designated facilities in the December 2022 Supplemental Proposal. For details, please see discussion in sections IV.G.1 (for NSPS OOOOb) and IV.G.2 (for EG OOOOc) of the December 2022 Supplemental Proposal preamble.<sup>20</sup> For EPA's response to comments on the December 2022 Supplemental Proposal, see Volume II, Chapter 10 (Centrifugal Compressors) and section XI.G of the final rule preamble.

#### 13.3.2.1 Routing to a control device

Comment: Commenter (1375-Kinder Morgan) provides detailed cost information that they state was more representative of actual costs for three combustion scenarios. Based on vendor quotes the commenter estimates the cost of installing a flare, as well as both a "low end" and a "high end" for the cost of routing emissions from the wet seal compressor to an enclosed combustion device. According to the commenter, the cost of the flare would consist of the equipment (\$120,000), piping (\$5,000), and contractor labor, installation, and civil/structural engineering consultation (\$60,000). However, the commenter does not believe that the flare is likely to be an effective control technology in this context. The costs for the enclosed combustion device would consist principally of the cost of a combustor, panel, and knockout vessel (\$40,000 - \$79,000); piping to assist gas as well as waste gas header pipe (\$5,000); and contractor labor, installation, and civil/structural engineering consultation (\$60,000). In Table 1 of their comment letter, included as Table 13-1 below, and using EPA cost calculation methodologies, the commenter

---

<sup>20</sup> 87 FR 74783-74792.

summarizes its estimated costs-per-ton to apply the wet seal centrifugal compressor proposal by controlling methane emissions by 95 percent.

Table 13-1. Kinder Morgan Cost-Effectiveness Analysis for Control of Wet Seals by 95% in the Transmission Segment

| Control Equipment         | Pollutant | Capital Cost | Total Annual Cost* | Emission Reduction | Cost Effectiveness |
|---------------------------|-----------|--------------|--------------------|--------------------|--------------------|
|                           |           | (\$)         | (\$)               | (TPY)              | (\$/ton reduced)   |
| <b>Combustor low-end</b>  | Methane   | \$105,000    | \$136,310          | 8.08               | \$16,880           |
| <b>Combustor high-end</b> | Methane   | \$144,000    | \$143,422          | 8.08               | \$17,761           |
| <b>Flare</b>              | Methane   | \$185,000    | \$150,900          | 8.08               | \$18,687           |

According to the commenter (1375-Kinder Morgan), whether they were to pursue control, neither proposed regulatory approach is cost-effective, by EPA's own measure. Further, EPA's cost-effectiveness conclusions are mistaken or outdated; first because very few if any transmission operators have been required to apply the 2016 NSPS OOOOa BSER to wet seals and second, because the actual data evaluated demonstrates that EPA underestimated costs and overestimated emissions. The commenter notes that the result is that the cost-per-ton of methane reduced is well above \$2,185/ton, let alone the previous estimate of \$1,093/ton. In conclusion, the commenter's analysis indicates that it is categorically cost prohibitive to implement EPA's proposed BSER to capture or control wet seal centrifugal compressors by 95 percent in the transmission segment.

Response I-13-15: In response to comments received on the November 2021 Proposal, EPA re-evaluated the November 2021 BSER for centrifugal compressor affected/designated facilities in the December 2022 Supplemental Proposal with consideration of the costs provided by the commenter. For details, please see discussion in sections IV.G.1 (for NSPS OOOOb) and IV.G.2 (for EG OOOOc) of the December 2022 Supplemental Proposal preamble.<sup>21</sup> For EPA's response to comments on the December 2022 Supplemental Proposal, see Volume II, Chapter 10 (Centrifugal Compressors) and section XI.G of the final rule preamble.

#### 13.3.2.2 Routing to a process

Comment: Commenter (1375-Kinder Morgan) states that EPA misstates the complexity of the re-routing process in general and significantly underestimates the costs of routing to process. The

<sup>21</sup> 87 FR 74783-74792.

commenter reports on research they conducted to determine what technologies might exist for the proposed capture and has identified one (and only one) potential capture technology; however, this technology remains untested for wet seals. Based on information from the third-party vendor, the commenter reports that the costs to route to capture include the cost of equipment (\$400,000) and contractor labor, installation, and civil/structural engineering consultation (\$300,000). According to the commenter, these costs are conservatively low because they do not include the cost of re-routing electrical infrastructure that could be required to power the new equipment, or in the alternative, the cost of installing a new engine, as applicable. In Table 13-3, below, and using the EPA methodologies, the commenter summarizes its estimated costs-per-ton to apply the wet seal centrifugal compressor proposal by capturing methane emissions by 95 percent and routing to process.

Table 13-3. Kinder Morgan Cost-Effectiveness Analysis for Capture of Wet Seals by 95% in the Transmission Segment

| Control Equipment | Pollutant | Capital Cost | Total Annual Cost* | Emission Reduction | Cost Effectiveness |
|-------------------|-----------|--------------|--------------------|--------------------|--------------------|
|                   |           | (\$)         | (\$)               | (TPY)              | (\$/ton reduced)   |
| Recapture system  | Methane   | \$700,000    | \$244,824          | 8.50               | \$28,803           |

According to the commenter (1375-Kinder Morgan), whether they were to pursue control, neither proposed regulatory approach is cost-effective, by EPA's own measure. Further, EPA's cost-effectiveness conclusions are mistaken or outdated; first because very few if any transmission operators have been required to apply the 2016 NSPS OOOOa BSER to wet seals and second, because the actual data evaluated demonstrates that EPA underestimated costs and overestimated emissions. In conclusion, the commenter's analysis indicates that it is categorically cost prohibitive to implement EPA's November 2021 proposed BSER to capture or control wet seal centrifugal compressors by 95 percent in the transmission segment.

**Response I-13-16:** In response to comments received on the November 2021 Proposal, EPA re-evaluated the November 2021 BSER for centrifugal compressor affected/designated facilities in the December 2022 Supplemental Proposal with consideration of the costs provided by the commenter. For details, please see discussion in sections IV.G.1 (for NSPS OOOOb) and IV.G.2 (for EG OOOOc) of the December 2022 Supplemental Proposal preamble.<sup>22</sup> For EPA's response to comments on the December 2022 Supplemental Proposal, see Volume II, Chapter 10 (Centrifugal Compressors) and section XI.G of the final rule preamble.

<sup>22</sup> 87 FR 74783-74792.

#### 13.3.2.3 Converting Wet Seals to Dry Seals

Comment: Commenter (1375-Kinder Morgan) states that they evaluated the cost to convert wet seals to dry seals. According to the commenter, the conversion would require upgrading the compressor, upgrading control systems, making skid modifications, procuring the necessary interconnect hardware, and installing and commissioning labor. The commenter reports that the conversion would total approximately \$1,400,000 per Solar unit, and \$1,250,000 per non-Solar unit, making the overall cost approximately \$260,950,000 for the wet seal units the commenter operates. The commenter asserts that, on a cost-per-ton basis, the result would not be reasonable. This is because, as described in the commenter's data analyses regarding wet seals and dry seals, the leak rates and potential emissions from its dry seals are comparable to the commenter's well-maintained wet seals.

The commenter (1375-Kinder Morgan) notes that there are also technical concerns associated with converting wet seals to dry seals, which could generate additional costs. For instance, the commenter states that one of the benefits of a wet seal system is that it maintains built-in damping for the compressor seals to limit or eliminate vibrations. When the unit is converted to a dry seal, this damping benefit is lost. As a result, the commenter would need to evaluate the converted system and potentially make other modifications to the compressor to avoid unsafe vibration issues and EPA would need to take these costs into account in its analysis. Consistent with its own analysis, the commenter requests that EPA modify the wet seal centrifugal compressor November 2021 Proposal as described herein to avoid an inappropriate standard outcome (*i.e.*, changing of wet seals to dry seals).

Response I-13-17: The EPA appreciates the cost and technical information provided by the commenter. The EPA has not proposed or included requirements in the final NSPS OOOOb standards and EG OOOOc presumptive standards to convert wet seals to dry seals.

#### 13.3.2.4 Maintenance and Repair Activities to Meet Numerical Emission Limit

Comment: Commenters (1375-Kinder Morgan, 0415/1391-INGAA) state that low emissions from centrifugal compressors equipped with wet seals are largely a function of proper maintenance and that requiring a 95 percent reduction standard or routing to a process creates an unintended result—the more careful an operator is with maintaining its wet seals, the more difficult and costly (on a cost-per-ton basis) controlling emissions in compliance with these requirements becomes.

Commenter (1375-Kinder Morgan) notes that their company institutes an annual monitoring plan and indicate that actions needed to reduce emissions or maintain a compressor such that it is low-emitting can range from correcting an identified issue immediately with minor maintenance, replacing O-rings on the filtration system, or having to rebuild the entire oil system. The commenter indicates that the implementation of such a program has resulted in average measured emissions of less than 0.5 scfm for compressors with wet seals.

Commenter (0415/1391-INGAA) recommends that the rule for existing compressors provide a procedure that would allow owners or operators to demonstrate that a particular wet seal configuration results in no or very small degassing emissions (for example, less than 3 scfm) per wet seal,<sup>23</sup> which is half the average emission rate for dry seal compressors (6 scfm), which EPA found too small to regulate previously) and thus be excluded from the control requirements for high-emitting wet seals under NSPS OOOOb and EG OOOOc. Another commenter (1375-Kinder Morgan) suggests that EPA consider an approach similar to that advocated by California Air Resource Board (CARB) in the California Greenhouse Gas Emissions Regulation. Pursuant to that regulation, “[a] compressor with a wet seal emission flow rate greater than three (3) scfm, or a combined flow rate greater than the number of wet seals multiplied by three (3) scfm, shall be successfully repaired within 30 calendar days of the initial flow rate measurement.” Whereas EPA mandates control of all wet seals, the commenter states that CARB’s rule focuses only on wet seals with emissions greater than 3 scfm. The commenter suggests that EPA could similarly adopt a scfm limit at above which a wet seal would need to be captured/controlled. Alternatively, they suggest that EPA could establish of an emissions applicability threshold where a wet seal compressor that has a measured flow rate less than a specified threshold would be exempt from regulatory requirements.

However, the commenter (1375-Kinder Morgan) cautions that further evaluation is required to understand the impacts and cost-effectiveness of the CARB proposal as applied to existing wet seal centrifugal compressors in the transmission segment. Specifically, the commenter states that EPA must continue to evaluate the various types of repairs that may be required, and the associated cost of repair, including the cost-per-ton of methane reduced and EPA must understand the timelines required for the necessary repairs or replacements.

The commenters (1375-Kinder Morgan, 0415/1391-INGAA) suggest that a threshold monitoring option is a more practical option for low-emitting centrifugal compressors with wet seals (as compared to the proposed requirement to route to a control device or to a process).

Response I-13-18: In response to comments received on the November 2021 Proposal, EPA re-evaluated the November 2021 BSER for centrifugal compressor affected/designated facilities in the December 2022 Supplemental Proposal with consideration of the commenters’ recommendations. For details, please see discussion in sections IV.G.1 (for NSPS OOOOb) and IV.G.2 (for EG OOOOc) of the December 2022 Supplemental Proposal preamble.<sup>24</sup> For EPA’s response to comments on the December 2022 Supplemental Proposal, see Volume II, Chapter 10 (Centrifugal Compressors) of this Response to Comment Document (hereinafter referred to as the RTC) and section XI.G of the final rule preamble. The EPA determined that implementing a volumetric flow rate standard for existing wet seal centrifugal compressors that would be subject

---

<sup>23</sup> The commenter notes that CARB recently issued a regulation that set forth a 3 scfm threshold for emissions from each wet seal at a centrifugal compressor as an alternative to controls similar to what is required in the Proposed Rule (*i.e.*, vapor collection and flaring or routing to a process). See CAL. CODE REGS. tit. 17, § 95668(d)(6) (requiring wet seal compressors *either* to install controls similar to OOOOa—*i.e.*, vapor recovery with degassing emissions routed to a flare or a process—or annual monitoring and repair where the leak rate is more than 3 scfm per wet seal).

<sup>24</sup> 87 FR 74783-74792.

to the EG OOOOc presumptive standards is BSER for the control of methane for the gathering and boosting, processing, and transmission and storage segments.

### ***13.3.4 Low emitting wet seal compressor designs***

Comment: Several commenters (0415/1391-INGAA, 0599-Marcellus Shale Coalition (MSC), 0782-Berkshire Hathaway Energy Company (BHE), 1375-Kinder Morgan) report that the process for wet seal degassing varies throughout the industry, and some manufacturers have a configuration that is essentially a closed process that ports the degassing emissions into the natural gas line at the compressor suction. According to the commenters, this type of wet seal centrifugal compressor configuration typically includes a primary chamber where initial degassing occurs (and is recovered), and chamber(s) with air sparging to release and recover residual gas volumes entrained in the oil. Rather than venting all the de-gassing volumes, the commenters note that the emissions are routed back to suction directly from the degassing/sparging chambers; the oil is ultimately recycled to the lube oil tank where any small amount of residual gas is released through a vent. The commenters state that field evaluation is not always feasible for this closed system configuration but reports that testing and modeling demonstrates that the residual natural gas volume vented is very small (much less than 1 percent of the total degassed natural gas volume). The commenters also note that for seals that emit *de minimis* levels of VOC or methane, it would be impracticable to further reduce such emissions and that assuming emissions can be calculated, the proposed BSER of routing emissions to a control device or to a process would be cost prohibitive.

Commenter (0782-BHE) states that the issues related to these low-emitting or self-contained wet seal compressors have not been resolved in NSPS OOOOa rulemakings because there were no or very few affected facilities and thus the issue was a low priority. However, the commenter states that the EG OOOOc requirements would affect hundreds of existing centrifugal compressors with wet seals in the transmission and storage (T&S) segment. The commenter states that most of centrifugal compressors with wet seals (e.g., manufactured by Solar) employ the low emitting technology.

Commenter (0415/1391-INGAA) suggests that EPA make clear that these types of compressors already incorporate one of the control options required under the November 2021 Proposal, namely collection and routing to a process and inclusion of appropriate language in the rule to address emissions that are predominantly recirculated.

Commenters (1375-Kinder Morgan, 0782-BHE) request that EPA clarify that certain existing closed-loop wet seal systems be exempt from any regulatory proposal, or at a minimum, that such systems should be considered in compliance with the BSER currently applicable to wet seals.

Response I-13-19: See section IV.G.b.ii (Lower-Emitting/Self-Contained Wet Seal Compressor Designs) of the December 2022 Supplemental Proposal preamble<sup>25</sup> for EPA's response to these

---

<sup>25</sup> 87 FR 74787-74788.

comments. See also section XI.G of the final rule preamble for a summary of the final centrifugal compressor requirements.

### ***13.3.5 Mechanical Seal Compressors***

Comment: Commenter (0415/1391-INGAA) states that another type of low-emissions wet seal utilized in compressors in the transmission and storage sector is a mechanical seal, in which metal (tungsten carbide) is seated against carbide, with oil pressing against the outside of the actual seal. One such mechanical wet seal is manufactured by Kaydon and utilized on DeLaval compressors. (Information for the Kaydon mechanical wet seal is provided in Attachment 7 of the comment letter.) Because the oil is not in contact with the natural gas, the commenter explains that these wet seals have generally zero degassing emissions. According to the commenter, it makes no sense to subject such a zero-emissions wet seal to control requirements. Accordingly, EPA should exclude compressors utilizing mechanical wet seals from the requirements otherwise applicable to wet seal compressors.

Response I-13-20: The EPA stated in the December 2022 Supplemental Proposal that the EPA is continuing to evaluate mechanical wet seal designs and the comments it has already received on the issue and solicited additional information on these and other wet seal compressor designs (with supporting emissions information) that are inherently low-emitting under operating conditions. See discussion in section IV.G.1.b.ii. of the December 2022 Supplemental Proposal preamble.<sup>26</sup> The commenter provided additional information on mechanical seals for EPA's consideration in their comments on the December 2022 Supplemental Proposal. See EPA's response based on additional information provided by the commenter in Volume II, Chapter 10, section 10.2.1, Response II-10-14 of this RTC, and section XI.G.4 (Other inherently low-emitting compressor with wet seal configurations) of the final rule preamble.

See also section XI.G of the final rule preamble for a summary of the final centrifugal compressor requirements.

### ***13.3.6 Low-Utilization Wet Seal Compressors***

Comment: Commenters (1375-Kinder Morgan, 0415/1391-INGAA, 0599-MSD) suggest that EPA consider a *de minimis* exemption, such as an exemption for limited use wet seal centrifugal compressors (*i.e.*, peak flow that operate infrequently). Commenter (0415/1391-INGAA) notes that 60 percent of its wet seal fleet fits this category. The 3-year average (covering years 2019-2021) of operating time for these wet seal compressors is 31 operating hours per year per compressor (utilization of 0.36 percent). By their nature, these limited-use compressors result in minimal actual emissions of methane and VOC; therefore, imposing control requirements for these units has an astronomical \$/ton value that is far beyond what would be considered reasonable. The commenter proposes a cutoff for such a *de minimis* exemption at 500 hours of operation per year, based on a 3-year average of actual operation. Another commenter (1375-Kinder Morgan) states they would support an exemption for wet seal centrifugal compressors

---

<sup>26</sup> See 87 FR 74788.

that operate for less than 500 hours per year, with a requirement to come into compliance within 180 days of exceeding 500 hours.

Response I-13-21: The EPA has not included a *de minimis* exemption in the December 2022 Supplemental Proposal or final rule requirements for wet seal centrifugal compressors in the NSPS OOOOb and EG OOOOc. While the EPA has not included a *de minimis* exemption for limited use wet seal centrifugal compressors, the final centrifugal compressor requirements in both the NSPS OOOOb and EG OOOOc provide alternative standard options for lower-emitting/self-contained wet seal compressor designs in addition to other compliance alternatives (e.g., routing to a process or control device).

Additionally, in response to these and other comments received on the numerical emission limit standard and limited-use centrifugal compressors, EPA proposed in the December 2022 Supplemental Proposal to allow owners and operators to conduct periodic reciprocating compressor flow rate monitoring based on the hours of operation (*i.e.*, 8,760 hours) in lieu of requiring monitoring based on a calendar year. For details, please see discussion in sections IV.G.1.b.i and IV.G.2.b of the December 2022 Supplemental Proposal preamble.<sup>27</sup> Please also see sections X.G.1 and X.G.2 of the preamble to the final rule which details EPA's final centrifugal compressor NSPS OOOOb and EG OOOOc standards/presumptive standards.

### ***13.3.7 Retrofit of Existing Wet Seal Centrifugal Compressors for 95% Reduction***

Comment: Commenters (0415/1391-INGAA, 1375-Kinder Morgan) express concern about having to retrofit existing wet seal centrifugal compressors to accommodate the November 2021 Proposal requiring owners and operators to reduce methane emissions from each centrifugal compressor wet seal fluid degassing system by 95 percent or greater. The commenters note that EPA over-simplifies what would be required to install combustion control or route to process, therefore, underestimates the associated technical feasibility and costs.

Commenter (1375-Kinder Morgan) states that the November 2021 Proposal for wet seal centrifugal compressors would require installation of an enclosed combustion device or a process flare in nearly every case as there are presently no flares or combustors located at their sites. The commenter notes that control is rarely needed at transmission sites and where control is required, the commenter would apply selective catalytic reduction as the relevant control technology instead of combustion. The commenter notes that, while theoretically an enclosed combustion device could be installed to control the minimal emissions on an individual wet seal compressor, a combustion device cannot be located just anywhere, especially not in close proximity to a transmission compressor station. The commenter further notes that a combustion device must be strategically located away from combustible materials, which typically requires a significant footprint, aboveground piping (above roadways), and in an elevated location. In addition, the commenter reports that, in order to install such a device, they would likely have to apply for and receive state and local permit modifications, which are not certain to be approved in each case.

---

<sup>27</sup> 87 FR 74783-74788, 87 FR 74791-74792.

The commenter (1375-Kinder Morgan) also states that routing to a control device could present safety concerns. For example, they note that attempts to capture a low-pressure natural gas vent stream, such as that of the wet seal, could result in inducing air into the gas stream, potentially creating a combustible mixture. The commenter reports that one manufacturer has previously “caution[ed] the use of flaring with gas seal vented emissions due to risk of the potential explosive hazard and back-flashing and serious risk of explosion.” At least one manufacturer (Solar) discourages flaring for this reason although some customers have successfully implemented it.

With respect to the routing to process option, the same commenter (1375-Kinder Morgan) notes that, while theoretically feasible, it would require a substantial revision to the existing process, and likely significant reconfiguration of the site. The commenter notes that the limited emissions, on average, approximately 0.46 scfm, are at a significantly lower pressure than the wet gas line. As a result of this significant disparity, to route emissions from a wet seal back to a process, the commenter reports that it would be required to (1) develop a process to ensure as much air as possible is removed from the gas stream; and (2) recompress that gas stream from a very low pressure (nearly atmospheric) to a much higher pressure, roughly 1,000 psi. To recompress the emissions stream to then re-introduce it back to process, the commenter states that they would be required to install an entirely new piece of equipment, which could require either a natural gas fired engine or a motor. The potentially available technologies for application to wet seals are untested by the commenter, and largely untested across the industry. They state that, a low flow gas stream cannot be safely or technically re-introduced back into their processes without significant, and resource-intensive attention to that minor emissions stream. According to the commenter, the unintended result would be that the additional equipment that would need to be installed to accomplish this routing back to process would not only be costly but could also result in additional emissions from other sources.

Commenters (0415/1391-INGAA, 1375-Kinder Morgan) state that EPA has not evaluated actual retrofits of a wet seal centrifugal compressor to understand the demonstrated and practical consequences of its proposal. Further, the commenters state that the costs of retrofitting transmission stations with combustion devices is significant and cannot be readily dismissed.

Response I-13-22: In response to comments received on the November 2021 Proposal, EPA proposed a different BSER for existing wet seal compressors in the December 2022 Supplemental Proposal. For details, please see discussion in sections IV.G.1.b and IV.G.2.b of the December 2022 Supplemental Proposal preamble.<sup>28</sup> Please also see section X.G.1 and X.G.2 of the preamble to the final rule which details EPA’s final centrifugal compressor NSPS OOOOb and EG OOOOc standards/presumptive standards. Based on the updated analysis presented in the December 2022 Supplemental Proposal, the EPA is finalizing that the presumptive standard of performance for existing sources is a volumetric flow rate of 3 scfm per seal; and BSER is for an owner or operator to conduct preventative maintenance and repair of their centrifugal compressors that use wet seals, as needed, to maintain the volumetric flow rate from each centrifugal compressor that uses a wet seal at or below 3 scfm per seal.

---

<sup>28</sup> 87 FR 74783-74788, 87 FR 74791-74792.

### ***13.3.8 Dry Seal Compressor Emissions and Standards***

Comment: Commenter (1375-Kinder Morgan) states that based on their data and experience, in many cases, a wet seal and a dry seal may have the same or similar emissions impact. The commenter estimates that the baseline uncontrolled emissions for each of its individual centrifugal wet seal compressors are 8.5 tpy methane and 0.41 tpy VOC, with an average leak rate of 0.46 scfm. Similar to the analysis conducted by commenter regarding wet seals, the commenter undertook extensive analysis of its existing measured data points for its dry seals. In particular, the commenter reviewed actual measurement data (leak rate, in scfm) from all of its dry seal units, the data covering the period of 2017 through 2021. The commenter reports that they have 290 measured data points across 147 (of a total 233) dry seal units. Where measured data for a particular unit was not available, the commenter calculated an average leak rate based on all documented measurements sourced from that particular model. If the commenter did not have measured data for a specific model, the commenter conservatively applied the average of all measured data as the leak rate. For the latter, the commenter notes that this generic average was only applied to 17 dry seal units. A few critical summary points provided by the commenter include the following:

- The average leak rate for all dry seal units was 0.76 scfm.
- The maximum measured leak rate was 8.74 scfm, and the minimum leak rate was 0 scfm.
- Further parsing this data, 93 of the 147 dry seal units that were tested had a 5-year average of 0 scfm. 223 of the 290 data points measured were 0 scfm.
- A total of 18 of the 147 dry seal units with measured data had at least one data point over 3 scfm over the last 5 years.
- Conservatively applying the maximum leak rate for each unit over the past 5 years, and assuming 8,760 hours of operation, [Assuming 8,760 hours of operation is conservatively high. These dry seals will only have a leak rate when in operation, and they do not operate 8,760 hours.] the total cubic feet of gas leaked for all 223 units is approximately 122,070 smcf for a single year, and the average is 557 smcf per unit.

The commenter (1375-Kinder Morgan) states that they then applied the same methodology EPA applied in the November 2021 Proposal to determine the estimated TPY of VOC and methane, per unit.

- Conservatively applying the max leak rate for each unit over the past 5 years, and assuming 8,760 hours of operation, for all 223 units the total methane emissions are estimated at 2890 tpy, and 11.6 tpy per unit.
- Conservatively applying the max leak rate for each unit over the past 5 years, and assuming 8,760 hours of operation, for all 223 units the total VOC emissions are estimated at 70 tpy, and 0.32 tpy per unit.

The commenter (1375-Kinder Morgan) notes that it is critical to develop a defensible and reasonable methodology for emissions calculations, recognizing that in most cases, the flow data likely represent mostly engine air. While the commenter is willing to engage with EPA on this

issue, the commenter provides that adopting the existing BSER for dry seals is not a feasible or desirable outcome.

Commenter (0844/0845-Environmental Defense Fund (EDF) *et al.*) suggests that EPA consider standards to reduce emissions from dry seal centrifugal compressors.

Response I-13-23: In response to comments received on the November 2021 Proposal, EPA proposed a 3 scfm per seal numerical standard for dry seal compressors for both new and existing dry seal compressors in the December 2022 Supplemental Proposal. Please see discussion in sections IV.G.1.b.iii and IV.G.2.b of the December 2022 Supplemental Proposal preamble.<sup>29</sup> The EPA received a lot of comments on the December 2022 Supplemental Proposal and BSER analyses proposed for dry seal compressors. In response to comments received on the December 2022 Supplemental Proposal, the EPA revised the proposed 3 scfm per seal numerical standard for dry seal compressors for both new and existing dry seal compressors in the final rule. Please see discussion in sections XI.G.1 of the preamble to the final rule. Please also see sections X.G.1 and X.G.2 of the preamble to the final rule which details EPA's final centrifugal compressor NSPS OOOOb and EG OOOOc standards/presumptive standards.

### **13.4 Other-Compressor Exhaust**

Comment: Commenter (0844/0845-EDF *et al.*) suggests that EPA develop standards to reduce emissions from compressor exhaust. The commenter estimates 393,355 tons of methane emissions resulting from gathering and boosting compressor exhaust in 2019. The commenter notes that as they have recommended to EPA in the past, EPA should consider requiring that compressors be driven by turbines or electric motors, since according to emissions factors in the GHGI, turbines produce less methane per horsepower-hour than reciprocal internal combustion engines (RICE) by about a factor of 25.<sup>30</sup>

Response I-13-24: Emissions from the engines used to power the compressors are not within the scope of this regulation.

### **13.5 Other Emission Reduction Systems**

Comment: Commenter (0785-John Crane Inc.) provides information regarding emission reduction systems developed by the commenter. Using products such as the commenter's AuraTM family of seals, the commenter can convert wet seals to dry gas seals to stop methane leakage. The Aura Zero-Emissions seal eliminates nearly all emissions from seals. The commenter states they have an expertise in overhauling complex pump and compressor systems to reduce emissions, while increasing efficiency and usage of products for producers. Various scenarios in oil and gas production often require varying solutions. The commenter recommends allowing for all solutions below in order to best account for particular compressor stations:

---

<sup>29</sup> 87 FR 74788-74789, 87 FR 74792.

<sup>30</sup> Sierra Club *et al.*, Comments on New Source Performance Standards: Oil and Natural Gas Sector; Review and Proposed Rule for Subpart OOOO, 48 (Nov. 30, 2011).

- When compressor can't be stopped and seals be retrofitted, the commenter proposes recovering methane emissions from dry gas seals. Leakage recovery system will allow to incorporate expected leakage during seal operation into compressor inlet. Emissions from primary vent will be processed and pressurized to be returned to compressor inlet.
- When applicable, the commenter proposes conversion of standard dry gas seals into the commenter's patented zero emission dry gas seal. This revolutionary new design incorporates upstream pumping technology to pressurize an inert gas to a pressure level sufficient to direct the inert gas into the compressor discharge. This approach prevents process gas (*i.e.*, methane) from leaking through the seal and into the primary vent. The gas panel support system is significantly simplified by eliminating the need to clean the process gas. With this, during normal operations, leaks are non-existent.

The commenter (0785-John Crane Inc.) recommends that the November 2021 proposed standard be updated to include wet seal systems with these emission mitigation systems installed, as it is not practical to reduce these emissions by an additional 95 percent.

The commenter (0785-John Crane Inc.) provides that the gas seal technology initially invented by the commenter is constantly being improved to solve challenging sealing applications. Seal designs are now available that are more compact allowing the retrofit of oil sealed compressors where the transitional gas seal designs would not fit. This effectively expands the number of oil sealed compressors that are candidates for gas seal retrofits to reduce potential emissions.

Response I-23-25: The EPA appreciates the information provided by the commenter on their gas seal technology/emission mitigation system. In response to comments received on the November 2021 Proposal, EPA proposed a different regulatory approach for centrifugal compressor affected/designated facilities in the December 2022 Supplemental Proposal, including adding requirements for dry seal compressors. For details, please see discussion in sections IV.G.1 (for NSPS OOOOb) and IV.G.2 (for EG OOOOc) of the December 2022 Supplemental Proposal.<sup>31</sup> For EPA's response to comments on the December 2022 Supplemental Proposal, see Volume II, Chapter 10 (Centrifugal Compressors) and section XI.G of the final rule preamble.

Please see section X.G.1 and X.G.2 of the preamble to the final rule which details EPA's final centrifugal compressor NSPS OOOOb and EG OOOOc standards/presumptive standards. An owner or operator would be able to employ the commenter's technology as long as the centrifugal compressor equipped with dry seals meets the requirements of the final rule.

---

<sup>31</sup> 87 FR 74783-74792.

## **Chapter 14. Reciprocating Compressors**

### **14.1 General Support/Opposition for Proposed Reciprocating Compressor Requirements**

Comment: Commenters (0787/1289-Atmos Energy Corporation (Atmos), 0844-Environmental Defense Fund (EDF) *et al.*, 0833-Environmental Programs Department, Ute Mountain Ute Tribe (Ute EPD), 0605-Muscogee (Creek) Nation, 0781-National Tribal Air Association (NTAA), 0391-Keweenaw Bay Indian Community (KBIC)) support the November 2021 proposed requirement to strengthen the standards for methane emissions for new reciprocating compressors and including those requirements as the presumptive standards for existing sources.

Commenters (0787/1289-Atmos) generally support using operating hour or methane emissions rate thresholds for triggering compressor rod packing maintenance.

Response I-14-1: Comments are supportive comments on an aspect of the November 2021 Proposal that has remained unchanged in the final rule; as such, no response is required.

### **14.2 Applicability/Exemptions**

#### ***14.2.1 Applicability of Compressor Standards to Well Sites/Centralized Production Facilities***

Comment: Commenter (0808-American Petroleum Institute (API)) requests that EPA clarify the applicability of compressor standards to well sites. The commenter states that the definition proposed for central production facility may extend applicability to compressors located at well sites, which have historically been exempt from the compressor standards. As EPA states they have not updated their cost analyses with new information with respect to well sites, the commenters believe that extending applicability to well sites was not EPA's intent.

Commenter (0923-Lambda Energy Resources LLC (Lambda)) urges EPA to keep the current compressor exemptions shown in both subparts NSPS OOOO and OOOOa stating compressors "located at a well site, or an adjacent well site and servicing more than one well site, is not an affected facility."

Commenter (0564-Arkansas Independent Producers and Royalty Owners (AIPRO)) suggests maintaining the existing definition of "compressor station" listed in NSPS OOOOa (compressors located at a well site are exempt from reciprocating compressor requirements).

Response I-14-2: The applicability of compressor standards to centralized production facilities does not extend to single well sites. See section XI.G.5 of the final rule preamble regarding the applicability of requirements to compressors located at centralized production facilities.

Comment: Commenters (0810-Petroleum Alliance of Oklahoma (Petroleum Alliance-OK), 0814-Independent Petroleum Association of America (IPAA) *et al.*) note that EPA states it will apply the November 2021 proposed monitoring requirement to reciprocating compressors

located at “centralized production facilities.” The commenters state that this may be beneficial in certain operations and where larger oil and gas operators may have the resources and equipment to monitor those emissions; however, they suggest that it should be an option/alternative, and not a mandatory requirement as it may unnecessarily create additional burdens and costs for smaller operators that send production from several marginal/low production wells to a “centralized production facility.” For marginal/low production well operators, centralized production facilities may be more cost efficient than having equipment at each well site and this practice reduces the overall the environmental footprint of the operation. The commenters suggest that it would be an unnecessary additional cost on small businesses and disincentivizes the use of centralized production facilities in this scenario. The commenters request the EPA remove this requirement for marginal/low production wells that send production to centralized production facilities.

Another commenter (0844-EDF *et al.*) supports the EPA’s November 2021 proposed definition of a centralized production facility and supports the extension of compressor standards to these sites. While the Greenhouse Gas Inventory (GHGI) does not contain data on the number of compressors in the production segment, the commenter reports that they analyzed data submitted in response to the EPA’s 2016 Information Collection Request (ICR) to assess the number of compressors across different facility types in the production segment. While the ICR data is not a full inventory, the commenter contends that it illustrates that there are a significant number of compressors utilized in the production segment, with most reciprocating compressors located at centralized production facilities. [Comment letter includes a Figure (Figure 25: ICR Compressor Counts at Wellsites and Centralized Production Facilities) presenting the discussed ICR compressor counts.]

Response I-14-3: See section XI.I.5 of the final rule preamble regarding the applicability of requirements to compressors located at centralized production facilities.

Comment: Commenters (0465-Jordan Development Company, LLC (JDC), 0946-Michigan Oil and Gas Association (MOGA)) request that EPA listen to the small business industry segment before creating a technically and financially infeasible “one-size-fits-all” approach to regulations based on generalized production modeling and special interest groups. The commenters recommend that EPA continue the exemption of both centrifugal and reciprocating compressors “located at a well site, or an adjacent well site and servicing more than one well site, is not an affected facility” as provided in both 40 CFR part 60, subpart OOOO and 40 CFR part 60, subpart OOOOa. The commenters explain that well operators visit and service these wells and associated compressors daily to inspect for proper operation, leaks and to conduct maintenance and repairs activities. Any necessary repairs are implemented as soon as possible to avoid product loss and to maximize profit returns. If EPA wishes to propose monitoring for well site compressors, the commenters recommend EPA allow the more feasible and cost-effective monthly auditory, visual, and olfactory (AVO) inspection and documentation, similar to the requirements allowed under 40 CFR 60.5416a.

Response I-14-4: The applicability of compressor standards to centralized production facilities does not extend to single well sites. See discussion in section IV.I.1.b.iii and I.2.b of the

December 2022 Supplemental Proposal preamble regarding EPA's proposed reciprocating compressor affected facility and designated facility under NSPS OOOOb and EG OOOOc.<sup>1</sup>

With regards to comments requesting that EPA listen to the small business industry segment before creating a technically and financially infeasible "one-size-fits-all" approach to regulations based on generalized production modeling and special interest groups, see comment response to similar comments in Chapter 23, section 23.17 (One-Size Fits All Approach) of this Response to Comment Document (hereinafter referred to as the RTC), Response I-23-70.

#### ***14.2.2 Limited-Use Reciprocating Compressors***

Comment: Commenter (0808-API) requests that EPA provide clarification that temporary compressors (*i.e.*, those onsite for less than 12 months) are not subject to these provisions.

Response I-14-5: See discussion in section IV.I.1.b.i of the December 2022 Supplemental Proposal on proposal to require volumetric flow rate monitoring based on compressor hours of operation versus calendar year, in part, to address limited-use reciprocating compressors.

Comment: Commenter (0814-IPAA *et al.*) suggests that well pads be exempt from rod packing replacements for those compressors not used 8,760 hours per year. The commenter notes that the amount of money spent may not be cost effective in reducing emissions from these compressors.

Response I-14-6: In response to the comment that suggests that well pads be exempt from rod packing replacements for those compressors not used 8,760 hours per year, the applicability of compressor standards to centralized production facilities does not extend to single well sites. See section XI.I.5 of the final rule preamble regarding the applicability of requirements to compressors located at centralized production facilities.

See also the discussion in section IV.I.1.b.i of the December 2022 Supplemental Proposal on proposal to require volumetric flow rate monitoring based on compressor hours of operation versus calendar year, in part, to address limited-use reciprocating compressors.

Comment: Commenter (0817-GPA Midstream Association (GPA)) urges EPA to consider an appropriate exemption for reciprocating compressors with low run times. The commenter explains that, due to the nature of gathering and boosting operations, natural gas throughput is directly related to upstream producer drilling operations and a field's production volumes. Both are variable depending upon market conditions. Declines in drilling operations, and thus gas throughput, can be either permanent or cyclical in nature. This means that reciprocating compressors may not be required for extended periods of time, even for over a year. The commenter suggests that the EPA only require annual measurements for reciprocating compressors with an annual runtime above a certain threshold, such as 2190 hours over a 12-month rolling basis, or on an annual basis. The commenter notes that EPA has long recognized the role of runtime in the useful life of rod packing, as well as for other equipment. See, *e.g.*, 40 CFR part 60, subpart ZZZZ, Table 2d (requiring various maintenance activities for reciprocating internal combustion engines at 500 hours, 1,000 hours, 1,440 hours, and 2,160 hours); see also

---

<sup>1</sup> 87 FR 74799-74800, December 6, 2022.

86 Fed. Reg. at 63,216 (recognizing that emission increases result from deterioration of parts with run time). According to the commenter, allowing a runtime threshold would avoid investing limited time and resources in monitoring a reciprocating compressor that has not operated, or barely operated, since the prior monitoring event, and ensure available resources are directed to the equipment that requires attention. The commenter provides that this is especially important given that upstream producers, not midstream operators, dictate how frequently reciprocating compressors run.

Response I-14-7: See discussion in section IV.I.1.b.i of the December 2022 Supplemental Proposal on proposal to require volumetric flow rate monitoring based on compressor hours of operation versus calendar year, in part, to address compressors with low run times.

### ***14.2.3 Applicability Thresholds Based on Reciprocating Compressor Type/Size/Stage/Gas Throughput***

Comment: Commenter (0808-API) recommends that EPA consider whether it is appropriate to establish applicability thresholds based on compressor size, stages, or gas throughput or exclude compressors used in specific applications (e.g., casing, injection, gas lift compressors).

Response I-14-8: There is insufficient information at this time to support the establishment of a standard based on compressor size, stages, or gas throughput. In situations where a reciprocating compressor is screened to have no leaks or the performance-based volumetric flow rate is maintained at or below 2 scfm, an owner or operator is only subject to minimal recordkeeping and reporting requirements.

The final requirements for reciprocating compressors under NSPS OOOOb and EG OOOOc also include several alternative compliance options to the performance-based volumetric flow rate standard that an owner or operator can comply with to meet the standards. See section X.I of the final rule preamble for a summary of the final reciprocating compressor requirements.

Comment: Commenter (0831-American Exploration and Production Council (AXPC)) states that there should be an exemption for small reciprocating compressors less than 100 horsepower (i.e., vapor recovery units) that experience has shown do not exhibit rod packing leaks even without replacement. The commenter contends that there are no benefits that come from requiring replacement for these smaller units while the cost would be significant.

Response I-14-9: The EPA has not included the requested small reciprocating compressor exemption in the final rule. While the EPA is not including an exemption for small compressors that the commenter claims do not exhibit leaks even without rod packing replacement, the EPA proposed in the December 2022 Supplemental Proposal (and is maintaining in the final rule) that an owner or operator does not have to conduct volumetric flow rate monitoring if screening for emissions or leaks from the reciprocating compressor rod packing using optical gas imaging (OGI) or Method 21 does not indicate a leak. See final test methods and procedures for reciprocating compressors at 40 CFR 60.5385b and 40 CFR 60.5405c.

Comment: Commenter (0814-IPAA *et al.*) expresses that EPA fails to appreciate the variety of reciprocating compressors utilized by different segments and plays across the country. The commenter notes that most of the low volume and low-pressure wells in the Appalachian Basin are connected to a compressor to get their produced gas to a market. The commenter adds that most of these wells consist of just a wellhead which EPA rightly has proposed to exempt from NSPS OOOOb or EG OOOOc regulation. According to the commenter, the compressors used by the small companies are most commonly of two types, booster compressors, and field compressors. The booster compressors are typically small single stage units with low horsepower drivers connected to a well or groups of low-pressure wells that would not be able to deliver gas into a gathering system without help. A typical situation gathers small volumes of gas at very low pressures from groups of legacy oil wells found in many areas of the Appalachian Basin. These wellhead compressors, which were exempt under the 2016 NSPS OOOOa regulations, typically move around 10 million cubic feet per day (Mcf/d) with a suction pressure as low as 0 psi and discharge pressures of between 8 and 20 psi. The commenter recommends that, because of the pressures at which these compressors operate, they have a very small potential for fugitive emissions and should continue to be exempt from NSPS OOOOb regulation.

Response I-14-10: The applicability of compressor standards does not extend to single well sites (which are exempt from reciprocating compressor requirements under NSPS OOOOb and EG OOOOc). See discussion in section IV.I.1.b.iii and I.2.b of the December 2022 Supplemental Proposal preamble regarding EPA’s proposed reciprocating compressor affected facility/designated facility.<sup>2</sup>

See also section XI.I.5 of the final rule preamble regarding the applicability of requirements to compressors located at centralized production facilities.

### **14.3 Definitions/Clarifications**

Comment: Commenter (0817-GPA) requests that EPA define “pressurized mode.” The commenter notes that the November 2021 Proposal states that rod packing replacement would be required “[w]hen the measured leak rate exceeds two standard cubic feet per minute (scfm) (in pressurized mode)...” 86 Fed. Reg. at 63,220. The commenter states that the term “pressurized mode” is not defined. The commenter interprets “pressurized mode” to mean that the compressor contains natural gas at pressure above atmospheric pressure.

Response I-14-11: The EPA has added a definition to the final NSPS OOOOb and EG OOOOc regulatory text to clarify that “pressurized mode” is when the compressor contains natural gas that is maintained at a pressure higher than the atmospheric pressure.

---

<sup>2</sup> 87 FR 74799-74800.

## 14.4 Best System of Emission Reduction (BSER) Analysis

### 14.4.1 Annual Flow Rate Measurement/Rod Packing Replacement Threshold

Comment: Commenter (0844-EDF *et al.*) suggests that EPA reduce the rod packing replacement threshold for reciprocating compressors based on annual monitoring from 2 standard cubic feet per minute (scfm) to 0.5 scfm. The commenter states that EPA has proposed requiring replacement when emissions exceed 2 scfm, which the agency estimates will achieve a 92 percent reduction in emissions for reciprocating compressors in all segments.<sup>3</sup> However, the commenter notes that, as explained in the Clean Air Task Force (CATF)'s Reciprocating Compressor Cost Memo and Spreadsheet (Attachments U and V to the commenter's letter), EPA likely overestimates the emissions reductions associated with replacement at the 2 scfm threshold, because only compressors with emissions that exceed that threshold will replace rod packing and thus reduce emissions. The commenter notes that, for compressors with emissions below that threshold, there will be no reduction in emissions. The commenter states that the 0.5 scfm threshold will reduce approximately 80 percent of compressor station emissions while remaining highly cost-effective. While EPA did not estimate the cost-effectiveness of replacement at lower thresholds, the commenter notes that the CATF estimates that imposing a 0.5 scfm threshold for rod packing replacement would entail a cost of \$270/ton of methane, not accounting for gas savings, and \$89/ton of methane after accounting for gas savings at gathering and boosting compressors, which is the highest cost segment. Figure 26 of the commenter's letter shows the cost summary for all oil and natural gas industry segments. The commenter states that these abatement costs are similar to costs for new sources as shown in EPA's November 2021 Technical Support Document (TSD) Tables 7-9 and 7-10. A detailed description of cost calculation methodology is in an attachment to their comment letter (*i.e.*, Reciprocating Compressor Cost Memo and Spreadsheet (Attachments U and V to the comment letter)). The commenter adds that a lower threshold is also in line with standards adopted in Canadian jurisdictions, which, as EPA notes, require rod packing replacement at vent volume thresholds ranging from 0.49 to 0.81 scfm/cylinder.<sup>4</sup>

Response I-14-12: The EPA received a similar comment from the commenter regarding their request for a lower performance-based volumetric flow rate standard per cylinder for reciprocating compressors on the December 2022 Supplemental Proposal. The EPA's response to this comment is provided at Volume II, Chapter 11, section 11.2.3, Response II-10-18.

See also section X.I of the final rule preamble for a summary of the final reciprocating compressor requirements.

Comment: Commenter (0817-GPA) suggests that the November 2021 proposed EG and NSPS fails to adequately consider the costs and technical challenges associated with retrofitting each cylinder for monitoring ports. The commenter notes that each throw does not have its own vent and alterations would need to be made to the piping to allow for monitoring to be conducted on a per-throw basis. The commenter states that the costs required to add new piping, so each throw

---

<sup>3</sup> EPA 2021 November TSD, Spreadsheet, Chapter 7 - 2021 Compressors Costs and Emissions.

<sup>4</sup> 86 Fed. Reg. at 63,218 (citing Canadian Federal standards: <http://gazette.gc.ca/rp-pr/p2/2018/2018-04-26-x1/pdf/g2-152x1.pdf>).

has its own vent and install monitoring ports have not been considered. The commenter recommends that if EPA chooses to move forward with the November 2021 Proposal, EPA issue guidelines allowing a phased approach to adequately account for port installation.

Response I-14-13: The final rule does not require that each cylinder be equipped with a monitoring port. Individual cylinders can be manifolded to a single open-ended vent line/vent, where the volumetric flow rate must not exceed the sum of the individual cylinders multiplied by 2 scfm. Further, EPA proposed in the December 2022 Supplemental Proposal (and is maintaining in the final rule) that an owner or operator does not have to conduct volumetric flow rate monitoring if screening for emissions or leaks from the reciprocating compressor rod packing using OGI or Method 21 does not indicate a leak. See final standards/presumptive standards at 40 CFR 60.5386b(a) and 40 CFR 60.5405c(a) test methods and procedures for reciprocating compressors.

Comment: Commenter (0564-AIPRO) states that the November 2021 Proposal is overly burdensome and not cost effective and proposes the following alternatives to the proposed annual survey and rod packing replacement when emissions exceed 2 scfm:

- 1) Operators should be allowed to utilize optical gas imaging (OGI) leak detection and repair (LDAR) inspections on the rod packings (conducted during required or voluntary surveys) to determine if leaks are present. If a leak is identified on the rod packings – then the proposed rod packing survey would be required. If the leak rate exceeds 2 scfm – then the rod packing would need to be replaced.
- 2) Propose that the annual leak survey is required every 3 years or 26,000 hours rather than annually.

The commenter believes that either of these alternatives provide EPA with sufficient methane reductions.

Commenter (0808-API) suggests that another potential option to streamline the monitoring burden is to allow operators to screen for leaks during annual OGI assessments and only perform measurement of the rod packing if it is identified as leaking during the OGI screening. The commenter states that this option has been approved under the Greenhouse Gas reporting Program (GHGRP) for gas processing and transmission facilities under 40 CFR part 98, subpart W.

Response I-14-14: Under the December 2022 Supplemental Proposal NSPS OOOOb and EG OOOOc proposed regulatory text (and final regulatory text), an owner or operator does not have to conduct volumetric flow rate monitoring if screening for emissions or leaks from the reciprocating compressor rod packing using optical gas imaging (OGI) or Method 21 does not indicate a leak. See final standards/presumptive standards at 40 CFR 60.5386b(a) and 40 CFR 60.5405c(a) test methods and procedures for reciprocating compressors.

The EPA disagrees with the commenter that volumetric flow rate monitoring should be reduced to every 3 years or 26,000 hours of operation rather than annually or every 8,760 hours of operation. As discussed in the December 2022 Supplemental, the BSER analysis is unchanged

from what was presented in the November 2021 proposal (see 86 FR 63214–63220, section XII.E. Reciprocating Compressors). The BSER for NSPS OOOOb and EG OOOOc for reducing GHGs and VOC from reciprocating compressors is the repair or replacement of the rod packing based on annual monitoring to maintain the volumetric flow rate per cylinder below 2 scfm. As an alternative to conducting required volumetric flow rate measurements, the final rule allows an owner or operator the option to comply by replacing the rod packing on or before 8,760 hours of operation after the effective date of the final rule for NSPS OOOOb (and 8,760 hours of operation after the effective date of an approved state or tribal plan for the EG OOOOc), or on or before 8,760 hours of operation after the previous flow rate measurement, or on or before 8,760 hours of operation after the date of the most recent compressor rod packing replacement, whichever is later.

See section X.I of the final rule preamble for a summary of the final reciprocating compressor requirements.

Comment: Commenter (0808-API) recommends that EPA re-evaluate the designated leak threshold of 2 scfm per cylinder, as it may not be appropriate for all applications. The commenter asserts that appropriate leak thresholds vary based upon the individual compressor type, size, and operating conditions. The commenter notes that their preliminary review indicates the 2 scfm/cylinder threshold proposed by EPA is an extension of regulations finalized in California.<sup>5</sup> In review of supporting documentation provided by the California Air Resources Board, the commenter notes that it seems that this threshold for rod packing replacement is based on data from a single vendor's alarm set point.<sup>6</sup> The commenter reports that publicly available data from another compressor manufacturer<sup>7,8</sup> indicates “expected packing leakage for typical alarm points is between 1.7 and 3.4 scfm,” and experience from some of the commenter's members indicates some maintenance may be conducted up to a 4 scfm threshold per manufacturer recommendations. Therefore, the commenter suggests that a more comprehensive review of compressor manufacturer information is required for determining an appropriate threshold for rod packing replacement under NSPS OOOOb and EG OOOOc.

Response I-14-15: First, the 2 scfm per cylinder performance-based volumetric flow rate standard in the final rule is not an emission limitation, but rather a performance standard associated with a work practice. Therefore, if the owner or operator obtains a measurement greater than 2 scfm, it is not a deviation of an emission limit. Rather, measures need to be taken to reduce the flow rate to 2 scfm per cylinder or less. It is not based on continuous monitoring of rod packing vents, but rather on periodic monitoring based on hours of operation. Finally, the EPA notes that the 2 scfm per cylinder performance-based volumetric flow rate standard falls within the commenter's reported “alarm point” range of 1.7 and 3.4 scfm.

<sup>7</sup> <https://www.arielcorp.com/company/newsroom/compressor-emissions-reduction-technology.html>.

<sup>8</sup> [https://www.arielcorp.com/application\\_manual/Arieldb.htm#Packing\\_Leakage.htm?Highlight=packing%20leakage](https://www.arielcorp.com/application_manual/Arieldb.htm#Packing_Leakage.htm?Highlight=packing%20leakage)

The final rule also provides alternative options to meeting the final standards and presumptive standards. See section X.I of the final rule preamble for a summary of the final reciprocating compressor requirements.

Comment: Commenter (0756-Baker Hughes) agrees with the November 2021 proposed method of emissions reductions however, they recommend raising the proposed leak rate of 2 scfm because frequent replacement of rod packing could lead to unnecessary blow downs. The commenter recommends tuning the leakage threshold based on the operating parameters of the compressor, mainly flow and pressures. According to the commenter, the operator should be allowed to adjust compressor performance in order to bring the leak rate down below the actionable level. The commenter also states that the detected leak rate should not require action if the packing leakage is being captured and routed for re-use or sales. The commenter suggests that continuous monitoring of compressor parameters can lead to earlier detection of unacceptable seal leakage.

Commenter (0756-Baker Hughes) also states that there are continuous monitoring methods, considering performance parameters, that can be used to predict the need for seal replacement in a timelier manner than annual seal leak monitoring and should be considered the BSER for minimizing compressor seal leakage. The commenter suggests that smart compression technology which monitors performance and other analytics of the compressor to ascertain if maintenance is required be considered where and operator can adjust performance of the compressor to optimize performance when degradation has been sensed.

Commenter (0756-Baker Hughes) adds that packing seals always leak some amount of the compressed media, even when newly installed. For larger applications, such as transmission compressors, historical data shows that newly installed packing leaks at a rate of approximately 1 scfm. The commenter states that the proposed actionable leak rate of 2 scfm will lead to a significant increase in packing replacement for large, transmission sector compressors. They explain that this in turn will lead to a significant increase in compressor blowdowns with associated large volumes of emitted blowdown methane. Before adopting such a proposal, the commenter recommends that EPA analyze the increased volume of methane emissions from more frequent blowdowns compared to increasing the actionable leak rate; especially for the larger transmission compressors.

Response I-14-16: The EPA received a similar comment from the commenter regarding their request for a higher performance-based volumetric flow rate standard per cylinder for reciprocating compressors on the December 2022 Supplemental Proposal. The EPA's response to this comment is provided at Volume II, Chapter 11, section 11.2.3, Response II-11-16.

With regards to continuous monitoring or smart compression technology, the EPA has not included the commenter's recommendation to require continuous flow rate measurements in the final rule, however, this option is available to owners and operators as an internal operational and maintenance procedure to constantly check the status of integrity of the rod packings to ensure that, when the periodic measurement is made that the flow rate is below 2 scfm per cylinder. As discussed in the December 2022 Supplemental, the BSER analysis is unchanged from what was presented in the November 2021 proposal (see 86 FR 63214–63220, section XII.E).

Reciprocating Compressors).<sup>9</sup> The BSE for NSPS OOOOb and EG OOOOc for reducing GHGs and VOC from reciprocating compressors is the repair or replacement of the rod packing based on annual monitoring to maintain the volumetric flow rate per cylinder below 2 scfm.

See section X.I of the final rule preamble for a summary of the final reciprocating compressor requirements, including provisions that allow for a delay of repair if repair would require a compressor blowdown to complete the repair.

The commenter also states that the detected leak rate should not require action if the packing leakage is being captured and routed for re-use or sales. Under the December 2022 Supplemental Proposal, the EPA proposed standards and presumptive standards that would allow owners or operators to comply by capturing and routing emissions to a process. “*Routed to a process or route to a process*” is defined to mean the emissions are conveyed via a closed vent system to any enclosed portion of a process that is operational where the emissions are predominantly recycled and/or consumed in the same manner as a material that fulfills the same function in the process and/or transformed by chemical reaction into materials that are not regulated materials and/or incorporated into a product; and/or recovered. Owners or operators complying with this alternative option would not be required to meet the requirements of the performance-based volumetric flow rate monitoring standard.

Comment: Commenter (1291-Cumberland Valley Resources, LLC (CVR)) finds that looking for emissions from compressors of 2 scf/hr is very difficult for a small operator. To the commenter’s knowledge, there is no easy way to measure volumes as small as 2 cubic feet coming from something as complicated to isolate as the piston housing of most natural gas compressors. For what it would cost an operator to have a third party come in four times a year and measure rod packing leaks, it may be more cost effective to just go back to the NSPS OOOOa requirements of replacing the rod packing on a predetermined schedule. The commenter notes that the schedule for small compressors run at low rpm and low pressures is more cost effective for small operators at 60 months of run time than 36 months.

The commenter (1291-CVR) requests that EPA continue to allow a predetermined interval for required rod repacking instead of fugitive emission surveys but increase the time frame from 36 to 60 months and take into account actual runtime of the compressor.

Response I-14-17: The methods required to measure flow rate from reciprocating compressors are simplified versions of the demonstrated methods that are required by CFR Part 98, subpart W. The final rule only requires measurement once every 8,760 hours of operation, so the four times per year frequency mentioned by the commenter is not applicable. Also see the discussion in section IV.I.1.b of the December 2022 Supplemental Proposal,<sup>10</sup> and section X.I of the final rule preamble for a summary of the final reciprocating compressor requirements.

Comment: Commenters (0749-Petroleum Association of Wyoming (PAW), 0810-Petroleum Alliance-OK) state that the November 2021 proposed leak rate and monitoring requirements do not appear to account for variability in compressor configurations (e.g., compressor stages,

---

<sup>9</sup> 87 FR 74796-74797.

<sup>10</sup> 87 FR 74797.

operating conditions, and compressor size). Each compressor would have separate leak rates. The commenters note that the vents can be monitored during OGI surveys which are currently required and may indicate when rod packing is worn and needs changed. According to the commenters, these rod packing changes are time consuming and costly. According to the commenters, the November 2021 Proposal based on 2 scfm threshold, irrespective of compressor model, may result in the need for more frequent changes especially on large units.

The commenters (0749-PAW, 0810-Petroleum Alliance-OK) add that wellsite compression will also bring in thousands of compressors to be monitored that will result in the need to have rod packing changes completed. The commenters contend that this would be burdensome as the wellsite compressors move frequently and maintaining even more records on small compressors. The commenters state that this additional burden does not seem valuable. They add that more work needs to be done to understand how rod packing vent rates would be measured, and costs for monitoring would then need to be considered.

Response I-14-18: There is insufficient information at this time to support the establishment of a standard based on compressor stages, operating conditions, and compressor size. It is anticipated that while there may be more frequent rod packing change outs for some reciprocating compressors, there will also likely be a reduction in rod packing change outs for other reciprocating compressors because of the performance-based volumetric flow rate standard. In situations where a reciprocating compressor is screened to have no leaks or the performance-based volumetric flow rate is maintained at or below 2 scfm, an owner or operator is only subject to minimal recordkeeping and reporting requirements.

The final requirements for reciprocating compressors under NSPS OOOOb and EG OOOOc also include several alternative compliance options to the performance-based volumetric flow rate standard that an owner or operator can comply with to meet the standards. See section X.I of the final rule preamble for a summary of the final reciprocating compressor requirements.

With regards to comments regarding wellsite compression, these compressors are not included in the definition of reciprocating compressor affected or designated facilities under NSPS OOOOb and EG OOOOc. The December 2022 Supplemental Proposal regulatory text for NSPS OOOOb and EG OOOOc defined each reciprocating compressor affected or designated facility as a single reciprocating compressor and specifies that a reciprocating compressor located at a well site is not an affected or designated facility under the standards/presumptive standards. This has been maintained in the final NSPS OOOOb and EG OOOOc.

With regards to comments that more work needs to be done to understand how rod packing vent rates would be measured, and that the costs for monitoring would then need to be considered, the December 2022 Supplemental Proposal proposed test methods and procedures for reciprocating compressors. See final standards/presumptive standards at 40 CFR 60.5386b(a) and 40 CFR 60.5405c(a) test methods and procedures for reciprocating compressors. Also note that volumetric flow rate monitoring of reciprocating compressors is also required under 40 CFR Part

98, Subpart W (subpart W) and costs considered under subpart W were used in the BSER analyses.<sup>11</sup>

See section X.I of the final rule preamble for a summary of the final reciprocating compressor requirements.

Comment: Commenters (0817-GPA, 1391-Interstate Natural Gas Association of America (INGAA)) agree with the proposed 2.0 scfm/cylinder leak rate threshold. The commenters acknowledge that this is the level that was adopted by the California Air Resource Board (CARB), allotting 2.0 scfm per compressor cylinder. However, the commenters express that the precise application of the proposed condition-based rod packing standard is unclear without regulatory text. One of the commenters (1391-INGAA) requests that the standard be adopted as a per cylinder standard (for example, 2 scfm/cylinder) for each reciprocating compressor unit. The commenter notes that most reciprocating compressor units have more than one cylinder, with the rod packing emissions from each individual cylinder being emitted through a vent that is common to all cylinders on the unit. The commenter explains that measurements of rod packing vent emissions for such units are typically made at the common vent, so they measure the aggregate leakage from all the cylinders that vent through the common vent. To accommodate these types of common vents, the commenter recommends that the condition-based standard allow for measurement at the common vent and the standard should have an option to be based on the total rod packing vent emissions for a unit, based on the number of cylinders, where an aggregate value would be acceptable at less than or equal to the number of operating cylinders on that compressor.

*Example:* If a Compressor had two active cylinders, each cylinder is allowed a maximum leakage rate of 2.0 scfm, an acceptable aggregate for this two-throw compressor would be 4.0 scfm. This aggregate method applies for all reciprocating compressors. These rates are more in line with the EPA's site review strategy-based tonnage thresholds of > 3.0 tons per year for initial review and < 3.0 tons for future site review. As mentioned above, the detection threshold of 10Kg/hr produces venting of 96.5 tons per year. The current the EPA guideline does not specify composite or aggregate rates.

Commenter (0817-GPA) supports the 2 scfm threshold and monitoring approach as long as EPA also provides that reciprocating compressor operators may use an average leak rate based on the number of cylinders routed to a common vent stack. The commenter explains that using an average is appropriate, as a single reciprocating compressor can have multiple cylinders (also referred to as throws), often routed to a common vent stack. In this situation, it is impractical and unreasonable to require operators to separately route each cylinder in order to gather cylinder-specific measurements. The commenter requests that EPA allow operators to use an average based on the number of cylinders routed to the common vent system. Under such a procedure, if the average leak rate exceeds 2 scfm, the operator would be required to timely identify the cylinder that failed and effect repairs, if necessary, in accordance with an appropriate delay of repair provision. The commenter states that averaging across cylinders where rod packing vents

---

<sup>11</sup> Greenhouse Gas Reporting Program (EPA ICR No. 2300.18, OMB Control No. 2060-0629) to the Office of Management and Budget (OMB).

are manifolded to a common header is consistent with the California regulations on which EPA based its 2 scfm leak rate proposal. 17 CCR § 95668(c)(4)(D).

Commenter (0577-Kansas Independent Oil & Gas Association (KIOGA)) inquires whether the 2 scfm threshold for reciprocating compressors identified in Table 3 at 86 Fed. Reg. 63121 is determined on a per cylinder basis or on a per compressor basis. The commenter states that some compressors have a common vent, which would require piping modifications if required to measure the vent rate from each cylinder.

Response I-14-19: The EPA received a similar comment on the December 2022 Supplemental Proposal from commenters regarding the need for clarification that the performance-based volumetric flow rate standard for reciprocating compressors is on a per cylinder basis. The EPA's response to this comment is provided at Volume II, Chapter 11, section 11.2.3, Response II-11-7 and section XI.I.3 (Clarification that the standard is based on a per-cylinder basis) of the preamble to the final rule responds to these comments.

See also section X.I of the final rule preamble for a summary of the final reciprocating compressor requirements.

#### ***14.4.2 Flow Rate Measurement Monitoring Interval***

##### ***14.4.2.1 Hours of Operation Versus Calendar Year***

Comment: Commenters (1391-INGAA, 0585-Kentucky Oil and Gas Association (KOGA), 0808-API, 0814-IPAA *et al.*, 0831-AXPC, 0820-Pioneer Natural Resources USA, Inc. (Pioneer), 0911-North Dakota Petroleum Council (NDPC)) on the November 2021 Proposal recommend that EPA consider requiring flow rate monitoring based on a compressor's hours of operation totaling one year (*i.e.*, 8,760 hours) in lieu of requiring annual flow rate measurements based on a calendar year (*i.e.*, 365 days). Commenters state that using the compressor's hours of operation would ensure that undue burden is not placed on owners and operators where compressors are not operational for multiple months or are used intermittently. The commenters explain that basing flow rate measurement requirements on a reciprocating compressor's hours of operation would allow owners and operators to stagger maintenance activity throughout the year and replacement would be based on actual use instead of potential use.

Commenter (0911-NDPC) suggests that as an alternative, EPA consider requiring reciprocating compressors be monitored every other calendar year.

Response I-14-20: See discussion in Section IV.I.1.b of the December 2022 Supplemental Proposal on proposal to require volumetric flow rate monitoring based on compressor hours of operation versus calendar year.<sup>12</sup>

---

<sup>12</sup> 87 FR 74797.

#### 14.4.2.2 Other Comments Related to Monitoring Intervals – NSPS OOOOa Requirements

Comment: Commenters (0814-IPAA *et al.*, 0585-KOGA) state that the current NSPS OOOOa requirement of replacing rod packing of a reciprocating compressor every 36 months is also a burden to the small operator. The commenters contend that unnecessary maintenance and down time hurts revenue with no material benefit. The commenters add that rod packing in compressors that run at relatively low pressures and rod packing can last well over 60 months, and even longer if the compressor runs intermittently. The commenters recommend that EPA increase the interval for required rod repacking from 36 to 60 months and consider actual runtime of the compressor. In addition, for compressors at wellheads, the commenters suggest that EPA allow the option for OGI surveys to monitor rod packing leaks. The commenters recommend that, if a leak is found during an annual survey, the measurement can be used to determine a rate and need for replacement.

Response I-14-21: In response to the comment that the current NSPS OOOOa requirement of replacing rod packing of a reciprocating compressor every 36 months is a burden to the small operator, the EPA is not reconsidering the requirements for reciprocating compressors under NSPS OOOOa. See Chapter 7 (Compressors) of the RTC document for *EPA's Proposed Oil and Natural Gas Sector: Emission Standards for New, Reconstructed, and Modified Sources* (2015 NSPS OOOOa Proposal) for comments on the 2015 NSPS OOOOa Proposal and EPA's responses to those comments. See also EPA's rationale for the proposed 2015 NSPS OOOOa in the preamble to proposed rule<sup>13</sup> and EPA's rationale for the final 2016 NSPS OOOOa in the preamble to the final rule.<sup>14</sup>

With regards to the requirements for reciprocating compressors at wellheads, these compressors are not considered reciprocating compressor affected or designated facilities under the NSPSs OOOOa and OOOOb and EG OOOOc. The December 2022 Supplemental Proposal regulatory text for NSPS OOOOb and EG OOOOc defined each reciprocating compressor affected or designated facility as a single reciprocating compressor and specifies that a reciprocating compressor located at a well site is not an affected or designated facility under the standards/presumptive standards. This has been maintained in the final NSPS OOOOb standards and EG OOOOc presumptive standards.

See December 2022 Supplemental Proposal preamble section IV.I.1.b for a discussion on EPA's proposal to require volumetric flow rate monitoring based on hours of operation versus calendar year. See also Response I-14-20 in section 14.4.2.1 of this RTC document on December 2022 Supplemental Proposal to require volumetric flow rate monitoring based on compressor hours of operation versus calendar year under the NSPS OOOOb and EG OOOOc standards and presumptive standards.

Finally, the final rule does not require that the rod packings be changed out at any specific interval. Rather, monitoring is required every 8,760 hours of operation. And this monitoring is only required if the compressor fails the initial screening. Therefore, if the rod packing integrity

---

<sup>13</sup> 40 CFR 56620-56622, September 18, 2015. See Section VIII.C (Proposed Standards for Reciprocating Compressors).

<sup>14</sup> 40 CFR 35848-35849, June 3, 2016. See Section VI.B (Reciprocating Compressors).

is sound and the flow rate remains below 2 scfm, the period between rod packing changeouts could be 60 months (or even more). Further, if the monitoring results in a flow rate greater than 2 scfm per cylinder, the owner or operator is not required to change out the rod packing if other measures could reduce the flow rate below that level. In conclusion, EPA feels that the final NSPS OOOOb standards and EG OOOOc presumptive standards are less burdensome than required rod packing changeouts.

Comment: Commenter (0789-Pennsylvania Department of Environmental Protection (PDEP)) recommends that EPA clarify that the proposed requirement for reciprocating compressors is the shorter of 36 calendar months or 26,000 hours of operation.

Response I-14-22: The November 2021 Proposal performance-based volumetric standard monitoring requirements for reciprocating compressors were based on annual monitoring. See December 2022 Supplemental Proposal preamble section IV.I.1.b for a discussion on EPA's proposal to require volumetric flow rate monitoring based on hours of operation versus calendar year.<sup>15</sup> See Response I-14-20 in section 14.4.2.1 of this RTC document on the December 2022 Supplemental Proposal to require volumetric flow rate monitoring based on compressor hours of operation versus calendar year. As an alternative to conducting required volumetric flow rate measurements, the final rule allows an owner or operator the option to comply by replacing the rod packing on or before 8,760 hours of operation after the effective date of the final rule for the NSPS OOOOb (and 8,760 hours of operation after the effective date of an approved state or tribal plan for the EG OOOOc), on or before 8,760 hours of operation after the previous flow rate measurement, or on or before 8,760 hours of operation after the date of the most recent compressor rod packing replacement, whichever is later.

#### 14.4.2.3 Retain NSPS OOOOa Reciprocating Compressor Rod Packing Replacement Requirements

Comment: The commenters state that some company programs and states have adopted the NSPS OOOOa standard. For example, the commenters report that the EPA Methane Challenge Program includes a fixed schedule program from reciprocating compressor rod packing based on NSPS OOOOa criteria as an accepted Best Management Practice (BMP) for the program. The commenters add that EPA's website indicates that over 200 facilities voluntarily implemented reciprocating compressor reductions in 2019.<sup>16</sup> Allowing a fixed schedule option allows companies consistency with NSPS OOOOa and voluntary programs, would maintain consistency with state permit conditions or requirements, and allow flexibility for existing compressors under EG OOOOc. The commenters state that EPA has not provided data to determine that scheduled rod packing replacement is no longer an adequate method, warranting elimination of this option entirely. Commenters further add that EPA has not provided enough real-world data on one option being better, and one may be less burdensome to some operators and equipment configurations.

---

<sup>15</sup> 87 FR 74797.

<sup>16</sup> U.S. EPA, Natural Gas STAR Methane Challenge Program: BMP Commitment Option Technical Document, at 14 (July 2020) [https://www.epa.gov/sites/default/files/2020-07/documents/mc\\_bmp\\_technicaldocument\\_2020-07.pdf](https://www.epa.gov/sites/default/files/2020-07/documents/mc_bmp_technicaldocument_2020-07.pdf)

Commenter (0817-GPA) notes based on information from the TSD calculation sheet, EPA assumes the rod packing will last for three to 4.4 years. Because this is the assumption used, it is reasonable to maintain the existing three-year replacement schedule as previous rulemakings have already determined it is a reasonable cost to reduce emissions. The commenters are not opposed to adding condition-based maintenance as an alternative to the prescribed maintenance schedule but recommend that both options be included with the operator selecting their preferred approach.

Commenters (0750-Flogistix, 0810-Petroleum Alliance-OK) state that they are concerned that EPA is proposing that the owner or operator of a reciprocating compressor-affected facility would now be required to monitor the rod packing emissions annually using a flow measurement. The commenters state that thousands of units would need measurement features added. In addition, they add that many operators use leased reciprocating compressors where vendors replace the rod packing as part of our 3 year/26,000-hour maintenance program. The commenters state that this schedule is preferable for ease of compliance, so they recommend EPA keep the existing requirements under NSPS OOOOa for these types of compressors.

Response I-14-23: With regards to comments that recommend retaining the current NSPS OOOOa requirements for rod packing based on a defined maintenance schedule in NSPS OOOOb and EG OOOOc, and supplement that requirement with optional use of condition-based maintenance as an alternative, the EPA maintains, as set out in sections XII.E.1.d and 2 of the November 2021 proposal preamble,<sup>17</sup> that annual rod packing flow rate monitoring and replacement of the packing where flow rate monitoring indicates a measurement that exceeds 2 scfm represents BSER for NSPS OOOOb for all segments including reciprocating compressors located at centralized productions facilities (with the exception of compressors at stand-alone well sites).

While not including a 3-year fixed schedule for rod packing replacement in the NSPS OOOOb standards and EG OOOOc presumptive standards, as an alternative to conducting the required volumetric flow rate measurements, an owner or operator can choose to comply by replacing the rod packing on or before 8,760 hours of operation after initial startup, on or before 8,760 hours of operation after the effective date of the final rule for NSPS OOOOb (and 8,760 hours of operation after the effective date of an approved state or tribal plan for the EG OOOOc), on or before 8,760 hours of operation after the previous flow rate measurement, or on or before 8,760 hours of operation after the date of the most recent compressor rod packing replacement, whichever is later.

With regards to comment that operators often use leased compressors where vendors replace the rod packing as part of their 3 year/26,000-hour maintenance program, the vendor would need to adjust its maintenance program to meet standards. Further, if the 3 year/26,000-hour maintenance program is sufficient to maintain the compressor vent volumetric flow rate at or below 2 scfm per cylinder, more frequent rod packing replacement would not be necessary.

With regards to comments that state that thousands of units would need measurement features added, see comment response I-14-13 that clarifies that the final rule does not require that each

---

<sup>17</sup> 86 FR 86 63215-63219.

cylinder be equipped with a monitoring port. The EPA recognizes, however, that equipment modifications may still be required to facilitate volumetric flow rate measurements where a company does not already conduct such measurements (*e.g.*, under a company's standard operating practices or to comply with 40 CFR Part 98, subpart W requirements).

The final requirements for reciprocating compressors under NSPS OOOOb and EG OOOOc also include other alternative compliance options to the performance-based volumetric flow rate standard that an owner or operator can comply with to meet the standards. See section X.I of the final rule preamble for a summary of the final reciprocating compressor requirements.

#### ***14.4.3 Routing Emissions to a Process Via a Closed Vent System Under Negative Pressure***

Comment: Commenter (0817-GPA) notes that routing emissions to a process should not require negative pressure, stating that some pressure differential is required to take gas out of the rod packing vent and into the desired location; whether it be a control device or routed back to the system. The commenter states that this process is already understood for flares, controls for pumps and tanks, and routing emissions to supplemental fuel do not require negative pressure. The commenter further states that the use of negative pressure can raise safety and operational issues, and that operating a crankcase collection system under negative pressure (*i.e.*, in a vacuum) creates the possibility of introducing oxygen into the system. The commenter adds that allowing for pressure differential without requiring operation under negative pressure could lead to larger emission reductions overall, and that the proposed negative pressure requirement eliminates the use of technologies that could reduce methane emissions further, for example routing rod packing to a combustor flare or SLIPSTREAM® systems to inject rod packing into the fuel system. Finally, the commenter states that without positive pressure in the closed vent system prior to the shut off valve, automatic ignition controls will not operate. The commenter suggests that where a closed vent system using positive pressure can be certified as providing effective control under maximum instantaneous flow rates without leaks, EPA permit its use.

Another commenter (0745-Step 2 Compliance, LLC (S2C)) similarly reports that the use of negative pressure presents safety concerns of creating an explosive mixture of natural gas and atmospheric air, should there be any leak between the negative pressure source and the packing vent. The commenter states that if the packing vent recovery system is at a lower pressure; the packing vent gas will be recovered without leaking to atmosphere and there will be no risk of introducing atmospheric air to the natural gas.

Commenter (0923-Lambda) states that routing compressors packings through a closed-loop system under negative pressure is infeasible at most of the commenter's compressor sites and should not be part of the final rule.

Response I-14-24: See December 2022 Supplemental Proposal preamble at section IV.I.1.b.ii for EPA's response to comments on routing emissions to a process via a closed vent system (CVS) under negative pressure.<sup>18</sup> The EPA proposed to revise (and has finalized) this compliance

---

<sup>18</sup> 87 FR 74798.

alternative by continuing to allow emissions to be routed to a process via a CVS but removing the requirement for this to occur under negative pressure.

#### ***14.4.4 Repair or Replacement/Delay of Repair/Performance Adjustment***

Comment: Commenter (0817-GPA) states that repair should be allowed as an alternative to replacement; with appropriate delay of repair as an option. Repairs, without complete repacking, should be an option as well. The commenter notes that for older units, replacing the rod packing does not always address emissions, as other maintenance issues can contribute to cylinder emissions, such as issues with the rod itself. The commenter asserts that operators should have the option of either approach, so long as that option ultimately results in compliance with a two scfm standard. Providing this flexibility can significantly impact personnel costs as a rod packing replacement on older units can require approximately 32-man hours per cylinder, while a repair may entail a significantly lower level of effort. The commenter notes that a repair alternative would be consistent with the California regulations on which EPA has based the two scfm standard for reciprocal compressors, as California provides repair as an option instead of repacking. See 17 CCR § 95668(c)(3)(D).

The commenter (0817-GPA) adds that the California regulations also allow for a delay of repair, with notification to the agency. The commenter recommends that EPA also provide a practical delay of repair component in the rule. According to the commenter, rod packing repair or replacement requires the compressor to be taken out of service, which requires the compressor to be blown down. This creates emissions. Ideally, the commenter states that the rod packing repair or replacement should happen in conjunction with the next preventative maintenance activity that requires a blowdown, or within two years (whichever is earlier), to minimize the blowdown emissions.

Response I-14-25: See section IV.I.1.b of the December 2022 Supplemental Proposal preamble for a discussion on allowing for repair as an alternative to complete replacement of rod packing and EPA's response to these comments. The EPA proposed (and has finalized) that an owner or operator would be allowed to repair or replace the rod packing to maintain the volumetric flow rate at or below the 2 scfm per cylinder emission limit.

The final NSPS OOOOb and EG OOOOc rules require rod packing repair (or rod packing replacement) within 90 calendar days after the date of a volumetric flow rate emissions measurement that indicates a volumetric flow rate greater than 2 scfm. Delay of repair would be allowed if the repair (or rod packing replacement) is technically infeasible, would require a vent blowdown, a compressor station shutdown, or would be unsafe to repair during operation of the unit. The repair in such cases must be completed during the next scheduled compressor station shutdown for maintenance, after a scheduled vent blowdown, or within 2 years, whichever is earliest.

In addition, if the repair requires replacement of the compressor rod packing or a part, but the necessary replacement rod packing or part cannot be acquired and installed within the repair timelines specified due to supplies being unavailable (where previously sufficiently-stocked), a delay of repair is allowed. However, in order to qualify for a delay of repair, the required rod

packing or parts replacement must be ordered no later than 10 calendar days after the reciprocating compressor is added to the delay of repair list due to parts unavailability.

Comment: Commenter (0756-Baker Hughes) requests that operators of compressors be allowed the capability to adjust performance of the compressor to decrease the packing leak rate. If performance of the compressor at a lower flowrate or lower pressure meets the needs of the operator, and by adjusting those performance parameters, the leak rate can be held down, this should be a viable mitigating action that allows the operator time to make repairs once seal wear leads to unacceptable performance. Further, the commenter requests that, if a packing leakage system is in place that captures all packing leakage in a closed loop that routes the leakage away for re-use or sales, then the packing leak rate should not be the trigger for abatement action as there are no emissions connected with the leak rate.

Response I-14-26: The EPA received similar comments from this commenter on the December 2022 Supplemental Proposal. EPA's response to this comment is provided at Volume II, Chapter 11, section 11.2.4 (Alternative Compliance Option), Response II-11-22.

#### ***14.4.5 Continuous Monitoring Technology***

Comment: Commenter (0450/1298-M-Squared Products and Services, Inc. (M2PS)) recommends continuous "point-of-source detection monitoring." The commenter states that in 2004 they designed the first prototype Packing Leak Detector (PLD) to address the on-going issue of measuring packing gland leakage from reciprocating compressor's packing gland vents. The PLDs are mechanical, non-invasive devices that can be easily installed on any reciprocating compressor cylinder packing vent to measure any leakage from the vent. The commenter explains that the unit was originally designed to measure wellhead gathering gas (specific gravity 0.65) but has since evolved to handle any type of specific gravity gas for single or multiple-service compressors. In 2015, the commenter notes that they were awarded several patents for the PLD. The commenter adds that this PLD technology has proven cost-effective and has been installed on land, offshore, gathering and storage compressor locations throughout the domestic U.S. The commenter provides that the average cost per compressor cylinder of \$10,000 including the PLD block, temperature and pressure transmitters, connection cables, mounting plate, wiring Conduit box and programmable logic controllers (PLC)-panel (for installation in existing on-site panel). Curtailing a leakage rate of greater than 8.0 Scfm/cylinder on a two-throw compressor (greater than 16.0 scfm) at \$3.00/Mcf, payout/return on investment (ROI) would occur in less than ten months. According to the commenter, this device requires no special, invasive installation and will work with all current and legacy compressors employed throughout the industry, making the PLD system the BSER and Best Available Current Technology (BACT).

The commenter (0450/1298-M2PS) provides significant information in their comments on the PLD system advantages and specifications and the following information supporting the need for point-of-source detection of those components. According to the commenter, they have seen operators selectively perform momentary observations, *e.g.*, OGI, on an annual or semi-annual basis for point-in-time leakage measurements. Annual or semi-annual measurements, like OGI, do not provide histological data about leak rates. Such measurements do not account for leaks that occur one hour/day/month, *etc.*, from that measurement point. New or remanufactured

equipment placed into service, is not measured for leakage until required by current EPA guidelines (current NSPS OOOOa regulations require packing change every 26,000 hours or thirty-six months). The equipment could be leaking unabated for months without being addressed. Hence, the commenter stresses the need for continuous point-of-service detection monitoring to identify and measure fugitive gas leakage. The commenter states that present EPA regulations do not account for unexpected leakage or hold the operator accountable for venting fugitive emissions.

*Example:* A new Ariel KBBV six throw compressor was put into service and both second stage cylinders were leaking at a rate of 20+ scfm each, measured via the PLD. Without the PLD, these compressor leakages could have gone unabated for several months without resolution. With the PLD, the operator was able to confirm and correct packing installation, emory cloth the piston rod to roughen the surface and adjust lubrication to reduce the packing gland leakage to < 1.0 scfm.

The commenter continues that OGI technicians may miss measuring existing leaks, or not measure them at all, because of the compressor's operating state. The commenter explains that where operators' shutdown compressors without blowing them down (*e.g.*, storage and transportation compressor sites), the packing gland seal is no longer in dynamic seal mode, and now is referred to as "static mode." In static mode, the packing gland assembly no longer has lubrication or piston rod movement. In this mode, the packing gland cannot prevent trapped pressurized gas in the piston area from leaking down the piston rod, through the packing gland and out the packing vent.

*Example:* A storage or pipeline transportation compressor may be shutdown, fully loaded. The dynamics packing gland seal is now in static mode and incapable of retaining trapped gas. OGI technicians, typically, do not measure shutdown units, thereby miss measuring fugitive emissions escaping from non-functioning seals. Based on measured effluent from existing compressors in a loaded shutdown state, leakage rates, as measured by the PLD, are typically 3-5 times more than of when the compressor is operating.

[Note: Further detailed information on the PLD system is included in Section 14.6 (Other) of this Chapter.]

Response I-14-27: The EPA has not included the commenter's recommendation to require continuous monitoring in the final rule, as we believe that the final reciprocating compressor requirements, specified in 40 CFR 60.5385b of NSPS OOOOb and 40 CFR 60.5393c of EG OOOOc, will be effective in reducing emissions in a cost-effective manner. Owners and operators are welcome to supplement the periodic requirement to screen and conduct flow rate measurements after 8,760 hours of operation with PLD monitoring.

Comment: Commenter (0785- John Crane Inc) calculates that in reference to section XI of the November 2021 Proposal where it states "reciprocating compressor proposed replacement of rod packing when an annual inspection exceeds 2 scfm has the potential to release methane to atmosphere for extended periods of time as the inspection interval is annually" – 2 scfm = 54.4 kg of methane per day, 1.6 metric tons methane per month, 48 CO<sub>2</sub>e tons per month at 86 percent

methane concentration. To reduce the potential of operation for extended periods of time with the vent flow above the alarm point, the commenter recommends continuous flow measurement be required with a high flow alarm point set at 2 scfm.

Response I-14-28: The EPA has not included the commenter's recommendation to require continuous flow rate measurements in the final rule, however, this option is available to owners and operators as an internal operational and maintenance procedure to constantly check the status of integrity of the rod packings to ensure that, when the periodic measurement is made that the flow rate at or below 2 scfm per cylinder. As discussed in the December 2022 Supplemental Proposal a, the BSER analysis is unchanged from what was presented in the November 2021 proposal (see 86 FR 63214–63220, section XII.E. Reciprocating Compressors).<sup>19</sup> The BSER for NSPS OOOOb and EG OOOOc for reducing GHGs and VOC emissions from reciprocating compressors continues to be the repair or replacement of the rod packing based on annual monitoring (not continuous monitoring) to maintain the volumetric flow rate per cylinder below 2 scfm.

## 14.5 Implementation Issues

Comment: Several commenters (0424-Division of Air Quality, West Virginia Department of Environmental Protection (WVDEP), 0782-BHE, 0808-API) ask if the 2 scfm threshold for reciprocating compressors identified in Table 3 at 86 Fed. Reg. 63121 is determined on a per cylinder basis or on a per compressor basis. One commenter (0424-WVDEP) states that some compressors have a common vent, which would require piping modifications if required to measure the vent rate from each cylinder. Similarly, another commenter (0817-GPA) states it is common practice to manifold the rod packing vents together and requests that operators be allowed to measure flow rate from the manifold and average based upon the number of throws collected.

Response I-14-29: The EPA received similar comments on the December 2022 Supplemental Proposal regarding the basis for the proposed volumetric flow rate standards/presumptive standards (*i.e.*, per cylinder or per compressor) and the ability to measure the volumetric flow rate from the manifold line and average. EPA's response to these comments is provided at Volume II, Chapter 11, section 11.2.2, and section XI.I.3 of the final rule preamble.

The December 2022 Supplemental Proposal included proposed regulatory text for NSPS OOOOb and EG OOOOc clarifying how the volumetric flow rate monitoring standard would be applied, including when reciprocating compressor cylinders are manifolded together. Comments on the December 2022 Supplemental Proposal proposed requirements and EPA's responses to those comments can be found at Volume II, Chapter 11, section 11.3.1 of this RTC. 40 CFR 60.5386b of NSPS OOOOb and 40 CFR 60.5405c specify the final rule test methods and procedures for reciprocating compressors and centrifugal compressors.

Comment: Commenters (0808-API, 0817-GPA, 1391-INGAA) state that EPA needs to clarify the timing for required rod packing replacement and provide flexibility in measurement timing.

---

<sup>19</sup> 87 FR 74796-74797, December 6, 2022.

One commenter (0817-GPA) continues that if a compressor stops operating before the rod packing measurement was conducted, and the compressor does not operate again for the rest of the year, the operator should not be out of compliance with the annual measurement standard. The commenter requests that EPA allow the annual measurement to be conducted at any point during the year (versus 12 months apart) to allow flexibility around the myriad of timing issues including maintenance coordination, measurement instrument availability, contractor availability, compressor shutdowns, and weather. The commenter states that EPA could, for example, allow operators to conduct the measurement at least twice in any three-year period.

Another commenter (0808-API) states that considerations on timing are the types of concerns that are well documented within subpart W for natural gas plants and transmission compressor stations. For example, the commenter provides that the requirements in 40 CFR part 98, subpart W, only require rod packing measurements when a compressor is in operating mode at the time the measurement is set to occur (*i.e.*, when the measurement team arrives onsite). The commenter notes that equipment modifications may be required to facilitate measurement of rod packing vents (*e.g.*, adding an accessible port in vent piping), and adequate implementation time must be provided.

Commenter (1391-INGAA) requests clarification regarding the timing for required rod packing replacement under a condition-based standard. The commenter explains that rod packing replacement is a major maintenance activity that must be done during an equipment shutdown. The commenter states that this maintenance must be allowed to be scheduled to minimize unnecessary interruptions to operations. The commenter recommends that replacement be required at the next planned shutdown for maintenance.

Response I-14-30: See discussion in section IV.I.1.b.i of the December 2022 Supplemental Proposal preamble on EPA's proposal to require volumetric flow rate monitoring based on compressor hours of operation (8,760 hours of operation) versus a calendar year.

See discussion in section X.I of the final rule preamble for a summary of the final NSPS OOOOb and EG OOOOc reciprocating compressor requirements (including repair and delay of repair requirements).

See also comment Response I-14-13 that clarifies that the final rule does not require that each cylinder be equipped with a monitoring port. The EPA recognizes, however, that equipment modifications may still be required to facilitate cylinder vent volumetric flow rate measurements. In consideration of this and other comments the final rule allows owners or operators to conduct their first volumetric flow rate measurements from their reciprocating compressor cylinder vents on or before 8,760 hours of operation after the effective date of the final rule for NSPS OOOOb (and 8,760 hours of operation after the effective date of an approved state or tribal plan for the EG OOOOc), or on or before 8,760 hours of operation after last rod packing replacement, or on or before 8,760 hours of operation after startup, whichever is later.

Comment: Several commenters (0782-BHE, 0808-API, 0813-Black Hills Energy, 1375-Kinder Morgan, 1391-INGAA) request regulation clarification including that EPA clearly state in the rule that the GHGRP subpart W methods be allowed for the flow rate measurements. These

commenters also requested that EPA clearly state the proposed reciprocating compressor annual monitoring threshold and the repair and rod packing replacement requirements. Specifically, they request that EPA provide certainty regarding the schedule for repair and “delay of repair” criteria to ensure unnecessary restrictions are not placed on repair schedules, and a clear explanation of operating requirements for measurement (*i.e.*, when the unit is operating).

Response I-14-31: See section IV.I.1.b of the December 2022 Supplemental Proposal preamble for a response to these regulation clarification comments.<sup>20</sup>

Comment: Commenter (0808-API) indicates that clarification is needed on how the annual monitoring standard is applied for certain packing vent configurations and systems. For example:

- If an operator uses a continuous meter on a rod packing vent, how would compliance be demonstrated against the annual measurement?
- How will replacing the packing due to a different reason/program affect the annual monitoring window?
- When packing vents are manifolded together, is the standard determined by multiplying the leak threshold by the number of cylinders?

Response I-14-32: The December 2022 Supplemental Proposal included proposed regulatory text for NSPS OOOOb and EG OOOOc clarifying how the volumetric flow rate monitoring standard would be applied, including when rod packing vents are manifolded together. Comments on the December 2022 Supplemental Proposal proposed requirements and EPA’s responses to those comments can be found at Volume II, Chapter 11, section 11.3.1 of this RTC.

See discussion in section IV.I.1.b.i of the December 2022 Supplemental Proposal preamble on EPA’s proposal to require volumetric flow rate monitoring based on compressor hours of operation (8,760 hours of operation) versus a calendar year.

## 14.6 Other

Comment: [Note: The following is additional detail provided by one commenter (vendor) for their Packing Leak Detector (PLD) system.] Commenter (0450/1298-M2PS) indicates that the PLD now comes in mechanical and/or digital format, capable of providing point-of-source detection, twenty-four (24) hours per day, 365 days per year. They explain that the digital unit provides information to the operating company via Modbus registers, allowing them to incorporate the data into their main PLC system to establish the following:

- Historical data of packing gland leaks (for continuous reporting capability).
- Set alarms (based on amount of leakage in scfm or other imperial/metric values, accurate to the third decimal place).
- Set shutdowns (based on amount of leakage in scfm or other imperial/metric values, accurate to the third decimal place).
- Monitor temperature.

---

<sup>20</sup> 87 FR 74797-74798, December 6, 2022.

- Monitor pressure.
- Develop alternate measuring parameters to fit operating companies or governing bodies guidelines.
- The PLD has been employed to measure other leak rates for distance-piece vents, large integral fuel valves, and more.
- PLD industry rating.

The commenter (0450/1298-M2PS) reports that PLD is designed to be permanently installed on compressors to meet or exceed the abrasive environment standards set by the oil & gas industries. The mechanical and digital blocks are designed to meet API-SPEC 6A. The commenter provides that digital PLD-PLC control module assembly, transmitters, cable, and conduit assemblies are designed to meet the following engineering approvals:

#### APPROVALS/CERTIFICATIONS

- CSA Class I, Division 2, Groups A, B, C, D T4
- ANSI/UL 122701 Single Seal
- ABS (American Bureau of Shipping)
- CE
- Pressure Transducers designed for 50 up to 30,000 PSI, operating temperature -40 to 125°C
- Temperature Transducers designed for -14.504 up to 1,451 PSI, operating temperature -50 to 250°C
- IP65/IP67
- UL NRAQ.E214119 Programmable Controllers, Communication and I/O modules
- EU Declaration of Conformity:
  - Low Voltage Directive (LVD): 2006/95/EC, 2014/35/EU, EN 61131-2:2007
  - EMC Directive: 2004/108/EC, 2014/30/EU, EN 61131-2:2007
  - RoHS Directive: 2011/65/EU, EN 50581:2012

*PLD Non-invasive installation:* The commenter (0450/1298-M2PS) notes that the PLD is typically installed as close to the operating cylinder packing gland vent as possible. Some compressor rental companies are employing the PLD's on a temporary basis using polyflow line and measuring each cylinders packing vent leakage, making corrections, disconnecting the PLD and moving it to the next cylinder for leakage testing (examples included in attached PowerPoint presentation). Rental compressor companies have used this method to prevent "Inks" on offshore and land locations. Currently the commenter reports that this method has been accepted by the prevailing inspecting authorities.

The commenter (0450/1298-M2PS) adds that the PLD system may incorporate the "Zero-Emission block," a clear, sealed component, allowing fugitive emissions that may leak past the internal measuring piston to remain captured and processed upstream, as an option. A Zero-Emissions block allows a clear visual sight of the mechanical measuring pin attached to the existing PLD block, capturing fugitive emissions to be processed upstream. The Zero-Emissions block is used in cases where leakage would be the expected norm, at pressures exceeding 10

pounds per square inch gauge (psig), and in locations where gas detection is employed. This will prevent gas detectors from actuating (*e.g.*, storage and transportation compressor sites with building enclosures that employ gas detection).

[Note: Commenter (0450/1298-M2PS) includes a diagram in their comment letter titled, “Anodized aluminum or stainless-steel block with pressure/temperature transmitters and Zero-Emissions block (unit above includes optional Zero Emission block, PLD mounting plate with Condulet flange box and hardware)”.]

According to the commenter (0450/1298-M2PS), the PLD system provides operators the following benefits:

- The first device/tool capable of measuring real-time “Zero-Leak” baselines, allowing operators the ability to diagnose their packing assembly, whether new or used, and correct issues to achieve a “Zero-Leak” baseline. Operators will no longer be reliant on OEM compressor manufactures for their nebulous packing gland leak values. Operators will be able to establish and document their own “Zero-Leak” baseline, from which they will be able to monitor and identify how much and which packing gland is actually venting/leaking and set limits.
- Allows operators to diagnose:
  - Over/under lubrication
  - Improper packing material
  - Incorrect packing installation
  - Piston rod hardness/smoothness
  - Piston ring wear/rod drop
- Provides real-time measured packing vent leakage (which cylinder, when, and how much)
- Provides leak rate on dynamic packing gland in static mode when compressors are shutdown loaded (without blowdown)
- Set limits for fugitive gas emissions
- Provides packing “health” data supporting proactive maintenance and servicing
- Compatible for different gas types & multiple services
- Return on investment (ROI) in less than a year
- 24-hour monitoring (dynamic or static state)

The commenter (0450/1298-M2PS) contends that the ability of the PLD to measure volumes of fugitive emissions provide operators the information necessary to design emissions capture systems. The PLD, in conjunction with a vapor recovery unit (VRU) and/or vapor recovery tank (VRT), can provide total measurement and capture capability for operating companies. They explain that these measured and captured fugitive emissions can be used as “blanket gas” in stock tanks, recompressed to be used as fuel gas for natural gas drivers for onsite compression, power generation or other rotating equipment, or to be reintroduced into the low-pressure compression streams for recompression as sales gas.

Response I-14-33: The EPA appreciates the information provided by the commenter on their PLD technology. See comment Response I-14-27 of section 14.4.5 of this Chapter for EPA's response to comment on requiring continuous monitoring.

## Chapter 15. Equipment Leaks at Natural Gas Processing Plants

### 15.1 General Support/Opposition

Comment: Commenters (0844-Environmental Defense Fund (EDF) *et al.*, 0912-Shell Oil Company (Shell), 0943-Sault Ste. Marie Tribe of Chippewa Indians, Sault Tribe Environmental Department (Sault EPD), 0391-Keweenaw Bay Indian Community (KBIC), 0781-National Tribal Air Association (NTAA), 0605-Musocogee (Creek) Nation, 0808-American Petroleum Institute (API), 0833-Environmental Programs Department, Ute Mountain Ute Tribe (Ute EPD)) support EPA's November 2021 Proposal to strengthen leak detection and repair (LDAR) requirements for new natural gas processing facilities and include those requirements as the presumptive standards for existing sources.

Response I-15-1: Comment is a supportive comment on an aspect of the November 2021 Proposal that has remained unchanged in the final rule; as such, no response is required.

### 15.2 Monitoring Requirements

Comment: Commenter (0844-EDF *et al.*) specifically expresses support for the EPA's November 2021 Proposal to require bimonthly optical gas imaging (OGI) monitoring in accordance with Appendix K for all pumps, valves, and connectors located within affected process units at onshore natural gas processing plants.

Commenter (0923-Lambda Energy Resources LLC (Lambda)) urges EPA to consider a semi-annual monitoring program given the usually small number of leaks found and considerable financial costs associated with OGI surveys and record keeping. This commenter noted their natural gas processing plants currently operate under an EPA Consent Decree that requires enhanced LDAR monitoring, including quarterly EPA Method 21 monitoring. Additionally, the plants conduct annual OGI surveys for purposes of reporting greenhouse gas (GHG) emissions under 40 CFR part 98, subpart W. They state that the proposed bimonthly OGI monitoring is overly burdensome for plant operations.

Commenters (0808-API, 0932-GHGSat, Inc.) generally supports the use of Appendix K for OGI monitoring at gas processing plants. Commenter (0808-API) suggests specified changes to the proposed Appendix K (addressed under comments on Appendix K [Protocol for Using Optical Gas Imaging to Detect Volatile Organic Compound and Greenhouse Gas Leaks]).

Response I-15-2: EPA acknowledges the commenter's support for the use of Appendix K for OGI monitoring at onshore natural gas processing plants. See Volume I, Chapter 22 and Volume II, Chapter 22 of this Response to Comments document regarding specific responses to comment on the requirements specified in Appendix K.

Regarding the monitoring frequency for OGI monitoring, the EPA has found that bimonthly OGI monitoring is the best system of emission reduction (BSER) for equipment leaks at onshore natural gas processing plants. EPA has also finalized an alternative LDAR program that allows the owner/operator to comply with an EPA Method 21 program like that required in New Source

Performance Standards (NSPS) OOOOa. This EPA Method 21 alternative is also like the requirements that commenter (0923-Lambda) described as part of their consent decree. There was no information provided to demonstrate that semiannual OGI monitoring would reflect the BSER for equipment leaks at onshore natural gas processing plants.

Comment: Commenter (0808-API) supports retention of NSPS VVa as an alternative monitoring option, as some facilities have compliance obligations through consent decrees or permits or are subject to state or local regulations that require the use of EPA Method 21.

Commenter (0817-GPA) asserts that EPA Method 21 should be available as a primary leak detection method. To be clear, even if EPA proceeds to propose a form of Appendix K to guide use of OGI, any rule should retain EPA Method 21 as provided for in present regulations. EPA Method 21 is a reliable and familiar leak detection method that should be regarded as a primary leak detection method, not an alternative standard or one that may only be used under certain conditions. Midstream facilities, specifically natural gas processing plants, have already invested immense time and resources to initiate a EPA Method 21 program. This includes the purchase of software systems, creation of component databases, and set up of tagging for EPA Method 21 surveys. The EPA should not consider forcing these facilities who already utilize EPA Method 21 to convert their entire monitoring system to OGI surveying where there is no emissions reduction value and conversion would require significant new administrative costs.

Response I-15-3: EPA acknowledges the commenter's support for the optional EPA Method 21 LDAR program. The final NSPS OOOOb includes an EPA Method 21 alternative LDAR program for onshore natural gas processing plants at §60.5401b instead of incorporating by reference the requirements in NSPS VVa. EPA is including this alternative LDAR program within NSPS OOOOb to provide clarity on what standards apply to equipment leaks at onshore natural gas processing plants because there has been confusion regarding the applicability of some standards (*e.g.*, connector monitoring) due to a stay of those standards in NSPS VVa.

Comment: Commenter (0932-GHGSat, Inc.) states that, typically, natural gas processing plants have additional sensors and procedures that allow for a closer monitoring of the operations when compared to other oil and gas infrastructure upstream of the processing plant. According to the commenter, the current requirement of performing EPA Method 21 for gas plants or even the annual EPA Method 21 when using OGI as the existing alternative method poses an extra burden on the operators and regulators side. In practice, the commenter notes that the current methodology creates a logistics problem by potentially having multiple points of current and previously identified leaks that might be very small but still have the same burden with respect to the paperwork trail.

Response I-15-4: EPA acknowledges the comments provided by this commenter. As described in the preamble to the November 2021 Proposal, EPA has found that bimonthly OGI monitoring is the BSER for equipment leaks at onshore natural gas processing plants. EPA has also finalized an alternative LDAR program that allows the owner/operator to comply with an EPA Method 21 program similar to that required in NSPS OOOOa.

Comment: Commenter (0932-GHGSat, Inc.) supports allowing for the consideration of other LDAR programs that could incorporate other remote sensing techniques such as satellites, aircraft, and data analytics into the LDAR program for natural gas processing plants. The commenter states that the BSER calculation when incorporating remote sensing technology into the LDAR program may be favorable when factoring a longer time horizon, as more frequent monitoring for large leaks will be in place.

Response I-15-5: EPA acknowledges the commenter's support for incorporation of alternative technologies into the LDAR program at onshore natural gas processing plants. While not evaluated for purposes of this rulemaking, EPA has provisions for the request to use an alternative means of emission limitation (AMEL) for work practice standards.

### **15.3 Equipment Classification**

Comment: Commenter (0844-EDF *et al.*) notes that common classifications of equipment at natural gas processing facilities include components in volatile organic compound (VOC) service and in non-VOC service. "In VOC service" is defined as a component containing or in contact with a process fluid that is at least 10 percent volatile organic compound (VOC) by weight or a component "in wet gas service," which is a component containing or in contact with field gas before extraction. "In non-VOC service" is defined as a component in methane service (at least 10 percent methane) that is not also in VOC service. The commenter (0844-EDF *et al.*) supports EPA's November 2021 Proposal to eliminate the "in VOC service" distinction for purposes of LDAR inspections and instead require bimonthly OGI at all pumps, valves, and connectors located within affected process units at processing plants. The commenter notes that EPA is correct that "a VOC concentration threshold bears no relationship to the LDAR for methane and is therefore not an appropriate threshold for determining whether LDAR for methane applies." The commenter adds that they also believe that EPA is correct that "since there would be no threshold for requiring LDAR for methane, any equipment not in VOC service would still be required to conduct LDAR for methane even if not for VOC." Accordingly, they state that it is appropriate to eliminate the VOC threshold for the purposes of this LDAR program.

Commenter (0808-API) requests that the EPA not remove the VOC concentration threshold from the proposed LDAR requirements and should instead propose a similar concentration threshold for methane. The commenter recommends that EPA retain the current 10.0 percent by weight threshold for VOC and add a 1.0 percent by weight threshold for methane. They explain that while EPA is correct that a VOC concentration threshold is not an appropriate threshold for determining whether LDAR for methane applies, EPA failed to realize that some streams at a gas processing plant have de minimis concentrations of VOC and methane (*e.g.*, purity ethane, produced water, wastewater). According to the commenter, without appropriate concentration thresholds, equipment with no appreciable amounts of VOC or methane would be subject to LDAR requirements, which they do not believe was EPA's intent with the November 2021 Proposal. The commenter adds that minimum concentration thresholds are especially important if an owner or operator chooses to use EPA Method 21 since tagging of components is required (along with accounting for and maintaining these tags); and monitoring additional components with no appreciable amounts of VOC or methane adds costs and uses personnel resources with little environmental benefit.

Commenter (0817-GPA Midstream Association (GPA)) suggests that EPA should retain “in VOC Service” and the VOC threshold and add an analogous methane threshold at natural gas processing plants. The commenter opposes the November 2021 Proposal to remove the “in VOC service” requirement and the 10 percent VOC by weight threshold. Further, the commenter believes that EPA should establish a similar threshold for equipment in methane service, such as a 10 percent methane threshold. Such thresholds are important because without them, operators would be wasting time and resources monitoring equipment in air, water, or steam service which have no potential to leak regulated pollutants.

Commenter (0817-GPA) believes the 10 percent VOC threshold is a valuable tool to ensure that the LDAR program is cost effective. Neither EPA Method 21 nor OGI cameras are likely to be able to detect leaks on process streams with less than 10 percent VOC, *i.e.*, those with greater than 90 percent inert materials. Monitoring components with process fluids below 10 percent VOC by weight would add a significant burden with no demonstrated benefit, even assuming that leaks could be detected. The low VOC content makes it much less likely that any components would exceed leak thresholds triggering repair obligations, but operators would spend significant resources unnecessarily monitoring these components. The commenter estimates that monitoring components in contact with streams containing less than 10 percent VOC could increase monitoring time by as much as 30 percent. Each of these arguments warrant establishing a threshold for methane as well. Both thresholds would avoid the expenditure of significant time and resources without any expectation of reducing emissions.

Commenter (0817-GPA) states that EPA justifies the elimination by stating that the “VOC concentration threshold bears no relationship to the LDAR for methane and is therefore not an appropriate threshold for determining whether LDAR for methane applies.” Respectfully, that misses the point, which is that the VOC concentration threshold serves as a tool to focus on monitoring equipment where leaks may occur at levels that can be detected. Hence, EPA’s argument only means that it should establish a comparable threshold for methane as well, such as 10 percent by weight, instead of eliminating the existing VOC threshold. Without any threshold for either pollutant, operators would be required to monitor numerous components with little or no chance for emissions. This prevents any ability for an operator to eliminate monitoring based on knowledge that components are not in VOC or methane service.

Response I-15-6: See discussion in section. IV.L.1.b of the December 2022 Supplemental Proposal.<sup>1</sup>

## **15.4 Overlapping NSPS Applicability**

Comment: Commenters (0424-Division of Air Quality, West Virginia Department of Environmental Protection (WVDEP), 0577-Kansas Independent Oil & Gas Association (KIOGA)) request applicability clarifications for existing designated facilities. Specifically, the commenters inquire whether designated existing facilities under emission guidelines (EG) OOOOc will continue to be subject to NSPS KKK. The commenters request that the EPA clarify whether both the NSPS KKK VOC standards and the EG OOOOc presumptively approvable

---

<sup>1</sup> 87 FR 74808.

methane standards will apply to these facilities, or if the NSPS KKK standards will no longer apply, and these sources will be regulated by the state under EG OOOOc. The commenters also request that, if the sources will be subject to regulation under both subparts, that EPA review these subparts to ensure that the sources will not be subject to conflicting requirements and that the requirements are streamlined.

Response I-15-7: Onshore natural gas processing plants subject to NSPS KKK would continue to comply with those VOC standards until a state or federal plan implementing EG OOOOc becomes effective. After that time, compliance with the implementing state or federal plan that is consistent with the presumptive standards in EG OOOOc would constitute compliance with the equipment leak requirements in NSPS KKK because the presumptive standards result in the same or greater emission reductions than NSPS KKK, except as noted here.

For wet seal centrifugal compressors currently subject to NSPS KKK, compliance with NSPS KKK would allow for compliance with the state or Federal plan implementing EG OOOOc because the zero emissions limit would also achieve the 3 scfm limit included in EG OOOOc. Because the NSPS KKK standard is more stringent for wet seal centrifugal compressors, NSPS KKK would continue to apply.

## **15.5 Request for an Exemptions**

Comment: Commenter (0923-Lambda) request that EPA consider an exemption of natural gas processing plants that are designed to process 10 million standard cubic feet per day or less. The commenter explains that the idea of exempting small plants is the same rationale that they ask for marginal wells. They note that surveillance of the entire plant is completed via audio, visual, olfactory (AVO) methods once or more daily. They add that if any leaks are found they are fixed as soon as possible since loss of product equals loss of revenue.

Response I-15-8: EPA has included specific exceptions to the requirements for process unit equipment affected facilities at §60.5402b of NSPS OOOOb and §60.5402c of the model rule in EG OOOOc. Specifically, §60.5402b(b)(1) allows for quarterly OGI monitoring (instead of bimonthly OGI monitoring) of pumps in light liquid service, pressure relief devices in gas/vapor service, valves in gas/vapor and light liquid service, and connectors in gas/vapor service and light liquid service that are located at a nonfractionating plant that does not have the design capacity to process 283,200 standard cubic meters per day (scmd) (10 million standard cubic feet per day) or more of field gas. Further, §60.5402b(b)(2) exempts this same equipment from routine monitoring if complying with the EPA Method 21 alternative standards of §60.5401b. There is an historical basis for reduced monitoring requirements at these facilities, as they are exempt from certain monitoring requirements at §60.5401a(d) of NSPS OOOOa. See Response II-12-21 in Volume 2, Chapter 12 of this Response to Comment Document.

Comment: Commenter (0911-North Dakota Petroleum Council (NDPC)) requests that temporary portable natural gas liquid processing skids in the natural gas production sector be exempt from requirements applicable to natural gas processing plants in the natural gas processing sector.

Response I-15-9: The term “natural gas processing plant” is defined in the final rule as follows:

*Natural gas processing plant (gas plant)* means any processing site engaged in the extraction of natural gas liquids from field gas, fractionation of mixed natural gas liquids to natural gas products, or both. A Joule-Thompson valve, a dew point depression valve, or an isolated or standalone Joule-Thompson skid is not a natural gas processing plant.

It is not clear from the comment if this definition is insufficient to address the commenter’s concerns about temporary portable natural gas liquid processing skids. Therefore, EPA has not made any additional changes to the definition. For additional information on the exclusion of Joule-Thompson skids from the definition of a natural gas processing plant, see Response to Public Comments on NSPS OOOO located at Document ID EPA-HQ-OAR-2010-0505-4546.

## **15.6 Closed Vent Systems and Equipment Designated as Having No Detectable Emissions**

Comment: Commenter (0844-EDF *et al.*) requests that the EPA extend bimonthly OGI monitoring to any equipment or components designated as having no detectable emissions. The commenter explains that, as bimonthly monitoring will already be required, surveying additional components and equipment will add very little cost. According to the commenter, this is an inexpensive solution for ensuring compliance that will also help operators detect any anomalous sources at the processing plant.

Commenter (0808-API) suggests that the proposed bimonthly OGI monitoring requirements should also apply to closed vent systems and equipment designated with no detectable emissions. The commenter suggests that this equipment should be treated like other fugitive emission components similar to the requirements option for quarterly EPA Method 21 monitoring of pressure relief devices in NSPS OOOO and NSPS OOOOa (40 CFR 60.401a5401(b)). According to the commenter, the increased frequency of bimonthly OGI monitoring compared to an annual EPA Method 21 survey should allow OGI to be as effective as EPA Method 21 at detecting leaks from this equipment. The commenter adds that bimonthly OGI monitoring would also decrease costs since a separate EPA Method 21 program would not be required.

Commenter (0817-GPA) requests that the EPA exclude no detectable emission components and closed vent systems from OGI monitoring requirements at natural gas processing plants. The commenter states that they support EPA’s November 2021 Proposal to retain the NSPS OOOOa requirements for closed vent systems and equipment designated as having no detectable emissions (NDE components). 86 FR 63182 (November 15, 2021). The commenter notes that EPA has, however, requested comment “on whether bimonthly OGI monitoring according to the proposed Appendix K is appropriate to demonstrate compliance with this requirement.” *Id.* The commenter states that, as noted in the November 2021 Proposal, EPA previously determined that OGI was not appropriate for monitoring closed vent systems and NDE equipment because it does not identify very small leaks and is incapable of identifying whether ““non-leaking/leakless equipment are truly nonleaking because the detection sensitivity of the optical gas imaging instrument is not sufficient.”” *Id.* (quoting 73 FR 78204 (December 22, 2008)). The commenter expresses that they are not aware of any advances in OGI technology that would allow it to

identify low-level leaks or NDE components. The commenter concludes that the current means of demonstrating compliance has worked well for many years and they believe that it should continue in that role.

Response I-15-10: See discussion in section IV.L.1.b of the December 2022 Supplemental Proposal.<sup>2</sup>

## 15.7 Leak Repair Timeline

Comment: Commenter (0844-EDF *et al.*) supports the proposed repair timeframe that would require leaks detected by OGI to be repaired within 5 days of detection, and final repairs completed no later than 15 days of detection.

Commenter (0923-Lambda) urges EPA to consider delay of repair (DOR) leniency in the event GHG components are found leaking and cannot be repaired or replaced without a process unit shutdown.

Response I-15-11: Due to the nature of OGI monitoring (i.e., surveying from a distance), the proper equipment needed for physically reaching a component may not be in place at the time of monitoring and may take longer than 5 days to put in place. The final NSPS OOOOb requires final repair completed no later than 15 days of detection. Further, the final NSPS OOOOb allows for the delay of repair for equipment that cannot be repaired or replaced without a process unit shutdown. These repair requirements apply regardless of the monitoring technique (OGI or EPA Method 21) used to detect the leak.

## 15.8 Initial Compliance Timeline

Comment: Commenter (0740-Utah Petroleum Association (UPA)) provides one small example of where the labor shortage will affect a Utah operator's ability to meet the myriad of new requirements. One Utah operator estimates the new requirements will triple the required number of leak detection and repair workers. Considering the labor shortage vis-à-vis the time needed to develop and implement new procedures, the commenter supports EPA's proposed 180 days to come into compliance with methane standards for the equipment leaks at onshore natural gas processing plants. However, the commenter also recommends that the initial compliance period for leak detection on any equipment in operation prior to the promulgating this final rule be extended to 365 days to address the planning needed and challenges resulting from the labor shortage.

Similarly, commenter (0755-Texas Pipeline Association (TPA)) supports the extension of the 180-day initial compliance deadline regarding methane standards for leaks at processing plants. In rule amendments made in 2020, EPA clarified that the initial compliance deadline for VOC equipment leak standards at natural gas processing plants was 180 days. This was a beneficial clarification for two reasons: first, it brought the NSPS OOOOa in line with existing requirements in NSPS KKK, and second, it gave owners and operators a reasonable and

---

<sup>2</sup> 87 FR 74807.

workable period within which to bring affected equipment into proper operation and to conduct a thorough and accurate check on whether the equipment is in conformance with applicable leak standards.

Response I-15-12: EPA acknowledges the commenters' support for the proposed extension of the initial compliance deadline for the methane leaks at processing plants. These comments are supportive comments on an aspect of the November 2021 Proposal that has remained unchanged in the final rule; as such, no response is required.

With regards to the comment recommending that the initial compliance period for leak detection on any equipment in operation prior to the promulgating this final rule be extended to 365 days to address the planning needed and challenges resulting from the labor shortage; the EPA has not granted this request.

See Volume II, Chapter 20 (Impacts of the Proposed Rule), Response II-20-33, for EPA's response to similar concerns regarding labor availability.

## 15.9 Leaking Valve Replacement

Comment: Commenter (0844-EDF *et al.*) suggests that when leaking valves need to be replaced, EPA should consider requiring Low-E valves and packing be installed. In a recent Colorado rulemaking, the commenter states that Colorado found these options to be similar in cost to non-Low-E valves and packing and directed operators to consider them.<sup>3</sup> The commenter reports that some manufacturers claim their Low-E packing can reduce emissions of harmful gases by up to 95 percent versus valves with traditional packing, with minimal cost impacts.<sup>4</sup>

Response I-15-13: The commenter's understanding of the cost for low-E valves aligns with that of EPA in that they are similar to non-low-E valves. Therefore, replacing leaking valves with low-E valves would result in lower emissions with no additional burden. The final NSPS OOOOb and EG OOOOc requires replacing leaking valves with low-E valves, where feasible.

Comment: Commenter (0459-Velan, Inc.) notes regarding API 622 or 624, there are other API standards, as well as ISO standards that should be included for reference. API standards for type testing of packing and valves for fugitive emissions include the following:

- Fugitive emissions testing:
  - API 622 (Packing). Note: API 622 is referenced in API 624 and API 641.
  - API 624 (Rising stem valves)
  - API 641 (Quarter turn valves)
- Valve standards:
  - API standards 599, 600, 602, 603 and 623 require type testing to API 624 and compliance for production valves when specified.

---

<sup>3</sup> See Colorado Air Pollution Control Division, Rebuttal Prehearing Statement, Proposed Revisions to Regulation Numbers 7 and 22 (Dec. 14-17, 2021), [https://drive.google.com/drive/folders/1mDU8Wc3iB\\_E4lj36R8AK\\_y8ptcU83Yao](https://drive.google.com/drive/folders/1mDU8Wc3iB_E4lj36R8AK_y8ptcU83Yao).

<sup>4</sup> Id.

- API standards 608 and 609 require type testing to API 641 and compliance for production valves when specified.
- API Standard 6D specifies that valves shall be qualified in accordance with API 624, API 641 or API 15848-1, when specified. Also, production valves shall comply with ISO 15848-2, when specified.

Commenter (0459-Velan, Inc.) continues, ISO standards for type testing and production of valves for fugitive emissions include the following:

- ISO 15848-1 – (Type testing of valves)<sup>5</sup>
- ISO 15848-2 – (Production acceptance test of valves)
- ISO TC 153 (Valves), WG 5 (Fugitive Emissions) is also in the process of developing a new standard for the type testing of stem seals for valves.

Commenter (0459-Velan, Inc.) notes these standards serve as a good basis for qualification of packing and valves for low-e service for the following reasons:

- They demonstrate low-e performance in an economically feasible manner and have, thus far, had a negligible or minor impact on the cost, price and availability of valves or valve packing.
- They are based on recognized and generally accepted good engineering practice (RAGAGEP), pursuant to CAA section 112(r).
- There are readily available products in the market that have been well accepted by stakeholders.
- They meet the requirements of fugitive emissions performance set out in various regulations.
- They are consensus standards, developed by industry stakeholders (oil & gas end users, packing and valve manufacturers, and engineering contractors) and represent a balanced and practical approach to meeting low-e requirements.
- Furthermore, the proposed statement that *“a low-e valve or valve packing product will include a manufacturer written warranty that it will not emit fugitive emissions at a concentration greater than 100 ppm within the first five years”*, states one of two alternative acceptable methods used in consent decrees to satisfy low-e requirements. The other alternative method is typically stated as follows:

A valve (including its specific packing assembly) that has been tested by the manufacturer or a qualified testing firm pursuant to generally-accepted good engineering practices for testing fugitive emissions and that, during the test, at no time leaked at greater than 500 ppm, and on Average, leaked at less than 100 ppm, or is an extension of another valve that qualified as “Low-E”.

---

<sup>5</sup> Note: ISO 15848-1 allows the use of either methane or helium, and specifies various Tightness Classes, as well as various optional testing parameters including temperature, pressure, mechanical and thermal cycles. For reference, Tightness Classes AM (50 ppmv, methane) and BM (100 ppmv, methane) are comparable to the fugitive emissions leakage requirements specified in the API standards cited above.

Commenter (0459-Velan, Inc.) argues this alternative method of compliance to low-e requirements should be included in the wording of the proposed rule. The commenter adds in their comment a reference a list of the standards mentioned in the comments above, in particular API Standards and ISO Standards.

Commenter (0422-Private Citizen) similarly provides a list of API standards in their comment letter for type testing of packing and valves for fugitive emissions, including API Standard 622, API Standard 624 (API 600, API 602, API 603, API 623), API Standard 641 (API 599, API 608, API 609), and API 6D: Specification for Pipeline and Piping Valves. The commenter also provides information on ISO standards for type testing and production of valves for fugitive emissions. The commenter believes the standards identified outline a good basis for the qualification of Low E packing and Low E valves. The commenter provides rationale supporting this recommendation in their comment letter.

Response I-15-14: The final NSPS OOOOb and EG OOOOc requires replacing leaking valves with low-E valves, where feasible.

## 15.10 Regulatory Language

Comment: Commenter (0817-GPA) requests that EPA clarify the interaction among the different leak detection approaches when it prepares the proposed regulatory language for natural gas processing plants so that operators can properly understand the interaction between Appendix K and the existing NSPS VVa standards (40 CFR §§60.480a, *et seq.*). According to the commenter, despite the November 2021 Proposal's discussion of how NSPS VVa will be retained in large part, *see, e.g.*, 86 FR 63233 (November 15, 2021), there are aspects of NSPS VVa that are not obviously compatible with Appendix K that should be clearly retained or explained. For example:

- NSPS VVa exempts various inaccessible components, such as insulated or buried connectors, dual mechanical seal pumps, pressure relief devices with rupture disks or those routed to closed vent systems, and compressors routed to closed vent systems. The commenter notes that the November 2021 Proposal preamble was not clear on whether these components will also be exempt from OGI. The commenter believes that these components should be exempt under both standards, but the regulatory text should confirm.
- NSPS VVa requires periodic AVO inspections for pumps, compressors, closed vent systems, and other components. The commenter states that it is not clear whether, and if so why, AVO inspections would still be required under a new regulation.
- The commenter states that the November 2021 Proposal preamble did not indicate how components designated as having no detectable emissions (NDE components) will be treated. The commenter requests that the EPA clarify whether an operator may continue to designate NDE components. *See* 40 CFR §60.5401a(b)(1). In addition, the commenter requests that EPA explain the treatment of NDE components if they are found to leak.

Specifically, whether a leaking NDE component is considered a deviation or treated as another component requiring repair and re-monitoring.<sup>6</sup>

- NSPS VVa exempts various components from monitoring so long as they meet certain criteria designed to minimize emissions. *See, e.g.,* 40 CFR §60.482-2a(d) (pumps with dual mechanical seal system with barrier fluid); 40 CFR §60.482-3a(h) (compressors routed to a closed vent system); 40 CFR §60.482-4a(c) (pressure relief devices equipped with upstream rupture disk). The commenter states that the November 2021 Proposal does not indicate how these components will be treated under Appendix K. The commenter urges that they remain exempt, as EPA established these exemptions based on its judgment that it sufficiently minimized emissions and operators invested resources in equipment to ensure that these components would be exempt from monitoring. The commenter suggests that there is no reason to disrupt this status quo.
- In-situ sampling systems and sampling systems without purges are currently exempt under 40 CFR §60.482-5a. The commenter states that the November 2021 Proposal does not indicate whether they would remain exempt under Appendix K. The commenter urges that they remain exempt, as EPA has not offered any data to support a change.
- The commenter notes that Appendix K is not clear about whether there are different standards for components in heavy liquid service and light liquid service, as there are in NSPS VVa.
- The commenter states that it is not clear how Difficult to Monitor or Unsafe to Monitor components will be treated under Appendix K. The commenter notes that some components may be monitored with OGI but difficult or unsafe to repair.
- The commenter contends that the November 2021 Proposal is not clear on whether there can be alternative monitoring frequencies for process units operating for less than 365 days per year, as permitted under NSPS VVa. *See* 40 CFR §60.482-1a(f)(1).

The commenter (0817-GPA) suggests that EPA propose regulatory text that resolves these issues, that would then be subject to public comment, before it finalizes any adoption of Appendix K.

Response I-15-15: See discussion in section IV.L.1.b of the December 2022 Supplemental Proposal<sup>7</sup> and the associated proposed regulatory text for both NSPS OOOOb<sup>8</sup> and EG OOOOc.<sup>9</sup>

Comment: Commenter (0817-GPA) requests that EPA provide guidelines in proposed regulatory text for enforcement standards. As the November 2021 Proposal acknowledges, EPA Method 21 and OGI define a “leak” differently.<sup>10</sup> An OGI camera, however, cannot consistently detect leaks below approximately 10,000 ppm. The commenter thinks that EPA should clarify that, where a facility opts to perform OGI camera monitoring, any inspection by EPA enforcement personnel

---

<sup>6</sup> The commenter notes that they would not oppose ending the NDE component designation. For midstream operations, they explain that there are typically few NDE components (usually pressure relief devices) that would still need to be monitored annually under the Proposed Rule. They suggest that eliminating the NDE component designation may simplify the regulations to a degree.

<sup>7</sup> 87 FR 74807.

<sup>8</sup> See Document ID No. EPA-HQ-OAR-2021-0317-1551.

<sup>9</sup> See Document ID No. EPA-HQ-OAR-2021-0317-1552.

<sup>10</sup> *See, e.g.,* 86 Fed. Reg. at 63,118, Table 2 (summarizing Method 21 leak definitions).

should also be required to use OGI camera monitoring instead of EPA Method 21. The commenter is concerned that a facility operator may properly use OGI cameras for LDAR but then be found to have violated LDAR requirements if an inspector uses EPA Method 21 to find leaking components at rates of greater than 500 ppm but less than 10,000 ppm, meaning those leaks that could not have been detected by the proper use of OGI cameras. The commenter has a similar concern where AVO inspections are required.<sup>11</sup> The EPA should clarify that an operator should not be subject to an enforcement action where it has performed the required AVO inspection, but a leak was discovered through a different leak detection method.

Response I-15-16: EPA disagrees that an operator is not subject to enforcement where EPA discovers leaks through detection methods other than the method required by the regulation. An EPA inspector's discovery of fugitive emissions, using any particular method or equipment, may or may not indicate a violation of leak detection and repair standards. But whether the evidence shows that a violation occurred is a separate question from whether certain types of evidence may be used to support an enforcement action. EPA may pursue enforcement "on the basis of any information available to the Administrator." 42 U.S.C. 7413(a), and Clean Air Act regulations make clear that EPA may use any credible evidence to establish a violation. *See* 40 C.F.R. § 60.11. That the rule identifies and allows certain leak detection equipment to be used for certain fugitive emission affected facilities, or that an owner selects a particular leak detection method or equipment, does not constrain EPA's ability to use other methods and equipment to investigate potential noncompliance or to rely on credible evidence from any method or equipment to demonstrate the existence of a violation. EPA may use any credible evidence, including evidence developed through the use of Method 21 or any other equipment or method, to establish the occurrence of a violation. Prohibiting the use of specific categories of evidence would illegally constrain EPA's enforcement authority.

---

<sup>11</sup> *See* 40 C.F.R. § 5411a(c)(2) (AVO inspections for closed vent systems).

## Chapter 16. Well Completions

### 16.1 Definitions – Hydraulically Fractured/Salable Gas

Comment: Commenter (0577-KIOGA) states that, for well completions of hydraulically fractured (or refractured) gas wells as well as greenhouse gas (GHG) and VOC standards for well completions of hydraulically fractured (or refractured) oil wells, 40 CFR 60.5430a provides the following definition of *Hydraulic fracturing*:

*Hydraulic fracturing* means the process of directing pressurized fluids containing any combination of water, proppant, and any added chemicals to penetrate tight formations, such as shale or coal formations, that subsequently require high rate, extended flowback to expel fracture fluids and solids during completions (P577).

The commenter (0577-KIOGA) believes well completions performed in Kansas, and other similar areas, do not meet EPA's definition of hydraulic fracturing for the geologic and engineering reasons provided below. The commenter recommends that the definition in NSPS OOOOa be amended to explicitly exclude conventional wells from the regulation because the work performed does not meet the definition provided in the regulation.

The commenter (0577-KIOGA) explains that operations in Kansas do utilize pressurized fluids that contain water, proppant, and/or chemicals. However, they add that the majority of the operations use a process that neither penetrates tight formations like shale or coal, nor require high rate, extended flowback, and that most Kansas operations result in little to no flowback from formations with higher quality reservoir properties than shale or coal. The commenter suggests that ignoring those two facts discounts two thirds of the definition as outlined by 40 CFR 60.5430a. According to the commenter, enforcing this regulation based on "the process of directing pressurized fluids" alone; but not based on the type of formation or subsequent flowback directly ignores the criteria outlined by the regulation.

The commenter (0577-KIOGA) states that these two criteria were included in the definition of hydraulic fracturing, as pertaining to this regulation, infers to distinguish the varying completion styles of small, vertical, conventional drilling targets from large, horizontal, tight, unconventional drilling targets (such as shale and coal).

Commenter (0577-KIOGA) assumes that this distinction was developed due to the difference in potential greenhouse gas emissions from the dissimilar formation types and completion styles. While the amount of greenhouse gases emitted from each reservoir type has yet to be quantified, the commenter assumes the greenhouse gas emissions will be proportional to the amount of hydrocarbons produced (*i.e.* the more oil and gas a well produces has the potential to produce greater amounts of greenhouse gases that well may emit). The commenter reports that the average Estimated Ultimate Recovery (EUR) for vertical wells in Kansas is 20,000-30,000 bbl/well, where shale wells yield much higher EURs. Per EIA data, the average EUR is 168,000 bbl/well for an Eagleford shale well and 243,000 bbl/well for an Eastern Bakken well. Based on these numbers, they state that a typical Kansas well will yield ~10% of the oil, and theoretically 10% of the greenhouse gas, of a typical oil shale well.

Table 7 of the commenters' (0577-KIOGA) comment letter (page 13 of the comment letter) is a comparison of typical reservoir and completion parameters for tight shale formations and for conventional formations targeted in Kansas. The commenter notes that many of the terms mentioned in the definition provided in 40 CFR 60.5430a are also included as a comparison between wells drilled in Kansas and by operators targeting tight, unconventional, shale formations.

Commenter (0577-KIOGA) explains that 99% of the oil produced in Kansas comes from sandstone and carbonate formations that have permeabilities up to six orders of magnitude times greater than that of average shale and coal formations. The commenter adds that this greater permeability in the producing formations in Kansas do not lead to high rate, extended flowback periods following well completions. According to the commenter, the average time from completion to being put on pump for production is less than 48 hours, with a majority of that time spent installing the production equipment.

The commenter (0577-KIOGA) reports that an examination of the engineering and geologic data provided in their comment letter shows that the high volume hydraulic fracture work that is completed on unconventional oil and gas wells are magnitudes greater than the hydraulic fracture work that is generally performed on conventional wells. The commenter adds that the potential for VOC and GHG emissions from an unconventional oil or gas well will proportionately be higher than conventional oil or gas wells.

The commenter (0577-KIOGA) states that the EPA states that the NSPS was intended for all oil and gas extraction, and that a well-by-well or formation-by-formation basis under the provided definition was inconsistent with EPA's express intent to address GHG and VOC emissions from all hydraulically fractured oil well completions. The commenter suggests that this is another case where EPA's attempt to develop a national regulation to cover all oil and gas operations did not consider the differences between large and small operators, or conventional and unconventional wells. The commenter offers to provide EPA with additional information upon request.

Commenter (0785-JohnCrane) recommends the following updated hydraulic fracturing definition:

...the process of directing pressurized fluids underground to exceed in-situ formation stress resulting in a permeable pathway for hydrocarbon production and consequently requiring a flowback period for return of fracturing fluids.

The commenter (0785-JohnCrane) contends that a numeric threshold for "tight formations" or "high rate, extended flowback" is not appropriate because a formation can be hydraulically fractured without being "tight" and the flowback period does not have to be "extended." The commenter recommends adjustment of the hydraulic fracturing definition to exclude those specific terms and those referring to a specific formation type (*i.e.*, shale, coal, etc.). Further, the commenter states that hydraulic fracturing can be performed using a variety of fluids, including water-based fluids, as well as acids and oil-based fluids, and does not have to occur using sand (as in the case of using acid for fracturing).

Commenter (0836-DEPA) recommends that EPA consider the following details and definition of hydraulic fracturing. Hydraulic fracturing (HF) is a completion technique that has been used since the 1940's in very tight formations with less than 1.0 mili-Darcie permeability. This completion technique was designed to release the oil from the formation rock when standard completion techniques would not work. Up to and until the shale renaissance, HF was used on conventional wells in order to accomplish the standard production flow regime expected from a more permeable reservoir rock. HF does not solely account for the high production rates and pressures that the shale wells are experiencing. Horizontal drilling accounts for the extremely high yields and production volumes. Without the high yields and production volumes, horizontal drilling would not be economical and therefore not feasible. Conventional vertical wells subjected to the same HF stimulation technique would not produce the same volumes in a shale formation and for that reason, have not heretofore been considered either technically or economically feasible. The vertical HF wells nowhere produce the high volumes on any conventional formations and therefore do not have the potential to produce the high air emission rates that EPA has claimed in this proposed rule. The higher pressures come from the shale formations when horizontally drilled and even those wells decline quickly as the available reservoir pressure that has been released through the HF technique begins to deplete. Consequently, any HF well that has declined to a lower production flow rate will not produce the same level of air emissions that would be expected from a higher producing higher yield, horizontal shale well. Knowing this fact, the commenter recommends that EPA not expect or consider these lower producing wells to be a significant source of air emissions and should not subject these lower economical wells to the same regulatory requirements.

Commenter (0729-EWTC) recommends that the HF definition include a clause (included as bold underlined text below) indicating that the purpose of the stimulation activities is for production of the well and not for other well intervention activities for added clarity. The commenter proposes the following addition to the definition. "The process of directing pressurized fluids containing any combination of water, proppant, and any added chemicals to penetrate tight formations, such as shale or coal formations, that subsequently require high rate, extended flowback to expel fracture fluids and solids during completions **for the purpose of production, NOT intervention.**"

The commenter (0729-EWTC) does not believe that that a numeric threshold is appropriate and applicable to all hydraulic fracturing operations, particularly those that are characterized as "tight formations" or "high rate, extended flowbacks". The commenter asserts that as different reservoirs will have different operating pressures, defining hydraulic fracturing at a single flow rate that is applied uniformly to all reservoirs is an over-generalization of the differing characteristics between reservoirs and will be difficult if not impossible to achieve. Additionally, the commenter notes that flowback will depend on individual characteristics of the particular well and how it was treated along with other factors. These factors, according to the commenter, are also constantly evolving with industry practices.

Commenter (0598-Countrymark) suggests that EPA intended to narrow the applicability of hydraulic fracturing from the broad application defined on their website to a narrower focus as presented in the 2016 NSPS. The commenter notes that the narrower focus of the 2016 NSPS only covers hydraulic fracture stimulation events that are related to unconventional wells, not

conventional wells (*i.e.*, tight formations such as coal or shale, high rate and extended flowback). The commenter states that the definition on EPA's website does not distinguish between formation type or flowback characteristics. Through multiple conversations with EPA discussing the definition provided in the 2016 NSPS, the commenter states that the EPA confirmed that they used the appropriate definition.

Commenter (0598-Countrymark) continues to advocate that the conventional wells that utilize low pressure, small volumes of water and proppant, and have a short flowback period (*i.e.*, hours or minutes) were not originally intended to be covered in the 2016 NSPS. The commenter recommends that the original definition of "hydraulic fracturing" be maintained from the 2016 NSPS and that the wells that do not meet this definition be exempt from NSPS OOOOa, OOOOb, and OOOOc. They state that their recommendation is based on the much lower potential to emit from wells that do not experience the high-volume, high-pressure fracture stimulation events that are utilized for the unconventional wells.

Commenters (0598-Countrymark, 0814-IPAA et al) provide the following three definition recommendations if numeric thresholds for "tight formations" or "high rate, extended flowback" are determined by EPA to be appropriate to include in the definition of hydraulic fracturing:

1. *Flow back time*: The commenter (0598-Countrymark) proposes that any well that has a flowback period of greater than 3 days is considered to be an extended flowback. This threshold is consistent with EPA's estimate that the minimum flowback period for high volume fracture stimulation events is at least 3 days.
2. *Tight formation*: The commenter (0598-Countrymark) notes that any formation that has a permeability that is less than one thousandth of a Darcie (0.001) should be considered to be a tight formation. Where Merriam-Webster defines a Darcie as, "a unit of porous permeability in physics equal to the permeability of a medium through which the rate of flow of a fluid having one centipoise viscosity under a pressure gradient of one atmosphere per centimeter would be one cubic centimeter per second per square centimeter cross section".
3. *Volume*: The commenter (0598-Countrymark) recommends that EPA provide guidelines that greater than 100,000 pounds of proppant and/or more than 1,000,000 gallons of water is considered to be high volume used to stimulate the formation.

The commenter (0598-Countrymark) recommends that any well stimulation event that does not meet the numeric requirements provided above not be subject to the NSPS requirements as the potential to emit from wells that are below these limits is considered to be sufficiently low.

Commenter (1341-PGCC et al) contends that EPA failed to consider and/or meaningfully address several key recommendations from the Panel and the Office of Advocacy of the U.S. Small Business Administration. The commenter notes, for example, the Panel Report recommended that EPA consider the fundamental differences between conventional, low-producing wells and unconventional wells and "propose definitions with numerical standards that give meaning to the entire regulatory definition of 'hydraulic fracturing,' based on the SERs'

characterization of the distinction between geological formations and operational characteristics Panel Report, at 33. The Panel Report for the Proposal can be found in the rulemaking docket.<sup>1</sup>

Commenter (0946- Michigan Oil and Gas Association (MOGA)) recommends that EPA clarify the definition of "hydraulically fractured" well, because various oil and gas producing regions interpret the definition differently based on specific operating parameters.

Response I-16-1: The definition of "hydraulic fracturing" in §§60.5430a, 60.5430b and §60.5430c of NSPSs OOOOa, OOOOb and OOOOc is not being reconsidered or amended under this action. NSPSs OOOOa, OOOOb and EG OOOOc define hydraulic fracturing as follows:

*Hydraulic fracturing* means the process of directing pressurized fluids containing any combination of water, proppant, and any added chemicals to penetrate tight formations, such as shale or coal formations, that subsequently require high rate, extended flowback to expel fracture fluids and solids during completions.

EPA notes that NSPS OOOOb does not include substantive changes in the completion requirements from those contained in NSPS OOOOa. The issues raised by the commenters have previously been considered by EPA and comments and responses on well completions and associated definitions (including the hydraulic fracturing definition) leading to the inclusion of this definition in the final 2016 NSPS subpart OOOOa rule can be found at Docket ID. EPA-HQ-OAR-2010-0505-7632, Chapter 3. Well Completions.

Comment: Commenter (0814-IPAA et al) appreciates EPA's review of standards for well completions and their understanding of completions involving conventional wells in low pressure and low permeability reservoirs as typically found in the Appalachian Basin. The commenter states that these low pressure and low permeability wells require stimulation to produce hydrocarbons at economic rates, but often can be produced economically for many decades. Because of the low pressures, the stimulations often include energized fluids, where an inert gas, such as nitrogen, is added to help bring the fluids out of the formation. In many cases, the stimulation is performed with just the inert gas. The inert gas makes green completions impossible and the typical duration of flow back very short, typically less than 48 hours. The challenge is that the flowback will not combust due to the high nitrogen content.

The commenter (0814-IPAA et al) reports that the majority of producing states and industry acknowledge the difference between "conventional" and "unconventional" wells. The commenter states that the EPA accepts the terminology but alleges that it always intended to regulate all hydraulically fractured wells.<sup>2</sup> The commenter notes that many of the Producer Associations that they represent have argued since 2011 that conventional wells have a very different

---

<sup>1</sup> *Final Report of the Small Business Advocacy Review Panel on EPA's Planned Proposed Rule Emission Standards for New, Reconstructed, and Modified Sources in the Oil and Natural Gas Sector*, Document ID No. EPA-HQ-OAR-2021-0317-0074 (Sept. 2021) (Panel Report).

<sup>2</sup> EPA cites various docket materials to support their assertion at footnotes 327 through 333. Most of the footnotes cite to Docket ID Item Nos. EPA-HQ-OAR-2010-0505-0445, EPA-HQ-OAR-2010-0505-05021, and EPA-HQ-OAR-2010-0505-07632. Certain representatives of the Producer Associations searched on multiple occasions for these docket materials and they were not available for review. It is difficult to evaluate the accuracy of EPA's assertions when the cited materials are not available to the general public for review.

environmental "footprint" than unconventional wells. The commenter adds that these associations and individual companies tried to have EPA promulgate a definition of a "low pressure well" that comported with industry knowledge of marginal or stripper wells. In 2015-2016 the focus changed to "low production wells." The commenter notes that, while the terminology utilized by EPA has changed over the past 10 years, the focus of the Producer Associations has been consistent and steadfast – conventional, vertically drilled wells are fundamentally different than large volume, horizontally drilled unconventional wells and one size does not fit all. According to the commenter, it is curious that in the November 2021 Proposal, EPA's definition of "hydraulic fracturing" contains certain terms or phrases that are vague and/or subjective that casts a very, very broad net. The commenter adds that, until the November 2021 Proposal, EPA has spent little effort to explain what "tight formations" and "high rate, extended flowback" means and perhaps engages in a certain amount of "back filling" to justify casting such a broad net.

Response I-16-2: See Response I-16-1 of this Chapter.

Also note, Docket ID No. EPA-HQ-OAR-2010-0505-5021 (not -05021) is the 2015 *Background Technical Support Document for the Proposed New Source Performance Standards, 40 CFR Part 60, subpart OOOOa*; and Docket ID No. EPA-HQ-OAR-2010-0505-7632 (not -07632) is the EPA's 2016 *Response to Public Comments on the EPA's Oil and Natural Gas Sector: Emission Standards for New, Reconstructed, and Modified Sources. 40 CFR Part 60, Subpart OOOOa*.

Comment: Commenter (0539-Alaska OGCC) notes that, in Table 2 and on page 63160 of the November 2021 proposal *Federal Register* notice, "salable gas" is referenced regarding well flowback on a hydraulically fracked well, but the term does not seem to be defined. The commenter explains that on much of the North Slope there's no gas sales market, and even where there is a market that market is very limited in size and any additional gas that may be produced during a well flowback would not be able to be sent to market anyways, so large volumes of gas could be flared/vented during a well flowback and may not be subject to the requirement to reinject or find other beneficial use for gas recovered from a development well (as required in Table 2 of the *Federal Register* notice) during flowback nor the reporting requirements listed on page 63160 of the November 2021 proposal *Federal Register* notice, depending on what the definition of salable gas actually is.

Response I-16-3: The EPA included a definition of "salable quality gas" in the December 2022 Supplemental Proposal regulatory text of NSPS OOOOb and EG OOOOc. See definition of "salable quality gas" in proposed regulatory text at [regulations.gov](https://www.epa.gov/regulations). See EPA-HQ-OAR-2021-0317-1551 and EPA-HQ-OAR-2021-0317-1552.

## **16.2 Well Completions Requirements**

Comment: Commenter (0844-EDF et al) argues that it is critical that EPA strengthen its well completions requirements to achieve the emission reductions that have been promised (and assumed in emissions inventories) since the adoption of EPA's reduced emission completion (REC) requirements in 2012.

First, the commenter (0844-EDF et al) urges EPA to tighten its venting and flaring restrictions across the completion process drawing from models that have been adopted at the state level. Specifically, the commenter proposes that for both categories of wells, EPA disallow venting in all instances except when (1) emergency circumstances are present and (2) the operator can demonstrate that “flaring is technically infeasible or would pose a risk to safe operations or personnel safety and venting is a safer alternative than flaring.”<sup>3</sup> The commenter suggests that the EPA limit emergency circumstances to cases of “a sudden unavoidable failure, breakdown, event, or malfunction, beyond the reasonable control of the Operator, of any equipment or process that results in abnormal operations and requires correction”<sup>4</sup> and that poses a danger to human safety.

Second, the commenter (0844-EDF et al) recommends that the EPA revise the current regulatory approach to require the operator to use REC equipment that is adequate for the particular flowback situation to control emissions from the beginning of flowback, rather than retaining the current approach. The commenter states that the technical infeasibility exemption has allowed operators to engage in extended periods of venting based on the performance limitations of inadequate or inappropriate equipment, or without even attempting to deploy REC equipment. In the 2020 technical revisions, the commenter notes that the EPA recognized and addressed one way in which operators had been exploiting this loophole, but that it was insufficient to fix the overall problem.<sup>5</sup>

Specifically, the commenter (0844-EDF et al) suggests that EPA require all flowback (including what EPA now characterizes as “initial flowback”) be routed to an enclosed vapor-tight flowback vessel, as Colorado requires, or to an enclosed controlled flowback vessel, as environmental advocates and Oxy USA Inc. have proposed in New Mexico.<sup>6</sup> The commenter explains that detailed technical testimony in the New Mexico proceedings makes it clear that the purpose of deploying properly designed REC equipment is to capture and control all flowback, including the gas, from the time when flowback begins.<sup>7</sup> The commenter adds that this is technically feasible, already standard practice for some companies, and does not present safety concerns.<sup>8</sup> According to the commenter, the current regulatory approach of identifying an “initial flowback stage” during which gas “is not subject to control” creates an unjustified and

---

<sup>3</sup> Wording quoted from New Mexico venting and flaring regulations, found at New Mexico Administrative Code, Venting and Flaring of Natural Gas, § 19.15.28.8 (“In all circumstances, the operator shall flare rather than vent natural gas except when flaring is technically infeasible or would pose a risk to safe operations or personnel safety and venting is a safer alternative than flaring.”).

<sup>4</sup> Wording quoted from Colorado venting and flaring regulations, found at 2 Colo. Code Regs. 404-1 § 100 (accessible at <https://www.sos.state.co.us/CCR/GenerateRulePdf.do?ruleVersionId=9245>).

<sup>5</sup> In the 2020 technical revisions, EPA clarified that the requirement to use a separator during flowback meant a separator designed to accommodate completion flowback, regardless of whether it was a production separator. This change prevented operators from continuing to decline to use a separator during flowback on the grounds that it was technically infeasible for a smaller production separator onsite to handle completion flowback rates. See 85 Fed. Reg. 57398 at 57403 (Sept. 15, 2020).

<sup>6</sup> 5 Colo. Code Regs. 1001-9 V.D.1.a.; see also Attachments X and Z.

<sup>7</sup> See Attachment AA at 4–10 of the comment letter (and supporting exhibits).

<sup>8</sup> Id.

unnecessary loophole that has been exploited in some instances to evade the overall intent to require green completions.<sup>9</sup>

The commenter (0844-EDF et al) states that from the flowback vessel or any connected REC equipment such as a separator, EPA should require the operator to route emissions to a gathering system, productive use, or reinjection, as the current regulations provide. The commenter adds that the EPA should not, however, include the existing exemption for technical feasibility. If there are in fact specific types of situations where the gas cannot be sold, put to productive use, or reinjected, the commenter suggests that the EPA should identify and define those specific situations in the regulations, rather than defaulting to an easily misused generic characterization of technical infeasibility. The commenter notes that Colorado's rules do not have similar general technical infeasibility exemptions that apply during the completion process. Colorado only allows flaring during the entire completion process with prior, written approval, or "to ensure safety or during an Upset Condition for a period not to exceed 24 cumulative hours."<sup>10</sup> If operators need to flare longer than 24 hours due to an upset, they must seek regulatory approval to continue.<sup>11</sup>

According to the commenter (0844-EDF et al), under Colorado and New Mexico rules, flaring is also permitted in pre-approved cases during pressure testing.<sup>12</sup> The commenter states that the EPA may choose to provide some kind of accommodation for pressure testing, although pressure testing without flares is possible, and the technology for this practice currently exists.<sup>13</sup> Finally, the commenter urges EPA to impose monitoring and reporting requirements for all instances of flaring during completion operations.

Response I-16-4: The EPA did not adopt the commenter's suggested changes, however, the EPA believes that the final rule NSPS OOOOb well completion standards balance the need for compliance flexibility based on differing areas/scenarios across the country. The EPA has proposed under 40 CFR 60.5375b (proposed rule text) that operators must capture emissions during the separation flowback period of each well completion, unless it is technically infeasible to do so. The owner or operator must direct captured emissions from the separator into a gas flow line or collection system, re-inject the recovered gas into the well or another well, use the recovered gas as an on-site fuel source, or use the recovered gas for another useful purpose that a purchased fuel or raw material would serve. The rule provision for use of captured gas for "any useful purpose" provides flexibility such as use for mobile natural gas refrigeration units or natural gas generators for onsite electricity. Under the final rule, only if these options are not technically feasible (which may include the lack of infrastructure and gathering line concerns) would captured emissions be routed to a completion combustion device. Owners or operators

also have a general duty to safely maximize resource recovery and minimize releases to the atmosphere during flowback and subsequent recovery.

### **16.3 Well Completion Fugitive Emissions Monitoring**

Comment: Commenter (0944-Kuva) suggests adding an additional category for fugitive emissions monitoring which is focused on well site completions, flow back and initial operation of new well sites. The commenter notes that Colorado has established continuous monitoring rules for new well sites requiring monitoring for the initial six months of operation of new well sites. The commenter explains that there is a specific concern during well completions and initial production stages due to the large variability of expected flow rates, potential under-sizing of equipment in case a well is producing more than expected, separation equipment that is not yet fully optimized and other process related causes. The commenter states that they are offering a relocatable continuous optical gas imaging (OGI) camera that is ideally suited for such temporary monitoring. The commenter suggests that the EPA conduct a cost-benefit analysis for such a requirement and to solicit industry comment on the cost of such an approach.

Response I-16-5: The EPA has not included the suggested additional category for fugitive emissions monitoring focused on well site completions, flow back and initial operation of new well sites. While the EPA acknowledges that there is large variability of expected flow rates, and other reasons why a well site completion may be producing and emitting more than expected, the final rule standards (see Response I-16-4 of this Chapter) would address emissions occurring during a well completion and the well site fugitive monitoring requirements of 40 CFR 60.5397b (What GHG and VOC standards apply to fugitive emissions components affected facilities?) would apply to fugitive well site emissions.

### **16.4 Gas Capture Plan**

Comment: Commenter (0941-350 Silicon Valley) suggests that in order to accomplish zero routine flaring and venting they recommend that all applications for drilling a new oil or gas well (including modifications or reconstructions) be required to include an acceptable Gas Capture Plan. The commenter states that this plan would include methods of operation and equipment that would ensure that no routine flaring or routine venting would be necessary. Approval of the plan would require agreements (1) between the applicant and a pipeline company guaranteeing transport of all its captured gas to market, (2) that well completion would not occur until gathering pipelines were available to receive the gas, (3) that production would be cut back if gathering pipelines became unable to accept its gas. The commenter adds that, if all the applicant's existing wells in the basin are not connected to gathering lines, the plan would require another agreement between the applicant and a pipeline company to attach existing wells to gathering pipelines according to a specified schedule. The commenter notes that British Petroleum (BP) recently announced that it would not drill any new well in the Permian Basin unless it has guaranteed access to a pipeline.

Response I-16-6: The EPA does not believe that a gas capture plan which requires agreements between the applicant and pipeline company where the pipeline company guarantees transport of all captured gas to market and not allowing a well completion until gathering pipelines are

available is appropriate under the NSPS. NSPSs are technology-based standards for new and modified sources of air pollution. These rules include a best available control technology (BACT) for categories of stationary air pollution sources. Standards can vary within each category according to class, type, and size of source. The NSPS establishes emission limitations achievable through application of adequately-demonstrated BACT, taking into account cost, non-air quality health or environmental impacts, and energy requirements. The EPA believes that the proposed and final rule standards (see Response I-16-4) balance the need for compliance with the need for emissions mitigation during well completions, including limiting flaring unless necessary. For additional comments requesting that EPA minimize or eliminate flaring, and EPA's responses to those comments, see Volume I, Chapter , section 17.2, and Volume II, Chapter 6, section 6.2.4 of this Response to Comment document.

## **16.5 Alaska Lat/Long Information**

Comment: Commenter (0539-Alaska OGCCO) states that page 63160 of the November 2021 proposal *Federal Register* notice requires reporting of well lat/long info in NAD83, but NAD27 is the standard in Alaska.

Response I-16-7: The EPA proposed to require NAD83 for consistency with Facility Registry Service (FRS) and CEDRI reporting systems. EPA understands that NAD83 was intended to replace NAD27 and is a stronger datum that simultaneously adjusted all previous existing horizontal stations and newer GPS surveyed stations. Positions in the North American Datum are based on the different shapes of the earth and use the best technology available at the time. The technology available in 1983 was newer and more accurate than the technology available in 1927, thus making the latitude and longitude coordinates more accurate. Additionally, EPA notes that both NSPS OOOO and OOOOa require reporting latitude and longitude based on NAD83, and as such, the November 2021 proposal is consistent with other rules in this sector.

## Chapter 17. Associated Gas

### 17.1 General Support/Opposition for Proposed Venting and Flaring Standards

Comment: Commenters (0391-Keweenaw Bay Indian Community (KBIC), 0781-National Tribal Air Association (NTAA), 0605-Muscogee (Creek) Nation, 0943-Sault Ste. Marie Tribe of Chippewa Indians, Sault Tribe Environmental Department (Sault EPD), 0833-Environmental Programs Department, Ute Mountain Ute Tribe (Ute EPD)) believe that for all equipment, the presumptive requirement should be zero emissions, and combustion should only be permitted with documentation that zero emissions is not feasible, with venting only allowed in documented emergencies. The commenters support the November 2021 Proposal's requirement for new oil wells with associated gas to capture gas for sale or use on site, or route to a flare. The commenters believe productive use should be the preference and routing for combustion, which is wasteful and still emits harmful pollutants even when burned completely, should only be allowed if productive use is technically infeasible. The commenters also support the requirements for record keeping ensuring that flares are operated correctly. The commenters believe that EPA should consider standards requiring greater than 95 percent emissions reduction when associated gas cannot be put to productive use.

Commenter (0737-Clarke Valve) supports EPA's stated goal to eliminate venting of associated gas from oil wells. However, the commenter recommends that EPA consider modifying the structure or format of not allowing flaring as a potential solution, as the November 2021 Proposal advances through the next steps in the regulatory process.

Commenter (0753-Institute of Governance & Sustainable Development (IGSD) and Center for Human Rights and the Environment (CHRE)) agrees that the capture of associated gas is the best system of emission reduction (BSER) for oil wells with associated gas. The commenter urges EPA to finalize capture as the BSER for oil wells with associated gas.

Commenter (0911-North Dakota Petroleum Council (NDPC)) disagrees with EPA's assumption that since there are no New Source Performance Standards (NSPS) that regulate associated gas venting and flaring, that one is therefore needed. The commenter notes that there are many emission sources not covered under a NSPS that are regulated through New Source Review and Title V permitting, as well as state air quality and oil and gas rules. The ratio of associated gas to barrels of oil produced (gas to oil ratio or "GOR") can vary significantly from field to field, from no associated gas to thousands of cubic feet of gas per barrel. The commenter adds that GOR can also vary with time and be episodic. They explain that, today it is uncommon for associated gas to be vented under normal circumstances for safety reasons, and many state regulations prohibit the venting of natural gas (*i.e.*, those in North Dakota). There are situations where a production field may have geographic, biological, or cultural boundaries that limit or prohibit linear infrastructure like pipelines and transmission lines from being constructed. In these situations, associated gas would need to be combusted on site if present. In response to EPA's solicitation of comments on what the definition of "access to a sales line" should be, the commenter reminds EPA that in most cases, the midstream company that designs, builds, and operates the gas gathering system (sales line) and gas processing plants is not the same as the well owner and

operators, landowners, and mineral lease owners and that one entity has little control over the other.

Commenter (0830-Devon Energy) is working to reduce flaring of associated gas across each of its operating areas and supports EPA's November 2021 Proposal to reduce methane and VOC emissions by routing associated gas to a sales line if available, using it onsite as fuel or another useful purpose, or routing to a control device.

Commenter (0738-Exxon Mobil Corporation (Exxon)) supports EPA's November 2021 Proposal to address flaring of associated gas and to apply monitoring requirements to ensure flares are operating properly.

Response I-17-1: See discussion in sections IV.F.2.a.ii and IV.F.2.a.iii of the December 2022 Supplemental Proposal preamble.<sup>1</sup>

## **17.2 Flaring**

### ***17.2.1 Reduce or Ban Flaring and Route Associated Gas***

Comment: Commenters (0195-Evangelical Environmental Network (EEN), 0196-EEN, 0215-EEN) call on EPA to ban flaring except in emergency situations. Commenters (0401-Mercy Investment Services, Inc. (Mercy), 0434-Impax Asset Management, LLC (Impax), 0443-Seventh Generation Interfaith Inc. (SGI), 0455-Radio Drama Network, Inc. (RDN), 0460-Trinity Health, 0538-Change Finance, PBC (Change)) urge EPA to end the wasteful practice of routine flaring of natural gas at oil and gas facilities, in line with regulations in Colorado and New Mexico. Commenter (0918-Colorado Local Government Coalition (COLGC)) supports the ban on routine flaring of associated gas from producing wells, in accordance with NSPS OOOOb and EG OOOOc. Commenter (0941-350 Silicon Valley) states that individual states are responsible for regulating gas flaring, but as the Office of Fossil Energy in the DOE concluded in its 2019 report on flaring “states are unlikely to significantly restrict oil production to eliminate the flaring of associated gas” because they benefit from oil production taxes, state royalties and jobs in the industry.<sup>2</sup>

Commenter (0560-Legal & General Investment Management America, Inc. (LGIM America)) suggests that the rules address routine flaring of associated gas at oil wells, which is another significant source of emissions and a practice that can be eliminated in a cost-effective manner.

Commenter (0844-Environmental Defense Fund (EDF) *et al.*) notes that during the oil extraction process, a significant amount of natural gas is often produced as “associated gas” along with the oil [comment letter includes an explanation of the processes of venting and flaring of associated gas]. The commenter acknowledges that venting and flaring of emissions can cause harmful emissions, especially methane. According to estimates by the commenter and Rystad Energy, the

---

<sup>1</sup> 87 FR 74779-74780.

<sup>2</sup> Office of Oil and Natural Gas, Office of Fossil Energy, “Natural Gas Flaring and Venting: State and Federal Regulatory Overview, Trends, and Impacts,” US Department of Energy, Natural Gas Flaring and Venting Report.pdf (energy.gov) June 2019, p.53.

commenter reports that flaring releases approximately 200,000 tons of methane into the atmosphere every year in the Permian Basin alone,<sup>3</sup> of which 87 percent is due to flaring from associated gas production.<sup>4</sup> Moreover, the commenter notes that, due to a combination of high initial production of associated gas and delays in developing gathering line infrastructure or other gas capture methods, new wells tend to flare at particularly high volumes.<sup>5</sup> For example, the commenter provides that wells drilled since 2018 accounted for 60 percent of all flaring in October 2021.<sup>6</sup> Colorado<sup>7</sup> and New Mexico<sup>8</sup> have already taken action to eliminate both venting and flaring in all non-emergency conditions, and the commenter urges EPA to do the same. The commenter supports EPA's November 2021 Proposal to eliminate non-emergency venting during production but urges EPA to strengthen its approach to flaring through performance standards, to ensure that its final standards achieve significant reductions in this damaging practice. Specifically, the commenter suggests that EPA determine that the BSER for emissions from associated gas is to capture and sell, productively use, or reinject the gas. Finally, the commenter recommends that, in any case in which flaring does occur, EPA require improved flare efficacy to minimize methane and other emissions.

Response I-17-2: See discussion in sections IV.F.2.a.ii and IV.F.2.a.iii. of the December 2022 Supplemental Proposal preamble.<sup>9</sup>

Comment: Commenter (0753-IGSD/CHRE) states that, while the November 2021 Proposal indicates that EPA's preferred system is to "route associated gas to a sales line," the November 2021 Proposal does not go far enough in ensuring that oil and gas operators will not flare associated gas. The November 2021 Proposal would allow for flaring when "access to a sales line is not available." The commenter suggests, because of its impact on climate, the environment, and public health, flaring is not the BSER for associated gas. The commenter states that EPA should only permit flaring for safety reasons and in emergency situations. Flaring methane and associated gases is dangerous to surrounding communities and should be avoided in all cases where alternatives are available. Health studies show that flaring can impact pregnancy term, exacerbate asthma, release carcinogens, and cause mental health and heart related conditions.<sup>10</sup> Flaring may release climate-warming gases such as carbon dioxide, methane, and black carbon to the atmosphere, and increase local terrestrial acidification.<sup>11</sup> According to the commenter, when flares are incompletely combusted or left unlit (a common occurrence),

<sup>9</sup> 87 FR 74779-74780.

<sup>10</sup> Cushing L., Chau K., Franklin M., & Johnston J. E. (2021) Up in smoke: characterizing the population exposed to flaring from unconventional oil and gas development in the contiguous US, ENVIRON. RES. LETT. 16:1–10, 7.

<sup>11</sup> Motte J., Alvarenga R. A. F., Thybaut J. W., & Dewulf J. (2021) Quantification of the global and regional impacts of gas flaring on human health via spatial differentiation, ENVIRON.POLLUT. 291:1–6, 2.

methane gas is vented to the atmosphere.<sup>12</sup> The commenter adds that unconventional oil and gas (UOG) drilling exacerbates the problem, as flaring emissions reported by state regulators are often underestimated,<sup>13</sup> impacting regulator's perceived risk of vulnerable communities.

The commenter (0753-IGSD/CHRE) adds that flaring exacerbates environmental injustice. Within major oil and gas regions, the commenter notes that the burden of flares falls largely on Native communities and low-income rural areas.<sup>14</sup> The commenter adds that there is evidence that flares also disproportionately impact Hispanic and Black communities.<sup>15</sup> One study found that 210,000 people living within 5km of oil and gas production are exposed to 100 or more flares nightly.<sup>16</sup> Firsthand accounts of these flares demonstrate the need to address this oil and gas activity: Nightly flares happen so frequently that affected communities call flaring "second sunrise."<sup>17</sup>

Commenter (0753-IGSD/CHRE) also encourages EPA to look to U.S. states like Colorado and New Mexico for model regulations that prohibit routine flaring. In 2020, Colorado strengthened its oil and gas regulations by banning routine venting and flaring.<sup>18</sup> In 2021, New Mexico similarly banned all routine flaring and venting.<sup>19</sup> As state regulators recognize, the commenter notes that banning routine flaring is viable and is critical to protecting the environment and public health. EPA should finalize regulations that do not allow for flaring as an option for associated gas from new and existing wells except in emergencies and for safety reasons.

Response I-17-3: The EPA has revised our supplemental proposal based on comments received. In this final rule EPA has defined the best system of emission reduction (BSER) for new sources as associated gas recovery with limited allowances for specific circumstances of temporary flaring and venting. EPA has finalized a standard for new sources that will mostly require routing of associated gas to a sales line, or an alternative that achieves equivalent emissions reductions. As explained in Sections X.F.2. and X.F.2. of the final rule preamble, the standards for new sources do include limited circumstances that could result in flaring. For the reasons explained there, EPA still finds that these are necessary to include. For all modified and some existing sources, EPA is finalizing our proposal that could allow for routine flaring, but only in limited circumstances after a demonstration that the discussed zero emissions options are technically infeasible. For the reasons explained in Sections X.F.2. and X.F.2. of the final rule preamble, EPA finds this appropriate. Lastly, in the context of existing sources, EPA's final EG OOOOc includes a subcategory for sources that produce 40 tpy methane or less of associated gas. The

presumptive standard for the subcategory allows routine flaring without a showing of technical infeasibility because EPA's analysis conducted after reviewing comments on the supplemental proposal indicated that it is not always reasonable with respect to cost to require these sources to route their associated gas to a sales line. See Sections X.F.2. and X.F.2. of the final rule preamble for further explanation of this subcategory.

Our data and that submitted by other commenters to the proposal and supplemental proposal indicate that alternatives to routine flaring are practical, in wide use, and increasingly cost-effective. Two state jurisdictions (NM and CO) have preceded ahead of EPA to prohibit long-term routine flaring, while two more (ND and TX) have placed significant restrictions and required similar analyses prior to allowing routine flaring. Please see the TSD chapter on associated gas in the docket regarding the cost of achieving BSER.

See Volume I, Chapter 6, Response I-6-5 of this Response to Comment Document for EPA's responses to comments on environmental justice.

Comment: Commenter (0844-EDF *et al.*) points out that as the Rystad report conveys in detail, at least one or more of the best practices for gas capture and sale, productive use, or reinjection described above are broadly available to operators at a reasonable cost in every basin and at every production level.

First, the commenter (0844-EDF *et al.*) notes that the routing gas to gathering lines for sale is very broadly available to operators. As Rystad notes, this approach is proven, ubiquitous, scalable, and relatively quick to deploy.<sup>20</sup> As 95 percent of associated gas produced in the U.S. is currently not being flared, most of this captured gas is presumably being sent to sale through gathering infrastructure.<sup>21</sup> Not only is the vast majority of associated gas routed to gathering lines, but of the quantities that are flared instead, "the vast majority of flaring is from wells that are hooked up to [infrastructure]" at some point in the wells' life.<sup>22</sup> Further, Rystad's analysis shows that a relatively small number of wells are responsible for a large proportion of total flaring across each of the states.<sup>23</sup> This ranges from 3 percent of the wells contributing 83 percent of the flaring in Colorado, to 16 percent of the wells contributing 77 percent of the flaring in North Dakota, and totals 7 percent of the wells contributing 70 percent of the flaring on average.<sup>24</sup> According to the commenter, this means that in every state analyzed, the majority of wells, and likely the great majority of wells, are already capturing gas and routing it to gathering lines.

With the exception of Colorado, the commenter (0844-EDF *et al.*) states that infrastructure access (as opposed to capacity) was identified as the constraining factor for capture for 3 percent or less of the total gas volumes flared, and upcoming compliance with Colorado's routine flaring prohibition will necessarily address the issues there.<sup>25</sup> Finally, the commenter notes that, for the

---

<sup>20</sup> Attachment W at pg. 43 of commenter's submission.

<sup>21</sup> Id. at 21.

<sup>22</sup> Id. at 78.

<sup>23</sup> Id. at 6.

<sup>24</sup> Id. at 27.

<sup>25</sup> Id. at 78.

very small proportion of associated gas production where infrastructure access (*i.e.*, distance from gathering infrastructure) is identified as the key constraint, other transport, on-site use, and reinjection options are available at potentially somewhat higher but still reasonable costs.<sup>26</sup>

Commenter (0844-EDF *et al.*) reports that a system of emissions reduction that is already used by most operators for the vast majority of associated gas, mostly because it has net negative costs, is the epitome of a broadly available and highly affordable solution. The commenter adds that the fact that there are instances where operators have not already found it worthwhile to capture gas only means that in some cases there will be small net costs to this pollution control system, not that sale, productive use, or reinjection of associated gas is not an available approach. The commenter contends that, while the Rystad report identifies challenges and some constraints to deploying each of these approaches, they are clearly almost never prohibitive for gas gathering. In addition, compressed natural gas (CNG) and reinjection, the two capture approaches that Rystad identifies as the next most promising options, have different, non-overlapping constraints. The commenter states that this makes them independent alternatives, and at least one if not both should be available to most of the wells where routing to gathering is temporarily unavailable (due to, *e.g.*, downstream outages) or is long-term cost-prohibitive (due to distance from infrastructure). Overall, the commenter states that the breadth of availability and the very reasonable costs of the options more than satisfy the criteria to find capture and sale, productive use, or reinjection the “best system.”

Commenter (0558-Center for Climate and Energy Solutions (C2ES)) suggests that improving the existing pipelines capacity would allow owners and operators to capture more associated gas instead of flaring it. Alternatively, the commenter notes that the gas can be compressed and trucked to a gas processing plant or another location where it can be used as a fuel in the absence of nearby pipelines. Also, the commenter adds that gas can be utilized for local power generation by converting the gas to electric power using small-scale generators (gas-to-power). The commenter adds that EPA can require project developers to define gas utilization plans prior to developing new fields. According to the commenter, while the cost associated with transport and processing infrastructure development might be high for some owners and operators, there is an opportunity for clustering flare developments to bring the overall cost down by enabling economies of scale. These flare clusters can be co-developed in a way that allow operators to share both risks and resources as they connect their associated gas to existing or new pipelines.

Response I-17-4: See response I-17-3. See also the discussion in sections IV.F.2.a.ii and IV.F.2.a.iii. of the December 2022 Supplemental Proposal preamble.<sup>27</sup>

Comment: Commenter (0941-350 Silicon Valley) recommends that the deadline for retrofitting flares at existing facilities be no later than January 2026. The commenter suggests that, to accomplish zero routine flaring and venting, all applications for drilling a new oil or gas well (including modifications or reconstructions) be required to include an acceptable Gas Capture Plan. The commenter suggests that this plan would include methods of operation and equipment that would ensure that no routine flaring, or routine venting would be necessary. Approval of the plan would require agreements (1) between the applicant and a pipeline company guaranteeing

---

<sup>26</sup> See generally Pederstad et al., *supra* note 30; Attachment W at pgs. 38-76 of commenter’s submission.

<sup>27</sup> 87 FR 74779-74780.

transport of all its captured gas to market, (2) that well completion would not occur until gathering pipelines were available to receive the gas, (3) that production would be cut back if gathering pipelines became unable to accept its gas. The commenter states that, if all the applicant's existing wells in the basin are not connected to gathering lines, the plan would require another agreement between the applicant and a pipeline company to attach existing wells to gathering pipelines according to a specified schedule. The commenter notes that BP recently announced that it would not drill any new well in the Permian Basin unless it has guaranteed access to a pipeline.

For existing wells, the commenter (0941-350 Silicon Valley) suggests that, if no gathering pipelines are available (either because none exist or because of insufficient capacity) and there are not sufficient on-site uses for the associated gas, operators be required to seek other outlets for their associated gas. According to the commenter, flaring is not an acceptable solution for removing associated gas from a well site. The commenter provides that studies have shown that compressing associated gas at the well site and trucking it to a nearby processing plant or a location where it can be added to the pipeline system can reduce flaring substantially. This CNG trucking solution, according to the commenter, can be scaled up to carry away nearly all associated gas produced<sup>28</sup>. If the associated gas has a high heavy carbon content, natural gas liquid (NGL) recovery of propane, butane, and pentane prior to compressing the gas can increase the value of the CNG, since it improves its use in engines or pipelines, and add another source of revenue.

Response I-17-5: See December 2022 Supplemental Proposal (87 FR 74779), in which the capture, compression, and transport of associated gas to a nearby processing plant, pipeline, or methane pyrolysis operation is noted, where we state that this option is provided for under the third criterion, "used for another useful purpose." See also Response I-17-3 of this Chapter.

### ***17.2.2 Flaring as a Viable Option***

Comment: Commenter (0597-Indiana Oil and Gas Association (INOGA)) suggests that the environmentalist groups who are advocating for EPA to eliminate oil and gas companies' ability to burn gas at well sites through a flare, are the same environmental groups who also oppose a new pipeline to move gas into markets. Without the ability to transport gas to market via pipeline, burning the gas through a flare is the last option available. Commenter (0598-Countrymark Energy Resources, LLC (CER)) agrees with the above statement, and reminds EPA that the Illinois Basin has been producing oil for more than 100 years, gas pipeline infrastructure was not constructed due to the lack of sufficient gas to sell into a nearby market. The commenter does not have the ability to sell the small volume of associated gas into a pipeline system to increase revenue. Eliminating the ability to flare associated gas will significantly impact their ability to produce oil for their refinery to process into high quality fuels for their customers. The commenter states that flaring operations provide a destruction rate of 90 percent to 95 percent, or greater, of VOCs and methane. This is a viable solution in controlling emissions. The commenter recommends that EPA maintain this solution for operators that are not able to sell gas.

---

<sup>28</sup> Lesley Fleischman, "Putting Out the Fire: Proven Technologies to Improve Utilization of 4 Associated Gas from Tight Oil Formations", Clean Air Task Force, November 17, 2015.

Commenter (0955-Vaquero Energy, Inc. (Vaquero)) also believes that flaring is often the only option available and urges EPA to consider the hypocrisy of these environmentalist groups.

Response I-17-6: See discussion in sections IV.F.2.a.ii and IV.F.2.a.iii. of the December 2022 Supplemental Proposal preamble.<sup>29</sup> In addition, EPA agrees with the commenter that the complete elimination of flaring of associated gas in all situations is not practical, for safety and other reasons. EPA therefore has designed our final rule to prohibit long term (routine) flaring for some sources, while leaving options open to other sources to manage associated gas in ways that makes flaring less frequent. See Section X.F.2. of the final rule preamble for discussion of the final standards for OOOOb as well as the final presumptive standards for OOOOc. In the context of existing sources of associated gas, EPA included a subcategory in the final emission guidelines for sources that produce 40 tpy or less of methane that allows those sources to flare routinely without a demonstration of technical infeasibility. In accordance with the final EG, existing sources that produce over 40 tpy of methane could also flare provided other options are technically infeasible. See the final notice regulatory text for model rule text in OOOOc on this point. As alluded to above, EPA's final standards also allow for flaring where circumstances are not routine and flaring is the reasonable option for interim periods such as malfunctions or interruptions in sales line service. See section 60.5377b and 60.5377c for specific regulatory language described here. EPA believes that these various allowances for flaring address the bulk of commenters concerns. The finalized standards are not an absolute prohibition on flaring. EPA further points out that the standards in OOOOb will apply to new wells, such that only those new wells will be subject to standards that do not allow routine flaring. Existing wells where the gas is already being captured and routed to a sales line could continue that practice. Upon being designated facilities under OOOOc EG, EPA does not see a problem to continue routing to a sales line. As stated in the previous paragraph, EPA's final standards allow for flaring where circumstances are not routine and flaring is the reasonable option for interim periods such as malfunctions or interruptions in sales line service.

Comment: Commenter (0793-Permian Basin Petroleum Association (PBPA)) contends that EPA and the oil and gas industry are aligned in seeking to reduce flaring. The commenter notes that EPA defines the "affected facility" as every oil well that produces associated gas<sup>30</sup> whether or not a sales line is accessible. Because EPA has not provided regulatory text, the commenter believes that the November 2021 Proposal could be interpreted as banning flaring where a sales line is accessible through requiring that all casinghead gas be routed to the sales line.

If it were that easy, the commenter (0793-PBPA) contends that EPA's November 2021 Proposal would be unobjectionable as a practical matter, but EPA's approach falls short of acknowledging the realities of active oil field settings. When a production facility is connected to a sales line, the commenter notes that flaring may still be periodically required in a number of situations: for safety reasons when there are unexpected facility or downstream malfunctions, when there are integrity issues with the sales line, when the specifications of produced gas do not meet those required by the third-party sales outlet, when produced gas exceeds the capacity of the sales line,

---

<sup>29</sup> 87 FR 74779-74780.

<sup>30</sup> 86 Fed. Reg. at 63,238. EPA also seeks comment on how to define "associated gas." Id. Associated gas should be defined as the main produced gas stream from an oil well and should not be defined to include any short-term or relatively small volumes of gas produced from maintenance events involving activities like equipment blowdowns.

compressor station downtime, and processing plant downtime. In the case of a midstream operator's facility malfunction or force majeure event, it is very unlikely that the upstream operator will receive any advance notice or have any control over when the downstream facility comes back online.

According to the commenter (0793-PBPA), a ban on flaring would also significantly chill new upstream production. The commenter explains that basic laws of economics dictate that development of midstream infrastructure like sales lines will always lag upstream development: midstream operators cannot be expected to build out infrastructure to a given area until after establishment of significant upstream production in that area. And chilling domestic production will do nothing to address consumer demand for fuels and may actually drive up fuel prices, especially given demand is only projected to increase as the economy recovers from COVID. The commenter adds that chilled domestic production also risks undermining EPA's greenhouse gas reduction goals because it will greatly increase the risk of carbon leakage (*i.e.*, increase importation of higher carbon intensity fuels produced in countries with relatively less stringent regulations). In brief, the commenter states that any final rules need to incorporate flexibility for operators and not penalize them if, after taking reasonable steps pursuant to best management practices, flaring is unavoidable.

Response I-17-7: See discussion in sections IV.F.2.a.ii and IV.F.2.a.iii. of the December 2022 Supplemental Proposal preamble.<sup>31</sup> See also Response I-17-6 of this Chapter.

### ***17.2.3 Flaring Control Efficiency/Monitoring***

Comment: Commenter (0844-EDF *et al.*) states that their study of flares in the Permian Basin found that 10 percent of all flares were either unlit or only partially functioning.<sup>32</sup> The commenter recommends that EPA adopt effective monitoring and reporting requirements to effectively address this widespread issue. Further, the commenter urges EPA to adopt regulations requiring that in any case in which flaring does occur, flare efficacy is improved to 98 percent control efficiency on a continuous basis.

Commenter (0844-EDF *et al.*) points out that there will still be residual flaring of associated gas due to phase-in of requirements and all nonroutine flaring. To minimize the resulting emissions, the commenter recommends that EPA enhance monitoring requirements and ensure flares are operating at optimum efficiency and deploying technologies that will help prevent malfunction. Accordingly, the commenter suggests that EPA exercise its authority under sections 111 and 114 of the Clean Air Act (CAA) to both enhance operational requirements and require well operators to report any flaring incidents, including both the total time of flaring and the total estimated emissions [commenter includes a description in their comment letter].

---

<sup>31</sup> 87 FR 74779-74780.

<sup>32</sup> EDF, Flaring Aerial Survey Results (2021), <https://www.permianmap.org/flaring-emissions/> (last accessed Oct. 27, 2021).

Response I-17-8: See discussion in section IV.H.2 of the December 2022 Supplemental Proposal preamble.<sup>33</sup>

#### ***17.2.4 Reporting Unplanned and Planned Flares***

Comment: Commenter (0844-EDF *et al.*) requests that in the case of unplanned flaring for reason of emergency, well operators should submit their report no later than 12 hours after the event,<sup>34</sup> and should be required to provide justification for the flare, demonstrating that its reason for flaring falls within EPA's narrowly defined set of emergency circumstances. The commenter (0844-EDF *et al.*) suggests that, to the extent that EPA chooses to permit flaring in other narrowly defined circumstances, such as pressure testing,<sup>35</sup> EPA require the operator to provide notice both no later than 24 hours before the event (at which time the operator should provide a projected estimate of total time and emissions) and no later than 12 hours after the event (at which time the operator should provide an estimate of time and emissions actually produced). The commenter contends that planned flaring instances should be rare and subject to specific EPA restrictions.

Response I-17-9: The EPA has revised the circumstances that allow for temporary flaring due to upset or malfunction. See 40 CFR 60.5377b for the revised rule text. See also the revised text for reporting and recordkeeping with respect to the obligation of affected facilities to record and report on upset and malfunction events that lead to a period of flaring. The EPA disagrees with the commenter on the need to require immediate notification of a malfunction that results in a flaring event. While such flaring events are a deviation from the requirement to avoid flaring by employing another form of emissions control, the EPA is not persuaded that a deviation requires immediate notification to the Administrator. The EPA also points out that such events are unfortunate but foreseeable, such that EPA has required that flares be immediately available to address malfunction events.

### **17.3 General Support/Opposition Regarding Venting**

#### ***17.3.1 Necessary Venting***

Comment: Commenters (1341-Pennsylvania Grade Crude Oil Coalition (PGCC) *et al.*) state that none of the November 2021 Proposal's compliance options are workable for the oil-producing members of the Conventional Group. According to the commenters, for many conventional oil wells in Pennsylvania and New York, a gas sales line is not reasonably available. The "associated gas" produced at these conventional oil and gas well sites would not be sufficient to sustain a flare, much less justify the changes and capital expenditures needed to attempt to use the gas onsite. EPA must expressly allow Pennsylvania and New York conventional oil producers to vent the small volumes of "associated gas," which is the only safe and environmentally sound method of dealing with associated gas at some Pennsylvania conventional oil wells. If finalized, the commenters contend that EPA's November 2021 Proposal

---

<sup>33</sup> 87 FR 74792.

<sup>34</sup> See 2 Colo. Code Regs. 404-1 § 903(a)(2).

<sup>35</sup> 2 Colo. Code Regs. 404-1 § 903(d)(1)(B),(E) (accessible at <https://www.sos.state.co.us/CCR/GenerateRulePdf.do?ruleVersionId=9245>).

would undoubtedly eliminate Venango Sands production in Pennsylvania's Venango County, the county in which Pennsylvania's first oil well was drilled in 1859.

Commenter (0831-American Exploration and Production Council (AXPC)) supports non-venting except for when there is technical infeasibility, safety concerns or other similar issues. However, the commenter states that it is also important to understand that there is a limitation on non-pipeline solutions for associated gas. The commenter adds that there are some technological solutions but there are certain circumstances when even the most advanced technological solutions do not work. Also, the oil and natural gas operator does not necessarily have the rights to surface property that would be necessary to implement a pipeline or non-pipeline solution – this is not something that operators have the power to do, nor does EPA have the authority to provide them with this power. Thus, the commenter wants to ensure that EPA understands that “access to a sales line” does not equate to availability.

Commenter (0814-Independent Petroleum Association of America (IPAA) *et al.*) states that EPA's efforts to restrict venting of associated gas may be appropriate for certain scenarios; however, there may be situations where new wells or existing wells that currently do not have gas sales pipeline line to them are either not available, feasible or economic. The commenter adds that there may not be adequate volumes or quality of gas to use onsite or route to a flare. The commenter recommends that EPA allow exemptions for these situations, especially for marginal/low production wells, where lack of adequate volumes or gas quality preclude its use onsite or routing to a flare. In all other situations, the commenter recommends that EPA allow options that operators can implement that best fit their operations.

Response I-17-10: See discussion in sections IV.F.2.a.ii and IV.F.2.a.iii. of the December 2022 Supplemental Proposal preamble.<sup>36</sup> See also Response I-17-9 of this Chapter.

### ***17.3.2 Eliminate Venting***

Comment: Commenter (0770-Northern Plains Resource Council (NPRC)) calls for the elimination of routine venting of associated gas from oil wells, and the requirement for owners and operators to route gas to sales lines, where available. Commenter (0578-Grand Canyon Trust (GCT)) supports EPA's November 2021 Proposal to eliminate venting at wells with associated gas except in the case of emergency. Commenter (0444-Damascus Citizens for Sustainability (DCS)) supports the November 2021 Proposal to prohibit venting of methane, which is a major source of emissions. Commenter (0437-New York Office of the State Comptroller (NYOSC)) supports the proposed measure to end the venting of associated natural gas.

Commenter (0808-American Petroleum Institute (API)) supports the elimination of venting from “each oil well that produces associated gas and does not route the gas to a sales line” with additional clarifications. While EPA's November 2021 Proposal is overly broad in its description, the commenter generally supports and recognizes the environmental benefit of the elimination of venting of associated gas from oil wells that do not currently route gas to a sales line (EPA's proposed Option 2).

---

<sup>36</sup> 87 FR 74780.

Response I-17-11: See discussion in sections IV.F.2.a.ii and IV.F.2.a.iii. of the December 2022 Supplemental Proposal preamble.<sup>37</sup>

## **17.4 General Support/Opposition of 95 Percent Emission Reduction**

Comment: Commenter (0391-KBIC, 0781-NTAA, 0605-Muscogee (Creek) Nation, 0943-Sault EPD, 0833-Ute EPD) believe that EPA should consider standards requiring greater than 95 percent emissions reduction when associated gas cannot be put to productive use.

Commenter (0808-API) recommends that, if associated gas cannot feasibly and economically be recovered to a sales line, that gas be required to be captured for a beneficial use or flaring the gas such that 95 percent control efficiency is achieved.

Response I-17-12: See discussion in sections IV.F.2.a.iii and IV.H.2 of the December 2022 Supplemental Proposal preamble.<sup>38</sup>

Comment: Commenter (0831-AXPC) states that it is unclear what EPA means when they say “continuous” when it comes to a 95 percent destruction. While the commenter does not have regulatory text to directly comment on, they believe that EPA means that it is a 95 percent threshold based on an average over at least 24 hours. The commenter also recommends that there be exemptions for when vent gas rates are insufficient to support continuous flare operation. In those situations, supplemental flare fuel gas would be required to support flare operation resulting in an emission profile exceeding that resulting from the minimal existing vent gas. This situation becomes more common as wells age and overall production rates decline.

Commenter (0831-AXPC) notes that operating a flare in compliance with 40 CFR 60.18 does not demonstrate that the flare is constantly achieving the required 95 percent Destruction Rate Efficient (DRE). The commenter explains that there have been studies that show that oil and gas flares can achieve an average DRE in excess of 95 percent (*e.g.*, Steffes).<sup>39</sup> They add that extreme weather condition can temporarily impact a flares DRE, however that annual average DRE will be equal to or greater than 95 percent.

Commenter (0831-AXPC) states that, for oil wells that produce little or intermittent associated gas, a flare or combustor cannot operate efficiently or in compliance with 40 CFR 60.18 without additional gas being supplemented (propane from a propane tank) to provide fuel gas for the pilot and sweep gas. For these situations, it is common to install a pit flare with an auto ignitor that will ignite the gas when present. According to the commenter, these are not as efficient as an engineered flare that complies with 40 CFR 60.18, but it is the best technology for the situation.

Response I-17-13: Regarding monitoring requirements for the flare, see discussion in section IV.H.2 of the December 2022 Supplemental Proposal preamble.<sup>40</sup> Regarding control efficiency

requirements for the flare, see discussion in section IV.H.2 of the December 2022 Supplemental Proposal preamble.<sup>41</sup>

## **17.5 Associated Gas from Wildcat/Delineation Wells**

Comment: Commenter (0808-API) asks for special considerations for handling associated gas at wildcat and delineation wells. The commenter notes that EPA did not allow provisions for wildcat or delineation wells in its proposal. By nature, these wells are typically located apart from other major oil developments including gathering infrastructure. Like provisions within NSPS OOOOa for well completions, the commenter recommends that EPA allow special considerations for handling associated gas at these types of operations. Specifically, the commenter recommends that any associated gas initially generated from wildcat or delineation wells be routed to a combustion device (except in conditions that may result in a fire hazard or explosion, or where high heat emissions from a combustion device may negatively impact tundra, permafrost, or waterways).

Response I-17-14: See discussion in section IV.F.2.a.ii of the December 2022 Supplemental Proposal preamble.<sup>42</sup> EPA has defined associated gas to exclude gas from exploratory and wildcat wells, if and until those wells become producing oil wells with associated gas. See the definition of associated gas in 40 CFR 60.5430b and 60.5430c.

## **17.6 Routing Associated Gas to Sales Line**

### ***17.6.1 Associated Gas with No Sales Line and Low Combustibility***

Comment: Commenter (0955-Vaquero) states that many older fields with heavier hydrocarbons have little to no produced gas. Furthermore, the commenter adds that certain fields require water or inert gas injection to produce oil resulting in associated gas streams diluted with inert gas (nitrogen, carbon dioxide, and water) that require excessive amounts of imported assist gas to achieve its lower flammable limit (LFL). For example, the commenter notes that the associated gas in parts of Wyoming are approximately 97 percent carbon dioxide and 3 percent hydrocarbon, with no combustible field gas available. As such, propane must be added to until the mixture is 11 percent molar volume of propane (or 333 Btu/scf) to reach its LFL.<sup>43</sup> As shown in Table 1 of the commenter's submission, this would require the addition of over 3 gallons of propane per Mscf combusted at a cost of over \$5,000 per ton of VOC removed. Further, the commenter states that the supplemental firing of propane introduces additional VOC to the gas stream. As a result, the commenter notes that the combustion control device would require 98.9 percent destruction efficiency to achieve a net control efficiency of 95 percent to account for the additional propane. Finally, Table 1 of the commenter's submission shows that 36.75 tons of CO<sub>2</sub>e are emitted per 500,000 Mscf (or 1 ton of VOC). According to the commenter, the addition

---

<sup>41</sup> 87 FR 74794-95.

<sup>42</sup> 87 FR 74780.

<sup>43</sup> Robert N. MacCallum, PhD, P.E., et al. Flammability of Mixtures of CO<sub>2</sub> and Hydrocarbons. <http://www.trimeric.com/assets/flammability-of-mixtures-of-co2-and-hydrocarbons.pdf>

of propane and subsequent combustion controls of modicum of methane while emitting an additional 2.9 tons of CO<sub>2</sub>. This results in a net increase of CO<sub>2e</sub> by 7.9 percent.

Commenter (0955-Vaquero) states that such associated gas has no utility as a fuel source and must be collected and compressed for offsite utilization or sequestration. The commenter explains that these fields are often sparsely mined and have no pipeline or electrical infrastructure resulting in the need to install miles of gathering and transmission lines as well as gas-fired field compression ignition engines. A gas-gathering pipeline is estimated to cost \$178,000 per inch-mile<sup>44</sup>, meaning that a 6" pipeline traveling 10 miles would cost over \$10MM not counting the costs of compression, operation, and maintenance. The commenter notes that such costs do not consider the secondary environmental impacts from construction, compression, and pipeline operations such as emissions, leaks, and ecosystem disturbance. As such, the commenter requests that the proposed rule provide a categorical exemption from control requirements for associated gas that has a heating value below its LFL. Operators may demonstrate this exemption by maintaining records of associated gas composition and LFL.

Commenter (0598-Countrymark Energy Resources, LLC) is concerned that, because of the low potential to emit (PTE) for their wells (i.e., low pressure and low gas to oil ratio (GOR)), they are unable to economically justify the cost of compliance with an increase in oil or gas sales, for any operational scenario. Further, the commenter states, there is no infrastructure in proximity to a high percentage of their oil wells to be able to sell gas for additional revenue. The commenter states that EPA has not entertained cost discussions with industry and specifically, small businesses were not consulted to see how the costs will impact their operations or overall viability.

Response I-17-15: See discussion in section IV.F.2.a.ii of the December 2022 Supplemental Proposal preamble.<sup>45</sup> With respect to the estimated cost of routing to a sales line, please see EPA's analysis of cost with respect to routing to a sales line. In the final rule, the EPA has adopted a prohibition on long-term routine flaring for new wells. For modified wells that demonstrated that routing to a sales line nor any of the alternative uses are technically feasible, the option to flare remains available. Within the presumptive standard in EG OOOOc, for designated well facilities with over 40 tpy methane that demonstrate that routing to a sales line nor any of the alternative uses are technically feasible, the option to flare remains available.

### ***17.6.2 Approval of Routing Gas and/or Using Associated Gas Onsite***

Comment: Commenter (0727-Oklahoma Secretary of Energy and Environment (OSEE) and Oklahoma Department of Environmental Quality (ODEQ)) states that for facilities with existing gas-powered equipment, using the gas onsite seems more logical than sending the gas off site through a sales line and bringing other gas in to power the equipment. Further, the commenter notes that routing gas to a sales line and using the gas onsite appear to be equally viable options.

---

<sup>44</sup> Global Energy Monitor.

[https://www.gem.wiki/Oil\\_and\\_Gas\\_Pipeline\\_Construction\\_Costs#:~:text=American%20Petroleum%20Institute%202017%20Estimate,In%20its%20study&text=Combined%20with%20the%20estimate%20of,or%20%243.32%20million%20per%20km.](https://www.gem.wiki/Oil_and_Gas_Pipeline_Construction_Costs#:~:text=American%20Petroleum%20Institute%202017%20Estimate,In%20its%20study&text=Combined%20with%20the%20estimate%20of,or%20%243.32%20million%20per%20km.)

<sup>45</sup> 87 FR 74780.

The commenter states that it is unclear why EPA distinguishes between the two and prefers one scenario over the other.

Response I-17-16: See discussion in section IV.F.2.a.ii of the December 2022 Supplemental Proposal preamble.<sup>46</sup>

### ***17.6.3 Exemptions for Routing to Sales Line***

Comment: Commenter (0810-Petroleum Alliance of Oklahoma (Petroleum Alliance-OK)) suggests in situations where gas sales pipelines to new or existing wells are not available, feasible or economic, or too small in volume, EPA allow exemptions for these situations, especially for marginal/low production wells. In all other situations, the commenter recommends that EPA allow operators the option to implement a proposed requirement (sales pipeline, onsite fuel use, another useful purpose or route to a flare or other control device that achieves 95 percent reduction in methane and VOC emissions) that best fit their operations.

Response I-17-17: See discussion in section IV.F.2.a.ii of the December 2022 Supplemental Proposal preamble.<sup>47</sup>

### ***17.6.4 Use of Associated Gas when a Sales Line is Available***

Comment: Commenter (0740-Utah Petroleum Association (UPA)) states that the wording of the November 2021 Proposal suggests that the gas cannot be used as an onsite fuel source or routed to a flare or other control device if a sales line is available. The commenter does not agree with this approach. The commenter recommends that the rule allow using the gas as an onsite fuel source whether a sales line is available or not. According to the commenter, this will improve cost effectiveness of the rule by not requiring expensive retrofits to add new power sources in locations such as rural Utah that may not have ready access to electrical power or might have other limitations and other obstacles as described above. Furthermore, the commenter adds that, even if a sales line is available, most oil wells in Utah do not produce gas at a high enough pressure to put the gas into a sales line and therefore would require a compressor at substantially added cost and additional use of energy and associated emissions. The commenter reports that the Bureau of Land Management recognized this fact in their final waste gas prevention rule wherein they included exemptions from requirements to route gases to a sales line where the operator determines that compliance would be technically infeasible or unduly costly.<sup>48</sup>

Response I-17-18: The CAA with respect to NSPS compels EPA to identify the Best System of Emission Reduction, BSER, and to set the standard applicable to affected sources. In this instance, the EPA has included options (alternatives) to BSER where an operator finds it to their advantage to implement an alternative that achieves equivalent emission reductions. Exercising any of those options is at the discretion of the operator and does not require EPA approval

---

<sup>46</sup> 87 FR 74779.

<sup>47</sup> 87 FR 74779.

<sup>48</sup> As cited by the commenter, “See “Waste Prevention, Production Subject to Royalties, and Resource Conservation” final rule; Federal Register Vol. 81, No. 223; November 18, 2016; p. 83008; rule language as adopted at 43 Code of Regulations, Chapter II §3179.203(c)(2) on p. 83086.”

because the alternatives are included in the rule itself (EPA has already determined equivalent emission reductions). For sources where routine flaring is allowed under the NSPS OOOOb and OOOOc EG, the operator must demonstrate that non-flaring options are infeasible on an annual basis (except for presumptive standard in EG OOOOc for wells with 40 tpy methane or less). See discussion in section IV.F.2.a.ii of the December 2022 Supplemental Proposal preamble.<sup>49</sup>

#### ***17.6.5 In Support of Use or Combustion in the Case of No Sales Line Accessibility***

Comment: Commenter (0808-API) agrees with EPA's statement that access to a sales line does not equate to availability of a sales line. Although in agreement, the commenter summarizes a few challenges for EPA's awareness and consideration:

- Topography: Mountains, rivers, lakes, *etc.* can limit a producer's ability to connect into a pipeline.
- A contractual right to flow into the gas gathering system must be agreed to with the company that owns the gathering line. In most cases, the company owning the well is different from the company that owns the gathering system. Therefore, contracts must be put in place to allow for flow to the gathering system. The company owning the gas gathering system must determine if the pipeline has the capacity to accept the additional well or wells being added and if the quality of gas meets their required specifications. Additionally, capacity issues could exist even in cases where the production company is also responsible for the gathering system.
- Necessary permits and right of way (ROW) must be obtained for the pipeline from the well site to the natural gas gathering system. Permits and ROW are required for installation of the pipeline to connect to the natural gas gathering system. Sometimes obtaining the necessary ROW can be difficult and may require a court order. On certain federal lands, operators have been required by Bureau of Land Management in recent years to reroute proposed pipelines or to adjust installation techniques, which significantly delays the completion of gathering systems. On private lands, individual landowners may deny rights.
- The natural gas must meet the specifications of the natural gas gathering line. Contracts with the gathering company include specifications for entering the gas gathering line, such as allowable concentrations of inert gases such as carbon dioxide or nitrogen, and hydrogen sulfide. The natural gas gathering system owner ultimately controls when an operator can send gas to sales.
- The natural gas gathering line must be operational. Natural gas gathering lines can be temporarily down or unavailable for a multitude of reasons including, but not limited to, compressor maintenance or repair, line maintenance, line inspection, a gas plant being shut down, or temporary reductions in capacity. In some instances, a well will be connected to sales, but if a compressor station has an emergency upset, then the wells tied into the gathering system will not be able to send gas through the pipeline. These instances are often episodic, temporary, and not in the well operator's control.

---

<sup>49</sup> 87 FR 74779.

Commenter (0808-API) states that, due to the various challenges described, EPA is correct in allowing the beneficial reuse of gas onsite or combusting the gas where accessing the pipeline is not available or technically feasible.

Response I-17-19: See discussion in section IV.F.2.a.iii of the December 2022 Supplemental Proposal preamble.<sup>50</sup> See also Response I-17-3 of this Chapter.

#### ***17.6.6 Costs of Routing Associated Gas to Sales Line***

Comment: Commenter (0946-Michigan Oil and Gas Association (MOGA)) provides a discussion regarding the innate issues regarding bringing associated gas to a “useful purpose rather than flared.” As stated in Comment #9 of the commenter’s letter, every producer would like the ability to sell all produced assets. The commenter notes, however, that the ability and cost are often not feasible because of conflicting regulations, landowner & community objection, Public Service Commission (PSC) restrictions, and the associated cost of pipeline, metering, compression, and transfer gate installation.

Commenter (0946-MOGA) reports that many wells drilled in the United States are not located at convenient spots. The inconvenient locations are in rural locations such as farmland, forests, and sparsely populated areas. Because these areas are remote and often isolated, the commenter notes that transmission or gathering lines that collect gas are located closer to major distribution areas. The commenter states that natural gas produced in these remote areas are referred to “stranded gas.” According to the commenter, the term “stranded” is used because the value of the gas will not pay for the pipeline needed to move the gas to a distribution line. If multiple wells are in a micro-geographic region, then connecting the flowlines to a distribution point, may justify the installation. However, the commenter states that landowners may object to having flowlines in their fields and local communities may not want subsurface piping down road easements, crossing driveways and stream crossings. So, the natural gas stays stranded, except for wellsite fuel or power generation. The commenter requests that EPA discuss and clarify whether the Biden Administration is proposing financial, regulatory, and political support necessary to install natural gas lines to move stranded gas to a “useful purpose rather than flared?”

Commenter (0946-MOGA) explains that the determination for flowline installation is based on economics for the estimated reserves. The commenter notes that a producing company may consider, based on current commodity price and volume of gas generated, the installation of a flowline to bring gas to market. However, the commenter adds that the purchaser of the natural gas will evaluate their costs to install the same flow line but incorporate a profit margin of \$2.00/MSCF or more and subsequently charge the producer for control equipment, emergency shut-off devices, custody transfer equipment and more. According to the commenter, because distribution companies are regulated by the Federal Trade Commission and individual state's PSC, these are over-designed for commercial and residential safety and are extremely expensive.

---

<sup>50</sup> 87 FR 74779.

Response I-17-20: See discussion in section IV.F.2.a.iii of the December 2022 Supplemental Proposal preamble.<sup>51</sup> See also Response I-17-3 and Response I-17-21 in this Chapter below.

Comment: Commenter (0425-Darrah Oil Company, LLC (Darrah)) suggests a rule requiring separation and selling of gas does not consider cost burdens and might create more environmental damage than it protects. For example, the commenter notes that the environmental impact of creating the plastic pipe and safely laying it in the ground may outweigh the lifetime of protection it was trying to create. The commenter asserts that any requirements mandating separation or sales should be stricken.

Response I-17-21: New Source Performance Standards are based on the best system of emission reductions (BSER), which could be particular technology or other measure that has been adequately demonstrated to improve emissions performance for a specific industry or process. In determining the BSER, EPA considers technical feasibility, cost, non-air quality health and environmental impacts, and energy requirements. The commenters' request for political and financial support for the installation of gathering and collection systems for associated gas is beyond the scope of the standards EPA is setting in this rulemaking. With respect to regulatory support, the EPA is not imposing a "one size fits all" requirement to compel the construction of collection systems to bring the gas directly to market. For all operators with associated gas, the final rule preserves the ability of operators to choose their best option that produces emission reductions equivalent to the standard. The final rule requires operators of new wells to route associated gas to a sales line within 24 months. Operators may choose from several other non-flaring alternatives in the rule at their discretion. These new sources may not flare but for specified exceptions for up to 24 hours in the case of malfunctions or upsets, and lesser periods for other circumstances that compel a source to flare.

For designated facility wells with over 40 tpy methane that will be subject to state plans in accordance with OOOOc EG, BSER (presumptive standard) is to connect to a sales line or similarly choose an alternative. The EG includes a subcategory for wells that have 40 tpy methane or less. In addition, EPA recognizes that for existing wells, states have flexibility under CAA 111(d). We think that this subcategory and flexibility for existing wells will address the commenters concern that associated gas could be stranded without any available or cost-effective route to a sales line.

As a general matter, the EPA does not consider flaring associated gas indefinitely as necessary for many sources, given the number of state jurisdictions that have employed various regulatory systems to curtail routine flaring. Similar to state standards such as New Mexico, and Colorado, the EPA has chosen to set a firm deadline to end routine flaring from new wells, while providing alternatives for modified wells and existing wells that address the concern under some circumstances routing to a sales line may not be feasible. The EPA did extensive analysis on the costs of addressing emissions from associated gas. However, within this rule, EPA did not address the comment about the alleged environmental impact of manufacturing and installing gas gathering or oil pipelines, compared to the practice of routine flaring, because the purpose of this NSPS is to address emissions from the oil and gas category. This comment is out of scope. Other NSPS and National Emission Standards for Hazardous Air Pollution address emissions from

---

<sup>51</sup> 87 FR 74779.

categories that produce (manufacture) the material and equipment used by the oil and gas sector. In the context of this rulemaking, an analysis of the kind the commenter asks for, even if such an investigative framework could be devised, would not contribute to a better NSPS or EG for the oil and gas category.

Comment: Commenter (0946-MOGA) notes that EPA does not consider the requirement of additional equipment including compression and dehydration required to make stranded gas “useful.” The commenter states that natural gas will require dehydration because of contract specifications. According to the commenter, if the heating content of the natural gas is greater than the contract limitations, gas conditioning will have to be implemented to sell the gas. The commenter adds that compression will also be required to “boost” the gas pressure high enough to enter the sales and/or transmission line. The commenter provides that compressors typical cost roughly \$50,000 per month to lease and service with an upfront cost of roughly \$500,000 to transport and install. The commenter notes that the inevitable depletion and production decline will make the operation of this equipment uneconomical over time. The commenter believes, as noted in other comments provided by the commenter, that EPA's estimates and feasibility for bringing stranded gas to market fall far short of the actual costs and the breakeven potential, if any.

Commenter (0946-MOGA) expresses that they would support federal regulations allowing oil and gas producers to bypass restrictive PSC rules and regulations to directly sell production and associated gas directly to local landowners, farmers, businesses, and residential dwellings.

Response I-17-22: EPA has established that the introduction of associated gas into a sales line is BSER. Our data and that submitted by other commenters to the proposed rule indicate that alternatives to routine flaring are practical, in wide use, and increasingly cost-effective. Two state jurisdictions (NM and CO) have preceded ahead of EPA to prohibit long-term routine flaring, while two more (ND and TX) have placed significant restrictions and required similar analyses prior to allowing routine flaring. Please see the technical support document in the docket regarding the cost of achieving BSER. The cost analysis that EPA has provided is based upon industry estimates and are comprehensive and detailed enough to reasonable estimates of typical costs that can be expected by operators complying with BSER by routing and connecting to a sales line. While not every source will find their costs to be at the exact level found in the analysis, our estimate is based on the best data available and used by the industry for various types of similar analyses.

EPA agrees with the commenter that certain users of associated gas should be able to continue to use the gas, such as a well operator that uses the gas for home heating on the site of or near the well itself. EPA considers such use to be within the meaning of the criteria of “Recover the associated gas from the separator and use the recovered gas for another useful purpose that a purchased fuel or raw material would serve” since in the absence of such use, the user would be required to find an alternative source of fuel for home use.

Comment: Commenter (0844-EDF *et al.*) points out that currently, most of the associated gas is captured and transported by sales line, and this will likely continue to be the preferred approach of most operators. When new wells are drilled in the vicinity of existing gathering systems, they

can be quickly and cheaply connected to the existing system.<sup>52</sup> The Rystad report shows that connecting wells to gathering line infrastructure is not only highly cost-effective but profitable for operators, with an average net negative cost of \$3.10 per thousand cubic feet (mcf).<sup>53</sup>

As a general practice, the commenter (0844-EDF *et al.*) states that EPA's determination of the BSER for controlling emissions from an affected facility is informed by its analysis of the control options for that emissions source. The commenter suggests that, while EPA recognizes that routing gas to a sales line is a highly attractive option for operators, the Technical Support Document (TSD) does not accurately describe the availability of this option, which is a critical shortcoming for purposes of determining BSER. The commenter notes that the TSD assumes that "access to a sales line" either is or is not available to an operator, without the operator having any ability to influence such availability, much less ensure it. Because gathering systems and natural gas processing capacity are more commonly owned by midstream companies, rather than the producers themselves, and because many of the options for avoiding routine flaring are not plug-and-play control technologies (unlike installing a compressor, which is exactly such a solution in the case of insufficient wellhead pressure), there has been a tendency to view the availability of infrastructure necessary for capture and sale as largely outside of producers' control. This is, indeed, how access to a sales line is treated in the TSD. According to the commenter, this key foundational assumption is not reality; nor is it the prevailing practice among producers that are successfully curtailing routine flaring.<sup>54</sup> The vast majority of routine flaring is fundamentally driven by business decisions, not technical constraints. The practical reality is that operators have substantial and relatively low-cost or negative-cost opportunities to ensure access to take-away capacity for their associated gas.

First, the commenter (0844-EDF *et al.*) states that it is worth noting that the oil and gas industry exists to produce and sell their products – their business model depends on getting these products to market. The commenter states that the United States has billions of dollars in infrastructure in place dedicated to producing, gathering, processing, transporting and delivering natural gas. Investment in this infrastructure responds to the market demands of oil and gas producers and suppliers. Operators of gas wells know how to ensure that they can capture and route gas for sale. They derive their revenues predominately from natural gas, and while there are some wasteful practices, they do not engage in routine flaring. The commenter notes that these operators make sure that the wells are connected to gathering lines with available capacity prior to bringing those wells into production, and when downstream facilities are not operating for extended periods of time, gas wells are commonly temporarily shut in.

The commenter (0844-EDF *et al.*) reports that routine flaring of associated gas is widespread not because gas from an oil well has a different value than gas from gas wells (although prices do vary somewhat by location),<sup>55</sup> but because of the comparative values of gas and oil. Oil has such a higher relative value than gas in recent years that many oil well operators optimize for oil production to the point of treating the associated gas as a waste product. Nevertheless, the commenter notes that, because associated gas does, in fact, have economic value, capturing it for

---

<sup>52</sup> Attachment W at pg. 43 of the commenter's submission.

<sup>53</sup> Id. at 11.

<sup>54</sup> Attachment W at pg. 79-80 of the commenter's submission.

<sup>55</sup> See, e.g., id. at 43-44, 78.

sale typically has net negative costs.<sup>56</sup> According to the commenter, even in a situation where an operator might not be able to ensure access to gathering capacity without incurring some net costs, those costs are likely to be modest overall even before (and certainly after) offsetting the value of the gas.<sup>57</sup> The commenter notes that this is quite different from a typical pollution control requirement that imposes only costs.

Second, the commenter (0844-EDF *et al.*) states that, as the Rystad report makes clear, operators can make operational and commercial adjustments to improve or ensure their access to a gathering system (as well as make alternative arrangements for periods of unavailability).<sup>58</sup> For example, the commenter explains that operators can provide information to midstream companies in advance about expected timing and quantities of gas production, allowing gathering system operators to expand capacity in a timely manner. The commenter adds that operators can require that their new wells are connected to a gathering system with available capacity prior to beginning production.<sup>59</sup> They can also enter into contractual arrangements that guarantee firm gathering or trunkline capacity, and/or that penalize midstream gatherers and processors for downtime.<sup>60</sup> According to the commenter, there are some costs to coordination, information sharing, and negotiating and paying for contractual guarantees, but by and large these should be quite small compared to typical hardware-based pollution control investments. Regardless, the commenter contends that these options make it clear that operators commonly have substantial control over their access to gathering capacity and can exercise this control at typically net negative costs to avoid routine flaring.

Response I-17-23: See Response I-17-21 of this Chapter. EPA generally agrees with the comment. The final rule requires that new sources must route to a sales line, or employ another non-flaring option to handle the associated gas. For modified sources under OOOOb, and existing sources under OOOOc EG, sources with more than 40 tpy methane must evaluate and certify that alternatives to flaring are not feasible before recurring to flaring. For sources with 40 tpy methane or less, the EPA has set BSER to flaring associated gas. EPA adopted routing to a sales line for new sources as BSER because we agree with the commenter that new wells will have the means to route to a sales line.

#### ***17.6.7 “Affected Facility” Definition***

Comment: Commenter (0793-PBPA) asserts that they believe that EPA’s November 2021 Proposal remains legally objectionable. The commenter states that a “standard of performance” is an emissions standard that “reflects the degree of emission limitation achievable through the application of the best system of emission reduction ....”<sup>61</sup> That is, according to the commenter, a standard of performance should reflect the capability of control technologies, not mandate reduced operation of control technologies. The commenter states that BSER stands for “best system of emission reduction,” not operation reduction, and Congress designed section 111 of

---

<sup>56</sup> Id. at 11.

<sup>57</sup> Id. at 39.

<sup>58</sup> Id. at 45.

<sup>59</sup> Id. at 80.

<sup>60</sup> Id.

<sup>61</sup> 42 U.S.C. §7411(a)(1).

the CAA to promote technology development.<sup>62</sup> The commenter adds that Congress in section 111 of the CAA differentiated between “operational standards” in section 111(h) (which might include operational reductions or restrictions) from “standards of performance” in sections 111(b) and (d), and Congress only permitted EPA to pursue the former in rare circumstances mostly limited to fugitive emissions.<sup>63</sup>

The commenter (0793-PBPA) recommends that EPA define the “affected facility” to only include oil wells producing associated gas where a sales line is inaccessible,<sup>64</sup> with inaccessibility including an analysis with exceptions for (a) distance from and availability (capacity-wise) of takeaway and processing facilities, including the cost to build takeaway infrastructure, (b) inability to acquire rights-of-way, (c) the composition of associated gas and whether it meets processing and pipeline specifications, and (d) volumes of expected associated gas.

Using this alternative definition, the commenter (0793-PBPA) recommends that the BSER be to beneficially use the associated gas (for example, as onsite fuel) or to route associated gas to a flare or other control device that achieves at least a 95 percent reduction in VOC emissions. According to the commenter, compelling use of non-flaring technologies should be off the table<sup>65</sup> because the availability of non-flaring technologies would vary by site. For example, the commenter states that if an oil producing site beneficially uses 96 percent of associated gas production for gas lift operations, the remaining 4 percent would need to be flared if the site is stranded from a takeaway pipeline perspective. That “excess” 4 percent of gas would be difficult to market due to its small volume and, for the same reason, non-flaring technologies may be unavailable or cost prohibitive. The commenter notes that it may be different from an oil producing site where larger volumes of gas cannot be put to beneficial use at all. The commenter suggests that using this alternative definition would also have the following benefits:

- It would ensure that these new federal regulations do not unnecessarily overlap with existing state regulations. These existing state regulations already prohibit or limit venting and/or flaring under appropriate circumstances, are enforced by agencies with relatively more on-the-ground knowledge than EPA and reflect states’ interests in conserving their own resources.<sup>66</sup> This is particularly important for the forthcoming EGs as it would allow states to develop plans that consider their own regulations and other local considerations.

---

<sup>62</sup> See, e.g., 79 Fed. Reg. 1,430, 1,465 (Jan 8, 2014).

<sup>63</sup> 42 U.S.C. §7411(h)(2).

<sup>64</sup> 86 Fed. Reg. at 63,238 (“As an alternative, the EPA is soliciting comments on defining the affected facility as each oil well that produces associated gas and does not route the gas to a sales line.”).

<sup>65</sup> Id. at 63,237 (“The EPA is interested in information on, and the feasibility, of options to utilize associated gas in some useful manner in situations where a sales line is not available. In addition to use as fuel, such options could include conversion technologies where methane is converted into hydrogen or other added value chemicals. The EPA is interested in information on these, as well as other, technologies.”).

<sup>66</sup> Id. at 63,237 (“Typically, State oil and gas regulatory agencies (or, on certain public and Tribal lands, the BLM) regulate venting and flaring of associated gas from oil wells to ensure oil and natural gas resources are conserved and utilized in a manner consistent with their respective statutes. State oil and gas regulatory agencies typically encourage, and in some cases require, capture (conservation) over flaring, then flaring over venting.”).

- It would focus regulation on wells that have the greatest potential of uncontrolled emissions—those that are truly stranded from a takeaway pipeline perspective.

Response I-17-24: EPA is not substantively responding to this comment because of comments received on the November 2021 Proposal, EPA proposed a different affected facility definition for this particular affected/designated facility in the December 2022 Supplemental Proposal. For details, please see discussion in sections IV.F.1 of the December 2022 Supplemental Proposal preamble.<sup>67</sup>

Comment: Commenter (0938-Texas Oil & Gas Association (TXOGA)) supports an alternative “affected facility” definition that would exclude oil wells that route all associated gas to a sales line as a sensible acknowledgment of the fact that if all associated gas is routed to a sales line, there would be no emissions to control under the standard.

Conversely, commenter (0797-North Dakota Department of Environmental Quality (NDDEQ) and North Dakota Industrial Commission (NDIC)) recommends that EPA not exclude oil wells that produced associated gas from the affected facility definition if they route the gas to a sales line. If adopted, the commenter believes that this alternative proposal will only complicate the reporting process and unduly burden both owners and operators in addition to the delegated entities in charge of ensuring compliance with the rule.

The commenter (0797-NDDEQ/NDIC) states that, since there is no draft regulatory text, the alternative proposal does not explain what documentation would be required for instances where access to the sales line is disrupted. In such a case, the commenter asks whether those oil wells would become an affected facility only for as long as the sales line was disrupted? The commenter further asks whether the reporting party would only report for that specific time period, and would there be an additional notification requirement for those oil wells if they would thus become an affected facility every time the sales line is unavailable? The commenter is concerned that for oil wells that produce associated gas and where sales line access is not a guarantee (as is common in North Dakota) they will be constantly changing their “affected facility” status.

The commenter (0797-NDDEQ/NDIC) states that it is also important to note that along with disruptions to the sales lines themselves, associated gas production can fluctuate significantly from larger oil well sites consisting of multiple oil wells, where predictable decreases in production over time is interrupted by dramatic spikes in production as new oil wells are drilled and brought into production, potentially displacing capacity in the sales lines for gas from older, lower producing wells. The commenter notes that this is in addition to the older wells themselves going through associated gas production fluctuations via workovers and recompletions. In such pipeline capacity situations, the commenter notes that access to a sales line may not be feasible even if there are no issues with the sales line itself. The commenter requires that control devices (such as flares) be operational even if all associated gas is routed to a sales line in case of such issues, as they are expected to occur.

---

<sup>67</sup> 87 FR 74778.

The commenter (0797- NDDEQ/NDIC) notes that the original proposed requirement in the November 2021 Proposal states for oil wells routing all associated gas to a sales line “the only requirement would be to certify that this is occurring.” 86 FR 63238. The commenter believes this is appropriate as it should already be known or easily available due to the royalty requirements on the sold gas. The commenter adds that the proposed requirement also allows a continuous record for all destinations of associated gas through either its sale, beneficial use, or control. In addition, the commenter believes it will serve as a reminder that when access to a sales line is not available the only appropriate alternatives for associated gas are beneficial use or control, not venting.

According to the commenter (0797-NDDEQ/NDIC), EPA should adopt the original proposal of the November 2021 Proposal every oil well that produces associated gas would be an “affected facility” and should not adopt the alternative interpretation offered in the November 2021 Proposal of defining the affected facility as each oil well that produces associated gas and does not route the gas to a sales line.

Response I-17-25: EPA is not substantively responding to this comment. Because of comments received on the November 2021 Proposal, EPA proposed a different affected facility definition for this particular affected/designated facility in the December 2022 Supplemental Proposal. For details, please see discussion in sections IV.F.1 of the December 2022 Supplemental Proposal preamble.<sup>68</sup>

Regarding comments on disruption of service, see discussion in section IV.F.2.a.ii of the December 2022 Supplemental Proposal preamble.<sup>69</sup>

## 17.7 Reinjection

Comment: Commenter (0844-EDF *et al.*) points out that in some circumstances, well operators may prefer to reinject associated gas. The commenter explains that reinjection is used widely in Alaska, where 90 percent of associated gas is injected into oil-bearing formations.<sup>70</sup> The commenter adds that reinjection as a method of gas capture has significant emissions reduction benefits, because it largely eliminates emissions of methane and other pollutants.<sup>71</sup>

Commenter (0844-EDF *et al.*) states that choosing to reinject associated gas may do so either by drilling a new injection well or by reappropriating an existing inactive production well.<sup>72</sup> According to the commenter, shale reservoirs are particularly well suited to injection because of their large storage capacity: “nanopores” in the rock formation can trap and store greenhouse

<sup>72</sup> See SADIQ J. ZARROUK & KATIE MCLEAN, “Geothermal Wells”, in GEOTHERMAL WELL TEST ANALYSIS, 39-61, 54 (2019).

gasses in an absorbed state.<sup>73</sup> The commenter adds that associated gas may also be injected and stored in natural aquifers, which may be suitable for gas storage when the sedimentary rock formation is overlaid with impermeable “cap” rock, or in salt caverns.<sup>74</sup> According to the commenter, reinjection costs vary depending on various factors, but Rystad finds that on average, costs are \$3.4/mcf, and \$177 per MT of methane flaring avoided.<sup>75</sup>

Response I-17-26: See discussion in section IV.F.1.a.ii of the December 2022 Supplemental Proposal preamble.<sup>76</sup>

## 17.8 Fuel Source or Gas-to-Wire

Comment: Commenter (0844-EDF *et al.*) suggests that in addition to the various methods of gas capture and redirection explored above, well operators can use associated gas for power needs on site and implement a gas-to-power system for local loads.<sup>77</sup> For wells that are not yet connected to the power grid, on-site gas-to-power technology can replace the diesel generators that would otherwise be used to power operations.<sup>78</sup> The commenter states that this is very beneficial from an emissions perspective, since diesel is a highly polluting fuel with elevated levels of nitrogen oxides, particulate matter, and toxic pollutant outputs.<sup>79</sup> They add that it can also provide significant cost saving because purchasing and transporting fuel from offsite carries a significant cost. As a result, the commenter notes that the Rystad reports that fully displacing diesel with associated gas for power demand at the well amounts to \$7-\$10/mcf saved— subtracting the cost of power generator and treatment and assuming 50 mcf per day of power used.<sup>80</sup>

Thus, the commenter (0844-EDF *et al.*) states that operators can significantly reduce both costs and emissions by utilizing available associated gas to meet well pad energy needs. And they can make a profit while doing so: Rystad estimates that on average, on-site use of gas nets a profit of \$8.60/mcf.<sup>81</sup> According to the commenter, this makes it a compelling alternative to routine flaring and an appropriate element of the BSER for reductions of associated gas at oil wells.

Commenter (0844-EDF *et al.*) suggests that another option is to use the associated gas to power a small electricity generation plant that sends power to the grid. The commenter reports that this approach depends on an ongoing supply of a relatively large quantity of gas to make the necessary investments worthwhile, so it is not suitable for every application. But where the gas

<sup>81</sup> *Id* at pg. 11.

volumes and grid access are available, the commenter adds that it can also be a net negative cost option.<sup>82</sup>

Response I-17-27: See discussion in section IV.F.1.a.ii of the December 2022 Supplemental Proposal.<sup>83</sup> The EPA proposed a hierarchy of uses that are alternatives to routing to a sales line. The uses suggested by the commenter are within the scope of the option to recover the associated gas from the separator and use the recovered gas for another useful purpose that a purchased fuel or raw material would serve. This would include capture and conversion to liquified natural gas, compressed natural gas, chemical or physical conversion to methanol or similar chemical feedstock, or use in gas-to-wire or gas-to-power processes.

## 17.9 Truck Transport of Compressed Natural Gas

Comment: Commenter (0844-EDF *et al.*) points out that in cases where existing well sites lack adequate existing gathering system infrastructure, or where gathering systems are at capacity on a temporary or ongoing basis, well operators may choose to forego construction of additional gathering capacity or coordination with third-party gatherers and instead convert associated gas onsite into CNG<sup>84</sup> and transport it by road in specialized tanker trucks.<sup>85</sup> The trucks would transport the gas to processing plants, where the gas is prepared to meet pipeline requirements.<sup>86</sup> Trucking can be both a long-term option for existing wells lacking adequate gathering line infrastructure or capacity, and a short-term solution in cases of low capacity due to outages, maintenance activities, or temporary system overload—either at the processing plant (in which case trucks could transfer the gas to an alternative plant) or on the gathering system (in which case the trucks can bypass the initial pipelines and transfer the gas directly to the plant).<sup>87</sup>

Commenter (0844-EDF *et al.*) states that a report from the New Mexico state Methane Advisory Panel, specifically examining CNG trucking, found that CNG trucking is a “portable, scalable and low or negative cost” approach to gas capture.<sup>88</sup> Indeed, the commenter notes that in many cases truck transport ultimately presents little or no additional cost to well operators because operators will incur only minimal net costs or achieve net benefits by reselling the gas. The commenter adds that various factors play into the total expense of a trucking operation, including distance traveled. The New Mexico report, for instance, found that trucking is most efficient

<sup>88</sup> NEW MEXICO ENVIRONMENT DEPARTMENT & NEW MEXICO ENERGY, MINERALS AND NATURAL RESOURCES DEPARTMENT: METHANE ADVISORY PANEL (2019), <https://www.emnrd.nm.gov/ocd/wpcontent/uploads/sites/6/OCD-Exhibit6-NMENRDNMED-MethaneAdvisoryPanel-Technical-Report.pdf> [hereinafter METHANE ADVISORY PANEL] at 178. New Mexico Administrative Code, Venting and Flaring of Natural Gas, § 19.15.27.8(A) (accessible at <https://www.emnrd.nm.gov/ocd/wpcontent/uploads/sites/6/Part27-FinalRule3.25.21a.pdf>).

when well sites are within 20-25 miles of a processing plant.<sup>89</sup> For CNG, the commenter states that operators must purchase an onsite compressor, the total one-time cost of which can be approximated at \$200,000 for the equipment and \$50,000 for the installation.<sup>90</sup> The commenter adds that operators will also need to pay the truck drivers, and may need to lease the appropriate trucking assembly.<sup>91</sup>

Commenter (0844-EDF *et al.*) provides that an analysis by ICF International reports that the quantities of gas transport needed for CNG trucking to break even as a method of gas capture—considering the costs of the onsite compressor, equipment lifetime, truck fuel, driver salary, and several other factors—range from 134 mcf to 345 mcf of captured gas per day, depending on gas prices.<sup>92</sup> Importantly, the commenter notes that this total volume need not be collected from a single well: instead, operators may capture gas from multiple wells in the same vicinity.<sup>93</sup> For particularly high producing wells, then, the commenter reports that CNG trucking will constitute a net benefit for operators. And overall, the net costs are reasonable in terms of methane emissions abatement: Rystad’s report finds that on average, CNG trucking will cost operators \$1.8/kcf, or \$94 per MT of methane flaring avoided.<sup>94</sup>

Response I-17-28: See the response to I-17-27. EPA has established that the introduction of associated gas into a sales line is BSER.. Our data and that submitted by other commenters to the proposed rule indicate that alternatives to routine flaring are practical, in wide use, and increasingly cost-effective. Two state jurisdictions (NM and CO) have preceded ahead of EPA to prohibit long-term routine flaring, while two more (ND and TX) have placed significant restrictions and required similar analyses prior to allowing routine flaring. Please see the TSD in the docket regarding the cost of achieving BSER.

For all operators with associated gas, the final rule preserves the ability of operators to choose their best option that produces emission reductions equivalent to the standard. The commenter’s suggestion is one of those alternatives that may be a cost-effective alternative to connection to a sales line in certain circumstances.

## **17.10 New Source Performance Standards**

Comment: Commenter (0831-AXPC) disagrees with EPA’s assumption that since there are no NSPS that regulate associated gas venting and flaring, that one is therefore needed. The commenter notes that there are many emission sources not covered under a NSPS. The commenter reports that emissions from associated gas venting and flaring are regulated under Federal and State New Source Review programs. Further, state and federal regulators charged with oversight of the production of oil and natural gas in their jurisdictions have the primary responsibility over regulating gas flaring and venting as part of their overall obligation. Also, today it is uncommon for associated gas to be vented under normal circumstances for safety

---

<sup>89</sup> See METHANE ADVISORY PANEL at 173, 178.

<sup>90</sup> See ICF INTERNATIONAL at 4.

<sup>91</sup> See *Id.*

<sup>92</sup> See ICF INTERNATIONAL at 9.

<sup>93</sup> See *Id.*

<sup>94</sup> Attachment W of the commenter’s submission at pg 39.

reasons, and many state regulations, like North Dakota, prohibit the venting of natural gas and have gas capture regulations that already limit the gas that can be flared without impacting the economics of the industry.

Response I-17-29: EPA disagrees with commenter’s claim that emissions from associated gas are currently regulated under NSR in all instances. The commenter did not provide any evidence to support this claim. EPA agrees that some states regulate emissions from associated gas, but not all states, and many of those state regulations take different approaches to regulation (some are more stringent than others). EPA still finds that regulating associated gas in this rule is necessary and reasonable for all the reasons stated in the 2021 proposal, 2022 supplemental proposal, and final rule. . Among other things, as stated in the preambles to the proposal and supplemental proposal, EPA is addressing methane emissions in an effort to address climate change. In addressing associated gas with the goal of addressing climate change, combustion of methane produces carbon dioxide, which also contributes to climate change. While flaring is preferable to venting associated gas when addressing climate concerns, using the gas for a useful purpose is preferable to flaring it as waste disposal. By incentivizing and regulating the use of gas over disposal, EPA is inducing sources regulated by the NSPS to further reduce climate emissions than if they merely flare associated gas. EPA also points out emissions from flares, even when operating properly, are a source of pollutants with potential to affect human health and the environment. To the extent that such emissions can be avoided by curtailing flaring, this is a direct environmental benefit.

## **17.11 Cost Benefit Analysis**

### ***17.11.1 Cost Benefit Analysis of Flare***

Comment: Commenter (0793-PBPA) states that EPA’s assumption in the 2021 November proposal that the flare capital cost is \$5,719.55 is a significant underestimate. The commenter informs that the “all-in” cost to install a flare is closer to \$61,500, which reflects the cost of a low-pressure flare (\$30,000), ultrasonic flare meter (\$24,000), and labor/material installation costs (\$7,500).

Commenters (0788-350Seattle, 0941-350Silicon Valley, 0948-Quirk) cite a Rystad Energy study commissioned by EDF to note that 84 percent of routine flaring could be eliminated at no net cost to producers.<sup>57</sup> Commenter (0788-350Seattle) notes that when market and nonmarket factors are taken into account (reduced mortality, avoided agricultural losses, avoided work loss from extreme heat), methane reduction benefits are \$4,300/ton, and 85 percent of the targeted measures have benefits that outweigh cost (Global Methane Assessment, UN Climate and Clean Air Coalition).

Commenter (0592/1340-CURED) recommends that EPA implement financial incentives to reduce flaring and other waste hydrocarbon resources. The commenter states that in the U.S., the market drives the economy. The commenter contends that wasting resources equals wasting money only if producers are held accountable for paying for every cubic foot of natural gas that comes out of the ground, whether on public or on private land. The commenter contends that wellhead metering (rather than at the gathering point) should be the point of taxation and royalty

application. To increase the effectiveness of such financial incentivization, the commenter recommends EPA consider sur-taxes for wasted gas. The commenter recognizes that the comment may be more applicable to minerals management agencies at the state and federal levels. If so, the commenter asks EPA to refer these comments to partner agencies and work with them for implementation as part of the plan to reduce emissions.

Commenter (0808-API) suggests that EPA underestimated the cost of installing a flare in its cost benefit analysis. The commenter contends that EPA used a value significantly lower than EPA estimates for flares for other affected facilities.

The commenter (0808-API) recommends that EPA re-evaluate the cost effectiveness using more relevant cost information that is consistent with how flares are costed for other emission sources. Throughout the TSD for the November 2021 Proposal, the commenter states that EPA has assumed various costs with respect to installing a flare or other combustion device.

In review of EPA's cost evaluation data for associated gas from oil wells, the commenter (0808-API) states that EPA assumed that a flare would cost only \$5,700. The commenter suggests that this value significantly underrepresents actual costs experienced by operators. According to the commenter, a more representative cost for installing a flare suitable to control associated gas would be \$100,579, based on the average costs EPA uses for analyzing storage vessel controls. To obtain an average cost of \$100,579 per flare, the commenter reports that they reviewed the direct capital costs associated with calculation sheets issued by EPA.<sup>95</sup> [The comment letter includes a Table of the results of the Model Plant (MP) EPA Flares Calculation sheets MP1, MP2, MP-G and MP-H and Average.]

The commenter (0808-API) provides that they did not include the costs from EPA's Workbook "MP1 Plus Monitors.xlsx" because they believe that would have further increased results due to inclusion of costs for a flow monitor and calorimeter, which EPA did describe in the November 2021 Proposal. The commenter notes that, if EPA pursues requirements that involve monitors or other requirements such as meeting compliance with §60.18 (as EPA has solicited comment), then additional compliance costs will apply and should be included within EPA's cost analysis.

Commenter (0425-Darrah) suggests that where emissions at sites are low, the impacts of flaring may outweigh the benefits.

Response I-17-30: See discussion in sections IV.H.2 and IV.H.3 of the December 2022 Supplemental Proposal.<sup>96</sup>

### ***17.11.2 Limitations on Beneficial Use by Public Service Commissions***

Comment: Commenter (0946-MOGA) recommends that EPA review each individual state's PSC regulations and provide individual cost analysis and feasibility analysis prior to imposing regulations designed to capture associated gas for useful purposes rather than flaring the gas. The commenter states that every oil and gas producer within the State of Michigan would gladly

---

<sup>95</sup> <https://www.regulations.gov/document/EPA-HQ-OAR-2021-0317-0039>.

<sup>96</sup> 87 FR 74792 and 74795.

bring associated gas to market or provide for local landowners, farmers, businesses, homes, *etc.* that would otherwise be combusted. However, the commenter notes that strict rules and regulations regarding the ability to bring associated gas to market prevent oil and gas producers from directing gas to a useful purpose rather than flaring the gas. Until EPA provides a comprehensive feasibility analysis to understand each state's PSC regulations and limitations, the commenter believes EPA should avoid proposing technically infeasible restrictions on oil and gas producers.

Response I-17-31: EPA cannot respond to this comment because it is too general in nature and the EPA cannot agree or disagree without further information. EPA reviewed available online information regarding the sphere of activity for the Public Service Commission (PSC) in Michigan, but could not identify with certainty examples of regulations with a potential for conflict with the NSPS as described by the commenter.

## 17.12 Other

Comment: Commenter (0594-Huntsman Corporation) suggests that - when access to a sales line is infeasible – their technology (methane pyrolysis) is an ideal candidate to serve as a bridge. The commenter states that the use of methane pyrolysis can simultaneously consume the associated gas while generating clean fuel that emits no GHGs and a commercially viable product with unique strength and weight properties. According to the commenter, this is a prime example of one of the agency's proposed control options of "beneficially using the associated gas."

Commenter (0231-West Virginia Attorney General) states that requiring oil wells that produce associated gas to route to a sales line compels source owners and operators to engage in transactions beyond their facilities' fencelines, and Section 111 does not grant EPA power to require beyond-the-fenceline market measures. The commenter also states that routing to a sales line may not accomplish any emission reductions, as any gas sold will ultimately be combusted by any gas purchaser.

Response I-17-32: With respect to methane pyrolysis technology, see the response to I-17-28.

EPA disagrees with the comment that requiring an oil well to route associated gas to a sales line is a beyond the fenceline measure. The technology that routes associated gas (a "waste" product created by oil extraction<sup>97</sup>) is a control that is applied at the source (the oil well) that reduces emissions at the source. It is true that the pipeline that carries the gas away from the source may extend beyond the fenceline of the facility, but at the source controls commonly require off-site disposal of waste captured by the control. Capturing the associated gas occurs within the fenceline at the site. Putting the captured gas into a pipeline also occurs within the fenceline at the site. At some point that gas will transfer into a pipe that exists outside the fenceline of the site where the gas was extracted, but that fact does not negate the fact that the control technique itself (capture gas and put gas into pipeline) happens within the fenceline at the site. Even if routing to a sales line is considered a beyond the fenceline measure, it remains permissible under CAA

---

<sup>97</sup> An owner/operator of a well that produces oil may consider associated gas to be waste because it is not the product which the operation intends to extract and sell. However, as EPA has explained in this rulemaking, the associated gas can be used and is therefore not waste to others.

Section 111. *See* EPA's Final Subpart Ba Rule discussing Section 111's requirements. 88 FR 80480 (November 17, 2023). Lastly, EPA disagrees with the commenter that routing to a sales line will not reduce emissions. As compared with venting, which releases uncombusted gas into the atmosphere, routing to a sales line still accomplishes emission reductions even taking into account the fact that the gas sold may later be combusted. Combusted gas has fewer methane emissions than uncombusted gas.

## **Chapter 18. Additional Emission Sources and Definitions**

### **18.1 Abandoned Wells**

Response I-18-1: In the November 2021 Proposal, EPA solicited comment and information on idled and unplugged wells due to the EPA's understanding and concern that these non-producing oil and natural gas wells are generally unmanned and many are in disrepair.

In the December 2022 Supplemental, EPA proposed that owners and operators of each well site or centralized production facility may stop the required fugitive emissions monitoring and repair for that site when the well site has been properly closed because in that event there should not be any equipment or other fugitive components onsite for monitoring. 87 FR 74736. EPA proposed this requirement as an important step in maintaining transparency for the responsible owner or operator and will also prevent well sites from becoming orphaned in the future. This would also help address concerns cited by many stakeholders regarding continuing emissions from orphaned wells and unplugged idled wells.

As stated in section X.A. of the final preamble, EPA is finalizing these well closure requirements under the fugitives monitoring requirements for actively producing wells. The final well closure requirements will prevent well sites from becoming orphaned or left in an idled and unplugged state with no form of emissions monitoring and repair. See RTC Volume II Chapter 4, section 4.1.6 (Well Closure Requirements) for response to comments on the well closure plan associated with the fugitive monitoring requirements. See 40 CFR 60.5397b(l) of NSPS OOOOb and 40 CFR 60.5397c(l) of EG OOOOc for the final well closure requirements.

We may consider regulation through a future action, including in the next 8-year review of the NSPS. The comment summaries are provided below for reference but substantive responses are not provided because no emissions standards have been proposed for this emissions source.

#### ***18.1.1 Regulatory Support***

Commenters (0391-Keweenaw Bay Indian Community (KBIC), 0781-National Tribal Air Association (NTAA), 0605-Muscogee (Creek) Nation, 0943-Sault Ste. Marie Tribe of Chippewa Indians, Sault Tribe Environmental Department (Sault EPD), 0833-Environmental Programs Department, Ute Mountain Ute Tribe (Ute EPD)) express interest in the supplemental proposal. The commenters assert that there are a significant number of abandoned wells throughout Indian country, many of which are not plugged and emitting harmful pollutants. The commenters also state that there are a significant number of oil and natural gas pipelines traversing Indian country that undergo pigging and blowdown activities. Until EPA proposes and finalizes the supplemental proposal, these emissions sources will remain largely uncontrolled. The commenters are concerned about the unknown emissions coming from these sources.

Commenter (0957-Wyoming Coalition of Local Governments (WYCLG)) states that the solicitation of comments on the potential for establishing standards for abandoned and unplugged wells is not appropriately included within the November 2021 Proposal because it fails to provide an adequate description of the issues involved or terms or substance of a proposed rule. The commenter recommends that EPA's request for additional information on other sources of

emissions instead be its own separate rulemaking, starting with an “Advance Notice of Proposed Rulemaking” to obtain the necessary information.

Commenter (0957-WYCLG) states that the November 2021 Proposal fails to document the scope and quantity of emissions from plugged or non-operating wells.

### ***18.1.2 Number of Abandoned Wells in the U.S.***

Commenter (1390-FracTracker Alliance (FTA)) suggests that EPA’s estimate of approximately 3.4 million orphaned and abandoned wells in the U.S. is an underestimate. Based on some peer-reviewed estimates, there could be as many as 750,000<sup>1</sup> such wells in Pennsylvania alone, suggesting that the scale of the problem could be even greater.

Commenter (0734-American Thoracic Society (ATS)) states there is an urgent need for the Biden Administration to curb emissions from abandoned wells and minds and ban routine flaring. The commenter reports that recent work indicates that there are approximately 4,000,000 abandoned oil and gas wells throughout the U.S., with these sites increasing over time.<sup>2</sup> The commenter suggests that EPA may be underestimating the annual methane (CH<sub>4</sub>) emissions from these sites by 20 percent.<sup>3</sup>

Commenter (1426-Public Citizen) reports that there are 6,400 orphaned wells in Texas. The commenter provides an October 2021 analysis from Environmental Defense Fund (EDF) using EPA data. The commenter’s analysis of the Texas Railroad Commission (RRC) data showed that 1,600 of these wells had been abandoned for 20+ years.<sup>4</sup>

### ***18.1.3 Abandoned Wells Emissions Estimates***

Commenter (0831- American Exploration and Production Council (AXPC))) suggests that emissions from abandoned wells are overestimated due to inconsistencies in terminology and a lack of relevant studies. The commenter notes that there appears to be a lot of confusion over the terminology that is leading to misconceptions and misunderstandings. For example, “abandonment” refers to the proper process of removing a well or pipe from service. Wells can be permanently plugged and abandoned, or temporarily abandoned if re-entry is anticipated, however both cases in general speak to leaving the well in a regulatorily compliant, protective state. Whereas EPA’s definition of “abandoned” includes all wells that are no longer in production; however, these wells may or may not be plugged. These terms are also often conflated with references to “orphan” wells or “idled” wells. According to the commenter, these sort of inconsistencies in terminology have led to incorrect counts and estimations as they relate to concerns on the landscape. Similarly, the commenter notes that there have not been many studies looking at emissions from abandoned and unplugged wells, or from orphan wells, and

---

<sup>1</sup> “Identification and characterization of high methane-emitting abandoned oil and gas wells.” Mary Kang, et al. <https://pubmed.ncbi.nlm.nih.gov/27849603/>.

<sup>2</sup> Williams, JP; Regehr, A & Kang, M. Methane Emissions from Abandoned Oil and Gas Wells in Canada and the United States. *Env. Sci Technol* 55, 570 (2021).

<sup>3</sup> Id.

<sup>4</sup> RRC, Orphan Wells with Delinquent P-5 Greater Than 12 Months, (Sept. 17, 2020, 9:09:12 AM) <https://rrc.texas.gov/oil-gas/researchand-statistics/well-information/orphan-wells-12-months/>.

what studies there are do not geographically represent the entire U.S. and/or were biased by the inclusion of noticeable outliers. For these reasons the commenter believes that emissions from abandoned wells are not as great as EPA suggests. The commenter reports that this type of information is part of an ongoing dialogue with EPA's Climate Change Division concerning potential updates to the U.S. Greenhouse Gas Inventory (GHGI).

Commenter (0808-American Petroleum Institute (API)) states that emissions from non-producing oil and gas wells are comparatively small and may currently be overestimated within the datasets used by EPA's Inventories Program on Climate Change. Under EPA's current methodology, the emissions from non-producing oil and gas wells constitute approximately 3 percent of all methane emissions from the energy sector – a number similar to rice cultivation.<sup>5</sup>

The commenter (0808-API) notes that definitional challenges across state agencies and data sets can lead to apples-to-oranges comparisons. For example, the commenter states that the distinction between “abandoned” and “abandoned and plugged” is considerable. Beyond the Interstate Oil and Gas Compact Commission (IOGCC) definitions, the oil and gas industry often refer to any well that has been properly plugged as “abandoned and plugged.” Similar to industry, EPA's definition of “abandoned” includes all wells that are no longer in production; however, these wells may or may not be plugged, and may or may not be considered “orphan” as defined by IOGCC. The commenter states that this type of information is part of an ongoing dialogue with EPA's Climate Change Division concerning potential updates to the U.S. GHGI.

In an attached letter<sup>6</sup> to the commenter's (0808-API) submission, dated November 16, 2021, to Ms. Melissa Weitz, the commenter recommended the following clarifications and revisions to EPA's proposed GHGI methodology,<sup>7</sup> all of which underscore the challenge of creating an accurate count of wells across data systems:

- Correcting assumptions concerning plugged vs. unplugged wells. The commenter requests that EPA provide a better explanation of how it estimated the number of 1.1 million historical abandoned wells, which are not captured in the Enverus database. Moreover, the commenter maintains that EPA should not assume that all historical (pre-Enverus) wells are unplugged, without further supporting information. Looking at the restructured Enverus data at the end of 1975, which is the date EPA used to develop its estimate of historical (pre-Enverus) wells, indicates that 72 percent of the wells that would be classed as “abandoned” by the criteria in Table 3 of the 2022 memo are shown as actually “plugged and abandoned.”<sup>8</sup> Hence, the commenter asserts that EPA should not ignore the Enverus data in favor of unsupported assumptions.

---

<sup>5</sup> GHGI United States Environmental Protection Agency, Global Greenhouse Gas Inventory (2019).

<sup>6</sup> Attachment D API Comments on EPA's Updates under Consideration for the 2022 Inventory of Greenhouse Gas (GHG) Emissions and Sinks, November 16, 2021.

<sup>7</sup> [https://www.epa.gov/system/files/documents/2021-09/2022-ghgi-update-abandoned-wells\\_sept-2021.pdf](https://www.epa.gov/system/files/documents/2021-09/2022-ghgi-update-abandoned-wells_sept-2021.pdf)  
2 IOGCC, 2019, Idle and Orphan Oil and Gas Wells: State and Provincial Regulatory Strategies.

<sup>8</sup> The commenter's analysis of Enverus data does not validate the information in Table 3 of the 2022 Abandoned Wells Update Memo as representative of calendar year 2019. However, the counts in Table 3 are broadly similar to the commenter's analysis of current date Enverus well counts. The commenter requests that EPA validate that their modified query of the Enverus database for 2019 counts is correct and provide this information to stakeholders in an updated Table 3 if changes are substantive.

- Using the IOGCC Data. The commenter suggests that an alternative estimate of historically abandoned wells could be based on data for “undocumented orphan wells” provided in the 2019 report issued by IOGCC.<sup>9</sup> According to the IOGCC 2019 report the total estimated number of undocumented orphan wells reported by the states is between 210,000 and 746,000.<sup>10</sup> Beyond the IOGCC information, the commenter is not aware of alternative, high quality sources of data readily available to inform the count of abandoned wells or the split into plugged and unplugged categories.
- Avoiding the double counting of dry wells. The commenter requests that EPA provide greater insight into the process of restructuring of the Enverus data set and the treatment of dry wells. The commenter notes that the designation of “Dry Wells” in the Enverus database indicate a production type rather than a status type and EPA’s approach of considering all wells with no cumulative production as abandoned wells is likely leading to double counting of dry wells in the abandoned well category since they are embedded in the well status counts. Furthermore, EPA’s assumption that dry wells are unplugged is neither consistent with the Enverus data nor State plugging requirements. Current Enverus data shows that 93 percent of dry holes are plugged. Texas requires the same plugging standards for dry holes as for idle production wells and other state requirements are believed to be similar. Moving forward, the commenter recommends that EPA should continue to use the Enverus production type field, where available, to classify wells into gas vs. oil and should also use the Enverus ‘Plugged and Abandoned’ (P&A) status for determining what dry holes are unplugged. The commenter further recommends that EPA should continue to use the cumulative production coupled with the well status and production type information to determine the count of dry wells.

In the same attached letter,<sup>11</sup> the commenter (0808-API) also highlights some data considerations which may lead to an overestimation of emissions from those wells:

- Considering the impact of state regulations. Many of the largest producing states have regulations in place spelling out emissions, discharge or integrity requirements that must be met when a well is non-producing. The commenter stipulates that the simple assignment of the ‘unplugged’ designation to all the status codes that are not ‘Excluded’ or “Plugged and Abandoned” (P&A) overlooks the potential impacts of such regulations and is therefore inaccurate. Such regulations, even if not directly promulgated to control volatile emissions, have the potential for lower emission rates from wells that are subject to regulation when inactive.
- Using geographically correct emission factors. The commenter commented previously on Abandoned Wells emissions when EPA introduced the update for the 2018 GHGI. The commenter noted that the studies conducted so far have limited geographical coverage and may not be nationally representative. To clarify, EPA uses the “entire U.S.” emission factors from the Townsend-Small study, which include the much higher Eastern U.S. (Appalachian - Ohio) emission factors. They then use these same Eastern U.S. factors

<sup>10</sup> Id. Table 1. Total Idle and Orphan Wells: All Surveyed States and Provinces (2018).

<sup>11</sup> Attachment D API Comments on EPA’s Updates under Consideration for the 2022 Inventory of Greenhouse Gas (GHG) Emissions and Sinks, November 21, 2021.

from Townsend-Small coupled with emissions from Kang 2016 to develop emission factors for Appalachian basin abandoned wells. The commenter recommends that EPA should use the more appropriate “western U.S.” emission factors for abandoned wells outside of the Appalachian basin.

- Treating outliers appropriately. Additionally, the Townsend-Small Appalachia data are dominated by one well with emissions of 146 grams/hour that is about an order of magnitude higher than any other well, plugged or unplugged, in the Townsend-Small data. The commenter contends that it is not appropriate to include this well in the emission factor for the entire US. Also, to date no emissions data are available from the state of Texas or many other major producing areas, calling into question the representativeness of the extrapolation of the results of the current studies to a nationwide estimate of the contribution of CH<sub>4</sub> emissions from Abandoned Wells to the GHGI.

Similarly, the commenter (0808-API) states that it is important to note that other parts of the U.S. government are already considering the question of outliers or super-emitters. During a recent presentation to the Health Effects Institute, the commenter reports that Natalie Pekney from the Department of Energy’s (DOE) National Energy Technology Lab (NETL) presented research showing that a comparatively small number of super-emitter wells are increasing the average emission rate.<sup>12</sup> This estimate was based on NETL’s techniques for locating undocumented orphan wells by searching for magnetic signatures (using walking, helicopters, and drones) which have been validated through field work in Pennsylvania, Oklahoma, and Kentucky. The commenter suggests that EPA may benefit from looking at NETL’s work in more detail, particularly since NETL intends to undertake more work in this area in Kentucky, New York, and Texas over the next few years.<sup>13</sup> The commenter notes that this observation would be consistent with the states’ established practice of prioritizing plugging and abandonment for individual wells; consequently, they suggest that EPA may benefit from learning more about both NETL’s research and considering how it may already be applied at the individual state level.

#### ***18.1.4 Abandoned Well Definition***

Commenter (0599-Marcellus Shale Coalition (MSC)) believes that abandoned wells do not meet the definition of an affected source for a new source performance standard (NSPS).

Commenter (0810-Petroleum Alliance of Oklahoma (Petroleum Alliance-OK)) recommends that EPA not broadly characterize wells collectively as they are very different. The commenter states that EPA broadly characterizes abandoned wells as oil or natural gas wells that have been taken out of production, which may include a wide range of non-producing wells such as idle, inactive, dormant, shut-in, and orphaned wells. The commenter explains that these wells, except for orphaned wells, typically have a responsible owner/operator but are not producing for a specific reason *e.g.*, product pricing, held by other production in the unit, or waiting on some specific activity like a workover. On the other hand, the commenter states that an orphaned well is a well

---

<sup>12</sup> Slide 8.Dr. Natalie Pekney, presentation on Health Effects Institute’s webinar concerning “Abandoned and Orphaned Oil and Gas Wells,” November 30, 2021.

<sup>13</sup> *Id.*

where there is no responsible owner/operator *e.g.*, the owner/operator has gone bankrupt.

Commenter (0808-API) notes that the IOGCC report provides helpful clarification of terminology, which is often misused in idle/orphan well conversations. The commenter encourages EPA to align its terminology with the terminology used by IOGCC to reduce confusion:

- Idle Wells. The IOGCC defines idle wells as “wells that have not been plugged and are not producing, injecting, or otherwise being used for their intended purposes.”<sup>14</sup> Similarly, IOGCC notes that “[M]any idle wells have potential for oil or gas production or associated uses.”<sup>15</sup> The future outcome for an idled well could be that it is brought into production, plugged, or converted to an injection well for enhanced oil recovery or for disposal. Most regulatory agencies set a timeline and requirements (whether statutory, by rule, or by specific written approval) for how long a well may remain idled before it must be plugged. The total number of approved idle wells reported by the states as of December 31, 2020, is 231,287, which is 14 percent of the total number of documented wells that have been drilled but not plugged.<sup>16</sup> Notably, despite including 4 more states in the 2021 report, this is down over 20 percent from the IOGCC’s 2019 figures, which featured “a total number of approved idle wells is 294,743, which is 15.6 percent of the total number of documented wells that have been drilled and not plugged.”<sup>17</sup> In the three years covered by this report, operators plugged 62,463 wells in the states.<sup>18</sup>
- Orphan Wells. IOGCC defines orphan wells as “idle wells for which the operator is unknown or insolvent. Most states and provinces have inventories of documented orphan wells and prioritize orphan wells for plugging according to risk. As of December 31, 2020, the states reported a total of 92,198 documented orphan wells, and the provinces reported a total of 5,015 documented orphan wells. In the states, the number of documented orphan wells increased by 50 percent from 2018 to 2020, due primarily to the efforts of states to document these wells through investigation and verification of the status of wells and their operators. In the three-year period from 2018 through 2020, the states plugged 9,774 orphan wells and the provinces plugged 4,930. In total through 2020, the states have plugged over 78,000 orphan wells and the provinces almost 6,300.”<sup>19</sup>
- Undocumented Wells. IOGCC identified undocumented wells as a category for further work, noting that these are mostly a historical concern. Unverified estimates “do not convey a reliable picture of the actual number or the potential associated risk. The estimates are by their nature imprecise, and many undocumented wells may not constitute a significant risk to the environment or public health and safety.”<sup>20</sup> The commenter states it is important to understand that the lack of plugging documentation for these wells does not mean they were never plugged and the lack of the locations for such wells

make any action or quantifications difficult. Thanks to modern record-keeping and regulation it is uncommon to be unable to identify the owner or operator a well. The majority of orphaned or undocumented wells occur as a result of development before the 1950s. For example, Pennsylvania is estimated to have the largest number of orphaned wells in the country, and the Pennsylvania Department of Environmental Protection (DEP) explains, “Since the first commercial oil well was drilled in Pennsylvania in 1859, it is estimated that 300,000 oil and gas wells have been drilled in the state. Only since 1956 has Pennsylvania been permitting new drilling operations, and not until 1985 were oil and gas operators required to register old wells.”<sup>21</sup>

#### ***18.1.5 Abandoned Wells in the Context of Environmental Justice***

Commenter (0573-Kansas Department of Health and Environment (KDHE)) requests that EPA consider abandoned and unplugged wells in the context of environmental justice (EJ) communities adjacent to affected facilities and that EPA incentivize appropriate well closure.

Commenter (0781-NTAA) requests that EPA work with Indian Tribes, the Department of Interior (DOI) and other federal agencies to expeditiously address orphaned and abandoned wells within Indian country. The commenter states that, with proper funding and support, Tribes can partner with EPA and other agencies to reclaim abandoned wells within Indian Country. The commenter suggests that EPA should explore funding options from potential funding streams from infrastructure funding, including a partial set-aside for Tribes from the \$150 million in the Infrastructure Investment and Jobs Act set aside for plugging and remediating orphan wells on Tribal lands. EPA’s response to this request can be provided within the supplemental proposal.

Commenter (0586-Navajo Nation Environmental Protection Agency (Navajo EPA)) requests that EPA work with the Navajo Nation and other federal agencies to expeditiously address abandoned wells on the Navajo Nation.

Commenters (0391-KBIC, 0605-Muscogee (Creek) Nation, 0943-Sault EPD, 0833-Ute EPD) request that EPA work with Indian Tribes and other federal agencies to expeditiously address abandoned wells within Indian country.

#### ***18.1.6 Support for Regulation of Emissions from Abandoned Wells***

Several commenters (0326-Private Citizen, 0391-KBIC, 0401-Mercy Investment Services, Inc. (Mercy), 0414-Waterspirit, 0435-Wespath Benefits and Investments (Wespath), 0437-New York Office of the State Comptroller (NYOSC), 0573-KDHE, 0586-Navajo EPA, 0605-Muscogee (Creek) Nation, 0723-Ceres, 0753-Institute of Governance & Sustainable Development (IGSD) and Center for Human Rights and the Environment (CHRE), 0770-Northern Plains Resource Council (NPRC), 0781-NTAA, 0795-American Lung Association (ALN) *et al.*, 0796-Asthma and Allergy Foundation of America-Michigan Chapter (AAFA-MI) *et al.*, 0833-Ute EPD, 0842-

Institute for Policy Integrity at NYU School of Law (NYU), 0844-Environmental Defense Fund (EDF) *et al.*, 0918-Colorado Local Government Coalition (COLGC), 0931-Essential Information, Inc. (Essential), 0943-Sault EPD, 1267-California Office of the Attorney General (CA AG) *et al.*, 1282-Earthworks, 1302-Wyoming Outdoor Council (WYOC) and the Powder River Basin Resource Council (PRBRC), 1330-Catskill Mountainkeeper, 1387-350 Bay Area Action (350 BAA), 1390-FTA) support EPA including requirements to reduce emissions from abandoned wells in the supplemental proposal. Some examples of specific comments provided are included in the following paragraphs.

Several commenters (0326-Private Citizen, 0401-Mercy, 0414-Waterspirit, 0435-Wespath, 0578-Grand Canyon Trust (GCT), 0753-IGSD/CHRE, 0795-ALN *et al.*, 0842-NYU, 0844-EDF *et al.*, 0918-COLGC, 0931-Essential, 1282-Earthworks, 1302-WYOC/PRBRC, 1330-Catskill Mountainkeeper, 1387-350 BAA) note the quantity of emissions and/or associated adverse health and climate impacts associated with methane and VOC emissions from abandoned wells as support for the need for regulation/mitigation of emissions.

Commenters ((0391-KBIC; 0586-Navajo EPA; 0605-Muscogee (Creek) Nation; 0781-NTAA; 0833-Ute EPD; 0943-Sault EPD) believe that EPA should also propose monitoring at abandoned and orphaned wellhead only well sites, which also release emissions.

Commenter (0918-COLGC) supports EPA's intention to issue a supplemental proposal in 2022 that will provide proposed regulations for additional sources of pollution of methane and VOC emissions from the oil and natural gas sector. The commenter notes that the EPA estimates that the U.S. population of abandoned wells (including orphaned wells and other non-producing wells) is around 3.4 million (with around 2.7 million abandoned oil wells and 0.6 million abandoned gas wells). EPA points out that wells that are plugged have much lower average emissions than wells that are unplugged (less than 1 kg CH<sub>4</sub> per well per year, versus over 100 kg CH<sub>4</sub> per well per year). Around 40 percent of the abandoned well population in the United States is plugged.

The commenter (0918-COLGC) notes that studies show idle and plugged wells can be super-emitters. A review of recent studies demonstrates an emerging consensus that inactive and plugged wells have the potential to emit methane. For this reason, the commenter supports the inclusion of abandoned and unplugged wells in EPA's upcoming supplemental proposal.

The commenter (0918-COLGC) reports that a 2016 study found that plugged and idle wells contributed 0.1 percent to 0.2 percent of methane emissions in the Denver-Julesburg Basin. It also concluded that methane samples from wells were from both natural gas and coalbed methane, indicating that there was a mechanism allowing for underlying coal formations to vent or leak methane into the wellbore. Another study found:

99% of emissions from plugged wells are attributable to the top 10% of emitters (super emitters), and. . . overall, the top 10% of emitters contribute to 96% of methane emissions from idle wells as a whole. Specifically, the 10 highest emitting wells with over 100 grams per hour of emissions contributed 65% of cumulative emissions from all studies.

Lastly, the commenter (0918-COLGC) states that the 2018 EPA GHG Inventory found that plugged wells emit less than 1 kilogram of methane per year, and that unplugged wells emit over 100 kilograms of methane per year. A 2020 study calculated an average emissions factor of 96 grams per day (equivalent to 4 grams per hour) for plugged wells, but found that this was skewed by a single plugged well that was leaking 1900 grams per day (79 grams per hour). The Colorado Oil and Gas Conservation Commission (COGCC) conducted a literature review in connection with their recent Financial Assurances rulemaking of multiple published, peer-reviewed and state-government scientific studies of methane emissions from idle, plugged, and active wells. These studies reflect that “super-emitter” wells have a significant impact on mean/median emissions values. Super-emitters are wells with a significant integrity issue or other problem that results in substantially higher emissions than other similarly situated wells. The commenter asserts that unplugged wells pose multiple risks to the environment, including methane and other harmful hydrocarbon leaks.

Commenter (0844-EDF *et al.*) appreciates EPA’s attention to this issue. The commenter is strongly in favor of EPA minimizing emissions from abandoned wells and urges EPA to explore various options to minimize emissions from abandoned wells. The commenter reports that abandoned wells that are improperly plugged or not plugged are a significant source of emissions and may pose a safety threat. EPA estimates there are 2.1 million unplugged and abandoned wells nationwide emitting methane into the atmosphere. EPA further estimates that these wells emitted 55,000 metric tons of methane in 2019 alone, and other studies suggest that the number may be much higher. The commenter notes that many wells are orphaned or owned by entities that cannot pay to properly plug them, leaving that task to states and taxpayers—and the price tag can be hefty. According to a 2010 Government Accountability Office (GAO) report, between 1988 and 2009, the Bureau of Land Management (BLM) reclaimed 295 orphaned wells and spent an average of \$12,788 per well, with costs ranging as high as \$582,829 for a single well.

Commenter (1302-WYOC/PRBRC) notes that according to estimates from the Wyoming Oil and Gas Conservation Commission, Wyoming has over 1,300 documented abandoned oil and gas wells on state or private lands alone.<sup>22</sup> This number is certainly an undercount of the true total found across all jurisdictions. Unfortunately, orphaned and abandoned wells can be significant emitters of methane and other harmful gasses as well as a public liability and hazard. In future rules, the commenter recommends that EPA structure regulatory requirements to ensure responsible maintenance and closure as well sites reach the end of their productive and economically viable lives.

Commenter (0578-GCT) recommends EPA require monitoring and plugging at abandoned and improperly plugged wells, not only will this create jobs within the oil and gas industry, it will also protect the health, safety, and environment of surrounding communities. The commenter notes that Colorado Plateau counties collectively are home to over 8,000 abandoned/orphan oil and gas wells. These wells often have no owner, and no party legally responsible for cleanup.

Commenter (0753-IGSD/CHRE) supports EPA’s intention to include abandoned and unplugged wells in the final rule. Because of their persistent emissions and interconnectivity with other oil and gas sources, they believe that abandoned and unplugged wells are properly regulated as a

---

<sup>22</sup> Wyoming Oil and Gas Conservation Commission. Orphaned Well Site Plugging, Remediation, and Restoration.

source within the Crude Oil and Natural Gas source category under the Clean Air Act (CAA) section 111. To fulfil its CAA mandates, the commenter recommends that EPA propose and finalize regulations that protect communities from the harms caused by abandoned and unplugged wells and hold well owners accountable to the greatest extent possible. The commenter recommends that EPA promulgate stringent requirements for new and idled wells that can be quickly implemented to prevent tens of thousands (or more) wells from being abandoned and sitting unplugged for years. According to one study, “In the U.S. from 2000 to 2013, an average of 18,600 wells were abandoned per year....”<sup>23</sup> The U.S. GHGI found that abandoned gas wells (including orphaned and other non-producing wells) in the U.S. had increased by 84 percent from the 1990s, leading to a 38 percent increase in methane and carbon dioxide (CO<sub>2</sub>) emissions from abandoned gas wells.<sup>24</sup> In a recent release, the commenter reports that the Department of Interior counted more than 130,000 abandoned or orphaned wells—more than double the figure it had announced in 2019.<sup>25</sup> As EPA notes in the November 2021 Proposal, the GHGI estimates that around 3.4 million abandoned oil and gas wells were responsible for 264 kilotons (kt) of methane in 2019.<sup>26</sup> Substantial as those numbers are, the commenter suggests they are likely grossly underestimated.<sup>27</sup> Using geospatial and statistical analysis, a 2021 report concluded that the actual magnitude of methane emissions from abandoned oil and gas wells is likely 20 percent more than EPA estimates.<sup>28</sup> Experts also worry

---

<sup>23</sup> Williams J.P., Regehr A., & Kang M. (2021) Methane Emissions from Abandoned Oil and Gas Wells in Canada and the United States, ENVIRON.SCI. & TECH. 55:563–570, 568 (“In the U.S. from 2000 to 2013, an average of 18,600 wells were abandoned per year, with a maximum of 35,500 in 2008 and a minimum of –4000 in 2009. The negative numbers of AOG wells drilled per year, represent a decrease in total AOG well numbers, and is likely a result of idle/inactive wells being re- entered into the production life cycle. Overall, the growing number of AOG wells implies that methane emissions from AOG wells are likely to be increasing.”).

<sup>24</sup> EPA (2021) U.S. Inventory of Greenhouse Gas Emissions and Sinks 1990-2019, 3-111.

<sup>25</sup> Budryk Z. (5 January 2022), Interior: US has twice as many abandoned oil and gas wells as previously thought, THE HILL (“In a memo Wednesday, the department said there are currently more than 130,000 documented abandoned, or orphaned, wells. Comparatively, a 2019 report from the Interior documented a total of 56,600 orphaned wells across 30 states. Across the entire country they found that the number of abandoned wells in that report ranged from zero to 13,226.”).

<sup>26</sup> EPA (2021) U.S. Inventory of Greenhouse Gas Emissions and Sinks 1990-2019, 3-111, tbl. 3-96 (2021).

<sup>27</sup> Williams J.P., Regehr A., & Kang M. (2021) Methane Emissions from Abandoned Oil and Gas Wells in Canada and the United States, ENVIRON. SCI. & TECH. 55:563–570, 568 (“Our estimates for annual methane emissions from AOG wells are consistently higher than those reported in the latest inventory report by 150%2 for Canada and by 20% for the U.S.1 The reasons for the larger degree of underestimation in the Canadian inventory are due to our use of a larger number of wells and higher emission factors. In contrast, the difference in the U.S. inventory is primarily due to our use of a larger number of wells. Nevertheless, emissions factors for the “entire U.S.” relied on data that were not distributed throughout the country but focused on western states, Wyoming, Utah, and Colorado and missing data from major oil- and gas-producing states such as Texas, Oklahoma, and California.”); Kang M., et al. (2021) Orphaned oil and gas well stimulus—Maximizing economic and environmental benefits, ELEMENTA 9:1–13, 3 (“According to state and provincial/territorial records, there are 4,653,000 historic and active oil and gas wells in the United States and another 788,000 in Canada (Tables S3 and S4). Of these, 1,954,000 (42%) and 313,000 (40%) wells are active in the United States and Canada, respectively. In the active well counts, we include wells drilled for enhanced recovery (e.g., injection wells) and disposal wells (e.g., saltwater disposal well that was formerly producing gas) in addition to those drilled to produce oil and gas. In the United States, 1,519,000 (33%) wells are plugged; while in Canada, 351,000 (45%) are plugged. Thus, two of three wells ever drilled in the United States are currently inactive, but only one in three are plugged (Tables S3 and S4).”)

<sup>28</sup> Williams J.P., Regehr A., & Kang M. (2021) Methane Emissions from Abandoned Oil and Gas Wells in Canada and the United States, ENVIRON. SCI. & TECH. 55:563–570, 569 (“Our estimates for annual methane emissions from AOG wells are consistently higher than those reported in the latest inventory report by 150%2 for Canada and

that the spate of oil and gas exploration and production companies that filed for bankruptcy or receivership in early 2020 may lead to an increase in abandoned wells.<sup>29</sup>

Commenter (0414-Waterspirit) asserts that indirect, direct, and cumulative emissions need to be considered.

Commenter (0723-Ceres) urges EPA to ensure strong methane emission performance standards by crafting a regulation that ensures abandoned wells are properly plugged at the end of their productive lives and do not leak methane in perpetuity.

Commenter (0326-Private Citizen) states that EPA must include many omitted methane sources in this proposal to ensure that the improvements due to increased monitoring are not offset by exemption loopholes and non-comprehensive oversight.

Commenters (0391-KBIC, 0781-NTAA, 0586-Navajo EPA, 0605-Muscogee (Creek) Nation, 0943-Sault EPD, 0833-Ute EPD) support: (1) the proper closure of abandoned oil and natural gas wells and restoration of the well site; (2) periodic inspection, and (3) monitoring of abandoned wells capable of emitting. The commenters also support requirements for owners/operators to submit a closure plan describing how the well would be closed and financial assurance or bonding to assure compliance with closure requirements.

Commenter (0573-KDHE) requests that EPA consider a program for capping abandoned wells to ensure those wells are properly closed and not leaking.

Commenter (0437-NYOSC) recommends that EPA develop a comprehensive policy that achieves significant emission reductions throughout the natural gas value chain and addresses emissions from the full complement of oil and gas production wells, including older, lower-producing wells and inactive or abandoned wells.

Commenter (1267-CA AG *et al.*) supports EPA's adoption of new source performance standards and emission guidelines that require fugitive emissions monitoring of idled and unplugged wells.

---

by 20% for the U.S.<sup>1</sup> The reasons for the larger degree of underestimation in the Canadian inventory are due to our use of a larger number of wells and higher emission factors. In contrast, the difference in the U.S. inventory is primarily due to our use of a larger number of wells. Nevertheless, emissions factors for the "entire U.S." relied on data that were not distributed throughout the country but focused on western states, Wyoming, Utah, and Colorado and missing data from major oil- and gas-producing states such as Texas, Oklahoma, and California.").

<sup>29</sup> E.g. Kang M., et al. (2021) Orphaned oil and gas well stimulus—Maximizing economic and environmental benefits, *ELEMENTA* 9:1–13, 2 ("In the first half of 2020, 30 oil and gas exploration and production companies filed for bankruptcy or receivership in the United States and Canada (Tables S1 and S2). Across the United States and Canada, these companies operate 116,245 wells in 32 states and four Canadian provinces/territories, with the most in California (37,620), Texas (16,529), and Oklahoma (12,258; Figure 2). Wells operated by companies going bankrupt are not necessarily orphaned but may change ownership or continue to produce within the restructured company (Schuwerk and Rogers, 2020). In some cases, wells change hands multiple times before being abandoned. As a result, available data cannot yet be used to understand precisely how many of the wells operated by bankrupt companies are being, or will be, orphaned across the United States and at what timescale (Figure S2). Nevertheless, data from Alberta show that a drop in oil price leads to an increase in the number of orphaned wells in the following approximately 3 years (Figure S3).")

Commenter (0770-NPRC) urges EPA to establish new standards to ensure oil and gas wells are properly shut down and plugged, to prevent them from leaking in perpetuity and to prevent closure costs from falling to taxpayers later. The commenter states that EPA has an obligation to strengthen its November 2021 Proposal and advance rules that leave no loopholes nor future opportunities for methane pollution from oil and gas infrastructure. The commenter notes that, as one testifier at EPA’s December public hearing noted, “[w]e have learned that most oil and gas operators only respond to that which is required by rule or law.”

Commenter (1390-FTA) recommends that locating and plugging should be approached with the utmost sense of urgency. Currently, the commenter suggests there exists a disincentive for states to locate and plug such wells, as they become the responsible party in the absence of a viable operator. They add that this perhaps explains why the official list of orphaned and abandoned wells in Pennsylvania is only 8,959 wells,<sup>30</sup> or about 1.2 percent of the estimated total of these wells. DEP has only been able to find resources to plug just a handful of wells<sup>31</sup> in recent years – to plug the full inventory would take millennia at this rate. Pennsylvania is shown as an example here; the commenter is aware that other oil and gas producing states find themselves in a similar predicament. It is the commenter’s opinion that those who seek to exacerbate the methane pollution crisis by drilling new wells should pay for the locating and plugging of wells. And yet, they believe that models based on permit fees can never suffice without drilling hundreds of thousands of new wells, thereby making the methane crisis all that much worse.

Commenter (1267-CA AG *et al.*) supports and strongly encourages EPA to address emissions from abandoned wells at the federal level through NSPS and EGs. The commenter supports EPA’s adoption of NSPS and EGs that establish uniform federal requirements to minimize or eliminate emissions from abandoned wells, including by establishing as the Best System of Emission Reduction (BSER) work practice or operational standards designed to prevent wells from becoming improperly abandoned in the first instance. The longer wells are allowed to remain idle, the greater the potential for them to deteriorate and leak or become orphan wells. Thus, the NSPS and EGs should limit as the BSER the time that operators are allowed to idle wells and require strict management plans for idled wells to ensure that wells are properly plugged and do not become orphan wells.

Commenter (0842-NYU) recommends that EPA propose supplemental standards to cover abandoned wells, flares, and other equipment within the oil and gas source category. Given the broad definition of the source category, and this additional equipment’s large contribution to methane emissions, the commenter recommends that EPA issue any additional standards that the agency determines are cost-benefit justified. The commenter believes that EPA should regulate these additional sources to the extent that doing so will increase net benefits for society. The commenter notes that additional sources undoubtedly fit within the oil and gas source category, as EPA has already concluded that the category is broad enough to include any equipment that is

<sup>30</sup> Pennsylvania Department of Environmental Protection Abandoned and Orphaned Well Report. [http://cedatareporting.pa.gov/Reportserver/Pages/ReportViewer.aspx?/Public/DEP/OG/SSRS/Abandoned\\_Orphan\\_Web](http://cedatareporting.pa.gov/Reportserver/Pages/ReportViewer.aspx?/Public/DEP/OG/SSRS/Abandoned_Orphan_Web).

<sup>31</sup> “DEP Well Plugging Program.” Pennsylvania DEP. <https://www.dep.pa.gov/Business/Energy/OilandGasPrograms/OilandGasMgmt/LegacyWells/Pages/Well-Plugging-Program.aspx>.

part of the sequence of functions that are interrelated and necessary for getting distributed gas ready for distribution. Furthermore, the commenter states that the benefits of regulating these additional sources standards are likely substantial, as EPA recognizes that abandoned and unplugged wells, flares, pipeline pigging operations, and tank truck loading operations generate significant methane emissions. Abandoned and idled wells have a particularly strong need for federal regulation given that such idling is frequently the result of market failures due to owner/operator bankruptcy with insufficient bonding or market conditions making continued production unprofitable.

Commenter (0842-NYU) contends that proposing supplemental standards for these sources would better fulfill EPA's statutory mandate to determine the best overall system of emission reduction for the source category, as well as with President Biden's recent memorandum reaffirming the principles of Executive Orders 12,866 and 13,563—including that agencies should select regulatory alternatives that “maximize net benefits” while also accounting for distributive impacts and equity. Accordingly, the commenter recommends that EPA fully evaluate the costs and benefits to controlling emissions from these additional sources and propose supplemental standards to the extent that such controls are net beneficial.

Commenter (0326-Private Citizen) recommends that EPA propose a jobs program to plug abandoned oil wells. The commenter suggests that one of the largest emitters of methane originates from unproductive oil wells. Leakage from abandoned oil and gas wells was estimated to be the third largest source of emissions in the industry by the Agency yet the November 2021 Proposal sets no requirements for plugging the 2.1 million inactive wells across the country. These numbers, according to the commenter, are likely to grow as oil production declines with the pandemic and as we move to cleaner sources of energy in the coming years, are already unmanageable by state budgets or current manpower. For this reason, the commenter notes that emerging methane mitigation objectives must be understood as job-creating opportunities. Some local governments abroad have already implemented well-plugging programs. Last spring, the government of Alberta in Canada financed a non-profit organization initiative to plug 1000 wells in the province, thereby creating 500 direct or indirect jobs. Given the scale of the abandoned wells problem in the U.S. however, the efficiency of a jobs program would require a better definition of abandoned wells. The commenter notes that EPA's November 2021 Proposal provides a broad definition of abandoned wells: “a wide range of non-producing wells (...) includes wells that state governments classify as idle, inactive, dormant, or shut-in, but not plugged.” This category mixes new, deeper, shale wells which would be more expensive to plug with wells abandoned since the 19th century. It also mixes inactive wells with known owners to “orphaned” sites. Since the plugging cost will likely vary according to the well's age and will be distributed differently depending on ownership, the commenter recommends that EPA provide a more precise definition of abandoned wells to allow more accurate impact analyses for future rulemaking.

The commenter (0326-Private Citizen) states that a well-plugging program's feasibility is also dependent on identifying an attainable target of leaking inactive wells. Fortunately, the reality is that not all wells are high emitters: one study found that only 16 percent of leaks account for 98 percent of methane emissions from idle wells. To focus efforts on high emitters, the first step is to incentivize the deployment of nationwide measurements of methane from abandoned wells.

This would provide more data on the number and location of wells to target as well as the volume of emissions that can be mitigated. The commenter recommends that EPA create a carbon offset program which attributes carbon credits to well-plugging projects according to methane leakage levels. This market-based incentive would require participating companies, non-profit organizations, and researchers to measure methane leaks and thus increase investments in technology to scale up leakage monitoring.

Commenter (0795-ALN *et al.*) provides that studies have found high rates of methane leakage from abandoned wells. For example, a study of inactive wells in Pennsylvania estimated the number of abandoned wells in that state to be between 470,000 and 750,000, significantly higher than previous estimates. The study estimated that, overall, Pennsylvania's abandoned wells contributed between five and eight percent of the state's annual greenhouse gas emissions.<sup>32</sup> A study of abandoned oil and gas wells in California found 124,000 abandoned wells. Based on measurements from a representative sampling of those wells, the study found that those with the highest leakage rates released enough methane to substantially impact the state's methane budget.<sup>33</sup>

Commenter (0795-ALN *et al.*) notes that methane leakage from abandoned wells varies widely, with a few high emitters responsible for a disproportionately large share of the problem. A 2020 study by a research team from McGill University in Canada collected and analyzed data on methane emissions from almost 600 abandoned wells in the United States and Canada, then extrapolated a cumulative total. The research team concluded that 96 percent of cumulative emissions came from 10 percent of wells, with unplugged abandoned gas wells being the highest emitters. While noting uncertainty about the actual quantity of these emissions, given that few abandoned oil and gas wells have been measured for leakage, the study indicated that for the U.S., methane emissions from abandoned wells were 20 percent higher than previously estimated.

Commenter (0795-ALN *et al.*) states that there are currently no federal regulations to require monitoring methane emissions from inactive and abandoned wells, although some states have their own requirements. Nor does the federal government currently govern the remediation of orphaned wells.<sup>34</sup> The commenter explains that states require oil and gas companies to put up bonds for well plugging prior to the onset of drilling, but the amounts of these bonds often fall dramatically short of the costs. In many cases, according to a California news report, "companies have no incentive to spend more money, and essentially walk away, leaving the responsibility and costs to state and federal governments."<sup>35</sup> The commenter notes that, as a consequence, as a

<sup>35</sup> Mark Olander, "Oil Bankruptcies Leave Environmental Cleanup Bills to California Taxpayers," *Desert Sun*, June 25, 2021, <https://www.desertsun.com/in-depth/news/environment/2021/06/25/oil-bankruptcies-leave-environment-cleanup-california-taxpayers/4977647001/>.

journal article noted, “Government agencies responsible for well plugging often face funding shortfalls and many orphaned wells remain unplugged.”<sup>36</sup>

Furthermore, the commenter (0795-ALN *et al.*) believes that oil and gas well owners should be held responsible for the prompt cleanup of their wells, and action should be taken promptly, as the risk of methane leaks increases as inactive wells age. The commenter asserts that strengthening monitoring requirements to require all wells to be subject to frequent leak detection and repair inspections, prohibiting the routine flaring of associated gas at oil and gas sites, engaging frontline communities and other observers in documenting pollution and emissions and addressing methane’s climate impact utilizing the all-important 20-year timeframe would strengthen EPA’s efforts to protect us from climate change and would convey immediate health benefits by reducing air pollution.

Commenter (0940-Responsible Drilling Alliance (RDA)) asks EPA to carefully consider the written comments of companies engaged in emission detection and mitigation, such as the one submitted by Smith Analytical. According to the commenter, Smith claims its methane/VOC mitigation system is far more cost effective than well plugging and can also be used for emissions from problematic equipment in active wells to eliminate methane, VOC, and hazardous air pollution (HAP) emissions with 99 percent effectiveness. The commenter urges EPA to test and consider such methods.

Commenter (0931-Essential) states that the 2021 GHGI estimates that in 2019 there were around 3.4 million abandoned wells (including orphaned wells and other non-producing wells). Of these, 2.7 million are abandoned oil wells and 0.6 million are natural gas. These non-producing wells often have significant and damaging methane, CO<sub>2</sub>, and VOC emissions. The GHGI estimates that abandoned oil wells emitted 209 kt of methane and 4 kt of CO<sub>2</sub> in 2019, while abandoned gas wells emitted 55 kt of methane and 2 kt of CO<sub>2</sub> in that year.

Commenter (1390-FTA) is concerned that the mechanism of having the various states act as the means of enforcement of the regulations puts the efficacy of the entire guidance in question. The commenter advises adding provisions to hold the states themselves accountable, so that the numerous shortcomings of co-regulation are not repeated. The commenter notes one glaring example of this failed co-regulation dynamic is the Underground Injection Control (UIC) program, which regulates fluid subterranean fluid injections. EPA has shared authority and responsibility with the various states in a patchwork system of primacy.<sup>37</sup> Based on the language of the November 2021 Proposal, the commenter is concerned that the mechanism for regulating methane emissions by sharing responsibility with the states from oil and gas sources will follow down this same foreboding path. The results of this model have been disastrous. In some states, UIC wells are permitted to in such quantities and permitted to inject in such volumes that

<sup>37</sup> “Primary Enforcement Authority for the Underground Injection Control Program.” Environmental Protection Agency. <https://www.epa.gov/uic/primary-enforcement-authority-underground-injection-control-program>.

widespread seismic activity has become commonplace. In others, affected neighbors dealing with ongoing health or environmental degradation must deal with both agencies, both of which frequently seem eager to claim that they are not responsible for overseeing the issue at hand. The system outlined in the proposed regulations seem like they could be designed in a similar way, with EPA providing emissions guidance to the various states, leaving enforcement up to them. As with the UIC program, any ambiguity with respect to which agency is in charge is likely to lead to inconsistencies, data gaps, and overall poor regulation. The commenter thinks that if EPA wishes to pursue a joint regulation with the states that they should do so with extreme caution, and that the various states must be held accountable for upholding their delegated authority. Without such enforcement mechanisms in place, the proposed rules are likely to be far less effective, and damaging emissions would therefore likely continue in a nearly unimpeded fashion.

#### ***18.1.7 Implications of Exempting Wells from Monitoring Under Fugitives Monitoring Requirements***

Commenter (0578-GCT) notes that EPA's recommendation not to monitor oil and gas wells that produce under 3 tons per year (tpy) of emissions each year leads to exempting declining sites such as abandoned oil and gas wells, as many of these wells produce less than 3 tpy per year of methane emissions.<sup>38</sup> The commenter reports that abandoned wells contribute a significant amount of emissions to the atmosphere. Like active wells, they emit methane and VOCs and HAPs which are known to harm human health. There are also documented incidents where methane from abandoned wells has made its way into nearby homes causing explosions.

Commenter (1390-FTA) states that major gaps remain in the November 2021 Proposal. The regulations appear to fully allow methane emissions at any well site that does not exceed 3 tpy. One problem with this is the very high number of oil and gas wells that are orphaned and abandoned that exist in unverified locations, which cannot be effectively regulated if they cannot be found.

Commenter (0844-EDF *et al.*) asserts that the November 2021 proposed exemption from regular monitoring for sites below 3 tpy is problematic for end-of-life well issues. Exempting these sites from federal regulatory standards enables strategic asset transfers that perpetuate the cycle of improper abandonment and orphaning.<sup>39</sup> When smaller and declining sites are exempt from standards that apply to all other wells, it creates a perverse incentive to keep those wells in production for far longer than if the true costs were internalized. It also allows operators to forgo upkeep and maintenance required by methane regulations, creating high-emitting and dangerous site conditions. With no federal regulatory oversight and highly inconsistent state oversight,<sup>40</sup> operators often keep wells open beyond when they otherwise might in order to avoid the cost of plugging; many such wells would likely not be profitable if they were obligated to internalize

---

<sup>40</sup> Ho et al., Managing Environmental Liability: An Evaluation of Bonding Requirements for Oil and Gas Wells in the United States, 52 Env. Sci. Tech. 3908 (2018), <https://pubs.acs.org/doi/10.1021/acs.est.7b06609>.

plugging costs. Many of these companies go bankrupt, leaving taxpayers holding the bag.<sup>41</sup> Exemptions for these sites allow operators to avoid yet another cost and disincentivize proper closure.

The commenter (0844-EDF *et al.*) uses the following definitions:

*An abandoned well* is a well that is not producing, and that the operator does not presently intend to return to production.

*An orphan well* is an abandoned well where the operator or owner is insolvent or unknown.

*A plugged well* is a well that is no longer in production and has been plugged.

*A shut-in well* is a well where the valves have been closed so it is not producing.

*A wellhead only* is a well where all equipment has been removed other than the Christmas tree piping.

Under CAA section 111, the commenter (0844-EDF *et al.*) states that EPA may define “affected facilities” in various ways and set the parameters that a source must meet to qualify as an affected facility.<sup>42</sup> For example, EPA has allowed operators to remove all major production and processing equipment from a well site to become a “wellhead only” site, which is not an affected facility for purposes of fugitive monitoring.<sup>43</sup> The commenter recommends that EPA clarify in the well site affected facility definitions that any well which has not been properly plugged with cement according to the applicable state or federal standards is still an affected facility subject to leak detection and repair (LDAR) and any other applicable standards.<sup>44</sup> This would incentivize proper closure because it would provide an off-ramp from affected facility status, allowing operators to avoid incurring compliance costs that would otherwise be mandatory. Operators of shut-in or abandoned wells would thus be forced to choose between compliance costs and plugging, rather than remaining in a potential gray area and doing neither.

The commenter (0844-EDF *et al.*) notes that the wellhead only exemption from LDAR is another potential barrier to this approach because many idle or abandoned wells will satisfy this definition and have little incentive to plug. The commenter recommends that EPA could resolve this problem easily by eliminating the wellhead only exemption. If EPA retains that exemption, it will have to otherwise address this issue, potentially by setting time limits on the applicability of the exemption or requiring reporting on the status of these wells.

---

<sup>41</sup> Alex Wolf, Bankruptcies Fueling Environmental Crisis at Abandoned Oil Wells, Bloomberg Law (Sept. 2, 2021), <https://news.bloomberglaw.com/bankruptcy-law/bankruptcies-fueling-environmental-crisis-at-abandoned-oilwells> (“More than 260 domestic oil producers filed Chapter 11 over a six-year period . . . . Many distressed fossil fuel companies are passing environmental obligations on to government bodies . . .”).

<sup>42</sup> See 42 U.S. Code § 7411(a).

<sup>43</sup> 40 CFR § 60.5430a.

<sup>44</sup> EPA might consider a variance from this requirement for orphaned wells that are already on a list to be plugged.

Commenter (1267-CA AG *et al.*) notes that, according to EPA, most idled and non-producing wells would be classified as wellhead only, which EPA is proposing to exclude from LDAR requirements. The commenter recommends that any idled “wellhead only” well should no longer be exempt from LDAR requirements given the risks associated with allowing wells to remain idled for long periods and to incentivize owners and operators to either produce or plug wells. The commenter recommends that EPA consider removing the “wellhead only” exemption entirely. Although “wellhead only” well sites have less ancillary equipment and therefore fewer fugitive emissions components, the wellhead itself does have emissions and should be inspected for leaks.<sup>45</sup> The commenter states that California’s regulation requires quarterly monitoring of “wellhead only” well sites,<sup>46</sup> which demonstrates feasibility of these requirements.

### ***18.1.8 Specific Abandoned Well Requirement Recommendations***

Several comments (1270-League of Women Voters of the United States (LWVUS), 0756-Baker Hughes, 0795-ALN *et al.*, 0828-Union of Concerned Scientists (UCS), 0918-COLGC, 0931-Essential) were received that provided specific recommendations for approaches to regulating/mitigating emissions from abandoned wells.

#### **18.1.8.1 Well Closure/Plugging Requirements**

Comment: Commenter (0931-Essential) recommends that EPA require owners to plug wells and restore well site for any well that is non-producing for four years that is producing methane emissions or VOC emissions of 1 tpy or more. The commenter explains that this four-year window gives owners adequate time to take a well temporarily out of production, and to decide whether they will invest more to seek to increase production, or to close up a well site. The commenter suggests that having an emissions guideline threshold should also put it within the purview of these rules.

Commenter (0756-Baker Hughes) recommends properly isolating zone(s) with flow potential deeper in the well before closing the well to the atmosphere near the surface. The commenter explains that, if only closing to the atmosphere (and not deeper in the well) there will be a risk of future leakage over time when corrosion compromises the casing integrity and formation near the surface cannot contain the well pressures from below.

The commenter (1270-LWVUS) explains that gas wells that are no longer in use can leak significant amounts of methane, along with aromatic hydrocarbons and water contaminated with toxic compounds-- either added during hydraulic fracturing or dissolved from deep in the earth. EPA studies,<sup>47</sup> as well as many others, have shown that unplugged or inadequately plugged wells

---

<sup>45</sup> Emissions from Oil and Gas Production Facilities, TCEQ Contract 582-7-84003, Prepared by Eastern Research Group, Inc., Aug. 31, 2007, available at [https://www.tceq.texas.gov/assets/public/implementation/air/am/contracts/reports/ei/582078400\\_3FY0701-20090831-erg-i-ei\\_from\\_old\\_gas\\_facilities.pdf](https://www.tceq.texas.gov/assets/public/implementation/air/am/contracts/reports/ei/582078400_3FY0701-20090831-erg-i-ei_from_old_gas_facilities.pdf). Wellhead emissions were estimated using emission factors, wellhead counts, and production data.

<sup>46</sup> See Cal. Code Regs. tit. 17, § 95669.

<sup>47</sup> Table 3-101 in <https://www.epa.gov/sites/default/files/2021-04/documents/us-ghg-inventory-2021-maintext.pdf?VersionId=yu89kg1O2qP754CdR8Qmyn4RRWc5iodZ>.

are a major source of methane emissions. A 2021 analysis by Reuters<sup>48</sup> indicated that in 2018 there were more than 3.2 million abandoned wells in the U.S. that emitted a total of 281 kilotons of methane that year. This was estimated to have the same global warming potential as the amount of oil used in one day in our country. This problem will grow significantly in the near future as many wells drilled in the past decade become insufficiently productive to be economically sustainable.

The commenter (1270-LWVUS) states that cement plugs are currently considered to be the best solution to stopping the leaks. A program to locate wells that are not plugged or improperly plugged, and ensure that they are appropriately capped- off, is necessary. Follow-up measurements will be needed on newly plugged wells because there are many factors that can interfere with formation of a strong, stable cement barrier. The cement must adhere firmly to the top of the wellhead and must also be free of contaminants such as drilling mud that could lead to the formation of leaks within a few years.<sup>49</sup>

The commenter (1270-LWVUS) adds that efforts to ensure that all wells remain properly plugged must continue on a long-term basis, because the cement plugs used on the wells have limited lifetimes, even when they are made using the best current practices. In general, cement plugs undergo environmental degradation resulting in a half-life of approximately 50 years. However, leakage may continue for many decades, or even centuries.<sup>50</sup>

Commenter (1270-LWVUS) states that since about 2015 there has been a steady increase in the use of longer laterals in horizontal drilling. This has led to significant increases in the flow of natural gas or oil. These increases lead to the use of more fracking fluid under higher pressure and thus these wells cost much more to plug.

Commenter (0756-Baker Hughes) provides details on proper well plugging. The commenter notes that requirements to properly plug wells vary across the world; nevertheless, there is broad industry understanding that wells are best sealed by "restoring the caprock."<sup>51</sup> This means placing a permanent barrier across the wellbore - effectively sealing all annuli and inside of the well - above a zone with flow potential. The caprock is a sealing formation, impermeable and with adequate strength to contain future pressures. The barrier material needs to be selected with permanence in mind, suitable for sealing in the specific wellbore environment. Barrier verification confirming the successful placement and isolation from the zone with flow potential is required. It is common to place a primary and secondary barrier above the zone(s) with flow potential.

<sup>50</sup> *Ib.*

<sup>51</sup> See API Recommended Practice (RP) 65-3, 1st Edition, Wellbore Plugging and Abandonment.

#### 18.1.8.2 Monitoring of Inactive and Abandoned Wells

Commenter (0918-COLGC) recommends that EPA issue a supplemental proposal requiring quarterly inspections of idle (*i.e.*, inactive, or temporarily abandoned), and annual inspections of plugged wells to detect and repair leaks.

To address leaks, and in particular super emitters, from idle and plugged wells, the commenter recommends the following:

- (1) Quarterly inspections of idle wells using optical gas imaging equipment or other technology capable of detecting surface leaks from idle wells; and
- (2) Annual inspections for plugged wells.

The commenter (0918-COLGC) notes that these recommendations reflect that properly plugged wells should not leak, and thus do not need to be inspected as frequently as idle wells. The commenter asserts that a quarterly inspection requirement for idle wells is consistent with EPA's November 2021 Proposal for producing wells, and since idle wells can be put back into production at any time and may or may not be subject to state requirements that can minimize the likelihood of leaks such as state inspection requirements, the commenter believes a quarterly inspection requirement is appropriate.

Commenter (0828-UCS) recommends, at a minimum, that EPA require periodic monitoring to identify potential leaks, and to ensure that there is a comprehensive well closure plan in place such that the nation's orphaned and abandoned well crisis gets no worse. The commenter states that for too long, the oil and gas industry has been allowed to abandon wells with impunity, repeatedly offloading the responsibility of well closure onto the general public at towering economic, health, and environmental costs. The commenter asserts that, while the country is now advancing efforts to remediate existing orphaned wells and multiple jurisdictions have or are revising some of the contributing factors that enabled such widespread abandonment, the fact is the threat of continued abandonments remains, and given their ongoing methane leakage, EPA has a responsibility to ensure standards reach this class of existing sources.

Commenter (0795-ALN *et al.*) encourages EPA to require that abandoned wells be monitored for methane leaks and, if found leaking, that they be plugged. Abandoned oil and gas wells – those that are not productive and have not been properly plugged – are among the high-volume methane emitters. The commenter adds that “orphaned” wells, which are abandoned wells whose owners are bankrupt or cannot be found, are also high-volume methane emitters.

Commenters (0757-Private Equity Stakeholder Project (PESP), 1282-Earthworks) argue that EPA must require monitoring and plugging of abandoned wells that are leaking methane. The commenter states that, according to a Reuters investigation, which conducted a comprehensive review of all available data in 2020, orphaned and abandoned wells in the United States were collectively responsible for emitting 281,000 tons of methane into the atmosphere in 2018. While orphaned wells no longer have an identifiable owner, abandoned wells are typically defined as an unproductive well with a known owner/operator. The commenters recommend that EPA require

twice-a-year monitoring at idle and unplugged wells, while also including a requirement for companies to submit comprehensive well closure plans in order to properly cap wells at their end of life.

#### 18.1.8.3 Bonding Requirements

Commenter (0931-Essential) recommends that EPA mandate bonding requirements for each new oil and gas well, of an amount sufficient to cover periodic monitoring, the full future costs of plugging and dismantling an oil or gas well, and complete restoration of the well site. The recommendation is in response to environmental concerns. The commenter notes that EPA recognizes that orphaned and abandoned oil and gas wells represent a major environmental problem. Furthermore, according to EPA data, “bonding requirements represent only a fraction of the actual costs to plug the well and restore the well site.”

#### 18.1.8.4 Liability for Costs of Plugging Wells

Commenter (0734-ATS) recommends that in a future version of this rule or in a separate rulemaking that EPA outline steps to ensure that companies are liable for the costs of plugging new and existing wells and mines. The commenter asserts that these protections must be built into the cost of new projects, and regulatory approvals should not proceed without clear allocation of funds for this purpose. The commenter recommends that future regulations and legislation outline mechanisms for industrial responsibility that curbs the ongoing proliferation of these polluting and dangerous sites across the country.

Commenter (0753-IGSD/CHRE) encourages EPA to use its broad authority under CAA section 111 to expand liability for original or other past owners and operators,<sup>52</sup> particularly where the transfer of unproductive wells to new ownership may have contributed to the ultimate improper abandonment of wells without regard to environmental risks, leading eventually to their orphaning. This rulemaking could also serve as an opportunity for EPA to discourage and reduce the unnecessary protracted maintenance of idled wells to avoid closure responsibility and costs. In addition, the commenter suggests that EPA should consider establishing new source performance standards and presumptive standards for abandoned wells that include expanded liability for past owners or operators. The absence of identifiable, liable parties for millions of orphaned wells is an underlying reality that demonstrates the need for EPA to help the sector ensure accountability of operators. The commenter suggests that EPA could use its broad authority under CAA section 111 to develop standards that would hold previous owners and operators accountable for cleanup and ensure orphaned wells are adequately addressed and properly plugged. For example, the commenter notes that, under California law, if the current operator goes bankrupt or does not have the funds to plug a well, the state can require a prior operator to plug the well.<sup>53</sup> EPA also can look to the successful Superfund program promulgated under the Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA) as a potential model for accountability mechanisms.

<sup>53</sup> Cal. Pub. Rec. Code § 3237 (2020).

#### 18.1.8.5 Idle Well Plans

Commenter (0941-350 Silicon Valley) recommends that permit applications for a new well require submission of an Idle Wells Plan, in addition to a Gas Capture Plan. The Idle Wells Plan would include a schedule for plugging and capping all the applicant's older idle wells, defined as those idle for 8 years or more, in the state. This Plan would also include purchase of a bond sufficient to cover the cost of plugging and capping new wells. If its current bonds are insufficient to cover the cost of plugging and sealing its existing wells then if legally possible, the commenter suggests that the dollar amount of those bonds should also be increased. The commenter recommends that in cases where the applicant fails to follow the agreed upon schedule for capping its old/idle wells, the company be required to reduce production at the new well site.

Commenter (1267-CA AG *et al.*) recommends that EPA place limits on the number of idle wells that an individual owner can hold, since a high percentage of idle wells may indicate an increased vulnerability of the operator becoming insolvent and leaving orphan wells. Further, the new source performance standards and emission guidelines should require prompt reporting of any transfer of well ownership.

#### 18.1.8.6 Well Closure Plans

Comment: Several commenters (0844-EDF *et al.*, 1267-CA AG *et al.*, 1282-Earthworks) requested that EPA require the submission of a well closure plan.

Commenter (1267-CA AG *et al.*) recommends that well operators are required to submit a well closure plan describing when and how the well will be closed and demonstrating their financial capacity to comply with the rules until it is closed. This demonstration should include financial assurance to provide money for plugging and restoration if the operator defaults. Allowable financial assurance instruments could include cash deposits, certificates of deposit, irrevocable letters of credit, and surety or performance bonds.

Commenter (1282-Earthworks) recommends that EPA require companies to submit a comprehensive well closure plan in order to properly cap wells at their end of life.

Commenter (0844-EDF *et al.*) recommends that EPA take steps to prevent wells from being improperly abandoned and orphaned by requiring operators to develop and comply with closure plans. The commenter also suggests that EPA require operators to submit plans detailing how they will comply with various standards, like the requirement to submit a fugitive monitoring plan. The commenter adds that EPA should use this approach when dealing with end-of-life wells by requiring operators of well site affected facilities to submit closure plans, detailing how the site will be monitored or plugged, and if the latter, identifying the financing that will be used for plugging, along with other relevant information.<sup>54</sup> When the operator chooses to close a well,

---

<sup>54</sup> Section 114, 42 U.S.C. § 7414, gives EPA broad information gathering authority that EPA could use to gain information on operator's financial health. EPA could use that information to identify wells at high risk of abandonment and take proactive steps to prevent those wells from becoming orphaned or transferred. EPA could also provide states with this information, which states could use to inform existing efforts to prevent orphan wells.

thereby removing it from affected facility status, it would be required to follow the steps in the plan. Failure to do so would cause the well site to remain an affected facility, and the operator would have to continue complying with fugitive monitoring and other applicable standards or face noncompliance penalties.

Alternatively, the commenter (0844-EDF *et al.*) suggests that EPA could create a separate abandoned well affected facility definition, for which the standard would be monitoring until proper closure. This would have the same effect as an approach that would allow owners and operators a choice between regular monitoring and well closure with proper plugging. Similar to the “closed landfill subcategory,” EPA could require operators to submit closure plans and require regular monitoring for leaks until the closure plan is completed. The commenter suggests that this option may be more difficult to administer, however, because it would require EPA to define abandoned well affected facilities.

#### 18.1.8.7 Emissions Guidelines Considerations

Commenter (1267-CA AG *et al.*) recommends that EPA address how states evaluate requests by owners/operators of idled and unplugged wells for variances from leak detection and repair requirements based on remaining useful life. EPA could explain, for example, that in reviewing whether a state plan is satisfactory, the agency will take into account whether any variances for these types of wells are conditioned on an enforceable shut down based on the source’s projected remaining useful life.

Commenter (0844-EDF *et al.*) states that, under section 111(d) of the CAA, EPA must allow states when applying a standard of performance to an existing source to consider the remaining useful life (RUL) of the source and other factors.<sup>55</sup> EPA has authority to define how states may consider remaining useful life and may also limit what other factors states consider.<sup>56</sup> The commenter asserts that EPA must require a source that is granted a compliance variance on RUL grounds to commit to a federally enforceable shut-down at the end of its useful life, and must specify the conditions of closure. Any variance justified by a short RUL necessarily entails a certain closure date, and EPA must not allow sources that are permitted to forgo required applicable to all other sources on RUL grounds to continue operating beyond that date.

Further, the commenter (0844-EDF *et al.*) adds that, under section 111(d) of the CAA, EPA can also specify and limit the “other factors” states are allowed to consider when applying a standard of performance to an existing source.<sup>57</sup> The commenter suggests, for example, EPA might require states to consider the financial stability of the operator and specify that EPA would not approve any variance for sources owned by operators with poor finances unless they provide financial assurances to EPA or the relevant state agency. The commenter notes that this could even be done on an operator-wide rather than source-by-source basis. Colorado is updating its financial assurance regulations and may consider the percentage of an operator’s portfolio that is

---

<sup>55</sup> 42 U.S.C. § 7411(d)(1).

<sup>56</sup> See *id.*

<sup>57</sup> *Id.*

active versus inactive as a proxy for financial stability.<sup>58</sup> The commenter suggests EPA could do something similar, for example, by requiring a financial demonstration as a condition of approving a variance, or simply not approving a variance for sources owned by an operator with a high percentage of inactive or risky wells.

### ***18.1.9 Identifying and Prioritizing of Abandoned Wells for Monitoring and Closure***

Commenter (0753-IGSD/CHRE) encourages EPA to explore methods for prioritizing, inventorying, and plugging existing abandoned wells based on: the magnitude of emissions; harms to public health, the environment, and the climate; and proximity to environmental justice communities. The commenter states that research demonstrates that a small number of high-emitting wells are responsible for a disproportionate share of methane emissions from abandoned wells.<sup>59</sup> Prioritizing these super-emitters, along with any lower-emitting wells near environmental justice communities first, will best address the climate and justice consequences of unplugged wells.

The commenter (0753-IGSD/CHRE) explains that such a hierarchy would be similar to the prioritization regime in the REGROW Act that Congress enacted as part of the Infrastructure and Investment Act<sup>60</sup> and existing state-level prioritization regimes.<sup>61</sup> The commenter states that

---

<sup>58</sup> See Colorado Oil and Gas Conservation Commission, Draft Financial Assurance Rules (Dec. 7, 2021), <https://cogcc.state.co.us/documents/sb19181/Rulemaking/Financial%20Assurance/COGCC%20Draft%20Financial%20Assurance%20Rules%2012-7-21%20-%20Redline%20against%2010-8-21%20Draft.pdf>; Mark Jaffe, Colorado doesn't want to foot the bill for abandoned oil and gas wells. Here's how it will avoid picking up the tab., Colorado Sun (June 17, 2021), <https://coloradosun.com/2021/06/17/colorado-orphan-oil-well-bonding-cogcc/>.

<sup>59</sup> Williams J.P., Regehr A., & Kang M. (2021) Methane Emissions from Abandoned Oil and Gas Wells in Canada and the United States, ENVIRON.SCI. & TECH. 55:563–570, 569 (“Only 10 high-emitting wells with over 100 g/h have been measured to date, yet they contribute roughly 65% of cumulative emissions (i.e., superemitters) from all studies. Although mitigating a small number of sites can reduce a large percentage of methane emissions, it also means that AOG wells with methane flow rates much higher than those measured to date may exist. Gathering new measurements from regions without prior data may greatly enhance the representativeness of emission factors, help characterize and identify the highest emitters that heavily influence emission factors, and provide information on how these emissions are distributed regionally and across well classifications.”).

<sup>60</sup> 42 U.S.C. §15907(b); Infrastructure Investment and Jobs Act, H.R. 3684, 117th Cong. §40601(b) (2021) (“(ii) ranking those orphaned wells for priority in plugging, remediation, and reclamation, based on-- “(I) public health and safety; “(II) potential environmental harm; and “(III) other subsurface impacts or land use priorities;”)

<sup>61</sup> Rotblat, C. (2017) Caring for the Orphans: Approaches for Mitigating Fugitive Methane Emissions from Orphaned Oil and Gas Wells, ENVIRON. L. REP. NEWS & ANALYSIS 47:10529–10541, 10535 (“States use these funds to maintain prioritized lists of orphaned wells and, as funding permits, to plug the highest priority wells. In 2008, the Interstate Oil and Gas Compact Commission (IOGCC) 97 developed a suggested prioritization schedule for plugging orphaned wells involving 10 factors related to the hazards posed by each well to health, safety, and the environment. However, states still maintain slightly different prioritization systems. For instance, in Texas, prioritization is based on ‘well completion,’ ‘wellbore conditions,’ ‘well locations with respect to sensitive areas,’ and ‘unique environmental, safety or economic concern.’<sup>99</sup> In Kansas, prioritization is based on the risk posed by the well to surface water, groundwater, and public safety. 100 And in Pennsylvania, prioritization is based on ‘whether the well is on public or private land; its distance from public or private water supplies, accessible areas or buildings; its distance from streams, bodies of water, or wetlands; and whether or not it is in a special protection watershed.’ 101 The volume of methane gas leaking from an orphaned well is often taken into account as a public safety factor, due to the risk of ignition or explosion, 102 but the climate change impacts of methane leaks do not appear to be part of any published prioritization system. As a result, even wells leaking significant amounts of methane may remain unplugged for extended periods if they are not located near a water source or occupied buildings. 103”).

EPA should ensure that when addressing abandoned and unplugged wells, methane emissions and climate damage are specifically considered, as well as environmental justice concerns. The commenter states that many existing hierarchies do not reach these critical issues.

Comment: Commenter (0844-EDF *et al.*) recommends that EPA work with states to identify wells at high risk of abandonment and to develop solutions.

Commenter (0753-IGSD/CHRE) encourages EPA to establish a program for identifying undocumented abandoned wells and monitoring emissions at abandoned wells. The existence of known super-emitters (as well as the likelihood that more super-emitters are identified through increased leak detection and repair (LDAR) actions) underscores the importance of monitoring to stop large leaks of methane and other pollutants.<sup>62</sup> Experts emphasize the need to enhance monitoring of abandoned wells (including once plugged) and to document wells not currently identified by states.<sup>63</sup>

Commenter (0598-Countrymark Energy Resources, LLC (CER)) recommends that each state be required to complete an assessment of the abandoned wells and plug the wells that are known to be leaking. The commenter states that this is not an area that EPA should be investing significant resources. High risk, high emission wells should be prioritized through the plugging program to eliminate the emissions source. Monitoring the remaining abandoned wells that may release small volumes of methane and VOCs will add costs for each state. This additional cost will disproportionately impact small businesses through increased fees by the agency responsible for monitoring the wells. Larger companies are better able to absorb the increase in fees to pay for the monitoring, whereas the increases are much more meaningful to the way that small entities

<sup>63</sup> E.g. Kang M., et al. (2021) Orphaned oil and gas well stimulus—Maximizing economic and environmental benefits, ELEMENTA 9:1–13, 8 (“Here, we outline six policy recommendations for monitoring and managing abandoned oil and gas wells including orphaned wells: 1. Monitor representative populations of plugged and unplugged abandoned wells across multiple basins to understand the ability of plugging to address the full suite and interdependency of environmental risks (Table 1). Ongoing analysis of monitoring results and well attributes are needed to identify representative populations of wells. Moreover, it is important to perform pre- and post-plugging monitoring and understand short-term variations (i.e., daily and seasonal). 2. Study the long-term—decadal to century-scale—impacts of abandoned wells. Such studies should include monitoring at the same wells over decades. 3. Monitor and manage abandoned wells regionally to account for inter-wellbore communication and complex subsurface leakage pathways. The region to investigate will depend on the geology, hydrogeology, and the history of oil and gas and other subsurface activities. Additional research involving field and modeling work is needed to develop a framework for selecting these regions. 4. Find and document wells that are not in current databases so that they can be addressed through plugging and site restoration in a systematic manner. 5. Develop national and international standards for documenting historical and modern wells to improve the long-term maintenance and usability of databases. 6. Train workers on well plugging, site restoration, environmental monitoring, and other jobs that will remain available during and after the transition to clean energy.”).

conduct business. The commenter notes the recently passed infrastructure bill has included funds to plug abandoned wells across the United States.

#### ***18.1.10 Consideration of State/Other Federal Requirements***

Commenters (0391-KBIC, 0781-NTAA, 0605-Muscogee (Creek) Nation, 0833-Ute EPD) are aware of information that the Western Regional Air Partnership has developed that may support EPA's regulation of these activities.<sup>64</sup>

Commenters (0391-KBIC, 0605-Muscogee (Creek) Nation, 0833-Ute EPD) note that they are also aware of the activities in states such as Pennsylvania and Ohio to identify and address abandoned and orphaned wells.<sup>65,66</sup>

Commenter (0803-Ohio Oil and Gas Association (OOGA)) asserts that EPA's regulation of abandoned wells in Ohio is unnecessary. In the November 2021 Proposal, the commenter notes that EPA requests comments to inform its potential development of NSPS and EG for emissions from abandoned wells. The commenter adds that EPA notes that it broadly defines "abandoned wells" as "oil and natural gas wells that have been taken out of production, which may include [wells that are] . . . idle, inactive, dormant, or shut-in, but not plugged. The Ohio Department of Natural Resources, Division of Oil and Gas (ODNR) is the agency vested with statutory authority to regulate all aspects of the permitting, location, and spacing of oil and gas wells and production operations, including, specifically, the plugging and abandonment of wells in Ohio. According to the commenter, EPA developing regulations to address emissions from abandoned wells is unnecessary and may potentially conflict with existing state regulations in Ohio.

Commenter (0424-Division of Air Quality, West Virginia Department of Environmental Protection (WVDEP)) notes that EPA identified a potential strategy to imply practices and procedures to ensure proper well closure that may conflict with existing state regulation. The commenter states that a federal air quality regulation addressing well closures would require significant interagency coordination beyond current levels. The commenter provides details on the West Virginia abandoned wells program, and states that lack of funding is problematic, not lack of regulation. The commenter adds that the Office of Oil and Gas (OOG) is the agency vested with the authority to regulate well closures in West Virginia. An OOG legislative rule establishes abandoned well requirements that include financial responsibility and a priority system for plugging abandoned wells. West Virginia estimates there are 15,000 documented abandoned wells, including 6,300 orphaned or unbonded wells in the state with a projected average cost of \$100,000 to plug each well. The commenter reports that the state began

<sup>66</sup> Kathiann M. Kowalski, Thousands of Abandoned Ohio Oil and Gas Wells May be Hidden. Drones Could Help Find Them, Energy News Network (May 10, 2021), <https://energynews.us/2021/05/10/thousands-of-abandoned-ohio-oil-and-gas-wells-may-be-hidden-drones-could-help-discover-them/>.

permitting wells in 1929, and it is unknown how many undocumented wells existed prior to 1929.

Commenter (0763-Texas Commission on Environmental Quality (TCEQ) and Railroad Commission (RRC)) suggests that any proposal to include abandoned and unplugged wells as additional sources for regulation under the CAA would be premature, considering all the ongoing work at the state level and the provisions for additional state plugging and abandoned well research and development expected pursuant to the Infrastructure Investment and Jobs Act of 2021.

Commenters (0810-Petroleum Alliance-OK, 0814-Independent Petroleum Association of America (IPAA) *et al.*) believe that EPA should defer to states to address future orphaned wells. If EPA proposes requirements, the commenters state that EPA needs to provide detailed rationale for its authority. The commenter states that in order to prevent wells from becoming orphaned in the future is complicated. States recognize this issue and are reviewing their programs, statutes, and rules to determine the best course of action to prevent the occurrence of these types of wells. States, like Oklahoma, according to the commenter, are in the best position to address future orphaned wells.

Commenter (0814-IPAA *et al.*) notes that a major issue not addressed in the November 2021 Proposal is various specific agreements, memorandums of understanding and plugging consent orders. The commenter suggests that for EPA come in run roughshod over these existing arrangements would represent a step backwards. The detailed rationale for its authority to regulate the “emission sources” should include why the states should not have primacy in addressing the issue. The commenter believes that EPA lacks authority regulate well bonding.

Commenter (0814-IPAA *et al.*) notes that EPA broadly characterizes abandoned wells as oil or natural gas wells that have been taken out of production, which may include a wide range of non-producing wells such as idle, inactive, dormant, shut-in, and orphaned wells. These wells, except for orphaned wells, typically have a responsible owner/operator but are not producing for a specific reason *e.g.*, product pricing, held by other production in the unit, or waiting on some specific activity like a workover. On the other hand, an orphaned well is a well where there is no responsible owner/operator *e.g.*, the owner/operator has gone bankrupt. The commenter recommends that EPA not broadly characterize these wells collectively as they are very different and the existing state programs are addressing this problem with much appreciated federal assistance. The commenter suggests that for EPA to attempt a federal overlay of the state programs would represent a step backwards.

Commenter (0744-New York State Department of Environmental Conservation (NYSDEC)) requests that EPA investigate the feasibility and practicality of federal regulation of abandoned wells in close coordination with New York and other oil and gas producing states as there are substantial differences among states with respect to the construction of oil and gas wells, the surrounding geology and the states’ regulatory programs. The commenter notes that EPA lumps idle and orphaned wells into the abandoned category, but states like New York have limited ability to regulate orphaned wells, compounded by a lack of access to these wells on private property. The commenter supports EPA's interest in reducing the numbers of future orphaned

wells by working with active operators now, however EPA should consider whether any requirements to retrofit wells to abate GHG emissions may lead to an increase in orphaned wells in New York. The commenter further supports well plugging and shut in requirements to prevent methane emissions and recommends that well conditions are carefully considered in any future requirements as well construction and conditions differ among states. The commenter states that sealing a well off from the atmosphere has the potential to impact the aquifer due to over-pressuring of the well bore. The commenter recommends that EPA reach out to oil and gas producing states to examine the different requirements and data collection activities currently in place. For example, New York requires operators to request shut-in status for wells that are not producing for one year. In addition, the commenter inspects wells prior to approving shut-in status. The commenter has provided information on New York's idle well program and provided orphaned and idle well counts to IOGCC previously and recommends this organization as a good source of statistics and information on the different programs in IOGCC's member states.

Commenter (0957-WYCLG) states that EPA must avoid adopting any duplicative regulations for the proposed NSPS that it may develop for abandoned and unplugged wells. The commenter suggests that one strategy EPA is considering for supplemental rulemaking is adopting practices and procedures to ensure proper well closure to help reduce emissions from abandoned wells. This would include the requirement to submit a closure plan describing when and how the well will be closed and demonstrating the financial capabilities of an operator to comply with closure requirements. However, the commenter notes that most of the oil and natural gas producing states require the plugging of non-producing wells and subsequent restoration of the well site.

Commenter (0808-API) believes that issues related to well closure are more appropriately addressed by the states and BLM. The commenter recommends that EPA consider all available information before developing policy. The commenter notes that substantial progress on – and additional information concerning - idle/orphaned well clean up may be expected based on recent federal funding. Passed as part of the Infrastructure and Investment Jobs Act of 2021, the REGROW Act provides funding to invest in the environment, and a skilled workforce. This includes \$4.275 billion for orphaned well clean up on states and private lands, \$400 million for orphaned well cleanup on public and tribal lands, and \$32 million for related research, development, and implementation.<sup>67</sup> Any applications from states for these grant funds can help provide more concrete numbers. Additionally, any of these funds that are distributed as grants to state agencies may contain additional environmental and reporting obligations, which, when viewed in the proper context, may lend additional light to this issue. The commenter states that these recent developments further minimize the need or justification for EPA to expand its regulatory efforts on this topic to encompass orphan wells.

The commenter (0808-API) notes that further granularity on idle/orphaned wells was provided in December 2021, when IOGCC released an update of its 2019 report on idle and orphaned wells to include 2019 – 2020 data. Because IOGCC's work is based on over 30 years of review, the commenter recommends that EPA consider this information carefully before determining a course of action.

---

<sup>67</sup> REGROW Act Infrastructure and Investment Jobs Act of 2021, H.R. 3684, 117th Congress (2021).

The commenter (0808-API) instructs that IOGCC is a multi-state government agency that promotes the conservation and efficient recovery of domestic oil and natural gas resources while protecting health, safety, and the environment. As an organization, IOGCC is committed to continuing to support the states and provinces in their efforts to continually improve their idle and orphan well programs and to providing a forum for information-sharing of effective tools and strategies. IOGCC has also been included in the (DOI) Memorandum of Understanding (MOU)<sup>68</sup> for the recently enacted grant program referenced above.

Across decades of studying idle and orphaned wells, the commenter (0808-API) reports that IOGCC has published reports on the issue in 1992, 1996, 2000, 2008, and 2019.<sup>69</sup> A new report covering data from 2019 and 2020 was published in December 2021.<sup>70</sup> As these reports show, IOGCC has been following this issue for 30 years. The commenter encourages EPA and other agencies interested in regulations on this topic to review the report in detail.

The commenter (0808-API) provides that the 2021 IOGCC report features survey responses from 32 IOGCC member and associate member states and five Canadian providences. It includes data from 2018 – 2020 and concerns the number of both idle and orphan wells, well plugging and site restoration costs, and remediation strategies (including regulatory tools and funding sources used to ensure idle wells are properly maintained). The commenter notes that oversight for idle, orphan, and historical undocumented orphan wells is state-specific according to local regulatory programs, most of which include requirements for wells to remain idle and established prioritization systems for known orphaned wells. Additionally, the commenter reports that most states already have funding mechanisms for plugging orphan wells, which are supported by industry taxes and fees. To avoid duplication or unintended consequences, the commenter recommends that EPA carefully examine these diverse programs and funding mechanisms prior to any additional regulatory work.

As an example of continuous improvement within the applicable states, the commenter (0808-API) reports that over half of the states and provinces participating in the IOGCC survey reported improvements in their idle and orphan well programs between the IOGCC reports in 2008 and 2021. In 2019, IOGCC noted that these included “process improvements in communication, collaboration, contracting, third-party plugging, compliance assurance, data systems, and bonding; implementation of program efficiencies; increases in staffing and funding; and application of Geographic Information System (GIS) and drone technologies. Through the decades, the states and provinces have made considerable progress in plugging orphan wells and reducing the likelihood of additional wells becoming orphaned. They have also continued to evaluate and adjust their financial assurance requirements and their plugging funds to ensure there will be funds available for well plugging and site restoration.”<sup>71</sup>

The commenter (0808-API) asserts that the 2021 IOGCC report expanded its description of regulatory strategies used by the various states which include, “requirements, such as periodic mechanical integrity testing, that must be met for wells to remain idle beyond a specified time.

---

<sup>68</sup> Orphan Well MOU (doi.gov).

<sup>69</sup> IOGCC, Idle and Orphan Oil and Gas Wells, (2019).

<sup>70</sup> IOGCC Idle and Orphan Oil and Gas Wells, (2021).

<sup>71</sup> IOGCC (2019) at 21.

These requirements may be set by statute, rule, or written approval. Most states and provinces also require financial assurance to provide money for plugging and restoration if the operator defaults. Financial assurance instruments include cash deposits, certificates of deposit, financial statements, irrevocable letters of credit, security interests, and surety or performance bonds. The types accepted and amounts required vary considerably among the states and provinces. The participating states all provide for single-well and blanket coverage, and the participating provinces provide for either single-well or blanket coverage, or both. The amounts may be uniform for all wells, or they may be based on the depth, location, type, or status of well or case-by-case evaluations. To supplement the funds provided through financial assurance instruments, most states and provinces have established funds dedicated to plugging orphan wells. Money for these funds comes primarily from taxes, fees, or other assessments on the oil and gas industry. Nineteen states and provinces reported on innovations and advancements in their idle and orphan well programs. Some have added staff, improved their data management systems, and streamlined their contract management processes. Some have adopted new idle well requirements, such as requirements to provide additional financial assurance, demonstrate well integrity, justify keeping wells in idle status, or limit the percentage of wells an operator may hold in idle status. Increasingly, states and provinces are using GIS and drone technologies to find orphan wells. They are also collaborating with operators and landowners to address idle and orphan wells and using grant programs, economic stimulus funds, and third-party partnerships for orphan well plugging and restoration.”<sup>72</sup>

The commenter (0808-API) adds that the activities on federal lands are regulated both by BLM regulations and by the state in which the operations are located. On federal lands, however, existing federal regulations obligate companies to bear the full costs of plugging and abandoning well sites.<sup>73</sup> In fact, companies cannot be released from liability until BLM determines they have properly done so. The April 2019 GAO report identified 296 orphaned wells which is a very small and manageable percentage of the 96,199 onshore federal wells.<sup>74</sup>

Beyond state and federal requirements, the commenter (0808-API) notes that the oil and gas industry has developed relevant standards and practices which apply on both state and federal lands. These are relevant throughout a well’s lifecycle; covering the safe conduct of drilling operations, standards for equipment and materials used during drilling and completion, and practices for well plugging and abandonment. In 2021, API’s Recommended Practice (RP63),<sup>5</sup>-Wellbore Plugging and Abandonment provided specific guidance for the design, placement and verification of cement plugs used in wells that will be temporarily or permanently closed.<sup>75</sup> The standard also provides guidance for well remediation and verification of annular barriers, reinforcing groundwater protection and emissions retention. RP 65-3 joins several established API standards already in use for decades, including but not limited to API 51R, Environmental

<sup>75</sup> API RP-63 American Petroleum Institute, Recommended Practice 65-3, Wellbore Plugging and Abandonment (2021).

Protection for Onshore Oil and Gas Production Operations and Leases and API 65-2, Isolating Potential Flow Zones During Well Construction. These are instructive templates for better understanding how industry practices work effectively across varying state and federal regulations.

Commenter (0831-AXPC) notes that the November 2021 Proposal suggests that EPA is considering requirements for operators to have to submit plans for plug and abandonment along with associated financial assurance for decommissioning obligations. The commenter believes issues related to well closure are more appropriately addressed by the states and federal land management agencies like the BLM. State oil and gas agencies and federal land management agencies (*i.e.*, BLM) have the authority to regulate the management and decommissioning of oil and gas wells. Operators are already subject to regulatory requirements for posting financial assurances to cover decommissioning costs and clean up, submittal of plans and technical procedures for temporarily abandoning or permanently decommissioning a well. In addition to this potential for creating redundant regulations, EPA has no authority under the CAA to impose such a financial assurance requirement.

The commenter (0831-AXPC) asserts that it is also important to note that state oil and gas regulators and other parts of the U.S. government are already considering and addressing the issues that EPA has raised related to the proper management of idle well inventories, providing for proper well abandonment, as well as addressing the existing inventory of orphan wells. For example, IOGCC is a multi-state government agency that promotes the conservation and efficient recovery of domestic oil and natural gas resources while protecting health, safety, and the environment. IOGCC has been studying this issue for 30 years and supporting states and provinces in their efforts to continually improve their idle and orphan well programs and sharing effective tools and strategies. As recent as December 2021,<sup>76</sup> IOGCC issued an updated report entitled “Idle and Orphan Oil And Gas Wells: State and Provincial Regulatory Strategies 2021.” In this report, IOGCC found that less than 6 percent of all drilled and not plugged (includes all operational wells) are considered orphaned by the states. Of these orphaned wells, the operator is known for 78 percent of the wells. Estimates for the number of undocumented wells, legacy wells typically drilled prior to the establishment of regulatory programs, are much higher. However, the commenter asserts that the existence of these undocumented wells should not be conflated with the modern definition of orphan wells, which are managed through various techniques such as bonding and state/operator funded orphan well plugging programs. IOGCC’s work and recent report should be relied upon for establishing consistent terminology, improving counts and estimations, and reviewed carefully before considering additional regulations.

### ***18.1.11 Regulatory Funding***

Commenter (0734-ATS) commends the Biden Administration for allocating \$4.7 billion in their infrastructure legislation to plug existing abandoned wells and mines.

Commenters (0808-API, 0810-Petroleum Alliance-OK, 0814-IPAA *et al.*) note that President Biden signed into law the infrastructure bill that includes over \$4 billion in funding to restore and plug orphaned wells on federal, state, private and tribal lands (aka REGROW Act of 2021). In

---

<sup>76</sup> [https://iogcc.ok.gov/sites/g/files/gmc836/f/iogcc\\_idle\\_and\\_orphan\\_wells\\_2021\\_final\\_web.pdf](https://iogcc.ok.gov/sites/g/files/gmc836/f/iogcc_idle_and_orphan_wells_2021_final_web.pdf).

December 2021, the Department of Interior released guidance on state applications for grants under the program. Since then, the commenters provide that many states, including Oklahoma, have applied for this funding, and are aggressively prioritizing and addressing the plugging of orphaned wells. The commenters add that IOGCC has been working with states and provinces to evaluate their idle- and orphan-well programs and identify useful regulatory tools and strategies to address this issue. In addition, in Oklahoma, the industry voluntarily takes responsibility for orphaned well sites and has invested over \$132 million to clean up over 18,000 orphaned wells sites.

Commenters (1270-LWVUS) state that plugging abandoned wells must be a top priority to help protect us from extreme global warming, but questions who will pay. In cases where the ownership of abandoned wells can be traced to companies still in business, the owners can be asked to provide funding, but there may be no legal route for extracting money from an unwilling owner. The commenter note that states were supposed to secure sufficient funding through bonding to pay for necessary decommissioning activities, including plugging. In general, the commenters report that they did not require anywhere near sufficient funds from owners to complete the work, and most will be unable to pay for it from state budgets.

Commenter (1270-LWVUS) notes that The Bipartisan Infrastructure Investment and Jobs Act, a Part of the “Build Back Better Plan” as envisioned in March, 2021, promised “. . . an immediate up-front investment of \$16 billion that will put hundreds of thousands to work in union jobs plugging oil and gas wells and restoring and reclaiming abandoned coal, hardrock, and uranium mines.”<sup>77</sup> The commenter states that this funding might have provided a start on plugging wells, but it isn’t clear that any such language will be included in whatever legislation is finally passed. The commenter notes that, if passed, the commenter believes that the Build Back Better legislation is likely to provide only a tiny portion of the funding that will eventually be required.

According to a 2020 analysis, commenter (1270-LWVUS) reports that an estimated \$280 billion in funding would be required to clean up the 2.6 million unplugged onshore mines that have been documented to date.<sup>78</sup> The commenter adds that an unknown sum will be required to plug an estimated 1.2 million onshore wells that are believed to be unplugged but are not yet documented. An estimated 1.7 million gas and oil wells are currently active.<sup>79</sup> The commenter states that many are likely to be closed down in the next decade. The commenter believes that the total cost of plugging all these wells will almost certainly exceed \$500 billion.

The commenter (1270-LWVUS) recommends that EPA plan for extensive and long-term work to identify and plug abandoned and orphaned wells. The commenter states that EPA will need to investigate a variety of possible funding sources to secure funding to carry out the vital campaign to plug abandoned wells.

---

<sup>77</sup> <https://www.whitehouse.gov/briefing-room/statements-releases/2021/03/31/fact-sheet-the-american-jobs-plan/>.

<sup>78</sup> <https://carbontracker.org/reports/billion-dollar-orphans>.

<sup>79</sup> Oil & Gas Activity in the U.S. (fractracker.org)

There are ~1.7 million active oil and gas wells in the U.S. This map includes both conventional and unconventional (e.g., fracking) wells.

Commenter (0573-KDHE) recommends that EPA or other federal agencies provide states with significant additional funding to address shortfall in plugging abandoned wells. In its 2021 annual report on abandoned oil and gas wells<sup>80</sup> the Kansas Corporation Commission provides estimates of the number of abandoned wells requiring action (5,632 currently), as well as the average cost of plugging by state district. These costs range from approximately \$4,000 per well in southeast Kansas, where shallow coalbed methane (CBM) wells predominate, to \$15,000 in the Hays District, where oil wells predominate. The current program had funds to plug only 159 wells in FY 2020.

Commenter (0598-CER) expresses concern that EPA's additional regulations will add costs to wells that are marginally profitable that could lead operators to decide to terminate their business. While operators are required to maintain bonding for each operator, in the event that this occurs, the commenter has witnessed that the funds from the surrendered bonds are not utilized to plug the operators remaining wells. As a result, the commenter suggests that taxpayers will ultimately pay to plug the wells. The commenter is concerned that the additional regulations will result in many more wells being surrendered to state agencies. Historically, the commenter has seen operators surrender their wells to state agencies to complete remediation of the unplugged wells at the time that the operator ceases to do business.

Commenter (0558-Center for Climate and Energy Solutions (C2ES)) recommends that EPA establish strict criteria that states must demonstrate to be granted funding, including proximity of abandoned wells to frontline communities and ensuring that funding is provided to orphan wells (*i.e.*, no known operator or owner). In 2019, EPA estimated that methane emissions from abandoned oil and gas wells are 6.6 MMT carbon dioxide equivalent (CO<sub>2e</sub>).<sup>81</sup> Fifty-nine percent of these abandoned oil and gas wells are unplugged (almost 2 million wells) which makes them more likely to pose greater health and environmental risks. While different states allocate funds dedicated to plugging abandoned wells and restoring well sites, the scale of the challenge is beyond their capabilities.<sup>82</sup> The commenter notes that the funding for legacy pollution clean-up included in the recently enacted Infrastructure Investment and Jobs Act, which includes establishing new state programs for orphaned wells plugging and remediation, should give EPA an opportunity to help states address methane emissions from abandoned wells.<sup>83</sup>

#### ***18.1.12 Opposition to Regulation of Emissions from Abandoned Wells Without Further Consideration***

Commenter (0792-Interstate Oil and Gas Compact Commission (IOGCC)) is concerned with EPA's solicitation of comments and information on "abandoned and unplugged wells." The commenter notes that the November 2021 Proposal includes a brainstorm of ideas on potential regulations for "abandoned, idled, and non-producing wells" without clearly defining the terms used, without understanding how various elements of a state regulatory program operate as a

---

<sup>80</sup> [https://kcc.ks.gov/images/PDFs/legislativeeports/2021\\_Abandoned\\_Oil\\_and\\_Gas\\_Well\\_Status\\_Report.pdf](https://kcc.ks.gov/images/PDFs/legislativeeports/2021_Abandoned_Oil_and_Gas_Well_Status_Report.pdf).

<sup>81</sup> U.S. Environmental Protection Agency, Inventory of U.S. Greenhouse Gas Emissions and Sinks: 1990 – 2019.

<sup>82</sup> IOGCC, Idle and Orphan Oil and Gas Wells: State and Provincial Regulatory Strategies (Oklahoma City, OK: IOGCC, 2019).

<sup>83</sup> Infrastructure Investment and Jobs Act, H.R. 3684, 117th Congress, (2021), <https://www.congress.gov/bill/117thcongress/house-bill/3684>.

system, and without considering the potential adverse impact of EPA's ideas on the state regulatory programs and the inventories of idle and orphan wells.

The commenter (0792-IOGCC) adds that the discussion of “abandoned wells” in the November 2021 Proposal highlights the imperative of immediate action to convene the IOGCC and EPA’s Memorandum of Understanding Task Force. The commenter suggests that, among the items the Task Force should discuss is IOGCC’s latest report, *Idle and Orphan Oil and Gas Wells: State and Provincial Regulatory Strategies 2021*, which was released in December 2021. This report outlines the regulatory tools and funding sources used to ensure that responsible operators properly maintain and timely plug idle wells and that states have funds to plug orphan wells. The commenter adds that the Task Force should also review the work underway in the states to accelerate the plugging of orphan wells with funding to be provided through the Infrastructure Investment and Jobs Act of 2021.

Commenter (0742-Alaska Department of Environmental Conservation (ADEC)) recommends that EPA exclude abandoned and unplugged wells from this proposal because these are best suited to be addressed by resource agencies devoted specifically to this issue as many states already have in place. Abandoned and unplugged wells are a separate issue in Alaska, where the majority of unplugged and abandoned wells are on federal lands.<sup>84</sup> As Alaska does not accept delegation of individual subparts at what would truly be minor or area sources, the requirement to deal with abandoned and unplugged wells in Alaska already primarily falls upon the federal government, not the state. In 1982, BLM inherited the responsibility to assess, plug, and clean up the wells that the U.S. Navy and United States Geological Survey (USGS) left behind.<sup>85</sup>

Commenter (0756-Baker Hughes) does not support expanding the proposed NSPS and EG to abandoned or non-producing wells because there is no clear authority under the CAA and the management of operating wells are regulated by the states under long-established programs for drilling, operations, well plugging, and site reclamation. To avoid duplication or unintended consequences, the commenter recommends that EPA carefully examine the authority under the CAA, the ability to regulate an asset that has no owner or operator, and existing state regulatory programs prior to any expanding the regulatory scope of the proposed NSPS and EG.

Commenter (0599-MSA) notes that existing wells will vary in construction and methods for appropriate mitigation and believes this is an issue best addressed at a state level.

Commenter (0585-Kentucky Oil and Gas Association (KOGA)) notes that the Kentucky Energy and Environment Division of Oil and Gas has had an active cataloging and plugging program for abandoned and orphan wells for decades. The Cabinet reports and estimated 14,000 orphaned and abandoned wells across the state. These wells were primarily abandoned before the Kentucky’s Oil and Gas Conservation Act of 1960 when permitting newly drilled wells began. Cataloging of these wells has included field inspections and prioritizing wells for plugging that pose the greatest environmental impacts. In 2020, the State of Kentucky plugged 299 wells and

---

<sup>84</sup> “legacy wells” that the federal government drilled between 1944 and 1981), Alaska Legacy Wells | Bureau of Land Management (blm.gov).

<sup>85</sup> <https://www.blm.gov/programs/energy-and-minerals/oil-and-gas/alaska-legacy-wells>.

could have plugged more but was limited by funding. The recently passed infrastructure bill has included funding to plug abandoned wells across the United States, and the KECC is already making plans to utilize those funds. The commenter does not foresee the benefit of EPA's potential monitoring requirements for wells that are included in the State of Kentucky's existing plugging program. Requiring Kentucky's Division of Oil and Gas to monitor the remaining abandoned wells, which may or may not release small volumes of methane and VOCs, will only increase operating costs for the division. The commenter states that these additional costs will shift the operating costs to operators through higher fees or citizens through higher taxes.

Commenters (0808-API, 0831-AXPC) state that EPA should exclude requiring a demonstration of financial capacity in the upcoming supplemental proposal because EPA does not have authority under the CAA to impose financial assurance requirements. The commenters note that EPA and states have authority under the CAA to establish "standards of performance" applicable to affected facilities as defined in CAA section 111(a)(1) to mean, in relevant part, "a standard for emissions of air pollutants" – *i.e.*, an emissions limitation or comparable requirement (such as an equipment or work practice standard). This is reinforced by the more broadly applicable CAA section 302(l) definition of "standard of performance," which defines that term to mean "a requirement of continuous emissions reduction." The commenters argue that neither of these definitions can reasonably be construed as authorizing EPA to issue financial assurance requirements for affected facilities. In conjunction with the obligation of EPA and states to issue standards of performance, the CAA section 114(a) provides authority to establish corresponding compliance assurance measures, such as monitoring, recordkeeping, and reporting requirements. However, the commenters explain that a financial assurance requirement is fundamentally different in kind from such measures. Monitoring, recordkeeping, and reporting are designed to provide information necessary to determine applicability and demonstrate compliance with a standard of performance. In contrast, a financial assurance requirement is designed to make sure enough money is available to implement a standard of performance at some point in the future. Notably, in instances where Congress wants EPA to require financial assurance, authorization has been explicit. See, *e.g.*, 42 U.S.C. section 6924(a)(6) (Requiring EPA to establish rules for treatment, storage, and disposal facilities regulated under the Resource Conservation and Recovery Act to ensure "the maintenance of operation of such facilities and requiring such additional qualifications as to ownership, continuity of operation, training for personnel, and financial responsibility (including financial responsibility for corrective action) as may be necessary or desirable."). The commenters assert that the absence of such an express provision in the CAA cannot be construed as a grant of authority.

### ***18.1.13 Continuous Monitoring and Emissions Mitigation (Containment) Technologies***

#### **18.1.13.1 Continuous Monitoring Systems**

Commenter (0933-LongPath Technologies, Inc. (Longpath)) provides details on their inexpensive continuous monitoring systems. The commenter notes that states, the federal government, and tribal nations are facing a challenge in effectively identifying and measuring methane emissions originating from legacy oil and gas wells.

The commenter (0933-Longpath) reports that it creates basin-wide continuous monitoring networks that make it extraordinarily inexpensive to provide either short-term or long-term monitoring of individual sites under the purview of a given node (laser system). Abandoned and orphaned wells share three critical characteristics that make them difficult to prioritize for repair: 1) emission rates are relatively low,<sup>86</sup> 2) emission rates are variable through time,<sup>87</sup> and 3) to cost-effectively prioritize repair, characterizing emissions must be done at a very low cost. The commenter contends that it is uniquely positioned to meet all three needs.

The commenter (0933-Longpath) notes that their system is the only peer-reviewed published continuous monitoring system capable of quantifying emission rates at a small enough rate to provide a match to abandoned wells. The thresholds of detection for aircraft surveys are, by contrast, orders of magnitude too high.

The commenter (0933-Longpath) provides continuous monitoring, which the literature shows is necessary for accurately characterizing abandoned well emissions. According to peer-reviewed studies, “high CH<sub>4</sub> emission events tend to be short-lived, so short-term (< 1 h) sampling is likely to miss them.”<sup>88</sup> Furthermore, continuous monitoring of emissions will be required following their full decommissioning to demonstrate repair effectiveness.

The commenter (0933-Longpath) contends that their unique method of networked area coverage means that marginal and abandoned well sites can be “subscribed” to monitoring coverage for a very low cost. According to the commenter, a very modest capital investment would provide the infrastructure necessary across large areas (e.g., the entirety of the Permian Basin), enabling low-cost continuous monitoring for all operators as well as for marginal and abandoned well sites.

#### 18.1.13.2 Well Closure/Plugging

Commenter (0364-WellHead Emissions Management Systems (WHEMS)) describes Abandoned Oil and Gas Wellheads (AOGW) emissions and a potential cost-effective mitigation solution.

- a. AOGW, by modest accounts, number over 3,000,000 across the United States, and by modest calculations emit over 7,000,000 metric tons of methane emissions per year.
- b. Methane is not the only emission coming from these AOGWs. VOCs and HAP are also freely emitted from the unplugged AOGW.
- c. Smith Analytical has recently used a mobile lab to test AOGWs along with operating wells at the Alabama-Coushatta Tribe of Texas and found benzene, toluene ethylbenzene, and xylene (BTEX) in the leaking effluent. The benzene was measured at rates 3,000 times higher than any refinery fence line program as defined by EPA Method 325A/B. When elevated benzene readings were measured, the toluene, ethylbenzene and xylenes were also elevated (See Table 1 in commenter’s letter).
- d. CH<sub>4</sub> emissions by itself is 90 times more potent than CO<sub>2</sub> which is thought to be the leading cause of climate change.
- e. AOGW, or improperly maintained operating wells, are a significant problem and are

---

<sup>86</sup> Kang et al., “Direct Measurements of Methane Emissions from Abandoned Oil and Gas Wells in Pennsylvania.”

<sup>87</sup> Riddick et al., “Variability Observed over Time in Methane Emissions from Abandoned Oil and Gas Wells.”

<sup>88</sup> Id.

acknowledged as such by Republicans, Democrats, as well as various non-profit advocacy organizations such as Greenpeace and Sierra Club.

The commenter (0364-WHEMS) states that the only way to remedy these AOGWs is through the plugging of the well. The commenter notes that this process is expensive, and no state in the U.S. requires that sufficient financial resources be allocated to cover oil and gas drilling, and well head repair costs. One plugging job can range in cost from \$25,000 - \$300,000 and add financial uncertainty for oil and gas companies. The commenter proposes the following Smith Analytical U.S. patented method (U.S. Patent 10,753,204 B2) industry solution to mitigate emissions, that results in over 99 percent elimination of all emissions (CH<sub>4</sub>, VOC, HAP).

1. The Methane/VOC Mitigation System (MVMS) uses a containment system produced of Tedlar® or more commonly steel containment system to encase the leaking AOGW or problematic equipment. Then, by measuring the lower explosive limit (LEL) of the air-hydrocarbon mixture inside the containment vessel, a Programmable Logic Controller (PLC) trips when the internal atmosphere is high enough to safely transfer the emissions to a converter such as the Emission Master, which eliminates the fugitive emissions from the AOGW at a rate of plus 99 percent.
2. The MVMS can also be configured to also scrub the emissions and capture them in a filtration system using 13X Zeolites.
3. Unlike the incredible expense of plugging these AOGWs, the MVMS can be installed and operated for around \$400/mo. (Note the monthly rate varies based on the location, emissions rate and the term of the rental).
4. The MVMS provides a datalink of real-time mitigation, allowing the stakeholder to observe the measurement of emissions in the effluent of the MVMS. The system provides hourly, monthly, and quarterly CH<sub>4</sub>/ VOC emissions reports and provides the Stake Holder with quantifiable information regarding the emissions which have been scrubbed or converted into CO<sub>2</sub>, water vapor and nitrogen (N<sub>2</sub>).
5. For the cost of one AOGW plugging or repair, the stakeholder can use the MVMS system on 5 to 42 AOGWs for a year. This creates an immediate measurable stop-gap solution that is both affordable and effective.

The commenter (0364-WHEMS) notes the following value-added benefits.

1. The Smith Analytical MVMS is a cost-effective application that saves its users millions/year, reduces emissions by nearly 100 percent, and identifies environmental, health, and safety impacts globally.
2. The Smith Analytical MVMS has a proprietary method for quantifying the leak rate of an AOGW using the steel containment system which is installed over the AOGW. As the MVMS is a relatively mobile platform, the stakeholder can have this system installed for a period of ten (10) to thirty (30) days to determine the severity of the leak. As the AOGW inventory is processed, the stakeholder can prioritize the long-term repair of the AOGW or locations that require a long-term MVMS.
3. The MVMS can be remotely monitored via a wireless network to ensure the hardware is performing as designed.

4. The MVMS requires 110VAC to operate or can be fitted with solar and or wind-powered generation hardware to provide the necessary power for the MVMS.

## **18.2 Pigging Operations**

Response I-18-2: In the November 2021 Proposal, EPA solicited comment and data to assist the Agency in evaluating the potential for developing emissions standards for additional emission sources, including pigging operations and related blowdown activities. EPA did not propose emissions standards pigging operations and related blowdown activities in the December 2022 Supplemental Proposal; therefore, this final action does not include emissions standards for these emission sources. We may consider regulation through a future action, including in the next 8-year review of the NSPS. The comment summaries are provided below for reference but substantive responses are not provided because no emissions standards have been proposed for this emissions source.

### ***18.2.1 Regulatory Support***

Commenters (0599-MSD, 0817-GPA Midstream Association (GPA)) state that EPA fails to provide clarity or proposed language on which the commenter can adequately comment. Definitive regulatory text is needed for the commenter to provide truly meaningful comments as to the effects of any proposed regulation. In addition, the commenters note that additional information regarding the feasibility and costs associated with any proposed control technologies are required pursuant to a proposed NSPS.

Commenters (0599-MSD, 0817-GPA) assert that implications of any sort of proposed regulation and/or classification regarding blowdowns cannot be ignored. For example, the commenters state that EPA must consider how such a regulation would impact permitting and how or whether regulated entities would be required to preemptively permit each and every meter station or valve where a blowdown may occur. The commenters contend that the NSPS continuous monitoring requirements would lead to similarly absurd results where blowdown is sporadic, random, and occurring as needed.

Commenter (0957-WYCLG) states that the solicitation of comments on the potential for establishing standards for pipeline pigging and related blowdown activities is not appropriately included within the November 2021 Proposal because it fails to provide an adequate description of the issues involved or terms or substance of a proposed rule. The commenter recommends that this request for additional information on other sources of emissions instead be its own separate rulemaking, starting with an “Advance Notice of Proposed Rulemaking” to obtain the necessary information.

### ***18.2.2 Support for Regulation of Emissions from Pigging Operations/Blowdowns***

Commenter (1414-Sane Energy Project (SEP)) asserts that fugitive methane emissions reportage must include gas emitted into the atmosphere via “blowdowns” (intentional venting) and leakages from compressor stations.

Several commenters (0391-KBIC, 0458-Maryland Department of the Environment (MDE), 0586-Navajo EPA, 0605-Muscogee (Creek) Nation, 0744-NYSDEC, 0776-Air Pollution Control Division, Colorado Department of Public Health and Environment (CDPHE), 0789-Pennsylvania Department of Environmental Protection (PADEP), 0781-NTAA, 0809-Earthjustice, 0832-New Mexico Environment Department (NMED), 0833-Ute EPD, 0943-Sault EPD, 0844-EDF *et al.*, 0918-COLGC, 1302-WYOC/PRBRC) express support for the regulation of emissions from pigging operations/blowdowns. Examples of some of the specific comments are provided in the following paragraphs.

Commenter (0809-Earthjustice) recommends that EPA not delay its duty to regulate these significant sources of uncontrolled emissions simply because of inadequate data. The commenter suggests that, if a targeted Information Collection Request (ICR) is necessary to supply the agency with data it requires, then the agency should undertake this information gathering without delay and well in advance of its rulemaking deadlines.

The commenter (0809-Earthjustice) notes that the November 2021 Proposal does not include standards, but rather seeks comments. The commenter asserts that pipeline pigging operations have the potential to emit large amounts of VOCs, methane, and HAPs. Emissions from pigging “can exceed fifty (50) tons of VOC per year” in oil operations and “in the range of one (1) to two (2) tons of VOC per year” in natural gas operations, according to comments provided to EPA by the Colorado Department of Health and the Environment.<sup>89</sup> These estimates align with recent permit reviews in Pennsylvania, where EPA has entered a consent decree requiring midstream operators to include emissions from pigging sources and requirements to control those emissions in applications for operating permits.<sup>90</sup>

Commenter (0789-PADEP) suggests that EPA consider regulating natural gas emissions from blowdown activities. The commenter notes that since 2018, Pennsylvania has required pigging operations to employ a variety of best management practices to minimize emissions, in addition to a 95 percent emission reduction requirement for high emitters. Based on the state’s experience, the commenter recommends that EPA define pigging operations as a source category and include appropriate emission limits.

Commenters (0391-KBIC, 0586-Navajo EPA, 0605-Muscogee (Creek) Nation, 0781-NTAA, 0833-Ute EPD, 0943-Sault EPD) support regulation of emissions from pigging operations and related blowdown activities. The commenters state that they understand that technologies are available, feasible, and cost effective to prevent harmful emissions of methane, VOCs, and HAPs during these operations. The commenters add that they support a combination of the strategies identified as potential control options.

---

<sup>89</sup> Reconsideration Petition, *supra*, at 29.

<sup>90</sup> See Memo from Bradley Spayd, Pa. Dep’t of Env’tl Protection to AQ Case File SOOP-63-00968, Re: Comment and Response Document, MarkWest Smith Compressor Station at 4 (Dec. 2020) [hereinafter DEP MarkWest Memo] (estimating facility’s potential to emit 2.08 tpy VOCs and 0.08 tpy HAPs from pigging), <https://ehb.courtapps.com/efile/documentViewer.php?documentID=48038> MarkWest Consent Decree, *supra*, at 22-23, app. 1, app. 3.

Commenter (0744-NYSDEC) is encouraged to see EPA considering requirements for pigging and blowdown activities in a potential supplemental proposal as it would result in both emissions reductions and public health benefits. The commenter notes that the state's regulation will include a notification threshold of 10,000 standard cubic feet (scf) for blowdowns and will require annual reporting of pigging activities. The commenter believes that a threshold of 10,000 scf for blowdown is sufficient to cover most blowdown events. Compressor stations, where these activities take place, may be located near populated areas and/or EJ communities. The commenter asserts that it is important that these communities are notified of blowdown activity in a timely manner. Blowdown events result in significant releases of methane and VOCs, which have a negative impact on public health.

Commenter (0832-NMED) asserts that pigging operations and related blowdown activities should be addressed in a supplemental proposal and encourages EPA to adopt requirements similar to New Mexico. The commenter proposed a comprehensive emission reduction and LDAR strategy for pigging operations in the proposed Part 50. Individual pipeline pig launcher and receiver operations with a potential to emit (PTE)  $\geq 1$  tpy VOC located within the property boundary of, and under common ownership or control with, well sites, tank batteries, gathering and boosting stations, natural gas processing plants, and transmission compressor stations, are subject to the requirements of Part 50.

Commenter (1302-WYOC/PRBRC) suggests that there are opportunities to strengthen supplemental rules that the agency is considering in the future by addressing additional emission sources and ensuring that resources are being used efficiently to quickly prioritize and repair the most significant emission sources. The commenter specifically recommends that the future rule focus on reducing emissions from pigging and pipeline operations. The commenter notes that cleaning pipes through pigging operations can be a significant source of greenhouse gas emissions, and that there are existing technologies (such as installing multi-pig barrels and pump-down systems) that are already being used by some operators to reduce the frequency and intensity of venting during this common process. Similarly, the commenter asserts that future rules should eliminate the use of uncontrolled well blowdowns and require that these emissions be captured, used, or routed to combustors. The commenter notes that in areas like Wyoming's Upper Green River Basin, these blowdown events have been documented frequently as a major source of fugitive emissions and waste methane that have led to air quality concerns.<sup>91</sup>

Commenter (0918-COLGC ) supports a supplemental proposal that will provide proposed regulations for additional sources of pollution of methane and VOC emissions from the oil and natural gas sector. The commenter supports EPA proposing regulations to address pipeline "pigging" operations and pipeline blowdowns because effective technology currently exists to control emissions from these sources and several states have robust rules addressing emissions from these sources. The commenter asserts that the following state rules demonstrate the feasibility and cost effectiveness of requiring capture and control requirements to address venting from pigging and blowdowns and provide a blueprint for EPA to base a supplemental proposal to address emissions from these sources.

---

<sup>91</sup> 5 CCR 1001-9, Part D, § II.H.3.f.

The commenter (0918-COLGC) notes that Colorado recently updated its rules related to pigging emissions and emissions from blowdowns. In Colorado, the commenter states that owners or operators must capture and recover gas from pigging and blowdown activities, and if not possible, must request approval to install and operate air pollution control equipment, such as vapor recovery, flare/combustors, or utilize an approved alternative to reduce hydrocarbon emissions.<sup>92</sup>

The commenter (0918-COLGC) reports that Colorado also requires the use of certain best practices to reduce either the need or frequency of pigging and blowdown events or reduce the emissions from those activities.<sup>93</sup> These include keeping pipeline access openings to the atmosphere on the pig receiver closed at all times except when a pig is being placed into or removed from the receiver or during active pipeline maintenance activities and where feasible for pipeline blowdowns other than for pigging operations, rerouting gas to the low-pressure system using existing piping connections between high- and low-pressure systems, temporarily resetting or bypassing pressure regulators to reduce system pressure prior to maintenance, or installing temporary connections between high- and low-pressure systems.<sup>94</sup> The rules also require creating or updating operating and maintenance plans to provide for the use, where practicable, of other best practices including using short pig barrels, where it reduces the gas volume for potential release; planning for venting-reduction steps, such as pipeline pump-downs techniques (*e.g.*, in-line compressors, portable compressors, ejector), when large vessels and pipelines need to be isolated and depressurized; minimizing the volume that must be released. For example, adding stops to isolate a smaller section of a pipeline to reduce the length of pipe that must be vented; using inert gases and pigs to perform pipeline purges; Hot tapping to make new connections to pipelines; coordinating operational repairs and routine maintenance to minimize the number of emissions events and volume.<sup>95</sup>

The commenter (0918-COLGC) notes that in its recent rulemaking, Colorado analyzed the costs of pigging and blowdown emission reductions. The state reported an average cost per ton of emission reductions of \$5,707.06 per tpy VOC and \$40.78 per mtCO<sub>2</sub>e/year. These costs, however, do not separate out pigging emissions or specific types of blowdowns (such as compressor blowdowns), but do exclude pipeline emissions which are subject to BMPs but not control requirements in the proposal.<sup>96</sup>

The commenter (0918-COLGC) reports that New Mexico is currently updating their rules for Ozone Precursor Pollutants in the Oil and Gas sector and has proposed rules for pig launching and receiving. Under the proposed rules, individual pipeline pig launcher and receiver operations with a PTE equal to or greater than 1 tpy VOC located within the property boundary of, and under common ownership or control with, well sites, tank batteries, gathering and boosting stations, natural gas processing plants, and transmission compressor stations would be subject to the proposed requirements. Under the proposed rules, owners and operators of affected pipeline

<sup>95</sup> 5 CCR 1001-9, Part D, § II.H.4.d.

<sup>96</sup> Colorado Air Quality Control Commission, Cost-Benefit Analysis, p. 32 (Dec. 3, 2021), [https://drive.google.com/drive/u/1/folders/1b9rQvQ4IZADyCGi-BD\\_rvOt6h3Xfyd0X](https://drive.google.com/drive/u/1/folders/1b9rQvQ4IZADyCGi-BD_rvOt6h3Xfyd0X).

pig launcher and receiver operations must capture and reduce VOC emissions from pigging operations by at least 95 percent within two years of the effective date of this Part. If a combustion control device is used, the combustion device must have a minimum design combustion efficiency of 98 percent. The owner or operator conducting an affected pig launching and receiving operation must also employ specified best management practices.<sup>97</sup>

The commenter (0918-COLGC) notes that in Pennsylvania, owners or operators that conduct pigging operations must employ best management practices to minimize the liquids present in the pig receiver chamber and to minimize emissions from the pig receiver chamber including, but not limited to, installing liquids ramps, installing liquids drain, routing high-pressure chambers to a low-pressure line or vessel, using ball valve type chambers, or using multiple pig chambers. For pigging operations with a methane emission rate of 200 tpy or greater, or a VOC emission rate of 2.7 tpy or greater, or a single HAP emission rate of 0.5 tpy or greater, or a total HAP emission rate of 1.0 tpy or greater, after employing best management practices, the owner or operator must control methane, VOC, and HAP emissions from all pigging operations by at least 95 percent with a condenser, flare, thermal oxidizer, vapor recovery unit, or other air cleaning device, or any approved alternative method.<sup>98</sup>

Commenter (0776-CDPHE) provides details on Colorado's regulatory program for reducing emissions from pigging activities. The commenter notes that operational and maintenance activities in the midstream segment are the largest contributors of methane for midstream operations (other than from fuel combustion equipment), based upon data reported to the Air Division under Regulation 7 for 2020. The commenter contends that a number of studies and materials have documented that there are cost effective and technically feasible best practices to reduce these emissions.<sup>99</sup> The commenter provides that the Colorado's Air Commission adopted a rule in December 2021 addressing pigging and blowdown emissions at midstream operations.

The commenter (0776-CDPHE) reports that the Air Division consulted stakeholders and EPA enforcement officials to evaluate pigging operations<sup>100</sup> and analyze the potential for emission reductions, particularly methane reductions, throughout the segment. Colorado's rule covers pigging units at natural gas compressor stations, natural gas processing plants, and "stand alone

<sup>97</sup> NMED Proposed 20.2.50 NMAC, Section 20.2.50.121 (Jan. 18, 2021, Version).

<sup>98</sup> Pennsylvania GP-5 Permit, Section K; Pennsylvania GP-5A Permit, Section K.

<sup>99</sup> See, e.g., Methane Guiding Principles, Reducing Methane Emissions: Best Practices Guide – Venting (Nov. 2019) (submitted herewith as Attachment 16); ZEVAC, Sales Sheet, Safely and quietly reduce emissions to ZERO with ZEVAC's patented vacuum and compression technology (submitted as Attachment 17 to the commenters' letter); Dominion Energy, Environmental Stewardship through Methane Emission Reduction (Feb. 19, 2021) (submitted herewith as Attachment 18); Summit Utilities, Colorado Natural Gas Innovates with Methane Recapture Technology (Jan 27, 2021) (submitted herewith as Attachment 19); EPA, Methane Emissions from the Natural Gas Industry, Volume 7: Blow and Purge Activities (June 1996) (submitted as Attachment 20 to the commenters' letter)

<sup>100</sup> Colorado defines "pigging" as the process pursuant to which a pig is used, unrelated to the purpose for which the activity is conducted. Reg. 7, Part D, Section II.A.31. The "pigging pipeline" is the length of pipeline along which the pig traveled during a particular pigging operation. Reg. 7, Part D, Section II.A.33. The "pigging unit" is the piece of equipment into which a pig is placed (pig launcher), and from which a pig is removed after traveling the pigging pipeline (pig receiver). Reg. 7, Part D, Section II.A.34. Pigging units release emissions during the process of placing and removing a pig. The "pigging facility" is the source at which the pigging unit is located (e.g., well production facility, standalone pigging station, compressor station, etc.). Reg. 7, Part D, Section II.A.32.

pigging stations.”<sup>101</sup> Through stakeholder engagement and consultation with government agencies, the commenter determined that there are a number of standalone pigging stations that are not located within the boundaries of natural gas compressor stations or natural gas processing plants, and that it was necessary to also address pigging at these stations.

The commenter (0776-CDPHE) states that Colorado’s rule requires most operators in the Denver-Julesburg (“DJ”) basin (where production includes a significant amount of hydrocarbon liquids) to employ a liquids management system. As a pig travels through the pigging pipeline, it pushes liquids into the pig receiver. These liquids must be appropriately handled. The commenter worked with stakeholders to ensure that these practices are designed to reduce the emissions from pigging operations by reducing the flashing of hydrocarbons entrained in the liquids when the pigging unit is opened to remove the pig.

The commenter (0776-CDPHE) states that Colorado also requires the capture of gas emitted during pigging.<sup>102</sup> Based upon consultation with EPA staff and stakeholders,<sup>103</sup> Colorado relies upon a matrix of the size and pressure of the pigging pipeline to determine applicability of capture requirements. Colorado determined that all pigging operations where the diameter of the pigging pipeline attached to the pigging unit is twelve (12) inches or greater and pigging operations where the pigging pipeline has a normal operating pressure over 500 pounds per square inch gauge (psig) must employ capture or control techniques.<sup>104</sup> For smaller size and lower pressure pigging pipelines, Colorado determined that an emissions-based threshold was an appropriate approach. These thresholds are based on the location of the pigging unit, and depend on the type of location, such as whether the unit is located in a disproportionately impacted community (more stringent thresholds apply to sources in disproportionately impacted communities). For both pigging and blowdown emissions, Colorado’s thresholds are based upon VOC and methane to capture pigging operations across the state where gas composition varies.<sup>105</sup>

Commenter (0458-MDE) recommends that EPA follow Maryland’s example of transparency and require the use of the internet to post large blowdown events. The commenter notes Maryland’s recent regulations for controls in the natural gas sector, final effective on November 16, 2020, can provide a basis for the commenter’s suggested improvements to the November 2021

---

<sup>101</sup> Standalone pigging stations are “a pigging unit or group of co-located pigging units owned or operated by a midstream segment owner or operator but not located at a natural gas compressor station or natural gas processing plant.” Reg. 7, Part D, Section II.A.39.

<sup>102</sup> Colorado’s regulation also allows for operators to use control equipment in certain cases, but establishes a clear regulatory preference for capture of the gas. Colorado’s rules recognize that a minimal amount of gas will be emitted even after the use of required capture techniques. The emission of this residual gas is still considered effective capture.

<sup>103</sup> See Midstream Segment Data Collection - Blowdowns of Pigging Operations (Proposed Section II.H.) (submitted as Attachment 21 to the commenters’ letter).

<sup>104</sup> For newly constructed compressor stations, gas plants, and standalone pigging stations, gas emitted during pigging must be captured on all pigging units attached to pipelines with a normal operating pressure over 500 psig, regardless of the diameter size of the pipeline. Reg. 7, Part D, Section II.H.1.d and II.H.2.a.

<sup>105</sup> All emission calculations under this Section II.H - for both pigging operations and blowdowns - must be done pursuant to a Division-approved calculation method.

Proposal. The commenter generally supports federal rules, which better serve environmental protection and provide for industry certainty.

Commenter (0844-EDF *et al.*) recommends that EPA include proposed NSPS and EGs for pigging and blowdown activities on gathering pipelines in its supplemental proposal and consider proposing such standards for transmission pipelines as well. The commenter notes that pipeline pigging and blowdown activities are notable sources of methane, and technology and work practices are readily available to mitigate these emissions. The commenter agrees with EPA's identification of this issue in the November 2021 Proposal as an area of concern. The commenter asserts that because pigging and blowdown activities are similar on transmission lines, EPA should consider proposing NSPS and EGs for pigging and blowdown activities on transmission pipelines. The commenter provides the following details on methane releases and the prevalence of pigging and blowdowns.

The commenter (0844-EDF *et al.*) asserts that gathering pipelines have historically been subject to minimal federal oversight and are drawing increasing scrutiny as an environmental and safety concern. There are currently over 430,000 miles of onshore gas gathering lines in the United States,<sup>106</sup> yet EPA has never regulated pollution emissions from this equipment, although it has regulated associated gathering and boosting infrastructure in its oversight of methane emissions from gas production and processing. In 2020, the Pipeline and Hazardous Materials Safety Administration (PHMSA) regulated only 11,569 miles of onshore gas gathering lines, which are subject to reporting and leak survey and repair requirements.<sup>107</sup>

The commenter (0844-EDF *et al.*) states that the surge in domestic U.S. gas production since 2006 resulted in a significant expansion in the mileage of the gathering pipeline network and the volume of gas transported by gathering lines<sup>108</sup> Before 2006, gathering lines were generally smaller-diameter and lower pressure-pipelines that were “thought to pose relatively low risk to the public and the environment.”<sup>109</sup> But as industry expansion has placed increasing demand on this infrastructure, “[m]odern gas gathering lines often bear a closer resemblance to large interstate transmission lines than the diffuse network of small, low-pressure lines that previously characterized gathering lines.”<sup>110</sup> The commenter states that larger pipelines pose a greater risk of safety and environmental incidents and release higher volumes of methane during blowdown and pigging events.<sup>111</sup>

<sup>111</sup> See M.J. Bradley & Associates, Pipeline Blowdown Emissions and Mitigation Options at 11 (June 2016), <http://blogs.edf.org/energyexchange/files/2016/07/PHMSA-Blowdown-Analysis-FINAL.pdf>

The commenter (0844-EDF *et al.*) notes that emissions from pipelines can be categorized as either fugitive emissions that result from leaks, or operational emissions that result from pigging, blowdowns, and other activities associated with operation of the pipeline. Recent surveys and research have found that gathering lines are a significant source of methane emissions, including super-emitting events. Airborne surveys in the Permian Basin across Texas and New Mexico found that about 30 facilities persistently emitted large volumes of methane over multiple years (2019-2021), and repairing those leaks could immediately reduce 100,000 metric tons of methane per year.<sup>112</sup> Nearly 20 percent of the persistent super-emitting leaks were from gathering pipelines.<sup>113</sup> While persistent emission points on gathering lines are likely attributable to pipeline leaks, intermittent methane super-emitter events have also been identified on gathering pipelines, and may be the result of pigging and blowdown activities.<sup>114</sup>

The commenter (0844-EDF *et al.*) states that blowdowns are conducted intermittently on natural gas pipelines for multiple reasons, including to conduct integrity inspections, clean a pipeline, or conduct repairs. Blowdowns conducted without mitigation practices can be significant emissions events, as all of the gas is evacuated from a segment of pipeline. A recent transmission pipeline blowdown by Kinder Morgan in Texas released approximately 25,000 dekatherms of methane as part of a road construction project, and the release was detected by a European Space Agency satellite.<sup>115</sup> Upstream of gas processing plants, blowdowns and pigging activities release not only methane, but significant amounts of other pollutants, including VOCs and HAPs.<sup>116</sup> Pipeline operators conduct blowdowns on all types of pipelines: gathering, transmission, and distribution pipelines. Although pigging activities are most common to clean gathering pipelines transporting unprocessed gas, they are also used on transmission and distribution lines—for example, smart pigs may be deployed in any type of pipeline for integrity management, to identify stress, corrosion, and leaks.<sup>117</sup>

Commenter (0844-EDF *et al.*) notes that EPA states in the November 2021 Proposal that through the 2019 Greenhouse Gas Reporting Program (GHGRP), operators reported “472,995 total individual blowdown events from 1,212 facilities for a combined 307,630 metric tons of methane emitted, including 79,746 events at pig launchers or receivers for a combined total of 19,066 metric tons of methane.” The commenter adds that EPA acknowledges that the GHGRP data only includes emissions from blowdown equipment with a “unique physical volume greater than 50 cubic feet and occurring at a facility with total emissions greater than 25,000 metric tons

CO<sub>2e</sub>.” The commenter suggests that, because there may be blowdown events on gathering lines below the EPA reporting threshold, it is likely that EPA’s data underreports the true extent of emissions from these events. Furthermore, small gathering line operators “are less likely to have data on the characteristics of their gathering lines readily available,” and that “data on the characteristics of older gathering lines are less likely to exist than for newer pipelines.”<sup>118</sup> For this reason also, the commenter believes that pipeline operators reporting to the GHGRP may provide data that underestimates the actual emissions resulting from blowdowns.

Commenter (0844-EDF *et al.*) states that the blowdown emissions EPA describes in the November 2021 Proposal appear to be limited to gathering lines, but similar activities occur on transmission and distribution pipelines and cause significant emissions. The commenter notes that EPA quantifies methane emissions from pipeline blowdowns under the following categories in the GHGI and presents a table presenting GHGI emissions: [see TABLE in commenters’ letter: Methane Emissions from Pipeline Blowdowns, 2019 lists the CH<sub>4</sub> emissions in kt from Production-G&B Pipeline Blowdowns (31.5), Transmission-Pipeline Venting (199.4), Distribution-Pipeline Blowdown (4.4), and Total (235.3) <sup>119</sup>]

### ***18.2.3 Specific Pigging Operation/Blowdown Requirement Considerations***

Commenter (0808-API) recommends that EPA focus on reducing emissions volumes associated with pigging operations, allowing facilities to implement necessary emission reduction alternatives that are most appropriate as each location has a different set of circumstances for its operations. The commenter notes, as mentioned by EPA, that there are several alternatives for reducing the various emissions from pigging operations. Some alternatives might be appropriate for broad application and other alternatives could require unreasonable cost and infrastructure modification for minimal emissions reductions. Existing programs and practices already implemented by operators also need to be considered. There is a distinction in the feasibility of capturing and controlling pigging emissions from those pig launchers and receivers co-located at a compressor station or gas plant as compared to remote launcher and receiver locations where supporting infrastructure (*i.e.*, electrical power, line jumpers to low pressure pipelines, flares, etc.) does not exist.

The commenter (0808-API) provides examples of how emissions from a pig launcher or receiver can vary widely. Emissions from a pig launcher or pig receiver occur primarily from opening the isolated pig barrel (and often a short distance of piping connected to the pig barrel) to either insert or remove a pig. The emissions are from the natural gas inside this isolated area when the pig barrel is opened, which is typically called a “blowdown.” When a pig receiver is opened, there may be some residual liquids in the receiver, primarily from liquid falling off the pig itself. The commenter notes that the volume of liquids in the receiver is unrelated to the amount of

---

<sup>118</sup> U.S. Gov’t Accountability Office, Operators of Natural Gas and Hazardous Liquid Gathering Lines Face Data Collection Challenges at 9, 10, Report No. GAO-22-104817 (Jan. 2022), <https://www.gao.gov/assets/gao-22-104817.pdf>.

<sup>119</sup> U.S. EPA, Natural Gas and Petroleum Systems in the GHG Inventory: Additional Information on the 1990-2019 GHG Inventor, Annex 3.6: Methodology for Estimating CH<sub>4</sub>, CO<sub>2</sub>, and N<sub>2</sub>O Emissions from Petroleum Systems (published Apr. 2021), <https://www.epa.gov/ghgemissions/natural-gas-and-petroleum-systems-ghg-inventory-additional-information-1990-2019-ghg>.

liquid a pig pushes down a pipeline. This limited amount of liquid in the receiver may have the potential for minimal flash emissions and perhaps volatilization.

The commenter (0808-API) explains that emissions from pig launchers and receivers vary widely based on several different, and sometimes interrelated factors: the diameter of the pig barrel and connecting midstream gathering pipeline; the length of the barrel or portion of the midstream gathering pipeline in between the pigging unit isolation valves; the pressure and composition of the gas within the unit; pig launching or receiving frequency; and the amount of liquids accumulation (applicable to receivers only). Consequently, frequency of pigging operations alone is not a good proxy for actual emissions as it is just one element that informs emissions. As a result, the commenter states that, if one were to compare two pig launchers that are each used once per month, where the temperature is the same and the gas composition is the same, but the barrels have different diameters and lengths and different pressures, the actual emissions—calculated using the ideal gas law—from the two launchers would not be equal, potentially by a wide margin.

Commenter (0755-Texas Pipeline Association (TPA)) urges EPA to allow operational flexibility in technology and avoid overly prescriptive requirements in any pigging operations regulations. In the area of pigging operations, there is no one-size-fits-all approach; the most effective, efficient, and environmentally sound procedure will vary greatly from site to site and is highly dependent on each individual site's particular characteristics. If any standard is implemented, the commenter recommends that it be one that sets a goal and leaves it to individual regulated entities as to how that goal is to be achieved. The commenter states that overly prescriptive standards are inadvisable for the additional reason that reduction of emissions in pigging operations is an emerging field with new technology being developed on an ongoing basis. A top-down prescriptive approach, *i.e.*, a rule that does not just say what the goal is but goes on to dictate how that goal must be achieved, would run the risk of stifling, if not altogether killing, the innovation that is currently underway as companies and consultants develop innovative and varied ways to reduce pigging emissions. The commenter recommends that EPA allow such emerging innovation to flourish.

Commenters (0599-MSA, 0817-GPA) recommend that any requirements be technology-neutral. If EPA determines that emissions controls are required for pigging operations, the commenter asserts that specific methods should not be mandated because of the differences in equipment and pipelines on which they are used (*e.g.*, diameter, pressure, available space). Each potential control method has limitations depending upon the specific application.

Commenter (0831-AXPC) states that, similar to upstream operations, it is important that any regulation of pipeline “pigging” operations provide for operational flexibility in technology and approach.

Commenter (0585-KOGA) understands EPA’s mission and wishes to support common sense and economically viable solutions to enhance emission reduction. The commenter provides pipeline operations details for consideration.

The commenter (0585-KOGA) states that pipeline operations differ considerably by product transported and geography. Natural gas is produced throughout the U.S. from varying plays and with that the constituents of the raw product ranges from very saturated to very dry, resulting in a wide array of configurations and operational requirements to manage pipeline gas quality concerns.

The commenter (0585-KOGA) explains that the frequency of pigging varies greatly and the necessity to complete pigging activates ranges from operational purposes to regulatory required options to support overall integrity of pipe systems. Although pigging valves are an excellent option for operational pigging those facilities typically are not viable when completing internal inspection utilizing “smart” devices.

*Multi-pig launcher systems:* The commenter (0585-KOGA) asserts that these systems are a valuable tool for operators of larger diameter pipes and systems that require pigging on a frequent basis. However, application of this type of device would require significant modifications and equipment upgrade from small operators who frequently pig smaller diameter and low volume pipes for operational fluid removal. Those existing pigging facilities are typically smaller in diameter and contain less volume by function and design.

*Liquids Management:* The commenter (0585-KOGA) generally supports guidance regarding pigging facility design allowing for fluid to be drained from the bottom portion of the facility. Many pigging facilities already have this design and retrofitting existing facilities for future compliance would be manageable.

The commenter (0585-KOGA) provides that the installation of a ramp to allow for free draining of potential liquids entrapped by pigging devices inside of the receiver barrel seems unnecessary as receiver barrels are typically designed with larger diameters than the pipeline facility thus allowing room around the pigging device for fluid draining. Similarly, the installation of impermeable membranes would be excessive providing appropriate drain line installation. Certainly, the utilization of absorbent pads or similar devices placed at the entrance door opening would be a viable alternative to recover any minor amounts of fluids experienced during post pigging assembly entrance. The commenter (0585-KOGA) does not want to create an unsafe situation by adding absorbent pads and requiring their employees to handle the pads.

The commenter (0585-KOGA) believes that installation of jumpers between facilities is a viable method to transition from high to lower pressure or volume facilities during planned maintenance activities. Providing those facilities are of like maximum pressure thresholds and consideration can be made to protect the established design Maximum Allowable Operating Pressure/Maximum Operating Pressure. However, the commenter reports that many operators may not have ability to complete this activity due to system configurations or upstream and downstream sensitive customer load demands.

*Utilizing barrel pump devices:* fixed or portable compression or pump devices are becoming more widely available; however, the commenter (0585-KOGA) states that a similar affect can be achieved utilizing the jumper method for depressurization and volume transfer where system configurations permit. Operators of smaller diameter, low volume facilities may find the capital

purchasing, training, and potential qualifications for personnel to utilize these types of device an uneconomic option.

Commenters (0599-MS, 0817-GPA) assert that EPA should not impose control options for pig launcher and pig receiver blowdowns. The commenters explain that methods to reduce emissions from pig launchers and pig receivers are continuing to emerge, and the commenter urges EPA not to stifle innovation by mandating prescriptive requirements. In addition, the commenters note that there are limitations with these methods—there is no “one size fits all” solution. As such, if EPA develops a proposal, the commenters recommend that EPA limit any requirements to documentation of work practices employed to reduce emissions rather than mandate which work practices must be used. In addition, the commenters believe that EPA should not mandate certain emission reduction percentages, as doing so would preclude the use of certain methods (*i.e.*, a 95 percent control requirement may preclude the use of barrel pump down systems as described below). The commenters note that a reduction percentage requirement would also force operators to record theoretical emissions (*i.e.*, if a multi-pig launcher is used, would operators record the theoretical emissions of a traditional pig launcher?).

The commenters (0599-MS, 0817-GPA) provide comments about six methods to reduce or control blowdown emissions from pig launchers and pig receivers:

1. *Multi-Pig Launcher Systems.* The commenters state that multi-pig launcher systems are not an appropriate emissions reduction system. The commenters recommend that EPA not consider mandating multi-pig launchers as an appropriate system for emission reduction. The commenters note that the EPA’s statement that it “understands that multi-pig launchers and receivers are most appropriate for large diameter pipelines,” 86 Fed. Reg. at 63,243, is somewhat oversimplified and should not be the foundation for regulatory requirements. Multi-pig barrels may refer to a specific technology where multiple pigs can be loaded into a launcher apparatus (usually accompanied by a multi-pig receiver). The use of such multi-pig launchers and receivers is usually dictated by the frequency of pigging. For example, the commenters provide that a multi-pig launcher that can accommodate seven pigs may be used when a pipeline must be pigged every day, and the downstream pig receiver is sized to hold seven pigs. Once a week, the pig receiver would be opened to retrieve the pigs, and the pigs would be loaded into the pig launcher. Or a multi-pig launcher may send multiple pigs a day. However, if pigging frequency is expected to decline rapidly over time (*e.g.*, from daily to monthly), pigs may be pulled per pigging event, and the larger multi-pig systems could have larger emissions per pigging event. Multi-pig systems are expensive, costing approximately \$1 million per system for a 16-inch pipeline.

Longer pig receiver barrels may also be referred to as “multi-pig barrels” because they could theoretically accommodate multiple pigs. These longer barrels are usually installed where “smart pigs” are used for pipeline inspections. However, in practice, the commenters report that most operators remove each pig as it is received to ensure all pigs are accounted for (*i.e.*, to ensure the pig isn’t stuck in the pipeline).

2. *Pig Ball Valves.* The commenters state that pig ball valves should not be considered valid

control devices as they are not commonly used. The apparatus tends to have many small crevices where liquids can get trapped and freeze. Further, where pig launchers and pig receivers operate close to production sites, debris (such as sand) in the pipeline fluid can damage the valve seals. In either case, the entire pipeline to the nearest upstream and downstream isolation valves must be blown down to repair the pig ball valve.

The commenters report that the cost of a pig ball valve varies by pipeline size, but operators report costs ranging from \$15,000 to \$60,000, which depends on the size of the pipeline. Generally, these are only cost effective for pipelines six inches or less in diameter. Further, should the pig ball valve need maintenance, to avoid blowing down the entire pipeline and creating a significant emissions event, operators may install isolation valves on either side of the pig ball valve, however, this significantly adds to the cost. Pig ball valves are best suited when physical space is too small to accommodate a traditional pig launcher or pig receiver.

The commenters add that another drawback is that some pig ball valves require the use of a specific manufacturer's pig or one of a particular type. This reduces operational flexibility and may add to costs. Notably, pig ball valves are not compatible with smart pigs. Therefore, operators may have to use both a pig ball valve and a traditional pig launcher or pig receiver to use smart pigs. This obviously involves increased costs.

3. *Jumper Lines.* The commenters recommend that jumper lines not be mandated due to their limited use. Jumper lines (which the commenter understands to be temporary or permanent hosing or piping) to route gas from a high-pressure system to a lower pressure system should not be mandated, as they are limited to pig launchers and pig receivers operating at higher pressure that are physically near to a low-pressure system, such as a low-pressure pipeline. The commenters estimate that jumper lines are only feasible for less than 5 percent of pig launchers and pig receivers.

The commenters add that jumper lines raise safety concerns due to the need to route higher pressure gas to a lower pressure system (including pipelines that are only rated to operate safely up to a certain pressure). Over-pressurization is a significant risk, so the use of jumper lines necessitates very specific operating procedures and, ideally, engineering "backstops" such as a rupture pin valve, to prevent over-pressurization.

Additionally, the commenters report that a low-pressure system would need to also provide some place for the gas to go or be used, which may not be available. For example, a fuel gas system at a compressor station is a low-pressure system, but only so much fuel is consumed. As a practical matter, the pressure "draw down" rate would be set according to the capacity of the low-pressure system to move or consume the gas.

According to the commenters, installing a low-pressure blowdown system at a facility would cost around \$100,000. One operator reports connecting three separate high-pressure pig barrels to low pressure lines that were 250 feet away at a cost of approximately \$35,000 (this included a hot tap, which was necessary to have a tie in point to the low-pressure system).

Further, the commenters add that EPA states that “[g]ases that remain in high pressure barrels after venting to low pressure systems, and gases in low pressure barrels, can be recovered during depressurization by discharging the gases to very low-pressure systems at the site (e.g., 10–15 psig).” 86 Fed. Reg. at 63,245. But some operators have vapor recovery unit (VRU) lower pressure suction shutdowns at 25 psig. Therefore, the commenter recommends that EPA not assume the pressure at which low pressure systems operate. Additionally, where VRUs are not available, low pressure gathering lines will act as the low-pressure system, and the pressure of these lines vary and more typically range from 40 psig to 200 psig.

4. *Barrel Pump Down Systems.* The commenters assert that barrel pump-down systems are a costly investment without the recovery that EPA assumes. The commenters state that in a pump-down system, the pig launcher or pig receiver is isolated from the main pipeline by closing the isolation valves. Once isolated, the launcher or receiver is connected by (an often temporary) pipe or hose to the pump down unit, which is then connected by (an often temporary) pipe or hose to the main pipeline. The pipe/hose and the pump down unit may need to be cleared of oxygen before they are put into service so some of the vapor in the isolated pig launcher or pig receiver is used to purge the pipe/hose and pump down unit. The remaining gas in the pig launcher or pig receiver is routed to the main pipeline. The pump down unit reduces the pressure of the isolated launcher or receiver to the lowest pressure allowable for the pump down unit (e.g., 5 psi). The gas remaining in the isolated pig launcher or pig receiver at this low pressure is blown down to atmosphere. The gas remaining in the piping/hosing and pump down unit are also released to atmosphere upon disconnecting the piping/hosing and pump down unit from the pig launcher or pig receiver.

The commenters add that some pump-down units are driven by an air compressor. The air compressor is driven by a diesel engine, truck engine, or electricity, if available. The commenters states that EPA’s claim that pump-down units recover greater than 99 percent of the depressurization vapors from pig launchers and pig receivers does not appear to account for purging the pipe/hose and pump down unit prior to commissioning, residual gas in the pig launcher or pig receiver once the lowest pressure is achieved, disconnecting the piping/hosing and pump down unit, and emissions from a generator or truck engine to drive the air compressor. The percent control achievable is largely a function of the pressure of the gas in the pig launcher and pig receiver after isolation, which is a function of the operations of that pipeline.

The commenters report that pump-down systems cost approximately \$500,000, excluding the cost of personnel to operate the equipment. According to the commenters, this can be significant because using these systems takes much longer than a blowdown, so operators would need to add staff to account for this additional time.

5. *Low-Capacity Combustion Devices.* The commenters state that low-capacity combustion devices are not appropriate control measures. The commenters note that temporary flares are generally not designed for a high pressure blow down that may contain some liquids, and this can cause smoking. Smoking can be reduced by assist air or gas but that is often

unavailable or infeasible at remote locations. The commenter is concerned that temporary flares do not meet NSPS control device requirements.

Where liquids are present, the commenters state that operators would need to employ a liquid knock out system and then manage those liquids. This would require two trailers at the site—a flare trailer and knockout skid trailer. Additionally, flares are designed for certain operations and services. A flare designed to combust gas from a low-pressure pig launcher or pig receiver would not be appropriate to combust gas from a high-pressure pig launcher or pig receiver; thus, operators may need to purchase multiple flares.

The commenters add that significant planning and coordination are required to use temporary flares safely and within the often-cramped confines of the right-of-way. Erecting trailer-mounted combustors many times a day throughout the field is simply an unacceptable safety hazard while permanent combustion devices at remote locations would be both economically infeasible and would likely be opposed by the public.

6. *Short” Pig Barrels.* The commenters assert that other technologies such as “short” pig barrels present issues and should not be mandated. The commenters oppose any regulation pertaining to the use of “short” pig barrels because these preclude the use of multi-pig launchers which may be better technologies for reducing emissions at certain operations. Also, the commenters note that short pig barrels may not accommodate smart pigs without the construction of duplicate pigging systems. The commenters’ statement is in response to EPA’s request for comment regarding other pigging operations technologies, and the commenter’s consideration of technologies and work practices included in consent decrees or state rules.

The commenters (0599-MS, 0817-GPA) recommend that EPA not mandate potential control options for pig receiver liquids management and present details regarding liquids management methods that are presented below.

The commenters (0599-MS, 0817-GPA) note that most liquids pushed by the pig either continue down the pipeline (if the pig receiver is not at a compressor station or gas plant) or are collected in a vessel such as a slug catcher (if the pig receiver is at a compressor station or gas plant). In other words, most of the liquids that are pushed by the pig are not retained in the pig receiver. Additionally, regarding work practices for managing pig receiver liquids, after the pig reaches the receiver, gas continues to flow through the receiver until the operator isolates it from the main pipeline. This provides a sweep of gas that also removes some residual liquids from the receivers. The commenters report that many operators restrict gas flow through the main line to push additional gas through the receiver and provide an additional “sweep” prior to isolation. The commenters assert that this work practice already assists greatly in liquids management. The commenters offer three points regarding liquids management:

1. *The commenters recommend that EPA not mandate condensate drain lines.* Liquids that drop out in a pipeline are pushed ahead by a pig (or pigs) for recovery. Some pig receivers have condensate drains connected to the main pipeline. When the drain line is open, gas pushes the residual liquids in the receiver to the pipeline. The drain line must

return to the pipeline at a lower elevation (often underground) than the pig receiver to create the necessary differential pressure. Although condensate drains are commonly used, compliance mandates would not be possible in all operating conditions/facilities. For example, cold weather has presented problems in certain regions and those operators cannot—and do not—install condensate drains due to freezing in the winter.

Even for those operators that can comply, the commenters state that retrofitting is a substantial effort. The process would likely require excavation to connect the line to the main pipeline, in addition to other requirements, and would be costly (\$30,000–\$75,000 depending on if a hot tap is required) and may trigger other regulatory or permitting requirements. According to the commenters, mandating condensate drain lines for existing pig receivers is, therefore, not appropriate.

2. *The commenters recommend that EPA not mandate pig ramps as they offer limited benefits and present safety risks.* A pig ramp is a structure built into a pig receiver barrel that slightly elevates the received pig to allow liquids to flow back to the barrel drain (if a drain is present). Liquids on the pig itself may also drain off. There is a small “lip” on the pig ramp near the door which may retain some liquids within the barrel. Pig ramps do not eliminate liquids in the receiver barrel; they only route them to drains.

The commenters add that pig ramps provide limited VOC and methane emission benefits. Draining the small amount of residual liquids may avoid some flash emissions or volatilization. Depending on liquid volume, liquid composition, and how well liquids are currently managed by nature of the pig receiver design, pig ramps may or may not be cost effective. Pig ramps are not commercially manufactured and require fabrication shop construction. The commenters are aware of only one operator using pig ramps and that is only due to a consent decree requirement. The commenters estimate that a pig ramp could cost \$1,000 to \$4,000, depending upon the pipeline diameter. This is based on the sole operator who has fabricated pig ramps and fabrication shop quotes from other operators.

According to the commenters, there are risks involved with using a pig ramp. The ramp must be affixed firmly because there is a risk of spark and explosion with metal-on-metal movement. Using plastic materials is not feasible. In certain circumstances, the barrel must be removed or purged with nitrogen during installation to mitigate explosion risk. The ramp cannot be present for “smart pigging” in all circumstances, requiring the installation of a temporary barrel. Ramps also increase crevice corrosion. This increases costs from inspection and replacement of certain components of the pig receiver. Unless installation and pigging schedules are very closely coordinated, especially for infrequently used pig receivers, installing pig ramps will necessitate an additional blowdown that would not otherwise occur. Because emissions from pig receiver blowdowns may be higher than emissions avoided, it is possible that pig ramp installation will increase emissions.<sup>120</sup>

---

<sup>120</sup> See Exhibit 1, Excerpt of the Joint Prehearing Statement of the Colorado Oil & Gas Association and American Petroleum Institute Colorado Before the Colorado Air Quality Control Commission In the Matter of Proposed Revisions to Colorado Air Quality Control Commission Regulation Number 7 and Regulation Number 22.

3. *The commenters state that enhanced liquid containment is not a workable option.* For field pig receivers, enhanced containment would require the operator to attach an impermeable cover over the catch basin after the pig liquids are removed. However, the commenters believe this is unworkable with little to no benefit. Residual hydrocarbon liquids in the pig receiver would begin to flash immediately upon opening the receive door. Even if flashing is not complete after the liquids are emptied to the catch basin, both the catch basin and impermeable lid would have to be pressure-containing and operators would have to develop a process to eliminate liquids and flashed vapors without emissions. The commenters are not aware of any real-world configurations like this.

At some compressor stations and natural gas plants, a system along these lines would include condensate drains on a pig receiver to a downstream pressurized “slug catcher” vessel. The vapor recovery unit on the vessel would route the vapors to the facility inlet. Liquids in the slug catcher would be managed with other liquids at the facility. The commenters report that there could be variations on this design, but it is a robust and complex engineering solution.

The commenters note that some operators have lids that slide over pig receiver liquid troughs, but these are used to prevent rainwater from entering the trough.

Commenters (0599-MS, 0817-GPA) recommend that, as EPA established with storage vessels, any control or work practice requirements developed should only apply to pigging operations that exceed an emission threshold, such as 1 tpy VOC, because the control scenarios will be costly to implement. The commenters believe this to be especially true at existing sources. The commenters contend that providing an emission threshold will also encourage operators to develop innovative engineering solutions that will avoid or prevent emissions from occurring.

Similarly, commenter (0755-TPA) recommends that EPA recognize that the scope and level of emissions varies greatly from one pigging operation and the next, and therefore it is reasonable for any new standard to contain applicability thresholds expressed in emissions amounts, measured at each individual receiver or launcher, to exclude those sources and operations that are not resulting in significant emissions. The commenter notes that in many cases the emissions from a launcher or receiver can be *de minimus*, while a more extensive operation at an upstream location could result in higher emissions. The commenter asserts that in keeping with other provisions in the NSPS, an applicability threshold is a reasonable and fair way to avoid undue burden on small sources and further avoid imposing requirements that do not meet a reasonable cost versus environmental benefit standard. The commenter states that an applicability threshold would have the additional benefit of incentivizing owners and operators to find ways to reduce emissions, to keep emissions below applicability levels.

Commenters (0599-MS, 0817-GPA) recommend that EPA only consider proposed language regarding the control of pigging emissions for new facility construction due to the significant capital required to add or modify or retrofit existing control devices.

Commenter (0755-TPA) recommends that EPA requirements on pipeline blowdowns should only apply to large blowdowns, as supported by a reasonable cost-benefit analysis in this area. The cost of reducing blowdown emissions can be substantial, as the effort would generally include procurement, installation, and operation of recovery or combustion control equipment such as pump down systems or temporary combustion devices. Installation of such equipment should not be required in the context of small blowdowns producing minimal emissions. Thus, any regulatory limits in this area should contain an exclusion for small blowdowns creating minimal emissions.

Commenters (0599-MSD, 0817-GPA) suggest that if regulations are developed, they apply based on a per event threshold and be limited to planned, non-emergency blowdown events.

Commenter (0789-PADEP) recommends that EPA review and consider the Consent Decree between EPA and Pennsylvania Department of Environmental Protection with Mark West Liberty Midstream & Resources, LLC and Ohio Gathering Company, LLC. The commenter notes that the consent decree requires installation of enclosed flares at select compressor stations and implementation of certain best management practices when conducting pigging operations, among other controls, that may be appropriate to incorporate in the proposed rule.

Commenter (0809-Earthjustice) states that EPA has a great deal of readily available information regarding the implementation, costs, feasibility, and emission reductions of pig launchers and receivers potential control options. The commenter notes that as part of its 2018 consent decree, EPA required the installation and operation of “pig-ramps” and “jumper lines” at existing and new pig launchers and receivers in Pennsylvania and Ohio.<sup>121</sup> The commenter adds that EPA also required MarkWest to “disseminate and make available for use by other oil and gas companies its proprietary design for Pig Ramps” and to educate other operators on the installation and use of pig ramps and jumper lines.<sup>122</sup>

Commenter (0944-Kuva Systems) reports that at sites with continuous OGI camera installations, emissions from pigging operations can be detected, recorded and quantified. This information may be used for checking compliance, and for training purposes to improve operational practices to minimize emissions. The commenter believes that C-OGI cameras are particularly suitable for this task as they generate images with color overlay of emissions that are easily understandable by operations staff and much more likely to result in behavioral change training with then non-visual tools. Moreover, the commenter adds that such information may be collected without incremental cost at sites where C-OGI cameras are installed for other reasons.

Commenter (0844-EDF *et al.*) provides details on technology and work practices that are readily available mitigation practices that can limit emissions from blowdown and pigging events. The commenter recommends that EPA consider these and all other potential options as it considers a supplemental proposal to address methane emissions from blowdown and pigging activities on pipelines.

---

<sup>121</sup> See MarkWest Consent Decree, *supra*, at 10-14.

<sup>122</sup> *Id.* at 16-17.

The commenter (0844-EDF *et al.*) notes that the November 2021 Proposal documents multiple proven technologies and practices that are available to reduce blowdown and pigging emissions, focusing on jumper lines, vapor recovery units or other fuel gas systems, small compressors (barrel pump-down systems), and flares. As discussed in a report by M.J. Bradley & Associates, the commenter reports that these kinds of mitigation technologies and practices can reduce methane emissions from gas pipeline blowdown by up to 90 percent.<sup>123</sup> The M.J. Bradley report details five mitigation options, four of which are also identified in EPA's November 2021 Proposal: pressure reduction with in-line compressors, pressure reduction with mobile compressors, transfer of gas to a low-pressure system, isolating a small pipeline section with stopples, and flaring. The report provides detailed cost and man-hour estimates for each mitigation option,<sup>124</sup> summarized in a table presented in their comment letter.

[See Table 6, Costs and Benefits of Blowdown Mitigation Options, lists the Interstate and Intrastate Costs (\$/event), Methane Reduction (MT/event), and Average Cost (\$/MT)]

The commenter (0844-EDF *et al.*) reports that the data show that all of these measures are highly cost-effective, and in most cases, one to two orders of magnitude lower than values that EPA has in the past defined as cost-effective for methane controls. However, consistent with the commenter's recommendations in these comments for other sources, they note that flaring is a decidedly inferior control strategy from both environmental and waste perspectives and should only be permitted as a means of avoiding venting during blowdown and pigging events when all other options are either truly unavailable or would present safety concerns. Furthermore, the commenter notes that the documentation of successful blowdown emissions mitigation efforts indicates the value of specific and detailed work practices. Operators must normalize and incorporate work practices into their regular operations so that consideration of methane abatement is part of the job. Below, the commenter describes some of the work practices (some of which overlap with the measures identified in the M.J. Bradley report) that can successfully curb emissions from pipeline blowdown and pigging events.

*California Gas Utility Methane Abatement Practices.* California law SB1371, enacted 2014, requires natural gas utilities to minimize methane emissions from the transmission and distribution systems. The California Public Utilities Commission approved a gas leak abatement program as part of SB1371 implementation, adopting 26 mandatory Best Practices ("BPs") for minimizing methane emissions that include multiple provisions to reduce blowdown emissions<sup>125</sup> These BPs, which could also help to reduce emissions from pigging activities, include the following:<sup>126</sup>

---

<sup>123</sup> M.J. Bradley & Associates, Pipeline Blowdown Emissions and Mitigation Options at 14 (June 2016), <http://blogs.edf.org/energyexchange/files/2016/07/PHMSA-Blowdown-Analysis-FINAL.pdf>.

<sup>124</sup> *Id.* at 14-20. The report also quantifies the benefits of each mitigation option based on the economic and social value of saved gas, but these values may no longer reflect the most recent and accurate Social Cost of Carbon and Social Cost of Methane values.

<sup>125</sup> California Public Utilities Commission, Decision Approving Natural Gas Leak Abatement Program Consistent with Senate Bill 1371, Decision 17-06-015, Appendix B: Best Practices for Natural Gas Leak Abatement Program (June 15, 2017).

<sup>126</sup> *Id.* at B5-B6, B14-B15.

- BP23, Minimize Emissions from Operations, Maintenance and Other Activities. – “Utilities shall minimize emissions from operations, maintenance and other activities, such as new construction or replacement, in the gas distribution and transmission systems and storage facilities. Utilities shall replace high-bleed pneumatic devices with technology that does not vent gas (*i.e.*, no-bleed) or vents significantly less natural gas (*i.e.*, low-bleed) devices. Utilities shall also reduce emissions from blowdowns, as much as operationally feasible.”
- BP5, Methane Evacuation Procedures. – Utilities shall establish “[w]ritten company procedures implementing the BPs approved for use to evacuate methane for non-emergency venting of high pressure distribution (above 60 psig), transmission or underground storage infrastructure and how to use them consistent with safe operations and considering alternative potential sources of supply to reliably serve customers.”
- BP6, Methane Evacuation Work Orders Policy. – Utilities shall establish a “[w]ritten company policy that requires that for any high pressure distribution (above 60 psig), transmission or underground storage infrastructure projects requiring evacuating methane, Work Planners shall clearly delineate, in procedural documents, such as work orders used in the field, the steps required to safely and efficiently reduce the pressure in the lines, prior to lines being vented, considering alternative potential sources of supply to reliably serve customers.”
- BP7, Bundling Work Policy. – Utilities shall establish a “[w]ritten company policy requiring bundling of work, whenever practicable, to prevent multiple venting of the same piping consistent with safe operations and considering alternative potential sources of supply to reliably serve customers. Company policy shall define situations where work bundling is not practicable.”

Commenter (0844-EDF *et al.*) provides that the California gas utility Pacific Gas & Electric Company (PG&E) has documented in detail the implementation of practices to minimize blowdown emissions in its Leak Abatement Compliance Plan, as required by SB1371.<sup>127</sup> The company reported that “[f]or non-emergency gas transmission pipeline blowdowns, PG&E abated approximately 80 percent of the total gas volume released from its transmission pipeline projects through drafting and cross compression.”<sup>128</sup> The breakdown of these emission reductions is presented in a table. [Per Table in comment letter: PG&E 2018 Transmission Pipeline and Regulator Station Abatement Activities details Total Gas Volume (Mscf) per Pipeline Activity type; Drafting (119,833), Cross Compression (504,320), Blowdown (159,215), Total Gas Baseline (783,372), Percent Gas Diverted to Drafting or Cross Compression (80 percent)]

The commenter (0844-EDF *et al.*) reports that to reduce methane emissions during non-emergency blowdowns, PG&E developed a new standard and procedure, TD-5601S and TD-5601P-01. The new standard provides numerous directives, including to “[s]chedule all planned gas transmission system construction projects with sufficient lead time to incorporate emission reduction strategies, including project bundling, drafting, cross compressing and flaring.”<sup>129</sup> The commenter adds that the company’s Plan also identifies numerous next steps that it will

<sup>127</sup> PG&E, 2020 Leak Abatement Compliance Plan (submitted Mar. 16, 2020; amended Oct. 19, 2020) .

<sup>128</sup> Id. at 1-1.

<sup>129</sup> Id. at 1-13, 1-55, 1-61.

undertake to improve on its existing best practices for blowdowns, suggesting that further methane emissions mitigation can be achieved. For example, the company describes a goal to purchase additional trailers with mobile compressors so that multiple compression jobs can proceed simultaneously; to investigate purchasing a “gas-driven mobile fill compressor and tube trailers . . . to use mobile compression” to reduce emissions from smaller blowdowns or pipelines that do not have a nearby pipeline to cross-compress into; and to “[e]xplore the applicability and feasibility of using multi-stage/boost compressors to further reduce the amount of gas released during backbone pipeline blowdowns.”<sup>130</sup>

The commenter (0844-EDF *et al.*) states that additionally, the company is evaluating new technology to replace flaring by catalytically oxidizing methane, through a pilot project with Stanford University and NYSEARCH.<sup>131</sup> The company is exploring other technologies to reduce blowdown emissions:

PG&E plans to explore the use of ZEVAC technology in gas operation activities. ZEVAC uses compressed air to eliminate emissions. The compressed air is used to suction the pipeline segment and compresses the gas into an adjacent pipeline or tank. The intake could then be discharged back into the system. ZEVAC technology will be assessed for use in reducing emissions from non-emergency blowdowns and has the potential to further reduce emissions from non-emergency blowdowns.<sup>132</sup>

*Methane Guiding Principles.* The Methane Guiding Principles (MGP) is a voluntary, international partnership that has issued detailed best practices to reduce methane emissions along the natural gas supply chain, developed by a coalition of industry and civil society organizations.<sup>133</sup> The commenter (0844-EDF *et al.*) explains that MGP includes best practices to reduce methane emissions from pipeline pigging and blowdown activities.

The commenter (0844-EDF *et al.*) reports that regarding pigging, the MGP recommends the use of pig ramps and jumper lines to reduce emissions during the insertion and removal of a pig from a pipeline. The operating requirements include “extra time . . . from the pig being received to it being removed from the receiver to allow the liquids to drain back to the pipeline,” as well as a low-pressure system “available on-site to accept the gas from the pig trap.”<sup>134</sup> The guide reports industry estimates that “using pig ramps and jumper lines can reduce emissions from pigging by up to 85 percent at a cost of approximately US \$8,175 per facility.”<sup>135</sup> Additionally, the commenter notes that MGP recommends use of a vapor recovery unit to capture the gas vented when a pig is launched/received, and the gas released from storage tanks that receive the liquid

<sup>135</sup> Id. at 12.

and debris removed by the pig.<sup>136</sup> As a last resort, captured gas can be flared rather than vented, although we emphasize again that flaring should only be used when other alternatives to venting are not feasible or would jeopardize safety.<sup>137</sup>

The commenter (0844-EDF *et al.*) reports that regarding blowdowns, the MGP recommends an initial practice of avoiding blowdowns whenever possible. Inline-inspection tools and smart pigs (with the other mitigation measures discussed to reduce pigging emissions) that can be deployed without having to blowdown a pipeline segment are preferable, and necessary blowdowns should be planned in advance and bundled to decrease overall emissions.<sup>138</sup> When blowdowns must occur, the MGP details additional mitigation strategies to reduce blowdown emissions, which are aligned with EPA's November 2021 Proposal:

- Lower the pressure in the pipeline by allowing consumer drawdown;
- Re-route the gas to an existing network with lower pressure or use it as fuel;
- Recompression;
- Mobile compressor stations;
- Install plugging equipment to shorten the segment of pipeline involved; use isolation valves to minimize impact;
- Make new connections and repair with a hot tap;
- Use in-line inspection (ILI), or 'smart pig' technologies instead of hydrotests;
- Reroute the natural gas to a duct burner, thermal oxidizer, or flare if possible, planned, and allowed (although flaring is not always possible during an emergency, and should only be used when other options are infeasible or unsafe).<sup>139</sup>

*Colorado Pigging and Blowdown Standards.* The commenter (0844-EDF *et al.*) states that the Colorado Air Quality Control Commission recently adopted standards to limit oil and gas methane and air pollution, including establishing requirements to reduce pipeline pigging and blowdown emissions.<sup>140</sup> The Commission requires that pipeline "owners or operators capture and recover gas from pigging and blowdown activities, and if not possible, to request Division approval to install and operate air pollution control equipment, such as vapor recovery, flare/combustors, or a Division-approved alternative to achieve a 95 percent reduction in hydrocarbon emissions."<sup>141</sup>

<sup>141</sup> *Id.* at p396, Part X., Statement of Basis, Specific Statutory Authority, and Purpose for December 17, 2021 Revisions.

The commenter (0844-EDF *et al.*) provides that the standard requires that pipeline owners or operators use “best practices to minimize emissions from pigging operations and blowdowns during normal operations.”<sup>142</sup> The identified best practices include (a) keeping pipeline access openings on the pig receiver closed at all times except when a pig is being placed into or removed from the receiver, or during active pipeline maintenance activities; (b) using liquids management system to reduce the accumulation of liquids in the pigging unit; (c) rerouting gas to a low-pressure system using existing piping connections, temporarily resetting or bypassing pressure regulators to reduce system pressure prior to maintenance, or installing temporary connections between high- and low-pressure systems. The commenter adds that standards also require that operators create or update an operating and maintenance plan to provide for the use of these additional best practices:

1. Using short pig barrels, where it reduces the gas volume for potential release.
2. Planning for venting-reduction steps, such as pipeline pump down techniques (*e.g.*, in-line compressors, portable compressors, ejector), when large vessels and pipelines need to be isolated and depressurized.
3. Minimizing the volume that must be released. For example, adding stops to isolate a smaller section of a pipeline to reduce the length of pipe that must be vented.
4. Using inert gases and pigs to perform pipeline purges.
5. Hot tapping to make new connections to pipelines.
6. Coordinating operational repairs and routine maintenance to minimize the number of emissions events and volume.<sup>143</sup>

The commenter (0844-EDF *et al.*) asserts that there are numerous cost-effective technologies and work practices that can significantly reduce methane emissions from pipeline blowdowns. The commenter notes that the examples provided above do not represent all available options or all operators using these practices.

#### ***18.2.4 Opposition to Regulation of Emissions from Pigging Operations Without Further Consideration***

Several commenters (0599-MSD, 0742-ADEC, 0755-TPA, 0782-Berkshire Hathaway Energy Company (BHE), 0815-American Gas Association (AGA), 0817-GPA, 0923-Lambda Energy Resources LLC (Lambda)) express opposition to regulating emissions from pigging operations and/or oppose without further consideration.

Commenter (0782-BHE) discourages EPA from adding vented emissions from pigging to the regulations, especially for the transmission and storage (T&S) segment. Related discussion in the November 2021 Proposal focuses on pigging operations upstream of T&S (and gas processing), where pigging may be conducted more frequently to manage liquids that can gather in lines. Liquids are removed upstream of T&S, and pigging is conducted in the T&S segment on a less frequent basis and for a different purpose – to manage pipeline integrity issues. Where possible, the commenter states that they employ best operating and maintenance practices to reduce pigging emissions; however, there are instances where public, employee, and contractor safety

---

<sup>142</sup> Id. at 5 CCR 1001-9 Section II.H.4 at p169.

<sup>143</sup> Id. at 5 CCR 1001-9 Section II.H.4.d. at p170.

and asset management are of the highest priority and importance and some venting may occur. At this time, there is limited information available on emissions from pigging operations for T&S, but operator experience indicates this is a relatively small emissions source for the T&S sector. Because a PHMSA program is in place and emissions characteristics are not well understood, the commenter recommends against EPA adding T&S pigging operations into the regulations. At most, the commenter suggests that EPA further investigate the characteristic emissions for T&S (*i.e.*, typical event emissions, frequency of events) before considering any additional action.

Commenters (0599-MS, 0817-GPA) state that “pipelines” should not be regulated as “affected facilities” for purposes of regulating pipeline blowdowns. The commenter notes that it is unclear whether EPA intends to propose language regulating pipeline blowdowns or the pipelines themselves. As a threshold matter, blowdowns associated with pigging operations must be considered separate and apart from blowdown associated with other pipeline operations. The commenters note that blowdowns associated with pigging operations occur at discrete pig launchers and pig receivers, are typically small, and are generally predictable. Pipeline blowdowns, on the other hand, can occur anywhere along the pipeline, can be large, and occur due to unpredictable maintenance or emergency needs.

The commenters (0599-MS, 0817-GPA) assert that before developing any proposal concerning pipelines as “affected facilities,” EPA must identify and explain for stakeholders the “stationary source” within which this “affected facility” would be found. Indeed, the commenter notes that no NSPS standard currently applies to pipelines as stationary sources and EPA has not historically defined pipelines as stationary sources and it is difficult, then, to understand EPA’s position that pipelines could be designated as “affected facilities.”<sup>144</sup> (See section 18.2.5 below for further comments on their position on designating pipelines as affected facilities.) Moreover, pipelines are highly regulated already. Hence, designating entire pipelines as either a stationary source or an affected facility would require coordination with the Federal Energy Regulatory Commission, the Pipeline and Hazardous Safety Administration, and state agencies and require extensive case-by-case evaluation of pipelines and related “affected facilities” that span miles, cross property lines and state borders, and may have multiple operators. Moreover, the commenters state that “pipelines” can be difficult to define. There are hundreds of thousands of pipeline segments and tracking NSPS applicability for individual segments would be burdensome and complicated. According to the commenters, the time, effort, and cost of this alone would be significant. Pipeline blowdowns can cover any combination of segments depending on the locations of isolation valves. Some of these segments would be classified as “existing” while others would be “new, modified, or reconstructed.” The commenters believe that this would likely lead to confusion as to which standard applies to multi-segment blowdowns and unnecessarily subjects operators to non-compliance concerns.

Regardless of how EPA attempts to define or designate pipelines, the commenters (0599-MS, 0817-GPA) assert that EPA should not regulate pipeline blowdowns under the NSPS. Blowdown is defined elsewhere within the CAA as the “act of emptying or depressurizing a vessel.” 40

---

<sup>144</sup> See *ASARCO, Inc. v. EPA*, 578 F.2d 319, 327 (D.C. Cir. 1978) (rejecting EPA’s arguments favoring the “bubble concept” and holding that the Act’s definition of “stationary source” precluded the EPA from changing the unit to which the NSPS at issue applied to a combination of units).

C.F.R. § 98.6 (emphasis added). This is not a consistent *source* of emissions, and this act often occurs in the field and in remote areas. Not all blowdown activities are planned as they are safety-driven and random in nature and, therefore, difficult to define in the context of an “affected facility” for purposes of NSPS. Although operators can, and do, reduce blowdown volume for planned, non-emergency blowdowns, there is very little ability to do this for emergency blowdowns. Further, emergency blowdowns are necessary, critical emergency operational practices required to keep pipelines operating safely. The commenters suggest that EPA can only consider regulating *planned* blowdown events, but that any regulation of planned events still does not fit within the NSPS scheme.

Commenter (0755-TPA) questions the appropriateness of imposing regulations regarding pipeline blowdowns under the NSPS or any existing source standards. To begin with, the commenter notes that pipeline blowdowns should not be regulated as a source category; a blowdown is not traditionally considered to be an identifiable source of emissions, but rather an action taken for safety and/or operational reasons in the field.<sup>145</sup> Moreover, source categories in the NSPS context have traditionally been limited to structures that serve as emission sources. See, e.g., 40 CFR § 60.2 (defining stationary source to mean “any building, structure, facility, or installation which emits or may emit any air pollutant.”). Pipelines, which are generally located underground and do not have normal operating emissions, do not fit that description, which may explain why they heretofore been subject to NSPS regulation as a separate source category.

In addition, the commenter (0755-TPA) asserts that regulations in this area would present unduly complex compliance issues. A pipeline blowdown can affect numerous different pipeline segments, some that might be considered new or modified under the rules, and some that might be considered existing. This would raise compliance questions of whether the pipeline affected by the blowdown activity was governed by standards applicable to new sources, existing sources, or both. The commenter states that this could be an extremely difficult question to answer in practice, given that pipelines can run for hundreds or thousands of miles and can be modified or replaced in numerous shorter segments within the overall pipeline length. In addition, they note that there are many types of pipelines outside of the oil and natural gas sector, and regulating pipeline emissions, which is essentially what this emission category would be, would require a broader look at emissions from pipelines prior to proposing a rule.

Commenter (0755-TPA) notes that, in contrast to planned non-emergency blowdowns, where operators are able to reduce blowdown volumes, exigent circumstances such as unplanned repairs or emergencies create a situation where operators have very limited ability to plan ahead and reduce blowdown volumes or emissions. The commenter asserts that it would be inappropriate to impose emissions limits in these circumstances, because it would present a safety issue if operators had to delay blowdowns in order to meet emissions limits, e.g., by delaying the blowdown until a portable control device was in place. EPA's rules should not have the effect of causing operators to delay critical emergency operational practices, which can be essential to keep pipelines operating safely and to meet regulatory emissions limits.

Commenter (0815-AGA) supports efforts to reduce emissions from blowdowns but asserts that EPA needs to offer a new opportunity for affected small entity representatives (SERs) to

---

<sup>145</sup> See, e.g., 40 CFR § 98.6 (a blowdown is “the act of emptying or depressuring”).

comment on how proposed standards would impact their costs and operations. The commenter states that this past summer, EPA did not allow an AGA member company that operates a small entity interstate natural gas transmission pipeline to provide testimony before EPA's SBAR panel on the grounds that EPA's proposed methane standards would only affect pipeline compression, not the pipeline itself, and the SER operated an interstate pipeline that had no compression. The commenter notes that it is difficult to determine at this stage how a proposed pipeline blowdown standard would affect such small interstate pipelines without a description of the possible regulatory options under consideration. The commenter states that if the agency wishes to proceed with a pipeline blowdown standard, it will need to convene the SBAR and allow affected interstate pipeline SERs to inform the agency on how the proposed standards would affect small interstate pipelines.

The commenter (0815-AGA) notes that their members have voluntarily sought to improve estimates of blowdown emissions and to reduce emissions from blowdowns on both distribution and transmission pipelines. The commenter adds that member subject matter experts developed the AGA's Blowdown Emission Reduction White Paper,<sup>146</sup> published in August 2020, to share lessons learned and leading practices for avoiding the need for blowdowns when possible and for reducing emissions when blowdowns are necessary. According to the commenter, there is still much to learn, and they plan to review and update the White Paper to help members achieve their emission reduction goals.

Commenter (0755-TPA) recommends that, at a minimum, any rulemaking in this area be preceded by an ICR aimed at gathering data that could allow EPA to fully assess the level of emissions at issue as well as the costs of imposing regulations in this area. The commenter asserts that EPA should not impose requirements on pigging activities at this time as there is currently insufficient data to adequately inform rulemaking. The commenters believe that EPA lacks sufficient information regarding the number of sources, emissions resulting from pigging, and similar basic information that traditionally would be input into a regulatory cost-benefit analysis and necessary to make a determination of BSER. The commenter notes that while EPA collects some data related to pig launchers and receivers through the greenhouse gas reporting program (GHGRP), this information is limited to relatively large operations (above 50 cubic feet actual volume) and the emissions data that is captured reflects aggregate emissions data from multiple sources across an entire basin in the context of gathering and boosting. The commenter asserts that such macro-level, imprecise, and limited data cannot reliably inform a useful cost-benefit analysis.

Commenters (0599-MS, 0817-GPA) contend that EPA must determine it has sufficient information to support the November 2021 Proposal, including support for any proposed regulation being cost-effective. The commenters recommend that EPA, at a minimum, first engage in data gathering to understand the issues presented. The commenters urge EPA not to develop any potential new source performance standards and existing source rules to address pipeline pigging—and blowdowns associated directly with pigging—because there is insufficient

---

<sup>146</sup> The AGA Blowdown Emission Reduction White Paper:  
<https://www.aga.org/contentassets/fdb295e9799449d78d3b07b4a0eac453/aga-blowdown-emissions-reductionwhite-paper-final-8.5.20.pdf>.

data regarding the inventory of pigging infrastructure, insufficient data regarding emission reductions associated with any proposed regulations, and broad regulation would fail to include the variety of pigging operations where benefits of emission reduction are unknown. Moreover, the commenters state that the November 2021 Proposal as it relates to other affected facilities will result in dramatic investments of time and resources that will be a challenge for the agency to finalize and then for the midstream sector to absorb.

Commenters (0599-MS, 0817-GPA) note that before regulating pigging operations, EPA should first conduct a thorough cost-benefit analysis to understand the emissions threshold at which additional regulation or control measures are cost-effective. The commenters recommend that EPA exempt from regulation pig launchers and pig receivers below such appropriate emission threshold as some pig launchers and receivers have zero or very low emissions, making the costs and benefits of regulating all equipment inappropriate. The commenters contend that reducing blowdown emissions through recovery or combustion control equipment requires significant capital and maintenance expenses, new operating procedures, and personnel time. Moreover, the commenters recommend that EPA only consider proposed language regarding the control of pigging emissions for new facility construction due to the significant capital required to add, or modify or retrofit existing control devices. The commenters suggest that EPA consider proxies for emissions, such as pipeline size, pressure, and/or blowdown frequency but any proxies should roughly equate to a reasonable emissions threshold where costs and benefits are appropriate.

The commenters (0599-MS, 0817-GPA) express that they are not aware of a nationwide inventory of pig launchers and pig receivers—or any other methodology to estimate such inventory. Nor are the commenters aware of sufficient data or methodologies to estimate the total emissions currently resulting from pigging operations. Indeed, according to the commenters, there are pig launchers and pig receivers that do not have appreciable emissions at all. As detailed further throughout their comments, they note that pigging operations are vastly diverse and without any meaningful data, broad regulation of these operations would fail. Because this is not a “one-size-fits-all” type of operation, and because the varying operations are often highly technical and individualized, the commenters contend it would be premature to advance any EPA regulation here.

Further, as evidenced by the language used in EPA’s requests for comment, the commenters (0599-MS, 0817-GPA) assert that the agency has little to no information regarding pigging operations beyond data associated with the currently-regulated reporting of certain blowdown events through the GHGRP. While blowdown data for pig launchers and pig receivers is collected through the GHGRP, this data set is limited. It only collects data for those pig launchers and pig receivers larger than 50 cubic feet actual volume and most launchers/receivers are smaller than this. Further, the emissions are reported as an aggregate within the reporting facility (*i.e.*, the entire basin for gathering and boosting), and thus do not provide information that would be useful for establishing performance standards for a specific affected facility. Moreover, potential emissions are going to vary widely depending on multiple factors, including frequency of activity, as well as the size, gas pressure, gas composition, temperature, and elevation changes in the pipeline.

At best, the commenters (0599-MS, 0817-GPA) suggest that EPA open a separate public docket to collect more information to help the agency determine whether, and if so how, pigging operations should be subject to federal regulations. The commenters recommend that EPA focus on seeking data identifying those pigging operations with potentially high enough emissions to justify federal rules—such as those with frequent blowdowns (*e.g.*, weekly or more), those operating at high pressure (*e.g.*, 500 pounds per square inch (psi) or greater), and those used on larger diameter pipelines (12 inches or greater).

Commenters (0599-MS, 0817-GPA) also urge EPA to engage further with stakeholders to understand fully the specifics of pigging operations before proceeding to develop a proposed rule to cover those operations. According to the commenters, absent further engagement with those most knowledgeable about these operations, they are generally concerned that any proposed language would apply an incorrect understanding of pigging and blowdown operations.

The commenters (0599-MS, 0817-GPA) assert that EPA does not appear to distinguish between pig launcher and pig receiver blowdown emissions (and potential reduction/control options) and pig receiver liquids (and potential liquids management options). The commenters explain that these are distinct issues that would need to be studied and understood fully before regulations are proposed. Pigs are pushed through the pipeline segment by natural gas via differential pressure (*i.e.*, the pressure behind the pig is higher than the pressure in front). The commenters note for clarity that most liquids pushed by the pig either continue down the pipeline (if the pig receiver is not at a compressor station or gas plant) or are collected in a vessel such as a slug catcher (if the pig receiver is at a compressor station or gas plant). In other words, most of the liquids that are pushed by the pig are not retained in the pig receiver. The vast majority of liquids either continue through the pipeline and/or are collected downstream in a vessel (such as a slug catcher). There are no liquids behind the pig. The commenters note this because when the pig enters the receiver barrel (which generally has a larger diameter than the pig), the differential pressure is “released,” and this flush of gas also pushes liquids out of the receiver. Generally, operators allow gas to sweep through the receiver before isolating the receiver, blowing it down, opening the door, and removing the pig (or pigs). Any residual liquids retained in the pig receiver typically range from a few cups to a few gallons. This liquid is a mix of condensate, water, used oils, and other non-hydrocarbon impurities. Upon opening the pig receiver door, these residual liquids are captured in a trough, sump, or bucket.

The commenters (0599-MS, 0817-GPA) assert that EPA similarly does not appear to recognize that although pig launcher and pig receiver blowdowns are planned and/or predictable, other emission events such as pipeline blowdown are not always planned.<sup>147</sup> The commenters suggest that any future regulation, if supported by data, must ensure terminology is appropriately defined and encapsulates a clear understanding of pigging operations (and distinctions between

---

<sup>147</sup> American Gas Association, Blowdown Emission Reduction White Paper, 5, 7 (available at <https://www.aga.org/contentassets/fdb295e9799449d78d3b07b4a0eac453/aga-blowdown-emissions-reductionwhite-paper-final-8.5.20.pdf>) (last accessed January 12, 2022) (Providing additional information regarding the various types of planned and unplanned blowdowns).

blowdown emissions and liquids management) and other pipeline blowdowns, which are generally unpredictable events.

Commenter (0923-Lambda) urges EPA to avoid new regulations to pipeline pigging operations. Pigging pipelines are a very necessary and frequent practice within the commenter's operations. Most pigging operations consist of minute amounts of hydrocarbons (est. 1-20 scf per event) being blown down from either a pig launcher or pig receiver. Because of the minimal amount of venting (est. 10 mcf [thousand cubic feet] per year for all events) associated with these operations, the commenter finds extra efforts to capture gas associated with this practice to be overly burdensome and in some cases infeasible and wasteful. In the event a line is evacuated of its product, the commenter would flare the gas (and report it in subpart W as combustion) or otherwise capture the product to sell.

Commenter (0742-ADEC) asserts that pipeline pigging has no place within the November 2021 Proposal as most states already have in place pipeline agencies that are best suited to strictly regulate pipeline operations. The commenter notes that no oil and gas production facility in Alaska owns a pipeline for which such requirements would be applicable. The pipelines are all owned and operated by separate entities and would comprise separate stationary sources. The commenter further states that no pigging operation alone triggers a permit in Alaska regulations based solely on emissions, and nowhere in the November 2021 Proposal does EPA suggest a Title V permit would be required simply due to source category for “pipeline pigging operations.” The commenter reports that Alaska regulates pipeline pigging operations as insignificant sources of emissions for Title V purposes.<sup>148</sup>

### ***18.2.5 Affected Facility***

Commenter (0844-EDF *et al.*) asserts that pipelines could be defined as an affected facility, defined by pipeline segments based on ownership and major geographic boundaries. The commenter notes that there are benefits to defining the pipeline as the affected facility. First, bundling multiple activities into a single blowdown event is a helpful practice to reduce the total number of required blowdowns on a pipeline and thus to reduce the overall methane emissions.<sup>149</sup> To facilitate planning in advance and ensuring maximum bundling to minimize emissions, the commenter suggests that it would be helpful to consider all different types of blowdowns (including pigging) and view the pipeline as a whole—or even a pipeline segment—as the affected facility.

Furthermore, the commenter (0844-EDF *et al.*) contends that it is beneficial to treat the pipeline itself as an affected facility because a blowdown is not necessarily limited to a discrete point on the pipeline. The amount of methane released during a blowdown is related to the length of the

---

<sup>148</sup> 18 AAC 50.326(f)(97).

<sup>149</sup> See Methane Guiding Principles, Reducing Methane Emissions: Best Practice Guide, Operational Repairs at 5 (Nov. 2019), <https://methaneguidingprinciples.org/wp-content/uploads/2019/11/Reducing-Methane-EmissionsOperational-Repairs-Guide.pdf>

(“Look for opportunities to co-ordinate operational repairs and routine maintenance and repairs to minimize the number of blowdowns.”); California Public Utilities Commission, Decision Approving Natural Gas Leak Abatement Program Consistent with Senate Bill 1371, Decision 17-06-015, Appendix B: Best Practices for Natural Gas Leak Abatement Program (June 15, 2017).

section of pipeline that must be blown down, which depends on where the pipeline has valves that can be closed. Thus, blowing down a longer length of pipeline will result in greater methane emissions:

The commenter (0844-EDF *et al.*) reports that, in order to blowdown a section of pipe, that section must be isolated from upstream and downstream pipe sections by closing valves. Valve spacing varies across the system but is generally ten to twenty miles between valves. This means that, without installing a new temporary valve[,], the minimum distance that can be blown down in order to allow for establishment of maximum allowable operating pressure (MAOP) using pressure testing is 10 – 20 miles (*i.e.*, the valve spacing on that segment of pipeline). As such, if only a two-mile section of pipe between valves needed to be pressure tested (for example because it was pre-1970 pipe in an HCA<sup>150</sup>) but the rest of the section between the valves did not need to be tested (because it was not in an HCA), then the total miles that would need to be blown down to accommodate the pressure testing could be five to ten times longer than the actual pressure test mileage.<sup>151</sup>

For ease of oversight and establishing the BSER, the commenter (0844-EDF *et al.*) recommends that EPA consider defining pipelines as the affected facility, with the endpoints of each pipeline facility established in segments where appropriate. Pipeline segments could be defined by pipeline ownership and major geographic boundaries.

Commenter (0424-WVDEP) asserts that EPA's consideration of whether the pipeline itself could be defined as an affected facility for the purposes of regulating blowdowns is flawed because pipelines do not meet the definition of a stationary source, as defined in section 111(a) of the CAA. The term "stationary source" means any building, structure, facility, or installation which emits or may emit any air pollutant. This definition requires boundaries to define the stationary source. Intrastate or interstate pipelines do not have an established boundary and therefore do not meet the definition. According to the Gas Pipeline Safety Division of the West Virginia Public Service Commission, there are approximately 14,000 miles of intrastate natural gas and hazardous liquid transmission and regulated gathering pipelines and natural gas distribution pipelines within the state. The commenter (0424-WVDEP) states that the characterization of the pipeline system in terms of miles rather than number of facilities is an illustration that pipelines do not meet the definition of a stationary source and should not be regulated as such. The commenter notes that in West Virginia, if a pigging operation and related blowdown activity meets the stationary source threshold the related air emissions are currently regulated as part of the stationary source, typically by limiting the number of events over a specified timeframe.

Commenters (0599-MS, 0817-GPA) note that EPA's request for comment implies it is considering the regulation of previously constructed pipelines-to which pigging infrastructure may be temporarily or permanently installed-as a stationary source. The commenters note that

---

<sup>150</sup> An HCA is a buffer around a section of a pipeline where there are higher concentrations of people, like in an urban community.

<sup>151</sup> M.J. Bradley & Associates, Pipeline Blowdown Emissions and Mitigation Options at 14 (June 2016), <http://blogs.edf.org/energyexchange/files/2016/07/PHMSA-Blowdown-Analysis-FINAL.pdf>.

the current record lacks support or reason for regulating “pigging operations” as an “affected facility”.

Although the commenters (0599-MS, 0817-GPA) believe that considering whether pigging operations should be “affected facilities” is, at best, premature, the following comments are offered. Subpart A of the Act’s regulatory framework provides the procedural application of the NSPS as established in other subparts and is applicable to “the owner or operator of any *stationary source* which contains an *affected facility*, the construction or modification of which is commenced after the date of publication in this part of any standard (or, if earlier, the date of publication of any proposed standard) applicable to that facility.” 40 C.F.R. § 60.1(a)–(b) (emphasis added). Each promulgated NSPS should explicitly define and describe the “affected facilities” to which it applies, but NSPS first must apply to a stationary source containing the affected facility. Both the statute and general NSPS regulations define “stationary source” as “any building, structure, or installation which emits or may emit any air pollutant.” 42 U.S.C. § 7411(a)(3); 40 C.F.R. § 60.2. And “affected facility,” with reference to a stationary source, means “any apparatus to which a standard is applicable.” 40 C.F.R. § 60.2 (further defining the terms “commenced” to mean “with respect to the definition of new source in section 111(a)(2) of the Act, that an owner or operator has undertaken a continuous program of construction or modification or that an owner or operator has entered into a contractual obligation to undertake and complete, within a reasonable time, a continuous program of construction or modification” and “construction” to mean “fabrication, erection, or installation of an affected facility.”).

#### ***18.2.6 Pipeline and Hazardous Materials Safety Administration (PHMSA) Coordination***

Commenter (0844-EDF *et al.*), as with other comments mentioned previously, recommend that EPA continue to coordinate with PHMSA at U.S. Department of Transportation (DOT), to ensure comprehensive oversight of pipeline methane emissions across agencies. The commenter notes that The PIPES Act of 2020 directed PHMSA to finalize new standards to extend its oversight of gathering lines.<sup>152</sup> In November 2021, PHMSA issued a final rule extending basic annual reporting requirements to all onshore gas gathering lines and extending leak survey and repair requirements to an additional 20,336 miles of gathering lines.<sup>153</sup> The rule represents an important step forward to increase transparency and heighten oversight of gathering pipelines. However, the commenter notes that it does not establish requirements to limit methane emissions from pigging and blowdown activities. The commenter recommends that EPA remedy this oversight and propose emission limitations for pigging and blowdowns on gathering lines in its forthcoming supplemental rulemaking.

Commenter (0755-TPA) recommends that any regulations in this area should only be implemented after coordination and consultation with PHMSA both to avoid regulatory overlap, duplication, and inconsistency, and in particular to ensure that PHMSA’s pipeline safety program is not jeopardized by rules that might incentivize operators to delay emergency blowdowns to remain in compliance with EPA emissions limits. Further consideration of these issues by EPA and PHMSA might lead to the conclusion that any regulation of blowdown

---

<sup>152</sup> FY2021 Omnibus and COVID Relief Response Act, HR133, Protecting our Infrastructure of Pipelines and Enhancing Safety Act of 2020 (PIPES Act of 2020) at § 112(a) (Dec. 27, 2020).

<sup>153</sup> PHMSA, Final Rule: Pipeline Safety: Safety of Gas Gathering Pipelines, 86 Fed. Reg. 63,266 (Nov. 15, 2021).

emissions should be accomplished through a program other than the traditional EPA NSPS rules or EGs for existing sources.

Similarly, commenter (0585-KOGA) notes that PHMSA is already working on similar requirements and recommends that EPA not duplicate emission requirements and additional reporting requirements for pipeline operators. The commenter asserts that there would be no environmental benefit and would only increase administrative costs to manage two separate regulations and reporting to two separate agencies for similar regulatory requirements.

The commenter (0585-KOGA) provides details on the PIPES Act and PHMSA work. The PIPES Act of 2020 (Pub. L. 116-260, Division R) was signed into law on December 27, 2020. This law contains several provisions that specifically address the elimination of hazardous leaks and minimization of releases of natural gas from pipeline facilities. Section 114(b) of the PIPES Act of 2020 contains self-executing provisions that apply directly to pipeline operators. This section requires each pipeline operator to update its inspection and maintenance plan required under 49 U.S.C. 60108(a) no later than one year after the date of enactment of the PIPES Act of 2020 (*i.e.*, by December 27, 2021) to address the elimination of hazardous leaks and minimization of releases of natural gas (including, and not limited to, intentional venting during normal operations and maintenance) from the operators' pipeline facilities (49 U.S.C. 60108(a)(2)(D)).

The commenter (0585-KOGA) adds that the PIPES Act of 2020 also requires those plans to address the replacement or remediation of pipelines that are known to leak due to their material (including cast iron, unprotected steel, wrought iron, and historic plastics with known issues), design, or past operating and maintenance history (49 U.S.C. 60108(a)(2)(E)). In addition, 49 U.S.C. 60108(a)(2) requires that operators continue updating these plans to meet the requirements of any future regulations related to leak detection and repair that are promulgated under 49 U.S.C. 60102(q). Pursuant to the PIPES Act of 2020, operators must have completed updates to their plans by December 27, 2021. PHMSA and state partners are required to inspect these plans in 2022.

On June 10, 2021, the commenter (0585-KOGA) notes that the PHMSA published an advisory bulletin in the Federal Register titled "Statutory Mandate to Update Inspection and Maintenance Plans to Address Eliminating Hazardous Leaks and Minimizing Releases of Natural Gas from Pipeline Facilities" (86 FR 31002) reminding pipeline operators of their obligation to comply with Section 114 of the PIPES Act of 2020 by December 27, 2021. That advisory bulletin reminded owners and operators of pipeline facilities that the PIPES Act of 2020 requires operators to update their inspection and maintenance plans to identify procedures to prevent and mitigate both vented/intentional and fugitive/unintentional pipeline emissions. Vented emissions can occur during repairs, maintenance, or operations of pressure relief systems, or other controlled activities. Fugitive emissions include leaks from mains or service lines, meters, or excavation damage, as well as other accidental releases.

Commenter (0831-AXPC) notes that PHMSA is already regulating the midstream pipeline system and recently passed the PHMSA reauthorization law that directed PHMSA to reduce methane emissions in the pipeline. To the extent that EPA believes that it is may be necessary to regulate pipeline pigging operations, the commenter recommends that EPA allow PHMSA to

first develop regulations and determine whether it would be appropriate for EPA to regulate on top of PHMSA.

Commenter (0782-BHE) recommends that EPA exclude T&S pigging operations from the regulations because there is a PHMSA program in place and emissions characteristics are not well understood. At most, the commenter suggests that EPA further investigate the characteristic emissions for T&S (*i.e.*, typical event emissions, frequency of events) before considering any additional action. The commenter notes that transmission pipeline operations, including pigging for pipeline integrity purposes, are regulated by PHMSA. In 2021, operators were required to review and update operating and maintenance (O&M) procedures and minimize vented and leak emissions. The commenter adds that PHMSA is implementing a program in 2022 to assess the status of O&M procedures and recommends allowing the assessment of the updated PHMSA program and requirements to occur before considering additional requirements from EPA. Depending on the significance of the pipeline defect, compromise, or anomaly discovered from pigging, PHMSA may require an immediate action to inspect and repair the fault or defect. When immediate action is required, there may be insufficient time to significantly reduce pipeline pressures and blowdown volumes that may be emitted from a pigging operation – which would most typically be relatively small for any particular event.

As EPA notes in the November 2021 Proposal, the commenter (0782-BHE) states that pigging operations are vital to maintaining the integrity of the pipeline. Pigging provides information to operators about the structural characteristics of the pipeline for safety and maintenance purposes. At this time, the commenter states there is limited information available on emissions from pigging operations for T&S, but operator experience indicates this is a relatively small emissions source for the T&S sector.

Commenter (1391-INGAA) reports that pigging operations are essential for pipeline safety, and its members are working to minimize emissions from these operations. The commenter asserts that EPA needs to be aware of PHMSA efforts and coordinate with the agency to avoid duplicative or conflicting regulations. The commenter contends that EPA should consider deferring to PHMSA on the issue of pigging emissions and supplement only if PHMSA's regulation prove to be lacking. The commenter provides details on pigging and blowdown activities for consideration.

The commenter (1391-INGAA) notes that PHMSA has numerous safety regulations with which their members must comply. In recent years, PHMSA has also been examining options to reduce methane emissions associated with pigging operations. For example, it issued a proposed rule in 2016 that would have regulated blowdown emissions from pipelines.<sup>154</sup> Although the proposed rule has not been finalized, the commenter reports that PHMSA has made it clear in response to

---

<sup>154</sup> 81 Fed. Reg. 20,722, 20,741 (Apr. 8, 2016) (noting “proposed rule is expected to prevent incidents, leaks, and other types of failure that might occur, thereby preventing future releases of greenhouse gases ... to the atmosphere, thus avoiding additional contributions to global climate change” and estimating “net GHG emissions abatement over 15 years of 69,000 to 122,000 metric tons of methane”).

President Biden’s executive orders on climate change that it will be examining methane emissions from pipelines.<sup>155</sup>

The commenter (1391-INGAA) states that it is important that EPA understand two key points. First, the purpose of pigging differs in each segment of the oil and gas industry, and that these differences impact the potential for emissions. Second, emissions from pigging operations depend on a variety of factors, including the frequency of pigging. The commenter elaborates on these two points.

The commenter (1391-INGAA) provides that, with regard to the *first point*, pigging is different in the transmission segment as compared to the gathering and boosting segment. The general function of a pig is either to clear a pipeline of liquids and debris to avoid reduced gas flow or to monitor the condition of the pipeline for safety purposes. It is the latter reason that pigging typically occurs in the transmission and storage segment.

With regard to the *second point*, the commenter (1391-INGAA) states that pigging happens far less frequently in the transmission segment. The transmission segment involves the movement of pipeline quality gas, which means that the gas has already been cleaned of most impurities at the gas plant and contains far fewer liquids. Thus, pigging to clear the transmission pipeline of liquids and debris occurs far less frequently than it does in the gathering and boosting segments. For example, in the gathering and boosting segments, gathering lines in some areas might be pigged on a weekly or even a daily basis. In contrast, one member of theirs reports that it sometimes mechanically pigs its pipelines annually—and at least every three years—for maintenance purposes. That member also typically conducts an in-line “smart pig” inspection of the pipeline for safety purposes once every five to seven years.<sup>156</sup> In addition, the commenter states that emissions from pigging operations involve emissions only from blowdowns of the pigging barrels—not the entire segment of the pipeline.

The commenter (1391-INGAA) states that these key points result in methane and VOC emissions from pigging operations in the transmission segment being extremely low. The commenter asserts that EPA cannot assume that all pigging operations are similarly situated, and the Agency must undertake segment-specific analysis as it continues to evaluate options for these sources.

Commenter (1391-INGAA) explains that pigging provides information to operators about the structural characteristics of the pipeline for safety and maintenance purposes. The commenter recognizes the need to reduce emissions from pigging operations while conducting integrity and maintenance-related work, where practical. These emissions can be reduced in many instances, but the safety of the public, employees, contractors, and assets must remain priorities. Before considering any additional action, the commenter recommends that EPA further investigate the characteristics of emissions for pigging in the transmission and storage segment. The commenter

---

<sup>155</sup> 75 See, e.g., 86 Fed. Reg. 31,002 (June 10, 2021) (PHMSA Advisory Bulletin requiring pipeline operators “to address eliminating hazardous leaks and minimizing releases of natural gas ... from their pipeline facilities”).

<sup>156</sup> PHMSA regulations require that all transmission pipelines within High Consequence Areas (*i.e.*, those areas with sufficient population close to the pipeline) are required to be assessed for integrity at least once every seven years. 49 C.F.R. § 192.937(a). These assessments are usually accomplished by an in-line pigging inspection.

reports that they are working to produce a white paper of best practices that will identify various strategies to reduce emissions from the interstate natural gas pipeline network.

With regard to blowdown emissions from pipelines, the commenter (1391-INGAA) notes that their members have three sets of options that they take to minimize emissions from these activities. First, members eliminate the need for a blowdown for anomaly repair work or project tie-ins, when possible, by using other repair options such as composite wraps or full encirclement “split” sleeves, and using hot taps for the project work. Using these repair procedures and in-service welding methods can eliminate the need for a blowdown. Second, when a blowdown is required for anomaly repair work or project tie ins, the commenters’ member companies typically reduce the emissions by using customer and company compression to lower the pressure prior to the blowdown. Third, members generally use company-owned or third-party portable compression and/or flares to further lower the pressure and reduce emissions prior to the blowdown. These options may eliminate methane emissions and will, at a minimum, reduce them by 75 percent.

The commenter (1391-INGAA) reports, however, that there are factors that can influence what options can be implemented. For example, in some situations, there is limited time because of the need to quickly address potential integrity concerns. Depending on the significance of the pipeline integrity anomaly, the commenter states that PHMSA may require an immediate excavation to inspect and repair the anomaly. When this occurs, there is not sufficient time to significantly reduce blowdown emissions. Whether the pipeline has a single line or parallel lines to compress the natural gas in the same right-of-way also affects the ability to reduce emissions. A parallel line in the right-of-way makes using the second and third options above much more effective and efficient. Finally, the commenter adds that other factors that can affect the ability to minimize blowdown emissions include limited time because of customer commitments (particularly on cold winter or hot summer days), constrained rights-of-way, and population, environmental, and highway considerations.

## **18.3 Tank Truck Loading**

Response I-18-3: In the November 2021 Proposal, EPA solicited comment and data to assist the Agency in evaluating the potential for developing emissions standards for additional emission sources, including tank truck loading. EPA did not propose emissions standards for tank truck loading in the December 2022 Supplemental Proposal; therefore, this final action does not include emissions standards for these emission sources. We may consider regulation through a future action, including in the next 8-year review of the NSPS. The comment summaries are provided below for reference but substantive responses are not provided because no emissions standards have been proposed for this emissions source.

### ***18.3.1 Regulatory Support***

Commenter (0957-WYCLG) states that the solicitation of comments on the potential for establishing standards for tank truck loading operations is not appropriately included within this notice of proposed rulemaking because it fails to provide an adequate description of the issues involved or terms or substance of a proposed rule. The commenter recommends that this request

for additional information on other sources of emission should instead be its own separate rulemaking, starting with an “Advance Notice of Proposed Rulemaking” to obtain the necessary information.

### ***18.3.2 Support for Regulation Under the NSPS/EG***

Several commenters (0391-KBIC, 0586-Navajo EPA, 0605-Muscogee (Creek) Nation, 0766-CO DPHE, 0781-NTAA, 0789-PADEP, 0809-Earthjustice, 0832-NMED, 0833-Ute EPD, 0918-COLGC, 0943-Sault EPD) support EPA considering the inclusion of requirements to reduce emissions from tank truck loading under the NSPS/EG. Some of these commenters (*e.g.*, 0599-MSD, 0817-GPA) only provide support for the use of bottom filling or submerged fill pipe requirements. Specific examples of comments provided are included in the following paragraphs. the use of bottom filling or a submerged fill pipe to reduce emissions.

Commenter (0809-Earthjustice) indicates that data from the 2017 National Emissions Inventory (NEI) showed that total VOC emissions from tank truck loading operations were approximately 72,448 tons per year nationwide.<sup>157</sup> These numbers are substantial and speak to the urgent need for the agency to address uncontrolled emission sources in this cycle of rulemaking.

Commenter (0809-Earthjustice) recommends that EPA not delay its duty to regulate these significant sources of uncontrolled emissions simply because of inadequate data. The commenter notes that, if a targeted ICR is necessary to supply the agency with data it requires, then the agency should undertake this information gathering without delay and well in advance of its rulemaking deadlines.

Commenter (0809-Earthjustice) recommends that EPA set emissions standards in the NSPS rulemaking, and in its reconsideration and CAA section 112(d)(6) review of the 2012 NESHAP rule because tank truck loading has the potential to emit large amounts of VOCs, methane, and HAPs.

The commenter (0809-Earthjustice) reports that it called on EPA to reconsider its decision not to regulate uncontrolled emissions from tank truck loading ten years ago.<sup>158</sup> The commenter renews their demand that EPA use its section 112 authority to set standards for all known sources of uncontrolled emissions in the oil and gas sector as required under the Clean Air Act. See LEAN, 955 F.3d at 1096.

Commenter (0832-NMED) notes that New Mexico proposed emission control requirements for truck loading operations in Part 50 and encourages EPA to adopt similar requirements in the proposed supplemental rule.

Commenter (0776-CDPHE) cites Colorado’s regulations related to truck loading operations:

Colorado adopted requirements to reduce emissions from tank truck loading operations in

---

<sup>157</sup> See also DEP MarkWest Memo, *supra*, at 4 (estimating facility’s potential to emit 1.30 tpy VOCs and 0.05 tpy HAPs from truck unloading)

<sup>158</sup> Reconsideration Petition, *supra*, at app. tbl. 1

2019.<sup>159</sup> In addition to the specific practices described below, Colorado also adopted provisions for “storage tank measurement systems,” which limit emissions from tank liquid measurement activities (for both quality and quantity), through the use of automatic tank gauges and sampling technologies and procedures that avoid opening of the thief hatch during these activities.<sup>160</sup>

Colorado’s regulations require owners or operators of well production facilities, natural gas compressor stations, and natural gas processing plants with hydrocarbon liquids loadout to transport vehicles throughput of greater than or equal to 5,000 barrels per year on a rolling 12- month basis to control emissions from the loadout of hydrocarbon liquids from controlled storage tanks to transport vehicles by using (a) submerged fill and (b) a vapor collection and return system and/or air pollution control equipment. Critically, owners or operators must also have signage on-site notifying third parties (*e.g.*, haulers) of these practices and must implement training for employees and third parties that conduct loadout operations. Operators must also periodically observe loadout to confirm that all storage tanks operate without venting. In 2020, Colorado expanded these requirements to owners or operators of class II disposal well facilities with VOC emissions from hydrocarbon liquids loadout to transport vehicles greater than or equal to two (2) tons uncontrolled actual emissions per year on a rolling 12-month basis.

Commenter (0918-COLGC) urges EPA to follow the lead of oil and gas producing states and propose a supplemental rule that addresses truck loading emissions. The commenter cites Colorado, Pennsylvania, and New Mexico examples to demonstrate that emissions capture or control is feasible and cost effective.

The commenter (0918-COLGC) states that in Colorado, operators must control venting from storage tank hydrocarbon liquids loadouts at well production facilities, Class II disposal well facilities, natural gas compressor stations and natural gas processing plants. Per this rule, operators must control emissions from the loadout of hydrocarbon liquids from controlled tanks to transport vehicles by either using submerged fill or a vapor collection system.<sup>161</sup> The state determined that the weighted average cost per ton VOC of requiring controls on loadout operations at facilities with tank throughput of 5,000 bbl/year would be \$12,998. The commenter notes that this does not account for the additional methane reductions to be realized from the requirement, nor does it recognize the additional reductions from avoiding the opening of the thief hatch during loadout.<sup>162</sup>

---

<sup>159</sup> Reg. 7, Part D, Section II.C.5. Colorado uses API gravity 40 to define “condensate”, not the 50 for which EPA solicits comments. Reg. 63,110, 63,245 (Nov. 15, 2021)

<sup>160</sup> Reg. 7, Part D, Section II.C.4. These practices also promote worker safety, due to avoiding the need for a person to climb up on the tank and open the thief hatch during gauging and sampling.

<sup>161</sup> Colorado Reg 7. Pt. D, § II.C.5.

<sup>162</sup> Colorado Air Quality Control Commission, Regulatory Analysis for Regulation Number 7 Revisions, p. 23 (Dec. 2019), <https://www.edf.org/sites/default/files/content/Attachment%20B%20-%20Regulatory%20Analysis%2C%20Colorado%20Dep%E2%80%99t%20of%20Public%20Health%20and%20the%20Environment%20%28Dec.%205%2C%202019%29.pdf>.

The commenter (0918-COLGC) states that in Pennsylvania, for all truck load-out operations that service a storage vessel with a total methane emission rate of 200 tpy or greater, a VOC emission rate of 2.7 tpy or greater, a single HAP emission rate of 0.5 tpy or greater, or a total HAP emission rate of 1.0 tpy or greater, where the loading rack was constructed and authorized to operate on or after August 8, 2018, the owner or operator must use a vapor balancing system when removing liquids from the storage vessel and ensure that each tanker truck that is used to remove liquids from the storage vessel has passed an annual leak test. Alternatively, VOC emissions must be controlled with 95 percent or greater efficiency.<sup>163</sup>

The commenter (0918-COLGC) notes that New Mexico is also proposing rules for hydrocarbon liquid transfers. The proposed rules require the owner or operator of a hydrocarbon liquid transfer operation to use vapor balance, vapor recovery, or a control device to control VOC emissions by at least 95 percent, when transferring hydrocarbon liquid from a storage vessel to a tanker truck or tanker railcar for transport. If a combustion control device is used, the combustion device must have a minimum design combustion efficiency of 98 percent.<sup>164</sup>

Commenters (0391-KBIC, 0586-Navajo EPA, 0605-Muscogee (Creek) Nation, 0781-NTAA, 0833-Ute EPD, 0943-Sault EPD) believe that EPA should require, at a minimum, the use of bottom filling or a submerged fill pipe to reduce emissions. Commenter (0586-Navajo EPA) notes that this requirement is what was recently proposed in its Oil and Natural Gas General Permit.

Commenters (0599-MSD, 0817-GPA) would support the use of submerged fill as a practice for truck loading because the work practice is already in place and therefore likely to be more cost-effective than a control efficiency requirement. The commenters note that quite a few states already require, and most third-party trucking companies already use, submerged fill. The commenter states that from an industry perspective, submerged fill is largely standard industry practice. The commenters do not oppose the proposed regulation to make this a requirement for trucks, as trucks designed for submerged fill have an arm extending to the bottom of the tank and where the hose is connected. The commenters contend that because this is part of the truck and not a separate apparatus a truck operator could install at the facility, EPA's inclusion of a proposed cost estimate for *facility operators* appears somewhat misguided. The commenters assert that any proposal should, therefore, focus on imposing requirements on the truck operator, not the operator of the facility.

### ***18.3.3 Opposition to Regulation Under the NSPS/EG***

#### **18.3.3.1 Federal Regulation of Tank Truck Loading is Not Supported**

Commenters (0599-MSD, 0817-GPA) urge EPA to revisit its understanding of tank to truck loading and related operations prior to proposing any regulatory language. As a threshold matter, EPA's request for comment suggesting the use of three "control options" is confusing. The commenters have concerns regarding any proposed regulation based on an incomplete understanding of tank to truck loading and related operations. Vapor balancing, for example, is

---

<sup>163</sup> Pennsylvania GP-5 Permit, Section F; Pennsylvania GP-5A Permit, Section F.

<sup>164</sup> Id. at Section 20.2.50.120, <https://www.env.nm.gov/opf/docketed-matters/>.

not a control option separate from closed vent operating. Rather, operators utilize this method in a more comprehensive manner to ensure safe and efficient truck loading and to ensure low risk of oxygen entering a unit during loading. And where facilities have the ability to pipe liquids downstream, tank truck loading is highly unlikely to even occur as it is unnecessary. However, should EPA determine it receives sufficient information to both understand operations and warrant regulations in addition to state requirements, the commenters provide comments for consideration. The commenters assert that if controls are required, operators will need lead time to account for capital budget planning, design and engineering, procurement, construction, training on new procedures, and other logistics related to installing new equipment. The commenters note that this may vary depending on the availability of equipment and contractors (new compliance requirements can lead to a shortage of both equipment and experienced contractors).

Commenter (0742-ADEC) asserts that tank truck loading operations requirements have no place in the current proposal and should be addressed in a separate rulemaking if at all. The commenter suggests that tank truck loading operations could be addressed in an update to NSPS Subpart KKK, 40 CFR 60.630 Standards of Performance for Equipment Leaks of VOC From Onshore Natural Gas Processing Plants for Which Construction, Reconstruction, or Modification Commenced After January 20, 1984, and on or Before August 23, 2011, or another already established subpart in a transportation sector that more closely aligns with the topic of leaks at non-primary function core facilities.

Commenter (0599-MSC) recommends no control requirements under EG OOOOc because the ability to control existing truck loading under EG OOOOc increases the difficulty of collecting and controlling emissions safely.

#### 18.3.3.2 Truck Loading Emissions Reduction Requirements Should be Left to the States

Commenter (0810-Petroleum Alliance-OK) recommends that EPA not include any tank truck loading requirements at well sites, especially marginal well sites, and instead leave tank truck loading to be addressed within state's permitting program. The commenter states that EPA's three options are costly, require significant training, and have potential safety issues. The first option, vapor balancing using a closed system, would require significant cost to setup the vapor balancing system and significant training for tank truck operators for proper operation and maintenance, and there are potential safety issues with the introduction of oxygen into atmospheric tanks. The second option, the use of a vapor recovery system, would require significant cost especially for marginal/low production wells. The third option considers requiring liquid pipeline connections for all locations. The commenter suggests that this is completely impractical and inordinately expensive. They explain that if a liquid pipeline was accessible and economically feasible, operators would be using pipelines. Finally, the commenter notes that the bulk of the fluids hauled by tank trucks in Oklahoma consist mostly of produced water with minimal emissions.

Commenter (0740-Utah Petroleum Association (UPA)) states that tank truck control requirements would yield marginal benefits, the state has regulations in place, and it would be impractical and impossible to directly pipe liquids downstream. The commenter reports that tank

truck loading only accounts for 1.1 percent of the Utah oil and gas emissions inventory, a very small amount,<sup>165</sup> therefore requirements would have only marginal benefit. The commenter notes that EPA’s Control Techniques Guidelines for oil and gas do not include tank truck loading controls. Nonetheless, Utah already has regulations in place requiring a vapor capture line plus bottom filling or submerged fill<sup>166</sup> and EPA’s proposed Federal Implementation Plan (FIP) requires bottom fill or submerged fill for tank truck loading.<sup>167</sup> The commenter states that Utah’s crude oil has a very high wax content and pour points well above typical ambient temperatures and must be stored in tanks heated to approximately 160 degrees Fahrenheit. The commenter asserts that it would be impractical and impossible to directly pipe the liquid downstream in a standard nonheated pipeline because the wax would solidify at cooler ambient temperatures, rendering the crude oil impossible to pump. The commenter does not recommend heating the pipelines because it consumes additional energy resulting in greater greenhouse gas emissions. Moreover, the commenter references a recent study by three Utah Universities found that Utah crude oil could be mixed with condensate to improve pipeline pumpability but would still likely require the addition of chemical additives to serve as flow improvers or pour point depressants.<sup>168</sup>

Commenters (0599-MS, 0817-GPA) state that tank to truck loading regulation is not appropriate for a NSPS rule and should be left to states. The commenters assert that tank trucks should not qualify as stationary sources within the meaning of section 111 of the CAA. And these trucks are not affixed to any other stationary source such that it would qualify as an “affected facility” within any proposed NSPS. On that basis alone, the commenters believe that regulation is inappropriate.

In addition, the commenters (0599-MS, 0817-GPA) report that there is already significant regulation of these sources at the state level—where regulation appears much more appropriate—and additional regulation from the federal level appears unnecessary, unduly burdensome, and lacking any significant basis. If EPA insists on regulating tank to truck loading, the commenters recommend that EPA consider the cost and benefits associated with additional regulation where state requirements already exist. Further, the commenters recommend that EPA consider reviewing state requirements as a basis for any proposed NSPS regulation to ensure consistency between state and federal programs. The commenters note that Texas already maintains requirements for truck loading of condensate that does not need federal

supplementation. However, the commenter suggests that EPA could rely on the Texas framework in considering a potential federal regulation, if appropriate.<sup>169</sup>

#### ***18.3.4 Specific Tank Truck Loading Requirement Considerations***

Several commenters request that EPA consider specific technical issues and exemptions if EPA proposes requirements under the NSPS and/or EG.

##### **18.3.4.1 Technical Considerations**

Commenter (0808-API) states that options typically used to reduce emissions from truck loading include routing emissions to a process (*e.g.*, by installing a vapor recovery unit (VRU) or to a combustion device. The commenter reports that many operators use a single, common VRU system or combustion device to control emissions from both hydrocarbon liquid transfers and storage tanks. The commenter provides the following practical, technical and safety issues details and recommends that EPA consider these when evaluating potential truck loading emissions controls:

- When loading emissions are to be routed to an existing combustion control device, substantial design evaluation work may be required to ensure that use of existing control devices is feasible, and if not, to design and install an additional or larger capacity combustion device.
- Some older facilities do not have the pad size to safely locate an additional combustor dedicated to loadout controls (if needed). Changes to the pad size require state agency and landowner approval, which may not be obtainable. Additionally, local governments and landowners may further prohibit operators expanding the footprint of a facility.
- If truck loadout vapors are routed through the storage tanks onsite prior to combustion, a new design analysis may be needed, which may generate costly modifications to low-producing sites (*e.g.*, adding additional combustion control, larger combustors, change pipe sizing, etc.) in order to properly design the facility.
- Loadout truck drivers, who may not be familiar with truck loadout air emission equipment being used at these older low production facilities, will need additional training to safely use the new equipment. In many situations, the trucking company is a separate entity that may change over time from the producer.
- Older vintage buried and semi-buried tanks are not designed to work with truck loadout equipment.
- Truck loadout controls may introduce excess oxygen in the system requiring the installation of an independent vapor control system.
- There are potential safety issues with the introduction of an oxygen rich vapor stream into atmospheric tanks that have minimal headspace. A higher oxygen percentage in the vapor mixture increases the risk of the vapor igniting and causing a fire or explosion. In these cases, the installation of an independent vapor control system may be required.

---

<sup>169</sup> Texas Commission on Environmental Quality, “Tank Truck Loading of Crude Oil or Condensate” (available at <https://www.tceq.texas.gov/assets/public/permitting/air/NewSourceReview/oilgas/tank-truck-load.pdf>) (last accessed January 25, 2022).

- Loading controls should not be required for sites where tanks are not required to be controlled.
- Lower producing facilities may have infrequent truck loadings based on production decline. EPA must evaluate the cost effectiveness of a reasonable threshold of crude oil/condensate prior to requiring any controls. Some states do not require loading controls if the number of loadouts is below a certain threshold or if the site routinely transfers liquids via a pipeline.

Commenter (0831-AXPC) states that truck loadout controls are added to existing facilities by the addition of new vent lines to an existing combustor and/or installation and operation of an additional or larger capacity combustor at the applicable facility. The commenter asserts that this analysis may require substantial design evaluation work to ensure that the use of existing control devices is feasible, and if not, to design and install a new combustor control device. The commenter notes that there are significant concerns with redesign requirements for older facilities, training of haulers, availability of space for new required combustor/flares, and introduction of excess oxygen to the system if routed to tanks (generally because flare lines may be too small to accommodate the instantaneous volume from a truck load). The commenter adds that these requirements will have disproportional impact on low-liquid-producing sites with infrequent loading/unloading events.

Commenter (0585-KOGA) presents three options for EPA's consideration.

- Vapor balancing which is used to route the vapors displaced during material loading from the tank truck back to the storage vessel.
- Use of a closed vent system operating with a reduction efficiency of 95 to 99 percent. A vapor capture system is used and routed to a vapor recovery device (VRD) or VRU which uses refrigeration, absorption, adsorption, and/or compression.
- Directly pipe liquids downstream. By directly piping liquids downstream, no emissions from tank truck loading are released to the atmosphere.

Commenters (0599-MSD, 0817-GPA) provide details on the availability of VRUs as control devices, VRU safety and emissions concerns, and VRUs impracticability for truck loading operations.

The commenters (0599-MSD, 0817-GPA) are concerned that EPA misunderstands the availability of VRUs. In their discussion of truck loading, the commenters note that EPA assumes that approximately 50 percent of storage vessels will be controlled by a VRU. But while there are facilities that use VRUs as a way of reducing tank emissions, the commenter asserts that all of these facilities do not have the ability to control truck loading emissions. For example, transmission and storage facilities and gathering and boosting facilities using floating roof storage tanks may not have a combustion device on location for vapor balancing. Therefore, facilities that do not have a combustion device available to vapor balance the truck emissions will need an exemption from any mandate. Regarding transmission, for facilities *only* using a VRU, there are other configurations that may lead to noncompliance with a proposed rule despite controlled emissions.

The commenters (0599-MS, 0817-GPA) contend that VRUs can impose serious safety and emissions concerns in truck loading operations. Even where installed, the commenter states that a VRU is generally not a viable option due to the propensity to introduce oxygen into the system, causing serious safety concerns. Additional oxygen can also cause increased flaring, and by introducing oxygen into the gas gathering system, cause increased gas line purging. It is also not correct, in the commenter's experience, to assume that a tank controlled by a VRU allows vapor balancing to the truck. Loading condensate or other products back into the tank system controlled by a VRU only introduces oxygen back into the vent system, sending the product down the line and implicating both safety and emissions concerns. Indeed, across the midstream sector, the commenters report that many regulated entities will not even install a VRU because of the technical concerns regarding introduction of oxygen to the system.

The commenters (0599-MS, 0817-GPA) state that VRUs are not a practicable nor feasible control for truck loading operations because not all tanks using a combustion device or flare have the ability to run vapor balance line to a control device as the control device may not be adequately set up for controlling truck loading vapors. Although circumstances vary, the commenters recommend that these variables in configuration be considered in the cost analysis for controlling truck loading compared to actual reductions gained from any sort of retrofitting or combustion device installation.

Commenters (0599-MS, 0817-GPA) assert that any regulation of truck loading operations must be based on individual truck loading points, not an aggregate emissions determination. The commenters recommend that EPA consider the "affected facility" as the truck loading point. However, the commenters state that EPA should not base truck loading emissions and control requirements on the total aggregate truck loading emissions for an entire facility but should instead base applicability on an individual truck loading point as the regulated facility. Most importantly, the commenters contend that regulating in any different manner would fail to account for the fact that facilities often have a sump or tank on distant outskirts of a facility, not located near any production tanks where the operator would be able to control truck loading operations.

The commenters (0599-MS, 0817-GPA) state that it is common for facilities to have multiple truck loading connections. However, many connections are used infrequently, have low throughput (such as for slop oil), are used for water truck loading, or are not located at a point in the facility where operators could safely route vapor balancing lines to a control device.

Commenters (0599-MS, 0817-GPA) assert that a 95 percent efficiency requirement should not be applied to tank truck loading. The commenters note that because there are significant challenges for routing low flow to combustion devices, midstream tank truck loading operations are very different from bulk gasoline terminals, regulated under Subpart XX. For similar reasons, the commenters contend that midstream tank truck loading connections could not meet the 98.7 percent capture efficiency required under the regulations of Subpart XX. The commenters note that there is varying guidance on what sort of capture efficiency one can claim for the amount of vapors from the truck that are getting to a control device and combusting. As one example, the

state of Texas has guidance providing that if a truck tested and certified consistent with certain DOT requirements, the truck can only claim up to a certain amount of capture.<sup>170</sup>

The commenters (0599-MS, 0817-GPA) note that the proposed language, however, does not consider what requirements are in place for capture efficiency. A blanket 95 percent control requirement would be difficult for truck loading in certain circumstances and there is little guidance on acceptable capture efficiencies outside of DOT, and even the basis for DOT's efficiency standards is not clearly articulated.

Commenter (0599-MS) recommends a threshold requirement for control such as 200 tpy methane, as currently incorporated in Pennsylvania's General Air Quality Permits for oil and gas. The commenter notes that these general permits also recognized safety concerns with controlling truck loading with vapor balancing and allow a general control option of 95 percent.

Comment: Commenters (0599-MS, 0817-GPA) recommend that EPA set a minimum annual emission threshold before a NSPS is triggered, below which loading operations would be exempt, such as for storage vessels.<sup>171</sup> The commenters assert that any such threshold should be determined according to a cost-benefit analysis conducted by EPA. The commenters note that a potential-to-emit demonstration for applicability is one option, but there are others that could be considered, such as composition and/or throughput. This would focus any regulation on emissions larger than *de minimis*.

Likewise, the commenters (0599-MS, 0817-GPA) assert that rather than base regulation on the API gravity of the condensate, any regulation of truck loading should be based on an emission threshold and *not* composition. The commenters note the reality of emissions from truck loading and that relationship to API gravity makes regulation on this basis inappropriate. They add that it is also inappropriate as the emissions from tank to truck loading are caused by vapors from the previous truck load that remain to be displaced into the atmosphere, meaning that the API gravity at the regulated site may be different from the last hydrocarbon load the truck hauled. Furthermore, they explain that emissions from tank to truck loading are already going to be fairly low but if EPA attempts to regulate through a composition requirement (e.g., all condensate, all crude, etc.), for example, instead of an emission threshold, it would be difficult to install a control device or vapor balance to address the emissions. The commenters suggest that a minimum emission threshold would help exclude those truly infrequent sources and aid in compliance monitoring and enforcement.

The commenters (0599-MS, 0817-GPA) explain that such a minimum emission threshold addresses cost effectiveness and safety concerns with low flow loading. The commenters add that truck loading operations may be so infrequent that the installation and maintenance of

---

<sup>170</sup> Texas Commission on Environmental Quality, "Air Permit Technical Guidance for New Source Review Loading Operations" 6–7 (Feb. 2021) (available at <https://www.tceq.texas.gov/assets/public/permitting/air/Guidance/NewSourceReview/loading-guidance.pdf>) (last accessed January 25, 2022); see also 49 C.F.R. §§ 173.33, 180.407.

<sup>171</sup> The number of truck loads could be used as an alternative threshold triggering application of the NSPS. This is especially appropriate for operations in remote areas or connected to pipelines but that require tank truck loading on rare occasions. This would help exclude those truly infrequent sources and address cost effectiveness of regulating these rare occurrences.

control devices is impractical at low emission levels. Low flow conditions also pose technical challenges in conveying waste gas to a combustor without introducing ambient air to process vessels through infiltration or other means. This would introduce excess oxygen into the process, creating the risk of an explosion or fire. Further, the commenters note that excess oxygen exacerbates corrosion and presents a risk of potential loss of primary containment.

#### 18.3.4.2 Exemptions

Commenters (0599-MSD, 0817-GPA) recommend that EPA exempt operations that do not already have a combustion control device that would allow for vapor balancing. Alternately the commenters request that EPA provide a relatively prolonged effective date where these control devices are not available and introduce safety risks, practical issues, and feasibility concerns.

Commenter (0938-Texas Oil & Gas Association (TXOGA)) recommends that any tank truck loading operations requirement exclude trucks that are connected to an oil pipeline or that remain under a VOC tpy threshold (similar to other states). The commenter also recommends that EPA exclude water trucking in any such standard, due to issues with the operation of emission control devices for these units, which are complex and would not be cost-effective, given the low potential emissions benefit. The commenter contends that there are not enough flashing/breathing/working losses on water tanks to operate an emission control device to 95 percent destruction efficiency, which means that additional assist gas would be required; the effects of providing such gas have not been considered in the November 2021 Proposal.

Commenter (0782-BHE) recommends that truck loading emissions requirements apply only to upstream operations and not to the T&S segments. The commenter contends that EPA's information solicitation applies only to production operations upstream of T&S. If EPA intends to consider broader applicability, the commenter encourages EPA to define subject liquids, and exclude liquids loading with insignificant emissions. In addition, if EPA elects to broaden applicability to T&S, the commenter requests justification and support. The commenter notes that without the proposed regulatory text it is unclear what EPA is considering.

The commenter (0782-BHE) notes that losses from loading operations are primarily a function of the physical and chemical characteristics of the pipeline pigging liquids and condensate, scrubber/strainer liquids, and other liquid waste recovered or dropped out of the pipeline at the stations. For T&S, the commenter suggests the corresponding volumes, frequency of these operations, liquid volatility, and subsequent emissions do not warrant inclusion.

## **18.4 Other Emission Sources**

Response I-18-4: In the November 2021 proposal preamble<sup>172</sup>, the EPA provided the legal basis for the scope of the proposal, which was to propose revisions to the NSPS for currently regulated VOC and methane emission sources, and to include the regulation of additional oil and gas VOC and methane emission sources in the production, processing, transmission and storage segments of the industry; and to promulgate Emissions Guidelines (EG) to require states to regulate

---

<sup>172</sup> 86 FR 63147, November 15, 2021.

methane emissions from existing sources in those segments. The EPA solicited comment on additional information on specific emission sources that the EPA was evaluating as potential new sources to regulate under the NSPS and EG. Those sources included abandoned and unplugged wells, pipeline pigging and related blowdown activities, and tank truck loading operations in the production, processing, and transmission and storage segments of the industry.

As provided below in section 18.4.1, the EPA received several comments on the proposal requesting that the EPA broaden the scope beyond the emissions sources and industry segments proposed by the EPA. Some of the comments expressed the need for EPA to provide oversight of all facilities involved in the transport of gas, from well pads to city gates and beyond, *i.e.*, all distribution lines and transmission lines. Some of the sources of concern expressed by the commenters are covered under the NSPS OOOOb and EG OOOOc (*i.e.*, well sites, compressor stations, gathering pipeline facilities, natural gas processing plant), while others do not fall within the scope of the source category (*i.e.*, pre-production, distribution segment, downstream emissions from transport). While many of the sources cited by the commenters are not within the scope of the NSPS OOOOb and EG OOOOc rules, they are covered by other air regulations under the Clean Air Act (CAA). For example, the EPA, in coordination with National Highway Traffic Safety Administration (NHTSA), has established greenhouse gas emissions and fuel economy standards for medium and heavy duty trucks manufactured in model years 2014-2018, and under Phase II of the rule, has finalized standards for medium- and heavy-duty vehicles through model year 2027 that will improve fuel efficiency and cut carbon pollution to reduce the impacts of climate change. The EPA has also proposed standards to further reduce harmful air pollutant emissions from light-duty and medium-duty vehicles starting with model year 2027.<sup>173</sup>

One commenter (see section 18.4.3) expressed that the EPA is missing a large emission source of methane emissions. Specifically, the commenter (0587-US Well Services, Inc. (USWSI)) urged EPA to (1) address pre-startup emissions and (2) require monitoring to obtain data to validate further the benefit of the use of electric motors powered by natural gas in the well drilling and fracturing process at the pre-production for sale phase of well site operations. While not within the scope of the NSPS OOOOb rule and EG OOOOc, pre-production electric motors powered by diesel fuel and natural gas in the well drilling fracturing process would generally be covered under the regulations for stationary reciprocating internal combustion engines (RICE). Emissions from stationary RICE are covered under 40 CFR part 63, subpart ZZZZ, 40 CFR part 60, subpart IIII and/or 40 CFR part 60, subpart JJJJ, depending on the specific stationary engine. Stationary RICE would not be covered under the proposed NSPS OOOOb and EG OOOOc requirements.

The Oil and Natural Gas source category includes the production, processing, and transmission and storage segments. (81 FR 35832-35833, June 3, 2016). Pre-production, distribution segment, and transportation downstream emission sources have not been covered by the NSPS historically and are not within the scope of the current NSPS OOOOb and EG OOOOc rules. The pollutants covered are VOCs, SO<sub>2</sub>, and methane. For sources within the scope of the Oil and Natural Gas source category that the EPA had sufficient information to conduct the requisite analyses and develop standards, the EPA has proposed standards and presumptive standards in the December 2022 supplemental proposal for the NSPS OOOOb and EG OOOOc.<sup>174</sup> The EPA did not

---

<sup>173</sup> <https://www.epa.gov/regulations-emissions-vehicles-and-engines>.

<sup>174</sup> 87 FR 74702, December 6, 2022.

consider emission sources that were not within the scope of the source category and pollutants to be covered under the NSPS and EG.

With regards to abandoned and unplugged wells, pipeline pigging and related blowdown activities, and tank truck loading operations emission sources, one commenter (see section 18.4.4) recommended that EPA evaluate the costs and benefits of controlling emissions from these additional sources and that EPA propose supplemental standards to the extent that such controls are net beneficial. Other commenters stated that expansion of the rules to include these additional emission sources would be burdensome to regulated entities and regulating agencies, and that there is currently insufficient data to support developing new regulations for these emission sources (see section 18.4.2). The EPA did not evaluate the costs and benefits or propose emissions standards for pipeline pigging operations and related blowdown activities, and tank truck loading operations in the December 2022 supplemental proposal because the EPA had insufficient information to conduct an analysis to establish standards at this time. The EPA may consider regulation of these emission sources through a future action, including in the next 8-year review of the NSPS. However, for abandoned wells, as stated in section X.A. of the final preamble, the EPA is finalizing well closure requirements under the fugitives monitoring standards that were proposed for actively producing wells in the December 2022 supplemental proposal. The final well closure requirements will prevent well sites from becoming orphaned or left in an idled and unplugged state with no form of emissions monitoring and repair. See RTC Volume II Chapter 4, section 4.1.6 (Well Closure Requirements) for response to comments on the well closure plan associated with the fugitive monitoring requirements. See 40 CFR 60.5397b(l) of NSPS OOOOb and 40 CFR 60.5397c(l) of EG OOOOc for the final well closure requirements.

The comment summaries referenced in the above response related to the scope of emissions sources covered under the NSPS and EG proposals are provided below.

#### ***18.4.1 Support Broadening Scope of the Rule to Include Additional Emission Sources***

Commenter (0414-Waterspirit) urges EPA to broaden the scope of the rule to include all facilities within the oil and natural gas supply chains resulting in a while cycle assessment wherein methane is reported from all facilities which enable the transport of methane from the well site to transmission pipelines (*i.e.*, interstate pipelines) and to distribution pipelines (*i.e.*, PSEG). The commenter suggests that leadership across agencies could assist in this opportunity for independent monitoring. The commenter contends that every facility along the entire network of pipelines (well sites, processing plants, holding pools, liquefaction plants, compressor stations, etc.) – emit methane into the air. The commenter states that thousands of facilities currently go unmeasured, many unreported entirely and some provide estimated emissions per the 100-year-old potency equivalent of carbon dioxide.

Commenter (0428-Private Citizen) recommends that EPA apply the November 2021 Proposal for methane emissions across all components and all facilities in the natural gas supply chain, starting from well sites, to the processing plants, to gathering pipeline facilities, to the distribution pipeline facilities and to the transmission end use direct customers, such as power plants. The commenter contends that this complete end-to-end methane emissions monitoring and reporting would provide a more accurate methane emissions from the natural gas supply

chain. The commenter urges EPA to ensure that even electric compressor stations are included, identified and reported in terms of methane emissions per year. The commenter further recommends that EPA require all natural gas transmission pipeline projects to additionally detail all upstream facilities in terms of current emissions and resulting increased emissions from the added capacity of the proposed project. The commenter believes that all capacity increases need to be detailed from well-site to the transmission pipeline project identified facilities proposed to be modified.

Commenter (1270-LWVUS) believes that the November 2021 Proposal represents a major step forward in limiting methane emissions from gas and oil well. However, the commenter also believes that some issues have not received sufficient consideration and need to be addressed in this regulation and/or a related regulation. The commenter recommends that EPA address downstream emissions from transport, distribution, processing and storage because these emissions are a major problem. The commenter understands EPA's decision to limit considerations of GHG emissions to only those emissions arising from well sites. The commenter hopes that rulemaking on downstream emissions can be completed in the near future, since these are believed to constitute 20 percent of total emissions.

Commenter (1414-SEP) contends that EPA's oversight of the emissions levels must include all facilities involved in the transport of gas, from well pads to city gates and beyond, *i.e.*, all distribution lines and transmission lines.

#### ***18.4.2 Insufficient Information Provided to Support Broadening Scope of the Rule to Include Additional Sources***

Commenter (0831-AXPC) has concerns about EPA's broad suggestion that it may regulate additional emission sources beyond those explicitly discussed in the Initial Methane Notice. The commenter states that they cannot provide informed comment on this topic without further information from EPA, to include both full analysis in the supplemental proposal and proposed regulatory text.

Commenter (0598-CER) believes EPA has not spent sufficient time developing the regulation to determine if the additional sources cited by EPA should be included in the regulation or omitted. The commenter believes that there is currently insufficient data to support developing new regulations for the proposed sources. The commenter recommends that EPA collect an appropriate volume of data and engage industry stakeholders prior to developing new regulations for the sources.

Commenter (0938-TXOGA) states that the public has not been given an opportunity to review and comment on data that would support establishing standards for abandoned wells, pipeline pigging operations, pipeline blowdowns, and tank truck loading sources. The commenter notes that any such proposal would necessarily include the data and analysis to support the proposed addition. As these sources are not included in the RIA for the proposed rulemaking, the commenter asserts that it will be important for EPA to conduct a complete analysis (as required by Section 307(d) of the Act) to support any future regulatory action.

Commenter (0742-ADEC) does not support addressing additional methane emission sources in this proposal. The scope and length of the November 2021 Proposal already makes compliance risk and uncertainty a very large reality and would overburden permit and compliance staff to try to deal with a widely varying set of disparate emitting devices. The commenter states that EPA has always limited proposals to single source categories; as an example, RICE engine emission standards do not expand to include a review of refinery production systems for sulfur limits of diesel fuel as well as the tank truck that brought the fuel from the loading rack.

Comment: Commenter (1270-LWVUS) believes better data on current methane emissions from oil and gas wells is needed to measure the efficacy of new regulations. The commenter asserts there is a strong need for EPA to financially support new studies on methane from gas and oil extraction, transport, storage, processing and use, and that EPA statistics are updated and promulgated in a timely manner to the scientific community and the public.

The commenter (1270-LWVUS) notes that current EPA literature indicates that 2.3 percent of the total volume of gas extracted will be lost through emissions on site and downstream as the gas goes through all the processes required to distribute it to its point of end-use. Many researchers consider this estimated percentage to be much too small. One recent study indicates that leakage from oil production is 90 percent greater than previously estimated and leakage from gas production is 50 percent greater.<sup>175</sup>

The commenter (1270-LWVUS) suggests that, with the proliferation of new equipment and with new approaches to handling data becoming available, the commenter believes that improved estimates may soon be possible and will be important for rulemaking on downstream emissions. The commenter recommends that EPA consider the many reports by independent citizens or groups who have identified leaks from pipelines and compressor stations. The commenter contends that following up on such reports will be useful in gaining more accurate data on the amounts of actual methane emitted through leaks along pipelines and at compressor stations.

### ***18.4.3 Pre-Production Emissions***

Commenter (0587-USWSI) believes that the November 2021 Proposal ignores the environmental impact of pre-production startup activity which is a significant source of methane and other emissions that can be eliminated or minimized. The commenter urges EPA to (1) address pre-startup emissions and (2) require monitoring to obtain data to validate further the benefit of the use of electric motors powered by natural gas in the well drilling and fracturing process at the pre-production for sale phase of well site operations. The commenter's experience and in-field data show that, though relatively short-term, such releases are significant. The commenter contends that monitoring of such emissions will not only provide wide-spread validation of their magnitude and significance but will also provide a basis and incentive for control, reduction or elimination of such emissions. The commenter and other well service providers have demonstrated that proven, effective technology exists to achieve reduction goals at the pre-production stage.

---

<sup>175</sup> <https://www.seas.harvard.edu/news/2021/03/oil-and-natural-gas-production-emit-more-methane-previously-thought>.

The commenter (0587-USWSI) states that the data and analysis in the Report<sup>176</sup> included as an attachment to their comments demonstrates that significant environmental benefits can be achieved by regulatory attention to emissions integral to natural gas exploration and production at the pre-start up stage. The commenter further states that, as shown in the report, the well development process prior to startup of production for output sale is an additional source of pollution that can be reduced or eliminated with proven, feasible, and cost-effective existing technology.

The commenter (0587-USWSI) notes that the information contained in the Report should be used to develop monitoring methodologies and to identify constituents and information to be reported. The commenter suggests that the report of monitoring should specify the source of onsite power used (whether diesel, natural gas, or other) for drilling and fracturing purposes. They add that monitoring should not be limited to minimum time or pollutant volume thresholds and results should be reported separately for the period from commencement of well drilling to startup of production.

The commenter (0587-USWSI) informs that other well service providers use electric motors powered by natural gas instead of diesel and have achieved reductions of methane emissions as compared with use of diesel-powered equipment. The commenter provides the example of Evolution Well Services documented significant CO<sub>2e</sub> reductions in a study of Evolution's operations using electric fracturing technology (see "Emissions Study On EWS Electric Fracturing (see Attachment 2 of comment letter)).

The commenter (0587-USWSI) notes that EPA has already determined in the context of NSPS for production well operations (40 CFR Part 60, subpart OOOOa) that the use of recovered (associated) gas as an onsite fuel source is a viable compliance option to control emissions. The use of such gas to power the drilling and fracturing phase of well site development would assure that this recognized emissions control benefit would be extended.

#### ***18.4.4 Evaluation of the Costs and Benefits to Controlling Emissions from Additional Emission Sources***

Commenter (0842-NYU) recommends that EPA evaluate the costs and benefits to controlling emissions from these additional sources and propose supplemental standards to the extent that such controls are net beneficial. A cost benefit analysis reaffirms the principles of Executive Orders 12,866 and 13,563<sup>177</sup>—including that agencies should select regulatory alternatives that “maximize net benefits” while also accounting for distributive impacts and equity.

## Chapter 19. State, Tribal, and Federal Plan Development for Existing Sources

### 19.1 General Comments on the Proposal for Existing Sources

Comment: Commenter (1382-NGUSA) supports the new requirements for states to develop plans to reduce emissions from existing sources, considering the safety and reliability of existing operations.

Conversely, the EPA also received several comments (0790-State AGs, 0793-PBPA, 0957-WCLG) that generally opposed EPA's proposed new presumptive standards and/or requirements to mitigate methane emissions from oil and natural gas existing sources. Examples of some of those comments are provided in the following paragraphs.

Commenter (0790-State AGs) states that while the CAA expects that EPA's regulatory efforts will show genuine respect for federalism and the role of the states, the November 2021 proposal does not. The commenter notes that states already regulate natural gas production and processing, so EPA should discount the minimal benefits from federal methane regulations like those in the November 2021 proposal given these state efforts.

Commenter (0790-State AGs) asserts that the November 2021 proposal imposes a series of direct burdens on the states that neither the CAA nor any other existing law permits. According to the commenter, the November 2021 proposal identifies only one potential implication for federalism—compliance costs, but EPA observes that the proposal “may” impose a burden on the states because of the “many hours of staff time” required to develop and implement the plans that the November 2021 proposal requires (citing *Federal Register*, Volume 86, page 63,261 (86 FR 63261)). The commenter indicates that these costs will burden states: Oklahoma, for example, has noted that the November 2021 proposal could subject hundreds of thousands of additional oil and gas facilities to more regulation; West Virginia estimates that implementation under EPA's preferred 2-year timetable could cost its environmental regulatory agency over \$278 million each year. The commenter adds that the November 2021 proposal does not contain any specific provisions explaining how EPA will help states bear these significant compliance costs. Commenter adds that these compliance estimates may undershoot actual costs, as other aspects of the November 2021 proposal—such as EPA's choice to declare any unloading event a “modification” that subjects the facility to new-source performance standards—makes it difficult to evaluate accurately the true reach of the proposal.

Commenter (0793-PBPA) states that neither Congress nor (until recently) EPA envisioned CAA section 111(d) being used to regulate whole sectors of the economy. According to the commenter, when EPA first established procedures and requirements for submittal of state plans for control of pollutants from existing facilities under CAA section 111(d), EPA stated that under section 111(d) “extensive control strategies are not required,” state plans would “be much less complex,” and “the number of designated facilities per state should be few” (citing 40 FR 53345, 1975). The commenter states that EPA has only rarely promulgated section 111(d) standards and only for industry-specific pollution issues like acid mist emissions from sulfuric acid plants. The commenter asserts that EPA's infrequent and narrow use of section 111(d) confirms that this

provision was understood to allow limited regulation of existing sources and that the provision was a secondary part of the overall statutory scheme.

Response I-19-1: See section IV.A (Statutory Background of CAA Sections 111(b), 111(d), and General Implementing Regulations) of the final rule preamble for a discussion of EPA’s authority to issue EG to reduce emissions from existing sources. Specifically, CAA section 111(d) requires that the EPA prescribe regulations to establish procedures under which states submit plans to establish, implement, and enforce standards of performance for existing sources for certain air pollutants to which a Federal NSPS would apply if such existing source were a new source. The EPA addresses this CAA requirement both through its promulgation of general implementing regulations for CAA section 111(d) as well as through specific EG.

In response to comments that EPA’s regulatory efforts under the November 2021 Proposal do not “show genuine respect for federalism and the role of the states”, see section XIII.C.2 (State flexibilities) of the final rule preamble. The EPA clarifies that it is not finalizing a framework that demands the state plan be identical to the EG. Under the EG, and consistent with the cooperative federalism framework of CAA section 111(d), states have the prerogative to develop state plans and have flexibility to adopt standards that diverge from the presumptive standards finalized here (including by considering RULOF in the development of their state plans). However, the EPA specifies that the designated facilities and the regulated pollutants must be the same as the EG. Further, unless the state is invoking RULOF to justify a less stringent standard, the state must demonstrate its plan achieves the degree of emission limitation in the EG in order to be approvable.

In response to comments on compliance cost estimates and the commenter’s example pointing to “modification” for liquids unloading events under the NSPS OOOOb, based on comments received on the November 2021 Proposal, the December 2022 Supplemental Proposal for NSPS OOOOb specified that a modification to an existing well occurs when the definition of modification in 40 Code of Federal Regulations (CFR) 60.14 is met, including when an existing well undergoes hydraulic fracturing or re-fracturing. The final rule maintains what was proposed in the December 2022 Supplemental Proposal. See discussion in sections IV.F.1, IV.F.3.a.i, IV.F.3.a.ii, and IV.F.3.a.iii of the December 2022 Supplemental Proposal preamble related to what EPA proposed as constituting a well affected facility/designated facility, and EPA’s request for comments regarding operational scenarios that would constitute a modification for liquids unloading operations. See section 6.4.1 (Applicability) of Volume II of this Response to Comment document (RTC) for comments and responses on the December 2022 Supplemental Proposal on the definition of a well affected/designated facility and what constitutes a modification under the NSPS OOOOb for liquids unloading operations. Lastly, see sections X.F.1 and 3 of the preamble to the final rule which details EPA’s final standards related to well affected facilities/designated facilities and what constitutes a modification for existing wells for liquids unloading operations.

With regards to comments that express concern over the burden that would be placed on states with the implementation of the EG, see section XVII.B (Paperwork Reduction Act) for EPA’s discussion on the estimated annual burden to states that would be associated with the final EG OOOOc collection of information (averaged over the first 3 years following promulgation).

The EPA does intend on working with tribes and states to develop plans tailored to the factors concerning the states. The plan development process, under which performance standards for existing sources are established within their jurisdiction and have the discretion to consider remaining useful life and other factors, is one that Congress established through the text and structure of CAA section 111(d). See discussions in section V.B.2.<sup>1</sup> and section V.B.3.<sup>2</sup> of the December 2022 Supplemental and section XIII of the final preamble and final rule, Adoption and Submittal of State Plans for Designated Facilities: Implementing Regulations Under Clean Air Act Section 111(d) at 88 FR 80480, November 17, 2023, and its corresponding Summary of Public Comments and Responses on Proposed Rule Adoption and Submittal of State Plans for Designated Facilities: Implementing Regulations Under Clean Air Act Section 111(d) (Subpart Ba) Docket ID No. EPA-HQ-OAR-2021-052.

The new standards will work hand-in-hand with new resources and programs in the Inflation Reduction Act, which will incentivize early implementation of innovative methane reduction technologies and support methane mitigation and monitoring activities. These efforts will achieve greater methane emissions reductions more quickly. For more information on the IRA, the Administration has created a guidebook that provides an overview of the clean energy, climate mitigation and resilience, agriculture, and conservation-related tax incentives and investment programs, including who is eligible to apply for funding and for what activities. See <https://www.whitehouse.gov/cleanenergy/inflation-reduction-act-guidebook/>.

Comment: Commenter (0842-IPI) states that regulating new sources, alone, without regulating existing sources at the same time, can perversely encourage existing sources to stay in operation longer than they otherwise would because new-source-only standards make constructing a new source relatively more expensive (and operating an old source relatively cheaper) than it would be if the level of regulation were consistent across all sources. Commenter notes that academics call the resulting distortion of retirement decisions the “old plant effect,” and it can significantly extend the operating lives of highly polluting facilities. Commenter asserts that by coordinating regulation of new and existing sources, EPA laudably mitigates the potential for such distortion.

In contrast, commenter (0793-PBPA) states that existing source standards should not be “co-proposed” with new source standards but should instead be informed by already-finalized new source standards and made less stringent as necessary to accommodate “other factors,” such as the remaining useful life of existing sources. According to the commenter, EPA previously proposed to require that existing source standards be proposed simultaneously with new source performance standards, but EPA ultimately declined, in part because “proposing (or publishing) an emission guideline after promulgation of the corresponding standard of performance” would allow “the Agency [to] benefit from the comments on the standard of performance in developing the emission guideline” (citing 40 FR 53340, 533345, November 17, 1975). Commenter states that if EPA proceeds as proposed, the opportunity to have the EG informed by the process of developing and implementing the new source performance standards (NSPS) would be lost, leaving EPA to take a one-size-fits-all approach through enacting existing source standards that largely mirror the new source standards. Accordingly, commenter suggests that EPA wait to propose the EG until after it finalizes the proposed NSPS so that it will have a basis to account

---

<sup>1</sup> 87 FR 74812.

<sup>2</sup> 87 FR 74816.

for useful life and “other factors” that compel tailored existing source standards, particularly because the EG will have a far greater impact on the oil and gas sector because there are far more existing sources than there are new sources subject to the NSPS program. Commenter adds that EPA’s patience would also allow it to consider the Department of Energy’s impending study on methane emissions from marginal oil and gas wells, which could address EPA’s stated concern that there are a large number of existing well sites that “are not complex” and that therefore should be treated differently from a fugitive emissions standpoint.

Response I-19-2: For the comment that supports regulating new and existing sources at the same time, this is a supportive comment of EPA’s Proposals and the Final Rule which establishes oil and natural gas affected facility standards for new sources and designated facility presumptive standards for existing sources; as such, no response is required.

For the comments that opposed regulating new and existing sources at the same time, please see section IV.A (Statutory Background of CAA Sections 111(b), 111(d), and General Implementing Regulations) of the final rule preamble for a discussion of EPA’s authority to issue EG to reduce emissions from existing sources. Specifically, CAA section 111(d) requires that the EPA prescribe regulations to establish procedures under which states submit plans to establish, implement, and enforce standards of performance for existing sources for certain air pollutants to which a Federal NSPS would apply if such existing source were a new source. The EPA addresses this CAA requirement both through its promulgation of general implementing regulations for CAA section 111(d) as well as through specific EG.

Also, as discussed in Response I-19-1 of this Chapter, under the EG, and consistent with the cooperative federalism framework of CAA section 111(d), states have the prerogative to develop state plans and have flexibility to adopt standards that diverge from the presumptive standards finalized here (including by considering RULOF in the development of their state plans). However, the EPA specifies that the designated facilities and the regulated pollutants must be the same as the EG. Further, unless the state is invoking RULOF to justify a less stringent standard, the state must demonstrate its plan achieves the degree of emission limitation in the EG in order to be approvable.

In response to comment that refers to the U.S. DOE study of emissions from low production wells, see EPA’s response to similar comments and EPA’s review of the study in section XI.A.1.d (Subcategorization of well sites) of the final rule preamble.

## **19.2 Rulemaking Process**

### ***19.2.1 EPA Rulemaking under CAA Section 111(d)***

Comment: Commenter (0922-NAM) provides comments regarding EPA’s authority under CAA section 111(d) to develop presumptive standards for the regulation of methane emissions from oil and natural gas operations.

Commenter (0922-NAM) states that any future rule can only include a best system of emission reduction (BSER) and provide for the development of standards of performance focused on what

can be accomplished at the source level. The commenter points out that the text of CAA section 111 mandates this source-specific approach, quoting the definition of “stationary source” found therein. The commenter notes that the regulations implementing CAA section 111(d) confirm this source-specific standard setting focus in this proposed rulemaking, and the commenter commends this following of the law. The commenter adds that until the judicially stayed Clean Power Plan in 2015, the EPA had in place regulations for five source categories under section 111(d), and in each of those the Agency had uniformly developed a BSER for the source category used to develop source-specific performance standards.

Commenter (0922-NAM) states that any existing source rule should set the BSER but leave it to individual states to set the standards of performance and then to sources to select compliance pathways. The commenter supports the EPA’s position, as stated in the November 2021 proposal, that the Agency determines the BSER. The commenter notes that this approach is clearly laid out in CAA section 111(d)(1), which also mandates that each state is to develop a state plan that establishes standards of performance for existing sources. The commenter points out that the existing source implementing regulations confirm this division of responsibility between the federal and state governments, where the federal EG reflect the BSER but do not include emission standards, and the state plans must include emission standards. The commenter believes that CAA section 111(d) further reinforces this by providing that states are the entities that apply a standard of performance to any source and are entitled to adjust the standard to account for the individual circumstances of the source.

Commenter (0922-NAM) states that EPA’s central task in any future rules should be to establish an appropriate BSER. Commenter notes that CAA section 111 requires EPA to determine that a system of emission reduction has been “adequately demonstrated” before it can be designated as the BSER. The commenter adds that the United States (U.S.) Court of Appeals for the District of Columbia (D.C. Circuit) has determined that “[a]n adequately demonstrated system” “has been shown to be reasonably reliable, reasonably efficient, and...[not] exorbitantly costly in an economic or environmental way” (citing *Essex Chem. Corp. v. Ruckelshaus*, 486 F.2d 427, 433 (D.C. Circuit 1973)), and that while EPA “may make a projection based on existing technology that projection is subject to the restraints of reasonableness and cannot be based on ‘crystal ball’ inquiry” (citing *Portland Cement Ass’n v. Ruckelshaus*, 486 F.2d 375, 391 (D.C. Circuit 1973) (addressing NSPS for new or modified Portland cement plants), superseded in part by statute, 15 U.S.C. 793(c)(1) (1974), as recognized in *Am. Trucking Ass’ns v. EPA*, 175 F.3d 1027 (D.C. Circuit 1999)).

Commenter (0922-NAM) believes that the EPA should ensure that any final rule for existing sources does not establish guidelines stricter than standards set for new sources under CAA section 111 for a given source category. According to the commenter, the statutory text and structure confirm this limitation in that section 111(d) only permits the establishment of standards of performance for existing sources “to which a standard of performance would apply if such existing source were a new source.” The commenter asserts that by making regulation of existing sources contingent upon the regulation of new sources, Congress demonstrated an unambiguous intent to make CAA section 111(d) a supplementary program. The commenter states that this approach allows any CAA section 111(d) regulation to be informed by the BSER analysis and standards of performance for new sources, although the statute provides additional

flexibility for existing sources considering cost-related and other issues associated with existing source retrofits—concerns that do not apply to new sources.

Response I-19-3: Please see section IV.A (Statutory Background of CAA Sections 111(b), 111(d), and General Implementing Regulations) of the final rule preamble for a discussion of EPA’s authority to issue EG to reduce emissions from existing sources. Specifically, CAA section 111(d) requires that the EPA prescribe regulations to establish procedures under which states submit plans to establish, implement, and enforce standards of performance for existing sources for certain air pollutants to which a Federal NSPS would apply if such existing source were a new source. The EPA addresses this CAA requirement both through its promulgation of general implementing regulations for CAA section 111(d) as well as through specific EG.

### ***19.2.2 Supplemental Proposal/Regulatory Text for the EG***

Comment: Commenter (0820-PNR) appreciates that EPA has acknowledged that the November 2021 Methane Rule publication does not constitute a complete proposed rule, as evidenced by EPA’s stated commitment to issuing a supplemental proposal that will contain the proposed regulatory text for new subparts NSPS OOOOb and EG OOOOc. The commenter strongly supports the issuance of a supplemental proposal and urges EPA to make the scope of that supplemental proposal, and the subjects on which it solicits comment, as broad as possible. The commenter believes that it would be poor policy and not good governance to narrowly restrict the scope of comment on the supplemental, particularly because EPA has not yet shown the public what regulatory text it proposes to codify nor the policy intentions it discusses with respect to these subparts in the preamble of the November 2021 publication. The commenter looks forward to reviewing the proposed regulatory text, as well as to any additional information and solicitation of comment that EPA includes in the supplemental proposal.

Response I-19-4: The EPA disagrees with the commenter accretion that the November 2021 proposal was not complete. As stated in the December 2022 supplemental, EPA CAA section 307(d)(3) specifies the information that a proposed rule under the CAA must contain, such as a statement of basis, supporting data, and major legal and policy considerations; the list of required information does not include proposed regulatory text. Similarly, the Administrative Procedures Act (APA), which governs most Federal rulemaking, does not require publication of the proposed regulatory text in the Federal Register. Section 553(b)(3) of the APA provides that a notice of proposed rulemaking shall include “either the terms or substance of the proposed rule or a description of the subjects and issues involved.” (Emphasis added). Thus, the APA clearly provides flexibility to describe the “subjects and issues involved” as an alternative to inclusion of the “terms or substance” of the proposed rule. See also *Rybachek v. EPA*, 904 F.2d 1276, 1287 (9th Cir. 1990) (the EPA’s “failure to propose in advance the actual wording” of a regulation does not make the regulation invalid where the “proposal . . . clearly describe[s] ‘the subjects and issues’ ” involved).<sup>3</sup>

On December 6, 2022, the EPA proposed regulatory text for NSPS OOOOb at Document I.D. No. EPA-HQ-OAR-2021-0317-1551 and EG OOOOc at Document I.D. No. EPA-HQ-OAR-2021-0317-1552 in the public docket. The December 2022 Supplemental offered stakeholders an

---

<sup>3</sup> 87 FR 74716.

additional opportunity engagement through a second round of public comment and held an additional three-day virtual public hearing on January 10, 11, 12, 2023.

Comment: Commenter (0424-WVDEP) disagrees with the assertion that the EPA satisfied its requirements under Code of Federal Regulations, title 40, part 60 (40 CFR part 60), subpart Ba by including description in four separate locations in sections X, XI, and XII of the November 2021 proposal preamble and the *Background Technical Support Document (TSD) for the Proposed New Source Performance Standards (NSPS) and Emission Guidelines (EG)* located at Docket ID No. EPA-HQ-OAR-2021-0317 because the EPA did not provide any proposed regulatory text. Commenter asserts that this is a piecemeal approach to a proposed rulemaking without providing proposed regulatory text, which absolutely does not meet the EPA's obligation under 40 CFR 60.22a(b).

Response I-19-5: EPA's November 2021 proposal satisfied the requirements applicable to draft emission guidelines within 40 CFR Part 60 Subpart Ba that existed at the time of the November 2021 proposal. EPA explained how it met each component of 40 CFR 60.22a(b), and included cross references to where within the proposed rule materials that information could be found. 86 FR 63110, 63248 – 63249 (November 15, 2021). The fact that EPA satisfied these requirements via the compilation of information that was located in various sections of the proposal and associated documents does not negate the fact that EPA complied with these requirements. EPA provided a clear roadmap to readers to demonstrate how the Agency met those requirements. Lastly, contrary to the commenter's suggestion, the provision cited by commenter, 40 CFR 60.22a(b), does not contain a requirement that EPA publish draft regulatory text for the emission guidelines.

Comment: Several commenters (0431-NOI, 0465-JDC, 0411-REM) express that the EPA did not propose NSPS OOOOb/EG OOOOc regulatory text. Small business entities with minimal staff and limited resources need direct, well-defined, and easily understood proposed regulations to evaluate for impacts and provide meaningful comment. Further, commenters note that approximately 1000 pages of preamble and technical support documents were published by the EPA with a limited response time of 77 days encompassing two major holidays. The commenter (0465-JDC) notes that this prevented them from fully deciphering and commenting on the potential short-term and long-term implications of proposed regulations. Another commenter (411-REM) notes that commenters are interpreting the proposed rules differently.

Commenters (0581-NACAA, 0813-BIHE, 0827-WESTAR) advise EPA to meet with state, tribal, and/or local air agencies to guide development of the EG regulatory text for the supplementary proposal.

Commenter (0581-NACAA) states that to achieve the cooperative potential of the CAA section 111(d) program, it is essential that EPA consult with state and local air agencies as it develops its supplemental proposal and its proposed rule concerning the implementation of section 111 programs. The commenter asserts that state and local air agencies charged with implementing the rule have unique regulatory expertise and are leaders in the arena of GHG emission reduction programs; in particular, in reducing methane from the oil and gas sector. The commenter notes that their January 15, 2021, transition letter calls for EPA to "mine the knowledge of state and

local regulators and apply it to the development of nationally consistent federal rules to reduce GHG emissions from industrial and other stationary sources regulated under the Clean Air Act.” The commenter notes that the CAA and section 111(d) are built on a model of cooperation that requires EPA to work in partnership with states, cities, and counties, among others, and by affording states additional – and essential – flexibility to chart compliance pathways, which can include emission limitations that are at least as stringent as the federal guidelines. The commenter requests that EPA retain its longstanding reliance on mandatory federal minimums coupled with state implementation flexibility to meet or exceed those environmental goals.

Commenter (0827-WESTAR) states that before proceeding with the proposed rulemaking activities, they suggest that EPA talk with individual state, tribal, and local air programs, document what was learned, and fully map the landscape of how methane and other emissions are controlled and managed. According to the commenter, a plan to meet with state, tribal, and local air programs; an effort to comprehensively gather necessary information; and the conduct of analyses adequately addressing the control concepts proposed are all necessary steps to developing effective and efficient regulations. Given that there was no detailed regulatory language in this proposal, the commenter requests that EPA provide ample time for public comment and engagement when the actual regulatory language is proposed, which will allow the state, tribal, and local air programs to provide more substantial comment and input based upon their experience and knowledge.

Commenter (0827-WESTAR) also asks that EPA equally address emission sources under its purview as the rulemaking process would require state, tribal, and local air agencies to do their parts, by also fully quantifying, tracking, and managing EPA-controlled existing emissions and control effectiveness in the context of this rulemaking proposal.

Commenter (0813-BIHE) encourages EPA to work cooperatively with states to ensure any new regulations for existing oil and gas sources are reasonable and effective, noting that additional regulatory burden without realized benefit is neither helpful to industry or the public, nor a valuable use of EPA’s time and resources.

Response I-19-6: With regards to comments about EPA proposing regulatory text and opportunities for engagement with EPA, please see Response I-19-4 within this Chapter.

EPA reviewed public comments on the November 2021 Proposal from various states, tribes, and other stakeholders. These comments helped to inform EPA’s December 2022 Supplemental Proposal which included additional details for how states would implement the EG through the development of state plans. EPA continued dialogue with various state and tribal agencies throughout the development of the 2021 proposal and 2022 supplemental proposal.<sup>4</sup> In EPA’s 2021 TSD<sup>5</sup> EPA identified existing federal, state, and local regulations to help inform the development of the EG which the EPA proposed to refine in the 2022 supplemental TSD.<sup>6</sup>

---

<sup>4</sup> For example, see Document I.D. Nos. EPA-HQ-OAR-2021-0317-0117, EPA-HQ-OAR-2021-0317-1474, EPA-HQ-OAR-2021-0317-1527, EPA-HQ-OAR-2021-0317-1510, and EPA-HQ-OAR-2021-0317-1524.

<sup>5</sup> See document I.D. EPA-HQ-OAR-2021-0317-0166.

<sup>6</sup> See document I.D. EPA-HQ-OAR-2021-0317-1578.

With regards to commenters request that EPA equally address emission sources under its purview by fully quantifying, tracking, and managing EPA-controlled existing emissions and control effectiveness, the EPA believes that we have accomplished that as presented in the Final TSD located in Docket No. EPA-HQ-OAR-2021-0317. Furthermore, the EPA has an obligation to promulgate a Federal plan if a state fails to submit a satisfactory plan. To the extent the commenter is requesting that EPA “equally address emission sources” in a federal plan, EPA notes that any such federal plan would be promulgated via a separate rulemaking process in the future.

EPA is committed to work cooperatively with states and tribes to ensure any plans submitted meet the necessary completeness criteria.

### ***19.2.3 Development of a Model Rule***

Comment: Commenters (0456-WDNR, 0581-NACAA, 0782-BHE) support development of a model rule by EPA.

Commenter (0456-WDNR) states that model rule language is critical for states without existing state programs regulating the oil and natural gas sector. Commenter (0581-NACAA) supports the development of an example state plan and model rule language for each segment of the oil and gas industry regulated by adopted rule that can be incorporated directly or by reference to meet EPA’s emission guidelines, believing that many agencies will benefit from a model rule. Commenter (0581-NACAA) adds that the opportunity to adopt preapproved rule language, in addition to the option to develop a unique state plan in accordance with the guidelines, is consistent with the CAA’s cooperative approach and will expand state compliance options while conserving state resources.

Commenter (0782-BHE) recommends that the EG include a model rule or example regulatory text for the states to consider that includes provisions that allow case-specific review analogous to alternative reasonably available control technology (RACT) provision in ozone state implementation plans (SIPs) and consideration of case-specific economic and technological feasibility.

Response I-19-7: The EG OOOOc regulatory text includes a model rule which is reflected in §§60.5385c through 60.5430c.<sup>7</sup> A proposed model rule was available in the public docket for public comment in conjunction with the 2022 supplemental proposal.

## **19.3 Presumptive Standards**

### ***19.3.1 General Comments on Presumptive Standards***

Comment: Commenter (0797-NDDEQ/IC) asserts that EPA lacks authority to establish standards of performance for existing sources under CAA section 111(d), which mandates that the states have the authority to set the standards of performance and emission limitations, and further

---

<sup>7</sup> See Document I.D. No. EPA-HQ-OAR-2021-0317-1552 in the public docket.

mandates that the states have the authority to make source-specific determinations in setting those standards of performance “for any existing source.” The commenter argues that any BSER guideline created by EPA must not infringe on the states’ authority to establish emission limitations and determine what emission limitations are “achievable” by existing sources, including the states’ authority to take source-specific factors into account in establishing the standards of performance. For example, the commenter believes that the November 2021 proposal violates this statutory separation of authority by proposing a fixed national standard of 95 percent VOC emissions reduction that would apply to both new and existing pneumatic controllers, asserting that EPA’s proposal to assume for itself the authority to impose fixed national emission standards on existing sources and thus displace the state’s authority to establish standards of performance for existing sources violates CAA section 111(d).

Commenter (0797-NDDEQ/IC) further argues that EPA’s attempt to label this 95 percent VOC emission reduction requirement as a “presumptive standard[] that States may use in the development of State plans for specific designated facilities” is a misnomer (citing 86 FR 63117). According to the commenter, this action, if finalized, would displace North Dakota’s sovereign authority to apply the BSER guidelines to determine the degree of emission limitation that is achievable, because EPA has already made that determination.

Commenter (0797-NDDEQ/IC) notes that this very issue is currently before the Supreme Court in *North Dakota v. EPA et. al.*, No. 20-1780 (Consolidated in Case No. 20-1530 with Case Nos. 20-1531 and 20-1778), where certiorari has been granted and oral argument is set to proceed on February 28, 2021. The commenter reports that one of the key issues the Supreme Court will soon rule on is the extent of EPA’s authority under CAA section 111(d) to impose emissions standards on existing sources. The commenter asserts that EPA should refrain from proposing and finalizing any regulatory provisions regarding existing sources in this rulemaking until the Supreme Court issues its decision.

Commenter (0790-State AGs) states that the November 2021 proposal ignores its consequences for federalism in creating presumptive standards for existing sources. According to the commenter, CAA section 111(d) contemplates that states will have more latitude to implement standards of performance than when EPA takes up this task—as where the statute says that states may consider a facility’s “remaining useful life”—but EPA instead notes that “it would likely be difficult for states to demonstrate that the presumptive standards are not reasonable for the vast majority of designated facilities” (citing 86 FR 63251). Given this, commenter believes that the November 2021 proposal would give states little choice but to implement the measures that comprise EPA’s BSER—lest EPA reject the states’ plans entirely. Commenter states that even then, EPA offers little reassurance to states, specifying that EPA still might not approve state plans that track the presumptive standards (citing 86 FR 63249), leaving states with trying to comply with EPA’s “presumptions” while hoping that EPA does not take the matter out of the states’ hands entirely.

Response I-19-8: EPA did not propose to establish standards of performance for existing sources. EPA is not finalizing any standards of performance that apply to existing sources. The presumptive standards are not “fixed national standards” as one commenter suggests, because they do not directly apply to any sources. In accordance with Section 111(d) of the Clean Air Act

(CAA), states are tasked with developing plans which establish standards of performance for existing sources. However, in accordance with EPA regulations, the agency is to publish emission guidelines (EG), and those guidelines are to include certain information. 40 CFR 60.22a. Among other information, the EG must include “[t]he degree of emission limitation achievable through the application of the best system of emission reduction (considering the cost of such achieving reduction and any nonair quality health and environmental impact and energy requirements) that has been adequately demonstrated for designated facilities.” Id. 60.22a(b)(5). The presumptive standards that commenters take issue with are a product of EPA’s compliance with its own regulations and are intended to assist states with the development of their plans. These presumptive standards do not deprive states of their authority to establish standards of performance, to make source-specific determinations, or to consider remaining useful life and other factors. States are not required to adopt the presumptive standards and are free to pursue a different approach in their state plan so long as their approach comports with applicable laws, regulations, and guidance.

The EPA is finalizing, for this EG, to translate the degree of emission limitation achievable through application of the BSER (i.e., level of stringency) into presumptive standards of performance that States may use in the development of State plans for specific emission points. The EPA believes that the presumptive standards of performance included in the EG will provide States with the level of stringency that the EPA would require to approve a State plan. Put another way, the EPA is choosing to format this EG such that if a State chooses to adopt the presumptive standards as the standards of performance in their State plan, then the EPA believes that such plan could be approved as meeting the requirements of CAA section 111(d) and the finalized EG, assuming the plan meets all other applicable requirements. In this way, the presumptive standards included in the EG serve a similar purpose as a model rule because they are intended to assist States in developing their plan submissions by providing the States with a starting point for their standards that are based on general industry parameters and assumptions. Some commenters have specifically requested that EPA provide this starting point. See comments and responses in section 19.2.3 of this Chapter. The EPA believes that providing these presumptive standards of performance will create a streamlined approach for States in developing plans and for the EPA in evaluating State plans. Of course, the EPA cannot predetermine the outcome of a future rulemaking process, and inclusion of these presumptive standards in this EG does not impact the rulemaking process associated with the EPA’s review of, and action on, a State plan submission. In its review of State plans, the EPA will consider the information in the final EG and the final presumptive standards, as well as information submitted by the State and the public. The EPA will evaluate the approvability of all plans through individual notice-and-comment rulemaking processes.

Further, EPA recognizes that the general industry parameters and assumptions underlying the presumptive standards may not be applicable to all sources in all situations. EPA acknowledges that a state may be able to establish an approvable standard of performance that differs from the presumptive standard. The inclusion of presumptive standards does not automatically foreclose this possibility.

Further, the EPA finalized provisions at 40 CFR part 60 subpart Ba to guide states that choose to apply a standard of performance to a particular source, to take into account the source’s

remaining useful life and other factors. The final Subpart Ba is published at 88 FR 80480 (November 17, 2023). The EPA's final EG issued under CAA section 111(d) do not impose binding requirements directly on sources, but instead provide requirements for States in developing their plans and criteria for assisting the EPA when judging the adequacy of such plans.

Finally, with respect to the challenge the commenter cites that was then-pending before the Supreme Court, the Court confirmed EPA's authority to establish the BSER and degree of emission limitation for existing sources: "Although the States set the actual rules governing existing power plants, EPA itself still retains the primary regulatory role in Section 111(d). [t]he Agency, not the States, decides the amount of pollution reduction that must ultimately be achieved." *West Virginia v. EPA*, 142 S. Ct. 2587, 2601-02 (2022).

### ***19.3.2 Proposed Numerical Presumptive Standards***

Comment: Commenters (0558-CCES, 0761-Exelon, 0793-PBPA, 0832-NMED, 1267-CA) state that EPA should allow states to adopt standards that take a different form than the "presumptive" numerical standards that EPA has proposed, if states can demonstrate equivalency. Commenter (0793-PBPA) states that this should be allowed out of respect for cooperative federalism and each state's on-the-ground expertise, given that CAA section 111(d) only requires EPA to "establish a procedure" under which each state can submit state plans, as opposed to requiring EPA to establish "presumptive" numerical standards. Commenter (1267-CA) similarly notes that allowing states to adopt a different form of the presumptive numerical standard is more consistent with the structure of CAA section 111(d), under which states have wide latitude in developing their plans provided that the required level of emission reduction is achieved, although the commenter understands the desirability of streamlining the preparation of state plans and simplifying EPA's review of those plans. Commenter (0761-Exelon) indicates that this should be allowed unless any facts and circumstances that are unique to the type of designated facility make the proposed form of the standard the only appropriate form. Commenter (0832-NMED) recommends that the EPA provide a streamlined demonstration of equivalency if state rules already require meaningful, cost-effective GHG and VOC emission reductions, noting that New Mexico just completed a multi-year comprehensive rulemaking process and has proposed a nationally leading regulation covering both new and existing oil and gas sources.

Response I-19-9: See discussion in section V.B.2 (Leveraging State Programs) of the December 2022 Supplemental Proposal preamble,<sup>8</sup> and section XIII.C.2 (State flexibilities) of the final rule preamble.

Comment: Commenter (0824-WDEQ) states that the November 2021 proposal's state plan requirements should be reconsidered. The commenter notes that EPA solicited comment on whether it should allow states to include a different form of numerical standards, but commenter believes that the establishment of a uniform standard does not account for the technical intricacies and site-specific conditions at each individual affected facility – and it also does not account for the feasibility or infeasibility for certain operators to achieve the standard. The commenter asserts that it is imperative that states have sufficient input on setting standards of

---

<sup>8</sup> 87 FR 74812.

performance that are both achievable and enforceable, and EPA should consider comments it receives that point out the technical concerns with achieving uniform standards - whether they are numeric or non-numeric.

Response I-19-10: See discussion in section V.B.2 (Leveraging State Programs)<sup>9</sup> and discussion in section V.B.3 (Remaining Useful Life and Other Factors (RULOF))<sup>10</sup> of the December 2022 Supplemental Proposal preamble; and sections XIII.C.2 (State flexibilities) and XIII.C.3 (Remaining useful life and other factors (RULOF)) of the final rule preamble.

See also Response I-19-9 of this Chapter.

Comment: Commenter (0938-TXOGA) states that in the development of presumptive standards for existing sources, EPA must not undercut the flexibility allowed in the site-specific alternate means of emissions limitation (AMEL) process for new sources and allow the application of site-specific AMELs to an existing source by operation of law. Commenter supports EPA's continued use and development of a more streamlined and improved AMEL process and fears, based on EPA's proposal to require standards in state plans to be of the same form as the numerical presumptive standards, that facilities obtaining AMEL approval for new sources would not be able to apply that same AMEL to existing sources subject to the EG. The commenter states that this proposal could be misinterpreted to mean that states would not have the flexibility under their plans to allow an AMEL that EPA has approved for NSPS OOOO, NSPS OOOOa, or NSPS OOOOb, even where a site contains new and existing facilities, and that states could not include in their own state plans the ability to approve AMELs themselves. The commenter indicates that while this may not be the intent, it is important for the regulations to be written to avoid such a result, and EPA should ensure that it has not cemented the "floor" for the EG in a manner that would preclude application of AMELs for existing sources. The commenter notes that as an AMEL must demonstrate at least an equivalent reduction in emissions for a new source, there is no basis to preclude their use for existing sources.

Commenter (0938-TXOGA) requests that EPA ensure its proposed regulations (when published) address this issue so that sources with an approved site-specific AMEL may employ that AMEL with respect to new, modified, and reconstructed affected facilities at a site and to existing designated facilities subject to EG OOOOc. Specifically, the commenter asserts that EPA should draft the proposed regulations consistent with the following principles:

1. If there is an approved AMEL for NSPS OOOO, NSPS OOOOa, or NSPS OOOOb, the AMEL should be deemed approved under state plans that track the requirements of the new source standards (in form or stringency).
2. State plans should not need to be amended to allow use of AMELs approved by EPA under NSPS OOOO, NSPS OOOOa, or NSPS OOOOb, regardless of when such approval occurs. The commenter is concerned that the "double-key" approach of SIP approvals, which has led to substantial backlogs for SIPs, not be replicated in this context.

---

<sup>9</sup> 87 FR 74812.

<sup>10</sup> 87 FR 74816.

3. Finally, states should have the authority to approve AMELs, without concurrent EPA approval (not the two-step process like for SIPs).

Response I-19-11: The AMEL provision in the Clean Air Act has been applied only in the context of new source performance standards issued under CAA section 111(b). See CAA 111(h)(3). CAA section 111(d) does not specifically incorporate the AMEL provision from 111(h)(3). EPA's rule promulgated under 111(b) does allow for AMEL for new, modified, and reconstructed sources. Further, states are free to consider site-specific factors when establishing standards of performance in their state plans regulating existing sources. If a state plan includes a standard that is different than the presumptive standard included in EPA's emission guidelines, and the state believes their standard will achieve emission reductions that are equivalent to or greater than the emission guidelines, then the state plan should explain why they believe this. EPA anticipates that such an explanation would be very similar in nature to an AMEL, but this is not the same as an AMEL application under CAA 111(h)(3). Further, if EPA approves an AMEL request in the context of the NSPS, that does not automatically mean that existing sources are allowed to make use of that AMEL. First, the AMEL provision only applies in the context of non-numerical standards under 111(h). Second, AMEL approvals can be site-specific in which case the approval would only apply to listed sources/sites, or perhaps similarly situated sources. Third, states establish standards for existing sources via the state planning process. Even if EPA were to approve a broadly-applicable AMEL request in the context of the oil and gas NSPS, a state would need to amend its state plan to allow existing sources in that state to make use of such an AMEL. States are free to amend their state plans as they see fit, but those revisions must be submitted to EPA for evaluation and action. If after approval of a state plan, a state determines there is another equivalent method to reduce emissions, whether EPA approved an AMEL for that new way or not, the state is free to amend their plan to include it. Lastly, the commenter is correct that states cannot allow for approval of AMEL for existing sources in their plan without EPA approval.

While states do not have the delegation authority to approve AMEL themselves, states have flexibility in the state planning process as discussed in section V.B.2 (Leveraging State Programs)<sup>11</sup> and in section V.B.3 (Remaining Useful Life and Other Factors (RULOF))<sup>12</sup> of the December 2022 Supplemental Proposal preamble; and sections XIII.C.2 (State flexibilities) and XIII.C.3 (Remaining useful life and other factors (RULOF)) of the final rule preamble.

As noted in the proposed §60.5373c, authorities that will not be delegated to a state, local, or tribal agency includes approval of alternatives to the emission limits and standards, approval of major alternatives to test methods, approval of major alternatives to monitoring, approval of major alternatives to recordkeeping and reporting, approval of an alternative to any electronic reporting to the EPA required by this subpart and performance test and data reduction waivers.<sup>13</sup>

---

<sup>11</sup> 87 FR 74812.

<sup>12</sup> 87 FR 74816.

<sup>13</sup> See Document I.D. No. EPA-HQ-OAR-2021-0317-1552 in the public docket.

### ***19.3.3 Proposed Non-Numerical Presumptive Standards***

Comment: Commenter (1267/1268/1269-CA AG et al) concurs with the approach that each state adopt the proposed presumptive standards or otherwise demonstrate that the state's alternative approach will achieve reduction in methane emissions at least equivalent to that of the presumptive standards.

Response I-19-12: Comment is a supportive comment on an aspect of the November 2021 Proposal that has remained unchanged in the final rule; as such, no response is required.

Comment: Commenter (0761-Exelon) states that even if states adopt the presumptive standards in their plans, states would still be able to include flexible compliance mechanisms based on consideration of a designated facility's "remaining useful life" and other source-specific factors.

Response I-19-13: See discussion in section XIII.C.3 (Remaining useful life and other factors (RULOF)) of the final rule preamble. See also the final rule, *Adoption and Submittal of State Plans for Designated Facilities: Implementing Regulations Under Clean Air Act Section 111(d)* at 88 FR 80480, November 17, 2023.

### ***19.3.4 More Stringent State Standards***

Comment: Commenters (0808-API, 0834-AAC, 0921-USCoC, 0938-TXOGA) state that EPA's proposed position that it has authority to approve, and make federally enforceable, state standards that are more stringent than the presumptive standards included in the final EG is not supportable under the law. Commenters (0808-API, 0834-AAC) note that CAA section 111(d)(1) requires states to develop "standards of performance" for existing affected facilities, and that the term "standard of performance" is defined in CAA section 111(a)(1) to mean an emissions standard "which reflects the degree of emission limitation achievable through the application of the best system of emissions reduction ... the Administrator determines has been adequately demonstrated." Commenter (0921-USCoC) states that CAA section 111(d) is fundamentally distinct from the SIP process under CAA section 110 in that section 111(d) does not prescribe minimum conditions but instead requires standards of performance that reflect BSER as determined by the Administrator. Commenter (0834-AAC) concludes that this means that state standards of performance must be based on BSER as determined by EPA. Commenters (0808-API, 0921-USCoC, 0938-TXDOGA) conclude that while a state has authority under CAA section 116 to implement more stringent standards as a matter of state law, there is no authority under CAA section 111 or 116 for EPA to federalize such state programs.

Commenter (0808-API) presents a detailed summary of the EPA's legal analysis on this topic in the November 2021 proposal and on the contradictory analysis EPA presented during the Affordable Clean Energy (ACE) rulemaking in 2019. Commenter then provided the following analysis of the *Union Electric Co. v. EPA*, 427 U.S. 246 (1976) decision (*Union Electric*) to which the EPA referred both in the 2019 ACE rulemaking and in the November 2021 proposal:

That case involved a 1972 Missouri state implementation plan ("SIP") for sulfur dioxide. *Union Electric Co. v. EPA*, 427 U.S. 246, 252 (1976). A local utility filed

a challenge to that SIP claiming that the SIP was invalid because it imposed technologically and economically infeasible emissions control requirements. *Id.* at 253.

The court upheld the SIP on the grounds that “Congress intended claims of economic and technological infeasibility to be wholly foreign to the Administrator’s consideration of a state implementation plan.” *Id.* at 256. More specifically, the court interpreted “the ‘as may be necessary’ requirement of § 110(a)(2)(B) to demand only that the implementation plan submitted by the State meet the ‘minimum conditions’ of the [1970 CAA] Amendments.” *Id.* at 264. “Beyond that, if a State makes the legislative determination that it desires a particular air quality by a certain date and that it is willing to force technology to attain it – or lose a certain industry if attainment is not possible – such a determination is fully consistent with the structure and purpose of the Amendments, and § 110(a)(2)(B) provides no basis for the EPA Administrator to object to the determination on the ground of infeasibility.” *Id.* at 265.

Thus, the court expressly held (as EPA observed in 2019) that CAA § 110(a)(2)(B) allows states to adopt more stringent programs than minimally required by the Act. In that context, its observation that CAA § 116 should not be read as only authorizing more stringent state-only emissions control programs, *id.* at 264, is limited to programs such as CAA § 110 that, in the first instance, allow states to adopt more stringent measures than minimally required under the Act.

Here, CAA § 111(d) unambiguously requires state existing source programs to prescribe “a standard of performance,” which is defined to mean “a standard for emissions of air pollutants which reflects the degree of emissions limitation achievable through the application of the best system of emissions reduction which (taking into account the cost of achieving such reduction and any nonair quality health and environmental impact and energy requirements) the Administrator determines has been adequately demonstrated.” CAA §§ 111(d)(1)(A) and 111(a)(1). There is no room for states to do anything more than prescribe standards of performance that reflect BSER. Thus, in sharp contrast to CAA § 110, CAA § 111(d) does not prescribe “minimum conditions” that may be exceeded by the states. Instead, CAA § 111(d) requires standards of performance that must reflect a BSER determination that is based, among other things, on consideration of costs and feasibility. If proposed state standards of performance do not meet these requirements, they must be rejected by EPA.

Therefore, “structural similarities” between CAA §§ 110 and 111 do not provide an adequate basis for EPA’s proposal that it may approve state standards of performance that are more stringent than required by CAA § 111(d). Such an approach unreasonably and unlawfully ignores the significant substantive differences between CAA §§ 110 and 111 and would violate the unambiguous requirement that state § 111(d) standards of performance must reflect BSER.

To be clear, API supports the coordination and consolidation of federal and state emissions control requirements for the oil and gas sector. Ideally, only one set of standards would apply – state devised and administered emissions control programs that simultaneously satisfy CAA § 111 requirements and address any unique state priorities and objectives. We believe there is sufficient latitude under CAA § 111(d) to allow for EPA approval of state programs in most cases because, in our experience, state programs are typically grounded in principles that would satisfy CAA § 111 standard setting criteria.

But it is at least theoretically possible that a state would seek to impose emissions control obligations that go so far beyond CAA § 111 principles that such obligations cannot be squared with the federal CAA requirements. In such cases, states have authority under CAA § 116 to implement their programs as a matter of state law. But there is no authority under CAA § 111 or 116 for EPA to federalize such state programs.

Commenter (0938-TXOGA) is concerned that EPA’s statements regarding approval and federal enforceability of standards more stringent than BSER could be construed to suggest that a state could simply establish an unachievable standard based on an undemonstrated control approach and that EPA would approve such a standard into a state plan without regard to the statutory considerations in CAA section 111, which commenter asserts is plainly not a permissible outcome under the statutory language. The commenter states that while a state agency may be free under CAA section 116 to make that assessment and to enforce its view under state law (to the extent such a rulemaking would be consistent with applicable state laws), it would not be free to transform such regulations into federal law.

Commenter (0938-TXOGA) states that the position EPA expressed in the preamble appears not to consider that, unlike the SIP approval criteria in CAA section 110, cost and feasibility considerations are fundamental to the standard-setting process under CAA section 111. According to the commenter, taken to its extreme, under the rationale in the preamble, EPA could approve as federal law a state plan that sets all emission standards at zero, even if there is no technology that can achieve that level of emission, and the consequence of that would be not only that EPA could enforce this standard, which all would agree it could not have promulgated under CAA section 111(b), but also citizens would be able to enforce the standard under CAA section 304. Commenter believes that if Congress had intended this result, which would be transformative, it clearly would have spoken directly to the question.

Response I-19-14: See section XIII.C.2 (State flexibilities) of the final rule preamble for a discussion on the flexibilities afforded states when establishing standards under their state plan. See also discussion in section XIII.C.3 (Remaining useful life and other factors (RULOF)) of the final rule preamble. See also the final rule, *Adoption and Submittal of State Plans for Designated Facilities: Implementing Regulations Under Clean Air Act Section 111(d)* at 88 FR 80480, November 17, 2023.

Comment: Commenter (1267/1268/1269-CA AG et al) summarizes the rationale in the November 2021 proposal’s discussion of *Union Electric* and CAA sections 111(d) and 110 and

agrees with EPA’s view of these statutory sections and its conclusion that EPA must approve a more stringent state plan that meets the criteria set forth in the emissions guidelines. Commenter also states that such an interpretation also promotes section 111’s focus on emissions “performance,” not on whether states have adopted identical methods set forth in EPA’s guidelines.

Response I-19-15: Comment is a supportive comment on an aspect of the November 2021 Proposal that has remained unchanged in the final rule; as such, no response is required.

Please see the Summary of Public Comments and Responses on Proposed Rule Adoption and Submittal of State Plans for Designated Facilities: Implementing Regulations Under Clean Air Act Section 111(d) (Subpart Ba) Docket ID No. EPA-HQ-OAR-2021-052. The final Subpart Ba is published at 88 FR 80480 (November 17, 2023).

## **19.4 Development of Section 111(d) State Plans**

### ***19.4.1 General Comments on State Plan Development***

Comment: Commenter (0722-MODNR) states that many states, including Missouri, lack comprehensive GHG emission tracking and reporting requirements and systems, and that this lack of data will hinder many states’ ability to develop adequate state plans pursuant to the EG. The commenter asserts that EPA should be mindful of this and provide a clearinghouse of data they have available at the federal level so that states will be in a better position to identify and engage with all the sources that must be regulated in the state plans they must develop.

Response I-19-16: States may find the following resources helpful to identify and engage with sources. EPA maintains the Greenhouse Gas Reporting Program (GHGRP) releases reported greenhouse gas emissions data annually. The most recent reporting year that is publicly available is 2022 data. GHGRP also produces resources like tools, profiles, fact sheets, and more on specific topics of interest to help the public use and derive value from the greenhouse gas reporting data. EPA also develops an annual report, called the Inventory of U.S. Greenhouse Gas Emissions and Sinks, that tracks U.S. greenhouse gas emissions and sinks by source, economic sector, and greenhouse gas going back to 1990. EPA also suggest that state review the final RIA associated with this final rulemaking.

See discussion in section V.B.5 of the December 2022 Supplemental Proposal preamble<sup>14</sup> and see discussion in section XIII.C.5 of the final preamble.

Comment: Commenters (0820-PNR, 0831-AXPC, 0922-NAM) urge EPA to provide flexibility to states in developing their plans that establish standards of performance for existing sources.

Commenters (0820-PNR, 0831-AXPC) contend that this is in keeping with the text and structure of CAA section 111, as well as with the common-sense observation that it is easier for regulated companies to plan and execute design and operational changes for new and modified sources

---

<sup>14</sup> 87 FR 74827.

than for existing sources. The commenters state that the existing-source program is a cooperative federalism program under which Congress intended that states would have considerably flexibility in establishing standards of performance for existing sources. The commenters assert that the supplemental proposal and final rule should reflect this by (1) allowing states to establish less stringent or no standards on sources with a short remaining useful life, (2) allowing states to submit any existing regulatory programs they may already have adopted with no or little alteration where those programs would appropriately serve the purposes of the CAA and comport with the framework established in this federal rulemaking, and (3) allowing states to provide their existing sources with broad latitude in choice of monitoring and other compliance measures.

Commenter (0922-NAM) suggests that EPA provide guidance to the states on how to set standards of performance for methane emissions from existing sources but should also ensure the states have ample flexibility in determining those standards and give sources maximum flexibility in achieving them. The commenter notes that while authority to set the specific performance standards that would satisfy BSER at sources must remain with the states, EPA should also consider including in any final rule sufficient guidance to provide states a path to implement a “presumptively approvable” performance standards, which could set out a process for the states to use to set source-specific performance standards based on demonstrated technology. The commenter recommends that EPA be clear that such an approach is not mandatory, but it would offer an option to the states that could streamline efforts to comply with BSER, expedite EPA’s review of state plans, and thereby facilitate regulatory certainty. The commenter cautions that EPA should avoid overly restrictive approaches that simply specify a prescriptive list of technological improvements that qualify toward the achievement of BSER and then require states to adopt a subset of them, which could unduly complicate the development of state performance standards and overly limit the latitude toward developing performance standards granted to the states.

Commenter (0722-MODNR) suggests that EPA make clear in the final EG that states have the ability to make necessary adjustments on a case-by-case basis that may allow for less stringent requirements in cases where states can justify that it would be significantly more reasonable to do so. According to the commenter, such considerations could include unusual circumstances that lead to significantly higher costs and remaining useful life for identified sources among others. For additional comments on “remaining useful life and other factors”, see section 9.4.2 of this Chapter.

Response I-19-17: See discussions in sections V.B.2.,<sup>15</sup> section V.B.3.,<sup>16</sup> and section IV.B.<sup>17</sup> of the December 2022 Supplemental Proposal preamble and the requirements for meaningful engagement included in the Adoption and Submittal of State Plans for Designated Facilities: Implementing Regulations Under Clean Air Act Section 111(d) at 88 FR 80480, November 17, 2023. With regard to guidance for states developing plans, including presumptive standards and state flexibilities, see section XIII.C of the final rule preamble.

<sup>15</sup> 87 FR 74812.

<sup>16</sup> 87 FR 74816.

<sup>17</sup> 87 FR 74740.

#### ***19.4.2 “Remaining Useful Life and Other Factors” (RULOF)***

Comment: Commenters (0814-IPAA, 0820-Pioneer, 0824-WDEQ, 0831-AXPC, 0922-NAM) note that CAA section 111(d) requires EPA to allow states to take into consideration the remaining useful life of the existing source and other factors in establishing standards of performance for individual designated sources. Commenter (0922-NAM) recommends that any future rules clearly reaffirm that the states have discretion to consider multiple factors when setting the standard appropriate for a particular source or class of sources because the CAA’s text mandates that states be permitted to consider a range of source-specific variables in setting those standards and the current existing source implementing regulations reflect that authority as inherent in the states. Where EPA “has determined that a designated pollutant may cause or contribute to endangerment of public welfare,” but has not made a conclusion regarding public health effects, states may weigh “other factors of public concern” in setting emission standards. Where EPA “has determined that a designated pollutant may cause or contribute to endangerment of public health,” the implementing regulations provide that state “emission standards...be no less.”

Commenters (0820-Pioneer, 0831-AXPC) state that the existing-source program is a "cooperative federalism" program under which Congress intended that states would have considerably flexibility in establishing standards of performance for existing sources. The commenters request that the EPA's supplemental proposal and final rule reflect this by providing for states with latitude in the standards they establish for their existing sources, to include: allowing states to establish less stringent or no standards on sources with a short remaining useful life; allowing for states to submit any existing regulatory programs they may already have adopted with no or little alteration where those programs would appropriately serve the purposes of the CAA and comport with the framework established in this federal rulemaking; and allowing states to provide their existing sources with broad latitude in choice of monitoring and other compliance measures.

Commenter (0824-WDEQ) has concerns regarding the infeasible cost of control to achieve a certain standard for stripper wells and other small operators that will likely result in ceasing operations, job losses, and lost state and federal revenue. The commenter asserts that EPA’s declaration that “it would likely be difficult for states to demonstrate that the presumptive standards are not reasonable for the vast majority of designated facilities” (citing 86 FR 63251) is discouraging and inaccurate. The commenter emphasizes that there are very justifiable and legitimate circumstances, such as site-specific variables, under which a different or lower performance standard should be allowed.

Commenter (0814-IPAA) expresses concern that although EPA acknowledges the right of states to take RULOF into consideration, EPA has prejudged the outcome based on the statement from EPA quoted in the previous paragraph. The commenter believes that this inherent bias before EPA even proposes revisions to the CAA section 111(d) regulation suggests a stacked deck against the rights of states to make decisions that reflect the diverse operations in their jurisdictions.

Response I-19-18: See discussion in section V.B.3. of the December 2022 Supplemental,<sup>18</sup> section XIII.C.3 of the final preamble, final rule, *Adoption and Submittal of State Plans for Designated Facilities: Implementing Regulations Under Clean Air Act Section 111(d)* at 88 FR 80480, November 17, 2023 and it's corresponding Summary of Public Comments and Responses on Proposed Rule Adoption and Submittal of State Plans for Designated Facilities: Implementing Regulations Under Clean Air Act Section 111(d) (Subpart Ba) Docket ID No. EPA-HQ-OAR-2021-052.

Comment: Commenter (0844/0855-EDF) states that EPA must ensure that any state plans submitted are rigorous and that safeguards are in place to ensure those performance standards do not fall short of EPA's guidelines. The commenter asserts that the language, structure, and history of the CAA make abundantly clear that EPA must set binding emission reduction requirements in its existing source guidelines, and that state plans may allow less effective emission standards only where a particular affected source with unique circumstances can demonstrate to the state, and the state can demonstrate to EPA, that need for a case-specific variance. After discussing the difference in EPA and state standard-setting responsibilities between CAA section 111(b) NSPS and CAA section 111(d) EG, the commenter states that under the statute, it is EPA's responsibility to specify the minimum degree of emission limitation to be incorporated in standards of performance, noting that section 111(a)(1) requires "the Administrator" to determine both the "best system of emission reduction" and the "achievable" "degree of emission limitation" therefrom. The commenter believes that this federal minimum emission limitation provides states and EPA with the substantive criteria for determining whether a state plan is "satisfactory." The commenter notes that state-issued standards of performance, in turn, translate EPA's technical determination of what pollution reductions are "achievable" into an enforceable emission limit that regulated sources cannot exceed, and EPA's regulations provide that a "standard of performance" must include "a legally enforceable regulation setting forth an allowable rate or limit of emissions into the atmosphere, or prescribing a design, equipment, work practice, or operational standard, or combination thereof" (citing 40 CFR 60.21a(f)). The commenter adds that EPA's implementing regulations for CAA section 111 have consistently recognized the agency's obligation to establish the minimum stringency level for state-issued standards of performance. The commenter notes that the regulations define "emission guideline" in terms that mirror CAA section 111(a)(1): as an emission limit reflecting the degree of emission limitation achievable through the EPA-determined "best system" and that, in turn, standards of performance in a satisfactory state plan must be "no less stringent than the corresponding emission guideline(s)" (citing 40 CFR 60.24a(c)).

Commenter (0844/0845-EDF) states that these implementing regulations directly reflect the text of CAA section 111, which commands EPA to establish a procedure under section 111 that is similar to the SIP process required under CAA section 110 wherein states adopt implementation plans to achieve and maintain the NAAQS, which EPA must then either approve or reject (in whole or in part) based on whether they satisfy the federal NAAQS. The commenter asserts that if EPA's EG did not provide clear and binding requirements to which state plans must adhere, there would be no manageable standards either for EPA to determine whether a state plan was satisfactory or for courts to review EPA's approval or denial of such plans.

---

<sup>18</sup> 87 FR 74816.

Response I-19-19: See discussion in section V.B.3. of the December 2022 Supplemental,<sup>19</sup> section XIII.C.3 of the final preamble, final rule, *Adoption and Submittal of State Plans for Designated Facilities: Implementing Regulations Under Clean Air Act Section 111(d)* at 88 FR 80480, November 17, 2023 and it's corresponding Summary of Public Comments and Responses on Proposed Rule Adoption and Submittal of State Plans for Designated Facilities: Implementing Regulations Under Clean Air Act Section 111(d) (Subpart Ba) Docket ID No. EPA-HQ-OAR-2021-052.

Comment: Commenter (0844/0845-EDF) discusses the flexibility included in CAA section 111(d) and the implementing regulations, stating that EPA can approve a state plan with a package of performance standards that differ from the emission limits specified in the EG if the agency determines that the state's standards will produce at least as much emission reduction as a plan whose standards conformed to those emission limits. The commenter notes that the statute allows a state to "take into consideration" a source's "remaining useful life" and "other factors" when "applying" a standard of performance to a "particular source" (citing CAA section 111(d)(1)). The commenter asserts that the state must include any such variances in its plan and demonstrate to EPA that those specific characteristics are present.

Commenter (0844/0845-EDF) asserts that CAA section 111(d) does not permit or require a state to grant, or EPA to approve, variances for all sources merely because they have a short remaining useful life, nor does it provide that the state and EPA must tailor each source's emission reduction obligations to reflect its remaining useful life. Rather, according to the commenter, sources are entitled to have states "consider" their arguments for lesser requirements based on remaining useful life or other factors, but states (and EPA) have the discretion to find those arguments unpersuasive. The commenter contends that this is clear in EPA's implementing regulations, which permit a state to set a different standard for a specific source only if the state "demonstrates" a need based on "plant age, location, or basic process design," "[p]hysical impossibility of installing necessary control equipment," or "[o]ther factors specific to the facility...that make application of a less stringent standard...significantly more reasonable" (citing 40 CFR 60.24a(e)). The commenter adds that EPA must approve any such demonstration of need before approving a state plan as "satisfactory." The commenter concludes from this that the mere fact that an affected source may be of advanced age, or have unusual characteristics, does not in and of itself permit a state to grant a variance or require EPA to approve any such variance; rather, the source must show some specific reason why those characteristics would justify a more lenient standard.

Commenter (0844/0845-EDF) agrees with EPA's November 2021 proposal preamble discussion at 86 FR 63251 that concluded that existing sources—even units with a short remaining useful life—are unlikely to be able to show sufficient reasons justifying a variance from otherwise applicable requirements.

Response I-19-20: See discussion in section V.B.3. of the December 2022 Supplemental,<sup>20</sup> section XIII.C.3 of the final preamble, final rule, *Adoption and Submittal of State Plans for Designated Facilities: Implementing Regulations Under Clean Air Act Section 111(d)* at 88 FR

---

<sup>19</sup> 87 FR 74816.

<sup>20</sup> 87 FR 74816.

80480, November 17, 2023 and it's corresponding Summary of Public Comments and Responses on Proposed Rule Adoption and Submittal of State Plans for Designated Facilities: Implementing Regulations Under Clean Air Act Section 111(d) (Subpart Ba) Docket ID No. EPA-HQ-OAR-2021-052.

Comment: Commenter (0844/0845-EDF) states that “remaining useful life” is a term of art used in engineering and accounting that refers to an estimate of the number of remaining years that a component in a production line is estimated to be able to function in accordance with its intended purpose before warranting replacement, and that Congress’s primary motivation for using this language in CAA section 111(d) was to avoid the problem of stranded assets, which are assets that have suffered from unanticipated or premature write-downs, devaluation or conversion to liabilities. The commenter notes that in environmental regulation, this may occur when (for example) an existing source nearing the end of its useful life becomes subject to new regulations that require the installation of expensive pollution control equipment – if the source then retires soon thereafter due on account of age, the control equipment will likely be stranded, since it will have been rendered useless before long before that equipment’s useful life has expired and its operator has fully paid off the capital it invested in the device. According to the commenter, this can be a significant issue for capital-heavy industries, but the oil and gas sector is different in several regards from many or most other industries regulated under CAA section 111 – the emitting sources themselves are much more numerous, much smaller, and, in most cases, less expensive than sources in other industries, and often rely on emission reduction practices that bear little resemblance to the kinds of expensive pollution control technologies that are often found in other industries, and oil and gas sector equipment often depreciates much more quickly than do the kinds of large-scale, capital-intensive infrastructure that exist in other industries.

Commenter (0844/0845-EDF) states that work practices for other equipment in the oil and gas industry may require operators to purchase and install new equipment, but these control methods are often much less expensive than in other industries and, in many cases, allow the operator to turn a net profit through conserved gas. As an example, the commenter notes that the leak detection and repair (LDAR) standards require very few upfront capital costs, almost none of which are tied to a specific facility; instead, an operator can simply contract with an LDAR provider who will conduct surveys across the operator’s facilities. The commenter observes that if one site shuts down, the operator experiences no loss or stranded assets, and that even in the situation where an operator decides to conduct in-house LDAR surveys and purchases monitoring equipment, that equipment would not become a stranded asset and is not tied to a particular well site because the operator could continue using the monitoring equipment at other sites or sell it and recover resale value.

As another example, the commenter (0844/0845-EDF) notes that the proposed requirements for reciprocating compressors would require operators either to replace rod packing when measured leak rate exceeds 2 standard cubic feet per minute (scfm) based on the results of annual monitoring, or to capture and route rod packing emissions to a process through a closed vent system under negative pressure. The commenter states that according to EPA, rod packing replacements would entail annual capital costs of approximately \$1,700 to \$2,300, which is orders of magnitude lower than control equipment for many other industries and, moreover, these costs can generally be recouped entirely through conserved gas within 6 to 24 months so

that EPA projects that its requirements for reciprocating compressors will have net negative costs. As a third example, the commenter notes that the 2021 November proposed standards for centrifugal compressors require operators to reduce emissions by 95 percent through use of a wet-seal degassing system, which EPA reports as having capital costs around \$33,000 per compressor—still four orders of magnitude lower than a flue gas desulfurization system—with a payback period of just one to five months. The commenter adds that it may be possible for operators to reuse such degassing systems—and potentially other pollution control equipment, like vapor recovery units—for newly installed facilities once the older facilities retire.

Commenter (0844/0845-EDF) asserts that, in determining how to apply the remaining useful life provision to the oil and gas source category, EPA should consider the following three considerations regarding the extent to which states should be permitted to grant a variance: (1) Is the cost of the new equipment so relatively negligible that variances simply should not be granted, regardless of a source's remaining useful life? (2) Do cost savings achieved through recovered gas either partially or totally offset the control equipment's cost within the source's remaining useful life window, and if so, should that mean that the stranded asset problem doesn't arise and that no variances should be granted? (3) Can the control equipment be used at another emissions source after the original emissions source retires, and if so, should that option obviate the need for a variance? As for point 1, the commenter states that it is worth noting that the NSPS OOOOa rule includes a formula for determining when a capital expenditure has occurred which appears to pertain to whether or not a source can be considered modified, but EPA should consider whether it is also appropriate for establishing a monetary threshold below which states should not be permitted variances even if a source retires before the depreciation schedule for the new control equipment has expired.

Response I-19-21: See discussion in section V.B.3. of the December 2022 Supplemental,<sup>21</sup> section XIII.C.3 of the final preamble, final rule, *Adoption and Submittal of State Plans for Designated Facilities: Implementing Regulations Under Clean Air Act Section 111(d)* at 88 FR 80480, November 17, 2023 and its corresponding Summary of Public Comments and Responses on Proposed Rule Adoption and Submittal of State Plans for Designated Facilities: Implementing Regulations Under Clean Air Act Section 111(d) (Subpart Ba) Docket ID No. EPA-HQ-OAR-2021-052.

Comment: Commenter (0844/0845-EDF) asserts that EPA must prohibit states from accounting for sources' profitability when determining whether to issue variances. According to the commenter, nothing in the CAA permits the agency to accommodate aging sources and prioritize their ability to achieve a profit, even after many years of operation, over environmental considerations. The commenter notes that for sources such as aging wells that produce only marginal amounts of oil or gas decades after being drilled, EPA must not allow these operators to be given relaxed standards simply due to low profit margins, arguing that any source that is so marginal such that (for example) spending several thousand each year for leak detect and repair monitoring would eliminate its ability to turn a profit should not be operating.

Commenter (0844/0845-EDF) also asserts that a source operator's subjective opinion about the extent of the source's remaining useful life should play no role in any determination as to

---

<sup>21</sup> 87 FR 74816.

whether the source should receive a variance. According to the commenter, whether a source is “useful” from an operator’s standpoint will in virtually all cases be based on its profitability rather than its actuarial value as an engineering asset, which is what CAA section 111(d)’s provision is intended to reflect. The commenter indicates that profitability—and the factors that influence it, such as oil and gas prices, the amount of recoverable product, and other considerations—are simply irrelevant to whether a control requirement would be objectively unreasonable in a particular, limited instance or would result in stranded assets. Rather than relying on operators’ own estimations of the remaining useful life of their equipment, the commenter recommends that EPA refer to Internal Revenue Service (IRS) depreciation schedules to establish clear and objective lifetimes for each type of equipment, and should also define a reasonable—and reasonably limited—number of years left on a source’s actuarial lifetime during which it can claim a variance based on remaining useful life, and even in those cases, the source should only be granted a variance if it can demonstrate particular hardship that would result from compliance based on the short window; again, marginal profitability should play no role in this determination.

Commenter (0844-EDF) states that once a source’s IRS-defined depreciation period has expired, it should no longer be permitted to qualify for a variance based on remaining useful life. The commenter indicates that operating equipment past the point in which the federal government considers it useful is poor engineering practice and often results in inefficient operation and, frequently, excess emissions. The commenter contends that to allow operators to benefit from a variance under such circumstances would not only reward the worst performers, it would incentivize operators to continue using old and failing equipment for as long as possible rather than invest in newer and more efficient infrastructure that would have no option for a variance. The commenter notes that this would defeat the entire purpose of CAA section 111(d) controls for existing sources.

Response I-19-22: See discussion in section V.B.3. of the December 2022 Supplemental,<sup>22</sup> section XIII.C.3 of the final preamble, final rule, *Adoption and Submittal of State Plans for Designated Facilities: Implementing Regulations Under Clean Air Act Section 111(d)* at 88 FR 80480, November 17, 2023 and it’s corresponding Summary of Public Comments and Responses on Proposed Rule Adoption and Submittal of State Plans for Designated Facilities: Implementing Regulations Under Clean Air Act Section 111(d) (Subpart Ba) Docket ID No. EPA-HQ-OAR-2021-052.

Comment: Commenter (0844/0845-EDF) states that where a source does qualify for a variance based on its remaining useful life, EPA must require that the source agree to a federally enforceable retirement date that reflects the expiration of the unit’s IRS depreciation schedule. The commenter notes that EPA’s 2019 ACE rule for existing fossil fuel-fired power plants, which the commenter believes took an inappropriately expansive view of CAA section 111(d)’s variance provision and which many commenters vigorously objected to and challenged in court, included a requirement that any source benefitting from the remaining useful life provision “specify the exact date by which the source’s remaining useful life will be zero” and that such source’s “associated retirement date will be federally enforceable upon approval by the EPA” (citing 84 FR 32558). Although the commenter strongly objects to the ACE Rule’s fundamental

---

<sup>22</sup> 87 FR 74816.

interpretation of the remaining useful life provision, they believe that this feature of the rule was appropriate and therefore urges EPA to include in the final EG this same requirement that source's receiving a variance based on remaining useful life submit to a federally enforceable retirement date linked to the years remaining in the source's IRS depreciation schedule. The commenter concludes that if no years remain, it should not be eligible for such a variance.

Response I-19-23: See discussion in section V.B.3. of the December 2022 Supplemental,<sup>23</sup> section XIII.C.3 of the final preamble, final rule, *Adoption and Submittal of State Plans for Designated Facilities: Implementing Regulations Under Clean Air Act Section 111(d)* at 88 FR 80480, November 17, 2023 and it's corresponding Summary of Public Comments and Responses on Proposed Rule Adoption and Submittal of State Plans for Designated Facilities: Implementing Regulations Under Clean Air Act Section 111(d) (Subpart Ba) Docket ID No. EPA-HQ-OAR-2021-052.

Comment: Commenter (0844/0845-EDF) states that EPA should revise its implementing guidelines to more precisely define the "other factors" that are discussed in CAA section 111(d)(1). Quoting the existing regulations at 40 CFR 60.24a(e)(1)-(3), the commenter suggests that the regulatory text be revised to offer more specific and useful directions as to what may and may not factor into a state's decision to grant a variance to a particular source. The commenter supports EPA's intention to provide further clarification regarding RULOF and encourages EPA to set clearer parameters to govern when variances may be granted. The commenter adds that the oil and gas industry has several unique features that justify limiting the usual scope of the variance provision in certain regards, and the implementing regulations make clear that "each emission guideline may include specific provisions in addition to or that supersede requirements of this subpart" (citing 40 CFR 60.20a(a)(1)).

Thus, commenter (0844/0845-EDF) asserts, in the context of the EG rulemaking in particular, EPA should identify a specific and more limited set of circumstances in which states may issue variances under this provision:

1. As discussed in a previous comment, EPA should define narrow and well-defined circumstances in which the likelihood of stranded assets might permit variances, incorporating a capital expenditure threshold, an operator's ability to defray compliance costs through sale of conserved gas, and the operator's ability to use control equipment at new sources after an old source retires.
2. The EPA should also retain the existing regulation's reasonable limitation regarding physical impossibility.
3. NSPS OOOOa already includes a number of limited exceptions in the requirements themselves based on (for example) safety or temperature considerations. For instance, LDAR repair requirements are relaxed when such repairs cannot be made safely, and sources on the Alaskan North Slope are exempt from certain requirements. In its emission guidelines for existing sources, EPA should clarify that these exemptions are among the "other factors" states may consider when granting variances.

---

<sup>23</sup> 87 FR 74816.

Response I-19-24: See discussion in section V.B.3. of the December 2022 Supplemental,<sup>24</sup> section XIII.C.3 of the final preamble, final rule, *Adoption and Submittal of State Plans for Designated Facilities: Implementing Regulations Under Clean Air Act Section 111(d)* at 88 FR 80480, November 17, 2023 and its corresponding Summary of Public Comments and Responses on Proposed Rule Adoption and Submittal of State Plans for Designated Facilities: Implementing Regulations Under Clean Air Act Section 111(d) (Subpart Ba) Docket ID No. EPA-HQ-OAR-2021-052.

Comment: Commenter (0458-MDE) asserts that state plans to address EG requirements for existing sources should adhere to the most stringent standards, based on the BSER, with little room to deviate, as climate change benefits do not differentiate between a new or existing source.

Commenter (0941-350 Silicon Valley) indicates that they do not support EPA allowing state plans for existing facilities to make exceptions for the “expected or useful life” of equipment or exceptions for economic hardship for low-producing wells. The commenter states that small or low-producing wells are often large emitters of methane and that if small wells are not producing enough oil or gas to make this simple retrofit economically beneficial after a few years, then the wells should cease production and be sealed and capped. According to the commenter, this would also help reduce the number of future orphan wells. The commenter suggests that EPA set up a program to provide assistance and training for employees working at marginal wells if they lose their jobs because their company cannot meet higher performance standards and ceases production.

Response I-19-25: See final rule, *Adoption and Submittal of State Plans for Designated Facilities: Implementing Regulations Under Clean Air Act Section 111(d)* at 88 FR 80480, November 17, 2023 and its corresponding Summary of Public Comments and Responses on Proposed Rule Adoption and Submittal of State Plans for Designated Facilities: Implementing Regulations Under Clean Air Act Section 111(d) (Subpart Ba) Docket ID No. EPA-HQ-OAR-2021-052.

Comment: Commenter (0727-OK DEQ) requests further explanation of “remaining useful life”. The commenter notes that the EPA states it “intends to provide further clarification on the general process and requirements for accounting for remaining useful life and other factors . . .” 86 Fed. Reg. 63251. The commenter states that, if EPA plans to issue guidance or specific provisions regarding remaining useful life, whether a part of this rulemaking or in the implementing regulations, these details need to be known now, in order to successfully evaluate and plan for the impacts of the proposed rule and the BSER. The commenter urges EPA to release this information as soon as possible as it may inform future comments on EPA's proposal.

Response I-19-26: See discussion in section V.B.3. of the December 2022 Supplemental,<sup>25</sup> section XIII.C.3 of the final preamble, final rule, *Adoption and Submittal of State Plans for Designated Facilities: Implementing Regulations Under Clean Air Act Section 111(d)* at 88 FR

---

<sup>25</sup> 87 FR 74816.

80480, November 17, 2023 and its corresponding Summary of Public Comments and Responses on Proposed Rule Adoption and Submittal of State Plans for Designated Facilities: Implementing Regulations Under Clean Air Act Section 111(d) (Subpart Ba) Docket ID No. EPA-HQ-OAR-2021-052.

### ***19.4.3 Integrating Existing State Programs with State Plans***

Comment: Commenter (0790-State AGs) states that the November 2021 proposal shows insufficient regard for the states in that the proposal does not account for existing state programs in any real way, merely noting their existence and saying that EPA “anticipates providing information on ways in which State plans can accommodate existing State programs.” The commenter opines that EPA intends to force states to essentially re-litigate the validity of their own programs in submitting their state plans (quoting 86 FR 63252 as proposing that states be required to “include a detailed explanation and analysis of how the relied upon existing State programs are at least as stringent as the requirements of the final [emission guidelines]”).

Response I-19-27: See discussion in section V.B.2 (Leveraging State Programs) of the December 2022 Supplemental Proposal preamble,<sup>26</sup> and section XIII.C.2 (State flexibilities) of the final rule preamble.

Comment: Commenter (0558-CCES) believes that it is extremely important to update state plans so that they align with the proposed EG. The commenter states that one of the most important elements of the EPA’s proposed standards is establishing the first-of-their-kind EG for states to reduce methane emissions from existing oil and natural gas facilities, noting that almost 86 percent of the projected emissions reductions and more than 83 percent of the projected climate benefits under the proposed rule are associated with regulating existing sources. The commenter points out that while some states have their own regulations for methane, these regulations vary widely in terms of emissions limits, testing frequency, and flexibility to use new leak detection and repair technologies.

Commenter (0558-CCES) states that there are different ways that can enable existing state programs to be adopted into state plans under the EG. For example, they suggest that for state programs that include less frequent leak detection and monitoring surveys, EPA can require these states to specify an emissions limit beyond which operators would need to perform more frequent leak tests. The commenter adds that state programs can also be updated to include a timeframe for fixing any detected leaks that does not exceed the period defined in the proposed EG.

Response I-19-28: See discussion in section V.B.2 (Leveraging State Programs) of the December 2022 Supplemental Proposal preamble,<sup>27</sup> and section XIII.C.2 (State flexibilities) of the final rule preamble.

Comment: Several commenters (0579-Chevron, 0581-NACAA, 0610-Oxy, 0775-CO DPHE, 0820-PNR, 0922-NAM, 0926-Austin, 1267/1268/1269-CA AG et al, 1381-MPA) support

---

<sup>26</sup> 87 FR 74812.

<sup>27</sup> 87 FR 74812.

flexibility in approval of existing state GHG regulatory programs in CAA section 111(d) state plans, and many of these commenters advocate for establishment of clear procedures for demonstrating equivalency.

Commenter (0581-NACAA) states that EPA should allow for programs with greater stringency or different, but at least equally stringent state approaches, by making a clear path for program equivalency application, demonstration, and determination. The commenter believes that where programs are less stringent in individual aspects but as or more stringent and protective overall, EPA should accommodate those tailored approaches that meet that state's needs. The commenter notes that EPA has demonstrated experience with creating a streamlined equivalency through the implementation of its NSPS OOOOa provisions since 2016. The commenter indicates that while there is widespread support from air agencies for an approach that awards federal credit for state programs designed to reduce GHG emissions from the oil and gas sector, it is important that any state-level measures credited toward federal compliance be at least as effective overall as the federal minimums at delivering emission reductions, even if specific aspects of the programs are less stringent because of local circumstances, constraints, and needs. The commenter adds that however EPA ultimately resolves these issues, the agency must be clear in its eventual guidance and offer a streamlined process for equivalency to give state and local agencies a high degree of certainty in leveraging their existing programs.

Commenter (0926-Austin) supports EPA's development of EG for states, including presumptive standards, and encourages EPA to engage with stakeholders on additional pathways for states to demonstrate that existing programs are at least as stringent as the final EG. The commenter believes that establishing a process for states to use successful existing programs and demonstrate those programs are at least as stringent as the final EG will facilitate cost effective emission reductions and avoid redundant compliance requirements. Additionally, the commenter urges EPA to look for ways to allow flexibility for states to demonstrate equivalency using advanced technologies, as they may provide more cost-effective pathways to reduce emissions. The commenter suggests that EPA might propose criteria for advanced technologies that EPA would use to determine equivalency with the EG.

Commenter (1381-MPA) states that the Montana Department of Environmental Quality already has a facilities registration program in place with regular inspections using optical gas imaging (OGI) cameras as well as enforcing LDAR. The commenter asserts that EPA should provide maximum flexibility under cooperative federalism to allow the individual states to manage the program and work with oil and gas operators on inspection technology and the related processes.

Commenter (0610-Oxy) states that EPA should avoid promulgating duplicative regulation that conflicts with state or other federal regulatory programs by providing flexibility for states to utilize their programs, which will allow operators to focus resources on implementing changes resulting in real emissions reductions and eliminate any confusion surrounding duplicative requirements.

Commenter (0775-CO DPHE) strongly encourages EPA to find that a state program for existing sources is equivalent to EPA's EG as EPA did for certain LDAR programs in NSPS OOOOa, even where the programs differ in some respects. The commenter notes that while Colorado's

program differs in some respects from the description of the EG in the preamble, the commenter believes that Colorado's program holistically achieves the same or better emissions reductions. The commenter asserts that for any final EG, it will be critical for EPA to leave flexibility in how states make this demonstration, particularly given that states cannot effectively begin this evaluation without a more specific proposal. The commenter suggests that EPA allow states to make a programmatic demonstration of equivalency, instead of having to demonstrate equivalency on a provision by provision or source type by source type basis (e.g., that a state's well unloading regulations are independently equivalent with the proposal). The commenter adds that states like Colorado have put considerable effort into developing the implementation structures necessary to ensure that their regulatory requirements achieve the expected emission reductions and requiring states to modify their programs based on a narrow conception of equivalency will undermine implementation processes and practices that have been developed over many years and can lead to less effective regulation.

Commenter (0775-CO DPHE) requests that EPA simplify and streamline the plan demonstration and review process for an initial CAA section 111(d) plan, as well as for any future revisions to the state program. The commenter notes that CAA section 111(d) plans are not SIPs and are therefore not subject to the same requirements and limitations. The commenter requests that EPA ensure that alternative approaches are approvable into state SIPs and section 111(d) plans. The commenter asserts that flexibility in the development, demonstration, and review of CAA section 111(d) plans for this industry is critical for effective regulation as technological innovation moves at a more rapid pace than regulatory development.

Commenter (1267-CA) recommends that EPA provide a streamlined demonstration of equivalency if the state rules already require meaningful, cost-effective GHG and VOC emission reductions. As an example, the commenter notes that New Mexico just completed a multi-year comprehensive rulemaking process and has proposed a nation-leading regulation covering both new and existing oil and natural gas sources.

Response I-19-29: See discussion in section V.B.2 (Leveraging State Programs) of the December 2022 Supplemental Proposal preamble,<sup>28</sup> and section XIII.C.2 (State flexibilities) of the final rule preamble.

Comment: Commenter (0775-CO DPHE) states that EPA should offer clarity into which components of a state's regulatory program can, or must, be included in a state's CAA section 111(d) plan. The commenter indicates that Colorado will undertake an evaluation of the efficacy of its program as compared to the proposals and will evaluate whether any additional rulemakings are necessary to prepare a CAA section 111(d) plan consistent with the CAA. Commenter notes that if Colorado can determine that its program is—or should be found—equivalent, Colorado would anticipate submitting a certification of equivalency along with a demonstration to EPA, which would identify which regulations (and other regulatory components, such as general permits or guidance documents) constitute Colorado's section 111(d) plan.

---

<sup>28</sup> 87 FR 74812.

Response I-19-30: See discussion in section V.B.2 (Leveraging State Programs) of the December 2022 Supplemental Proposal preamble,<sup>29</sup> and section XIII.C.2 (State flexibilities) of the final rule preamble.

Comment: Commenter (0581-NACAA) indicates that states that have rules or well-developed proposals have already gone through robust public processes and rulemakings. The commenter states that inasmuch as the forthcoming implementation rule proposal seeks to accommodate state programs, it should consider regulatory actions and timelines required in those states and integrate flexibility into the rule that accommodates them.

Similarly, commenter (0579-Chevron) notes that many state agencies have already implemented regulations to reduce emissions from the same source categories that EPA is proposing to regulate in this rule. The commenter encourages EPA to recognize the structure and independence of state agencies to ensure consistency in requirements from different regulators, which will improve the effective allocation of resources on the part of all stakeholders.

Response I-19-31: See discussion in section V.B.2 (Leveraging State Programs) of the December 2022 Supplemental Proposal preamble,<sup>30</sup> and section XIII.C.2 (State flexibilities) of the final rule preamble.

Comment: Commenter (0935-COGA) asserts that Colorado’s existing regulations achieve equivalent or greater emission reductions than the proposed EG’s presumptive standards of performance, noting that many of the presumptive standards are based on Colorado Air Quality Control Commission (AQCC) rules, and that the November 2021 proposal preamble compares the proposed standards to Colorado’s regulations approximately 30 times. The commenter acknowledges that there are minor differences between the provisions of AQCC Regulation 7 and the draft presumptive standards, but states that such differences are allowable and do not prevent approval of a state plan. The commenter cites a decision by the federal D.C. Circuit (*Am. Lung Ass’n v. EPA*, 985 F.3d 914, 942-943; D.C. Circuit 2021) which states:

That the standards must ‘reflect’ the emission guidelines does not mean that they must embody the methods EPA contemplated in identifying the best system; rather, the States have flexibility in determining the specifics of the standards they issue so long as they accomplish the ‘degree of emission limitation’ the EPA calculated based on its ‘best system.’

Commenter (0935-COGA) asserts that Colorado’s Regulation 7 is more stringent than the draft presumptive standards in many respects, and that the Colorado rules achieve sufficient emission reductions to overcome any circumstances where the presumptive standards of performance may be more stringent than Regulation 7. The commenter concludes that Colorado Regulation 7 therefore meets or exceeds, without further rule revisions, the minimum requirements for a state plan establishing standards of performance under CAA section 111(d).

---

<sup>29</sup> 87 FR 74812.

<sup>30</sup> 87 FR 74812.

Response I-19-32: See discussion in section V.B.2 (Leveraging State Programs) of the December 2022 Supplemental Proposal preamble,<sup>31</sup> and section XIII.C.2 (State flexibilities) of the final rule preamble.

Comment: Commenter (0775-CO DPHE) requests that EPA allow states to modify their CAA section 111(d) plans without needing to submit each plan revision to EPA for approval, as is required for SIP revisions. The commenter points out that under 40 CFR 60.23(a)(2), states must submit to EPA their initial CAA section 111(d) plans and any plan revisions necessary to address a final revised guideline issued by EPA, but the regulation is silent as to changes made to a state's CAA section 111(d) plan other than those relating to a revised EG from EPA. The commenter states that Colorado will need flexibility to modify its regulations covered under its CAA section 111(d) plan without waiting on EPA approval, as it must with SIP revisions. At a minimum, the commenter suggests that EPA allow states to modify their CAA section 111(d) plans without further EPA approval where the modifications do not result in less stringent regulatory programs, or where the changes are minor recordkeeping and reporting program adjustments. Alternatively, the commenter suggests that EPA consider an expedited review process for minor program changes that would not delay progress in regulating emissions from this industry.

Response I-19-33: Significant state plan revision includes, but is not limited to, any revision to standards of performance or to measures that provide for the implementation or enforcement of such standards. See the final Adoption and Submittal of State Plans for Designated Facilities: Implementing Regulations Under Clean Air Act Section 111(d) at 88 FR 80480, and its corresponding Summary of Public Comments and Responses on Proposed Rule Adoption and Submittal of State Plans for Designated Facilities: Implementing Regulations Under Clean Air Act Section 111(d) (Subpart Ba) Docket ID No. EPA-HQ-OAR-2021-052.

Comment: Commenter (1267/1268/1269-CA AG et al) encourages EPA to create a technology hub that allows states to review and approve alternative and innovative technologies and methodologies, for states whose programs are deemed equivalent to the requirements of the EG more quickly.

Response I-19-34: See discussion in section V.C. of the December 2022 Supplemental,<sup>32</sup> section XIII of the final rule, and Response I-19-11 earlier in this chapter.

#### ***19.4.4 Compliance Measures in State Plans***

Comment: Commenters (0820-PNR, 0831-AXPC, 0922-NAM) urge EPA to confirm in the final rule that states may include a wide range of compliance measures. Specific examples are provided in the following paragraphs.

Noting that CAA section 111(d)(1) leaves implementation and enforcement of the standards to the states, commenter (0922-NAM) indicates that states can rely on state law in addition to the CAA and can use alternative means to achieve the same level of emissions reduction. The

---

<sup>31</sup> 87 FR 74812.

<sup>32</sup> 87 FR 74830.

commenter points out that CAA section 111(d) incorporates certain elements of CAA section 110; for example, section 111(d) states that the “procedure” under which states submit plans establishing performance standards for existing sources should be “similar to that provided by” section 110. According to the commenter, CAA section 110(a)(2) provides that SIPs should include “other control measures,” including “economic incentives such as fees, marketable permits, and auctions of emissions rights” and allows SIPs to use these types of techniques “to meet the applicable requirements of this chapter,” which include CAA section 111(d). The commenter adds that this includes the ability to interact with other states’ programs and sources to accomplish the reductions described by the performance standards. The commenter states that any final rule should make clear that states should give sources substantial flexibility in establishing compliance measures in their state plans.

Commenter (0922-NAM) indicates that one way to reduce regulatory costs and burdens is for EPA to make it clear that a state can have a plan where there is cost sharing of emissions detection (whether drones, satellite imagery, software, or other sensors usage) by sources. The commenter asserts that any rule should explicitly recognize the states’ responsibility to adopt flexible compliance mechanisms and encourage states to ensure existing sources have the flexibility to adopt other approaches to comply with the final emission guidelines and standards.

Response I-19-35: See discussions on advanced methane detection work practices in sections X.B (Advanced Methane Detection Technology Work Practices) and XI.B (Advanced Methane Detection Technology Work Practices) of the final rule preamble.

Comment: Commenter (1267/1268/1269-CA AG et al) urges EPA to authorize the use of next generation monitoring tools to determine compliance with the requirements of the November 2021 proposal. The commenter notes that there are several innovative compliance approaches that can be used to monitor sources effectively and efficiently for compliance, while balancing the already strained resources of state agencies, and asserts that EPA should consider allowing technologies that provide quantifiable, verifiable, and consistent monitoring and compliance data at a scale that can accommodate large remote regional areas consisting of hundreds or even thousands of facilities. The commenter supports the use of remote sensing technologies at well pads, and notes that innovative remote sensing technologies for monitoring fugitive and large emission events could include aerial, truck-based, satellite, and continuous monitoring. The commenter supports these innovative approaches and points out that states like New Mexico have provided such a mechanism for their use in its proposed regulations. The commenter asserts that alternative monitoring strategies must be effective, enforceable, and equivalent, and will be a critical option for ensuring that emission leaks are identified and repaired as required.

Response I-19-36: See discussions on advanced methane detection work practices in sections X.B (Advanced Methane Detection Technology Work Practices) and XI.B (Advanced Methane Detection Technology Work Practices) of the final rule preamble.

Comment: Commenter (1267/1268/1269-CA AG et al) provides the measures that two states, California, and Pennsylvania, use to enforce their existing regulations for oil and gas facilities:

California's regulations require that operators submit reports annually containing information on LDAR inspections, tank emissions, compressor emission rates, pneumatic device emission rates, liquids unloading vented gas volumes, well casing vent emission rates, and data from underground natural gas storage ambient monitoring. Operators are also required to update their equipment inventories each year if any equipment is added or removed. CARB then uses the reported data to verify compliance, evaluate implementation of the regulation, and estimate emission reductions.

In Pennsylvania, general permits set forth standardized terms and conditions related to best available technology, compliance certification, notification, recordkeeping, reporting, and source testing requirements. While the terms and conditions of the general permits applicable to oil and natural gas operations incorporate both federal and state requirements, it is the duty of the responsible official to ensure that the facility is in compliance with all applicable federal, state, and local laws and regulations. The responsible official must sign and submit a certification of compliance with the annual report. The annual report serves as the basis for the compliance certification. Any records generated as part of the terms and conditions of the general permits are required to be maintained on site or at the nearest local field office for a minimum of 5 years and may be maintained in electronic format. The key records generated and maintained by the owner or operator of a facility authorized under the general permit are those that show the facility is in compliance with the facility-wide emission limits on a 12-month rolling basis. All records, reports, or other information obtained by the Pennsylvania Department of Environmental Protection under the general permit are publicly available unless the owner or operator of the facility shows cause that the information is confidential. Under no circumstance are records of emission data eligible for confidentiality.

Response I-19-37: EPA acknowledges the information provided by the commenter.

#### ***19.4.5 Comments on Emissions Inventories in State Plans***

Comment: Commenters (0424-WVDEP, 0580-KDAQ, 0727-OK DEQ, 0775/0776-CO DPHE, 0824-WDEQ, 0832-NMED, 1267/1268/1269-CA AG et al) agree with the EPA that it is not practical to require states to compile emissions inventories in the same way that is typically expected for other industries under other EG and support superseding the requirements of 40 CFR 60.25a(a) for the purposes of the EG.

Commenter (0424-WVDEP) is concerned with the resources it would take to develop a source-specific or unit-specific inventory of all designated facilities, including emission rate data for the designated pollutants correlated with applicable standards of performance for the oil and gas industry and with the annual progress reports. The commenter notes that in addition to the vast number of sources and the frequent change of configurations and ownership within this industry, the BSER as proposed does not take the form of an emission rate and would complicate the correlated demonstration as required under 40 CFR 60.25a.

Commenter (0824-WDEQ) favors this approach and emphasizes that they believe this is the only viable pathway for state agencies like Wyoming's with limited staff resources for compiling emission inventories. The commenter states that there is no achievable approach for commenter's agency to submit source-specific or unit-specific data for a proposed rulemaking that expands the scope of affected facilities on such a massive scale. The commenter agrees with EPA's approach that "allows States to utilize existing inventories and emissions data" (citing 86 FR 63253) and requests that EPA further clarify this approach.

Commenter (0832-NMED) agrees with the EPA that a highly detailed GHG emissions inventory is not necessary for states to develop standards of performance, and that such standards of performance could be developed using a different type of emissions inventory data. Accordingly, the commenter supports the proposal to allow states flexibility to utilize existing inventories and emissions data to develop their state plans as they pertain to EG OOOOc.

Commenter (1267/1268/1269-CA AG et al) states that EPA should allow states to utilize existing inventories and emissions data, even if that data might not fully align with the designated facilities in the EG and may exclude some facilities that are subject to the EG. The commenter notes that allowing states to leverage existing data would obviate the need to duplicate work developing emissions inventories, if the data submitted by states is rigorous and comprehensive enough to accurately capture emissions from the oil and natural gas industry.

Commenter (0775/0776-CO DPHE) notes that based on 2020 leak inspection reporting, Colorado's best estimate is that there are over 15,000 well production facilities in the state. The commenter believes that there is little benefit, and great burden, to having to specifically identify each such facility, less yet every single natural gas-driven pneumatic controller, in the section 111(d) plan and any revisions. The commenter points out (citing 86 FR 63253) that EPA has solicited comments on the practicability of states compiling an inventory of all designated facilities and may require state emission inventories to determine equivalency, and that EPA appears to also be considering accepting its Greenhouse Gas Reporting Program (GHGRP) as a proxy. The commenter asserts that Colorado already has a robust annual emissions reporting program for upstream and midstream (gathering, boosting, and processing) sources, and should be permitted to rely upon its comprehensive system both for identification of sources and for a demonstration of equivalency.

Response I-19-38: See discussions in section V.B.5 (Emissions Inventories) of the December 2022 Supplemental<sup>33</sup> and section XIII.C.5 (Emissions inventories) of the final preamble.

Comment: Commenter (0727-OK DEQ) recommends that, in superseding the requirements of 40 C.F.R. 60.25a(a), they provide the following suggestions on how EPA should accomplish this goal:

(1) EPA should simplify the requirement to identify designated facilities potentially subject to the EG, taking into consideration the large number of such facilities and

---

<sup>33</sup> 87 FR 74827.

(2) EPA should accept emissions data for these facilities in accordance with the provisions of the Air Emissions Reporting Requirements (AERR), with detailed requirements for designated facilities that are classified as AERR Type A and B sources and the use of alternative methods (e.g., a nonpoint tool) for designated facilities that would be classified as nonpoint sources under the AERR.

Notably, the commenter (0727-OK DEQ et al) states that 40 C.F.R. 60.25a contains outdated language, especially in reference to Appendix D, which predates the AERR and even predates AERR's predecessor, the Consolidated Emissions Reporting Requirements (CERR). Appendix D was last updated in 1975, and it appears the National Emissions Data System (NEDS), as referenced in Appendix D, was last updated in 1980, although it is difficult to find a historical timeline of its use. The CERR was finalized in 2002, and the AERR was finalized in 2008. The commenter notes that inventories have not been collected in the manner 40 C.F.R. 60.25a dictates for quite some time. The commenter suggests that EPA update the rules to reference 40 C.F.R. 51a, i.e., the AERR. Furthermore, the commenter adds that AERR already has emissions thresholds for what should be inventoried as a point source, and what is being captured in the National Emissions Inventory (NEI) as a nonpoint source. The commenter believes the rule should align with the AERR thresholds and requirements.

Response I-19-39: See discussions in section V.B.5 (Emissions Inventories) of the December 2022 Supplemental Proposal<sup>34</sup> and section XIII.C.5 (Emissions inventories) of the final rule preamble.

Comment: While agreeing with the EPA that it is not practical to require states to compile emissions inventories in the same way that is typically expected for other industries under other EG, commenter (0832-NMED) does not agree that the GHGRP data should be used. The commenter notes that the reporting threshold of 25,000 metric tons under the GHGRP would exclude the emissions from thousands of smaller upstream oil and gas facilities, which in the aggregate represent a significant amount of GHG and criteria pollutant emissions. The commenter supports allowing states to use other available existing inventory information, so long as the inventory adequately captures data, or estimates emissions, from all potential designated facilities.

Similarly, commenter (0727-OK DEQ/OSEE) does not support leveraging the GHGRP for purposes of the EG because (1) the GHGRP would not reflect emissions from smaller operators and (2) the GHGRP has default emission factors and default equipment counts built in that do not necessarily reflect actual data on site. The commenter believes that the National Emissions Inventory (NEI) does a better job of quantifying emissions from all sources.

Response I-19-40: See discussions in section V.B.5 (Emissions Inventories) of the December 2022 Supplemental<sup>35</sup> and section XIII.C.5 (Emissions inventories) of the final preamble.

---

<sup>34</sup> 87 FR 74827.

<sup>35</sup> 87 FR 74827.

#### ***19.4.6 Meaningful Engagement***

Comment: Commenters (0391-KBIC, 0605-Muscogee, 0781-NTAA, 0833-UMUTE PD, 0943-SSMTCI) support requiring states to include community engagement as part of the program approval for State Plans for existing sources. Commenters (0391-KBIC, 0781-NTAA, 0833-UMUTE PD, 0943-SSMTCI) add that it is equally, if not more important to include consultation and coordination with neighboring Tribal Governments. The commenters assert that this will be particularly important in the checker boarded areas where jurisdiction between state, tribe, and federal agencies can be convoluted and confusing. The commenters believe that requiring consultation and coordination between all government entities will provide more consistent understanding of the requirements, implementation, and enforcement across jurisdictions.

Response I-19-41: Comment is a supportive comment on an aspect of the November 2021 Proposal that is not being finalized in this action; as such, no response is required. See section XIII.C.6 (Meaningful engagement) discussion of the final rule preamble. See also the requirements for meaningful engagement included in the *Adoption and Submittal of State Plans for Designated Facilities: Implementing Regulations Under Clean Air Act Section 111(d)* at 88 FR 80480, November 17, 2023, and its corresponding Summary of Public Comments and Responses on Proposed Rule Adoption and Submittal of State Plans for Designated Facilities: Implementing Regulations Under Clean Air Act Section 111(d) (Subpart Ba) Docket ID No. EPA-HQ-OAR-2021-052.

Comment: Commenter (0763-TCEQ) states that EPA should clarify its authority to require “meaningful engagement” before requiring such burdensome actions by states.

Commenter (0938-TXOGA) notes that the November 2021 proposal does not identify the legal authority for this requirement beyond high-level statements that such authority is provided by CAA sections 111(d) and 301(a)(1) (citing 86 FR 63145). The commenter has concerns that these provisions do not provide the authority that EPA claims, and states that the proposal lacks sufficient detail to allow for meaningful comment on this issue. The commenter requests that this authority be further substantiated in EPA’s subsequent proposal.

Commenter (0921-USCoC) states that while they support meaningful engagement with members of the public and with members of disadvantaged communities, neither CAA section 111(d) nor section 301 provides a legal basis for EPA’s proposed actions requiring meaningful engagement. According to the commenter, EPA has not adequately explained how the CAA could allow EPA to promulgate environmental justice (EJ) requirements as part of an NSPS or EG, or how EPA could require states to provide EJ regulatory requirements as a part of a state plan. The commenter asserts that the CAA provides no authority for EPA to include EJ requirements in the EG as the model for states, and that EPA can neither compel states to include EJ requirements in state plans nor disapprove a state plan if a state fails to include EJ analysis. The commenter goes on to assert that if a state, based on its own authorities, voluntarily includes EJ requirements as part of its state plan, EPA cannot convert the EJ elements into federally enforceable requirements, and that when issuing a federal implementation plan (FIP) for states that fail to develop appropriate state plans, EPA cannot include EJ requirements, as that would exceed the scope of EPA’s CAA authority.

Commenter (0808-API) states that, while they support EPA's goals for meaningful engagement, the Agency has not provided sufficient detail in the proposal to allow the commenter to comment in a meaningful way. The commenter notes that there is no explanation of the substantive legal underpinnings other than broad statements that the requirements are authorized under CAA sections 111(d) and 301(a)(2), with no explanation of the substantive legal underpinnings of this concept.

Response I-19-42: See section XIII.C.6 (Meaningful engagement) discussion of the final rule preamble. See also the requirements for meaningful engagement included in the *Adoption and Submittal of State Plans for Designated Facilities: Implementing Regulations Under Clean Air Act Section 111(d)* at 88 FR 80480, November 17, 2023, and its corresponding Summary of Public Comments and Responses on Proposed Rule Adoption and Submittal of State Plans for Designated Facilities: Implementing Regulations Under Clean Air Act Section 111(d) (Subpart Ba) Docket ID No. EPA-HQ-OAR-2021-052.

Comment: Commenter (0790-State AGs) states that the November 2021 proposal shows insufficient regard for the states in that the proposal would regulate the way in which the states will solicit comments on potential state plans. The commenter indicates that it is not clear what new requirements for "meaningful engagement" EPA wants to impose beyond public hearings, but this apparent intrusion into the basics of the states' administrative processes would constitute troubling and unfounded federal overreach into state administration.

Response I-19-43: See section XIII.C.6 (Meaningful engagement) discussion of the final rule preamble. See also the requirements for meaningful engagement included in the *Adoption and Submittal of State Plans for Designated Facilities: Implementing Regulations Under Clean Air Act Section 111(d)* at 88 FR 80480, November 17, 2023, and its corresponding Summary of Public Comments and Responses on Proposed Rule Adoption and Submittal of State Plans for Designated Facilities: Implementing Regulations Under Clean Air Act Section 111(d) (Subpart Ba) Docket ID No. EPA-HQ-OAR-2021-052.

Comment: Commenter (0727-OK DEQ/OSEE) supports robust public participation in state rulemaking efforts and states that Oklahoma conducts public participation processes in accordance with the law. The commenter adds that states are already required to take measures to consider EJ in state activities and asserts that an additional EJ requirement within this rulemaking seems unfounded and redundant.

Response I-19-44: See section XIII.C.6 (Meaningful engagement) discussion of the final rule preamble. See also the requirements for meaningful engagement included in the *Adoption and Submittal of State Plans for Designated Facilities: Implementing Regulations Under Clean Air Act Section 111(d)* at 88 FR 80480, November 17, 2023, and its corresponding Summary of Public Comments and Responses on Proposed Rule Adoption and Submittal of State Plans for Designated Facilities: Implementing Regulations Under Clean Air Act Section 111(d) (Subpart Ba) Docket ID No. EPA-HQ-OAR-2021-052.

Comment: Commenters (0828-UCS, 0832-NMED, 0844/0855-EDF) support the community participation requirements described in the proposal. Commenter (0844/0855-EDF) agrees that

“robust and meaningful public involvement in the development of a State plan should go beyond the minimum requirement to hold a public hearing,” but must instead include “ensuring that States share information with and solicit input from stakeholders at critical junctures during plan development, which helps ensure that a plan is adequately addressing the potential impacts to public health and welfare that are the core concern of CAA section 111.”

Commenter (0832-NMED) similarly states that requiring states to share information and solicit input from stakeholders at critical junctures during plan development will ensure communities have abundant opportunities to participate in the plan development process. The commenter states that the proposed reasonable notice requirement, with an additional and separate meaning from “public hearing,” will ensure the public has reasonable notice of relevant information, as well as the opportunity to participate in the state plan development. The commenter believes that requiring states to provide this opportunity to stakeholders directly addresses a major issue of environmental inequity – the ability for stakeholders to participate in the process that determines impacts and risks to their health and environment.

Commenter (0828-UCS) states that the proposal to require state plans be developed with “meaningful engagement” from members of the public, including overburdened and underserved communities, is an important stride in better incorporating EJ concerns into the rulemaking process. The commenter asserts that EPA must ensure that the final rule include strong implementation of this provision.

Response I-19-45: Comment is a supportive comment on an aspect of the November 2021 Proposal that is not being finalized in this action; as such, no response is required. See also the requirements for meaningful engagement included in the *Adoption and Submittal of State Plans for Designated Facilities: Implementing Regulations Under Clean Air Act Section 111(d)* at 88 FR 80480, November 17, 2023, and its corresponding Summary of Public Comments and Responses on Proposed Rule Adoption and Submittal of State Plans for Designated Facilities: Implementing Regulations Under Clean Air Act Section 111(d) (Subpart Ba) Docket ID No. EPA-HQ-OAR-2021-052.

Comment: Commenters (0581-NACAA, 0832-NMED, 1267/1268/1269-CA AG et al) support the EPA’s proposal to require a robust and meaningful public participation process during state plan development but advise EPA to provide flexibility. One of these commenters (1267-CA) adds that because some states have developed more robust environmental justice programs than others—including with respect to public participation—EPA should take existing state practices into account.

Another of the commenters (0832-NMED) wants to ensure that the EPA will allow states the flexibility to craft these plans to the unique economic and demographic features of each state. The commenter recommends that the EPA permit both new and traditional communication technologies to qualify to conduct meaningful public engagement, adding that modern communications technology (such as video conferencing, social media, and smart phone apps) has made it much easier for states to effectively communicate with various communities and stakeholders. The commenter believes that while there may be barriers involving accessibility to these technologies that should be considered, these technologies should still be utilized during

the meaningful engagement process. The commenter states that considering recent events, it is clear that video conferencing can be an effective planning tool that allows for planners and state officials to communicate with community members and other stakeholders, which is why commenter believes these technologies should be utilized as a way to meaningfully engage with communities and stakeholders.

Commenter (0581-NACAA) suggests that where agencies have completed their own analyses and developed tools and programs in consultation with their local communities and advisory groups, EPA should allow these to serve compliance needs, rather than simply mandating national adoption of federal tools. The commenter notes that some NACAA members are at the cutting edge of achieving meaningful involvement of vulnerable communities in agency decision-making, with programs that have far longer track records and that are more robust than anything at the federal level. The commenter suggests that EPA can and should draw from and benefit from their experience. The commenter adds that allowing state and local agencies flexibility will enable meaningful interaction that yields real benefits without being simply a performative checklist. The commenter indicates that state and local programs with deep experience in advancing clean air protection with and for vulnerable communities have learned that these efforts are very time- and resource-intensive, not just for agencies but for the communities themselves. The commenter concludes that given the tremendous variety of communities, their needs, and their constraints, EPA should set expectations realistically and allow for the flexibility to truly meet the unique needs of these communities, as well as to reflect the economics and demographics of individual states.

Response I-19-46: See section XIII.C.6 (Meaningful engagement) discussion of the final rule preamble. See also the requirements for meaningful engagement included in the *Adoption and Submittal of State Plans for Designated Facilities: Implementing Regulations Under Clean Air Act Section 111(d)* at 88 FR 80480, November 17, 2023, and its corresponding Summary of Public Comments and Responses on Proposed Rule Adoption and Submittal of State Plans for Designated Facilities: Implementing Regulations Under Clean Air Act Section 111(d) (Subpart Ba) Docket ID No. EPA-HQ-OAR-2021-052.

Comment: Commenter (0844-EDF) encourages EPA to require that state plans engage the public in a way that is receptive to the needs and characteristics of the affected communities and gives two examples: (1) If a state's oil and gas industry has a significant impact on a community that includes many members who primarily speak a language other than English, the state must account for that fact as it engages that community in the plan development process; and (2) If an affected community includes many individuals who lack access to broadband internet, the state must make a serious effort to conduct outreach through means other than just the internet. The commenter notes that some states already have community outreach and engagement procedures in place and suggests that EPA should survey these existing procedures in leading states and develop a model for others to follow.

Commenter (0733-CVNM) urges that the EPA require the State of New Mexico to comply with the mandates for meaningful engagement in a manner that takes the nature of the state's population into account adequately. The commenter states that presenting notice of opportunities for involvement in the preparation of the New Mexico state plan in written English and Spanish

will not reach some members of communities in northwestern New Mexico, where there is significant oil and gas activity. The commenter notes that in those communities and other Native American communities in New Mexico, many people communicate by means of languages that are not written. The commenter asserts that the EPA therefore should require that the State of New Mexico provide notice of opportunities to be involved in the preparation of the state's plan by other means, such as advertisements on television and radio and announcements in locations that are likely to reach residents such as Chapter Houses, churches, and community centers.

Response I-19-47: See section XIII.C.6 (Meaningful engagement) discussion of the final rule preamble. See also the requirements for meaningful engagement included in the *Adoption and Submittal of State Plans for Designated Facilities: Implementing Regulations Under Clean Air Act Section 111(d)* at 88 FR 80480, November 17, 2023, and its corresponding Summary of Public Comments and Responses on Proposed Rule Adoption and Submittal of State Plans for Designated Facilities: Implementing Regulations Under Clean Air Act Section 111(d) (Subpart Ba) Docket ID No. EPA-HQ-OAR-2021-052.

Comment: Some commenters urge EPA to ensure that communities that benefit from the oil and gas industry are included in “meaningful engagement” outreach.

Commenter (0822-TXAEP) supports “robust and meaningful public engagement” with “underserved or overburdened communities” and notes the production of oil and natural gas allows communities across the U.S. to heat their homes and take advantage of affordable, abundant power for their personal and business aspirations. The commenter states that many rural communities in producing states depend on oil and natural gas production for their livelihoods and would suffer adversely if that production is lost. The commenter adds that beyond the homeowners and farmers that directly rely on gas from wells and/or pipelines, there are many communities that rely exclusively on gas supplied by marginal wells located geographically close to their homes and would not be served if low production wells are shut in.

Commenter (0814-IPAA) states that EPA has appropriately placed much of its concern about EJ on disadvantaged communities; however, it can also be an issue for those that rely on the production of oil and natural gas for their energy or for royalties that sustain their farms or ranches or local communities. The commenter believes that drawing the intricate balances on these issues will be neither straightforward nor without conflict, and that states will need clear and thorough guidance and training to undertake these tasks. The commenter adds that depending on how EPA crafts the requirements, states may need authorizing state legislation to implement them. Commenter indicates that EPA needs to fully set forth all the factors when it proposes its revisions to CAA section 111(d) regulations.

Commenter (0938-TXOGA) suggests that EPA ensure that EJ analyses consider how productive operations benefit EJ communities and how regulations may impact those benefits (e.g., economic impacts, effects on tax base for schools). The commenter states that EPA must recognize that in rural communities, the gas from these wells is important not only for comfort heating and cooking but also for their economic well-being, providing critical sources of income. According to the commenter, these benefits are important to consider in any such analysis.

Commenter (0581-NACAA) states that as EPA brings its own community support resources to bear, it should not be forgotten that some of the most affected communities will be closely tied socially and economically to the oil and gas industry. The commenter believes that resources should be targeted to help mitigate impacts to these affected communities as well. For additional comments related to environmental justice meaningful engagement considerations, see section 3.3 (EJ Outreach and Engagement) of Chapter 3 of this document.

Response I-19-48: See section XIII.C.6 (Meaningful engagement) discussion of the final rule preamble. See also the requirements for meaningful engagement included in the *Adoption and Submittal of State Plans for Designated Facilities: Implementing Regulations Under Clean Air Act Section 111(d)* at 88 FR 80480, November 17, 2023, and its corresponding Summary of Public Comments and Responses on Proposed Rule Adoption and Submittal of State Plans for Designated Facilities: Implementing Regulations Under Clean Air Act Section 111(d) (Subpart Ba) Docket ID No. EPA-HQ-OAR-2021-052.

Comment: Commenter (0844-EDF) asserts that a state should be required to engage all communities that have a stake in its plan development, including those that may live across the border in another state; if a state's economic activity has a detrimental impact on residents in another state, it is only appropriate that the state address that fact as it develops plans to reduce emissions. The commenter notes that the CAA explicitly recognizes this in other context: in developing SIPs under the national ambient air quality standards program—a program that CAA section 111(d) expressly cross-references—states must include provisions that “prohibit ... any source or other emissions activity with the State which will ... contribute significantly to nonattainment in, or interfere with maintenance by, any other State.” The commenter adds that requiring states to conduct appropriately robust outreach to affected communities in other states is a far more modest requirement than this, and EPA should include it in the final EG OOOOc rule.

Commenter (0832-NMED), responding to the request for comments and suggestions on how to coordinate emissions crossing state borders, indicates that states, local governments, community organizations, and other stakeholders may find it helpful to create organized groups that can help address interstate air quality issues. The commenter reports that they participate in the Four Corners Air Quality Group, which could serve as a model for such coordination; New Mexico, along with the Navajo Nation, Colorado, Arizona, and Utah meet regularly to address common air quality issues in the region. The commenter adds that the Four Corners Air Quality Group includes a variety of different stakeholders such as community members and organizations and industry leaders. The commenter states that the goals and functions of any cross-border groups can, and should, be crafted to the unique needs of the area(s) in which they serve, and that these organizations open a dialogue between all stakeholders and consist of government officials and staff members that can directly address any issues of concern.

Response I-19-49: See section XIII.C.6 (Meaningful engagement) discussion of the final rule preamble. See also the requirements for meaningful engagement included in the *Adoption and Submittal of State Plans for Designated Facilities: Implementing Regulations Under Clean Air Act Section 111(d)* at 88 FR 80480, November 17, 2023, and its corresponding Summary of Public Comments and Responses on Proposed Rule Adoption and Submittal of State Plans for

Designated Facilities: Implementing Regulations Under Clean Air Act Section 111(d) (Subpart Ba) Docket ID No. EPA-HQ-OAR-2021-052.

Comment: Several commenters request that EPA provide additional information on what constitutes acceptable “meaningful engagement” in state plans.

Commenter (1267-CA) supports setting forth in the final rule some minimum criteria for the meaningful engagement requirements. The commenter also states that, with respect to some of the meaningful engagement criteria that EPA has identified, it would be helpful if the agency provided some additional information in the final rule. As an example, the commenter suggests that EPA could offer thoughts on how states could go about making public meetings or workshops safe spaces for undocumented members of overburdened or underserved communities; similarly, EPA could specify that information about the rulemaking to be shared at a public meeting or workshop be translated in communities with linguistic barriers by EPA’s duties under Title VI the Civil Rights Act.

Commenter (0456-WDNR) recommends that, given the varying needs of vulnerable communities across the country, EPA should work with states to set clear and reasonable expectations and allow for the flexibility to meet the unique needs of local communities. The commenter believes that air agencies will be more efficient and effective in providing meaningful and timely engagement if EPA gives more input on what constitutes meaningful engagement with the target populations and the specific actions that could be taken during the state plan development process to meet this new requirement. The commenter adds that new funding mechanisms such as federal grants should be made available to assist implementing agencies with the new public engagement requirements.

Commenter (OK DEQ) requests that EPA clarify the term “meaningful engagement” and exactly what is required by states to fulfill this standard. The commenter believes that the breadth of the term “meaningful engagement” is unclear in the proposed rule, and without further definition could create pitfalls for states when carrying out the requirement. The commenter states that clarity is needed on exactly how states should identify these communities and then engage with them, asserting that without further guidance, the granularity of the meaningful engagement requirement is unclear and could possibly lead to absurd interpretations from third parties. While supporting support robust public participation, the commenter states that extent to which states must commit resources to additional public engagement above what is currently required by law is unclear, and states need to know the extent of said requirement to appropriately allocate their very limited resources.

Commenter (0763-TCEQ) states that the EPA should issue timely guidance to states regarding the expected procedures for states to follow in conducting and documenting meaningful engagement as part of state plan development and implementation. Noting that EPA also proposed that states may apply for, and the EPA may approve, alternate meaningful engagement procedures, the commenter also states that EPA should provide guidance on how a request for alternative procedures should be made, how it would be evaluated by the EPA, and the expected timing in the state planning process for states to make and the EPA to act on such requests.

Commenter (0445-IDEM) believes that states would benefit from further guidance on the scope of public participation in areas that EPA defines as overburdened and underserved and that EPA would expect to see in an approvable plan. The commenter notes that as many of the affected sources in Indiana are in rural areas, Indiana is particularly interested in further guidance on what “meaningful outreach and engagement” would mean with respect to rural communities.

Commenter (0445-IDEM) also notes that Indiana is statutorily restricted in its ability to promulgate rules that are more stringent than federal environmental regulations but targeting select communities with additional public involvement could create expectations from the communities that the state would require sources to comply with provisions beyond the scope of the presumptive limits provided in the federal rule. The commenter states that Indiana likely could not comply with the additional process requirements that would be needed to deviate from the presumptive federal standards and meet the federal statutory deadlines for submitting a plan to EPA. The commenter requests that since states have not previously been asked to include these steps in state plans, EPA should provide additional guidance to states on what it expects to see in an approvable plan, while providing the flexibility to tailor outreach efforts to the needs and state statutory requirements of their respective states.

Commenter (0722-MODNR) urges EPA to understand the need for regulatory certainty when it comes to requirements that will affect the approvability of state plans and states that EPA should provide a clear regulatory definition of “underserved and overburdened communities.” Commenter asserts that the regulatory text should also clearly describe what requirements states must follow with regard to engaging with these communities. The commenter believes that it would be inappropriate for EPA to address these issues and expectations solely through preamble text or non-regulatory guidance or memos, and asserts that without regulatory certainty that explains how states identify these communities and precisely what additional requirements states must meet with respect to engaging with them, it will result in inconsistency across the country and could cause other regulatory authority issues for many states. The commenter notes that this is especially true for states, like Missouri, that have statutes to prevent SIPs or state regulations from being more stringent than required by the CAA.

Commenter (0458-MDE) states that community discussion, public meetings, and email notifications of the regulation development process are good tools to implement prior to the formal regulatory adoption process.

Commenter (0938-TXOGA) states that the November 2021 proposal did not detail the standards for meaningful engagement. Commenter is concerned that this requirement could be invoked to disapprove a state plan on a subjective judgment of what engagement is “meaningful.” The commenter believes that this issue is important because states and the public expend significant resources in developing a state plan for submittal, and the consequence of disapproval is that these costly processes would need to be repeated to remedy the deficiency. The commenter asserts that it is important for any standard of “meaningful” engagement to be defined clearly ahead of the rulemaking processes that states will undertake to develop their plans.

Commenter (0581-NACAA) states that should EPA mandate more robust public engagement and make it a federal requirement for plan approval, the agency must be more specific about

what will be approvable and provide guidance to states. The commenter notes that some states have conducted robust analyses and implemented sophisticated programs, but not all agencies have done this work – EPA can help implementing agencies meet clearly articulated federal requirements by providing resources, guidance, trainings, and other support.

Commenter (0808-API) states that, while they support EPA’s goals, the Agency has not provided sufficient detail in the proposal to allow the commenter to comment in a meaningful way. The commenter notes that there is no proposed language to understand the impact of what the Agency intends to do.

Response I-19-50: See section XIII.C.6 (Meaningful engagement) discussion of the final rule preamble. See also the requirements for meaningful engagement included in the *Adoption and Submittal of State Plans for Designated Facilities: Implementing Regulations Under Clean Air Act Section 111(d)* at 88 FR 80480, November 17, 2023, and its corresponding Summary of Public Comments and Responses on Proposed Rule Adoption and Submittal of State Plans for Designated Facilities: Implementing Regulations Under Clean Air Act Section 111(d) (Subpart Ba) Docket ID No. EPA-HQ-OAR-2021-052.

Comment: Commenter (0775/0776-Air Pollution Control Division, Colorado Department of Public Health and Environment (CDPHE)) states that Colorado has taken a great many strides towards pursuing environmental justice and addressing the disproportionate impacts of air pollution on communities. CDPHE recently created an Environmental Justice Unit that seeks to strengthen community engagement by building trust and working to reduce disproportionate harm and increase environmental and health protections. The commenter provides that they have an Environmental Justice Unit that manages the state’s new Environmental Justice Action Task Force<sup>36</sup> and the Environmental Justice Advisory Board<sup>37</sup>. Starting on July 1, 2021, the commenter states that the CDPHE began implementing new legislation that directs a meaningful level of engagement with disproportionately impacted communities<sup>38</sup> when considering new regulations. The commenter states that the CDPHE’s Environmental Justice Unit, in

---

<sup>36</sup> The Environmental Justice Action Task Force (“Task Force”) was created by the Colorado Environmental Justice Act to “recommend and promote strategies for incorporating environmental justice and equity into how state agencies discharge their responsibilities.” Colo. Rev. Stat. § 25-1-133(1)(a). “The mission of the Task Force is to propose recommendations to the General Assembly regarding practical means of addressing environmental justice inequities by: (a) Promoting environmental justice across state agencies and improving collaboration among state agencies in identifying and addressing the human health and environmental effects of programs, policies, practices, and activities on disproportionately impacted communities; (b) Improving cooperation on environmental justice initiatives between the state government, tribal governments, and local governments; (c) Ensuring meaningful involvement and due process in the development, implementation, and enforcement of environmental laws and policies; and (d) Addressing environmental health, pollution, and public health burdens in disproportionately impacted communities and building healthy, sustainable, and resilient communities.” Id. at -133(2).

<sup>37</sup> The Environmental Justice Advisory Board is a volunteer board with 12 members appointed by Colorado’s Governor and Executive Director of CDPHE. Colo. Rev. Stat. § 25-1-134(2). The Board serves Colorado by: Coordinating with the Environmental Justice Ombudsperson; advising CDPHE on best practices for engaging disproportionately impacted communities; responding to environmental justice policy matters referred by the Governor’s Office or CDPHE; and creating and overseeing an environmental justice grants program.

<sup>38</sup> Colo. Rev. Stat. § 24-4-109(2)(b)(II).

implementing the legislation, has found the following engagement practices to be effective at improving a two-way communication pathway with communities:

- Scheduling variable times of day and days of the week for opportunities for public input on the proposed action, including at least one weekend time, one evening time, and one morning time for public input;
- Providing notice at least thirty days before any public input opportunity or before the start of any public comment period;
- Utilizing several different methods of outreach and ways to publicize the proposed action, including disseminating information through schools, clinics, social media, social and activity clubs, local governments, tribal governments, libraries, religious organizations, civic associations, community-based environmental justice organizations, or other local services;
- Providing several methods for the public to give input, such as in-person meetings, virtual and online meetings, online comment portals or e-mail, and call-in meetings;
- Considering use of a variety of locations for public input on the proposed action, including meeting locations in urban centers, in neighborhoods whose populations are predominantly black, indigenous, or people of color and have an average income below the state's average, and in rural locations in various regions of the state; and
- Creating outreach materials concerning the proposed state action in layperson's terms, translated into the top two languages spoken in a community, that inform people of opportunities to provide input on the proposed state action, their rights, the possible outcomes, and upcoming public input process.<sup>39</sup>

Commenter (0775/0776-CDPHE) recognizes the importance of language justice in communicating with communities where English is not the only, or primary, language spoken by residents. For example, the commenter states that they seek to make plain language fact sheets about rulemaking available in both English and Spanish, given demographics and languages spoken in parts of Colorado with significant oil and gas development. As a specific example, the commenter states that, in Weld County, where 86% of Colorado's oil was produced in 2021, 17.5% of the population speaks Spanish at home.<sup>40</sup> The commenter states that CDPHE seeks to provide Spanish interpretation services during public meetings, and allows for Spanish language public comments, which can be translated into English for purposes of comment response.

Commenter (0775/0776-CDPHE) states that, as it pertains to adopting regulations designed to protect residents who live and work near oil and gas operations, CDPHE used a combined approach, incorporating stricter standards for operations in disproportionately impacted communities and, in some cases, where the operations are located within 1,000 feet of an

---

<sup>39</sup> Colo. Rev. Stat. § 24-4-109.

<sup>40</sup> For Weld County percentage of oil production, source is COGCC data page, <https://cogcc.state.co.us/data4.html#/production>, select "Monthly Production by County," production year 2021, export to Xcel; in "Oil produced" category, with data through November 2021, Weld County produced 106,584,883 BBL out of 124,009,383 BBL total, which is 85.949%. For Spanish speaking data, source is U.S. Census Bureau American Community Survey (ACS) 2019 1-Year Subject Estimates, <https://data.census.gov/cedsci/table?q=United%20States&t=Language%20Spoken%20at%20Home&g=0500000US08123> (select "Weld County" for geography" and "Language Spoken at Home"); Weld County population is 301,838, with Spanish spoken at home by 52,842 residents or 17.5%.

occupied area.<sup>41</sup> In disproportionately impacted communities, the commenter notes that Regulation Number 7 now: ensures quicker and more frequent testing of combustion devices; requires more frequent leak inspections and earlier repair of leaking components; ensures quicker, and more, reductions from midstream pigging and blowdown operations; and requires control of more well liquids unloading events. The commenter reports that these rules were designed to reduce emissions in disproportionately impacted communities, and therefore reduce the local health and environmental impacts of oil and gas operations. The commenter states that CDPHE consulted with community members, community organizations, and parties representing the interests of disproportionately impacted communities in the development of these regulations.

Commenter (0775/0776-CDPHE) states that, in addition to the CDPHE actions described above, the commenter notes that during its Mission Change Rulemaking, Colorado Oil and Gas Conservation Commission (COGCC) also adopted both substantive and procedural standards for applications to site new oil and gas facilities within disproportionately impacted communities. COGCC's Mission Change rules define and map disproportionately impacted communities, require that permit applicants provide information about whether the proposed development is located in a disproportionately impacted community, and identify whether there are other existing oil and gas or other industrial impacts nearby. This will allow COGCC to evaluate the potential cumulative impacts of proposed oil and gas development on disproportionately impacted communities over time.

According to the commenter (0775/0776-CDPHE), another key substantive standard for disproportionately impacted communities is the alternative location analysis, Rule 304.b.(2),<sup>42</sup> which requires operators proposing oil and gas development near homes within a disproportionately impacted community to evaluate alternative locations, describe their community engagement work, and identify other existing nearby facilities. The commenter notes that this allows COGCC to evaluate whether there is an alternative location where a facility could be built that would result in fewer impacts, or that would more equitably distribute impacts in an area that is bearing relatively less burden from existing development.

Finally, commenter (0775/0776-CDPHE) states that COGCC also adopted several very important procedural standards for permit applications in disproportionately impacted communities. These procedural standards are designed to ensure that residents of disproportionately impacted communities have a meaningful opportunity to engage in COGCC's administrative process of reviewing and deciding whether to approve or deny an oil and gas development plan. The commenter provides that these standards include longer public comment

---

<sup>41</sup> "Occupied Areas" means (1) a building or structure designed for use as a place of residency by a person, a family, or families. The term includes manufactured, mobile, and modular homes, except to the extent that any such manufactured, mobile, or modular home is intended for temporary occupancy or for business purposes; (2) indoor or outdoor spaces associated with a school that students use commonly as part of their curriculum or extracurricular activities; (3) five thousand (5,000) or more square feet of building floor area in commercial facilities that are operating and normally occupied during working hours; and (4) an outdoor venue or recreation area, such as a playground, permanent sports field, amphitheater, or other similar place of outdoor public assembly." Reg. 7, Part D, Section II.A.16.

<sup>42</sup> 2 Code Colo. Regs. § 404-1:304.b.(2).

periods, longer consultation periods, and several rules requiring information to be made available in languages other than English.

Response I-19-51: See section XIII.C.6 (Meaningful engagement) discussion of the final rule preamble. See also the requirements for meaningful engagement included in the *Adoption and Submittal of State Plans for Designated Facilities: Implementing Regulations Under Clean Air Act Section 111(d)* at 88 FR 80480, November 17, 2023, and its corresponding Summary of Public Comments and Responses on Proposed Rule Adoption and Submittal of State Plans for Designated Facilities: Implementing Regulations Under Clean Air Act Section 111(d) (Subpart Ba) Docket ID No. EPA-HQ-OAR-2021-052.

#### ***19.4.7 Support for States to Develop, Implement and Enforce Rule***

Comment: Commenters (0456-WDNR, 0581-NACAA, 0824-WDEQ, 0832-NMED) state that EPA should provide support to states to identify designated sources and to implement and enforce the rule. Commenter (0456-WDNR) notes that considerable effort will be needed to implement and enforce this rule, especially as it affects sources that have never been subject to permitting under the CAA. The commenter indicates that even to prepare and submit a state plan, a state must first identify existing facilities within its borders that meet the applicability requirements in the final EG. The commenter believes that because the regulation of greenhouse gases under CAA sections 111(b) and 111(d) is a relatively recent development, some facilities, such as those in the natural gas distribution category (North American Industry Classification System code 221210) will be completely unfamiliar with these types of air pollution regulations and their need to comply. The commenter urges EPA to consider funding mechanisms, including federal grants, to support implementation and enforcement of this rule, especially as it affects sources currently not subject to CAA permitting or emissions reporting programs.

Commenter (0824-WDEQ) expresses concern that, if the expectation is for states to develop, implement, and enforce State plans that profoundly expand their air quality division's overall scope of work associated with these requirements, it is imperative that EPA provide states with the necessary financial resources to comply instead of providing states with an unfunded mandate. The commenter (0824-WDEQ) expresses specific concerns regarding the resource burden associated with states having to include appropriate monitoring, reporting, and recordkeeping requirements to ensure that state plans adequately provide for the implementation and enforcement of standards of performance.

Commenter (0832-NMED) states that New Mexico will require considerable staffing and financial resources to implement and enforce the proposed rules and urges EPA to provide sufficient funding to states to ensure effective and consistent implementation and compliance with the requirements of the proposed rules. The commenter urges EPA to provide proportionate funding to those states with significant oil and gas activities and to fund states based on their proportion of the total national oil and gas production. The commenter notes that New Mexico's oil and gas sources contribute more than 53 percent of the state's total GHG emissions profile and rising ozone levels over significantly large and rural geographic land areas means ensuring compliance is resource intensive using traditional staff approaches, and expensive using innovative high-altitude platform stations. To that end, the commenter believes that the EPA

should consider including compliance assurance activities in federal grants, such as in the CAA section 105 grant and the Performance Partnership Grant. Because these rules will bring in thousands of new sources under the agency's regulatory jurisdiction, the commenter states that a concomitant level of resources and financial assistance is critical to ensure the rule's significant and important emission reductions are achieved. The commenter asserts that frontline communities are critically aware that many states already lack sufficient resources to effectively implement and enforce current air regulations, and that without new and sufficient resources to states to guarantee effective implementation and compliance, the emissions reductions and public health benefits contemplated from the proposed rules will not be realized, and the health of frontline communities and the environment will continue to be impacted.

Commenter (0581-NACAA) points out that state and local clean air agencies face a wide variety of circumstances and situations that will affect their ability to implement this rule if it is finalized as proposed. The commenter identifies some of these issues and offers recommendations that would affect successful implementation of the rule. In particular, state and local air agencies have seen flat federal funding support for CAA implementation for nearly two decades, and for some agencies, meeting the additional regulatory requirements proposed will require additional resources. In addition to the commenter reiterating their longstanding call for EPA to meet its obligation to support adequate funding for its state and local co-regulators, the commenter's recommendations include steps EPA can take to streamline regulatory burdens, meet varied state needs with appropriate flexibility, support state and local agency implementation capacity, and acknowledge and avoid constraints.

Response I-19-52: The EPA does intend on working with tribes and states to develop plans tailored to the factors concerning the states. The plan development process, under which performance standards for existing sources are established within their jurisdiction and have the discretion to consider remaining useful life and other factors, is one that Congress established through the text and structure of CAA section 111(d). See discussions in section V.B.2.<sup>43</sup> and section V.B.3.<sup>44</sup> of the December 2022 Supplemental and section XIII of the final preamble and final rule, Adoption and Submittal of State Plans for Designated Facilities: Implementing Regulations Under Clean Air Act Section 111(d) at 88 FR 80480, November 17, 2023, and its corresponding Summary of Public Comments and Responses on Proposed Rule Adoption and Submittal of State Plans for Designated Facilities: Implementing Regulations Under Clean Air Act Section 111(d) (Subpart Ba) Docket ID No. EPA-HQ-OAR-2021-052.

The new standards will work hand-in-hand with new resources and programs in the Inflation Reduction Act, which will incentivize early implementation of innovative methane reduction technologies and support methane mitigation and monitoring activities. These efforts will achieve greater methane emissions reductions more quickly. For more information on the IRA, the Administration has created a guidebook that provides an overview of the clean energy, climate mitigation and resilience, agriculture, and conservation-related tax incentives and investment programs, including who is eligible to apply for funding and for what activities. See <https://www.whitehouse.gov/cleanenergy/inflation-reduction-act-guidebook/>

<sup>44</sup> 87 FR 74816.

## 19.5 Review of Section 111(d) State Plans

Comment: Commenter (0844/0845-EDF) states that the proposal appropriately adheres to the CAA section 111(d) implementing regulations' criteria for completeness, technical and administrative matters, and emission inventories. The commenter believes these requirements are critical for ensuring that state plans will in practice achieve the emission reductions required under the guidelines, and no reasons exist to deviate from them here.

Response I-19-53: Comment is a supportive comment on an aspect of the November 2021 Proposal that has remained unchanged in the final rule; as such, no response is required.

Comment: Commenter (0844/0845-EDF) states that EPA has appropriately proposed to grant streamlined approval for state plans that adhere to EG OOOOc's presumptive standards (analogous to a model rule). According to the commenter, plans that do not deviate in any material way from EPA's guidelines are the likeliest to achieve the anticipated level of emission reductions, and a streamlined approval process will ensure that those reductions happen at the earliest possible time. While supporting rigorous review of state plans, the commenter believes that those that directly adhere to EG OOOOc's presumptive standards should not be subject to an unnecessary degree of administrative review when critical emission reductions are needed as soon as possible.

Response I-19-54: Comment is a supportive comment on an aspect of the November 2021 Proposal that has remained unchanged in the final rule; as such, no response is required. See section XIII.E.3 (Compliance timelines) of the final rule preamble for a discussion on the EPA's final compliance timelines. Other timelines can be found in the *Adoption and Submittal of State Plans for Designated Facilities: Implementing Regulations Under Clean Air Act Section 111(d)* at 88 FR 80480, November 17, 2023, and additional discussion in the corresponding Summary of Public Comments and Responses on Proposed Rule Adoption and Submittal of State Plans for Designated Facilities: Implementing Regulations Under Clean Air Act Section 111(d) (Subpart Ba) Docket ID No. EPA-HQ-OAR-2021-052.

## 19.6 Proposed Timelines

### 19.6.1 Timeline for Development of State Plans

Comment: Commenter (0424-WVDEP) notes that Footnote 339 of the November 2021 proposal preamble mentions that "(t)he EPA intends to address the timing aspect of this provision in the near future" (citing 86 FR 63252). The commenter opines that this is an example of the piecemeal approach to this proposed rulemaking and asks how commenters are to provide meaningful comments when the EPA does not propose a comprehensive rulemaking.

Response I-19-55: See section XIII.E.3 (Compliance timelines) of the final rule preamble for a discussion on the EPA's final compliance timelines. Other timelines can be found in the *Adoption and Submittal of State Plans for Designated Facilities: Implementing Regulations Under Clean Air Act Section 111(d)* at 88 FR 80480, November 17, 2023, and additional discussion in the corresponding Summary of Public Comments and Responses on Proposed Rule

Adoption and Submittal of State Plans for Designated Facilities: Implementing Regulations Under Clean Air Act Section 111(d) (Subpart Ba) Docket ID No. EPA-HQ-OAR-2021-052.

Comment: Commenter (0763-TCEQ) urges the EPA to take expeditious action to address the timing provisions for state plan submission and propose a timeline for public comment. Commenter (0727-OK DEQ/OSEE) similarly states that the implementing regulations in 40 CFR part 60, subpart Ba need to be addressed now so states know what timing is going to be expected for the state plan submittal and have an opportunity to make meaningful comments.

Response I-19-56: See section XIII.E.3 (Compliance timelines) of the final rule preamble for a discussion on the EPA's final compliance timelines. Other timelines can be found in the *Adoption and Submittal of State Plans for Designated Facilities: Implementing Regulations Under Clean Air Act Section 111(d)* at 88 FR 80480, November 17, 2023, and additional discussion in the corresponding Summary of Public Comments and Responses on Proposed Rule Adoption and Submittal of State Plans for Designated Facilities: Implementing Regulations Under Clean Air Act Section 111(d) (Subpart Ba) Docket ID No. EPA-HQ-OAR-2021-052.

Comment: Commenter (0797-NDDEQ/IC) notes that EPA did not propose a timeframe for states to develop state plans but interprets the Regulatory Impact Analysis (RIA) to say that the process will take 3 years. The commenter agrees that the process will take substantial time, but states that in the absence of proposed regulatory text, they do not understand how, and cannot realistically comment on how, EPA reached this conclusion.

Commenter (0797-NDDEQ/IC) indicates that North Dakota consists of several federally recognized Indian Nations including the Mandan, Hidatsa, and Arikara Nation which has substantial oil and gas development within its borders. While the commenter does not have CAA delegation for those areas, they expect to have consultations with affected tribal authorities during the development of the state plan, and these discussions will impose additional time constraints upon North Dakota that must be considered in any proposed or final rule.

Commenter (0790-State AGs) states that the November 2021 proposal imposes an unrealistic timeframe for the states to design state plans. The commenter cites comments by the West Virginia Department of Environmental Protection (WVDEP) indicating that the sheer number of new regulated entities— and the quantity of data that these new regulations will require—would make it extraordinarily challenging for states to develop a plan in just 3 years. The commenter fears that EPA intends to use this artificial time press to open the door for more aggressive and direct regulation by the agency through promulgation of a federal plan. The commenter opines that the CAA does not anticipate this kind of significant, rushed reordering of the states' environmental regulatory structures.

Some commenters believe that EPA should allow more than 3 years for states to submit a state plan. Commenter (0763-TCEQ) believes that at a minimum, states should have 3 years for the development and submittal of a state plan, as is given under the statutory and regulatory framework a SIP. The commenter notes that in the preamble to the proposed rule, the EPA proposed completeness and approval/disapproval determinations would be based on CAA section 110. With the additional requirements proposed by the EPA for meaningful public

engagement, commenter states that more than 3 years is expected to be necessary for state plan development. The commenter adds that provisions to provide additional time upon request should also be available for states that have large numbers of applicable sources that require evaluation.

Commenter (0424-WVDEP) states that they would generally agree that 3 years is an appropriate time frame to develop a state plan for submittal to EPA based on the EG (as opposed to the nine-month time frame allowed under 40 CFR part 60, subpart B) to allow sufficient time for legislative rulemaking prior to state plan development; however, given the vast number of potential affected sources and limited state resources, commenter urges EPA to consider a longer time frame to develop an Oil and Natural Gas State Plan. The commenter cites concerns include a potential conflict with the state code regarding standards for fuels used in dwellings and the anticipated difficulty getting the political support needed to promulgate legislative rules implementing the proposed EG.

Commenter (0424-WVDEP) states that although states may have an estimate of the number of oil and natural gas wells within the state, not every well will meet the definition of an affected source. The commenter notes that considerable time is required to collect the data and evaluate almost 65,000 wells to determine whether they should be included in the state plan inventory, and that in addition to the 65,000 well sites, natural gas gathering and boosting compressor stations, processing sites, and transmission and storage sites will also require evaluation.

Commenter (0424-WVDEP) points out that the definition of an affected source [or designated facility] for storage vessels is based on a numeric emissions rate for the tank battery, therefore emissions data must be collected for each potential source prior to the evaluation to determine whether it meets the definition of an affected facility. The commenter states that at well sites, fugitive emissions above zero will meet the definition of a designated facility; however as proposed, facility designations vary based on the amount of fugitive emissions. The commenter asserts that it is not practical for the state to obtain component counts (valves, connectors, flanges, and open-ended lines) needed for fugitive emission calculations for the purposes of specifying how much each existing wellsite would be characterized in terms of fugitive emissions in advance of the state plan development. Additionally, the commenter expects the EPA to provide the emission factors and calculation methodology in the yet to be proposed regulatory text.

Commenter (0424-WVDEP) adds that the proposal to define any well liquids unloading event as a modification presents timing concerns: (1) The emissions inventory development for a state plan would be a moving target as liquid unloading events occur as part of normal well site operations, and (2) An existing and previously unregulated well that has a liquid unloading event would also require immediate compliance with the NSPS, without consideration of the time involved to design and install control equipment. For additional comments on liquids unloading operations and regulatory requirement applicability (e.g., what constitutes a modification triggering applicability of rule requirements) and EPA's response to those comments, see section 12.1 (Applicability) of Chapter 12 (Well Liquids Unloading Operations) of this document.

Finally, commenter (0424-WVDEP) notes that, in addition to the timing concerns related to the vastness of the proposal and evaluation of over 65,000 wells in the state, the proposed rule requires more involved community outreach throughout the process that will take considerable time given the 53 of the 55 counties in West Virginia have oil and natural gas activities.

Response I-19-57: See section XIII.E.3 (Compliance timelines) of the final rule preamble for a discussion on the EPA's final compliance timelines. Other timelines can be found in the *Adoption and Submittal of State Plans for Designated Facilities: Implementing Regulations Under Clean Air Act Section 111(d)* at 88 FR 80480, November 17, 2023, and additional discussion in the corresponding Summary of Public Comments and Responses on Proposed Rule Adoption and Submittal of State Plans for Designated Facilities: Implementing Regulations Under Clean Air Act Section 111(d) (Subpart Ba) Docket ID No. EPA-HQ-OAR-2021-052.

With respect to comments citing liquids unloading provisions as an example, see discussions in section IV.F.3. Gas Well Liquids Unloading Operations of the December 2022 Supplemental<sup>45</sup> and sections X.F.3 and XI.F.3 in the final preamble.

Comment: Commenter (0831-AXPC) appreciates that EPA is committed to proposing the timeline for submittal of state plans in its forthcoming supplemental proposal and soliciting comment on this forthcoming proposed timeline. The commenter believes that it is vital for states to be given an appropriate amount of time to develop and submit their plans, although the commenter notes that they cannot take a definitive position as to how much time is required for state plan formulation and submittal until the supplemental proposal is published, to include proposed regulatory text for new EG OOOOc. However, the commenter states that the default period of 9 months, as provided for in the 1975 general implementing regulations for CAA section 111(d), is facially inappropriate here. The commenter notes that the state plan process for the existing-source rule will contain more sources than any such previous rule—potentially several orders of magnitude more—and existing facilities in this sector are likely more subject to site-specific variations than any category of existing sources that EPA has previously regulated under CAA section 111(d). The commenter asserts that an appropriate timeline here would certainly be measured in years, not months.

Commenter (0580-KDAQ) notes that EPA did not propose a specific timeline for requiring the submission of state plans in November 2021 proposal and concurs that additional time for comment is needed once EPA determines the deadline for submitting state plans under a supplemental proposal. The commenter states that additional time beyond 9 months after the final EG rule is published, as currently required by 40 CFR 60.23(a), is needed due to the extensive number of sources potentially subject to the proposed rule, the time necessary to complete state rulemaking processes, and the need for collaboration with agencies that regulate oil and gas entities in Kentucky.

Commenter (1267-CA) suggests that EPA use a framework in the current rulemaking that is similar to the long-extant timing provisions in its implementing regulations, which provided 9 months for states to submit plans and 4 months for EPA review. To account for states with a large number of designated facilities, the commenter proposes a slightly longer period for state

---

<sup>45</sup> 87 FR 74781.

plan submission of 12 months after EPA’s promulgation of the final EG (with the ability to seek additional time depending on a state’s specific statutory requirements for creation and adoption of state plans); EPA’s review would then have to be completed within 4 months of a state plan submission, and federal plans would be due within 6 months of the state’s failure to submit a satisfactory plan. The commenter believes that with the design of the Proposed Rule—including its use of work practices and presumptive emission limits—states should be able to meet a 12-month submittal deadline. The commenter states that this time frame for state plan submission and for EPA review (and imposition, as necessary, of a federal plan) is also appropriate given EPA’s statement that “strong, rapid, and sustained methane reductions are critical to reducing near-term disruption of the climate system” (citing 86 FR 63113).

Commenter (0775-CO DPHE) states that given the complexity and far-ranging nature of EPA’s proposal and considering that EPA has not yet made specific regulatory language available for review, Colorado will need time to review EPA’s final action and compare those provisions to Colorado’s own comprehensive regulatory regime for the oil and gas industry. The commenter supports giving states at least 12 months to conduct this analysis, particularly recognizing Colorado’s procedural and stakeholder engagement requirements for rulemakings, should one become necessary for Colorado to undertake.

Commenter (1294-OOCA) asserts that time is of the essence, and a 2-year deadline for the development of state plans should be more than sufficient given that implementation will take even more time. The commenter believes that a longer time period will lead to dawdling on the part of resistant states - meanwhile the climate crisis will continue to worsen.

Commenter (0941-350SV) notes that the November 2021 proposal suggested that it might take up to 3 years for states to begin implementing their EG plans for existing facilities. The commenter notes that states have known since President Biden’s Executive Order in early 2021 that they would be required to change their oil and gas industry regulations to reduce methane emissions. The commenter recommends that the deadline for EG state plans to become operational be mid-2024 (based on the commenter’s expectation that the final rule would be adopted by mid-2022). The commenter adds that more difficult parts of the plan might be delayed until 2025, but it is important to get started on implementing better performance standards as soon as possible. The commenter suggests that the EPA consider offering grants and technical assistance for developing state plans if a state agrees to implement its plan by mid-2024. Commenter (0832-NMED) notes that in New Mexico there are thousands of large and small designated facilities that would need to provide data required in 40 CFR 60.25a for the state plan. The commenter states that many owners and operators have operations in both New Mexico and other states and will be required to provide data for all their designated facilities at the same time that they are required to provide data to the State of New Mexico, which may lead to a bottleneck in states’ plan development. The commenter urges the EPA to allow states sufficient time to collect the required data for plan development and for the states to develop their plans accordingly.

Commenter (0832-NMED) also urges the EPA to allow states sufficient time to conduct thorough outreach to stakeholders, noting that states must implement a robust outreach program, which is essential to any rulemaking procedure. The commenter believes that it is crucial to

inform, and allow all public and private entities, especially those disadvantaged communities directly affected by the oil and gas sector, to be made aware of the proposed rulemaking and to provide input during the rulemaking process. In a recent rulemaking, commenter provided an initial informal comment period and an extended formal comment period to allow all interested parties the opportunity to comment on the proposed rule. The commenter requests that the EPA provide ample time to ensure a thorough and robust outreach program, which will allow for informed engagement during the rulemaking process and the potential to reduce contention during the rulemaking hearing.

Response I-19-58: See section XIII.E.3 (Compliance timelines) of the final rule preamble for a discussion on the EPA's final compliance timelines. Other timelines can be found in the *Adoption and Submittal of State Plans for Designated Facilities: Implementing Regulations Under Clean Air Act Section 111(d)* at 88 FR 80480, November 17, 2023, and additional discussion in the corresponding Summary of Public Comments and Responses on Proposed Rule Adoption and Submittal of State Plans for Designated Facilities: Implementing Regulations Under Clean Air Act Section 111(d) (Subpart Ba) Docket ID No. EPA-HQ-OAR-2021-052.

#### 19.6.2 Compliance Timeline for Designated Facilities

Comment: Commenter (0844-EDF) strongly supports the proposed requirement that state plans include a compliance timeline within no more than 2 years of plan submission and urge the agency to consider whether a more abbreviated compliance timeline is warranted. The commenter notes that as proposed, EPA does not project emission reductions from the emission guidelines until 2026, but to align with the scientific imperatives and the U.S. climate commitments, it is critical these reductions occur as swiftly as feasible. Commenter states that owners and operators of existing sources are now aware that they will be required to comply with EPA standards in the coming years and will have more than 3 years to begin preparing for compliance. The commenter believes that with so much lead time, and with many of the standards (like fugitive monitoring) requiring very little time to achieve compliance in any event, a phase-in approach beyond the maximum 2-year compliance timeline EPA has proposed would be inappropriate, whereas a shorter timeframe may well be justified.

Commenter (1267-CA) states that EPA should require in its final rule that the compliance deadline for presumptive standards based on leak detection and repair be no longer than 1 year. The commenter asserts that compliance with these standards likely will not require the installation of any pollution control equipment, and LDAR using OGI is a well-established practice in the industry. Commenter notes that when EPA finalized the 2016 NSPS OOOOa standards, it required oil and natural gas sources to complete their initial leak detection surveys within 1 year.

Some commenters (0424-WVDEP, 0463-Southern Ute Tribal Council, 0573-KDHE, 0740-Utah Petroleum Association, 0782-BHE, 0790-State AGs, 0814-IPAA, 0832-NMED, 0842-WDEQ) state that the compliance timeline for designated facilities should be longer than 2 years. Commenter (0922-NAM) indicates that the compliance timeline should be at least 2 years.

Commenter (0573-KDHE) suggests that the time allowed for affected facilities to be in full compliance with the State Plan based on the proposed EGs (two years from State Plan development) is not realistic and should be extended. The commenter notes that each newly designated facility would be required to apply for and obtain an air quality permit. They added that this would "overwhelm" existing staff is a gross understatement. For sources to be in full compliance within two years, the commenter notes that the state would have to issue the air quality permits in advance of the compliance date for the sources to have regulatory requirements with which to demonstrate compliance. The newly affected designated facilities will not be subject to the federal EGs directly; therefore, the enforceable mechanism would be a new state rule and subsequent air quality permit. The commenter explains that, to issue all newly required permitting actions within the first year after State Plan submittal would require a huge amount of new permit engineers to be hired by the commenter. They add that the time to hire, train, purchase computers and other equipment for this many new employees is completely unreasonable. The commenter states that they would support an option for the EGs to require different compliance times and phase-in approaches for different designated facilities for the reasons provided above.

Commenter (0740-Utah Petroleum Association) recommends that states be encouraged to allow as much time as possible for facilities to come into compliance with regulations adopted in-state to address EG OOOOc. Otherwise, acute regional shortages may occur. EPA is soliciting comment on whether a 2-year compliance time is sufficient for complying with state plans submitted under the EGs or if it should be longer or shorter. Due to the uncertainties imposed by the supply chain shortage as well as the labor shortage, the commenter recommends that EPA allow up to three years for implementation for both existing new facilities under OOOOb and for existing facilities under the EGs, especially considering the many thousands of facilities nationwide that will be competing to obtain the same types of equipment. Furthermore, EPA should allow case-by-case extensions of the compliance dates. No one can foresee the compounding effects on supply chains and skilled labor of the vast number of facilities attempting to comply with the same rules at the same time. Case-by-case extensions to the compliance date may be the only feasible alternative for many facilities.

Commenter (0814-IPAA) states that EPA refers to the 24-month timeline for compliance with approved state regulations under EPA approved plans. Another timeline within the vacated regulations provides for states to have three years to develop their plans. EPA should retain a timeline of at least this length in its proposed Section 111(d) regulations. Regulatory development is already complicated and EPA indicates that it intends to create new mandates on the state planning process addressing EJ and community involvement actions that it wants addressed by states. The commenter suggests that there are real consequences that result from EPA's timeline choices. The commenter goes on to explain these consequences by using examples from comments made by the West Virginia DEP which generally focus on the costs that are associated with the given timeline.

Commenter (0790-State AGs) states that the November 2021 proposal imposes an unrealistic timeframe for regulated entities to implement the state plans. The commenter indicates that the 2-year proposed timeframe for implementation of this vast permitting process would compel even smaller states like West Virginia to hire thousands of new permitting engineers to finish the

job in time (citing the WVDEP comments). The commenter opines that the CAA does not anticipate this kind of significant, rushed reordering of the states' environmental regulatory structures.

Commenter (0424-WVDEP) states that the time allowed for affected sources to be in full compliance with the state plan based on the proposed EG (2 years from state plan development) is not realistic and should be extended given that each newly designated facility would be required to apply for and obtain an air quality permit, which would greatly overwhelm existing staff. The commenter indicates that for sources to be in full compliance within 2 years, the state would have to issue the air quality permits in advance of the compliance date for the sources to have regulatory requirements with which to demonstrate compliance because the newly affected designated facilities will not be subject to the federal EG directly; therefore, the enforceable mechanism would be a new state rule and subsequent air quality permit. The commenter estimates that to issue all newly required permitting actions within the first year after state plan submittal would require approximately 2,600 new permit engineers, and notes that the time to hire, train, purchase computers and other equipment for this many new employees is considerable. The commenter adds that if permitting actions spanned a 10-year period, it would still require hiring approximately 260 new permit engineers in the first year.

Commenter (0424-WVDEP) notes that assuming that an existing facility is not currently controlled, the facility would have to design, purchase, receive, install, and train operators for the controls as appropriate. Given the anticipated number of newly designated facilities, the commenter believes that there is a distinct possibility of supply chain issues, which will require longer lead times for design services or equipment. The commenter lists the following controls that may have to be added at facilities:

- Storage vessels - 95% control device
- Pneumatic controllers at wells sites and gathering and boosting stations - replace with zero emission rate controllers
- Pneumatic controllers at processing plants - instrument air system
- Centrifugal compressors - route to control to 95%
- Pneumatic pumps at processing plants - zero emissions from diaphragm and piston pumps
- Pneumatic pumps at well sites - route to control
- Associated gas from oil wells must be routed or used onsite

For the reasons provided in the comments above, the commenter (0424-WVDEP) supports an option for the EG to require different compliance times and phase-in approaches for different designated facilities.

Commenter (0842-WDEQ) disagrees with EPA's assessment that "two years is an appropriate amount of time for designated facilities to ensure compliance based on the EPA's general understanding of the industry and the proposed presumptive standards" (citing 86 FR 63256). The commenter states that without knowing the length of time that states must develop plans, a two-year compliance timeline places significant hardship on designated facilities that must scramble to meet the requirements. The commenter believes this timeline also significantly

shortchanges the amount of time necessary for state agencies to ready their respective programs (including the time and expense associated with the hiring and training of the necessary additional staff) to effectively implement the compliance schedule.

Commenter (0832-NMED) states that a 2-year compliance schedule may prove to be difficult for the designated facilities to meet. The commenter understands the urgency for designated facilities to be brought into compliance as soon as possible but given the many thousands of existing designated facilities, providing an attainable compliance deadline that sets realistic deadlines is paramount to achieving meaningful emissions reductions.

Commenter (0782-BHE) states that any compliance schedule must take into account the different milestones within the process, i.e., release of the final EG, development of state plans, EPA review of approval of the plans, state agency development of implementing regulations that supplement the state plan, and the compliance schedules therein. The commenter asserts that a compressed schedule will not allow operators adequate time to comply with state regulations and suggests that EPA should recommend a phased implementation approach that allows at least 3 years for existing source compliance.

Commenter (0782-BHE) recommends that the EG and implementation schedules consider factors that affect implementation schedules: affected operators need time to plan, develop, and implement the required programs and strategies; hire and train personnel; enter contracts with third-party service providers to conduct monitoring; and procure additional monitoring equipment. The commenter points out that the existing source regulations will affect thousands of newly affected sources, with a multitude of new requirements and affected equipment at each source, adding that build out of these systems will be time intensive.

Commenter (0463-Southern Ute Tribal Council) supports the goals of EPA's proposed rule but urges EPA to establish a realistic timeframe for compliance and implementation. Regulations should not be so rigorous that the incremental benefit of the regulations does not justify the costs and burdens of compliance (for industry) and administration (for the regulator). While not opposed to the establishment of emission guidelines to limit GHGs and VOCs from existing sources, applying such guidelines to existing sources is an especially significant change. The burden on regulators to modify permits and conduct inspections will be great. The new guidelines will disproportionately impact tribal regulatory agencies because many states have already implemented rules similar to the proposed rule. To ensure that the new rule is not unreasonably burdensome for regulators and industry, the commenter suggests a phased approach to implementation with a timeframe of five to ten years.

Response I-19-59: See section XIII.E.3 (Compliance timelines) of the final rule preamble for a discussion on the EPA's final compliance timelines.

Comment: Commenter (0727-OK DEQ/OSEE) comments on the compliance timeline for existing well sites. The commenter states that it appears that every existing well site could need a site-specific OGI survey to confirm actual baseline methane emissions, with the baseline estimate based on major equipment counts and the process described in the GHGRP. The commenter believes that EPA's expectation that this will be accomplished within 3 years to be

problematic. The commenter recommends that EPA consider phasing in this requirement over 5-7 years based on the age of the well.

Commenter (0727-OK DEQ/OSEE) suggests that rather than requiring every well site to undergo a one-time OGI survey, EPA could consider setting a reasonable default emissions estimation approach for existing wells based on site complexity, while allowing companies to adopt more sophisticated approaches as an alternative. The commenter indicates that along with this default approach, the rule could require statistically representative spot checks to confirm the status of a subset of wells subject to the EG. The commenter believes that if properly configured, an on-going requirement for statistically representative spot checks (with OGI surveys of those facilities) could have a higher probability of detecting large emissions while reducing costs for the well operators. The commenter states that these alternatives are especially important considering the number of existing facilities that could be subject to the EG, as there are over 200,000 existing active wells in the State of Oklahoma alone. The commenter asserts that it is unreasonable to expect this number of surveys to be done in the time frame proposed.

Response I-19-60: See section XIII.E.3 (Compliance timelines) of the final rule preamble for a discussion on the EPA's final compliance timelines.

Comment: Commenter (0425-Darrah) states that small business owners such the commenter often work on thin margins and must roll up their sleeves to keep up with additional regulations as they do not have excess capacity to throw at them. Thus, the commenter requests that small producers with higher well counts but lower hydrocarbon volumes be allowed extra time for implementation. Similarly, another commenter (0800-State of Utah) states that small businesses that own and operate the many low-producing wells within the Utah will need support and time to understand requirements, acquire and install new equipment, and make necessary procedural changes. Commenter (0800-State of Utah) encourages EPA to allow a longer implementation time for such low producing wells.

Response I-19-61: See section XIII.E.3 (Compliance timelines) of the final rule preamble for a discussion on the EPA's final compliance timelines.

Comment: Commenter (0782-BHE) supports compliance schedules that phase in requirements and affected sources within the large number of newly affected existing transmission and storage facilities.

Response I-19-62: See section XIII.E.3 (Compliance timelines) of the final rule preamble for a discussion on the EPA's final compliance timelines.

Comment: Commenter (0782-BHE) proposes including a phase-in period for LDAR for existing sources to ensure resources are available to conduct quarterly LDAR surveys. The commenter states that survey contractors may not be available to address the demand, especially if the proposed Appendix K methodology for OGI surveys is not significantly streamlined. Commenter recommends a multi-year phase-in period for operators to build out quarterly LDAR programs to minimize logistical issues. The commenter believes that resource availability, such as the availability of certified OGI technicians, could be significantly compromised if Appendix K is

adopted as proposed, and that even if EPA incorporates the changes to Appendix K recommended by the commenter, a multi-year phase-in period is needed to ensure that adequate time is allowed for commercial resources to meet demand.

Response I-19-63: See section XIII.E.3 (Compliance timelines) of the final rule preamble for a discussion on the EPA's final compliance timelines.

Comment: Commenter (0739-COGC) requests that the EPA consider a 2-year phase-in approach for all existing sources as noted in the "Possible Phase-In Approach for Existing Sources" section of the November 2021 proposal because availability of equipment and subsequent inventory/supply levels are at historic lows because of unprecedented COVID-19 supply chain impacts. The commenter notes the following specific impacted designated facilities:

- Adding a new methane threshold for existing tank batteries that exceed 20 tons or more per year methane to reduce emissions by 95 percent under the proposed EG would result in a significant increase in demand for new storage vessels, capture, and control equipment, as well as associated closed tank venting and control systems.
- Proposed "Zero Bleed Rate" and other pneumatic controller revisions for existing sources will result in a significant increased demand for zero bleed equipment. Reliability and availability of alternate zero bleed options (i.e., solar powered/battery backup systems, and electric, self-contained systems) are a major concern for safe and reliable operations.
- Proposed "Zero natural gas emission rate" for pneumatic pumps and inclusion of previously exempt piston pumps for new and existing sources will result in a significant increased demand for zero emission pumps. Reliability and availability of alternate zero emission options (i.e., solar powered/battery backup systems, and electric, self-contained systems) are a major concern for safe and reliable operations.

Response I-19-64: See section XIII.E.3 (Compliance timelines) of the final rule preamble for a discussion on the EPA's final compliance timelines.

Comment: Commenter (0782-BHE) states that allowing for phasing in of compliance of the EG provisions to allow case-specific review analogous to "alternative RACT" provision in ozone SIPs and consideration of case-specific economic and technological feasibility is important. The commenter recommends that the EG include a model rule or example regulatory text for the states to consider that clearly indicates case-specific applicability review and alternative RACT are allowed for existing sources. The commenter believes that it is impossible to consider the array of existing configurations that can impact emissions mitigation feasibility when developing the EG, and that prescriptive requirements could be environmentally detrimental and cost prohibitive in some cases. The commenter notes that longstanding precedent for addressing such situations is inherent in current state programs, such as alternative RACT analysis/feasibility assessment for VOC RACT or NOx RACT under ozone SIPs, and suggests an analogous process could be accessible to operators for methane regulations adopted following the EG. The commenter adds that such review can affect the permitting and compliance schedules for such sources, and schedules need to include adequate time for such actions

Response I-19-65: See section XIII.E.3 (Compliance timelines) of the final rule preamble for a discussion on the EPA's final compliance timelines.

## **19.7 Development of a Section 111(d) Federal Plan**

Comment: Commenter (0456-WDNR) states that, given the unique challenges states will face developing and implementing this proposed rule, EPA should ensure a federal plan is developed promptly according to procedural requirements outlined in 40 CFR 60.27a(c).

Response I-19-66: Comment is a supportive comment on an aspect of the November 2021 Proposal that has remained unchanged in the final rule; as such, no response is required. The EPA refers the commenter to the final EPA timelines can be found in the *Adoption and Submittal of State Plans for Designated Facilities: Implementing Regulations Under Clean Air Act Section 111(d)* at 88 FR 80480, November 17, 2023.<sup>46</sup>

## **19.8 Tribes and the Planning Process Under CAA Section 111(d)**

Comment: Several commenters (0391-KBIC, 0605-Muscogee, 0781-NTAA, 0833-UMUTEPD) note that EPA typically delays promulgating a Federal Plan until after a state fails to submit a plan, which has the potential of delaying implementation for a significant amount of time. The commenters note that only a few tribes will have the capacity to develop a tribal plan to address existing sources, so EPA will be responsible for developing a FP in much of Indian country. The commenters state that tribal communities will see more expeditious emissions reductions if EPA aggressively promulgates a FP for Indian country. The commenters indicate that a FP can expedite tribal program implementation because the FP can be delegated to interested tribes or the tribes can develop a tribal plan that, once approved, can replace the federal plan. The commenters also believe that EPA should use all available resources to help tribes address emissions from existing oil and natural gas sources in Indian country as soon as possible.

Commenter (0740-UTPA) similarly states that EPA must not delay finalizing its proposed rulemaking for controls on tribal lands, adding that any rulemaking that EPA might undertake on behalf of the Ute Tribe should be expeditious, unlike the FIP, which EPA proposed 2 years ago and, as of this writing, has not yet been sent to the White House Office of Management and Budget for final inter-agency review prior to promulgation.

Response I-19-67: The final EPA timelines can be found in the *Adoption and Submittal of State Plans for Designated Facilities: Implementing Regulations Under Clean Air Act Section 111(d)* at 88 FR 80480, November 17, 2023.<sup>47</sup>

---

<sup>46</sup> <https://www.federalregister.gov/documents/2023/11/17/2023-25269/adoption-and-submittal-of-state-plans-for-designated-facilities-implementing-regulations-under-clean>.

<sup>47</sup> <https://www.federalregister.gov/documents/2023/11/17/2023-25269/adoption-and-submittal-of-state-plans-for-designated-facilities-implementing-regulations-under-clean>.

The EPA remains committed to working with tribes and strives to maintain consistency in its collaboration with tribes to ensure that implementation of the EG will be uniform.

Please see the final rule titled, Federal Implementation Plan for Managing Emissions From Oil and Natural Gas Sources on Indian Country Lands Within the Uintah and Ouray Indian Reservation in Utah at 87 FR 75334.<sup>48</sup>

Comment: Commenter (0740-UTPA) asserts that EPA must have sufficient consultation with the Ute Tribe to ensure that it fully supports Tribal preferences for EG OOOOc implementation on Tribal lands, noting that many of the commenter's organization's member companies operate on Tribal lands in the Uinta Basin of Utah. The commenter encourages EPA to proactively discuss the EPA rulemaking with the Ute Tribe, to fully understand the Tribe's preference for implementation, and to support the Tribal efforts while also acknowledging issues associated with a level playing field between Tribal and non-tribal lands. The commenter suggests that any rulemaking by EPA must also involve appropriate Tribal consultation to the satisfaction of the Tribe.

Response I-19-68: On November 16, 2021, EPA sent a letter to all 575 Federally Recognized Tribes inviting Tribes to participate in Tribal Consultation on the November 15, 2021 proposed rule, "Standards of Performance for New, Reconstructed, and Modified Sources and Emissions Guidelines for Existing Sources: Oil and Natural Gas Sector Climate Review." Three tribes requested consultation. The following consultations were held: Tribal Consultation with MHA Nation (The Mandan, Hidatsa and Arikara Nation- Three Affiliate Tribes) on January 24, 2022; Tribal Consultation with the Northern Arapaho Tribe on January 24, 2022; Tribal Consultation with the Eastern Shoshone Tribe on January 25, 2022.<sup>49</sup> On November 14, 2022, EPA sent an additional letter to all 575 Federally Recognized Tribes inviting Tribes to participate in a follow up Tribal Consultation on the 2022 Supplemental proposed rule. The following consultations were held: Tribal Consultation with MHA Nation (The Mandan, Hidatsa and Arikara Nation- Three Affiliate Tribes) on February 7, 2023 and an informational meeting was held with the Ute Tribe on February 24, 2023.

Comment: Commenter (0463-S UTE) notes that the proposed changes to this NSPS are extensive and will require substantial financial resources if promulgated. The commenter notes that Tribes such as the commenter's, with delegations of CAA programs such as the Title V Operating Permit Program, rely on federal funding to support these programs. The commenter states that federal funding to support these programs has been inconsistent and sometimes non-existent at best. Given that tribes will face substantial financial and resource burdens if this regulation is changed as proposed, the commenter asks how the EPA proposes to ensure that tribes with these CAA delegations will receive adequate funding to support the regulation development, permitting, compliance and enforcement work that will come with this revised regulation. This is an area of significant concern to the commenter because EPA's plan in this regard will directly impact the ability of the commenter's Tribe to effectively administer this

---

<sup>48</sup> [https://www.epa.gov/system/files/documents/2022-12/EPA-R08-OAR-2015-0709-0160\\_content.pdf](https://www.epa.gov/system/files/documents/2022-12/EPA-R08-OAR-2015-0709-0160_content.pdf).

<sup>49</sup> See Document I.D. EPA-HQ-OAR-2021-0317-1510.

program. The commenter looks forward to the opportunity to discuss this comment in more detail with EPA Region 8.

Similarly, commenter (0800-State of Utah) states that the new requirements of the EG will require a large investment of Utah's state resources to achieve; yet without full and equitable effort by EPA to meet a similar timeframe, the state's efforts alone cannot be effective for all the communities in the Uinta Basin. The commenter states that they would like the opportunity to work closely with Region 8 and the Ute Tribe to address future regulatory actions and planning such that the State of Utah presents a consistent and equitable regulatory environment for oil and gas sources operating within the Uinta Basin.

Commenter (1301-NATBC) similarly states that EPA should assist tribes to attain compliance with the November 2021 proposal where applicable and to develop Tribal Plans because this complex new regulation imposes considerable new requirements on resource extraction and transmission operations. Where those mandates fall on tribes or tribal partners, the commenter believes that EPA should provide funding and technical support to facilitate performance in conformity with the new proposed standards.

Commenter (1301-NATBC) states that EPA should enhance technical assistance and gap funding so that tribes have access to the necessary expertise and resources to develop Tribal Plans in adherence to the governing regulations. The commenter notes that the EG establishes requirements that tribes must follow in developing Tribal Plans and establishing, implementing, and enforcing performance standards, and also mandates that tribal standards must be at least as stringent as the EG's presumptive standards. The commenter states that such a comprehensive regulatory structure should be accompanied by commensurate EPA logistical and financial support for tribes that take on development of their own standards in adherence to the EG.

Response I-19-69: See response I-19-52 earlier in this Chapter.

Comment: Commenter (1301-NATBC) expresses concern that tribal participation in implementation of the rule relies heavily on the Treatment in a Similar Manner as States (TAS) process, which has historically been very slow, subject to litigation, and resource intensive. The commenter proposes that EPA detail the anticipated TAS process and provide robust grant funding for tribes to complete and implement the program.

Commenter (1301-NATBC) is glad to see the November 2021 proposal includes an option for tribes to exercise their inherent sovereignty by achieving TAS and developing and implementing TIPs, as provided under the CAA section 111(d). The commenter states that EPA should offer an expedited TAS and TIP development and approval process and expanded grant funding for this purpose to maximize limited tribal resources and staff capacity. The commenter notes that their experience demonstrates that the TAS process can take years and impose significant expenses and risks for tribes, including protracted litigation. The commenter indicates that the TAS and TIP should rely as much as possible on already-approved programs, to avoid redundant process.

Commenter (0794-MHAN) believes that in developing its proposed oil and gas industry methane regulations, EPA should consider mechanisms to allow greater tribal deference when developing

plans and implementing standards. The commenter supports the ability of tribes to enforce CAA programs within the exterior boundaries of the reservation but believes the process for obtaining TAS status or otherwise enforcing CAA programs should operate in support of tribes exercising sovereign authority rather than as a barrier to it. The commenter asserts that the process for obtaining TAS status for implementing CAA programs, and the NSPS in particular, has proved especially challenging for tribes, noting that as of November 2021, only two tribes had achieved TAS status to implement the NSPS. The commenter states that while the EPA maintains that tribes can develop their own plans under the November 2021 proposal, most tribes must rely on a federal plan because of EPA's restrictions on tribes' ability to obtain TAS status.

Commenter (0794-MHAN) asserts that tribes have inherent sovereign authority to regulate conduct within the boundaries of the reservation that threatens the health and welfare of tribal members (citing *Montana v. United States*, 450 U.S. 544, 565-66 (1981)). The commenter states that in promulgating the Tribal Authority Rule implementing CAA section 301(d), even though the EPA interpreted the CAA as providing tribes an express delegation of authority to regulate air resources, it still found that tribes generally "have inherent authority over air pollution sources" even on fee lands within the boundaries of the reservation (citing 63 FR 7257, February 12, 1998). While the commenter's tribe intends to pursue TAS status to implement methane regulations that effectively balance adequate environmental protections with continued oil and gas development, commenter firmly believes the CAA TAS process should operate in support of tribes exercising inherent sovereign authority to regulate air quality rather than as an obstacle to it. Moreover, the commenter opines, EPA should show greater deference to tribes in implementing clean air regulations.

Response I-19-70: Several federal environmental laws authorize EPA to treat eligible federally recognized Indian tribes as a state (TAS) for the purpose of implementing and managing certain environmental programs and functions, and for grant funding. A tribe with TAS may then oversee the specific regulatory programs for which they have TAS which are developed and adopted by the tribe for submission to, and approval by, EPA that involve an exercise of regulatory authority by the applicant tribe. This also allows the tribe the flexibility to prepare and submit a Tribal Implementation Plan (TIP). In the interim, EPA may issue a Federal Plan and at a later date the tribe could implement the rule by a future tribal plan.<sup>50</sup>

Comment: Commenter (1301-NATBC) states that the November 2021 proposal is not clear whether a single federal plan would apply to all Indian reservations without Tribal Plans or whether individual federal plans will be developed for each such Indian reservation. The commenter notes that during Northern Arapaho's January 24, 2022, consultation with EPA regarding the proposed rule, EPA representatives indicated that EPA had not yet determined how the federal plan structure for Indian reservations would work.

Commenter (1301-NATBC) advises EPA to develop individual federal plans for Indian reservations without Tribal Plans because the circumstances and remaining useful life of existing sources differ on each reservation. The commenter adds that those plans should be developed in consultation with the affected tribes. The commenter also asks that, when known, EPA provide further information on whether such plans would be reservation-specific or apply to Indian

---

<sup>50</sup> <https://www.epa.gov/tribal-air/tribal-authority-rule-tar-under-clean-air-act>.

country generally, how the federal plans would be developed, whether and how such plans will differ from the standards of general application under the proposal, and the anticipated timelines for development and implementation of the plans.

Response I-19-71: The federal plan rulemaking will go through its own separate rulemaking process with opportunity for public comment and public hearing.

## Chapter 20. Emissions and Regulatory Impacts

### 20.1 Impacts of GHGs, VOC and SO<sub>2</sub> Emissions on Public Health and Welfare

#### 20.1.1 Climate Change Impacts

Comment: Several commenters (0196-Meyaard-Schaap, 0216-Montana HPHC, 0276- Greater Boston Physicians for SR, 0317-Several Organizations, 0340-Mothers and Others, 0357-NPCA, 0364-WellHead, 0401-Mercury Investments, 0414-Waterspirit, 0426-League of Women Voters, 0434-Pax World, 0435-Wespath, 0437-NY State Comptroller, 0441-Hukee, 0443-SGI, 0449-Public Employees, 0455-Radio Drama, 0458-MDE, 0460-Trinity Health, 0538-PBC, 0557-Reform Judaism, 0578-Grand Canyon Trust, 0581-NACAA, 0594-Huntsman, 0721- Moms Clean Air Force, 0769-CARB, 0794-MHA Nation, 0795-Allergy and Asthma Network, 0796-Asthma and Allergy Foundation, 0812-Ohio Farmers Union, 0917-Our Children's Trust, 0918-CO CCA, 0937- FB POWER, 0947-Several Conservation/Advocacy Groups, 0958-Climate Code Blue, 1160-United Methodist Women-SW Conference, 1267-CA AG et al, 1271-LM AME Church (Cleveland), 1282-Earthworks, 1294-OCCA, 1301-NATBC, 1302-Wyoming Outdoor Council, 1377- Lander Climate Action Network, 1389-VERIS Wealth Partners) express concern about global warming and the contribution of methane emissions from oil and gas operations contributing to climate change. In general, these commenters provide support for methane regulations that can achieve greenhouse gas (GHG) emissions reductions to mitigate the worst impacts of climate change which they report disproportionately affect low-wealth communities and communities of color. Some of these comments are provided below. Commenter (0449-Public Employees) states that, each year, the U.S. oil and natural gas industry emits 13 million metric tons of methane, a potent GHG.<sup>1</sup> EPA's Proposed Standards aim to curb these emissions – and, by extension, climate change. Examples of some of the comments provided are presented in the following paragraphs.

Commenter (0557-Reform Judaism) states that reducing gas venting and leaks by enacting strong methane pollution standards for both large and small producers will significantly reduce methane pollution, protect frontline communities, and help address climate change.

Commenter (0918-CO CCA) expresses, that, in Colorado, climate changes are already evident. The commenter provides that the Marshall Fire in Boulder County, which occurred in late December and outside of typical fire season, was among the most damaging in the state's history, destroying nearly 1,100 homes valued at over a half billion dollars and forcing tens of thousands of residents to evacuate.<sup>2</sup> The commenter notes that local meteorologists and climate experts say drought, heavy winds, and recent warm weather created the atmosphere for the

---

<sup>2</sup> Karin Brulliard, Can They Go Home Again? Wash. Post (Jan. 25, 2022), [https://www.washingtonpost.com/nation/interactive/2022/marshall-fire-colorado-rebuilding/?itid=hp-top-tablemain; Colorado Wildfire: What We Know, N.Y. Times \(Dec. 31, 2021, Updated Jan. 11, 2022\) https://www.nytimes.com/2021/12/31/us/colorado-wildfires.html](https://www.washingtonpost.com/nation/interactive/2022/marshall-fire-colorado-rebuilding/?itid=hp-top-tablemain; Colorado Wildfire: What We Know, N.Y. Times (Dec. 31, 2021, Updated Jan. 11, 2022) https://www.nytimes.com/2021/12/31/us/colorado-wildfires.html).

wildfire to flourish.<sup>3</sup> And Colorado, as with much of the West, is experiencing these types of destructive fires in increasing numbers in recent years. The commenter provides several pages on the impacts and increases in adverse climate change disruptions and problems in Colorado and nationally (e.g., increases in heat waves, droughts, water supply issues, wildfires, smoke-related particulate matter (PM), ozone and GHG pollution impacts, fire aftermath related erosion/other issues, flooding). The commenter emphasizes the potential for future adverse climate scenarios for Colorado, including the Denver metro area, Front Range cities and mountain communities.

Commenter (1282-Earthworks) contends that, to head off climate catastrophe, fossil fuel production and consumption must decline steeply and rapidly. They state that fossil fuels pose risks at almost all stages: from the moment oil and gas are pulled from the ground to final consumption, these fuels threaten our health, environment, and climate. The commenter states that, while methane emissions reductions under the Clean Air Act (CAA) are an important tool for harm reduction, the only real solution to the climate crisis is to halt fossil fuel extraction and begin a just transition by providing energy workers with family-sustaining jobs in the renewable sector.

The commenter (1282-Earthworks) suggests that the President has the authority to declare a national climate emergency, which would grant him special powers. President Biden could use it to reinstate the crude oil export ban and make it easier for federal agencies to deny permits for new infrastructure intended to facilitate oil and gas exports, including export terminals and new pipelines. They add that the White House could also direct the Department of Interior to end permitting of oil and gas extraction on public lands managed by the federal government. They argue that merely reducing methane emissions from the oil and gas industry will not make drilling and fracking safe, or natural gas “clean.” They add that rules to cut methane emissions are an important first step on the road to what is truly needed to stave off climate catastrophe. planet.

Commenter (0917-Our Children’s Trust) states that, in order for the U.S. to be in line with a < 350 ppm trajectory by 2100 [to mitigate climate impacts], there is a limited amount of natural gas that can be produced in the next 30 years to meet energy demand as fossil fuels are scaled back. The commenter suggests that, to ensure that the necessary emission reductions are achieved in the most effective and cost-effective manner and in the appropriate timeframe, EPA must plan to reduce both methane leakage and overall oil and gas production. The commenter suggests that strong rules to eliminate venting and flaring, to close loopholes allowing wells to forgo regular inspection, and to effectively plug and close operations are a start, but such regulations will simply be used to continue activities that they state scientists deem to be inconsistent with restoring Earth’s energy balance. Indeed, the commenter adds that the oil and gas industry often points to their efforts to contain methane leakage as a justification for ongoing operations, which does not account for the ongoing production of a dangerous product. As control devices are known to fail, the commenter requests that companies be held accountable for GHG emissions that result from their activities, including from abandoned unplugged wells. The commenter also states that the EPA must also develop a plan to end these operations and wind down oil and natural gas production. During this phase out period, the commenter

---

<sup>3</sup> High winds, severe drought, and warm temps led to Colorado's historic wildfire, NPR (Dec. 31, 2021) <https://www.npr.org/2021/12/31/1069416715/colorado-marshall-fire-caused-by-high-winds-drought>.

recommends that only companies with a successful track record for achieving maximum emission reductions be permitted to continue operating to meet the amount of oil and gas that is needed to be produced to meet our energy demands in a way that is consistent with achieving the <350 ppm target.

Commenter (0216-Montana HPHC) asserts that wildfires demonstrate all too well how climate change is a threat multiplier, amplifying other processes that already exist. The commenter states that, in the case of wildfires increased temperatures from climate change result in drier soils, increased evapotranspiration from plants and trees, and less winterkill of pests that also can spread across a broader range, thereby worsening the conditions created by ill-advised forest management decisions of the past hundred years. The commenter notes, as health care providers, all that results in them having to warn patients who they care for about the potential for wildfire smoke to worsen lung diseases like asthma, cause heart attacks and strokes, and even affect fetuses still in their mothers' wombs or cause preterm labor. The commenter adds that they also warn parents not to allow their children to play and exercise outside for large parts of the summer and to seek safe havens from the smoke; safe havens that don't exist for many.

The commenter (0216-Montana HPHC) adds that the effects are more far reaching than just the smoke and ash. As reported by Bloomberg News today, a recent example comes from British Columbia, devastated by wildfires this summer, then again by torrential downpours in recent weeks, along with the northwest U.S. While not everyone lost homes to the fires or floods, the commenter states that tens of thousands were affected. The forest fires killed trees, which loosened soil, which led to mudslides in the torrential downpours; downpours predicted by climate models. The mudslides shut down critical rail lines from the Port of Vancouver, a major shipping center from Asian markets, where large portions of Christmas-bound consumer goods are manufactured. Flooding and fire have also presented barriers to Christmas-tree exports, for which Canada is the world's largest exporter, the US being its largest customer.

Commenter (0937-FB Power) contends that the EPA has the authority, and oil and gas companies have the tools and technology, to cut methane pollution 65% below 2012 levels by 2025.

Commenter (0594-Huntsman) states that the impacts from GHG emissions "are changing the climate at a pace and in a way that threatens human health, society, and the natural environment," and "emissions from human sources have already more than doubled." Methane is a critical GHG which the Intergovernmental Panel on Climate Change (IPCC) has characterized as a short-lived climate forcer (SLCF). As the 2021 November proposed rule explains, "[o]ne ton of methane in the atmosphere has 80 times the warming impacts of a ton of carbon dioxide [CO<sub>2</sub>] and contributes to the creation of ground-level ozone." Reducing methane emissions has been identified as "one of the best opportunities for reducing near term warming" with "the potential to limit temperature rise." According to the commenter, the need is immediate, particularly when one considers that the 2020 concentration of methane "was almost 13 ppb over 2019, the largest annual increase in methane concentrations of the period since the early 1990s."

Commenter (0812-Ohio Farmers Union) states that agriculture, food, and related industries contributed more than \$1.1 trillion to the U.S. economy annually in 2019 and provided 19.7

million full- and part time jobs in 2020. However, the commenter adds that the future of their industry is at stake if they do not take bold and commonsense action to cut climate change. The commenter notes that sustained, severe drought in the West is already threatening the water supplies they depend upon for their crops and livestock. In 2021, the commenter reports that the Colorado River had the first-ever water shortage leading to supply cuts for western farmers. In the Midwest and East, strange and severe weather events have flooded farmland. The commenter adds that drought and flooding have already cost the agricultural industry billions of dollars and put into question the future livelihood of farmers and ranchers everywhere. They further add that increased temperatures and changing climates will also lead to an increased range of pests, more disease and lower crop and livestock yields.

Commenter (0578-Grand Canyon Trust) reports that the Colorado Plateau is home to over 50,000 active oil and gas wells, and over 8,000 abandoned/orphan oil and gas wells. Collectively, the commenter states that these wells generate nearly a fifth of Colorado Plateau counties' GHG emissions. The commenter adds that the Four Corners region sits beneath a methane cloud, of which 66-75% comes from natural gas and coal bed methane operations in the San Juan Basin, and another 5% from oil and gas to the south in New Mexico.<sup>4</sup>

Commenter (0357-NPCA) states that the leaking, venting and flaring of methane from oil and gas production contributes to climate change, harming people, wildlife and our lands and waters, including the places and resources that make up the 423 units of our national park system. Methane and other air pollution (like volatile organic compounds, or VOCs) from oil and gas operations contributes to ground-level ozone in places like Carlsbad Caverns and Joshua Tree national parks. These pollutants combine to produce smog marring scenic views and can lead to asthma attacks and other respiratory ailments. High levels of ground-level ozone can also harm plants and trees, like the quaking aspen in Rocky Mountain National Park. According to the commenter, in the over 100 years since the creation of the National Parks Conservation Association (NPCA), parks and their dependent communities have never faced a threat on the scope or scale of the unfolding impacts of the climate crisis. The commenter contends that, from historic structures lost to fire, coastal communities and ecosystems destroyed by sea level rise and hurricanes and species pushed to extinction from loss of habitat, the cultural and natural landscapes we work to protect have never known change at the current pace and scale. The commenter concludes that addressing the host of harmful pollution from the oil and gas sector is critical for national parks and the values they represent.

Similarly, commenter (0441-PLS) suggests that with the growth in remote work and skyrocketing demand for outdoor access, healthy public lands are bringing both visitors and business investment to rural communities across the country. But this important economic driver is threatened when methane from oil and gas development is not properly managed. For this reason, our businesses support a strong EPA Methane Rule that protects our nation's environment and supports outdoor recreation on shared public lands. The commenter adds that we also need a strong methane rule to reduce air and climate pollution to give rural communities

---

<sup>4</sup> National Oceanic and Atmospheric Administration (NOAA) Research. NOAA Research News. US methane "hotspot" is snapshot of local pollution. November 24, 2020. Available at: <https://research.noaa.gov/article/ArtMID/587/ArticleID/2691/US-methane-%E2%80%9Chotspot%E2%80%9D-issnapshot-of-local-pollution>.

a future and ensure that all Americans will continue to enjoy hiking, biking, swimming, climbing, skiing, and rafting on our federal and native lands.

Commenter (0364-WellHead Systems) states that methane emissions by itself is 90 times more potent than CO<sub>2</sub> which is thought to be the leading cause of climate change.

Commenter (0437-NY State Comptroller) states that climate change poses significant risks and opportunities. To address these risks and opportunities, the commenter notes that it has adopted a Climate Action Plan involving company and investment manager assessments and engagements, a dedicated sustainable investment program, and support for climate risk mitigation policies.<sup>5</sup> The commenter notes that sound methane regulation at the national level is essential to mitigating the worst effects of climate change. Given methane's global warming potential (80 times that of CO<sub>2</sub> over a 20- year period) and the significant percentage of anthropogenic methane emissions emitted by the oil and gas industry (30 percent), the commenter asserts that the EPA proposal to regulate this industry's emissions is a crucial step in avoiding the worst impacts of climate change and can contribute significantly to the reduction of near-term warming.<sup>6</sup> The commenter adds that Federal regulation of methane will also benefit investors by providing certainty to companies and lowering the overall GHG intensity of oil and gas produced in the U.S. This will make U.S. oil and gas products more attractive to a global marketplace that increasingly requires reductions in GHG intensity. Clear and consistent methane regulations can achieve GHG emissions reductions while simultaneously helping American industries become cleaner and more competitive.

Commenter (0557-Reform Judaism) expresses that methane's impact is twenty-five times greater than CO<sub>2</sub> over a 100-year period. Methane accounts for 10 percent of U.S. GHG emissions, with about one-third of those emissions coming from the oil and gas industry.

Commenters (0406-Boone, 0538-PBC) At least a quarter of today's global warming is caused by methane emissions from human sources. Commenters (0455-Radio Drama, 0460-Trinity Health, 0538-PBC) note that methane is a short-term climate forcer, 86 times more potent than CO<sub>2</sub> over a 20-year period. Commenter (0406-Boone) states that activities relating to the oil and gas industry release approximately 16 million metric tons of methane into the atmosphere annually. The commenter notes that reducing methane pollution from the oil and gas industry is the fastest, most cost-effective way to slow reduce GHG emissions – and comes with broad support from the industry, the banking community, the environmental community, and members of the sportsmen and women's community.

Commenters (0401-Mercury Investment, 0434-Impax Asset, 0435-Wespath, 0443-SGI, 0460-Trinity Health, 0538-PBC, 1388-Private Citizen, 0795-ALA et al) reference the recent IPCC report that identifies methane pollution as one of the key drivers of climate change and underscores the urgent need for protective action to reduce methane emissions and limit global warming.

---

<sup>5</sup> <https://www.osc.state.ny.us/files/reports/special-topics/pdf/climate-action-plan-2019.pdf>

<sup>6</sup> Overview of Greenhouse Gases, United States Environmental Protection Agency, available at: <https://www.epa.gov/ghgemissions/overview-greenhouse-gases#methane>

Commenters (0399-Garden Club of America) assert that methane's contribution to climate change was underestimated until recently, in part given its much smaller concentration in the atmosphere relative to CO<sub>2</sub>. But because methane has a radiative forcing factor 80 times that of CO<sub>2</sub> in the short term (20 years), it has a powerful impact. The commenters state that scientists estimate that 25% to 30% of the warming occurring today is caused by methane emissions, second only to CO<sub>2</sub>. The commenters add that concentrations of methane reached 1879 parts per billion in 2020, which is more than two and a half times the pre-industrial concentration of 722 parts per billion.

Commenters (0399-Garden Club of America) report that methane also contributes to climate change by causing atmospheric chemical reactions, producing tropospheric ozone and stratospheric water vapor. According to the commenters, it is estimated that about half of ozone increases since the pre-industrial era have been created by these methane atmospheric interactions.

Commenter (0391-KBIC) supports the White House Office of Domestic Climate Policy's Methane Emissions Reduction Action Plan, including the significant role of EPA in that Plan. The commenter agrees that significantly reducing methane in the oil and natural gas industry will generate significant climate benefits as well as direct health benefits to communities harmed by local and regional emissions. The commenter adds that they support efforts from the EPA and other federal agencies to reduce emissions from the entire oil and natural gas industry, including extraction and production, processing, transmission, and distribution.

Commenter (0398-House of Representatives) expresses that there is no time to waste in curbing methane pollution and tackling the climate crisis. The commenter asserts that our children's health, the safety of those living in oil and gas communities, and the future of the planet all hang in the balance. We must tackle this growing crisis head on before it is too late.

Commenter (0186-Snoqualmie Tribe) states that they are already negatively affected by climate change and are doing what they can to plan for and adapt to the changes that are coming. (<https://iopscience.iop.org/article/10.1088/1748-9326/abf393/meta>). The commenter supports reducing pollution through rulemaking as proposed. The commenter emphasizes that there is an overarching and overpowering need to begin to diminish our collective pollution of our planet, including humans' industrial contributions to climate change, which the proposed performance standards would support.

Commenter (1388-W.L.) contends that climate change is the biggest threat that humankind has ever faced. The commenter notes that climate changes will especially negatively impact the very young, and the yet to be born, who will follow us, and will inherit a diminished and hostile world that we have passed on to them. The commenter emphasizes that it is essential that we stop discharging methane, CO<sub>2</sub>, and other GHGs as soon as possible. The commenter recommends that rule be improved to further limit GHG emissions than the rule currently requires and prohibiting all GHG emissions within 3 years. Although they acknowledge this would be difficult, they contend it is necessary.

Commenter (0351-Columbia) reports that the most recent IPCC report states that reducing methane emissions is a major opportunity to slow climate change quickly. The commenter states that cutting methane emissions is a major opportunity to slow the rate of global warming in the coming decades. The commenter suggests that reducing methane and co-pollutant emissions from oil and gas wells could immediately improve public health and environmental justice concerns nearby and slow long-term climate change that threatens our species.

Response I-20-1: EPA agrees with commenters that methane is a powerful greenhouse gas. Methane is 28 times as potent as CO<sub>2</sub> over a 100-year time frame, and historical emissions of methane have contributed about a third of today's warming. Methane also contributes to increases in global tropospheric ozone levels, which damages human health and ecosystems. This action will contribute to reductions in methane emissions.

Comment: Commenter (0597-IN OGA) notes that, according to a White Paper published by two atmospheric physicists W. A. van Wijngaarden of York University, Canada, and W. Happer of the Princeton University Department of Physics, "methane contributes only about 30/300 or 1/10 of the already small warming from CO<sub>2</sub>". The commenter states that the White Paper provides calculations demonstrating the small impact of methane emissions on the environment as a basis that methane emissions should not be regulated due to potential global warming potential. The commenter asserts that, while many comments have been submitted to EPA that recite the same talking points about methane's global warming potential, Wijngaarden and Happer provide the calculations to demonstrate the small impact that methane has on the atmosphere.

Response I-20-2: Methane is a powerful greenhouse gas. Methane is 28 times as potent as CO<sub>2</sub> over a 100-year time frame, and historical emissions of methane have contributed about a third of today's warming. Methane also contributes to increases in global tropospheric ozone levels, which damages human health and ecosystems. This action will contribute to reductions in methane emissions. See Response I-20-8 for a more detailed response to the cited White Paper.

### ***20.1.2 Adverse Health Impacts***

Comment: Several commenters (0195-EEN, 0196-Meyaard-Schaap, 0199-ALA et al) 0215-EEN, 0276-Greater Boston Physicians for SR, 0340-Mothers and Others, 0351-Columbia, 0370-NM State Rep, 0385-Silent Spring, 0414-Waterspirit, 0440-Missionary Sisters, 0444-DCS, 0458-MDE, 0559-Texas State Senator, 0578-Grand Canyon Trust, 0581-NACAA, 0721-Moms Clean Air Force, 0733- Conservation Voters of NM, 0734-ATS, 0753-IGSD et al, 0794-MHA Nation, 0795-Allergy and Asthma Network, 0796-Asthma and Allergy Foundation, 0844-EDF et al, 0949- Liveable Arlington, 1267-CA AG et al, 1294-Occa, 1301-NATBC, 1302-Wyoming Outdoor Council) express concern regarding, and/or provide studies and references supporting, the adverse health impacts associated with exposure to emissions from oil and natural gas operations. Examples of some of the comments provided are presented in the following paragraphs.

Commenter (1267-CA AG et al) states that robust enforcement of the final rule will be critical to achieving the rule's significant emission reductions of methane, VOC, and hazardous air

pollutants. The State Attorneys' General who signed the comment are interested in using their enforcement authority in collaboration with EPA and the Department of Justice to see those pollution reductions are realized.

Commenter (1301-NATBC) contends that the proposed rule has implications for the health of the Northern Arapaho people. Northern Arapaho Tribal members who reside on the Wind River Reservation live near oil and gas operations, which can degrade air quality, threaten water quality, and contaminate soil among other environmental harms. The commenter notes that they know firsthand how the burdens of resource extraction fall disproportionately on tribal peoples, while the lion's share of profits from those activities have not remained in our community to benefit our people.

Commenter (0844-EDF et al) references a longstanding body of scientific research, including numerous EPA assessments, that demonstrate that exposure to ground-level ozone harms human health. These effects range from decreases in lung function among healthy adults to increases in

respiratory-related hospital admissions and emergency room visits, to premature death.<sup>7,8,,9,10,11,12,13,14,15,16,17,18,19,20,21,22,23,24,25,26</sup>

The commenter also provides that EPA has also cataloged the harmful effects of benzene and other specific air toxics emitted from oil and gas operations, including toluene, carbonyl sulfide, ethylbenzene, mixed xylenes, n-hexane, and other air toxics.<sup>27</sup> The commenter adds that there are several studies that suggest that the proximity to oil and gas development is associated with adverse health outcomes. They note that there are over 120 million people living in ozone non-

attainment areas in the U.S. according to EPA calculations<sup>28</sup> and nationwide, it is estimated that almost 18 million people live within 1 mile of at least one active oil and/or gas site.<sup>29</sup> The commenter adds that new studies document associations between such proximity to nonconventional oil and gas development and negative human health effects generally and provides several example studies (see pages 33 to 35 of the commenters' comments).

Commenter (0276-Greater Boston Physicians for SR) reports that the gas emitted at compressor stations or leaked in our streets or burned in our gas stoves or furnaces is a mixture of methane and hexane (a neurotoxin); but it is likely that many of the observed health outcomes are due to what travels with it: things like benzene and formaldehyde, both known carcinogens; metals and radionuclides from the Earth's crust that can include (depending on the geographic region from which methane is extracted) lead, mercury and radioactive radon, uranium and thorium that are highly harmful to human health; and the criteria air pollutants produced in the burning of methane gas, like ground level ozone and particulate matter. The commenter adds that there is a wealth of peer-reviewed studies that provide documentation of the health hazards of natural gas infrastructure: asthma, COPD, childhood acute lymphocytic leukemia, miscarriage, congenital heart defects and increased premature birth. These are best defined at the drill rig, where more babies being born prematurely; more babies with heart defects, more kids with asthma; more children diagnosed with leukemia. The commenter states that there are also many other recorded health effects: increased pneumonia in those living near natural gas infrastructure; increased heart disease; increased thyroid and bladder cancer.

Commenter (1302-Wyoming Outdoor Council) reports that volatile organic compounds (VOCs), ozone, and other pollutants can increase the risk of chronic respiratory issues like asthma, and even short-term exposure can cause acute symptoms like headaches and dizziness.<sup>30</sup> Furthermore, the commenter states that Wyoming residents are not protected by adequate setback distances. Oil and gas operations can be located as close to homes as 500 feet. According to a 2019 Colorado Department of Health Study, health risks from oil and gas operations are elevated for people who live within 2000 feet of an oil or gas pad, including an elevated risk of cancer.<sup>31</sup> According to the commenter, stronger rules to reduce methane emissions like those proposed here would have the beneficial effect of reducing VOC emissions and the risk of ozone formation as well, a critical step in protecting the health of citizens and communities living near oil and gas operations.

Commenter (1160-United Methodist Women – SW Conference) reports that, in Arizona, there are 6,572 childhood asthma attacks a year due to oil and gas ozone smog. They add that there are 4,791 school days lost to oil and gas ozone smog. They contend that this is the result of 39 oil

<sup>31</sup> *Id.*

and gas facilities in our state. They report that 925 students live within the threat radius, and there are 2 schools threatened by these pollutants.

Commenter (0370-NM State Rep) reports that the concentration of methane in the San Juan Basin is the highest in the nation and is a safety concern for the workers, families, and the whole community in this area. The commenter asserts that the pollution emitted is particularly troubling and is causing a public health emergency. They note that the Air Quality Bureau has recorded levels of ozone that have come close to the National Ambient Air Quality Standards for Ozone in the San Juan Basin. In the American Lung Association's 2021 State of the Air Reports, New Mexico's top oil-and-gas producing counties, those where the San Juan and Permian Basins are located, received an f grade for ozone pollution.

Commenter (0734-ATS) states that, acting as a respiratory irritant with oxidative potential, ozone can trigger cough in healthy individuals, lead to exacerbations of pre-existing respiratory diseases (COPD and asthma), and is even a risk factor for the development of asthma and decreases in lung growth and function in children.<sup>32,33,34</sup> They add that pulmonary inflammation caused by long-term ozone exposure leading to systemic inflammation is one underlying cause of the increased mortality risk from cardiac and pulmonary diseases.<sup>35</sup> In addition to the decades of ozone research on cardiopulmonary disease, the commenter notes that emerging research on the association between ozone exposure and an increased risk of Alzheimer's disease has raised concern for the neurocognitive risks of ozone.<sup>36</sup> The commenter adds that there is also emerging data linking increased ground-level ozone with increased mortality in COVID infection,<sup>37,38</sup> which may be related to upregulation of genes and molecular pathways associated with severe COVID-19.<sup>39</sup> The commenter concludes that, overall, the contribution of methane and VOC emissions to increased ozone concentrations can cause serious health consequences nationwide. The commenter contends that the proposed rule will be of particular benefit in rural communities that struggle with elevated wintertime ozone levels. They add that the VOC emission reductions that will accompany actions taken under the proposed rule will result in meaningful

improvements in ambient ozone concentrations in communities with few other policy options to address this health risk.

Commenter (0733-Conservation of Voters of NM) reports that a comment provided by Dr. Brita Lundberg, who is the Chair of the Board of Greater Boston Physicians for Social Responsibility, pointed out that the gas emitted at compressor stations or leaked or burned in gas furnaces and stoves is a mixture of methane and hexane – which is a neurotoxin – and that many of the effects of that gas are due to the benzene, formaldehyde, and other substances that travel with the gas. As another example, the commenter states that the Silent Spring Institute’s comment explained that VOCs are a primary precursor to tropospheric ozone pollution, which is recognized as a concern for human health because it contributes to respiratory disease, congestive heart failure, and lung cancer.

Commenter (0578-Grand Canyon Trust) notes that methane unintentionally escapes and is intentionally released (through venting and flaring) during extraction and processing of natural gas. The commenter adds that when methane is released either intentionally or unintentionally from these operations, it is accompanied by VOCs and hazardous air pollutants (HAPs), and ground level ozone all of which adversely affect human health, especially tribal communities across the Colorado Plateau. Ozone harms human health and depending on the level of exposure, can aggravate lung diseases and increase the frequency of asthma attacks. It is also associated with death from respiratory complications.<sup>40</sup> The United Nations Environment Programme found that reducing human caused methane emissions would prevent 255,000 premature deaths each year, 775,000 asthma related hospital visits.<sup>41</sup>

Commenter (0753-IGSD et al) suggests that, given the health risks associated with oil and gas development, states are increasing required setback distances. The commenter notes that the location of wells (whether active or abandoned) in residential communities, near vulnerable populations or in the proximity of schools, hospitals, and other buildings where people congregate, poses serious health risks to communities, especially disadvantaged communities which already suffer from systemic historical discrimination. As of October 2021, the commenter reports that California’s governor Newsom proposed to require a “setback” distance of 3,200 feet for new wells from sensitive community locations, and more pollution control regulations for wells already existing within this distance.<sup>42</sup> According to the commenter, this is

---

<sup>42</sup> California Officer of Governor (21 Oct. 2021) California Moves to Prevent New Oil Drilling Near Communities, Expand Health Protections, Press Release (“Moving to protect communities as the state works to phase out fossil fuels, Governor Gavin Newsom today announced that the Department of Conservation’s Geologic Energy Management Division (CalGEM) has released a proposed regulation that would prohibit new wells and facilities within a 3,200-foot exclusion area – or setback – from homes, schools, hospitals, nursing homes and other sensitive locations. It would also require pollution controls for existing wells and facilities within the same 3,200-foot setback area.”) (“The state is proposing a 3,200-foot setback in order to protect public health. A 15-member public health expert panel selected by University of California, Berkeley and Physicians, Scientists, and Engineers (PSE) for Healthy Energy helped inform the draft rule announced today. The panel concluded that when oil and gas

the greatest set-back distance proposed thus far, demonstrating a fix to a historical public health issue experienced nationwide. The commenter recommends that stringent federal standards be developed to complement these efforts and protect communities from the harms of oil and gas production.

Commenter (0557-Reform Judaism) states that pollution from methane contributes to contaminated air and increased health issues like asthma, especially for those living near oil and gas facilities.

Commenter (0402-Cancer Free) states that they are specifically concerned with rising cancer rates—it is now estimated that one in three people in the U.S. will be diagnosed with cancer at some point in their lives<sup>43</sup>—and a growing body of research points to chemicals in our environment as important, and preventable, risk factors for cancer.<sup>44</sup> Per EPA’s analysis, the primary proposed NSPS OOOOb and EG OOOOc rules under the proposed Standards of Performance for New, Reconstructed, and Modified Sources and Emissions Guidelines for Existing Sources: Oil and Natural Gas Sector are expected to reduce the combined emissions of methane by 41 million short tons, VOCs by 12 million short tons, and HAPs by 0.48 million short tons between 2023 and 2035 alone.<sup>45</sup> According to the commenter, these emission reductions are specifically significant, and vitally necessary, given the health impacts of these three emission classes (which they outline in several paragraphs of their comment letter describing the health effects related to methane, VOC and HAP emitted from oil and gas operations).

Commenter (0414-Waterspirit) states that humans are suffering physically and mentally from the ill effects of undisclosed chemicals used in natural gas infrastructure, such as the highly potent GHG, methane. New Jersey is home to the first landmark legislation that considers cumulative environmental impact and related health impacts to burdened communities prior to awarding permit approval for proposed projects. The evaluation of health impacts afflicting children and expectant mothers is necessary given the clear linked evidence to undisclosed chemicals gone unregulated and unchecked. November 19th, 2021 “Air Pollution Can Alter Our Brains In Ways that Increase Mental Illness Risk: Emerging research finds polluted air linked to mental health problems, leaving Western Pennsylvania children and environmental justice communities at high risk.” (Kristina, Marusic, Environmental Health News) On October 27th, 2021, an event took place entitled “The Real Voices of the Marcellus Shale.” The story of a Pennsylvania mother whose 19-year-old son succumbed to fossil fuel emissions related cancer was shared. Cancer is

---

developments are within 3,200 feet, there is a strong connection to higher rates of adverse birth outcomes, respiratory diseases such as asthma, and heart disease, among other health impacts. The panel’s research supports both moving oil production farther away from communities in combination with pollution controls for operating wells.”)

<sup>45</sup> U.S. Environmental Protection Agency. (2020). Regulatory Impact Analysis for the Proposed Standards of Performance for New, Reconstructed, and Modified Sources and Emissions Guidelines for Existing Sources: Oil and Natural Gas Sector Climate Review. Office of Air Quality Planning and Standards Health and Environmental Impacts Division. [https://www.epa.gov/system/files/documents/2021-11/proposal-ria-oil-and-gas-nsps-eg-climate-review\\_0.pdf](https://www.epa.gov/system/files/documents/2021-11/proposal-ria-oil-and-gas-nsps-eg-climate-review_0.pdf).

costly and mental anguish for survivors is cumulative and permanent. Preventable death and grief alone demonstrate time and again the true costs of pollution. Providing subsidies to fossil fuel companies for decades - and ongoing - helps ensure carbon schemes and resulting permanent damage to once healthy aquifers, communities, family, life. Children see these priorities being made.

Commenter (0317-Several Organizations) states that methane and its by-products have well known, deleterious health impacts. Exposure to tropospheric ozone (a key component of smog) in the short term (under one month) is considered causative of respiratory impacts (in particular asthma) which is responsible for a large share of emergency room visits. The commenter adds that, in the U.S. over 25 million people suffer from asthma. In the long term, ozone is also considered a likely cause of cardiovascular issues and respiratory mortality.

For example, commenter (0385-Silent Spring) notes that air pollutants, specifically those emitted by the oil and gas industry, are of concern for many human health endpoints including cancer. They note that, per EPA's analysis, it is expected that primary proposed NSPS OOOOb and EG OOOOc rules could reduce the combined emissions of VOCs by 12 million short tons and reduce emissions of HAPs by 0.48 million short tons between 2023 and 2035 alone.

Commenter (0385-Silent Spring and others) notes that VOCs are a primary precursor to tropospheric ozone (O<sub>3</sub>) pollution, which is already recognized by the EPA as a human health concern,<sup>46</sup> as research has classified ozone as a respiratory irritant<sup>47</sup> that contributes significantly to respiratory disease, asthma, congestive heart failure, and lung cancer.<sup>48</sup> In fact, the commenter reports that models estimate that respiratory-related deaths of 1.04–1.23 million adults worldwide are attributable to tropospheric ozone pollution.<sup>49</sup>

Moreover, the commenter (0385-Silent Spring and others) reports that VOCs are also a primary precursor to fine particulate matter, or PM<sub>2.5</sub>, which is also a profound respiratory irritant.<sup>50</sup> In 2011, the International Agency on Cancer Research (IARC) classified PM as a Group 1 carcinogen.<sup>51</sup> Research has well established statistically significant associations between

half-mile radius of natural gas development leads to increased brain, spine, or spinal cord birth defects.<sup>64</sup>

Commenter (0196-Meyaard-Schaap) states that methane pollution emitted alongside methane, such as benzene, exacerbates asthma and affects lung development in young children. The medical community has long known pollution and other environmental impacts harm unborn children. Studies show that smog, VOCs, and air toxics have a disproportionate impact upon life in the womb—from birth defects to low birth weight to increased brain, spine, or spinal cord malformation. All of it linked to proximity to methane infrastructure. Now is the time to address dangerous methane leaks from our oil and gas infrastructure, which at least one study has found leaks at a rate most likely 60% greater than current EPA estimates. Now is the time to ensure that the entire process of bringing oil and natural gas to market—from production to transportation to distribution—is free from unnecessary and wasteful leaking, venting, and flaring and is safe for every American.

Commenter (0215-EEN) states that it was once thought that unborn children were protected from pollutants, but medical research repeatedly shows that this is untrue. The exposure of expectant mothers, like myself only months ago, to air polluted with smog, VOCs, and air toxics from wasteful methane leaks during pregnancy puts their unborn children at increased risk for low birth weight<sup>65</sup> and birth defects<sup>66,67</sup>. The commenter notes that this is not a small or isolated problem - 2.9 million children attend a school located within with 0.5 miles of an oil/gas facility and 12.6 million Americans households are also within that radius.<sup>68</sup> Over 85% of the medical studies<sup>69</sup> that have studied the gas industry's impact on health find that that emissions from oil

and gas facilities and infrastructure is highly detrimental to the health of both children and adults – this includes heart failure,<sup>70</sup> asthma,<sup>71</sup> and the exposure to known carcinogens.<sup>72</sup>

Combined, commenters state (0195-EEN, 0215-EEN) the two standards will save \$6.6 - \$9.2 billion in avoided health costs and loss of life.

Commenter (0351-Columbia) reports that they have been studying the health of populations living near oil and gas development since 2013. Their studies have used spatial methods and electronic health record data on thousands of individuals where we could control for both individual and area-level factors (Casey et al. 2016, Casey et al. 2018, Casey et al. 2019, Tustin et al. 2017, Rasmussen et al. 2016). They have found relationships between living closer to more wells and more actively producing wells and increased risk of preterm birth, migraine headache, depression, and cardiovascular disease in Pennsylvania. The commenter adds that, in studies in California with Dr. Rachel Morello-Frosch we have also used statewide birth certificate data and found that living within 1km of an oil or gas well was associated with increased odds of low birth weight, small for gestational age birth, and decreased term birth weight among individuals living in rural areas (Tran et al. 2020). They add that another study in Texas has found an increased risk of preterm birth among women exposed to gas flaring (Cushing et al. 2020).

Response I-20-3: We include an analysis of the impact of changes in VOC releases via their impact on ozone formation in chapters 3 and 4 of the final RIA. We are currently unable to estimate or monetize the impact of changes in HAPs releases due to data limitations, most notably the lack of sufficient emission location specificity to perform such analyses. The HAP impacts available in EPA's 2017 AirToxScreen dataset are provided for the entire oil and natural gas sector, which includes sources outside the scope of this regulation. We do not have current modeling of HAP impacts specific to only the sources subject to the regulation; therefore, we cannot estimate risks, including any reductions, solely attributed to the source category. Furthermore, more refined emissions data would be needed to conduct an assessment at the census block level, where we could draw more accurate conclusions about the human health risks.

Comment: In addition to requesting stronger regulation to mitigate emissions, many commenters (e.g., 0351-Columbia, 0421-Biosphere, 0559-Texas State Senator, 0216- Montana HPHC) request that EPA end or minimize routine flaring from oil and gas facilities. Commenter (0351-Columbia) states that this is because studies have shown that incomplete combustion during

flaring can lead to emissions of volatile organic compounds, polycyclic aromatic hydrocarbons, carbon monoxide, nitrogen oxides, heavy metals, and black carbon. According to the commenter, the Cushing et al study from 2020 also found links between flaring exposure and adverse birth outcomes.

Commenter (0559-Texas State Senator) states that flaring often releases additional pollutants such as sulfur dioxide, ammonia, or VOCs.<sup>73</sup> Some of these compounds, such as benzene are known carcinogens.<sup>74</sup> Toluene is a neurotoxin that can cause miscarriages and birth defects. One recently published study examining the Eagle Ford Shale region found that “pregnant women who lived near areas where flaring is common had 50 percent greater odds of giving birth prematurely than those who did not.”<sup>75</sup> Beyond the human suffering itself, these health effects have an estimated economic impact of \$13-29 billion each year.<sup>76</sup>

Response I-20-4: We are currently unable to estimate or monetize the impact of changes in HAPs releases due to data limitations, most notably the lack of sufficient emission location specificity to perform such analyses. The HAP impacts available in EPA’s 2017 AirToxScreen dataset are provided for the entire oil and natural gas sector, which includes sources outside the scope of this regulation. We do not have current modeling of HAP impacts specific to only the sources subject to the regulation; therefore, we cannot estimate risks, including any reductions, solely attributed to the source category.

## **20.2 Regulatory Impacts Analyses (RIA)**

### **20.2.1 Cost-Benefit Analysis**

Comment: Commenter (0842-NYU School of Law) suggests that EPA note that its proposed standards for each source type within the category are net beneficial. The 2021 November RIA makes unambiguously clear that its proposed standards for new and existing sources, overall, are net beneficial. The commenter adds, however, that the EPA further disaggregate its analysis to show that, in addition to the entire proposal taken as a whole, each individual proposed policy change is net beneficial. For example, the commenter recommends that the EPA report net benefits for proposed standards for each type of regulated source—e.g., net benefits for the statutory best system of emission reduction (BSER) that applies to well sites, to gathering and boosting stations, and so on. According to the commenter, the EPA has the data needed to perform such calculations. The commenter notes that extending its analysis in this way would demonstrate that, in addition to a net beneficial set of proposed standards, each individual proposed standard is net beneficial and therefore creates value for society.

<sup>74</sup> American Cancer Society, “Benzene and cancer risk”, 2017, <https://www.cancer.org/cancer/cancercauses/benzene.html>

<sup>75</sup> New York Times, “Study Links Gas Flares to Preterm Births, With Hispanic Women at High Risk”, Jul 22, 2020, <https://www.nytimes.com/2020/07/22/climate/gas-flares-premature-babies.html>

<sup>76</sup> Natural Resources Defense Council, “Methane Leaks from Oil & Gas Exploration: A Health Nightmare”, Dec 4, 2018, <https://www.nrdc.org/experts/vijay-limaye/methane-leaks-oil-gas-exploration-health-nightmare>

Likewise, the commenter (0842-NYU School of Law) suggests that the EPA also disaggregate the net benefits of each alternative standard. The 2021 November RIA reports the net benefits of its primary set of BSER standards, along with less stringent and more stringent standards, and a co-proposal. This information confirms that the primary proposal carries the highest net benefits of any alternative. But it does not show whether more stringent standards could carry higher net benefits within one or more source types. Without a more granular analysis, the commenter contends that the public cannot know whether the EPA's primary proposal would forego some net benefits for individual BSERs. The commenter recommends that, if the EPA does find such opportunities for higher net benefits for some BSERs, it should pursue them, or at least explain rigorously why it declines to do so.

Response I-20-5: In Table 5-6 of the Final Rule RIA, the EPA provides source-level information on estimated climate benefits and compliance costs of the finalized rule. In the interest of parsimonious presentation of results, however, the EPA does not present source-level estimates for the alternative scenarios assessed for the RIA, though the modeling scripts and data relied upon to generate those tables are available in the docket.

With respect to the commenter's suggestion regarding the use of source-level net benefit analysis in the RIA, the EPA notes that the EPA's standard-setting duties and authority are derived under section 111 of the CAA, and its decisions on emissions standards are made within the confines of that authority. Under the language of the statute, the EPA must consider the costs of control (as well as energy requirements and nonair quality health, and environmental impacts). The EPA has done so here. The monetized benefits analysis in the RIA prepared under Executive Order 12866 is entirely distinct from the statutory BSER determinations and are presented solely for the purposes of complying with E.O. 12866.

Comment: Commenter (0842- NYU School of Law) suggests that the EPA consider expanding and strengthening its cost-benefit analysis. Specifically, the commenter recommends that the EPA extend the timeframe of its analysis rather than assuming zero benefits past 2035. In addition, the commenter suggests that the EPA consider quantifying co-benefits from reducing non-methane VOC, PM, and HAP (see section 20.2.4 for further comment on quantifying co-benefits from reducing other non-methane pollutants). Finally, the commenter suggests that the EPA consider disaggregating costs and benefits by source type to demonstrate that its proposed standards and guidelines are individually, as well as cumulatively, net beneficial.

The commenter (0842- NYU School of Law) also recommends that the EPA expand its distributional analysis to evaluate the impacts of the 2021 November proposed rule and alternatives. In addition to baseline conditions, the commenter recommends that EPA also analyze the distributional impacts of its proposed standards and alternatives to evaluate the relative distributional impacts of its available regulatory options.

Response I-20-6: The EPA has addressed several of the commenter's points in the Final Rule RIA. First, the EPA extended the analysis horizon beyond 2035 to 2038 but declined to extend the analysis further due to the significant uncertainties in projected long-run sectoral trends. In addition, the EPA notes that the monetized climate benefits associated with the 2023-2038 CH<sub>4</sub> emission reductions reflects the discounted stream of benefits resulting from those emission

reductions over a much longer time horizon (out to 2300). Second, the EPA has added the quantification of the impact of changes in VOC releases via their impact on ozone formation in the Final RIA. However, the EPA is currently unable to estimate or monetize the impact of changes in HAPs releases due to data limitations (see Response I-20-3 for more information). Third, the EPA provides source-level information on estimated climate benefits and compliance costs in Table 5-6 of the Final RIA. Finally, in response to the commenter's suggestion regarding distributional analysis, the EPA expanded its distributional environmental justice analysis for ozone to include the estimated distributional impacts from the policy option in addition to baseline conditions. However, the EPA is unable to perform similar analysis regarding HAP emissions (see Response I-20-4 for more information).

Comment: Commenter (0793-PBPA) suggests that the EPA erred in its analysis when it compared current industry capital expenditures to capital expenditures under the proposed rule. Ultimately, the commenter states that the EPA concluded that capital expenditures under the proposed rule would only increase 0.3% when compared to the current capital expenditures.<sup>77</sup> According to the commenter, because operations within the oil and gas industry are so varied, many companies and segments of operations spend little to no capital annually. Most capital spent by the industry is in new drilling and completion of wells. The commenter concludes that the EPA's analysis is overbroad and should be refined to look at actual segments and types of operations rather than a one-size-fits-all approach applied to hundreds of thousands of sites.

Response I-20-7: While the EPA acknowledges the limitations of comparing estimated capital expenditures resulting from the regulation to overall industry-wide capital expenditures, it is not aware of existing data that could be used for the more disaggregated analysis that the commenter suggests. Moreover, while the commenter claims that many companies and segments of the oil and gas industry spend little to no capital annually, no specific information to support those claims was provided.

Though it was unable to perform a more disaggregated capital cost analysis, for the Final RIA, EPA developed a financial analysis of marginal oil and natural gas wells in Chapter 6 of the Final Rule TSD. EPA finds that marginal wells may continue to operate at low or negative profits rather than be shut-in and plugged due to a variety of reasons, including low operating costs, high plugging costs, low state bonding requirements, accounting practices, and tax credits available to the oil and gas industry.

### ***20.2.2 Global Warming Potential (GWP) of Methane***

Comment: Commenter (0577-KIOGA) indicates that they find it disconcerting that the EPA references conflicting GWP for methane (80, 30, 29.8, 27.2, and 5) throughout the proposal instead of using the established GWP used for emissions inventory purposes.

Commenter (0585-KOGA) provides that, according to a White Paper published by two distinguished atmospheric physicists W. A. van Wijngaarden of York University, Canada, and W. Happer of the Princeton University Department of Physics, "methane contributes only about 30/300 or 1/10 of the already small warming from CO<sub>2</sub>". In their White Paper, the commenter

---

<sup>77</sup> 86 Fed. Reg. at 63,157

reports that they provide calculations demonstrating the small impact of methane emissions on the environment as a basis that methane emissions should not be regulated due to potential global warming potential. According to the commenter, while many comments have been submitted to the EPA that recite the same talking points about methane's GWP, Wijngaarden and Happer provide the calculations to demonstrate the small impact that methane has on the atmosphere.

Commenter (0585-KOGA) adds that Wijngaarden and Happer note that for current concentrations of GHGs, methane has about 30 times greater impact than CO<sub>2</sub>. They also note that the addition of CO<sub>2</sub> to the atmosphere is about 300 times greater than the rate of increase of methane to the atmosphere. With the small rate of methane being added to the atmosphere, the calculated increase in global temperature is 0.012 degrees C/year. According to the commenter, with an impact this small, they believe that the EPA should focus efforts in other areas that provide a better cost/benefit ratio.

Commenter (0597-IN OGA) notes that, according to a White Paper published by two atmospheric physicists W. A. van Wijngaarden of York University, Canada, and W. Happer of the Princeton University Department of Physics, "methane contributes only about 30/300 or 1/10 of the already small warming from CO<sub>2</sub>". The commenter states that the White Paper provides calculations demonstrating the small impact of methane emissions on the environment as a basis that methane emissions should not be regulated due to potential global warming potential. The commenter asserts that, while many comments have been submitted to EPA that recite the same talking points about methane's global warming potential, Wijngaarden and Happer provide the calculations to demonstrate the small impact that methane has on the atmosphere.

Commenter (0428-Kfrost) asks EPA to prevent methane from being reported as CO<sub>2</sub>e from oil and natural gas sources. Please require all agencies to first identify actual methane emissions as methane emissions. Let's not have any source or agency providing methane as CO<sub>2</sub>e. No agency is using the CO<sub>2</sub>e correctly to identify potency of methane. To identify 2019 methane emissions as CO<sub>2</sub>e 100-year potency is just wrong and false. CO<sub>2</sub>e should only be used by scientists presenting current or future methane load analysis and use potencies corresponding to each year of emissions evaluated. For emissions 3 years ago, use the methane potency of 102 times carbon dioxide; and for emissions this year, use the potency of 120 times carbon dioxide. That is the proper use of carbon dioxide potency equivalency.

Commenter (0420-Kfrost) states that the Global Warming Potency for methane starts at 120 times carbon dioxide (CO<sub>2</sub>) in potency for the first year and the potency decreases over time ([https://www.researchgate.net/figure/Global-warming-potentials-for-methane-kgCO<sub>2</sub>-emissions-equivalent-to-a-kg-of-methane\\_fig2\\_263283839](https://www.researchgate.net/figure/Global-warming-potentials-for-methane-kgCO2-emissions-equivalent-to-a-kg-of-methane_fig2_263283839)). The commenter contends that, to represent all years regardless of how recent or how long ago, reported as all CO<sub>2</sub>e in multiples times 25 CO<sub>2</sub> for the 100-year potency is misrepresentative. The commenter suggests that it enables natural gas facilities to hide methane emissions into a 100-year equivalent of CO<sub>2</sub> in terms of past and future potential emissions rather than reporting actual methane emissions. The commenter adds that it creates a flawed notion of CO<sub>2</sub>-equivalent (CO<sub>2</sub>e) of methane potency that is not true. They note: 2019 methane emissions do not currently have the potency of 25, in fact, the potency of 25 times CO<sub>2</sub> for 2019 emissions would occur in 2119.

Commenter (0795-Allergy and Asthma Network) requests that EPA acknowledge the extreme potency of methane's contribution to climate change by referencing its climate impact over a 20-year timeframe. The commenter notes that it is true that after 100 years in the atmosphere, methane "traps about 30 times as much heat as carbon dioxide," as EPA says in their November 2, 2021 press release about the 2021 November proposed rule.<sup>78</sup> However, they contend that grossly underestimates methane's impacts in the all-important next few years. According to the commenter, the timeframe that is truly relevant is the 20-year timeframe – roughly the timeframe available to us to head off catastrophic climate change impacts. The commenter states that utilizing this more relevant time frame is necessary to convey to the American people the true urgency of reducing methane emissions.

Commenters (0449-Public Employees, 0454-Kayrros) support the use of the 20-year GWP of methane rather than the 100-year GWP and agree with the EPA's stated reasoning. Commenter (0454-Kayrros) notes that the EPA estimates the social cost of methane at approximately \$1,800/ton but they believe that, given the 20-year GWP is more appropriate than the 100-year GWP, calculations of the social cost of methane should also be based on the 20-year GWP.

Commenter (0449-Public Employees) notes that the 2021 November proposed standards acknowledge the higher 20-year GWP, but the 2021 November RIA calculates methane's climate impact only using the 100-year GWP.<sup>79</sup> As the commenter explains below, the commenter recommends that the 2021 November RIA also calculate its impact using a 20-year GWP.

The commenter (0449-Public Employees) states that the EPA explains that its decision to use a 100-year GWP is "in accordance with the practice of the EPA [GHG Inventory], the EPA [GHG Reporting Program], and international reporting standards under the UN Framework Convention on Climate Change." However, the commenter states that the EPA does not specify why those programs' using a 100-year GWP preclude it from using the 20-year GWP here. The commenter contends that this lack of explanation is troubling, given the growing body of scientific evidence that favors using a 20-year GWP when crafting methane regulations. According to the commenter, several climate "tipping points" either have been triggered or will be in a matter of decades, not centuries. The IPCC sees a high probability of methane release from permafrost thaw in the 21st century.<sup>80</sup> The commenter adds that scientists have also found evidence that other tipping points, such as collapse of the Antarctic ice sheets or dieback of the Amazon rain forest, are fast approaching or already under way.<sup>81</sup> The commenter stresses that this situation demands that EPA regulate the short-term impact of GHGs.

Commenter (0449-Public Employees) states that scientists are beginning to recognize that the 100-year GWP, on its own, is ill-suited for this purpose. They provide that a 2020 paper observed that "there was no clear reason for [the Intergovernmental Panel on Climate Change]

EPA-452/R21-003, Regulatory Impact Analysis, (October 2021), Document ID No. EPA-HQ-OAR-2021-0317- 0173, at 2-38, 1-10, 2-30, 5-2, 3-2.

<sup>80</sup> IPCC, AR6 Climate Change 2021: The Physical Science Basis (2021), <https://www.ipcc.ch/report/ar6/wg1/>, 5-79.

<sup>81</sup> Timothy M. Lenton et al, Climate Tipping Points – Too Risky to Bet Against, 575 NATURE 592 (2019).

using this [100-year] value rather than 20 years or 500 years, and more recently the IPCC has stated the 100-year time period is arbitrary.”<sup>82</sup> They add that other recent peer-reviewed papers have argued that policymakers should use the 20-year GWP alongside the 100-year GWP.<sup>83</sup>

Commenter (0449-Public Employees) provides that some policymakers are already using the 20-year GWP. In 2019, New York lawmakers required the state’s Department of Environmental Conservation to use this value in preparing its annual Statewide Greenhouse Gas Emissions Report.<sup>84</sup> Internationally, a report prepared for the UN Framework Convention on Climate Change (UNFCCC) incorporated the 20-year GWP into its recommendations for reducing methane emissions from the oil and gas sector.<sup>85</sup> The commenter notes that EPA had claimed that given that some programs use the 100-year GWP they are precluded from adopting the 20-year one. According to the commenter, New York and the UNFCCC’s efforts suggest that the 20-year GWP can nonetheless be incorporated into climate policy.

Commenter (0449-Public Employees) states that the White House Office of Management and Budget (OMB) recognized this possibility during development of the Proposed Standards. Its comments on the rule’s 2021 November RIA noted that “the discussion of short vs. long lived (sic) gases could benefit from explicit use/discussion of the 20-year GWP.”<sup>86</sup> The commenter adds that OMB further noted that “the [Proposed Standards’] preamble has a good exploration of why it’s relevant that we’re dealing with a [short-lived climate pollutant] but [the RIA] never completes the thought by mentioning or applying the 20-year value. The commenter suggests that it is very easy to just add a column to a table showing a second CO<sub>2</sub>e estimate using the 20-year one while stressing that the 100-year one is the central estimate per US and international protocols.” The commenter notes that the EPA left the “Response” section to this comment blank.<sup>87</sup> The commenter reports that they have filed a Freedom of Information Act request for more information about why it used the 100-year global warming potential in these documents, but as of this writing it has not been completed. The commenter requests that EPA provide a response to OMB’s inquiry when it publishes the final Performance Standards.

In addition, commenter (0449-Public Employees) suggests, for the reasons described above, that EPA publish a RIA updated with the following information: Tables 1-3, 2-6, 2-11, 3-2, and 5- with an additional column for methane CO<sub>2</sub>e emission reductions calculated using methane’s 20-year GWP of 81. If any of these requested changes are impractical, the commenter asks that EPA

<sup>87</sup> *Id.*

explain why, and not simply cite other reporting programs that use the 100-year GWP. By providing this information, the commenter believes that the EPA will ensure that scientists and the American public can evaluate the Performance Standards' effectiveness in addressing climate change.

Response I-20-8: Commenters (0585-KOGA and 0597-IN OGA) reference an article by Wijngaarden and Happer. As far as EPA is aware, this article has not gone through any peer review process. While the article presents an analysis of radiative influence that is consistent with scientific assessments (e.g., an influence of methane that is about 30 times the influence of CO<sub>2</sub> per molecule), the article's conclusions rely in large part on an extrapolation of concentration trends, rather than an analysis of the impacts of emissions of methane or CO<sub>2</sub>. Because of the short lifetime of methane, if methane emissions were to stop, then the concentration of methane would fall. Therefore, looking only at the increase of methane concentrations from year to year does not account for the full impact of methane emissions, a large part of which go to just keeping up with methane destruction. A better approach to attributing warming to different gases was done by the IPCC: see figure SPM.2 in the IPCC AR6 WGI Summary for Policymakers<sup>88</sup> which shows that human emissions of methane have contributed to about a third of the current warming due to human emissions of greenhouse gases (which, in total, contribute to more warming than has been observed, because they are partly offset by human emissions of cooling aerosols).

Moreover, the article does not make any attempt to actually determine the impacts on human health or welfare resulting from these emissions. Therefore, the article has not performed an analysis that is appropriate for making conclusions regarding the net costs and benefits of methane reductions.

Numerous commenters have suggested that EPA should use the 20-year GWP to value methane. However, only looking at relative impacts over the next 20 years is an incomplete comparison of methane and CO<sub>2</sub> impacts. The 100-year GWP value is more consistent with temporal valuation used elsewhere in US government cost benefit analyses. See, e.g., Sarofim and Giordano (2018, <https://esd.copernicus.org/articles/9/1013/2018/>) and Mallapragada and Mignone (2020, <https://link.springer.com/article/10.1007/s10584-019-02486-7>) which show that the 100-year GWP is equivalent to valuing future impacts with discount rate of about 3%, which is also the OMB Circular A-4 (2003) recommended discount rate for social goods.<sup>89</sup> A 20-year GWP would be equivalent to valuing future impacts at a much higher discount rate, which is inconsistent with how EPA (and many others) recommend valuing future damages and damages avoided. A 20-year GWP is not a good solution for avoiding tipping points: because it is a relative measure, using a 20-year GWP would lead to increased CO<sub>2</sub> emissions to balance reduced CH<sub>4</sub> emissions,

<sup>89</sup> OMB Circular A-4 (2023) recommended a discount rate of 2.0% for such goods, which would be even less consistent with a 20-year GWP.

which would reduce the probability of near-term tipping point exceedances at the cost of increasing the probability of passing tipping points in the longer term.

### **20.2.3 Social Cost of Methane**

#### 20.2.3.1 IWG Recommended Interim SC-GHG Estimates

##### *General*

Comment: Commenter (0828-UCS) states that as it currently stands, the proposed rule is estimated to result in methane emission reductions on the order of 41 million short tons by 2035. Importantly, these estimates rely on an interim social cost of methane (SC-CH<sub>4</sub> or SCM), as re-established in February 2021 following Executive Order (EO) 13990. As these values are updated by the Interagency Working Group (IWG) to reflect the latest science and economics, the EPA should be sure to adjust its analyses accordingly.

Commenter (0423-RFF) describes the current RFF Social Cost of Carbon (SCC) initiative status. According to the commenter, the SCC initiative was established in 2017 as a multi-institutional, collaborative effort between Resources for the Future (RFF) and the University of California-Berkeley, with additional contributors from Duke University, Harvard University, Princeton University, and the University of Washington, among others. The commenter reports that the initiative has now completed the necessary research and implemented the near-term National Academies of Science, Engineering and Medicine (NASEM) recommendations to improve the scientific basis and transparency of the SC-GHG estimates across the full estimation methodology. The commenter reports that the initiative addresses:

- *Modularization of SC-GHG estimation methodology.* The commenter states that they have accomplished the modularization of the SC-GHG estimation process and corresponding improvement of transparency of the estimates through the provision of a new open-source software framework (Mimi.jl) for building integrated assessment models (IAMs). MMimi.jl has been utilized by the EPA in its RIA for the *Final Rule - Phasedown of Hydrofluorocarbons: Establishing the Allowance Allocation and Trading Program under the AIM Act*.
- *Long-run socioeconomic projections.* The commenter has used a combination of statistical information and expert judgement to generate long-run socioeconomic projections, with associated uncertainty bounds, of global emissions and regional economic growth and population that account for future politics and dependencies between the variables. This work, detailed here, has completed scientific peer review and is forthcoming in the Brookings Papers on Economic Activity (Rennert et. al).
- *Improved climate model.* The commenter notes that they have implemented the Finite Amplitude Impulse Response (FAIR, Smith et al. 2008) model highlighted in the NASEM report as used in the Intergovernmental Panel on Climate Change Sixth Assessment Report (Forster et al. 2021)
- *Updated damage functions.* We have implemented updated damage functions, which relate changes to the climate to economic impacts values in dollars, for key sectors based on the latest peer-reviewed scientific literature.

- *Economic discounting.* We have developed and implemented a methodology for empirically calibrating the key discounting parameters required for implementing NASEM recommendations to link discounting with uncertain economic growth projections, while also reflecting the empirical literature on the term structure of interest rates and being consistent with near-term rates associated with related federal discounting guidance. The methodology described here has completed peer-review and is forthcoming in the Journal of the Association of Environmental and Resource Economists.

The commenter (0423-RFF) notes that they have assembled these elements, each of which has undergone its own scientific peer review, into a new IAM on the Mimi platform that is responsive to the near-term recommendations of the NASEM report. They add that the updated estimates of the SC-CH<sub>4</sub> based on this new model are expected to be substantially higher than those employed in the 2021 November RIA for this proposed action. They conclude by reporting that the updated model and estimates are anticipated to complete peer-review in a timeframe relevant for consideration by the EPA as it finalizes the rule.

Response I-20-9: In response to comment, EPA has incorporated the use of the models developed under the RFF/Berkeley Social Cost of Carbon Initiative in the Final RIA. See the EPA's *Report on the Social Cost of Greenhouse Gases: Estimates Incorporating Recent Scientific Advances* that is included as Supplementary Material to the Final RIA for more details. A detailed response to comments pertaining to EPA's November 2022 draft of this report can be found in the Appendix of this RTC.

Comment: Commenter (0808-API) recommends that updates to the social cost estimates be considered with robust stakeholder engagement. As noted in their comments to OMB regarding the interim social cost estimates in June 2021, they believe that the actions taken thus far by the IWG do not reflect this administration's commitment to "public participation and an open exchange of ideas."<sup>90</sup> To date, the commenter reports that there has been only one opportunity for stakeholder engagement in the social cost estimate development process initiated by EO 13990 – one that amounted to a request for information not an opportunity to comment on the work undertaken by the IWG. They report that a recent brief filed by the DOJ suggests that stakeholders will have an opportunity to comment on the revised social cost estimates that the IWG will propose in spring of 2022. In its brief, the DOJ stated that the IWG will "publish its proposed final estimates within the next two months," and that the public will be given the opportunity to comment on these proposed estimates.<sup>91</sup> Further, the commenter states that the EPA has published a request for nominations to form a panel to provide an independent, scientific peer-review of the forthcoming estimates.<sup>92</sup> The commenter notes that the indication of both an independent, expert peer-review and a public notice and comment period is a welcome development. The commenter encourages the IWG to use the forthcoming opportunities to engage with stakeholders, address comments that are provided and seek further feedback. Along

<sup>90</sup> Executive Order 13563, Improving Regulation and Regulatory Review (January 28, 2011), at Sec. 1(a). [https://www.whitehouse.gov/sites/whitehouse.gov/files/omb/inforeg/inforeg/eo12866/eo13563\\_01182011.pdf](https://www.whitehouse.gov/sites/whitehouse.gov/files/omb/inforeg/inforeg/eo12866/eo13563_01182011.pdf).

<sup>91</sup> Def. Supp. Br., 23, *La. v. Biden*, No. 2:21-cv-01074 (W.D. La. Jan. 21, 2022).

<sup>92</sup> On Tuesday, January 25th, the commenter notes that the EPA published a request for nominations of experts to act as reviewers of the proposed final estimates and the accompanying Technical Supporting Document (TSD). 87 Fed. Reg. 3801 (January 25, 2022)

these lines, they encourage EPA to submit for public comment a list of questions EPA is considering to guide the expert peer-review along with the list of candidates as outlined in the EPA request for nominations.<sup>93</sup> According to the commenter, these forthcoming engagements represent an opportunity for the IWG and EPA to improve their process.

Separately, the commenter (0808-API) reports that the DOJ brief also indicated that the IWG has not yet submitted recommendations for the use of the social cost estimates across federal decision-making. API encourages the IWG and the White House to publish those recommendations, in full, for public comment.

The commenter (0808-API) suggests that a failure to engage with stakeholders directly during the process or during a public comment period specifically to address the methodology of the estimates may jeopardize the durability of regulations dependent on this analysis. The commenter encourages EPA, as a member of the IWG, to direct the IWG to follow through on the administration's commitment to public participation by opening the process and engaging directly with stakeholders.

Given the timeline set by this administration, and the updated timeline for the proposal of revised social cost estimates, the commenter (0808-API) states that it is likely that the IWG will have proposed a revised set of social cost estimates for stakeholder review and comment prior to EPA issuing a supplemental proposal or a final rulemaking for methane emissions from the oil and natural gas sector. The commenter encourages EPA to complete a revised RIA including these new estimates and other factors as necessary before moving forward.

Response I-20-10: While EPA continues to participate in the work of the IWG under E.O. 13990, EPA presented a set of updated social cost of greenhouse gas (SC-GHG) estimates in sensitivity analysis in the 2022 Supplemental RIA that address recommendations of the National Academies of Sciences, Engineering, and Medicine (2017), and invited public comment on the sensitivity analysis and on the technical report, titled *External Review Draft: Report on the Social Cost of Greenhouse Gases: Estimates Incorporating Recent Scientific Advances*, explaining the methodological updates that was included as Supplementary Material to the RIA. The EPA identified numerous unique substantive public comment submissions to the docket that were relevant to the updated SC-GHG estimates. The EPA is using the updated SC-GHG estimates in the Final RIA and is responding to the public comments received regarding these estimates in the Appendix of this RTC. The EPA also conducted an external expert peer review of the External Review Draft of the SC-GHG Report consistent with the guidelines set forth in EPA's Peer Review Handbook 4th Edition, 2015. In addition to two opportunities for comment during the peer review selection process (described in the Appendix to this RTC), the public was also invited to attend the meeting of the peer review panel on March 29, 2023. The EPA posted the charge questions on the EPA webpage and provided public notice of the peer reviewer meeting 3 weeks in advance. Since the public comment period on the Supplemental Proposal closed on February 13, 2023, the public comments received on the Supplemental Proposal were also available to the peer reviewers as they conducted their review. Some peer reviewers even cited public comments in their final report. The EPA posted a recording of the public meeting on the

---

<sup>93</sup> 87 Fed. Reg. 3803 (January 25, 2022)

webpage and posted the final peer review report following its completion in May 2023. Complete information about the external peer review, including the peer reviewer selection process, the charge questions and final report with individual recommendations from peer reviewers, and the EPA's response to each recommendation is available at: <https://www.epa.gov/environmental-economics/scghg-tsd-peer-review>.

Regarding the IWG work conducted under E.O. 13990 to develop recommendations regarding areas of Federal Agency decision making for which SC-GHG may be applied, the EPA refers the commenter to the September 2023 White House announcement regarding the use of SC-GHG estimates in facilitating comparison of the climate consequences of alternative options in budgeting, procurement, and other agency decisions. See <https://www.whitehouse.gov/briefing-room/statements-releases/2023/09/21/fact-sheet-biden-harris-administration-announces-new-actions-to-reduce-greenhouse-gas-emissions-and-combat-the-climate-crisis/#:~:text=The%20President's%20Day%20One%20Executive,agencies%20should%20consider%20the%20Social>.

### *Support for Use of IWG Recommended Interim SC-GHG Estimates*

Comment: Commenters (0761-Excelon Corporation, 0844-EDF et al, 1267-CA) support the EPA's use of the interim SCM established in the IWG on Social Cost of Greenhouse Gases' recently published Technical Support Document (TSD) (2021 IWG TSD)<sup>94</sup> in evaluating the costs and benefits of the Proposed Rule.<sup>95</sup> The commenters believe that the EPA's 2021 November proposed rule RIA understates the benefits of its proposal. While the commenter supports the use of the IWG's February 2021 Social Cost of Methane (SC-CH<sub>4</sub>) and its global perspective, they contend that it understates the true cost of methane.

Commenter (0761-Excelon Corporation) agrees that EPA should use the social cost of methane, estimated by the IWG on SC-CH<sub>4</sub>, in the cost-benefit calculation for the Proposal. The commenter states that federal agencies should incorporate the social cost of GHGs in all relevant areas of decision making including regulatory analyses, and the social cost of methane is the appropriate value to use in conducting benefit-cost analyses and estimating the climate impacts of policies that affect methane emissions.

Commenter (0804-EDF et al) cautions EPA that it must defend against common criticisms of the IWG social cost valuation methodology (e.g., that claim that the IAMs)—the damage functions for translating climate impacts into economic losses—are flawed and arbitrary) and suggests responses in the text of their comment letter (see pages 34 and 35 of their comment letter), to common criticisms that have been offered by opponents.<sup>96</sup>

---

<sup>94</sup> Interagency Working Group on Social Cost of Greenhouse Gases, Technical Support Document: Social Cost of Carbon, Methane, and Nitrous Oxide Interim Estimate Under Executive Order 13,990 (Feb. 2021).

<sup>95</sup> See 86 Fed. Reg. at 63,122-23.

<sup>96</sup> William Nordhaus, An Optimal Transition Path for Controlling Greenhouse Gas Emissions, 258 SCIENCE 1315 (1992); Memorandum by Dr Chris Hope, Judge Institute of Management, University of Cambridge, (Jan. 14, 2005), <https://publications.parliament.uk/pa/ld200506/ldselect/ldconaf/12/5011805.htm>; *Ctr. for Biological Diversity v. NHTSA*, 538 F.3d 1172 (9th Cir. 2008); 2010 TSD, supra note 28; Interagency Working Group on the Social Cost of

Commenter (0844-EDF et al) provides that the SC-CH<sub>4</sub> measures the net economic harm to society due to climate change for every additional ton of methane emitted, or the economic value of avoiding those emissions. The SC-CH<sub>4</sub> is meant to encompass the value of all climate change impacts including human health effects, property damage, conflict, and changes to ecosystem services.<sup>97</sup> The SC-CH<sub>4</sub> is appropriate to use in cost-benefit analyses in the finalized rule. Because even the most accurate SC-CH<sub>4</sub> reflects the societal value of reducing methane emissions and represents net benefits to society, the commenter states that the SC-CH<sub>4</sub> is reasonable and is thus a useful measure in determining the cost-effectiveness of a rule. The commenter reports that the U.S. Government Accountability Office (GAO) reviewed the IWG's process and concluded that the IWG: (1) used consensus-based decision making; (2) relied largely on existing academic literature and models, including technical assistance from outside resources; and (3) took steps to disclose limitations and incorporate new information by considering public comments and revising the estimates as updated research became available.<sup>98</sup> Notably, the commenter adds that several court decisions recognize that the social cost of GHGs (SC-GHG) is a reliable and scientifically validated approach to monetizing climate change impacts that should be incorporated into federal decision-making. The commenter urges the agency in its final rule to use an updated SC-CH<sub>4</sub> that better reflects the true social cost of methane.<sup>99</sup> The commenter further states:

- The EPA's finalized rule should maintain a global perspective in its SC-CH<sub>4</sub> calculation because the IWG and the EPA have correctly recognized that methane is a global pollutant whose economic impacts can only be fully accounted for by considering its effects both within the U.S. and abroad. Furthermore, there is a national interest in encouraging other jurisdictions to fully account for the costs of climate pollution, which would be put at risk if the EPA were to focus solely on domestic costs.
- They agree with the EPA's recognition that the SCM must consider global, not just domestic, emissions. Economic principles suggest that the full costs to society of emissions should be considered to identify the policy that maximizes the net benefits to society, i.e., achieves an efficient outcome. Estimates of global benefits capture more of the full value to society than

<sup>97</sup> Proposal, 559.

<sup>98</sup> U.S. Gov't Accountability Off., Regulatory Impact Analysis: Development of Social Cost of Carbon Estimates, at 8 (July 2014), available at <https://www.gao.gov/assets/gao-14-663.pdf>,

<sup>99</sup> Beyond the discussion here, many of the joint commenters have also signed onto a comment submitted by the Institute for Policy Integrity which discusses the legal issues associated with the social cost of methane in more depth

domestic estimates and can therefore help guide policies towards higher global net benefits for GHG reductions. The consideration of global impacts is also fully within the authority of federal agencies.

- The EPA was correct to abandon a 7% discount rate. While an even lower range of discount rates would be more appropriate, see *infra* subsection v, abandoning the 7% rate better aligns with what the expert consensus recommends for analyzing the impacts of a high-risk, long-term, multi-generational crisis such as global climate change. However, the EPA fails to present any valuation of the climate benefits using such lower discount rates. Conducting such evaluations should not be overly burdensome for the agency and will provide useful additional information on the benefits of the rule.
- The EPA has full legal authority to apply the IWG's approach to the SC-CH<sub>4</sub>. The commenter suggests that EPA take the opportunity to clarify in its final rule the legal authority that supports its use of a global perspective and range of lower discount rates. The agency should first highlight the multitude of authorities that allow and support the use of a global calculation. For example, the National Environmental Policy Act (NEPA) the United Nations Framework Convention on Climate Change, and *Zero Zone v. Department of Energy* (the Seventh Circuit upheld a Department of Energy (DOE) regulatory analysis). Further, the use of the social cost of SC-GHG in evaluating the costs and benefits of a commenter states that the proposed rule has been upheld by courts and does not violate the major questions or any other legal doctrine.
- The EPA recognizes that the interim SC-GHG likely underestimates the true cost of methane pollution. Although the IWG's 2021 SC-CH<sub>4</sub> is the best and most representative set of estimates for the social cost of methane that the federal government has thus far produced, numerous experts, including the EPA itself (see 2021 November proposed rule RIA 3-13), agree that all currently available estimates of social cost of GHGs (including the IWG's SC-CH<sub>4</sub>) are likely still too low.<sup>100</sup> Proposed areas for revision include decreasing the discount rate to further account for the welfare of future generations, improving economic damage estimates, and updating the underlying climate science. For certain policy decisions, non-climate health impacts, such as methane damages to human health via ozone formation, should also be included. The SC-CH<sub>4</sub> does not incorporate non-climate impacts on local health. Recent epidemiologically derived research suggests that such non-climate impacts from methane may be significant. Methane-induced changes in surface ozone affect air quality, human health, and agricultural productivity in ways that have significant costs. The Sarofim et al. (2015)<sup>101</sup> and Shindell (2015)<sup>102</sup> studies aim to extend the methodology underlying the IWG SC-CH<sub>4</sub>, resulting in cost ranges that would be much higher than current values. The EPA and the IWG agree that, taken together, these features suggest that the interim SCM estimates used in this proposed rule likely underestimate the damages from methane.<sup>103</sup> According to another commenter (1267-CA), although the EPA has recognized

<sup>103</sup> 2021 November Proposed Rule RIA 3-13.

these limitations, the commenter states that the EPA should improve its disclosure and evaluation of those limitations.

- The EPA has also recognized several areas of damages that are not quantified in the models including ecosystems, increased fire risk and wildfires, sea level rise and storm surges, pests and pathogens and catastrophic impacts, and loss of cultural heritage, and favored landscapes.

Response I-20-11: The EPA acknowledges the comments. As mentioned in the previous response, the EPA presented a set of updated social cost of greenhouse gas (SC-GHG) estimates in sensitivity analysis in the 2022 Supplemental RIA that address recommendations of the National Academies of Sciences, Engineering, and Medicine (2017), and invited public comment on the sensitivity analysis and on the technical report, titled *External Review Draft: Report on the Social Cost of Greenhouse Gases: Estimates Incorporating Recent Scientific Advances*, explaining the methodological updates that was included as Supplementary Material to the RIA. The EPA is using the updated SC-GHG estimates in the Final RIA and is responding to the public comments received regarding these estimates in the Appendix of this RTC.

Comment: Commenter (0936-U.S. House of Representatives) states that the rule's current legally required cost-benefit analysis makes two questionable assumptions:

1. It assumes a discount rate of only 3 percent.<sup>104</sup> With the recent spike in inflation for the U.S. economy hitting 40-year highs of 6.8 percent<sup>105</sup>, it is vital to choose the steps we follow wisely and efficiently. Pursuing any other path will potentially hamper future natural gas.
2. Producer prices are currently running close to 10 percent, this peg at 3 percent is overly optimistic. Likewise, the EPA includes in its cost-benefit analysis a price for natural gas at \$3.13, which is the U.S. Energy Information Administration's prospective average price for 2022.

Commenter (0936-U.S. House of Representatives) asserts that given the rapid rise in energy prices over the past year and threats affecting future spikes, the accuracy of average price above is questionable. The commenter notes that the rule uses the IPCC as the exclusive source for many of its claims, including that the oceans are rising, hurricanes and storms are getting more severe, and that the last decade "might have been" the warmest in the last century.<sup>106</sup> A comparison of IPCC claims and other scientific opinions are necessary here. The EPA has used the IPCC as its single source to justify this rule with very alarmist language. According to the commenter, a nationwide ruling of vast scope and impact should include information and analysis from multiple independent sources before it is implemented.

Response I-20-12: It is assumed that the commenter is questioning assumptions used in BSER analyses conducted for NSPS OOOOb affected facilities and EG OOOOc designated facilities

<sup>104</sup> EPA Regulatory Impact Analysis for the Proposed Standards of Performance, Page 1-11, January 31, 2022. [https://www.epa.gov/system/files/documents/2021-11/proposal-ria-oil-and-gas-nsps-eg-climate-review\\_0](https://www.epa.gov/system/files/documents/2021-11/proposal-ria-oil-and-gas-nsps-eg-climate-review_0).

<sup>105</sup> Bureau Labor and Statistics, <https://www.bls.gov/opub/ted/2021/consumer-prices-up-6-8-percent-for-year-ended-november-2021.htm>, January 31, 2022.

<sup>106</sup> Regulatory Impact Analysis for the Proposed Standards of Performance, [https://www.epa.gov/system/files/documents/2021-11/proposal-ria-oil-and-gas-nsps-eg-climate-review\\_0.pdf](https://www.epa.gov/system/files/documents/2021-11/proposal-ria-oil-and-gas-nsps-eg-climate-review_0.pdf). January 31, 2022.

and not the benefit cost analysis conducted under the December 2022 Supplemental Proposal RIA. With regards to the comment on the EPA's use of a discount rate of 3 percent in BSER analyses as being optimistic, the EPA agrees that it is optimistic in the short term due to increases in producer prices driven by external factors. However, the BSER analyses conducted for NSPS OOOOb affected facilities and EG OOOOc designated facilities use a discount rate of 7 percent (and sometimes 3 percent along with 7 percent) when estimating the capital recovery cost component of the annual cost of equipment considering the life of the equipment. The use of 7 percent is reasonable from a long-term perspective of 10 to 15 years, which is generally the number of years assumed for equipment life in analyses.

In response to comment that the EPA's assumption of a natural gas price at \$3.13/mcf (the average price for 2022) was not reasonable given the rapid rise in energy prices, the EPA disagrees. While the natural gas price may be volatile, from a long-term perspective, this estimate was and is reasonable to use in BSER analyses. It is important to note, however, that while the \$3.13/mcf<sup>107</sup> was used in differing BSER analyses to represent the price of natural gas when calculating the natural gas cost savings that would be associated with various regulatory options, the calculated gas savings estimates illustrate the benefits of varying regulatory options being considered but are not used as a sole determinant of what constitutes BSER. Notably, this offset does not apply where the owner or operator does not own the gas and would not likely realize the monetary value of the natural gas saved (*e.g.*, transmission stations and storage facilities).

Comment: Commenter (0808-API) recognizes the importance of including the potential impacts of climate change in the RIA. When performing a benefit-cost analysis as part of a RIA, the commenter notes that the EPA is justified in applying an estimate of the value of the impacts of a regulation to reduce GHGs. This is especially true in a regulation which has as its primary purpose the reduction of GHGs. As noted in OMB Circular A-4 (2003), the commenter states that monetization of as many impacts as possible, and especially those central to the regulation, is essential to a properly conducted benefit-cost analysis.<sup>108</sup> However, the commenter recommends that specific care be taken when using the social cost of methane estimates (SC-CH<sub>4</sub>) as an input to the RIA. Per the recommendations of the National Academies of Science, Engineering and Medicine (NASEM) in their 2017 review of the social cost of carbon estimates (SCC),<sup>109</sup> the commenter suggests that the social cost estimates be presented with a full discussion of the uncertainties associated with the development and presentation of those estimates. The commenter notes that the 2021 November proposed rule RIA describes some of the uncertainties well and includes a presentation of the frequency distributions used to generate the social cost estimates. However, according to the commenter, there are some issues that have not been addressed, including the inability to use a consistent set of socioeconomic and

emissions scenarios to generate both the social cost estimates and other benefits and costs associated with the regulation, and a consistent application of discount rates.

Response I-20-13: As mentioned in the previous response, EPA presented a set of updated social cost of greenhouse gas (SC-GHG) estimates in sensitivity analysis in the 2022 Supplemental RIA that address recommendations of the National Academies of Sciences, Engineering, and Medicine (2017), and invited public comment on the sensitivity analysis and on the technical report, titled *External Review Draft: Report on the Social Cost of Greenhouse Gases: Estimates Incorporating Recent Scientific Advances*, explaining the methodological updates that was included as Supplementary Material to the RIA. The EPA is using the updated SC-GHG estimates in the Final RIA and is responding to the public comments received regarding these estimates (including comments received from this same commenter (API) in the Appendix of this RTC.

### *Opposition for Use of IWG Recommended Interim SC-GHG Estimates*

Comment: Commenters (0910-AGKY, 0824-WDEQ) state that the Methane Notice relies extensively upon the SC-GHG estimates in analyzing the costs and benefits of the EPA's new approach. The commenters contend that these estimates are fundamentally flawed and at odds with the CAA.

Commenter (0910-AGKY) contends that, reliance on the SC-GHG estimates in any form would render any new rulemaking arbitrary and unlawful. Below is support that they provide for their contention:

- The IWG can point to no statutory authority whatsoever authorizing it to promulgate the SC-GHG. This is a major rule if there ever was one, so it can only be promulgated based on specific statutory authority and in compliance with the APA's processes. But the only statutory authorities addressing the issue expressly preclude consideration of global effects.
- The SC-GHG estimates break with decades of best regulatory practice; in particular, they jettison Circular A-4 (2003)'s domestic-effects focus and discount-rate range for no good reason.
- The estimates fail to account for significant state interests in cooperative federalism regimes and the harm they will cause to the States and their citizens.
- The IAMs underlying the SC-GHG estimates are inherently flawed and weighted toward a particular outcome.
- The Obama Administration's SCC estimates have been flawed from their inception. The administration rejected and ignored public comments on the underlying models and announced it would delay substantive revisions in response to public comment until the National Academy of Sciences (NAS) finalized its recommendations. But such substantive revisions were never made. Yet even the paltry public input the Administration allowed revealed fatal flaws in the Estimates and the underlying IAMs.
- The Obama Administration never clearly identified the statutory authority for the SC-GHG. Though a Ninth Circuit opinion prompted it to come up with some measure of costs from carbon, the Administration failed to look to the law to determine the scope of those costs.

Commenters suggest that, if the Administration had looked at the law, it would have noted Congress's consistent preclusion of the consideration of global benefits.

- Experts note the sheer arbitrariness of the IAMs underlying the SCC estimates. These models rest on a three-hundred-year time horizon, meaning they purport to predict political, technological, economic, social, and geopolitical developments three centuries into the future. Other commentors note the SCC estimates rest on flawed and arbitrary damage functions: "These damage functions translate variables, such as projected sea level rise, to estimated economic damages. By their nature, we know very little about the correct functional form of damage functions." In fact, the commenter notes that even the Obama Administration's DOE noted that the SCC was not ready for prime time but continued to implement it anyway. To Louisiana's knowledge, no other regulatory tool rests on such uncertainty and guesswork.
- The commenter notes the sheer uncertainty of the SCC estimate caused by the IWG's break with the Executive Branch's longstanding approach to discount rates. They contend that the IWG arbitrarily jettisoned the longstanding 7 percent discount rate and employed an entirely new spectrum going as low as 2.5 percent and even encouraging agencies to depart downward.
- The IWG's process fails key good-government transparency standards such as personnel involved and whether outside consultants participated. The commenter states that such failures violate longstanding OMB regulatory-integrity guidelines. They add that it appears that history is repeating itself in the present process.
- According to the commenter, the failings of the Obama IWG's enterprise can perhaps best be seen by recognizing the agencies that used the SCC estimates: only those that had to follow them used the SCC estimates. Traditionally independent agencies—who were not compelled to use the SCC estimates—recognized the estimates' flaws and chose not to use them.

Commenter (0910-AGKY) reports that the Biden Administration picked up where the Obama Administration left off in 2016. Per EO 13990, the IWG produced the SC-GHG estimates that are the subject of this comment period. According to the commenter, the SC-GHG estimates are inherently flawed for several independent reasons:

- The SC-GHG estimates ignore and contravene the law. The SC-GHG estimates are not authorized by, and directly conflict with, the law. Like the Obama IWG, the Biden IWG has not been able to point to statutory authorization for the SC-GHG estimates. This failure is particularly egregious given the national importance of the SC-GHG calculations. Yet the IWG cites no authority for its unprecedented approach to regulatory practice that will impose hundreds of billions or trillions of dollars in regulatory costs on the U.S. economy in future years and decades and fundamentally transform American life. If Congress wishes to authorize the President to implement sweeping new costs for GHGs—and test the limits of the nondelegation doctrine, the Commerce Clause, and the Tenth Amendment—it must do so clearly. The IWG's silence on statutory authority is deafening.
- The SC-GHG estimates' political, regulatory, and constitutional implications but were never subject to robust and independent notice and comment process. This meager comment period is not sufficient to cure this defect because agencies have already taken significant actions in reliance upon the 2021 SC-GHG Estimates. But the SC-GHG Estimates don't just exceed congressional authorization—they are specifically prohibited by several discrete statutes.

- First, as discussed above, the Estimates cannot be reconciled with the CAA. When Congress addresses global effects in the CAA, it does so through specific procedures outside of the domestic regulatory process, which remains focused exclusively on domestic effects.
- The estimates' global focus contravenes the Energy Policy and Conservation Act (EPCA). EPCA is structured to "increase domestic energy supplies and availability; to restrain energy demand; to prepare for energy emergencies; and for other purposes." EPCA's structure buttresses this domestic focus; it specifically authorizes the Secretary of Energy to consider international effects only in limited circumstances that have nothing to do with domestic regulation. When Congress wishes for agencies to consider international effects, it does so explicitly. It has not done so in EPCA, which retains its domestic-only focus.
- The National Environmental Policy Act's (NEPA) explicit domestic focus leaves no room for the SC-GHG Estimates' consideration of global effects. The Council on Environmental Quality's (CEQ) binding NEPA implementation regulations also preclude the SC-GHG's use of highly uncertain models to predict the effects of GHGs hundreds of years into the future. As CEQ's regulations instruct—and the Supreme Court has held—agencies must consider only effects that are "reasonably foreseeable" and bear a "reasonably close causal relationship" to the proposed action, "analogous to proximate cause in tort law." This proximate-cause standard is fundamentally at odds with the expansive approach embedded in the SC-GHG Estimates. But the IWG does not acknowledge the existence of CEQ's standard, or that it is compelling agencies to use a fundamentally different causation standard when calculating environmental effects for cost/benefit purposes than the standard they must use when calculating the same effects under NEPA.
- The SC-GHG Estimates are fundamentally incompatible with the Outer Continental Shelf Lands Act (OCSLA), which was enacted and then amended to "achieve national economic and energy policy goals, assure national security, reduce dependence on foreign sources, and maintain a favorable balance of payments in world trade." 43 U.S.C. §1802(1); By inevitably restricting the number of parcels that will be made available in OCSLA sales, and making it harder to obtain drilling permits, the Biden SC-GHG Estimates contravene the Secretary of the Interior's duty to make the Outer Continental Shelf "available for expeditious and orderly development, subject to environmental safeguards, in a manner which is consistent with the maintenance of competition and other national needs.
- This systematic clash with statutory authority is particularly damaging due to EO 13990's mandatory command directing agencies to employ the SC-GHG Estimates. Indeed, agencies followed the Obama Administration's mandatory command rather than considering whether the IWG's values conflicted with statutory factors: Perhaps emboldened by [the IWG's] general dismissal of statutory constraints, agencies using the globally scoped SCC have appeared to ignore the question of statutory authority entirely. There is no reason to expect that agencies will respond differently to the Biden Administration's mandatory command.
- According to the commenter, the IWG's SC-GHG estimates represent an emphatic break from time-tested Executive Branch regulatory best practices. The Estimates first break best practice in that the IWG has never adequately justified its use of a global rather than domestic scope in calculating costs. And second, the IWG breaks from decades of Executive Branch practice regarding discount rates. The IWG fundamentally alters this longstanding practice without a reasoned justification. Circular A-4 (2003) explains that the 7 percent discount rate is essential to reasoned cost/benefit analysis.

- The SC-GHG estimates ignore the substantial reliance interests that have reasonably grown up around decades of regulatory practice. The Methane Notice ignores decades of specific reliance on the EPA's prior approach to regulating Methane. But the SC-GHG Estimates also ignore several other reliance interests. IWG ignores the significant federalism costs caused by the SC-GHG Estimates. Despite this clear directive, the IWG nowhere considers that the higher SC-GHG Estimates will encroach on the States' traditional police power. The SC-GHG Estimates fail to consider the muddled and conflicting standards and implementation costs imposed upon the States by its fundamental shift in methodology. For example, States must comply with federal standards in programs such as the National Ambient Air Quality Standards (NAAQS), 42 U.S.C. §7410. Because these NAAQS are now required to be set based on the IWG's SC-GHG Estimates, states must employ the estimates or their state implementation plans (SIP) will be disapproved. And if a SIP is disapproved by the EPA, the EPA must impose a federal implementation plan (FIP)—which must be based upon the SC-GHG Estimates—upon the State. This harm is far from speculative—the EPA has already published a final rule relying on the Biden SC-GHG Estimates to impose more stringent NAAQS good-neighbor FIPs on several Plaintiff states including Louisiana, Kentucky, and Texas.
- IWG neglected to consider the effects the SC-GHG estimates will have upon state revenue. states stand to lose millions immediately—and billions in the long run—in revenue because of the SC-GHG Estimates. This constitutes yet another important aspect of the problem that the IWG failed to recognize. As clear from the Methane Notice, States will also be required to shoulder increased regulatory costs. The States' economic well-being, statutorily conferred role in cooperative federalism programs, and reliance upon existing regulatory practices are important aspects of the problem. Yet the IWG acted as if the States do not exist.
- The commenter posits that the IAMs are irremediably flawed and fail to account for positive externalities. The IAMs themselves, and the process used to produce the Estimates from their disparate results, demonstrate the fundamental flaws. Some of the equations that go into IAMs— especially the damage functions and the long and unpredictable timeframes that are patently absurd and depart from best regulatory practice. As experts have explained, the models rest more on science fiction than the best available science.
- The estimates also fail to consider the positive externalities of energy production. The Working Group arbitrarily focused only upon energy production's negative aspects without considering the benefits affordable energy has on economic development, social welfare, economic and energy independence, and international peace. Instead, it continued to rely upon IAMs that arbitrarily refuse to consider potential benefits from a warming climate.
- Both the IWG and the underlying models also demonstrate their bias by systematically refusing to consider the economic and health benefits, indicating a determination to bend science to a particular policy outcome.
- The method by which IWG uses these flawed models is equally arbitrary. Each model produces different SC-GHG values. Instead of accounting for the relative flaws and strengths of each model, the Biden IWG (like the Obama IWG) simply averages the SC-GHG values produced by these models to reach the definitive SC-GHG Estimates that agencies must follow. The SC-GHG Estimates are a simple average of three flawed models—nothing more. It is hard to imagine a more arbitrary process.

According to the commenter (0910-AGKY), the entire SC-GHG is driven by out of date, arbitrary, and politically biased models that purport to know how human society will look in the year 2300.

Commenter (0824-WDEQ) states that the proposed rule's consideration of the social cost of methane is not in line with the actual costs that are associated with methane emission reductions. And, on the other side of the cost benefit analysis, the proposed rule would have immense economic impacts upon Wyoming's economy that simply are not considered quantitatively or qualitatively in the 2021 November proposal RIA. Oil and gas severance taxes and royalties contribute funding to state highway and county road construction and maintenance; water projects; local governments; school districts, scholarships, and the University of Wyoming and community colleges; and state-government agencies. Combined, oil and natural gas brought in more than \$372,000,000 in severance taxes for the state coffers during fiscal year 2021.<sup>110</sup> This also extends to the direct and indirect employment of tens of thousands of workers. In 2019, when Wyoming oil production was at an all-time high, these oil and gas extraction and support workers received upwards of \$1.1 billion in total wages to spend in their communities.

According to the commenter (0824-WDEQ), the EPA's methodologies for calculating the social cost of methane in the proposed rule overstate societal benefits, while significantly underestimating the immense costs associated with implementation of the rule for state regulatory agencies, regulated entities, and entire state economies. The commenter recommends that EPA start over-using a realistic predictor of the actual costs and benefits resulting from the proposed rule. When it does, the commenter (Wyoming Department of Environmental Quality (WDEQ)) states that it is confident that the costs of the proposed rule will substantially outweigh its benefits.

Response I-20-14: The commenters contend that the reliance of SC-GHG estimates render any new rulemaking arbitrary and unlawful. Within this final rule, EPA updated the SC-GHG estimates from the Final SC-GHG Report. EPA believes that the Final Report of the SC-GHG represents the latest available science and follows the recommendations of the National Academies of Science, Engineering, and Medicine. Please refer to the RTC Appendix for detailed responses pertaining to the rigor of the updated methodology, including the discounting approach, and responses pertaining to the global focus of the SC-GHG estimates. The EPA disagrees with commenter's (0824-WDEQ) assertion that the rule would have immense economic impacts on Wyoming's economy. In the EPA's assessment of impacts on overall oil and natural gas production, it estimated that the reduction in U.S. oil production would be approximately 1.05% or less, while the reduction in gas production would be approximately 0.75% or less. The commenter provides a high-level overview of the economic impact of the oil and natural gas industry on Wyoming's economy but fails to provide specific evidence of how the rule would have a significant impact on the state beyond generic claims. Relatedly, the EPA disagrees with commenter's (0824-WDEQ) assertion that it significantly underestimates the costs associated with the rule. Beyond generic summary statistics of baseline conditions, commenter provides no supporting data or analysis for its claim regarding regulated entities and

---

<sup>110</sup> Wyoming State Geological Survey, Erin A. Campbell, Director, and State Geologist, "Oil & Natural Gas Resources in Wyoming," January 2022 Summary Report.

state economies. With respect to implementation costs for state agencies, see Volume I, Chapter 21, Response I-21-9 of this RTC document.

Comment: Commenter (0921-USCC) supports appropriate consideration of GHG emissions and social cost estimates as part of the cost-benefit analyses for regulatory actions required under the EO 12866 only after the IWG on the SC-GHG develops durable SC-GHG estimates that are established through a robust science, economic, and stakeholder engagement process.<sup>111</sup> Through the process mandated by EO 13990, the discount rates that underpin the SC-GHG are being revised and will substantially affect how those standards ultimately get finalized.<sup>112</sup> A recent brief filed by the Department of Justice (DOJ) in litigation challenging the interim SCC estimates suggested that the IWG will propose revised final SCC estimates in the spring of 2022, and that the public will be given an opportunity to comment.<sup>113</sup> The commenter recommends that EPA allow the process of the IWG to conclude and should then conduct a further robust notice and comment process before finalizing the cost-benefit analysis relating to this Proposal. An open public process is critical to public trust in scientific information, analysis, and its real-world application. The commenter adds that any reliance on SC-GHG estimates as currently published should proceed cautiously, as the federal government's SC-GHG estimates are all under review and subject to change.

Commenter (0921-USCC) suggests that EPA, in its cost-benefit analysis for the methane regulation, continue to follow longstanding requirements and principles that apply to the development of such analyses and should treat the SC-GHG estimates with appropriate caution, as these estimates are not yet final and are not appropriately reliable at this time.<sup>114</sup> The EPA's RIA for the 2021 November proposal makes a number of assumptions that feed into the monetized benefits and costs associated with the rule (e.g., climate benefits, compliance costs, and value of product recovery generated by the capture of natural gas). The EPA should carefully consider how it applies the estimates so as not to prejudge, or create problematic inconsistencies with, the outcomes of the IWG process, which we now know is expected to be a more thorough evaluation of the SC-GHG estimates. Through the process to revise the SC-GHG estimates, the commenter suggests that the IWG has an excellent opportunity to establish sound estimates

<sup>111</sup> See U.S. Chamber of Commerce et al., Comments on Notice of Availability and Request for Comment on the "Technical Support Document: Social Cost of Carbon, Methane, and Nitrous Oxide Interim Estimates Under Executive Order 13990" (June 21, 2021); see also U.S. Chamber of Commerce et al., Comments on "Certification of New Interstate Natural Gas Facilities (Docket No. PL18-1-000)" (May 26, 2021).

<sup>112</sup> See Memorandum for the Heads of Executive Departments and Agencies, "Modernizing Regulatory Review, January 20, 2021, 86 Fed. Reg. 7223 (Jan. 26, 2021), which amongst other matters directs the Office of Management and Budget ("OMB") to recommend ways to revise OMB's 2003 Circular A-4, Regulatory Analysis – a document detailing best practices for measuring costs and benefits by federal agencies – so that the new circular "fully accounts for regulatory benefits that are difficult or impossible to quantify." See also IWG on Social Cost of Greenhouse Gases "Technical Support Document: Social Cost of Carbon, Methane, and Nitrous Oxide Interim Estimates under Executive Order 13990, United States Government" (Feb. 2021), 86 Fed. Reg. 24,669 (May 7, 2021). SC-GHG estimates are commonly calculated using economic models known as IAMs to translate a marginal increase in emissions into a future physical climate response and then into a subsequent economic impact. A discount rate is applied to convert future damages into present-day value. Key considerations in calculating SC-GHG estimates include the geographic scope, discount rate, and IAM used (as well as the model's assumptions, many of which are user-defined).

<sup>113</sup> Def. Supp. Br., 23, *La. v. Biden*, No. 2:21-cv-01074 (W.D. La. Jan. 21, 2022).

<sup>114</sup> See Opposition of U.S. Dep't of Justice Motion for Preliminary Injunction, *Louisiana v. Biden*, No. 2:21-cv01074-JDC-KK (W.D. La. Sept. 1, 2021), ECF No 68.

based on the best available, peer-reviewed science. The Chamber wants to assist the IWG in this regard as this process continues.<sup>115</sup> The commenter further recommends that EPA's supplemental methane proposal allow for the IWG process to conclude and should utilize the full outcome of the IWG process in an updated cost-benefit analysis for the Proposal.

Commenter (0763-TCEQ) believes the EPA's use of the interim estimates for the social cost of methane (SC-CH<sub>4</sub>) in the 2021 November proposal RIA, as directed under EO 13990, for the proposed rule is illegal. The commenter (0763-TCEQ) states that the SC-CH<sub>4</sub> interim estimates are central to the EPA's RIA for this proposed rulemaking. However, the interim values themselves have not been subject to scrutiny outside the IWG through a notice and comment proceeding as required under the federal Administrative Procedures Act (APA). The commenter contends that the EPA cannot use a metric so integral to its rulemaking action that has not been available to the public, is not a final agency action subject to judicial review, and that by its own admission is subject to change before this proposal is final.

Response I-20-15: The interim SC-GHG estimates recommended by the IWG in February 2021 and used in the primary benefit-cost analysis in both the November 2021 Proposal RIA and the December 2022 Supplemental Proposal RIA are the same as the values developed by the IWG prior to the group being disbanded in 2017, adjusted for inflation. Those estimates were subject to public comment in a dedicated OMB led public comment period in 2013 and in the context of dozens of EPA proposed rulemakings that used the estimates. The EPA responded to the comments received within final rulemakings that used the estimates. In addition, the public has had opportunity to comment on the interim IWG estimates following their use in EPA regulatory analyses for numerous proposed rulemakings published since the release of the February 2021 TSD, including in the November 2021 Proposal RIA and the December 2022 Supplemental Proposal RIA.

EPA presented a set of updated SC-GHG estimates in sensitivity analysis in the 2022 Supplemental RIA that address recommendations of the National Academies of Sciences, Engineering, and Medicine (2017), and invited public comment on the sensitivity analysis and on the technical report, titled *External Review Draft: Report on the Social Cost of Greenhouse Gases: Estimates Incorporating Recent Scientific Advances*, explaining the methodological updates that was included as Supplementary Material to the RIA. The EPA is using the updated SC-GHG estimates in the Final RIA and is responding to the public comments received regarding these estimates and their development in the Appendix of this RTC.

#### 20.2.3.2 Use of Global vs. Domestic Values for Social Cost of Methane (SC-CH<sub>4</sub>)

Comment: Commenters (0577-KIOGA, 0763-TCEQ, 0797-ND DEQ/ND IC, 0802-Kraken Oil & Gas, 0921-US Chamber of Commerce) disagree with EPA's approach for using the global social cost of methane (SC-CH<sub>4</sub>). Commenters (0577-KIOGA; 0802-Kraken Oil & Gas; 0797-ND DEQ/ND IC) recommend that EPA use domestic SC-CH<sub>4</sub> values instead.

---

<sup>115</sup> See U.S. Chamber of Commerce et al. Comments on Notice of Availability and Request for Comment on the "Technical Support Document: Social Cost of Carbon, Methane, and Nitrous Oxide Interim Estimates Under Executive Order 13990" (June 21, 2021), pp. 5-6.

Commenter (0763-TCEQ) states that, in the 2021 November proposal RIA, the EPA uses a SC-CH<sub>4</sub> metric that significantly overestimates the benefits and underestimates the costs of regulating methane from this industrial sector of the U.S. economy. The EPA applied its SC-CH<sub>4</sub>, based on global climate impacts, to the methane emission reductions expected from this proposed rule and came up with, for example, an average benefit yield of \$190 million in 2023 increasing to \$4.8 billion in 2035 (based on a 3% discount rate). By comparison, estimating SC-CH<sub>4</sub> using climate impact/damages only within the U.S. yields a climate benefit of \$25 million in 2023 and \$920 million in 2035. This is a significant reduction in benefits when looking at only impacts within the U.S. from a regulation that affects only U.S. sources.

The commenter (0763-TCEQ) adds that the EPA fails to adequately explain why estimating climate benefits or impacts that may occur internationally to U.S. citizens' health and welfare are readily available and accurately ascertainable. The commenter explains that this rulemaking impacts only the U.S. oil and gas industry emissions, but the EPA claims an accurate assessment of total climate damages must account for impacts outside the U.S. However, the commenter adds that the EPA only assumes that this regulation will have "spillover effects" (2021 November proposal RIA, p. 315, Table 3-4, fn b) on mitigation efforts elsewhere in the world. ("In addition, assessing the benefits of the U.S. GHG mitigation activities requires consideration of how those actions may affect mitigation activities by other countries, as those international mitigation actions will provide a benefit to U.S. citizens and residents by mitigating impacts that affect U.S. citizens and residents." (2021 November proposal RIA, p. 3-9)) According to the commenter, the EPA provides no evidence that these international actions are likely to occur in the future. And yet, the EPA also agrees with the IWG's claim in its TSD that estimating climate benefits occurring solely within the U.S. are more subject to uncertainty or underestimation, arguing that the lower climate benefits from looking only within the U.S. were only an "approximation."

Commenter (0802-Kraken Oil & Gas) states that contrary to the intent of "Actions Concerning Regulations That Significantly Affect Energy Supply, Distribution or Use" under EO 13211, 2021 November proposed actions are based on a fundamentally flawed cost-benefit analysis by comparing global benefits of methane emissions reductions with domestic cost of compliance, thereby skewing the balance in favor of the benefits of the proposed actions for NSPS OOOOa, NSPS OOOOb, and EG OOOOc. The commenter states that the significant cost of carbon difference (i.e., the global SC-CH<sub>4</sub> is \$51/ton and the US SC-CH<sub>4</sub> is \$7/ton) creates an unbalanced regulatory cost-benefit analysis, a fundamentally flawed GHG emission calculation basis, which in turn leads to overstated domestic GHG emissions, more GHG emissions than would result in the absence of regulation, and EPA making regulatory decisions to restrict domestic activity based on a global calculation basis. The commenter further states that the EPA does not have any basis in the CAA that would allow this comparison. The commenter cites to Western Energy Alliance (WEA) comments on "Technical Support Document: Social Cost of Carbon, Methane, and Nitrous Oxide Interim Estimates Under Executive Order 13990" (submitted June 21, 2021, via Regulations.gov) in which WEA reiterated the purpose of the CAA regarding determining the impact from proposed rulemaking actions.

A focus on domestic impacts only also aligns well with the principles laid out in the Clean Air Act. In section 101(b)(1) of the Clean Air Act, for example, Congress wrote that the purpose of the Act is to "protect and enhance the quality of the Nation's air

resources so as to promote the public health and welfare and productive capacity of its population.” This language has led to interpretation used by multiple agencies that the Clean Air Act is limited to covering impacts and benefits of regulation domestically.

Commenter (0921-US Chamber of Commerce) states that EPA’s cost-benefit analysis should be completed only after the IWG on the SC-CH<sub>4</sub> develops durable SC-CH<sub>4</sub> estimates that are established through a robust public stakeholder engagement process.

Commenter (0797-ND DEQ/ND IC) states that EPA’s SC-CH<sub>4</sub> calculations (and the output of the calculations) are entirely speculative, and that EPA is lacking in jurisdiction and expertise to attach a global cost to U.S. methane emissions. According to the commenter, relying on “global benefits” to justify the domestic costs of the 2021 NSPS Proposal is arbitrary and capricious and contrary to law, as decided in *Wyoming vs. Jewell*, the commenter states. The commenter states that the 2021 November proposal RIA provided by EPA does not attempt to calculate the domestic benefits of the 2021 NSPS Proposal, and calculates benefits based solely on alleged global benefits. Even assuming that the SC-CH<sub>4</sub> can be estimated with any reasonable degree of accuracy, the commenter argues, the global estimates can be over 20 times higher per ton of carbon emissions than the equivalent domestic estimates. The commenter suggests that, to adequately justify the 2021 NSPS Proposal, EPA must break out the domestic versus global carbon benefits of the proposal, as was done in the RIA for the 2020 rule. The commenter contends that, until EPA does so, the EPA has not supported this proposed rule with a single dollar arising from a specifically identified benefit accruing to U.S. citizens associated with the reduced methane emissions claimed for this proposal.<sup>116</sup>

Conversely, other commenters (1267-CA, 0804-EDF et al) support the use of the global estimates for SC-CH<sub>4</sub>.

Commenter (1267-CA) states that EPA is not precluded from considering the interim value for the SC-CH<sub>4</sub> established by the IWG, by the major questions doctrine or any other legal doctrine. The commenter explains that EPA’s use of the SC-CH<sub>4</sub> to assess the benefits and impacts of the rule is well within the scope of EPA’s authority to consider the costs and benefits of its actions. The commenter explains that on a handful of occasions, the Supreme Court has invalidated agency regulations on the ground that they, in the Court’s view, far exceeded the agency’s statutory authority, and thus crossed into the realm of legislative policy-making.<sup>117</sup> In these cases, the commenter summarizes that the Court determined that the agencies had made an error

---

<sup>116</sup> In citing to *Wyoming vs. Jewell*, the commenter summarizes that “EPA cannot rely on purported benefits that might accrue to citizens outside the United States to justify the imposition of burdens on the citizens of the United States” and that “EPA cannot evade that judicial determination with vague and unquantified references to the effect that climate change impacts occurring outside of U.S. borders might affect the welfare of U.S. citizens by affecting tourism or “spillover pathways” such as economic or political destabilization”; Social Cost of Carbon, Identifying a Federal Entity to Address the National Academies’ Recommendations Could Strengthen Regulatory Analysis, GAO 20-245 (June 2020); Regulatory Impact Analysis for the Proposed Emission Guidelines for Greenhouse Gas Emissions from Existing Electric Utility Generating Units, Revisions to Emission Guideline Implementing Regulations, Revisions to New Source Review Program at Chapter 7, Section 7.3 (Forgone Global Climate Benefits).

<sup>117</sup> *Utility Air Regulatory Group v. EPA*, 573 U.S. 302, 324 (2014); *FDA v. Brown & Williamson Tobacco Corp.*, 529 U.S. 120, 159-60 (2000); *MCI Telecommunications Corp. v. AT&T*, 512 U.S. 218, 231 (1994).

of kind, not just degree, by crossing specific statutory lines Congress had drawn.<sup>118</sup> The commenter explains, however, that nothing in those cases prohibits an agency, when acting within a clear delegation of statutory authority,<sup>119</sup> to consider the costs and benefits of its action using a well-established, scientifically sound analytical tool such as the SC-CH<sub>4</sub>.<sup>120</sup> The commenter believes that the SC-CH<sub>4</sub> is an important analytical tool that is used by agencies to translate certain impacts of GHG-emitting actions that they may consider into dollars and this dollar figure can then be compared to other projected costs or benefits to better inform agency decision-making. The commenter believes this cost-benefit analysis is consistent with CAA section 111, which instructs EPA to consider “cost” as well as “non air quality health and environmental impact[s]” when evaluating the BSER.<sup>121</sup> According to the commenter (1267-CA), this approach is also consistent with longstanding administrative practice: citing to EOs and White House guidance documents which have, for decades and across Presidential administrations, instructed agencies to “use the best available techniques to quantify anticipated present and future benefits and costs as accurately as possible.”<sup>122</sup> The commenter cites to the Supreme Court which stated that “[c]onsideration of cost reflects the understanding that reasonable regulation ordinarily requires paying attention to the advantages and the disadvantages of agency decisions.”<sup>123</sup> Further, the commenter argues, agencies across the federal government, as well as state agencies and local governments, have incorporated some form of SC-CH<sub>4</sub> for years now, resulting in an increase in the rationality of agency decision-making, not the imposition of any unwarranted economic harm. The commenter believes that an evaluation of the cost and benefits of an agency action that will impact methane emissions that does not use the SC-CH<sub>4</sub> would be woefully incomplete.<sup>124</sup>

Moreover, the commenter (1267-CA) states, the SC-CH<sub>4</sub> does not dictate the outcome of any specific agency rulemaking, including this one. In the proposal, the commenter understands that while EPA considers the SC-CH<sub>4</sub> in evaluating the costs and benefits of the proposed rule (as it must), nowhere does the agency suggest that those values were used to determine the BSER for the oil and natural gas sector, or that they will be determinative of its ultimate decision to promulgate the rule. The commenter believes that approach is consistent with CAA section 111, which directs EPA to take costs “into account,” but does not require EPA to precisely balance

---

<sup>118</sup> *UARG*, 573 U.S. at 325 (the commenter summarizes the Court rejected EPA’s decision to “rewrite[e] unambiguous statutory terms”); *Brown & Williamson*, 529 U.S. at 141 (the commenter states the Court said that FDA’s regulation of tobacco would be “incompatible with” other statutory provisions).

<sup>119</sup> 42 U.S.C. § 7411.

<sup>120</sup> *Biden v. Missouri*, Case Nos. 21A240 & 21A241, Slip Op. at 6 (Jan. 13, 2022) (per curiam) (the commenter summarizes the case upheld the vaccine mandate for healthcare workers promulgated by the Department of Health and Human Services because it was consistent with “longstanding practice” of agency to impose conditions necessary to “address the safe and effective provision of healthcare”).

<sup>121</sup> 42 U.S.C. § 7411(a)(1).

<sup>122</sup> Improving Regulation and Regulatory Review, EO 13563 § 1(c), 76 Fed. Reg. 3821 (Jan. 18, 2011); accord Regulatory Planning and Review, EO 12866 §§ 1, 6(a)(3)(C), 58 Fed. Reg. 51735 (Oct. 4, 1993) (the commenter states this requires agencies to assess “all costs and benefits” of regulatory actions and alternatives, including “quantifiable measures[] to the fullest extent that [they] can be usefully estimated”); OMB, Circular A-4: Regulatory Analysis at 2, 18 (2003) (the commenter states Circular A-4 instructs agencies that expression of “potential real incremental benefits and costs” of their actions “in monetary units” provides “useful information for decision makers and the public”).

<sup>123</sup> *Michigan v. U.S. Env’t Prot. Agency*, 576 U.S. 743, 753 (2015).

<sup>124</sup> *Michigan*, 576 U.S. at 752 (the commenter states that “‘cost’ includes more than the expense of complying with regulations; any disadvantage could be termed a cost.”); *Center for Biological Diversity*, 538 F.3d at 1200-1201.

costs against benefits before promulgating a CAA section 111 regulation. Indeed, the commenter states, the 2021 November proposal RIA also evaluates several “non-monetized benefits” and that the SC-CH<sub>4</sub> is simply one additional tool for monetizing some of the benefits of a regulation that would otherwise be non-monetized, not a thumb on the scale of agency cost-benefit analyses.<sup>125</sup>

Finally, the commenter (1267-CA) states that none of the cases upholding federal environmental reviews that declined to use the SC-CH<sub>4</sub> demonstrate that the SC-CH<sub>4</sub> cannot be employed by federal agencies. The commenter cites by way of example, *EarthReports, Inc. v. FERC*, where the D.C. Circuit held only that FERC was not required to use the SC-CH<sub>4</sub>, based on the specific record before it, but did not suggest FERC was barred from using the SC-CH<sub>4</sub>.<sup>126</sup>

Commenter (0804-EDF et al) states that EPA should rely on legal requirements under the CAA, the NEPA, the APA and other key sources of law that not only permit, but in fact require EPA to consider national effects. The commenter states that section 111 of the CAA charges EPA with regulating “air pollution which may reasonably be anticipated to endanger public health or welfare,” where “welfare” is defined to include “effects on . . . weather . . . and climate.” When interpreting similar language in section 202 of the CAA, the commenter summarizes, the Supreme Court found “there is nothing counterintuitive to the notion that EPA can curtail the emission of substances that are putting the global climate out of kilter.” The commenter cites to another case, when industry challenged another EPA climate program under Title I of the CAA, by arguing that the statute “was concerned about local, not global effects.” The commenter summarizes that the U.S. Court of Appeals for the D.C. Circuit had “little trouble disposing of Industry Petitioners’ argument that the [CAA’s prevention of significant deterioration] program is specifically focused solely on localized air pollution,” finding instead that the statute was “meant to address a much broader range of harms,” including “precisely the types of harms caused by greenhouse gases.”<sup>127</sup>

The commenter (0804-EDF, et. al.) also draws on statements from environmental and administrative law scholar Richard Revesz. According to the commenter, Mr. Revesz has exhaustively reviewed the legislative history of the CAA’s definition of “welfare” and has concluded that “when Congress included the ‘effects on . . . climate’ language in the statute, it understood that adverse climate effects could occur on a global scale.” The commenter provides statements from U.S. senators, by way of example and concludes that Congress’s clear concern

<sup>125</sup> 42 U.S.C. § 7411(a)(1); *Portland Cement Ass’n v. Train*, 513 F.2d 506, 508 (D.C. Cir. 1975) (the commenter summarized that although EPA conceded that relating costs of section 111 standard to benefits was “practical impossibility,” industry failed to show it could not “adjust itself in a healthy economic fashion” to the rule).

<sup>126</sup> 828 F.3d 949, 956 (D.C. Cir. 2017).

<sup>127</sup> 42 U.S.C. § 7411(b)(1)(A); U.S.C. § 7602(h); *Massachusetts v. EPA*, 127 S. Ct. 1438, 1447 (2007); *Massachusetts*, 127 S. Ct. at 1461 (the commenter summarized that this case concerned section 202 of the CAA, which similarly permits EPA to regulate “any air pollutant . . . which may reasonably be anticipated to endanger public health or welfare”); *Id.* at 1454 (quoting 42 U.S.C. § 7521(a)(1)); *Coalition for Responsible Regulation v. EPA*, 684 F.3d 102, 137-38 (D.C. Cir. 2012), *aff’d in part, rev’d in part sub nom. Util. Air Regulatory Grp. v. EPA*, 134 S. Ct. 2427 (2014).

for the effects of domestic pollution on the global climate demonstrates that a global perspective is appropriate, if not required, when EPA regulates under the CAA.<sup>128</sup>

Regarding NEPA, the commenter (0804-EDF, et. al.) states that adopting a global perspective on climate damages will advance U.S. foreign policy goals, NEPA requires EPA to interpret all its laws, including the CAA, in ways that recognize the worldwide character of environmental problems; using global social cost of GHG estimates helps fulfill that requirement. The commenter states that the interpretation [that EPA must consider global impacts] is further compelled because NEPA much more broadly declares a national environmental policy and requires of all agencies that “to the fullest extent possible[,] the policies, regulations, and public laws of the United States shall be interpreted and administered in accordance with the policies set forth in this chapter,” including the need to “recognize the worldwide and long-range character of environmental problems” and to “lend appropriate support” to help “maximize international cooperation.”<sup>129</sup>

The commenter (0804-EDF et al) believes that other key legal commitments<sup>130</sup> compel this same conclusion.

---

<sup>128</sup> Richard L. Revesz, Bostock, and the End of the Climate Change Double Standard, 46 COLUM. J. ENV'T L. 1, 9 (2020); Senator Caleb Boggs, a Republican from Delaware and ranking minority member of the Public Works Subcommittee on Air and Water Pollution, which was considering the CAA in 1970, entered a report into the record stating that air pollution “alters climate and may produce global changes in temperature” and Senator Jennings Randolph of West Virginia likewise submitted a statement into the record explaining that U.S. air pollution could “produce unacceptable worldwide climate changes.” Id. at 32–33.

<sup>129</sup> 42 U.S.C. § 4332(1); Id. § 4332(2)(F); see also *EDF v. Massey*, 986 F.2d 528, 536 (D.C. Cir. 1993) (the commenter summarizes that “[s]ection 102(2)(F) further supports the conclusion that Congress, when enacting NEPA, was concerned with worldwide as well as domestic problems facing the environment...[c]ompliance with one of the subsections can hardly be construed to relieve the agency from its duty to fulfill the obligations articulated in other subsections”); *NRDC v. NRC*, 647 F.2d 1345, 1387 (D.C. Cir. 1981) (J. Robinson, concurring; J. Wilkey wrote for the Court, but there was no majority opinion) (the commenter summarizes that the Court concluded that even if a conflict with another statute prevents the agency from conducting an environmental impact statement, that “does not imply that NRC may ignore its other NEPA obligations,” including the “provision for multinational cooperation” and the “policy of the United States with respect to the ecological well-being of this planet”; rather, the agency “should remain cognizant of this responsibility”); *Greene County Planning Bd. v. Federal Power Comm’n*, 455 F.2d 412, 424 (2d Cir. 1972) (the commenter summarizes that the Court found “[t]he Commission’s ‘hands-off’ attitude is even more startling in view of the explicit requirement in NEPA that the Commission ‘recognize the worldwide and long-range character of environmental problems’ and interpret its mandate under the Federal Power Act in accordance with the policies set forth in NEPA”).

<sup>130</sup> See United Nations Framework Convention on Climate Change (Convention), S. Treaty Doc. No. 102-38; S. Exec. Rept. No. 102-55; U.N. Framework Convention on Climate Change art. 3(3), May 9, 1992, 1771 U.N.T.S. 107; see also id. art. 3(1) (the commenter summarizes that “[t]he Parties should protect the climate system for the benefit of present and future generations of humankind, on the basis of equity and in accordance with their common but differentiated responsibilities and respective capabilities”); id. art. 4(2)(a) (the commenter summarizes commitments by developed countries to adopt policies that account for “the need for equitable and appropriate contributions by each of these Parties to the global effort”); Id. art. 4(1)(f); see also id. art. 3(2) (the commenter summarizes the requirement of parties to give “full consideration” to those developing countries “particularly vulnerable to the adverse effects of climate change”); see also North American Agreement on Environmental Cooperation art. 10(7), Jan. 1, 1994, 32 I.L.M. 1480 (the commenter summarizes the commitment of the United States to the development of principles for transboundary environmental impact assessments); Comment Letter from U.S. Sens. Feinstein, Snowe, Nelson, Cantwell, Sanders, Kerry, Durbin, Reed, Boxer, & Cardin to Mary Peters,

Finally, the commenter (0804-EDF et al) examines requirements under APA, where the commenter states it is arbitrary and capricious for agencies to “entirely fail[] to consider an important aspect of the problem” - an obligation, the commenter states, a federal court held requires federal agencies to consider international climate impacts. The commenter summarizes that the court found that the global values developed by the IWG reflected “the best available science about monetizing the impacts of greenhouse gas emissions,” whereas “focusing solely on domestic effects has been soundly rejected by economists as improper and unsupported by science.” The commenter also cites to statements by the court that relevant executive orders, including Executive Order (EO) 12866, require consideration of “all” costs and benefits, based on the “best reasonably obtainable scientific, technical, economic, and other information,” and concluded that “no[] . . . regulatory rules or orders require exclusion of global impacts.” More recently, the commenter states, EO 13990 instructed agencies to “tak[e] global damages into account,” because “[d]oing so facilitates sound decision-making, recognizes the breadth of climate impacts, and support the international leadership of the United States on climate issues.”<sup>131</sup>

In addition to legal requirements under the CAA, NEPA, and APA, the commenter (0804-EDF et al) states that spillover impacts into the U.S. and transboundary resources also support the use of global damage valuations, as significant costs to trade, human health, and security will inevitably “spill over” to the U.S. as other regions of the planet experience climate change damages. According to the commenter, all these individual spillover effects can also interact and trigger feedback loops that will propagate additional spillover damages, according to the commenter. The commenter states that experts on SC-CH<sub>4</sub> have therefore concluded that, because the IAMs that underlie the IWG’s social cost valuations currently do not capture many of these key inter-regional costs, use of the global values can be further justified as a proxy for capturing all spillover effects. The commenter recommends that, in addition to the spillover effects that EPA already mentions, EPA should argue that transboundary spillovers, feedback loops, information spillovers, and other effects justify a focus on the full global values, either independently or in combination with other strategic and ethical considerations.<sup>132</sup>

Schwarcz, Systemic Risk, 97 *GEO. L.J.* 193, 249 (2008) (the commenter references the

The commenter (0804-EDF et al) makes related points that it is in the strategic interest of the U.S. to encourage all other countries to think globally in setting their climate policies and that the U.S. can advance this objective by itself adopting the full global social cost of GHGs. The commenter states, both empirical evidence and economic theory strongly support a strategic choice for U.S. agencies to adopt the full global estimates of the social cost of GHGs, as this facilitates international reductions in GHG pollution that directly benefits the U.S. The commenter urges EPA to provide current evidence of foreign reciprocity to further support its focus on the full global valuations of the social cost of GHGs. The commenter believes there already is evidence that the U.S. strategy of combining its domestic efforts, including the global valuation of climate damages, with its diplomatic engagement is spurring foreign reciprocity. Conversely, by failing to take international climate damages into account, the commenter states, EPA, and other U.S. agencies would incentivize other countries to do the same, which in turn would cause greater GHG pollution originating in other countries that causes climate damage within the U.S.<sup>133</sup>

relatives, ancestral homes, cultural and religious sites, and natural resources located abroad, and U.S. altruism toward the people, animals, and natural habitats across the globe.<sup>134</sup>

Commenter (0804-EDF et al) states that in instances where EPA discusses domestic climate impacts, EPA uses a flawed domestic-only values developed under the now revoked EO 13783 (the commenter states this was acknowledged by EPA in the recently published regulatory impact statement for the final vehicle emissions standards). The commenter states EPA should make clear (in this rule) that the values are arbitrary and invalid and should not be relied on. Further, the commenter states that EPA should consider conducting a sensitivity analysis using a more realistic domestic-only valuation of the social cost of GHGs and should look to the IWG's past (and future, when available) guidance to ascertain values, while still maintaining that the global perspective is the correct focus for its main analysis. Such sensitivity analysis by EPA of domestic climate impacts, the commenter states, would confirm that the proposed rule would be cost-benefit justified using domestic-only values, and thus the use of such valuations would not affect the agency's regulatory approach.<sup>135</sup>

Response I-20-16: EPA presented a set of updated social cost of greenhouse gas (SC-GHG) estimates in sensitivity analysis in the 2022 Supplemental RIA that address recommendations of the National Academies of Sciences, Engineering, and Medicine (2017), and invited public comment on the sensitivity analysis and on the technical report, titled *External Review Draft: Report on the Social Cost of Greenhouse Gases: Estimates Incorporating Recent Scientific Advances*, explaining the methodological updates that was included as Supplementary Material

to the RIA. The EPA is using the updated SC-GHG estimates in the Final RIA and is responding to the public comments received regarding these estimates, including comments pertaining to the global focus of the SC-GHG estimates, in the Appendix of this RTC.

Comment: Commenters (0577-KIOGA, 0804-EDF et al) discuss the use of global estimates for SC-CH<sub>4</sub> within the context of compliance costs. Commenter (0577-KIOGA) states that their experience is that EPA often underestimates the cost of compliance and overestimates the benefits provided by proposed regulations. The commenter provides a table (see Table 1 of their comment letter) in their comment letter, comparing the changes in tons of pollutants reduced (methane, VOC, and HAP), climate benefits, total capital expenditures, total engineering expenditures and beneficial value of methane recovered, between the proposed and final NSPS OOOOa rulemaking. Commenter (0804-EDF et. al.) states that all industry compliance costs ultimately fall on the owners, employees, investors, or customers of regulated and affected firms and a significant portion ultimately will accrue to foreign customers or foreign investors. Because EPA does not distinguish between compliance costs which accrue to foreign entities (as opposed to U.S. citizens or entities), the cost implicitly includes all global effects; considering global climate benefits is consistent with that approach. The commenter recommends that EPA highlight its consistent treatment of costs and benefits as further justification for relying on global social cost of GHG valuations.<sup>136</sup>

Response I-20-17: The EPA presented a set of updated social cost of greenhouse gas (SC-GHG) estimates in sensitivity analysis in the 2022 Supplemental RIA that address recommendations of the National Academies of Sciences, Engineering, and Medicine (2017), and invited public comment on the sensitivity analysis and on the technical report, titled *External Review Draft: Report on the Social Cost of Greenhouse Gases: Estimates Incorporating Recent Scientific Advances*, explaining the methodological updates that was included as Supplementary Material to the RIA. The EPA is using the updated SC-GHG estimates in the Final RIA and is responding to the public comments received regarding these estimates, including comments pertaining to the global focus of the SC-GHG estimates, in the Appendix of this RTC.

#### 20.2.3.3 Use of Consumption-Based Discount Rates, Choice of Appropriate Discount Rate, and Determination of Present Value of Future Climate Benefits

Comment: Commenter (0910-AGKY) notes the sheer uncertainty of the SCC estimate caused by the IWG's break with the Executive Branch's longstanding approach to discount rates. See, e.g., Cong. Research Serv., *Attaching a Price to Greenhouse Gas Emissions with a Carbon Tax or Emissions Fee: Considerations and Potential Impacts* 6-8 (Mar. 22, 2019), <https://bit.ly/3v1oifZ> ("One potential challenge of relying on SC-CO<sub>2</sub> estimates to set a carbon fee are methodological

concerns. ... No estimates of impacts are comprehensive at this time, and many of the risks are difficult to estimate and value. ... In addition, the element of time in climate change impacts particularly complicates the valuation. ... Economists do not agree on the appropriate discount rate(s) to use for a multi-generational, largely non-market issue such as human-induced climate change.”). They contend that the IWG arbitrarily jettisoned the longstanding 7 percent discount rate and employed an entirely new spectrum going as low as 2.5 percent and even encouraging agencies to depart downward. Susan E. Dudley et al., *The Office of Management and Budget’s Draft 2010 Report to Congress on the Benefits and Costs of Federal Regulations*, at 12, GW Regulatory Studies Center, <https://bit.ly/3euQiCf> (“The 7 percent rate remains an appropriate estimate of the average before-tax rate of return to provide capital in the U.S. economy.”).

Commenter (0804-EDF et al) suggests that, while they agree with EPA’s conclusion that the 7% capital-based discount rate is inappropriate for climate effects, EPA should provide additional justification for its discount rate choices and conduct sensitivity analysis using discount rates lower than 2.5% - such as a 2% discount rate. The commenter states that, although OMB Circular A-4 (2003) provides discount rates of 3% and 7% as a default assumption, it also requires agency analysts to do more than rigidly apply default assumptions; Circular A-4 (2003) requires agencies to justify the choice of discount rates for each analysis. The commenter states that based on Circular A-4 (2003)’s criteria, there are numerous reasons why applying a 7% discount rate to climate effects that occur over a 300-year time horizon would be unjustifiable—and that discount rates of 3% or lower are appropriate. The commenter suggests that EPA could look to the “value of carbon” estimates from the New York State Department of Environmental Conservation (“DEC”), which applied a 2% discount rate as its central value. Pursuant to DEC’s estimates, at a discount rate of 2% social cost valuations for year 2020 emissions equal \$125 per ton of carbon dioxide, \$2,782 per ton of methane, and \$44,727 per ton of nitrous oxide. The commenter adds that the DEC also recommended using a 1% discount rate for climate impacts and provided annual social cost values for doing so. Because these valuations are based off the Working Group’s methodology, and differ only through the discount rate, the commenter suggests, EPA can apply these valuations if it applies additional sensitivity analysis around lower discount rates.

Further, the commenter (0804-EDF et al) contends that there are several reasons which support the use of the consumption rate of interest. First, the commenter states, the discount rate should be based on the consumption rate of interest (3%) not the private return to capital (7%) because climate change concerns public well-being broadly rather than market participants narrowly and mostly affects large-scale consumption, as opposed to capital investment. The commenter states that because SC-CH<sub>4</sub> is presented in consumption-equivalent units, OMB Circular A-4 (2003) in fact dictates application of consumption-based discount rates. Second, the commenter states, uncertainty over the long-time horizon for climate effects should result in the selection of a lower discount rate. Third, the commenter notes that the 7% discount rate ignores catastrophic risks and welfare of future generations – as EPA showed in a recent cost-benefit analysis, the 7% rate truncates the long right-hand tail of social costs relative to the 3% rate’s distribution, where the long right-hand tail represents the possibility of catastrophic damages. Fourth, the commenter states, long-term time horizons in general counsel strongly against application of a capital-based rate. Fifth, the commenter states, several standard justifications for capital-based discount rates break down given the threats of climate change. The commenter provides by way of example,

that one argument for capital-based discount rates is that spending capital on climate abatement policies has opportunity costs and so, in policy analysis, future costs and benefits should be discounted at the rate of return to capital. However, the irreversible, uncertain, and catastrophic risks of climate change may disrupt this “opportunity cost” rationale: while it may seem, for instance, that future, wealthier generations might have better opportunities to address climate change for themselves, irreversible or catastrophic damages could arise that make future mitigation efforts more expensive or impossible, according to the commenter. Sixth, the commenter asserts that the 7% discount rate is inappropriate because it is based on outdated data and diverges from the current economic consensus. The commenter reports that the Council of Economic Advisers (CEA) detailed recently that Circular A-4 (2003)’s guidance on discount rates needs an update.

Commenter (0804-EDF et al) also provides further argument as to why the 7% rate is too high – the market return on an oil and gas operation can externalize some of the costs of its pollution onto society. Especially when crafting long-term climate policies, the commenter states, it would be inappropriate to discount future welfare because the current generation of investors prefers the high market returns that are now available partly because of such externalities. Finally, the commenter states, OMB Circular A-4 (2003) recognizes that intergenerational contexts raise unique ethical issues that further counsel for lower discount rates as most market data reflects at best individual’s current preferences for their own welfare over time and so simply does not capture society’s preferences toward or ethical obligations to future generations. The commenter states that EO 13990 instructs agencies to ensure that the social cost of GHG values adequately account for “intergenerational equity” and a 7% rate ignores much of future generations’ welfare and so would be inconsistent with that mandate.<sup>137</sup>

Dep’t of Env’t Conserv., *Appendix: Value of Carbon* (2020), [https://www.dec.ny.gov/docs/administration\\_pdf/vocapprev.pdf](https://www.dec.ny.gov/docs/administration_pdf/vocapprev.pdf).

Commenter (0804-EDF, et. al.) also states EPA appears to have chosen to ensure that all climate benefits are discounted in an internally consistent way, by applying the same discount rate used to estimate the underlying social cost values (e.g., 2.5%, 3%, or 5%) to calculate the present values of future climate benefits, which follows the IWG's guidance. But, the commenter states, it also means EPA is calculating the present value of reduced GHG emissions differently than the present value of other costs and benefits (which, per Circular A-4 (2003)'s current default recommendations, are calculated at 3% and 7% discount rates). The commenter recommends that EPA expand on its justification to its current approach to discounting through two approaches: (1) explaining why a general focus on discounting all costs and benefits at consumption-based rates, rather than at a 7% capital-based rate, is appropriate in this particular rulemaking; and (2) further explaining why special legal, economic, and policy considerations justify a different approach to discounting climate effects as distinct from other costs and benefits. Further, the commenter recommends that EPA should consider working with OMB and the IWG to move toward a declining discount rate framework that can straightforwardly resolve all these issues of consistent discounting, by adopting a single schedule of applicable discount rates that steadily declines over time.<sup>138</sup>

Response I-20-18: In the Final RIA, monetized climate effects are presented under a 2 percent near-term Ramsey discount rate, consistent with the EPA's updated estimates of the SC-GHG. The 2003 version of OMB's Circular A-4 had generally recommended 3 percent and 7 percent as default discount rates for costs and benefits, though as part of the Interagency Working Group on the Social Cost of Greenhouse Gases, OMB had also long recognized that climate effects should be discounted only at appropriate consumption-based discount rates. While the Final RIA was being drafted and reviewed, OMB finalized an update to Circular A-4, in which it recommended the general application of a 2.0 percent discount rate to costs and benefits (subject to regular updates), as well as the consideration of the shadow price of capital when costs or benefits are likely to accrue to capital (OMB 2023). Because the SC-GHG estimates reflect net climate change damages in terms of reduced consumption (or monetary consumption equivalents), the use of the social rate of return on capital (7 percent under OMB Circular A-4 (2003)) to discount damages estimated in terms of reduced consumption would inappropriately underestimate the impacts of climate change for the purposes of estimating the SC-GHG. See Section 3.2 of the Final RIA for more discussion.

In addition, a detailed response regarding the use of the consumption rate of interest and the omission of SC-GHG estimates using the 7% discount rate can be found in the Appendix of this RTC where responses are provided on comments pertaining to the EPA's September 2022 *Draft Report on the Social Cost of Greenhouse Gases: Estimates Incorporating Recent Scientific Advances*.

#### 20.2.4 Criteria and HAP Pollutant Benefits Analysis

Comment: Commenter (0842- NYU School of Law) states that the EPA declines to monetize several benefits that the Proposed Rule would yield, including the benefits of reducing VOC and hazardous air pollutant (HAP) emissions. The commenter notes that the 2021 November proposal RIA does report how many tons of each pollutant its proposed standards would abate, but it does not assign any monetary value to such figures.<sup>139</sup> As a result, the commenter contends that the EPA’s estimate of total monetized benefits understates the health and environmental gains from the rule.

The commenter (0842-NYU School of Law) states that the EPA discusses two categories of benefits associated with reducing VOC emissions: those related to ozone and those related to fine particulate matter (PM<sub>2.5</sub>).<sup>140</sup> The commenter notes that the EPA claims it cannot monetize ozone-related benefits because underlying data are too spatially coarse to derive meaningful estimates.<sup>141</sup> The commenter adds that the EPA then claims that it cannot monetize PM<sub>2.5</sub>-related benefits because “it is unlikely that the VOC emissions reductions projected to occur under this proposal would have a large contribution to ambient secondary organic carbon aerosols.”<sup>142</sup>

Yet, the commenter (0842-NYU School of Law) suggests that, in prior analyses of its regulations of the oil and gas sector, EPA has monetized the value of VOC reductions. For instance, the commenter states that, in an RIA for a 2016 rule related to methane in the oil and gas sector (the 2016 Rule), EPA presented a range of epidemiology studies estimating the value of reducing a ton of VOC in 2012 dollars: \$300 to \$7,500.<sup>143</sup> According to the commenter, even conservatively presenting results at the low end of that range—say, \$300, updated for inflation—would yield a more comprehensive picture of the benefits of EPA’s proposed standards. Put differently, they state that it would better capture the fact that, while there may be “a range of values” for VOC emission-reduction benefits, that value “is certainly not zero.”<sup>144</sup>

Commenter (0842- NYU School of Law) provides that the EPA claims that, “[w]ith the data available, it was not possible to estimate the change in emissions of each individual HAP,” and that “methodology and data limitations” preclude “monetize[ing] the health benefits of reductions in HAP.”<sup>145</sup> As with VOCs, the commenter recommends that the EPA present any quantitative information available to it, even if incomplete or uncertain.<sup>146</sup>

---

<sup>139</sup> 2021 NSPS OOOOb and EG OOOOc RIA (2021 PRIA). at 5-8 tbl.5-4 (estimating that EPA’s “Primary Proposal” would abate 12,000,000 short tons of VOC emissions and 480,000 short tons of HAP emissions).

<sup>144</sup> *Ctr. for Biological Diversity v. Nat’l Highway Traffic Safety Admin.*, 538 F.3d 1172, 1200 (9th Cir. 2008)

<sup>145</sup> 2021 PRIA, *supra* note 3, at 3-22.

<sup>146</sup> Circular A-4 (2003), *supra* note 34, at 27 (“If you are not able to quantify the effects, you should present any relevant quantitative information along with a description of the unquantified effects[.]”)

Two other commenters (0844-EDF et al, 0828-UCS) suggest that the EPA quantify and monetize the Proposal's non-climate health benefits. Commenter (0844-EDF et al) states that the EPA has not attempted to monetize the proposal's non-climate health impacts, so those significant benefits are left out of the calculations of net benefits for the regulatory options. The commenter recommends that EPA consider and account for, in as much detail as possible, the many significant non-climate health benefits of the proposal. Wherever possible, they suggest that health benefits be quantified and monetized. In cases of high levels of uncertainty, they suggest that the EPA quantify and monetize these benefits using conservative estimates rather than not monetizing or quantifying them at all (which is the agency's current approach) and should present them alongside a discussion of any limitations in the analysis. To the extent that the EPA is truly unable to monetize the proposal's non-climate health impacts, the commenter stresses that it must emphasize that the EPA's 2021 November proposal RIA underestimates the overall benefits of the proposal as a result.

Commenter (0844-EDF et al) recommends that the EPA seek to connect the reduced emissions of methane, VOCs, and HAPs to actual health outcomes. The commenter explains that they believe that some measure of the anticipated improvement in public health outcomes should be included, even if that figure represents the lower bound of the estimates or the minimum anticipated benefit. The commenter contends that including such a figure would allow for a better comparison of the costs and benefits of the four regulatory options.

The commenter (0844-EDF et al) refers to a table (Table 3-1 of their comment letter) that lists the currently unquantified health benefits of the proposal's projected emissions reductions, including various measurable health outcomes. According to this table, the commenter notes that the proposal would reduce premature mortality from short-term and long-term exposure to ozone and PM<sub>2.5</sub>, infant mortality, hospital admissions and emergency department visits, heart attacks, strokes, asthma onset and symptoms, allergic symptoms, minor restricted-activity days, school absence days, decreased outdoor worker productivity days, and morbidity from exposure to HAPs. The commenter appreciates the EPA's tabulation of the beneficial health outcomes of reducing methane, VOC, and HAP emissions, and urges the agency to quantify, to the greatest extent possible, the known health impacts of these emissions and the benefits of reducing these emissions.

The commenter (0844-EDF et al) adds that quantifying and monetizing the proposal's health benefits would also help to strengthen the EPA's environmental justice analysis. In the absence of quantified and monetized data on health impacts, the commenter states that environmental justice analysis currently fails to capture the full panoply of benefits that the proposal would afford if finalized. The commenter suggests that, by quantifying and monetizing the local and regional benefits of reduced methane, VOC, and HAP emissions, the EPA would be able to perform a more robust assessment of the proposal's environmental justice impacts.

The commenter (0844-EDF et al) mentions that the EPA includes an "illustrative screening analysis" in which it monetizes VOC-related ozone health benefits. The commenter urges the EPA to perform analogous supplemental analyses that monetize HAP-related health benefits, as well as all other benefits that are currently unmonetized. Particularly if the EPA intends to keep

these analyses as supplemental and outside the overall benefits calculation, we urge the agency to present the results even if they are associated with higher levels of uncertainty.

Although completing additional similar supplemental analyses would strengthen the EPA's assessment of the proposal's health benefits, the commenter (0844-EDF et al) recommends that EPA also reconsider its decision to leave the non-climate health benefits unmonetized in its overall benefit calculations. According to the commenter, the EPA does not adequately explain why it cannot incorporate this analysis in some fashion into the proposal's monetized benefits. The commenter provides that the RIA's discussion of the illustrative screening acknowledges the uncertainties associated with that approach. However, given that the EPA found the state of the science certain enough to perform this analysis, the commenter suggests that the EPA consider more broadly incorporating these benefit estimates into the overall benefits summary or explain why it has chosen not to do so. In other words, the commenter believes that the EPA can conclude that the proposed rule will have at least a certain dollar benefit in terms of health benefits derived from reductions in VOC emissions and corresponding estimated reductions in premature mortality and illnesses, such as those in Table B-3 of Appendix B. The commenter suggests that EPA add those estimates to the tables summarizing the proposal's benefits.

Additionally, the commenter (0844-EDF et al) notes that the current state of the data and available modeling methods supports quantifying and monetizing the proposal's health benefits. There is a body of peer-reviewed studies that quantify reduced mortality and morbidity and/or monetize health benefits of various emission-reduction scenarios in the U.S., including some that have used the community edition of the EPA's Environmental Benefits Mapping and Analysis Program (BenMAP-CE). The commenter recommends that the EPA use the available modeling methods to the greatest extent feasible.

Response I-20-19: The EPA has updated the analysis in the RIA for the final rule which now includes monetized ozone benefits from VOC emissions reductions. This provides quantified benefits for one source of previously unquantified non-climate benefits. We are currently unable to estimate or monetize the impact of changes in HAP releases due to data limitations, most notably the lack of sufficient emission location specificity to perform such analyses. The HAP impacts available in EPA's 2017 AirToxScreen dataset are provided for the entire oil and natural gas sector, which includes sources outside the scope of this regulation. We do not have current modeling of HAP impacts specific to only the sources subject to the regulation; therefore, we cannot estimate risks, including any reductions, solely attributed to the source category. Furthermore, more refined emissions data would be needed to conduct an assessment at the census block level, where we could draw more accurate conclusions about the human health risks.

Comment: Commenter (0581-NACAA) notes, with regards to criteria pollutants, that the anticipated reductions in ozone precursors as a result of the 2021 November proposal would help state and local agencies in their efforts to achieve and maintain compliance with the National Ambient Air Quality Standards (NAAQS). The commenter states that the EPA says its 2021 November proposed rule would reduce an estimated 12 million tons of VOCs from 2023 to 2035. According to the commenter, this will be particularly important as more areas face reclassification under the 2015 ozone standards. Moreover, they note that one predicted outcome

of increased anthropogenic climate change is longer and more harmful ozone seasons. This may mean greater effort will be needed by states and localities to meet and maintain compliance with the ozone NAAQS. In addition to significant local benefits from lower VOC emissions that might be reasonably anticipated in areas with high amounts of oil and natural gas sector activity, the commenter states that these reduced emissions will also reduce impacts from air pollution transported across state lines, which raise complex challenges for downwind states.

Commenter (0581-NACAA) provides that oil and gas operations also emit other criteria pollutants such as sulfur dioxide and nitrogen oxides, as well as air toxics including benzene, formaldehyde, toluene, ethylbenzene and xylene. EPA says that its 2021 November proposed rule would reduce 480,000 tons of air toxic pollutants from 2023 to 2035. NACAA endorses and welcomes these potential pollution reductions. EPA also states that its 2021 November proposal would reduce 41 million tons of methane emissions from the oil and natural gas industry between 2023 and 2035. The commenter asserts that these methane reductions should not only reduce harms and offer public health protections on a local basis but on a global one; they would help address the ongoing crisis facing the planet's climate. While not a criteria pollutant covered by the NAAQS, methane remains a potent climate pollutant with a global warming potential nearly 30 times that of CO<sub>2</sub>. Restoring the methane NSPS advances the agency's legal obligation to limit methane emissions from existing oil and natural gas sector sources.

Response I-20-20: The analysis in the RIA for the final rule has been updated to quantify monetized ozone benefits resulting from changes in VOC releases. This information can be found in Section 3 of the RIA. The EPA is currently unable to estimate or monetize the impact of changes in HAPs releases due to data limitations, most notably the lack of sufficient emission location specificity to perform such analyses. The HAP impacts available in EPA's 2017 AirToxScreen dataset are provided for the entire oil and natural gas sector, which includes sources outside the scope of this regulation. The EPA does not have current modeling of HAP impacts specific to only the sources subject to the regulation; therefore, the EPA cannot estimate risks, including any reductions, solely attributed to the source category. Furthermore, more refined emissions data would be needed to conduct an assessment at the census block level, where the EPA could draw more accurate conclusions about the human health risks.

## ***20.2.5 Economic Impacts***

### **20.2.5.1 State Resource Funds-Royalties**

Comment: Commenters (0411- REM, 0431-NOI, 1300-PLS) state that the revenue from states of Michigan and Montana-owned wells go into state resource funds (i.e., Michigan Natural Resources Trust Fund, State of Michigan, State of Montana's General Fund). The commenters complain that plugging wells earlier in their life would deprive the Funds of revenue which would cause irreparable harm to the Trust Fund. Commenter (0411-REM) specifically states that plugging wells earlier in their life will also lead to less state [Michigan] revenues, not only for production taxes, but also for royalties paid to private landowners and the State of Michigan (the State of Michigan is the largest royalty holder in Michigan).

Commenter (0597-IOGA) notes that high compliance costs could lead to the potential for oil and gas wells to be prematurely plugged which would impact royalty payments that have been received for decades and are relied upon by Indiana residents for living expenses.

Response I-20-21: The EPA developed a financial analysis of marginal oil and natural gas wells in Chapter 6 of the Final Rule TSD. The EPA finds that marginal wells may continue to operate at low or negative profits rather than be shut-in and plugged due to a variety of reasons, including low operating costs, high plugging costs, low state bonding requirements, accounting practices, and tax credits available to the oil and gas industry. With the available data and the complexity described, the EPA cannot estimate the impacts of the final regulation on the owners or operators of marginal wells. To the extent that any marginal wells might be plugged in relation to anything contained within this rulemaking (which is speculative), the analysis suggests that they would be extremely low-producing wells, and therefore the impact of lost royalties and state revenue would be minimal.

#### 20.2.5.2 State Economic Impacts

Comment: Several commenters provide comment on the state impacts that they anticipate because of the 2021 November proposal. Some of the specific comments received are provided in the following paragraphs.

Commenter (0763-TCEQ) believes that the EPA has underestimated the overall number of affected facilities. As an example, they state that defining oil wells with associated gas as an affected facility and requiring these sources to route gas to a sales line, use the gas at the site, or route the gas to a control device could require the submittal of at least 100,000 projects for new or modified sites to the State. They add that it is not typical that production wells will always be drilled in areas where a pipeline exists or is readily available at the time of drilling. The commenter asserts that the implementation of the 2021 November proposed rules will dramatically increase the fiscal burden on Texas and will likely adversely affect other states across the nation with similar oil and gas production activities and facilities.

The commenter (0763-TCEQ) adds that the EPA's RIA should include the curtailment of economic and societal benefits generated by oil and gas production that will occur because of this rulemaking. In Texas this includes impacts to school districts, veterans, and universities that rely on oil and gas production revenue. They add that there will be an overall impact to state government budgets and revenue, including the Texas Economic Stabilization Fund ("Rainy Day" Fund). According to the commenter, this will have a significant impact on delivery of state services to citizens and local communities.

Commenter (0800-UPLP) is concerned that the cost of implementing said measures may do much to harm the oil and gas industry's resilience in the state [Utah]. Compliance would require oil and gas operators to retrofit and update existing infrastructure to standards at costs which have not yet been fully quantified. Not only would the compliance costs be passed down to the producers, but so would the increased cost of product recovery. Thus, while the net benefits may be somewhat equitably distributed, the costs would be unevenly borne by the states and oil and gas operators. The commenter states that the 2021 November proposal does not seem to contemplate that, due to the added costs associated with compliance (again imposed on the oil

and gas operators), many oil and gas sources would become uneconomical to extract and would instead leave tons of natural gas stranded and unproduced. While the commenter notes that the state [Utah] is supportive of finding innovative ways to reduce air pollution and methane emissions, they assert that it must be done in a way that equitably allocates costs and benefits, and without jeopardizing the resilience of the state's [Utah's] oil and gas industry.

Commenter (0946-MOGA) reports that they conducted an analysis of variable operational costs which included seasonal variation in requirements pertaining to snowfall, temperatures, travel restrictions, formation dynamics, operational agendas, resource recovery costs, land-owner contracts, royalties, etc. The analysis notes remaining reserves, annual decline rate, production life, operating costs, and analyzes potential gross revenue over remaining well life, before and after regulation. The commenter states that the results of their analysis include an estimated loss of \$2,514 per well. They report that this economic loss is driven solely by future proposed regulations outlined in NSPS OOOO(b) and EG OOOO(c) and would lead to early plugging of wells and waste of State of Michigan resources. The commenter (MOGA) views the proposed regulations under NSPS OOOO(b) and EG OOOO(c) as short-sighted, wasteful, and having a significant impact on the State of Michigan's natural resources, small businesses, and economic climate.

Similarly, commenter (0411-REM) states that the overall effect of forcing additional capital expenditures on marginal wells will force a certain percentage of wells to be plugged due to a lack of economic payout. The result will be less oil and gas on the free market, resulting in eventual price increases to consumers. It will also result in a loss of good paying jobs [in Michigan] as well counts decline and workers are laid off.

Commenter (0910-AGKY) states that setting EGs for methane GHGs represents a stark departure from decades of EPA practice. The commenter notes that the EPA's previous approach of nonregulation avoided harm to Louisiana, allowed the State to invest heavily in natural gas, and influenced the State's policy. The commenter adds that the 2021 November proposal also upsets decades of settled reliance on the EPA's prior approach of not setting a nationwide EG standard. The commenter provides that Louisiana has structured its energy priorities around natural gas, which has in turn become a driver of the state's economy and tax base. Specifically, the commenter reports that Louisiana is one of the top five states in both natural gas production and reserves and accounts for about 9% of U.S. production and 8% of U.S. reserves. And the industry accounted for almost \$4.5 billion of State and local tax revenue—a whopping 14.6% of all state taxes, licenses, and fees collected. They contend that the 2021 November proposal will impose harm on rural Louisiana areas. For example, the commenter explains that the natural gas industry is the lifeblood of the renewal of impoverished areas such as DeSoto Parish and industry makes up 7 percent of all local property tax for Cameron Parish. In addition, they add that it will cost the State of Louisiana tens of millions to implement; potentially require hundreds or even thousands of new state employees around the country; and could also potentially lead to backlogs for existing pipeline infrastructure maintenance creating serious environmental risks and undermining the integrity of the energy grid.

Commenter (0910-AGKY) expresses that the EPA nowhere acknowledges these harms or Louisiana's and industry's reliance on the current regime. Given these substantial reliance interests, a national standard would require an extensive analysis of its effect on Louisiana and

other co-signing states. The commenter suggests that the agency has a duty to explain why it deemed it necessary to overrule its previous position on which decades of reliance has been built, however, they complain that no discussion is provided in the 2021 November proposal.

Conversely, commenter (1302-WOC) believes that direct methane regulation will encourage technological innovation and help grow Wyoming's economy around methane mitigation in the long run. The commenter estimates that there are approximately 13 businesses across Wyoming working in the methane emission mitigation industry.<sup>147</sup> Some of these businesses manufacture equipment needed for leak detection and repair work, while others are more focused on consulting and compliance services.

The commenter (1302-WOC) applauds the efforts of this new rule to encourage responsible stewardship of non-renewable resources for taxpayer benefit. Regulating waste methane from new and existing sources will help ensure that Wyomingites are fairly compensated for the extraction and use of non-renewable resources.

The commenter (1302-WOC) and its partners estimated that in 2018, Wyoming lost an estimated annual \$51 million to \$96 million worth of natural gas due to intentional flaring, venting and careless leaks. This translated to \$8.8 -16.1 million lost in annual royalty payments to the state. Of this amount, \$3.4 million to \$6.5 million was lost ad valorem revenue (property tax that goes directly to counties) that could have gone to the purchase of emergency equipment, or road and bridge repair, or human services like public health nurses and libraries.<sup>148</sup> The commenter states that these are critical revenue streams that taxpayers and budget strapped communities deserve to see for the depletion of natural resources, particularly given ongoing statewide budget cuts.

Response I-20-22: The EPA disagrees with commenters' assertions that the rule will have significant negative impacts on production levels or on oil and natural gas prices. The EPA estimates that the reduction in U.S. oil production would be approximately 1.05% or less, while the reduction in gas production would be approximately 0.75% or less. The EPA estimates that the impact on natural gas prices will be \$0.06/Mcf or less, and the impact oil prices will be \$0.25/bbl or less. These represent changes of approximately 1.76% and 0.33%, respectively. Notably, none of the commenters provide specific data or analysis to support general claims of production and price impacts at the state or national level.

Likewise, the EPA disagrees with commenters' assertions that the rule would have a significant negative impact on state economies and budgets. In addition to the sectoral analysis described above that found limited impact to national levels of production or prices, the EPA also developed a financial analysis of marginal oil and natural gas wells in Chapter 6 of the Final Rule TSD. The EPA finds that marginal wells may continue to operate at low or negative profits rather than be shut-in and plugged due to a variety of reasons, including low operating costs, high plugging costs, low state bonding requirements, accounting practices, and tax credits available to the oil and gas industry. With the available data and the complexity described, the EPA cannot estimate the impacts of the final regulation on the owners or operators of marginal wells. Moreover, To the extent that any marginal wells might be plugged in relation to anything

---

<sup>147</sup> Environmental Defense Fund. Methane Fact Sheet for Wyoming Methane Economy. 2021 Report.

<sup>148</sup> Wyoming Outdoor Council. 2018 Oil and Gas Waste Report.

contained within this rulemaking (which is speculative), the analysis suggests that they would be extremely low-producing wells, and therefore the impact of lost royalties and state revenue would be minimal. In addition, as one commenter (1302-WOC) points out, several elements of the rule are expected to have positive impacts on royalty payments and ad valorem tax revenue by encouraging additional capture of natural gas. As such, EPA believes the claims of significant social costs borne by state governments and related entities (schools, universities, etc.) are overstated by commenters.

In response to one commenter (0946-MOGA), EPA disagrees that the “*economic loss is driven solely by future proposed regulations outlined in Subpart OOOO(b) and Subpart OOOO(c) and would lead to early plugging of wells...*” and notes that the profit or loss of the cited well is determined by the variability of oil prices and the assumption that the cited well has 1,200 barrels of oil reserves. At the September 2023 monthly average WTI price of \$89.43, the commenter’s cited well would earn a profit of \$24,390 over 15-years based on the commenter’s assumptions. A larger amount of oil reserves would also increase the earnings from the cited well.

In response to one commenter’s (0763-TCEQ) claim that EPA has underestimated the number of affected facilities, using associated gas as an example, EPA notes that its estimates of associated gas affected facilities, presented in Table 2-5 of the Final RIA, are based on data from the Greenhouse Gas Reporting Program (GHGRP). The commenter does not provide sufficient information to assess the validity of its claim, for associated gas or any other affected facility type.

Comment: Commenters (0929-NSWA, 0585-KOGA) note that historically, operators surrender their wells to state agencies to complete remediation of the unplugged wells at the time that the operator ceases to do business. The commenters are concerned that the EPA’s additional regulations will add enough cost to wells that are marginally profitable (i.e. low production wells) that the operators will decide to terminate their business, leading to many more wells being surrendered to state agencies. While operators are required to maintain bonding for each well, in the event that this occurs, funds from the surrendered bonds are often not utilized to plug the operator’s remaining wells. As a result, the taxpayers ultimately pay to plug the wells.

Response I-20-23: EPA developed a financial analysis of marginal oil and natural gas wells in Chapter 6 of the Final Rule TSD. EPA finds that marginal wells may continue to operate at low or negative profits rather than be shut-in and plugged due to a variety of reasons, including low operating costs, high plugging costs, low state bonding requirements, accounting practices, and tax credits available to the oil and gas industry. To mitigate the impact of orphaned wells, the Inflation Reduction Act (IRA) provides \$700 million for methane and greenhouse gas mitigation activities for conventional marginal wells. The Department of Energy and the EPA have issued a joint Notice of Intent to provide grants up to \$350 million for conventional marginal well plugging as an initial effort to distribute the IRA funds. The goal of marginal well funding from the IRA is to offset the cost of plugging low producing wells. Additionally, the federal money reduces the possibility that the operator files for bankruptcy and orphans their well(s).

To maintain transparency for the responsible owner or operator and prevent well sites from becoming orphaned, EPA is finalizing the rule with a well closure plan requirement which

requires fugitive monitoring of well sites for the life of the well and can only be discontinued if the well site is properly plugged and an OGI survey is done to ensure there are no emissions from the site. EPA is also requiring owners and operators to submit, through an annual ownership report, changes in ownership at individual well sites so it is clear who the responsible owners and operators are until the site is plugged and closed and fugitive emissions monitoring is no longer required.

#### 20.2.5.3 Tribal Economic Impacts

Comment: Commenter (1301-NATBC) expresses concern regarding the cost of implementation and potential direct and indirect economic effects. Specifically, commenter is concerned that the 2021 November Proposed Rule would directly and significantly impact the Northern Arapaho Tribe. Oil and natural gas extraction is a substantial presence on the Wind River Reservation and has an important role in the Tribe's economic wellbeing. The Northern Arapaho Tribe, in co-tenancy with the Eastern Shoshone Tribe, owns or leases oil and gas operations within the Reservation. In 2021, the Tribes assumed control of the largest oil field on the Reservation, Circle Ridge Field, which accounts for about 60 percent of the oil produced on the Reservation. Revenue from petroleum and natural gas production sustains their people economically, funds many aspects of Tribal government and services, and based on royalties enables per capital payments which are relied upon by the Tribe's members for daily necessities.

Commenter (0794-MHAN) states that in promulgating regulations that will have far-reaching implications for the oil and gas industry, which is known to operate on tribal lands, the EPA must consider how those regulations may interfere with tribal treaty rights. Commenter asserts that if the EPA were to finalize regulations that unreasonably restrict or burden development of tribal oil and gas resources, these regulations would interfere with the MHA Nation's treaty-protected right to engage in trade. More specifically, commenter notes, under Article 5 of the 1825 Treaties between the United States and the MHA Nation, the federal government agreed "to admit and license traders to hold intercourse with said tribe, under mild and equitable regulations ..." (citing Treaty with the Arikara, 7 Stat. 259 (July 1825); Treaty with the Mandan, 7 Stat. 264 (July 1825); Treaty with the Hidatsa, 7 Stat. 261 (July 1825)). Commenter states that in promulgating its methane regulations for the oil and gas industry EPA must adequately consider tribal treaty rights – national requirements that would unduly or inequitably burden development of tribal resources cannot be considered "mild and equitable." Commenter asserts that EPA's forthcoming regulations should be appropriately tailored to provide for cost effective emissions reductions while still providing for continued oil and gas development on the Fort Berthold Reservation.

Response I-20-24: Regarding concerns about cost of implementation, please see the Final Rule preamble at Section VIII.B for a discussion of how the EPA considered control costs in development of the Final Rule.

Regarding the issue of tribal treaty rights raised by the commenter, the EPA notes that commenter does not argue that the Proposed Rule would, in fact, interfere with tribal treaty rights or that it would unduly or inequitably burden the development of tribal resources. Nor does it explain with specificity how the Proposed Rule would interfere with tribal treaty rights. Nonetheless, the EPA acknowledges the commenter's concerns. As stated in the Final Rule at

Section XVI.F, the EPA acknowledges that this rule will have certain tribal implications. In accordance with the EPA Policy on Consultation and Coordination with Indian Tribes, the EPA will continue to consult with tribal officials and engage with tribes on a government-to-government basis as these rules become implemented. The EPA encourages tribes to meaningfully engage with the agency in these processes. Please see Section XVI.F for more detail regarding the EPA's consideration of tribal implications and EPA's consultation with tribes in relation to this rulemaking.

### ***20.2.6 Energy Impacts***

Comment: Several commenters express concern that the 2021 November proposed rule will result in decreased domestic oil and natural gas production. Some of the specific representative comments received are provided in the following paragraphs.

Commenter (0334-GOAWV) recommends that the rules recognize the critical role that oil and gas plays in meeting the nation's energy and environmental needs. According to the commenter, the final rules must have a pathway to reasonable and cost-effective compliance. The commenter asserts that U.S. produced oil, natural gas and natural gas liquids are critical to providing affordable, clean energy to heat and power millions of American homes and businesses, fueling manufacturers, including the production of personal protective equipment (PPE), medicines and medical equipment, and providing for enhanced national security.

Commenter (0793-PBPA) notes that the EPA estimates the 2021 November proposed rule will result in a reduced domestic production of 12.2 million barrels per year.<sup>149</sup> Based on the commenter's analysis of the cost of the 2021 November proposed rule, the actual operators that will be impacted, and the economic realities in the oilfield, the actual reduction in domestic production will be significantly higher than estimated by the EPA. The commenter recommends that EPA not make rules without investigating the scope and effect of what those rules will be, especially rules that will impact hundreds of thousands of sites. They add that the impacts could have a significant effect on domestic energy prices as well as drive a significant number of oil wells into uneconomic territory.

Commenter (0822-TAEP) states that the EPA acknowledges that the initial proposal costs could result in notable consequences to production in the U.S. The commenter notes that an overreach in regulation could have profound negative consequences to increasing emissions globally by reducing domestic production and forcing domestic and global demand to rely more on sources of oil and natural gas from producing countries with lower environmental and labor standards. The commenter urges EPA to undertake a robust analysis to determine if the global harm to any shift in production overseas would result in more pollution, and the extent to which the advantages of domestic production and the benefits derived from that production far outweigh any negative externalities from pollution by an overseas competitor. The commenter believes that the EPA's mandate to protect human health and the environment while tackling the climate crisis at home and abroad necessitates a higher level of review than what is currently contemplated in this proposal. The commenter adds that this analysis should by no means be limited to oil and natural gas as numerous industrial processes and manufacturing have been

---

<sup>149</sup> 86 Fed. Reg. at 63,258.

exported overseas but the extent to which the EPA is contemplating new regulations on oil and natural gas production, they urge it to start there.

Similarly, commenter (0743-WEA) contends that certain provisions in the rule would render large swaths of production in the U.S. uneconomic to continue to operate, which will only further constrain domestic supply and force domestic energy users to be more dependent on oil produced overseas, where the EPA's jurisdiction doesn't extend. The commenter adds that creating rules that force the shutting in of wells in the U.S. to instead ship more oil across the ocean from less regulated countries ultimately increases global GHG emissions and introduces negative externalities that the EPA has seemingly ignored in the development of this rulemaking.

Commenter (0431-NOI) notes that if it is assumed that stripper wells produce approximately 10 barrels of crude oil (bbl)/day that would mean over 7 Million bbl would be taken out of U.S. production. According to the commenter, since the U.S. utilizes or has a current demand of approximately 19.8 Million barrels per day (bpd) that would essentially put the U.S. in a severe bind to make up the lost 7 Million barrels. The commenter does not believe other countries could or would make up those volumes but rather would benefit from the rise in prices to over \$15 per barrel and cause gasoline to rise to perhaps \$11 per gallon, if that lost supply even becomes available to make gasoline or jet fuel.

Commenter (0595-Consumer Energy Alliance) agrees it is important to prioritize emission impacts during rulemaking. However, these decisions must also consider the significant progress that has already been made, and carefully consider the economic welfare of families and businesses nationwide. Affordable energy and environmental stewardship are important to all Americans.

Response I-20-25: The EPA disagrees with commenters' assertions that the regulation would have profound impacts on domestic oil and natural gas production. Several commenters assert severe impacts but fail to provide specific information to support those claims. The EPA models the impact of the rule on oil and natural gas supply in Section 4.1 of the Final RIA. The EPA estimates that the reduction in U.S. oil production would be approximately 1.05% or less, while the reduction in gas production would be approximately 0.75% or less. EPA estimates that the impact on natural gas prices will be \$0.06/Mcf or less, and the impact oil prices will be \$0.25/bbl or less. These represent changes of approximately 1.76% and 0.33%, respectively. Further, the EPA disagrees with the commenters assertion that this regulation will remove 7 million barrels of oil per day from U. S. production. The EPA developed a financial analysis of marginal oil and natural gas wells in Chapter 6 of the Final Rule TSD. The EPA finds that marginal wells may continue to operate at low or negative profits rather than be shut-in and plugged due to a variety of reasons, including low operating costs, high plugging costs, low state bonding requirements, accounting practices, and tax credits available to the oil and gas industry.

We estimate that the change in oil imports would be an increase of 0.52% or less but are unable to quantify the impact on GHG emissions of changes in imports. However, the relatively small estimated increase in imports suggests that the net effect on GHG emissions will be negligible.

Comment: Commenter (0922-NAM) opines that any well-tailored NSPS rule should not drive an unnecessary increase in oil, natural gas, or electricity costs, noting that affordable and reliable

electricity provides domestic manufacturers a competitive advantage in the global economy. Commenter believes that any efforts to develop new rulemakings should take great care to avoid measures that would raise the cost of electricity for consumers and businesses and threaten that important economic advantage manufacturers enjoy.

Response I-20-26: The EPA estimates that the impact on natural gas prices will be \$0.06/Mcf or less, and the impact oil prices will be \$0.25/bbl or less. These represent changes of approximately 1.75% and 0.33%, respectively. We do not formally model the impact on electricity prices. We anticipate that in settings in which oil or natural gas electricity generating units are marginal electricity generators, the impact on electricity prices would be comparable, while in settings in which other energy sources are the marginal electricity generating units, the impact would be smaller.

### ***20.2.7 Impact on Small Business***

Comment: A prevailing concern from numerous commenters (0193-NFIB, 0411-REM, 0424-WV DEPDAQ, 0431-NOI, 0464-MOPC, 0465-JDC, 0425-Darrah, 0577-KIOGA, 0585-KOGA, 0597-IOGA, 0749-PAW, 0763-TCEQ, 0778-USCongress, 0793-PBPA, 0824-WDEQ 0923-Lambda, 0924-USSBA, 0929-NSWA, 0946-MOGA, 1155-Bean Ridge Resources, 1300-PLS, 1341-Conventional Groups, 1380-MOGA, 1381-MPA, 1422-U.S. Congress) is that the new requirements and regulatory costs of the proposed rule will have a significant and disproportionate economic and employment impact on small business, individual and farmers and independent operators and owners of marginal/low production and stripper wells and they recommend that these wells be exempt from the proposed rules. The compliance costs are perceived to have the potential to cause a premature, landslide plugging of wells. According to some commenters, this shut-in of wells is anticipated to result in a significant decrease in production of oil and natural gas which will particularly impact small, rural communities that rely not only on the employment, revenues, royalties from that production but also on the natural gas produced and used locally. The commenters collectively note a common concern that the EPA has overestimated the cost-effectiveness of the measures proposed as BSER and underestimated the significant impact this rule will have on small businesses. Some of the comments received state that while there are some concessions for smaller producers, the proposed regulations could put extreme financial burdens on them and puts small businesses at a significant disadvantage. Commenters add that this particularly applies to individual homeowners, farmers, or companies with very few employees such as family limited partnerships who are owners/operators of wells.

As a specific example, commenter (0946-MOGA) notes the proposed NSPS and EG regulations would potentially burden Michigan's small business marginal well producers with significant costs to achieve less than the maximum resource recovery, which they say directly contradicts the State of Michigan's laws regarding waste of state resources. The commenter reports that the State of Michigan views early plugging and abandonment of wells with remaining production horizons as waste. Part 615 of the state's regulatory framework stipulates the minimization of waste by efficiently managing operational endeavors to achieve maximum resource recovery. The commenter adds that many of Michigan's small entity producers facilitate this mandate by minimizing operational costs, negotiating production contracts, adjusting operational production schedules, and minimizing all costs when available. As such, the commenter reports that

Michigan's small entity and small business producers require flexibility to meet the State of Michigan's objective to maximize resource recovery.

Several commenters (0424-WV DEQDAQ, 0431-NOI, 0577-KIOGA, 0597-IOGA, 0924-USSBA, 1341-Conventional Groups) also state that there are unique aspects of small business that the EPA did not consider in the development of the cost/benefit analysis for the proposed regulation. Some of the specific comments provided include:

- American businesses of every size cannot get the employees they need to grow their business because the U.S. labor force has millions fewer workers available than it had in 2019.<sup>150</sup>
- American businesses of every size cannot get on time the goods and materials they need, because their supply chains have failed.
- American businesses of every size must pay more for the goods and materials they buy, and the fuel, electricity, and other sources or forms of energy they need to operate, as inflation roars
- The regulations require the purchase and installation of new equipment; however, they are last in line with suppliers. They also believe that they pay more per unit because they are generally purchasing fewer identical items and require more customization per installation. Commenter (0431-NOI) notes that if the proposed regulations are adopted in their current condition, they are finding that the equipment needed for compliance is not available and probably would have limited availability for 2 to 3 years because of supply issues.
- Many individuals do not have the knowledge to perform a fugitive emissions survey or to perform air emissions calculations for a well that has existed perhaps for multiple generations on their land.
- There is no available trained workforce to handle or install the equipment needed. Commenter (0924-USSBA) states that generally, for similar sets of regulatory requirements, small businesses face a greater cost of compliance. For example, they note that when a new regulation requires additional human resources, identifying, hiring, and retaining employees becomes a major concern for small entities, especially in the current tight labor environment. The commenter states that, according to the U.S. Census Small Business Pulse Survey, the number one concern of surveyed small businesses is the difficulty finding and hiring staff. The commenter further states that small businesses frequently lack the benefits packages larger businesses have (quality of healthcare, and other benefits) leaving smaller businesses at a disadvantage when hiring compliance staff.
- Smaller producers do not have the same economies of scale as larger producers and cannot spread increases in fixed compliance costs over as many projects.

Several commenters (0924-USSBA, 0597 IOGA, 1341-Conventional Groups) suggest that several factors have led the EPA to overestimate the cost-effectiveness of the measures proposed as BSER and underestimate the significant impact this rule will have on small businesses. Notably, the commenters note that these impacts extend beyond the impacts on small businesses the EPA considered under the RFA.

---

<sup>150</sup> Federal Reserve Bank of St. Louis, Civilian Labor Force Level (CLF160V), available at <https://fred.stlouisfed.org/series/CLF160W> (visited November 16, 2021) (size of labor force in 2019 and 2021).

- The impacts are likely more severe for small businesses that own and operate existing sources not previously subject to the EPA regulation, particularly for those requirements that will require retrofitting equipment.
- The use of a single average annual number to represent entire sectors of the industry puts small businesses at a significant disadvantage compared to large businesses.
- The model plants the EPA uses to perform its BSER evaluations are very different from, and do not represent, the extremely small well sites and associated facilities owned and operated by their members. For example, the commenter states that primarily low-producing stripper wells, or "marginal wells," operated by members of the Conventional Groups generate far less revenue than large unconventional wells and therefore, operate on a much smaller return on investment from conventional wells.
- Annual averaging puts small businesses at a disadvantage. Small businesses generally cannot finance capital equipment over the time horizons used in the EPA estimates.
- The EPA distorts the financial outlook for small businesses by presenting cost savings from regulatory requirements as a simple subtraction from the annualized costs.

Several commenters (0411-REM, 1341-Conventional Groups, 0824-WDEQ, 0577-KIOGA, 0431-NOI, 0924-USSBA) contend that the EPA must perform small business-specific cost evaluation for all sources under the proposed rule using a more granular approach to the cost-effectiveness analysis. Specific comments include the following:

- Commenters contend that the analysis lacks transparency to uncover how it impacts various sizes of entities whether smaller, more vulnerable entities are disproportionately impacted by a regulation. For example, commenter (0924-USSBA) notes that while the size standard for the crude petroleum extraction industry (NAICS 211120) is 1,250 employees, 70 percent of firms in this industry have 5 employees or fewer. Those with 5 employees or fewer have an average revenue of \$769,000 in an industry with extremely high fixed costs. Due to this vulnerability, Advocacy recommends comparing the cost of the regulation not by the average of an entire NAICS code, but rather by different size categories within each NAICS code.<sup>151</sup>
- Commenters recommend that the EPA present an analysis of the economic impacts this rule would have on small businesses that own or operate existing sources which would be required to retrofit equipment under the EG OOOOc As these are typically older producing sites, commenter (0924-USSBA) states that they generally have much lower production than new sources, so there would be less revenue per unit across which to spread regulatory costs.
- Update of costs with details supporting. Commenters (0431-NOI, 0824-WDEQ) note they find that the estimated costs are understated. Commenter (0431-NOI) states that the 2016 EPA estimated one-time initial cost and estimated on-going annual costs for compliance are very low compared to what we the commenter is getting back from their contractors for this work. However, their costs are 2021 or 2022 estimates and the commenter states that it appears that EPA has not accounted for inflation of the compliance costs that have had a remarkable increase in 2021 (which will continue in 2022 according to their suppliers).
- Commenter (0824-WDEQ) suggests that particular attention be applied to the cost associated with monitoring surveys outlined in Section 9 of Appendix K, which they contend would

---

<sup>151</sup> See SBA Office of Advocacy, How to Comply with the Regulatory Flexibility Act, Updated August 2017 (available at <https://cdn.advocacy.sba.gov/wp-content/uploads/2019/06/21110349/How-to-Comply-with-the-RFA.pdf>.) pp. 36.

impose impossible expenses upon small operators that exceed their revenues. For example, the optical gas imaging (OGI) cameras required under this proposal can cost producers more than \$100,000 in addition to the costs for building new reporting systems that come with additional increases in payroll costs as new employees will be needed to process all the documentation requirements.

- Update of emissions profiles for low production, marginal and stripper wells. Commenters (0577 KIOGA, 0824-WDEQ) state that the EPA has never taken any significant data to identify the emissions profile of low production wells. Only the U.S. DOE has initiated a study of emissions from low production wells. That study should be completed in 2021.<sup>152</sup>
- Address various producing areas, For example, Michigan's Antrim basin. (0411-REM)
- The EPA should consider the risk that these businesses will leave the industry and whether there is a risk that wells will be abandoned because of the regulations. (0924-USSBA)

Commenter (1422-U.S. Congress) believes the proposed regulations could put extreme financial burdens on small businesses. For example, they state that optical gas imaging cameras required under this proposal can cost producers more than \$100,000. On top of expensive one-time investments required by the proposed regulation, the additional documentation costs cannot be overlooked. Building new reporting systems is expensive and will come with additional increases in payroll costs as new employees will be needed to process all of the required documentation. The commenter asserts that these added costs are simply not feasible for smaller operations. Smaller producers do not have the same economies of scale as larger producers and cannot spread increases in fixed compliance costs over as many projects. This could result in many of them going out of business as they struggle to maintain profitability.

Several commenters (0793-PBPA, 0924-USSBA, 0411-REM, 0824-WDEQ, 1341-Conventional Groups, 0431-NOI, 0577-KIOGA, 0946-MOGA) in support of their concerns, provide data and analysis related to small businesses, marginal wells, stripper wells and low-production wells for EPA consideration.

Commenter (0793-PBPA) states that databases such as ones developed by Enverus' (formerly known as Drillinginfo), shows that there are approximately 2,960 different operators operating 186,338 Texas oil wells that produce approximately 4,900,000 bpd. Eighty percent of the daily production is generated from the top 1% of the total operators. Furthermore, 49% of the wells are operated by the top 1% of operators. On the other hand, 94% of operators produce only 3% of the total oil production (152,000 bpd) and operate 37% of the wells in Texas. Most of the 94% described above would be considered small businesses, and those entities' average production per well is about 2.2 bpd—dwarfed by average production per well of 56.5 bpd for the largest 1% of operators. The commenter contends that the proposed rule will disproportionately impact these small operators. For example, the additional burden of quarterly leak detection and repair (LDAR) surveys will be significant and, using the EPA's own numbers, will equate to approximately 25% of the operating revenue for those wells.

Using the same example above, the commenter (0793-PBPA) notes that the average production for 94% of Texas operators is 2.2 bpd, which sells for approximately \$55 per barrel. At the same

---

<sup>152</sup> "Quantification of Methane Emissions from Marginal (Small Producing) Oil and Gas Wells" (under review), U.S. Department of Energy, National Energy Technology Laboratory: <https://netl.doe.gov/node/9373>

time, the commenter reports that the annual compliance cost associated with replacing existing pneumatic valves and quarterly LDAR at each facility and semiannual well sites is roughly \$5,880, or almost 18% of gross revenues for 94% of Texas operators. The commenter adds that new OGI requirements in Appendix K will cost up to three times the existing costs, pushing compliance costs for 94% of Texas operators to over 50% of existing revenues. According to the commenter, that's all prior to considering other operating costs.

To illustrate the effect of increasing costs 18%, the commenter (0793-PBPA) states that a company operating approximately 1,350 wells averaging 79 bpd would have approximately 15% of all wells become immediately uneconomic if costs increased \$5,880 per year at \$55 per barrel. That means that for this one operator, the production of 550 bpd (0.5% of immediate production) immediately becomes uneconomic. The EPA estimated that, at its peak, the rule would impact approximately 33,400 bpd of domestic production, but the immediate effect in Texas alone is likely to be more than five times that number. Thus, over the life of the rule, the commenter contends that the compliance costs could reduce expected recoverable reserves by about 6%, or for the operator described above, 8.5 million barrels. The commenter suggests that, if compliance costs are anything more than estimated by the EPA, such increase will have a proportional effect on production and be even greater than the above example.

Another commenter (0924-USSBA) states that small businesses also face a greater burden proportionally to comply with reporting and recordkeeping costs. For example, the EPA estimates the annual reporting and recordkeeping burden of NSPS OOOOa compliance to be 87 hours per respondent.<sup>153</sup> Using the above example of the crude petroleum extraction industry, for a firm of five employees, this would mean that no less than 0.84 percent of the business's total hours in a year would be devoted to regulatory compliance for just this component. However, for a business with 500 employees, they would presumably have 1,040,000 labor hours per year (500 employees working 2,080 hours a year) at their disposal, meaning the percent of total hours they would have to use to comply with this regulation would be 0.008 percent. Therefore, smaller businesses would have to spend a greater percentage of their time and labor costs complying than larger businesses.

Another commenter (0411-REM) states that in Michigan's Antrim producing horizon the average well only produces 15 thousand cubic feet (Mcf) per day. The profit margins are minimal to keep these wells economic to produce, yet with over 10,000 of these wells producing they supply vital heat for Michigan homes through long cold winters. Using the EPA's \$3.13/Mcf, the Michigan basin averages a \$0.19/Mcf lower gas price basis than the normal gas index price. An average Antrim well would generate \$1,058.40 a month after paying a 20% royalty to landowners before expenses. To transport this gas to market and treat the gas to make it sellable costs on average \$0.30/Mcf for transportation and \$0.35/Mcf for treating, costing \$234 per month. Costs for operating and compression average \$1.10/Mcf or \$396 per month. Overhead for office and administration averages \$250/well/month. All in, after expenses, an average Michigan Antrim well has a net profit of \$178.40 per month, leaving little room for capital investment.

---

<sup>153</sup> 2021 November RIA, pp. 4-54.

Another commenter (0824-WDEQ) notes that the requirements would affect many stripper wells in Wyoming (defined by the Wyoming Oil and Gas Conservation Commission (WOGCC) as wells that produce an average of 15 bbls or less per day) and some very small-scale, independent well site operations that strictly operate on a single owner's private property. According to the WOGCC, Wyoming has approximately 6,524 stripper wells. The commenter adds that the shift to a 3 ton-per-year (tpy) total site-level baseline methane emissions threshold for triggering quarterly OGI monitoring is concerning. The commenter anticipates this new emissions threshold could lead to the quarterly monitoring requirements for many existing stripper wells. According to the commenter, many of these smaller sites simply cannot shoulder the financial burden associated with these requirements and the economic ramifications could be significant. According to the WOGCC, in 2019, there were 6,848 stripper wells in Wyoming that produced a total of 6,959,356 bbls of oil for the year and in 2020, there were 6,524 stripper wells in Wyoming that produced a total of 5,970,758 bbls of oil. Loss of these wells would eliminate jobs and reduce revenue to Wyoming and local communities with no significant environmental benefit.

Another commenter (1341-Conventional Groups) states that conventional wells have lower profitability than unconventional wells and are strongly influenced by oil and natural gas commodity prices and other market forces. For example, in 2020, the commenter reports that Pennsylvania's conventional producers suffered deficits ranging from \$0.50 to \$1.20 per Mcf. They add that, at an annual production of less than 2000 Mcf (expected to occur at about year 17), the average conventional gas well's net revenue becomes inadequate to cover all operating costs. Recovery of capital costs, while more likely with the conventional oil well, is still infeasible in the face of the operating costs. Like the average gas well, the average oil well's net revenue becomes inadequate to cover all operating costs at about year 13, even if the matter of the repayment of the capital costs are ignored.

Commenter (0431-NOI) states that their company operates 170 natural gas wells and 11 oil stripper wells. They consider a well a stripper well if it is less than 15 barrels of oil per day. Since these are low producing wells, they are also minimally profitable especially with occasionally lower per barrel oil sales price. The commenter's small business operational objective is to minimize costs to produce oil from these marginally economical wells to make a profit. The commenter estimates that 75% to 85% of the 770,000 stripper wells in the U.S. would essentially be plugged because compliance would make them uneconomical, and the producers would be under severe stress to comply making it too difficult to endure the cost and added penalties of compliance. In other words, the commenter contends that the remaining reserves of those stripper wells would not allow those wells to be profitable versus the cost it would take to comply. The commenter suggests that, with the current availability of contractors, they expect it would take 3+ year to plug all the stripper wells in our area let alone other parts of the country.

Another commenter (0577-KIOGA) notes that oil and natural gas production systems account for about 1.2% of the US Green House Gases Inventory (GHGI). Low production wells account for about 10-11% of U.S. production. Their emissions would be in the 0.10-0.20% range of the GHGI. There are about 1,000,000 existing oil and natural gas wells. Approximately 150,000 of these wells have been regulated under NSPS OOOO and now NSPS OOOOa. That number grows each year. Of the remainder, 770,000 are low production wells. Nationally, low production wells average about 2.5-2.7 bpd if they are oil wells and 22- 24 Mcf per day if they

are natural gas wells. The commenter states that Kentucky has more than 1,000 oil and gas companies registered to do business with the Kentucky Energy and Environmental Cabinet (KECC) Division of Oil and Gas. This does not include the number of support companies that oil and gas operators contract with to produce energy products. Almost all these operators meet the definition of a Small Business Entity. The proposed regulations will be economically demanding and technically challenging for most of the oil and gas companies throughout Kentucky.

The commenter (0577-KIOGA) adds that the 2021 November proposed emission guidelines (EG) would impose a burden and costs for the small businesses that make up the independent oil and gas industry and for the state of Kansas. The commenter explains that there are over 62,000 oil wells and over 20,000 natural gas wells in Kansas. They note that other comparable states estimated costs to develop and implement the 2021 November proposed rulemaking to be over \$40 million annually. Furthermore, these states estimate the cost on the proposed timing (final compliance within 2 years) is higher (over \$278 million annually). The commenter states that this estimate includes the need for 2,708 additional full time equivalent persons to be hired. They assert that Kansas would incur similar costs.

Commenter (0946-MOGA) provides information related to small businesses in Michigan:

- Approximately 98.8-99% of all oil companies are owned by small businesses and that approximately 92.9-93. 7% of all natural gas companies are owned by small businesses.
- MOGA membership constitutes around 650 members.
- In total, the oil and gas industry in Michigan directly or indirectly employs roughly 47,000 voting residents.

Another commenter (0749-PAW) states that Wyoming is a top-10 producer of oil and natural gas. And that recent studies show this industry supports over 68,000 jobs in Wyoming and contributes \$10 billion in economic activity. According to the commenter, the 2021 November regulatory proposal will have consequential implications across the industry and will have an acute impact on the economics of smaller operations, of which Wyoming is home to many.

Response I-20-27: EPA disagrees with commenters' assertions that it has not adequately considered the impacts of the rule on small producers. As a general matter, EPA's position is that, for the purposes of RFA compliance, only the NSPS OOOOb is relevant at the time of promulgation of this final rule; compliance with the RFA regarding the EG OOOOc will be addressed as part of the process of developing the federal plan. Still, much of the discussion of regulatory flexibility alternatives in the revised IRFA found in the December 2022 RIA and the FRFA found in the final rule RIA apply to affected sources under each subpart.

In the revised IRFA and FRFA, EPA provides an extensive discussion of regulatory flexibility alternatives and notes key areas where options were chosen to reduce regulatory burden on small businesses. For example, in response to commenters (e.g., 0824-WDEQ, 1422-U.S. Congress, and 0793-PBPA) concerns about the cost of Appendix K and OGI monitoring in general, EPA revised its proposed fugitive emissions monitoring requirements at well sites to allow for AVO inspections at sites with little or no equipment, which EPA believes disproportionately alleviates regulatory burden on small businesses without sacrificing significant environmental benefits. In

addition, EPA's analysis suggests that sites with little to no equipment are less likely to be impacted by process controller and pump requirements.

In addition, contrary to some commenters' assertions (0431-NOI, 0793-PBPA) EPA disagrees that the regulation will lead to the plugging of most (75-80%) marginal wells or significant losses of production. Neither commenter included enough information about the assumptions underlying their assertions for EPA to assess the claims made, but EPA developed a financial analysis of marginal oil and natural gas wells in Chapter 6 of the Final Rule TSD. EPA finds that marginal wells may continue to operate at low or negative profits rather than be shut-in and plugged due to a variety of reasons, including low operating costs, high plugging costs, low state bonding requirements, accounting practices, and tax credits available to the oil and gas industry. Moreover, to mitigate the impact of abandoned wells, the Inflation Reduction Act (IRA) provides \$700 million for methane and greenhouse gas mitigation activities for conventional marginal wells. The Department of Energy and the EPA have issued a joint Notice of Intent to provide grants up to \$350 million for conventional marginal well plugging as an initial effort to distribute the IRA funds. The goal of marginal well funding from the IRA is to offset the cost of plugging low producing wells. Additionally, the federal money reduces the possibility that the operator files for bankruptcy and orphans their well(s). EPA is unable to assess the viability of the owners and operators of the marginal wells, and as such, EPA is therefore unable to predict which firms will be most adversely affected by regulatory costs.

In response to comments that state that the EPA must perform small business-specific cost evaluation for all sources under the proposed rule using a more granular approach to the cost-effectiveness analysis and that unique aspects of small businesses were not considered in the development of analyses, we disagree. When conducting BSER for affected facilities/designated facilities, one aspect is to evaluate the cost of a control. As part of that evaluation, the EPA considers various associated costs, including capital costs and operating costs (and retrofit costs and challenges), including costs provided by commenters (including small businesses). While our analyses do not reflect every known scenario and equipment configuration, the EPA addresses unique circumstances presented by commenters where it is supported. As an example, see section XI.G.6 (Wet seal compressors equipped with a seal oil gas separation system utilized on the Alaska North Slope (ANS)) of the final rule preamble, where a commenter provided information to support an alternative performance-based volumetric flow rate standard for wet seal compressors equipped with a seal oil gas separation system utilized on the ANS.

As discussed in section VIII.B (How does EPA evaluate control costs in this final action?) of the final rule preamble, the final standards will impose some new costs on industry (including small businesses). Many of the standards, however, reflect control mechanisms and measures that many companies and sources around the country are already implementing — again, without deleterious effect on industry as a whole — which shows not only that such controls are “adequately demonstrated” but also underscores their reasonableness from a cost perspective. The EPA provides the cost effectiveness estimates for reducing VOC and methane emissions for various control options considered in the November 2021 Proposal and the December 2022 Supplemental Proposal, as well as in section XI of this preamble and associated TSDs. See also Volume II, Chapter 4 (Fugitive Emissions from Well Sites, Centralized Production Facilities, and Compressor Stations), section 4.3.4 (Small Business/Cost Concerns) comments and responses on small business/cost concerns related to fugitive emissions requirements.

With regards to comment that the estimated costs are understated. The EPA updated costs in December 2022 Supplemental Proposal analyses based on specific costs provided by differing commenters on the November 2021 Proposal for several affected facilities/designated facilities, as appropriate. The EPA has maintained costs used in BSER analyses to represent 2019 dollars.

Also, as noted above, the revised IRFA and FRFA provides an extensive discussion of regulatory flexibility alternatives and notes key areas where options were chosen to reduce regulatory burden on small businesses. In addition to providing several compliance alternatives for affected facilities under NSPS OOOOb and designated facilities under EG OOOOc, the EPA has also considered issues such as lingering supply chain issues and increased demand for equipment and services when establishing compliance, and repair and delay of repair provisions included in the final NSPS OOOOb and EG OOOOc rules to account for parts not being available.<sup>154</sup>

Additionally, both NSPS OOOOb and EG OOOOc include provisions that could be pursued for an alternative but equivalent compliance option under NSPS OOOOb or equivalent or less stringent requirements considering remaining useful life and other factors (RULOF) under EG OOOOc under a state plan. 40 CFR 60.5399b (What are the alternative means of emission limitations for GHG and VOC emissions from well completions, liquids unloading operations, centrifugal compressors, reciprocating compressors, fugitive emissions components, and process unit equipment affected facilities; and what are the alternative fugitive emissions standards based on state, local, and tribal programs?) of NSPS OOOOb provides procedures for the submittal and approval of alternative means of emission limitation for GHG and VOC based on work practices for well completions, liquids unloading operations, centrifugal compressors, reciprocating compressors, fugitive emissions components and process unit equipment affected facilities. See section XIII.C (Establishing Standards of Performance in State Plans) of the final rule preamble for state plan requirements and sub-section XIII.C.3 (Remaining useful life and other factors (RULOF)) of the final rule preamble for a summary of the RULOF provisions that have been finalized in the subpart Ba rulemaking (codified at 40 CFR part 60, subpart Ba).

For other comments arguing that EPA's one-size fits all approach does not adequately address the variability across the industry and EPA's responses, see Volume I, Chapter 23 (Miscellaneous Other Comments), section 23.17 (One-Size Fits All Approach) of this RTC document.

In response to the comment suggesting that the monitoring surveys outlined in section 9 of Appendix K would impose impossible expenses on small operators, the EPA, in response to the comments received on the November 2021 Proposal, proposed a different regulatory approach for fugitive emissions from well sites, centralized production facilities, and compressor stations in the December 2022 Supplemental Proposal. In the final rule, the EPA is not requiring OGI monitoring in accordance with the proposed appendix K for well sites or centralized production facilities, as was proposed in the November 2021 Proposal. Instead, the EPA is requiring OGI surveys following the procedures specified in the regulatory text for NSPS OOOOb (at 40 CFR 60.5397b) or according to EPA Method 21. This change is consistent with the requirements for OGI surveys found in NSPS OOOOa at 40 CFR 60.5397a. For details, please see discussion in

---

<sup>154</sup> See sections XI.A.1.e (Delay of repair due to parts unavailability) of the final rule preamble for example.

section IV.A.1.a.ii and IV.A.2.a of the December 2022 Supplemental Proposal<sup>155</sup> related to fugitive emissions from well sites, centralized production facilities, and compressor stations; and discussion in section XVII (Regulatory Flexibility Analysis (RFA)) in the final rule preamble.

In response to comment that refers to the U.S. DOE study of emissions from low production wells, see EPA's responses to similar comments and EPA's review of the study in section XI.A.1.d (Subcategorization of well sites) of the final rule preamble.

Comment: Several commenters (0929-NSWA, 0585-KOGA, 0425-Darrah, 0424-WV DEPDAQ, 0464-MOPC, 0465-JDC, 0424-WV DEPDAQ) express concern that the proposed regulations will facilitate a landslide of premature well plugging in rural communities. Particularly of wells owned by individual homeowners, farmers, or small business entities such as family limited partnerships. Additional impact to these rural community is loss of the well energy source. Many homeowners use natural gas production from their wells to heat their homes. Many farmers utilize farm taps to existing energy assets on, or near, their farm to provide heat to their home and farm buildings / grain drying equipment. The current electric power infrastructure will not support the increase in power demand for some of the homeowners/farmers that are currently supplied by natural gas. The loss of energy and revenue will also have a ripple effect on other support and service sector small businesses, as well as rural towns themselves that rely on the industry to survive. Notably these small operators serve hundreds of customers in small towns and rural areas who heat and cook with natural gas, this potential outcome would negatively impact these citizens; many of whom are low income or on fixed incomes.

Commenter (0424-WV DEPDAQ) is deeply concerned about the subset of existing well sites that are owned by individual homeowners, farmers, or companies with very few employees such as family limited partnerships. The commenter states that the RIA for the 2021 November proposed rulemaking does not address the cost burden to homeowners and farmers who heat their home with a natural gas well that either is on their property or have access to it for allowing right-of-way for a pipeline across their property. The commenter suggests that, because the EPA has not been fully able to evaluate the cost burden on homeowners and farmers who use the natural gas production for the purpose of heating their home [86 Fed. Reg. 63174], those individuals or very small businesses should be exempt from regulation.

Response I-20-28: In the revised IRFA and FRFA, EPA provides an extensive discussion of regulatory flexibility alternatives and notes key areas where options were chosen to reduce regulatory burden on small businesses. While, as a general matter, EPA's position is that, for the purposes of RFA compliance, only the NSPS OOOOb is relevant at the time of promulgation of this final rule, much of the discussion of regulatory flexibility alternatives in the revised IRFA found in the December 2022 RIA and the FRFA found in the final rule RIA apply to affected sources under each subpart. As an example, EPA revised its proposed fugitive emissions monitoring requirements at well sites to allow for AVO inspections at sites with little or no equipment, which EPA believes disproportionately alleviates regulatory burden on small businesses without sacrificing significant environmental benefits. In addition, EPA's analysis

---

<sup>155</sup> 87 FR 74722-74723 and 74739.

suggests that sites with little to no equipment are less likely to be impacted by process controller and pump requirements.

In addition, EPA developed a financial analysis of marginal oil and natural gas wells in Chapter 6 of the Final Rule TSD. EPA finds that marginal wells may continue to operate at low or negative profits rather than be shut-in and plugged due to a variety of reasons, including low operating costs, high plugging costs, low state bonding requirements, accounting practices, and tax credits available to the oil and gas industry. To mitigate the impact of abandoned wells, the Inflation Reduction Act (IRA) provides \$700 million for methane and greenhouse gas mitigation activities for conventional marginal wells. The Department of Energy and the EPA have issued a joint Notice of Intent to provide grants up to \$350 million for conventional marginal well plugging as an initial effort to distribute the IRA funds. The goal of marginal well funding from the IRA is to offset the cost of plugging low producing wells. Additionally, the federal money reduces the possibility that the operator files for bankruptcy and orphans their well(s).

Comment: Several commenters recommend relief for small businesses, marginal wells, stripper wells and low-production wells. Suggestions provided include:

- The threshold for emissions monitoring in tons per year (tpy) needs to be at least doubled because of the cost of compliance is simply too high versus the benefit that would be derived from it.
- Individual homeowners, farmers, and small business with very few employees should be exempt. (0424-WVDAQ, 0577-KIOGA)
- Marginally producing wells (15 barrels of oil equivalent per day (BOEPD)/90 thousand cubic feet per day (MCFPD) or less) must be exempt from EPA rules because the emissions are insignificant, and the rules would be uneconomic. There must be a regulatory "off ramp" for wells such as ours that are low producers. (0464-MOPC, 0465-JDC, 0923-Lambda)
- Recommend that the same exemptions allowed for Alaska be provided for other areas with the same cold weather challenges. (0431-NOI)
- Grandfather in marginal wells to preserve production while focusing on higher producing, more profitable wells for emissions related capital expenditures. (0411-REM)
- Withdraw the regulations for small business. (0193-NFIB)

Commenter (1341-Conventional Groups) states that the EPA's projected cost for the 2021 November proposed new LDAR requirements of \$4,227 per well site in the first year and \$3,200 per well site per year on an ongoing basis would be financially devastating to virtually every member of the Conventional Groups. The commenter adds that:

- The vast majority of Pennsylvania conventional oil and gas wells were drilled more than 15 years ago. The same is generally true for those in New York.
- It is no longer economical to drill new conventional oil or gas wells in Pennsylvania, due to the significant drop in natural gas prices in Pennsylvania caused by unconventional gas well production.
- These economic forces have resulted in no new conventional gas wells being drilled in southwestern Pennsylvania in over five years.

- In all, the drilling of new conventional oil and gas wells has dropped 98% over those last 15 years.

According to the commenter (1341-Conventional Groups), given that most of the conventional oil and gas wells were drilled more than 10 years ago, those wells have already reached the point where annual gross revenue is close to and may be below the EPA's projected first-year compliance cost for the Proposal's LDAR requirements. The commenter states that such projected compliance costs are certainly "exorbitant," "excessive," "unreasonable," and far "greater than the industry could bear to survive. The commenter suggests that EPA should not be proposing LDAR requirements that would place the critically important conventional oil and gas industry in economic peril, simply so any methane and VOC emission from these low-producing and low-emitting well sites can be reduced by a fraction.

Response I-20-29: In the revised IRFA and FRFA, EPA provides an extensive discussion of regulatory flexibility alternatives and notes key areas where options were chosen to reduce regulatory burden on small businesses. While, as a general matter, EPA's position is that, for the purposes of RFA compliance, only the NSPS OOOOb is relevant at the time of promulgation of this final rule, much of the discussion of regulatory flexibility alternatives in the revised IRFA found in the December 2022 RIA and the FRFA found in the final rule RIA apply to affected sources under each subpart. As an example, EPA revised its proposed fugitive emissions monitoring requirements at well sites to allow for AVO inspections at sites with little or no equipment, which EPA believes disproportionately alleviates regulatory burden on small businesses without sacrificing significant environmental benefits. In addition, EPA's analysis suggests that sites with little to no equipment are less likely to be impacted by process controller and pump requirements.

In addition, EPA developed a financial analysis of marginal oil and natural gas wells in Chapter 6 of the Final Rule TSD. EPA finds that marginal wells may continue to operate at low or negative profits rather than be shut-in and plugged due to a variety of reasons, including low operating costs, high plugging costs, low state bonding requirements, accounting practices, and tax credits available to the oil and gas industry. To mitigate the impact of orphaned wells, the Inflation Reduction Act (IRA) provides \$700 million for methane and greenhouse gas mitigation activities for conventional marginal wells. The Department of Energy and the EPA have issued a joint Notice of Intent to provide grants up to \$350 million for conventional marginal well plugging as an initial effort to distribute the IRA funds. The goal of marginal well funding from the IRA is to offset the cost of plugging low producing wells. Additionally, the federal money reduces the possibility that the operator files for bankruptcy and orphans their well(s).

Comment: Commenter (0822-TAEP) states that the proposed requirements will require new hires and expenditures that will hit small business operators especially hard, and the commenter urges the EPA to reconsider measures to protect small businesses from costly regulation that limits their ability to compete, let alone function, under the added administrative burdens. Employment in the industry has been severely impacted by COVID-19 and a contraction of the industry since the EPA did their last analysis on manpower cost and time requirements. These factors, combined with the increasing burden of inflation will likely result in higher servicing and equipment costs for operators, further exacerbating the burden of compliance. The commenter suggests that the DOE's analysis of marginal wells and their potential emissions may

help to shed additional light on the potential risk profile of those assets which are universal across the industry, held by small and large operator alike. In both cases, if the costs to operate exceed the facility's production value, those operators will shut-in that asset, losing domestic production.

Commenters (0946-MOGO, 0824-WDEQ, 1341-Conventional Groups) express concern with EPA's apparent lack of knowledge, characterization and generalization of the oil and gas production environment, which they believe will result in a discriminatory "one-size-fits-all" approach which will place a tremendous financial burden on small business operators based on incorrect assumptions and data. Commenter (0824-WDEQ) suggests that EPA fully integrate all existing control program approaches and the benefits and costs of technology standards before adding more regulations.

Commenter (0763-TCEQ) is concerned that EPA's analysis of the costs associated with the proposal are based on the overall capital expenditures and income of the industry as a whole, whereas the companies in Texas involved in the oil and gas industry vary greatly in size and resources. The commenter is concerned that basing the reasonableness of regulations on industry-wide data misses the greater impact to small businesses, especially those operating low-production wells. The commenter states that the costs of complying with the proposed requirements at the numerous small mom and pop operators will be extremely high compared to the income from their operations. By way of example, the commenter states that in Texas alone, over 4,100 operators own and operate 10 or less oil leases and gas wells.

Response I-20-30: In the revised IRFA and FRFA, EPA provides an extensive discussion of regulatory flexibility alternatives and notes key areas where options were chosen to reduce regulatory burden on small businesses. While, as a general matter, EPA's position is that, for the purposes of RFA compliance, only the NSPS OOOOb is relevant at the time of promulgation of this final rule, much of the discussion of regulatory flexibility alternatives in the revised IRFA found in the December 2022 RIA and the FRFA found in the final rule RIA apply to affected sources under each subpart. As an example, EPA revised its proposed fugitive emissions monitoring requirements at well sites to allow for AVO inspections at sites with little or no equipment, which EPA believes disproportionately alleviates regulatory burden on small businesses without sacrificing significant environmental benefits. In addition, EPA's analysis suggests that sites with little to no equipment are less likely to be impacted by process controller and pump requirements.

In addition, EPA developed a financial analysis of marginal oil and natural gas wells in Chapter 6 of the Final Rule TSD. EPA finds that marginal wells may continue to operate at low or negative profits rather than be shut-in and plugged due to a variety of reasons, including low operating costs, high plugging costs, low state bonding requirements, accounting practices, and tax credits available to the oil and gas industry. To mitigate the impact of abandoned wells, the Inflation Reduction Act (IRA) provides \$700 million for methane and greenhouse gas mitigation activities for conventional marginal wells. The Department of Energy and the EPA have issued a joint Notice of Intent to provide grants up to \$350 million for conventional marginal well plugging as an initial effort to distribute the IRA funds. The goal of marginal well funding from

the IRA is to offset the cost of plugging low producing wells. Additionally, the federal money reduces the possibility that the operator files for bankruptcy and orphans their well(s).

Comment: Commenter (0946-MOGA) notes that the EPA did not consider or incorporate comments and concerns regarding the technical and financial infeasibility resulting from limited and condensed interactions with the small business segment of the oil and gas production industry before proposing new regulations. The commenter and others participated as a small entity representative (SER) on the Small Business Advocacy Review ("SBAR") Panel Process required under the Regulatory Flexibility Act ("RFA"), as amended by the Small Business Regulatory Enforcement Fairness Act (SBREFA). The commenter is reiterating several of our final comments submitted to the EPA on August 12, 2021, to highlight their concern with the EPA's lack of consideration and incorporation of SER's concerns and comments prior to the publication of the current proposed regulations.

Response I-20-31: In the revised IRFA and FRFA, EPA provides an extensive discussion of regulatory flexibility alternatives and notes key areas where options were chosen to reduce regulatory burden on small businesses. While, as a general matter, EPA's position is that, for the purposes of RFA compliance, only the NSPS OOOOb is relevant at the time of promulgation of this final rule, much of the discussion of regulatory flexibility alternatives in the revised IRFA found in the December 2022 RIA and the FRFA found in the final rule RIA apply to affected sources under each subpart. As an example, EPA revised its proposed fugitive emissions monitoring requirements at well sites to allow for AVO inspections at sites with little or no equipment, which EPA believes disproportionately alleviates regulatory burden on small businesses without sacrificing significant environmental benefits. In addition, EPA's analysis suggests that sites with little to no equipment are less likely to be impacted by process controller and pump requirements.

### ***20.2.8 Employment Impacts***

Comment: Several commenters provide input regarding how they believe the 2021 November proposed rule will affect industry employment overall and in their states. Examples of some of the comments provided are included in the following paragraphs.

Commenter (0822-TAEP) notes that the EPA's proposal will necessitate additional workforce to facilitate equipment changeovers, additional monitoring and reporting duties, and a growing administrative compliance obligation. The commenter asserts that the need for new hires will hit small business operators especially hard.

Commenter (1302-WOC) believes that as the standards around methane emissions are developed, the oil and natural gas sector is poised to grow and create new jobs, helping Wyoming modernize its oil and gas infrastructure and stay competitive as consumer energy preferences change to favor low-carbon fuel sources. The commenter states that the creation of new jobs in this sector could help employ current and former workers in the oil and gas industry. They add that the EPA's new methane rules will continue to encourage the growth of similar such monitoring technologies and businesses, creating new jobs, more cost-effective ways to

implement and scale leak detection and repair, and reducing the impact of energy development on climate change and air quality.

Commenter (1423-USCongress) states that reducing methane emissions can create good, high-quality jobs. The methane mitigation service sector in the U.S. has nearly doubled in size since 2017 and would have further opportunity to grow.<sup>156</sup>

Conversely, commenter (0728-OK DEQ) states that one issue of concern they have is the lack of any detailed projections of likely reductions in oil and gas employment. They explain that this is particularly concerning in Oklahoma due to the number of marginal wells that remain in operation and whose financial viability may be precarious. The commenter adds that the jobs in the oil and gas sector are particularly well-paying when compared to alternatives, especially in rural areas and, because job losses are likely to be localized, the effects are magnified in those communities. Further, they state that it is their contention that the economic impacts of the proposed rules will likely be significantly harmful to rural communities dependent on this industry. It is with this concern in mind that the commenter recommends that the EPA consider economic impacts of the proposed rulemaking with the same level of granularity and diligence that was used in evaluating benefits of the rule for environmental justice comments. The importance of oil and gas jobs is further warranted by the information in Table 4-8 of the 2021 November proposed rule RIA which shows that the average income for oil and natural gas workers is \$110,000 while the average income for other workers in “oil and gas communities” is \$40,000. Thus, for every oil and gas job lost, even if there is a new non-oil and gas job created in the same community, there will be a net loss of \$71,000 with additional spillover effects in the community.

Commenter (0597-IOGA) indicates that in addition to losing energy sources and royalty income, jobs will also be lost as the needed staff decreases. As a substantial number of marginal wells are plugged, our members will be forced to reduce staff because they cannot afford to continue to pay them with a smaller revenue stream. The commenter contends that this loss of good paying jobs will have a direct impact on our communities. We believe that the EPA’s proposed regulations will continue to support the decline in oil production throughout the state of Indiana. According to the commenter, the additional costs from NSPS OOOOa discouraged many operators from performing work on their assets due to the additional compliance costs. The commenter reports that their members provide a critical energy source and reliable income for communities.

Commenter (1300-PLS) states that, as noted above (section 20.2.7), they believe that the proposed rules will result in huge financial burdens for Small Independent Oil & Gas Operators making stripper wells uneconomic to produce. According to the commenter, if these natural gas and oil wells cease to produce, there will be numerous good-paying jobs lost in our rural Montana communities, with subsequent loss in local tax dollars for community infrastructure. The commenter explains that these small highline communities cannot be compared to other communities, due to the rural nature and sparse population, being under 1,100 people, who

<sup>156</sup> Lowe, Marcy, et al.. “Find, Measure, Mix: Jobs in the U.S. Methane Emissions Mitigation Industry.” Environmental Defense Fund Report, Prepared by Datu Research, June 2021.  
<https://www.edf.org/sites/default/files/content/FindMeasureFixReport2021.pdf>

depend heavily on these natural resource jobs. The commenter recommends that stripper natural gas and oil wells be exempt from these rules and regulations.

Commenters (0431-NOI, 1341-Conventional Groups) note that they cannot find contractors or personnel now that could both modify the equipment for compliance to meet 2021 November proposed requirements and to handle the daily or quarterly compliance issues. As discussed in section 20.2.7 of this Chapter, commenter (0924-USSBA) notes that small businesses frequently lack the benefits packages larger businesses have (quality of healthcare, and other benefits) leaving smaller businesses at a disadvantage when hiring compliance staff.

Response I-20-32: EPA acknowledges the challenge in assessing the employment impacts of the regulation. To the extent that regulatory costs lead to reduced production, sector employment could be reduced, though this is not guaranteed as firms could simultaneously reallocate expenditures on productive inputs away from capital and towards labor because of the regulation. In addition, as noted by some commenters, the regulation may also increase employment by increasing the demand for compliance-related labor. The net effect is ambiguous without sufficient data, which hasn't been provided by commenters.

Specific to small business employment, in the revised IRFA and FRFA, EPA provides an extensive discussion of regulatory flexibility alternatives and notes key areas where options were chosen to reduce regulatory burden on small businesses. While, as a general matter, EPA's position is that, for the purposes of RFA compliance, only the NSPS OOOOb is relevant at the time of promulgation of this final rule, much of the discussion of regulatory flexibility alternatives in the revised IRFA found in the December 2022 RIA and the FRFA found in the final rule RIA apply to affected sources under each subpart. According to commenters, the steps taken to alleviate burden on small businesses should mitigate impacts on employment at those firms.

### ***20.2.9 Intergovernmental Panel Climate Change (IPCC) Climate Report – Social Cost Metrics***

Comment: Commenter (0804- CCES et al) states that critics allege that the chosen Equilibrium Climate Sensitivity (ECS) distribution—that is, the amount of warming that is expected to result from a doubling of the atmospheric CO<sub>2</sub> concentration—is outdated and fails to account for recent evidence showing that sensitivity to be lower than previously believed. According to the commenter, these arguments rely on cherry-picked data and ignore the scientific consensus.

In 2016, the commenter (0804- CCES et al) states that the National Academies of Sciences (NAS) dedicated an entire report to whether the Working Group should update the social cost metrics to reflect more recent science on the ECS. The NAS decided that such an update was unnecessary, “recommend[ing] against a near-term change in the distributional form of the ECS” and explaining that any reasonable revisions on this front would “have a minimal impact on estimates of the [social cost of greenhouse gases].”<sup>157</sup>

---

<sup>157</sup> Nat'l Acad. Scis., Eng'g & Med., Assessment of Approaches to Updating the Social Cost of Carbon: Phase 1 Report on a Near-Term Update 34, 46 (2016), available at <https://perma.cc/TJM6-XE65> [hereinafter “NAS 2016 Report”].

On top of the NAS' rejection of this argument, the commenter (0804- CCES et al) asserts that there is little support for the claim that the Working Group overstated the pace of climate change. The most recent estimate from the IPCC—which reflects consensus estimates from the worldwide scientific community—projects an ECS range from 2.5°C to 4°C, with 3°C as a “best estimate.”<sup>158</sup> According to the commenter, this is consistent with the range applied by the Working Group—based off of Roe & Baker—which uses 3°C as its median and 3.5 °C as its mean ECS value.<sup>159</sup> In evaluating the ECS, the Working Group assessed estimates from a wide range of experts and selected consensus values. In fact, as the Working Group acknowledged, some ECS estimate ranges go as high as 10° C, making its selected ECS distribution substantially lower than these high-end estimates and a reasonable middle range.<sup>160</sup>

In previous dockets, the commenter (0804- CCES et al) states that opponents of the Working Group's estimates have cited Lewis & Curry (2015)—which estimates a median ECS of 1.64 °C with an uncertainty range (5–95%) of 1.05–4.05 °C—to suggest that the Working Group applied an inappropriately high ECS range.<sup>161</sup> But in light of the consensus estimates discussed above, that paper is a severe outlier. Since its publication, in fact, Lewis & Curry (2015) has been criticized by other climate scientists for methodological deficiencies that cause it to underestimate the ECS.<sup>162</sup> And as noted above, the National Academies did not think that Lewis & Curry (2015) merited an update to the Working Group's valuations to revise the ECS estimates.<sup>163</sup>

The commenter (0804- CCES et al) adds that critics further argue that the ECS distribution applied by the Working Group inappropriately skews rightward, meaning that its mean ECS value exceeds the median value of 3° C that the IPCC has indicated. But that decision is a feature, not a bug. As the National Academies explained, the IPCC has found that there is a “positively skewed distributional form for [the ECS] parameter” similar to the ECS distribution applied by the Working Group.<sup>164</sup> In other words, the commenter states that the mean ECS value should be higher than the median ECS value, and the Working Group applied an appropriate distribution. Criticisms to the contrary are meritless.

Commenter (0804-CCES et al) notes that critics further argue that the Working Group's valuations are an overestimate because they apply outdated emission scenarios that exaggerate the baseline level of atmospheric greenhouse gas levels. The commenter explains that using a higher baseline level of emissions raises the social cost estimates because the harm from an additional unit of emissions increases with the baseline atmospheric emissions level. However, the commenter states that the Working Group used a reasonable emissions baseline that reflects different possible mitigation scenarios.

<sup>163</sup> NAS 2016 Report, *supra* note 207.

<sup>164</sup> *Id.* at 25.

According to the commenter (0804-CCES et al), while the Working Group assumed a baseline emissions range of 13–118 gigatons of carbon dioxide emitted per year by 2100,<sup>165</sup> recent projections from the Climate Action Tracker indicate that baseline emissions will reach between 14–175 gigatons of carbon dioxide by 2100 under a range of scenarios reflecting different levels of mitigation.<sup>166</sup> Thus, the commenter contends that the baselines used by the Working Group potentially understate baseline emissions rather than overvalue them as opponents argue. In fact, several of the Working Group’s supposedly “business-as-usual” scenarios are actually more consistent with baseline estimates reflecting policy projections.<sup>167</sup> Accordingly, they add that the criticism that the Working Group overestimated future greenhouse gas concentrations in the atmosphere falls flat.

Moreover, the commenter (0804-CCES et al) states that this choice does not particularly affect the social cost valuations. In comparison to the Working Group’s central social cost of carbon estimate in 2020 of \$51 per ton, the commenter reports that the average social cost of carbon under the Working Group’s supposed business-as-usual emissions scenarios is \$53 per ton and \$41 per ton under the emissions scenario that is consistent with sustained and widespread mitigatory action.<sup>168</sup> While relying less on the Working Group’s supposed business-as-usual scenarios would therefore modestly decrease the interim social cost valuations in a vacuum, more holistic updates to the metrics as recommended by the NAS would very likely increase the social cost valuations overall due to the omitted damages discussed above and recent evidence regarding intergenerational discount rates.<sup>169</sup> At best, therefore, the comment contends that this argument makes a mountain out of a molehill.

Commenter (0804-CCES et al) states that critics further claim that the IAMs—the damage functions for translating climate impacts into economic losses—are flawed and arbitrary. However, the damage functions are based on reasonable assumptions made by a range of experts.<sup>170</sup> They have also withstood scientific scrutiny, and while opponents of climate reform frequently highlight criticism of the damage functions by a notable economist, they take this criticism out of context.

The commenter (0804-CCES et al) explains that the Working Group selected three models of climate damages that were the most widely used and cited models in the economics literature linking physical climate impacts to economic damages<sup>171</sup>: the DICE, FUND, and PAGE models.<sup>172</sup> These models were developed by outside experts, published in peer-reviewed

<sup>169</sup> See 2021 TSD, supra note 5, at 4 (Working Group acknowledging that its current social cost valuations “likely underestimate societal damages from [greenhouse gas] emissions”).

<sup>170</sup> Response to Comments, supra note 106, at 8.

<sup>171</sup> Id.

<sup>172</sup> 2010 TSD, supra note 91, at 5.

economic literature,<sup>173</sup> and were the product of extensive scholarship and expertise. One of the models, DICE, was developed by William Nordhaus, an economics professor and former provost of Yale university who won a Nobel Memorial Prize in Economic Sciences for developing the model. And PAGE's developer, Chris Hope, was a lead author and review editor for the Third and Fourth Assessment Reports of the IPCC, which shared the Nobel Peace Prize in 2007 with former U.S. Vice President Al Gore.<sup>174</sup>

The commenter (0804-CCES et al) states that the three models reflect a wide diversity of methodological assumptions about a range of key parameters and inputs.<sup>175</sup> This reflects, in part, different judgments about the experts who developed the models. For instance, Richard Tol, who developed the FUND model, has stated that “[t]he impact of climate change is relatively small,” and dismissed much of the research behind climate change as “scaremongering” rather than “sound science.”<sup>176</sup> Unsurprisingly, his model produces the lowest damage estimates of the three models incorporated by the Working Group.<sup>177</sup> William Nordhaus, who developed the DICE model, is widely credited with popularizing the goal that global temperatures increase no more than 2° Celsius (or 3.6° Fahrenheit) below pre-industrial levels<sup>178</sup>—a goal now considered conservative by the global community.<sup>179</sup> His model produces higher damage estimates that are close to the Working Group's average damage valuations.<sup>180</sup>

The commenter (0804-CCES et al) adds that opponents of climate mitigation policy frequently point to criticisms from Robert S. Pindyck, a noted climate economist who has been critical of the Working Group's choice of damage functions. But as Professor Pindyck has himself stated, his “writings continue to be taken out of context by some to unfairly attack the Interagency Working Group's methodology and its interim estimates.”<sup>181</sup> While Professor Pindyck has questioned the shape of the models' damage functions,<sup>182</sup> he has acknowledged that the damage functions reflect “common beliefs” about the effects of two or three degrees of warming.

The commenter (0804-CCES et al) further adds that Pindyck states that uncertainty about the social cost estimates, including the damage functions, “does not imply that [their] value should be set to zero until the uncertainty is resolved.”<sup>183</sup> In fact, he actually advocates for an even

higher social cost value than that produced by the Working Group,<sup>184</sup> and has emphatically declared that “the federal government should continue to use the [Working Group’s] interim estimates . . . as lower bound estimates.”<sup>185</sup> In other words, the best critic of the Working Group’s methodology that opponents could find supports continued use of the Working Group’s estimates and considers them to be conservative underestimates of the true cost to society of greenhouse gas emissions.

Response I-20-33: As mentioned in previous responses, EPA presented a set of updated social cost of greenhouse gas (SC-GHG) estimates in sensitivity analysis in the 2022 Supplemental RIA that address recommendations of the National Academies of Sciences, Engineering, and Medicine (2017), and invited public comment on the sensitivity analysis and on the technical report, titled *External Review Draft: Report on the Social Cost of Greenhouse Gases: Estimates Incorporating Recent Scientific Advances*, explaining the methodological updates that was included as Supplementary Material to the RIA. The EPA is using the updated SC-GHG estimates in the Final RIA and is responding to the public comments received regarding these estimates in the Appendix of this RTC. These estimates have taken on the latest and most up to date science, including updates to the climate model, the socioeconomic, and the damage estimation components. Please refer to the RTC Appendix for detailed responses on these topics. Comment: Commenter (0746-Methane Action) suggests that in the final rule or the next proposal, include the most recent, more demanding, metrics for evaluating the effects of methane and alternatives for removing CH<sub>4</sub>, CO<sub>2</sub>, and related pollutants.

Commenter (0746-Methane Action) asks EPA to respond in the final rulemaking to the suggestions included in these comments, including comments based on a January 26th paper from Stanford University scientists Abernethy and Jackson. The commenter also asks EPA to respond to their suggestion that EPA use the same method for estimating the removal rate that would be necessary to restore or come closer to restoring healthier and safer temperature levels and reducing associated weather and ecological damage from that which we are experiencing at 1.1 degrees C already.

“Global temperature goals should determine the time horizons for greenhouse gas emission metrics”<sup>1</sup> Emission metrics, a crucial tool in setting effective exchange rates between greenhouse gases, currently require an arbitrary choice of time horizon. Here, the commenter (0746-Methane Action) proposes a novel framework that calculates the time horizon that aligns with scenarios achieving a specific temperature goal.

According to the commenter (0746-Methane Action), it must be understood that the reference to “the Biden Administration’s explicit goal” being to keep warming below 1.5 degrees Celsius was in reference to the UNFCCC/Paris Agreement’s COP26 context where changing that goal was not on the formal agenda. The commenter states that they do not intend to suggest here that the EPA limit its regulations, in this case or others, to measures designed to barely or just meet that goal. In fact, U.S. law requires the EPA to use the “BSER” or best available control technologies or to remove as much as possible of hazardous pollutants, depending on which section of the U.S. Code is used and which methods are shown to work. The law is not a license to pollute at

---

<sup>184</sup> Pindyck, supra note 231, at 1.

<sup>185</sup> Id.

any level, if pollution is unnecessary or avoidable and we are rapidly learning how to make do with much less methane and the pollutants caused by its production and use and how to remove those that have been emitted.

Response I-20-34: The EPA acknowledges commenter's thoughts regarding the appropriate metric to use for valuing methane. However, the EPA disagrees with the conclusions of the paper by Abernathy and Jackson that metrics should be designed to be optimized for the time horizon at which the temperature threshold to be avoided (e.g., 1.5 degrees C) is expected to be met. There are two flaws in the reasoning from Abernathy and Jackson.<sup>186</sup> First, time does not stop after the time horizon year: the authors recognize this ("it implicitly ignores temperature impacts that occur after the peak"). The second is that the metric design assumes the success of the policy to achieve the peak temperature. The combined problem of these two flaws is that basing policy on the higher value of methane relative to carbon dioxide resulting from this approach could lead to more long-term committed warming. In contrast, the EPA uses the SC-GHG to place a monetary value on methane reductions, which is an estimate of the net damages to society caused by the emissions of a given gas and is an appropriate metric to use for cost benefit analysis. The EPA also uses the 100-year GWP as the internationally recognized standard for reporting emission inventories: the use of an established metric makes it straightforward to compare emissions inventories from different sources. Moreover, several papers have found that the use of 100 years for the GWP time horizon is fairly consistent with a discount rate of 3% (Sarofim and Giordano, 2018, and Mallapragada and Mignone, 2020)<sup>187</sup>, and the use of a shorter time horizon would imply a higher discount rate which is contrary to most studies regarding temporal valuation and Circular A-4 (2023).<sup>188</sup>

Comment: Commenter (0461-High Tide et al) states that their mission is to have a significant, measurable impact on climate change mitigation. The commenter intends for their funding to be catalytic and support scalable solutions to the difficult issue of methane leakage. The commenter partners with a wide variety of nonprofits, foundations, climate philanthropists, companies, universities, and governments to advance the goal of reducing greenhouse gases.

Commenter (0461-High Tide et al) led the effort to raise \$125 million in funding for Carbon Mapper, a non-profit that aims to operate a constellation of satellites to identify methane super-emitters. The commenter also spearheaded the effort to raise \$225 million to establish Methane Hub. This non-profit is working to accelerate the mitigation of methane emissions in the oil and gas, landfill, and agricultural sectors.

The commenter (0461-High Tide et al) is not alone in investing in advanced technology designed to reduce methane emissions from the oil and gas industry. The commenter points to the Climate

<sup>188</sup> <https://www.whitehouse.gov/wp-content/uploads/2023/11/CircularA-4.pdf>.

Investments arm of the Oil & Gas Climate Initiative, which has pledged to invest \$1 billion in technologies and projects that accelerate decarbonization in oil and gas, industry, and commercial transport.<sup>189</sup> A substantial fraction of this fund has been directed to methane emission reduction.<sup>190</sup>

The commenter (0461-High Tide et al) believes these investments would be inappropriate and unwise if existing, advanced means of methane emission detection and remediation were efficient and effective. Unfortunately, they are not. As evidence, the commenter cites the United States report to the secretariat of the United Nations Framework Convention on Climate Change (UNFCCC), *Inventory of U.S. Greenhouse Gas Emissions and Sinks, 1990-2019*<sup>191</sup>, together with its natural gas and petroleum systems Methodology Annexes.<sup>192</sup> Methane emissions from regulated activities in the natural gas and petroleum sectors, normalized to those emissions in 2013, are shown in the figure below. Although comprehensive methane reduction rules were imposed by 40 CFR 60 Subpart OOOO in 2012 (vertical dashed line) and enhanced by 40 CFR 60 Subpart OOOOa in 2016, emission trends have been on a steady but very slow decline since 1990. The commenter finds the compound annual growth rate unimpressive at -0.3%. The commenter contrasts this to the Obama administration's pledge in 2016 to reduce methane emissions at a compound annual growth rate of roughly -6%.<sup>193</sup>

Response I-20-35: The EPA acknowledges the comment.

Comment: Commenter (0414-Waterspirit) urges EPA to stop reporting methane per the 100-year-old emissions CO<sub>2</sub>e; take into account the full life cycle of emissions throughout fossil fuel supply chains.

- Changing this standard will better legitimize the process which moves toward sound policy based upon credibly collected data.
- The current EPA rules encourage all states and agencies to present methane emissions using the older IPCC assessment for the potency of methane at 100 years. Even in this proposed rule, EPA presents Table 7 total Methane emissions using the obsolete 100-year carbon equivalency for quantifying the amount of methane that occurred in 2019, 2010, 1990.
- The original EPA numbers provided are substantially lower given the absent methane emissions not accounted for. Methane emissions have been ever increasing; present-day load is surpassing all current projections of greenhouse gas emissions. No federal agency has taken on assessing the full scope of methane emissions. Reporting of emissions from

<sup>193</sup> Leaders' Statement on a North American Climate, Clean Energy, and Environment Partnership, 29 June 2016 <https://obamawhitehouse.archives.gov/the-press-office/ 2016/ 06/ 29/ leaders-statement-north-american-climateclean- energy-and-environment>.

energy companies should be independently reviewed and monitored to reflect present day load and real time data.

Response I-20-36: The commenter requests that EPA stop reporting using the “obsolete” carbon equivalency metric and to take into account the full lifecycle of emissions. With regard to the carbon equivalency metric, the EPA uses the 100-year GWPs from the AR5 IPCC assessment, published in 2013. This complies with international GHG reporting standards under the United Nations Framework Convention on Climate Change (UNFCCC). The AR5 GWP for methane of 28 is very similar to the IPCC AR6 value for methane of 27.2. Regarding lifecycle accounting and data collection, the EPA works to use the best available, practical methods to account for emissions across the economy. Please consult EPA’s Inventory of U.S. Greenhouse Gas Emissions and Sinks<sup>194</sup> for more data regarding EPA’s processes and the most recent estimates of national emissions.

## **20.3 Other Emissions and Regulatory Impacts Comments**

### ***20.3.1 General Support/Opposition for Proposal to Reduce Emissions***

#### Support

Comment: Several commenters provide general support or opposition to EPA’s 2021 November proposal to reduce methane and VOC emissions from oil and gas operations. Examples of some of those comments are provided in the following paragraphs.

Commenters (0391-Keweenaw Bay Indian Community (KBIC), 0781-National Tribal Air Association (NTAA), 0833-UMUT EPD) believe that EPA’s proposed controls are cost effective and encourage EPA to consider and compare the costs of the controls to the full range of negative costs experienced from the oil and natural gas industry’s high methane, volatile organic compound (VOC), and hazardous air pollutants (HAP) emissions.

Commenter (0458-MDE) supports the proposed rule as it will clearly have a positive impact on mitigating climate change and improving air quality, noting that Environmental Protection Agency (EPA) estimates that 41 million tons of methane emissions will be reduced from the industry between 2023 and 2035 (which is the equivalent of 920 million metric tons of carbon dioxide), and the proposed rule would reduce an estimated 12 million tons of volatile organic compounds (VOC) and 480,000 tons of air toxic pollutants from 2023 to 2035.

Commenter (1294-OCCA) states that the proposed rule changes are a step in the right direction but asserts that it is critical for EPA to adopt rules and regulations that reach across state borders to have a national impact. The commenter believes that the authority to develop these critical regulations must not be delegated to states because some state regulations would be stringent and protective of health while states that are dominated by the fossil fuel industry would be almost certain to have weak or no standards.

---

<sup>194</sup> <https://www.epa.gov/ghgemissions/inventory-us-greenhouse-gas-emissions-and-sinks>.

Commenter (0912-Shell) states that they support the EPA's efforts to establish rigorous performance standards for reducing methane emissions from new and existing facilities within all segments of the oil and gas sector. The commenter believes that these methane control requirements generally reflect best available control measures.

Commenter (0402-Cancer Free) primary proposed NSPS OOOOb and EG OOOOc rules are a significant first step in reducing GHG and toxic emissions from oil and gas operations. However, they assert that much more stringent emission limits are needed to truly reduce the environmental and human health burden of fossil fuel extraction and production. To date, the commenter notes that most of the research on the human health effects of oil and gas wells is based on proximity to operations—much more refined research is needed, including exposure measurement and biomonitoring, to truly comprehend the range and magnitude of oil and gas operation's effects on human health. In the meantime, the commenter states that more protective emission limits are needed to protect human health, especially given the gap of comprehensive knowledge.

Commenter (0842-NYU School of Law) contends that the 2021 November proposed rule is necessary to correct a market failure which is leading oil and gas producers to capture less pollution that is socially optimal. The commenter states that because methane (a primary component of natural gas) is a valuable commodity, private operators have some incentive to avoid methane leaks, as some methane can be profitably captured and resold. However, the commenter argues, the upfront cost of buying and installing leak detection, repair, and prevention equipment may deter some companies from addressing leaks at their wells. The commenter reasons that absent regulation, oil and gas producers will only capture as much methane and VOC emissions as they can profitably do, from a private welfare-maximizing perspective. But, the commenter cautions, GHG and VOC emissions also impose significant costs on society—such as negative climate, health, and welfare impacts—that are not reflected in the market price of methane. In the absence of regulation, the commenter states, these costs will be borne not by the polluting firm, but by society as a whole and voluntary programs are insufficient to reach optimal levels of methane reduction. The commenter concludes that because methane and VOCs are externalities that impose costs on society—which can be estimated using tools like SC-CH<sub>4</sub>—regulation is required to capture all the methane and VOC emissions that are cost-benefit justified from a social welfare-maximizing perspective.

Commenter (0456-WI DNR) states that the proposed rule addresses needed reductions in methane and VOC emissions from the oil and gas sector that will benefit air quality.

Commenter (0456-WI DNR) states that the reduction of methane emissions from this proposed rule will play a critical role in meeting national GHG emission reduction targets and addressing climate change. EPA notes that methane is a potent GHG with a global warming potential 30 times that of CO<sub>2</sub> and is responsible for approximately one third of current warming due to human activity. EPA also notes that the oil and gas sector is the largest industrial contributor of methane nationwide. This proposal will also reduce VOC emissions that contribute to ozone formation in Wisconsin. While the commenter does not anticipate the proposed rule will significantly decrease VOC emissions from sources in Wisconsin (their state), several states that significantly contribute to ozone nonattainment or maintenance along the Lake Michigan shoreline have large oil and natural gas sectors. Upwind VOC emissions reductions from this

proposed rule may be significant and may improve Wisconsin's ability to attain and maintain ozone standards.

Commenter (0943-SSMTCI) states that they are supportive of the EPA's proposed improvements over the 2012 and 2016 standards and the acknowledgement of technological advancements in the oil and natural gas industry sector over the past few years and appreciates the EPA's explicit recognition that climate change and the oil and natural gas operations disproportionately impact near source low wealth, minority communities, and particularly Tribal communities. The commenter believes that the EPA's proposed controls are cost effective. And encourages the EPA to consider and compare the costs of the controls to the full range of negative costs experienced from the oil and natural gas industry's high methane, VOC, and HAP emissions.

Commenter (0842- NYU School of Law) states that the proposed rule is laudable for significantly reducing methane emission in a legally sound and cost beneficial manner. The Proposed Rule builds on earlier standards for control of methane and VOCs for new sources and is well grounded in the EPA's authority under the Clean Air Act. By regulating existing sources, the EPA wisely avoids the problem of grandfathering. And the Proposed Rule is necessary to correct market failures that are currently producing unaddressed externalities to the public. In addition, the EPA has appropriately monetized the benefits of reducing methane emissions through its use of the social cost of methane.

### Opposition

Conversely, commenters (0750-Flogx, 0439-Paxton, 0577-KIOGA) state that the EPA has applied a one-size-fits-all approach to the regulation of an incredibly diverse industry which they say is already one of the most highly regulated industries in the nation.

Commenter (0439-Paxton) states that as a small-independent producer in Michigan, the margins on which they already operate can vary widely and implementing regulations which are "one-size fits all" will have a devastating effect on their ability to continue to operate at all. The regulations will not only affect the private landowners who are paid royalties for their minerals but the economy of State of Michigan itself. The commenter continues that oil and natural gas will remain the foundation of our gigantic energy complex even as we transition to new alternatives. However, as a business, it is impossible to continue to plan to meet increased energy demands if the very nature of the science and engineering we are implementing is so broadly misunderstood by regulators.

Another commenter (0577-KIOGA) notes that the EPA states that much of the methane and VOCs that are captured because of this regulation will be sold into the natural gas market. The EPA is expecting owners and operators to use the gas sales to offset compliance costs. However, most of the gas that is not being sold today costs too much for owners and operators to collect, process, transport, and sell into the natural gas market. Many wells drilled and produced in Kansas have associated gas that needs to be purified to make it pipeline quality, which is a significant investment for a small volume of produced gas and if projects to collect, process, and sell gas were economically attractive, companies would have already made the investment. The commenter stated that they performed Monte Carlo simulations around expected Kansas gas

production, gas quality, compliance cost, operating cost, and product pricing. The outcome of their simulations shows that none of the scenarios are profitable (positive Net Present Value (NPV)) and any management team would reject the investment opportunity. Every well drilled will only have additional compliance costs added and no economic benefit will be realized.

Commenter (0923-Lambda) notes that they and other producers have been complying with emission reduction rule changes since 2012 with NSPS OOOO, in 2016 with NSPS OOOOa, in 2020 (a policy change), in 2021 (a technical change) and now again with the current rule change. With so many changes to regulations in a short period of time, the commenter asks how EPA can know whether the previous regulations have been effective? Section 111 of the CAA requires a review every eight years, and although waiting the full eight years may not be prudent, many changes within that time frame cost producers an exorbitant amount of time, capital investment on equipment, increased 3rd-party outsourcing costs, and new burdens on compliance staff. The commenter's position is that NSPS OOOOa is already effective at regulating new sources and achieves the goals of reducing emissions on the largest known source of emissions (new sources with high production), in addition to providing regulatory coverage of modified existing facilities with new emission sources.

Commenter (0193-NFIB) states that America depends upon affordable oil products and natural gas for the energy that keeps the American economy going. The commenter states that American businesses of every size: (1) cannot get the employees they need to grow their business because the U.S. labor force has millions fewer workers available than it had in 2019;<sup>195</sup> (2) cannot get goods and materials they need on time, because supply chains have failed; and (3) must pay more for the goods and materials they buy, and the fuel, electricity, and other sources or forms of energy they need to operate, as inflation roars. However, the commenter states that the EPA has responded with the new proposal for more burdensome and costly regulations on the oil and gas industry, which they contend will hike the cost of regulatory compliance for the regulated oil and gas businesses and will hike the cost of energy for all businesses.

Commenter (0946-MOGA) questions the EPA's use of 2019 emissions data to justify the current proposed regulations. Based on historic rulemaking efforts, if the full implementation of Subpart OOOOa did not begin until roughly 2018 (considering the 2-year & 90-day court stay), how can the EPA determine the effectiveness of the NSPS OOOOa regulations and justify the new proposed regulations? As shown in the emissions reduction tables in Comment #2 of the commenter's letter, Michigan producers have been successful in reducing emissions through NSPS OOOO and NSPS OOOOa regulations. The commenter reports that the three small businesses illustrated in the commenter's letter in the emissions reduction tables have invested significant capital to achieve emissions reductions without the EPA allowing enough time to recover costs. Based on this data, the commenter believes that the EPA should allow more time to evaluate current regulations applied to new sources and future modifications of previously non-regulated sources before amending regulations resulting in another substantial economic burden on small business producers.

---

<sup>195</sup> Federal Reserve Bank of St. Louis, Civilian Labor Force Level (CLF160V), available at <https://fred.stlouisfed.org/series/CLF160W> (visited November 16, 2021) (size of labor force in 2019 and 2021).

Response I-20-37: With respect to supportive comments, EPA agrees that the rule will reduce methane and VOC emissions from oil and natural gas operations in the United States.

In response to commenter who argues that EPA's approach and regulations will have a devastating effect on small independent producers and private landowners who are paid royalties for their minerals to continue to operate, which will also impact the economy of the State of Michigan itself, the commenter did not provide specifics to support their position. Please see comments and responses provided to comments in section 20.2.7 (Impact on Small Business) for similar concerns expressed by small businesses.

In response to comment that most of the gas that is not being sold today costs too much for owners and operators to collect, process, transport, and sell into the natural gas market, the EPA acknowledges that this is a practical reality. In fact, the final rule provisions address that practical reality for associated gas wells at well affected facilities in the required infeasibility demonstration and certification provisions applicable to situations where routing the associated gas to a sales line, using it as onsite fuel or for another beneficial purpose, or injecting/reinjecting is not feasible. See section XI.F.2.g (Infeasibility demonstration and certification) for discussion of the infeasibility demonstration and certification provisions in the final rule. It is also important to know that the calculated gas savings estimated by the EPA illustrate the potential for gas savings of varying regulatory options being considered but are not used as a determinant of what constitutes BSER. Notably, the EPA also acknowledges that this offset would not apply where the owner or operator does not own the gas and would not likely realize the monetary value of the natural gas saved (*e.g.*, transmission stations and storage facilities).

In response to the commenter that states that NSPS OOOOa is already effective at regulating new sources and achieves the goals of reducing emissions on the largest known source of emissions (new sources with high production), in addition to providing regulatory coverage of modified existing facilities with new emission sources, the EPA agrees that NSPS OOOOa has been effective. However, greater emissions reductions of VOC and methane emissions are needed. As discussed in the final rule preamble, these final actions stem from the EPA's authority and obligation under CAA section 111 to directly regulate categories of new stationary sources that cause or contribute to endangerment from air pollution and to promulgate EG for states to follow in regulating existing sources (designated facilities) in the source category. See section II (Executive Summary), subsections A (Summary of the Major Provisions of this Regulatory Action) and B (Purpose of the Regulatory Actions), and section IV (Statutory Background and History) of the final rule preamble for support for the development of the NSPS OOOOb standards and EG OOOOc presumptive standards.

In response to comment concerned that America depends upon affordable oil products and natural gas for the energy that keeps the American economy going and that the EPA's proposed rules will only add to burdensome and costly regulations on the oil and gas industry will result in a hike of the cost of energy for all businesses, the variables that contribute to the cost of oil products and natural gas is influenced less by regulations than by other factors (*e.g.*, taxes, OPEC production, consumer demand, refinery capacity). Nonetheless, the EPA evaluated and streamlined compliance and recordkeeping and reporting requirements, where feasible, and included multiple compliance alternatives for several affected facilities/designated facilities

under the final NSPS OOOOb and EG OOOOc rules. See section X (Summary of Final Standards NSPS OOOOb and EG OOOOc) of the final rule preamble for a summary of the final standards/presumptive standards.

### ***20.3.2 Emissions Data/Verification/Analyses***

Comment: Commenter (0426-League of Women Voters of New Jersey) suggests that in order to properly evaluate our current situation regarding methane emissions from upstream gas and oil facilities and to determine if the proposed abatement rules are effective, the commenter recommends that the EPA undertake an analysis of recent peer-reviewed studies on emissions from gas and oil extraction, transportation, processing (including separation, liquefaction and refining), distribution and use. After carrying out any further studies deemed absolutely necessary, the EPA should promulgate this data so that all our country's scientists are using the same basic data. Workers at gas extraction, processing and pipeline facilities need to know how to measure emissions on their sites and compare them with EPA data.

Response I-20-38: EPA acknowledges the commenter's input. The EPA reviewed available data during the course of this rulemaking, including data submitted by commenters. Additionally, the EPA has recently taken up multiple rulemakings, including NSPS OOOOb, revisions to 40 CFR part 98 subpart W (greenhouse gas reporting rule), and the Methane Emissions Reduction Program, which will also generate data to better quantify emissions from this sector. NSPS OOOOb and EG OOOOc include required methods for measuring emissions from various sources, such as control devices on affected facilities, in the final rulemaking.

Development and promulgation of a database of oil and natural gas studies and emissions database are beyond the scope of the final rulemaking and this document.

Comment: Commenter (0941-350 Silicon Valley) recommends that the EPA assume responsibility for verifying methane emissions data reported to the U.S. government by states and companies and work with the National Aeronautics and Space Administration (NASA), DOE, National Oceanic and Atmospheric Administration (NOAA) and the Bureau of Land Management (BLM) to set up a system for verifying methane emissions from the oil and gas industry. The commenter further recommends that EPA seek to include more funding in the Build Back Better bill for the collection and analysis of satellite GHG emissions data (especially methane, carbon dioxide, and nitrous oxide), and to establish a federal inter-agency group to develop better estimates of methane emissions.

Response I-20-39: EPA acknowledges the commenter's input. Funding data studies and interagency workgroups are beyond the scope of this final rulemaking and this document.

Comment: Commenter (0768-MR) states that emissions data are particularly important in this rulemaking because of the role and nature of advanced technology for detecting and measuring emissions, particularly high volume, intermittent sources. To achieve the common goal of a transparent regulatory framework that facilitates efficient and effective enforcement and compliance, the commenter suggests that EPA take comment on ways it can encourage the submission of emissions data for compliance purposes. For example, they suggest that EPA take

comment on the cost and feasibility of collecting emissions estimation data and direct measurements from leak detection surveys. According to the commenter, doing so would allow EPA to take advantage of emissions data that is more readily available from advanced technologies while ensuring the reporting requirements do not create a disincentive to adopt these technologies.

The commenter (0768-MR) suggests that, as data improve and become more robust, they can serve several purposes beyond compliance assurance. Data can be used to periodically update emissions simulation models and technology testing protocols to better reflect what is known about emissions distributions. In turn, that will facilitate identification of new monitoring technologies and methodologies. And, in the longer term, improved data may enable EPA or states to add, clarify, or update an emission performance standard.

The commenter (0768-MR) adds that the EPA could also provide improved data on emissions and technology advancements to help states develop their CAA 111(d) plans. Finally, they suggest that the emissions data can be used to improve EPA and state GHG inventories. The commenter provides that the EPA has already proposed that calculation of well site annual emissions should incorporate any updates made to inventory emissions factors. However, the commenter states that the EPA should also consider whether and how data gathered under EG OOOOc and CAA 111(d) plans might be incorporated into GHG inventories including Subpart W of the federal GHG Reporting Rule. They stress that it is important for EPA to recognize the value of this CAA 111 rule as an advanced technology data gathering mechanism and to ensure that data gathered from this CAA 111 rule are used to inform future Subpart W changes.

Thus, the commenter (0768-MR) recommends that EPA address or seek input on the following in the Supplemental Rule Proposal:

- How can monitoring data from advanced technologies be used to streamline and improve compliance?
- How can emissions data be used to evaluate the rule's effectiveness in meeting the U.S.'s emission reduction goals?
- What incentives can EPA offer to operators to provide emissions data that will support evaluations of overall rule effectiveness, inform emissions simulation models, and improve greenhouse gas inventories?
- What data would EPA need from industry and other stakeholders to ultimately support development and use of an emissions performance standard in state plans, including a methane intensity standard?
- How should EPA consider emissions data developed by oil and operators subject to the rule compared to data developed by third parties (including community organizations)?

Response I-20-40: EPA acknowledges the commenter's input. In the December 2022 Supplemental Proposal, EPA took comment on the required reporting for owners and operators who use advanced methane detection technologies to conduct inspections for fugitive emissions. EPA received comment from various stakeholders on the use of advanced methane detection technologies in response to that proposal. See Volume II, Chapter 5 for responses to comments on advanced methane detection technologies.

For discussion on emissions distributions and the modeling conducted to develop the periodic screening matrices used for advanced methane detection technologies, see section XI.B.1.a of the preamble to the final rule. Clean Air Act Section 111 requires that at least every 8 years, the EPA review and, if appropriate, revise standards of performance for regulated NSPS sources. EPA may use the data collected from this rulemaking, including data that owners and operators submit from fugitive emissions periodic screenings or continuous monitoring using advanced methane detection technologies, in a future review process.

EPA will evaluate data submitted both by oil and gas operators and third parties to determine whether the data meets the data quality objectives for the purpose for which it is used. By requiring owners and operators, as well as third parties who submit data under the super-emitter program, to use methods approved by EPA, we have taken steps to ensure all data submitted to the agency as a result of this final rulemaking will meet a minimum level of data quality.<sup>196</sup>

EPA notes that it has outlined the requirements for state plans in EG 0000c.

Development of emission inventories, including those under 40 CFR part 98 subpart W, are outside the scope of the final rulemaking and this document.

Comment: Commenter (0800-UPLP) asserts that, because the development of this standard is reliant on determining emission thresholds, the commenter requests that EPA provide support to create consistent guidelines for how to estimate emissions for development of an oil and gas emission inventory for VOCs.

Response I-20-41: Development of emission inventories are outside the scope of the final rulemaking and this document.

### ***20.3.3 Impacts of the Proposed Regulations on Existing Contracts***

Comment: Commenter (0946-MOGA) states that the EPA did not solicit comments from the oil and gas production industry and small businesses or attempt to understand the potential impacts of the proposed regulations on existing contracts. The commenter explains that, before a well is drilled or a facility is constructed, surface and underground asset contracts are prepared and presented to the landowners for review, discussion, modifications, and final authorization. These contracts allow the potential producing company to enter the property for review, acknowledgement of the complication in the terrain and apply for additional permits and contracts, negotiate with the landowner for mineral rights, access fees and mineral distributions. Additional contracts with utilities, transportation companies, pipeline operators and regulators are prepared, reviewed, and signed before a well is drilled and determined to be commercial and viable. All the above-mentioned contractual obligations becomes null and void if the well is not economically sustainable. The commenter believes that the EPA needs to address the potential costs and problems associated with breach of contract before expanding regulations to existing sources. Further, the commenter recommends that the EPA include these costs and ramifications

---

<sup>196</sup> Advanced methane detection technology used for both fugitive emissions inspections and the super-emitter program must be approved by EPA in accordance with 40 CFR 60.5398b(d).

into their cost per ton of methane reduction to adequately represent the true costs of imposing future regulations on the industry.

Response I-20-42: The EPA does not agree with the commenter that potential costs and problems associated with breach of contract ought to be considered in the EPA's cost per ton analysis for existing sources. This comment is too general for the EPA to fully evaluate the merits of the commenter's claim. The commenter appears to assume that EPA's final EG will somehow make some wells "not economically sustainable." The commenter does not explain what this phrase is intended to convey or how the EPA's EG will supposedly do this. The EPA finds this claim to be speculative and unsupported by the commenter.

It is unclear to the EPA exactly how the commenter suggests it should have done so. Commenter neither provides any specific data or analysis to support its argument, nor explains how any such analysis might have affected the EPA's establishment of standards of performance. It is unclear to the EPA how any analysis of contracts would have influenced the final rule.

#### ***20.3.4 European Union Intensity Standards – Liquid Natural Gas Exports***

Comment: Commenter (0912-Shell) states that believes that these methane control requirements generally reflect best available control measures that are generally aligned with any methane intensity target considered by the European Union in the future for the upstream segment of the natural gas supply chain in the U.S. Based on these methane control requirements, oil and gas producers, liquid natural gas (LNG) traders, and shippers would not have to add another layer of verification to prove that their natural gas meets the European Union intensity standard. Without an equivalence – if the European Union proceeds with an emissions intensity standard – demonstrating compliance with that standard to upstream emissions could potentially put U.S. LNG exports at a competitive disadvantage because the only possible way to avoid financial penalties would be through costly and potentially unworkable added monitoring, reporting and verification (MRV) schemes that could require tracing of natural gas molecules from individual producers along complex natural gas delivery chains.

Response I-20-43: EPA acknowledges the supportive comment.

## Chapter 21. Statutory and Executive Order Reviews

### 21.1 Executive Order 12866: Regulatory Planning and Review and Executive Order 13563: Improving Regulation and Regulatory Review

Comment: Commenter (0831-American Exploration and Production Council (AXPC)) references and incorporates comments made and submitted to EPA on the November 2021 Proposal (*i.e.*, OMB-2021-0006-0087), which the commenter notes, “estimates benefits from the methane emission reductions it projects this rulemaking will cause by using the interim social cost of methane estimates contained in the February 2021 publication from the Interagency Working Group (86 Fed. Reg. at 63,258/3).” According to the commenter, remarks made varied but included comments on the importance of “communicating the significant uncertainties within the estimates and limiting their use to regulatory impact analysis pursuant to interagency review under [EO 12866].”

Response I-21-1: As discussed in section XVI.E (What are the benefits?) of the final rule preamble, the EPA is a member of the Interagency Working Group (IWG) and is participating in the IWG’s work under E.O. 13990. While that process continues, as noted in previous EPA RIAs, the EPA is continuously reviewing developments in the scientific literature on the SC-GHG, including more robust methodologies for estimating damages from emissions, and looking for opportunities to further improve SC-GHG estimation going forward. In the RIA for the December 2022 Supplemental Proposal, the EPA included a sensitivity analysis of the climate benefits of the supplemental proposal using a new set of SC-GHG estimates that incorporates recent research addressing recommendations of the National Academies of Science, Engineering, and Medicine (2017), in addition to using the IWG recommended interim SC-GHG estimates presented in the Technical Support Document: Social Cost of Carbon, Methane, and Nitrous Oxide Interim Estimates under Executive Order 13990, published in February 2021 (IWG, 2021).

The EPA solicited public comment on the sensitivity analysis and the accompanying draft technical report, which explains the methodology underlying the new set of estimates, in the December 2022 Supplemental Proposal to ensure that the methodological updates adopted in the technical report are consistent with economic theory and reflect the latest science, the EPA also initiated an external peer review panel to conduct a high-quality review of the technical report, completed in May 2023. The peer reviewers commended the agency on its development of this update, calling it a much-needed improvement in estimating the SC-GHG and a significant step towards addressing the National Academies’ recommendations with defensible modeling choices based on current science. The peer reviewers provided numerous recommendations for refining the presentation and for future modeling improvements, especially with respect to climate change impacts and associated damages that are not currently included in the analysis. Additional discussion of omitted impacts and other updates have been incorporated into the technical report to address peer reviewer recommendations. Complete information about the external peer review, including the peer reviewer selection process, the final report with individual recommendations from peer reviewers, and the EPA’s response to each recommendation is available on EPA’s website. The EPA is a member of the IWG on the SC-GHG and continues to participate in its work. The EPA’s new SC-GHG estimates along with the

peer review of the updated methodology will be among the many technical inputs available to the IWG as it continues its work.

An overview of the methodological updates incorporated into the new SC-GHG estimates is provided in the final RIA. A more detailed explanation of each input and the modeling process is provided in the technical report, *EPA Report on the Social Cost of Greenhouse Gases: Estimates Incorporating Recent Scientific Advances* (EPA 2023), which is also included as supporting material for the final RIA in the docket.

Comment: Commenter (0797-North Dakota Department of Environmental Quality (NDDEQ) and North Dakota Industrial Commission (NDIC)) disagrees with EPA's use of EO 13990 and EO 12866 (e.g., Technical Support Document: Social Cost of Carbon, Methane, and Nitrous Oxide Interim Estimates under EO 13990 or IWG 2021 support document) as justification for issuing the November 2021 NSPS Proposal as a whole, but more specifically in justifying their quantification of the "social cost of carbon." The commenter suggests that the EPA acted beyond its authority; stating that "EPA's authority to promulgate NSPS regulations must be based on its statutory authority under the Clean Air Act as authorized by Congress," which the commenter underscores "cannot be expanded or amended" by Presidential orders. Specifically, the commenter maintains that the EPA cannot justify "costs that will be imposed on American citizens and businesses if the November 2021 NSPS Proposal was finalized by trying to balance those costs against speculative global benefits that might be reaped outside of the United States using the very dubious 'social cost of carbon' calculations directed by EO 12866." The commenter contends that courts have already rejected arguments/claims made that use or rely on "global benefits" to justify national costs/impacts. To further illustrate their point the commenter references a small number of court rulings and other failed attempts made by federal agencies to use "global benefits" as justification for domestic impacts – e.g., *Wyoming et al. v. Jewell et al.* [See Chapter 20. Emissions and Regulatory Impacts of this document for additional comments on the use of "global benefits" as justification for domestic impacts.]

Response I-21-2: See Response I-21-1 of this Chapter.

## **21.2 Paperwork Reduction Act (PRA)**

Comment: Commenter (0924-U.S. Small Business Administration (SBA)) states that EPA has not prepared an information collection request (ICR) for the requirements of the proposed NSPS OOOOb, EG OOOOc or Appendix K, as would be required under the PRA and 44 U.S.C. 3507(d)(1) for a proposed rule. The commenter advocates that the EPA explicitly re-open all elements of the November 2021 proposed NSPS OOOOb and EG OOOOc rules for public comment when the supplemental proposal is developed.

Response I-21-3: See the following ICR Supporting Statements located at Document ID Nos. EPA-HQ-OAR-2021-0317-0144 (NSPS OOOO & OOOOa), EPA-HQ-OAR-2021-0317-1556 (NSPS OOOOb), EPA-HQ-OAR-2021-0317-1553 (EG OOOOc) for this action located at Docket ID No. EPA-HQ-OAR-2021-0317. Burden associated with Appendix K is included in

the burden with natural gas processing plants which mirrors how the best system of emission reduction (BSER) was analyzed for equipment leaks at gas plants.<sup>1</sup>

## 21.3 Regulatory Flexibility Act (RFA)

Comment: Commenter (1341-Pennsylvania Grade Crude Oil Coalition (PGCC) *et al.*) notes that pursuant to RFA section 609(b), as amended by the Small Business Regulatory Enforcement Fairness Act (SBREFA), EPA convened a Panel including EPA's Small Business Advocacy Chairperson, to discuss the effects of EPA's November 2021 Proposal on small businesses. The commenter reports that after considering the information given to it by EPA and various small entity representatives (SERs) in the oil and gas sector, the Panel issued a final Panel Report containing various recommendations to EPA regarding its November 2021 Proposal. Unfortunately, according to the commenter, EPA has failed to consider and/or meaningfully address several key observations and recommendations.

Response I-21-4: The EPA disagrees with the commenter's assertion. Please see the complete IRFA is available in the RIA for the December 2022 Supplemental Proposal (see section 4.3 of the RIA), the summary of the FRFA section XVII.C. of the final preamble, and section 4.4 of the final RIA.

Comment: Commenter (0924-SBA) suggests that EPA fails to comply with the requirements of the RFA, because it failed to adequately account for or consider the economic impact of proposed Appendix K or include any consideration of the burdens due to the November 2021 proposed NSPS OOOOb. The commenter contends that the RFA requires EPA to consider the potential impact of its proposed rules on small entities, and further claims that the November 2021 Proposal initial regulatory flexibility analysis (IRFA) accompanying this rule lacks a sufficient discussion of regulatory alternatives that would minimize the impacts on small businesses.

For instance, the commenter (0924-SBA) states that in the quantification of the burden, EPA provides only the burden of NSPS OOOOa, not the proposed new NSPS OOOOb. Additionally, the commenter notes that EPA only provides an average across the next three years, which, according to the commenter is not sufficient to describe the burden of the proposed requirements for purposes of an IRFA, particularly when a requirement is phased in. The commenter recommends that EPA reevaluate the total economic impacts on small entities and prepare a new IRFA.

Response I-21-5: In the December 2022 Supplemental Proposal, EPA did not require optical gas imaging (OGI) monitoring in accordance with the proposed Appendix K for well sites or centralized production facilities, as was proposed in the November 2021 Proposal. In the December 2022 Supplemental Proposal, EPA proposed that equipment leaks at gas plants are monitored using OGI in accordance with Appendix K.<sup>2</sup> Burden associated with Appendix K is

---

<sup>1</sup> 86 FR 63232.

<sup>2</sup> 87 FR 74807.

included in the burden with natural gas processing plants which mirrors how BSER was analyzed for equipment leaks at gas plants.<sup>3</sup>

See the following ICR Supporting Statements located at Document ID Nos. EPA-HQ-OAR-2021-0317-0144 (NSPS OOOO & OOOOa), EPA-HQ-OAR-2021-0317-1556 (NSPS OOOOb), EPA-HQ-OAR-2021-0317-1553 (EG OOOOc) for this action located at Docket ID No. EPA-HQ-OAR-2021-0317.

Pursuant to section 603 of the RFA, EPA prepared an IRFA that examined the impact of the proposed rule on small entities along with regulatory alternatives that could minimize that impact. Please see the complete IRFA is available in the RIA for the December 2022 Supplemental Proposal (see section 4.3 of the RIA), the summary of the FRFA section XVII.C. of the final preamble, and section 4.4 of the final RIA.

Comment: Commenter (0924-SBA) believes that repeating SBREFA's panel report recommendations without change is insufficient to satisfy the requirement – the IRFA “contain[s] a description of any significant alternatives to the proposed rule which accomplish the stated objectives of applicable statutes and which minimize any significant economic impact of the proposed rule on small entities” – further arguing that the SBREFA panel report does not reflect the issued November 2021 Proposal. The commenter maintains that EPA's responsibility to identify significant regulatory alternatives for the IRFA does not end with the conclusion of the SBREFA panel, particularly when there are significant changes during and after the SBREFA panel consultations. To illustrate their point, the commenter notes, for this rule, EPA developed new regulatory alternatives for monitoring requirements, liquids unloading, and pneumatic controllers that became EPA's preferred alternative, which the commenter writes could reduce the impact on small entities, are not reflected in the IRFA. The commenter underscores the point that while regulatory alternatives are discussed in the *Federal Register*, they are not referenced in the IRFA, nor are they mentioned in response to the panel's recommendations.

In a similar point, commenter (0924-SBA) believes that a re-statement of SBREFA's panel report recommendations, particularly where panel members disagree, is not the same as an analysis and reasoned consideration of alternatives. Specifically, the commenter feels that it is insufficient to adopt verbatim the alternatives section of the panel's report as the description of alternatives required in the IRFA. Although the commenter acknowledges that EPA is correct to incorporate new information into its November 2021 Proposal and analysis as it is developed, and the commenter does not expect a proposed rule or analysis to be in its final form during the conduct of a SBREFA panel. According to the commenter, however, such a change should be accompanied by changes in the IRFA to reflect the availability and consideration of different regulatory alternatives. The commenter insists that EPA issue a revised IRFA to include alternatives reflective of the November 2021 Proposal and supplemental proposed rule.

Response I-21-6: Pursuant to section 603 of the RFA, EPA prepared an IRFA and FRFA that describes the economic impact of the proposed and subsequently final rule on small entities and the steps taken to minimize the significant impact on small entities consistent with the stated objectives of applicable statutes. EPA also examined regulatory alternatives that could minimize

---

<sup>3</sup> 86 FR 63232.

that impact. Please see the complete IRFA available in the RIA for the December 2022 Supplemental Proposal (see section 4.3 of the RIA), the summary of the FRFA section XVII.C. of the final preamble, and section 4.4 of the final RIA.

Comment: Commenter (0924-SBA) maintains that there are significant gaps in EPA's RFA and advise EPA to prepare a revised RFA, along with a revised IRFA to reflect the entirety of the November 2021 Proposal and supplemental proposal. The commenter supports the use of supplemental proposed rules to remedy gaps in the record; however, in this case, the commenter argues that the supplemental proposal will serve more as a proposed rule than a simple supplemental. According to the commenter, EPA has committed to publishing a supplemental proposal for this rulemaking because it recognizes that the record to support this rule is incomplete. The commenter suggests that EPA has issued a proposed rule without providing rule text for the proposed NSPS OOOOb and proposed EG OOOOc.

Response I-21-7: The EPA prepared a revised IRFA for the December 2022 Supplemental Proposal. The complete IRFA is available for review in the 2022 RIA (see section 4.3).<sup>4</sup> Please see the summary of the FRFA section XVII.C. of the final preamble, and section 4.4 of the final RIA.

## **21.4 Unfunded Mandates Reform Act (UMRA)**

Comment: Commenter (0797-NDDEQ/NDIC) does not believe that EPA could reasonably make the calculation that the November 2021 Proposal “does not contain a Federal mandate that may result in expenditures of \$100 million or more for State, local, and Tribal governments, in the aggregate or the private sector in any one year” in accordance with UMRA when EPA has not proposed regulatory text. 86 Fed. Reg. at 63,260. In the RIA cited for that calculation, EPA concedes that for evaluating the regulatory actions “[w]e do not analyze the regulatory impacts of all proposed requirements because we either do not have sufficient data or because it is assumed the provisions would not result in compliance cost or emissions impacts; in these instances, we qualitatively discuss the proposed requirements.” See Regulatory Impact Analysis for the Proposed Standards of Performance for New, Reconstructed, and Modified Sources and Emissions Guidelines for Existing Sources: Oil and Natural Gas Sector Climate Review, at 1-4. The commenter adds that EPA also acknowledges that state programs have varying requirements but then proceeds to select California and Colorado as a baseline to evaluate other state programs. See *id.* at 2-29 (noting that “California and Colorado have requirements at least as stringent as those in the proposed rule for well site and compressor station fugitives; natural gas processing plant leaks; pneumatic controllers; pneumatic pumps in the production, gathering and boosting, and processing segments; pre-OOOO reciprocating and wet-seal centrifugal compressors in the gathering and boosting and processing segments; and storage vessels”). The commenter notes that this is based in part on EPA's assumption that “California and Colorado have requirements at least as stringent as those in the proposed rule” and that they “contribute significantly to national production levels” for the oil and gas industry. *Id.* at 2-29. The commenter believes that the conclusion that California and Colorado are good and representative models for the costs of the November 2021 NSPS Proposal and as the baseline to evaluate other

---

<sup>4</sup> Document ID No. EPA-HQ-OAR-2021-0317-1566.

state programs is arbitrary and fails to take into account the actual oil and gas production sector in the United States. The commenter believes EPA cannot fairly characterize the costs in the absence of an actual proposed rule, and in any event has underestimated the compliance costs that states will incur in developing the required EG plans for OOOOc. The RIA does not appear to have sufficient data to accurately calculate these costs and the baseline data that is biased. Overall, in both the proposed rule and related RIA, EPA downplays the burden of developing these plans.

Response I-21-8: See discussion in section VIII.D. of the December 2022 Supplemental Proposal<sup>5</sup> and section XVII.D of the final preamble. See the proposed regulatory text for NSPS OOOOb at Document ID No. EPA-HQ-OAR-2021-0317-1551 and EG OOOOc at Document ID No. EPA-HQ-OAR-2021-0317-1552 in the public docket. See the following proposed ICR Supporting Statements located at Document ID Nos. EPA-HQ-OAR-2021-0317-0144 (NSPS OOOO & OOOOa), EPA-HQ-OAR-2021-0317-1556 (NSPS OOOOb), EPA-HQ-OAR-2021-0317-1553 (EG OOOOc) and the final ICR Supporting Statements for this rulemaking located in Docket ID No. EPA-HQ-OAR-2021-0317.

As to the comments regarding EPA's representation of state regulations in California and Colorado in the RIA, EPA believes the commenter has misunderstood the meaning of the RIA baseline. EPA is not using California and Colorado as baselines to evaluate other state regulations as the commenter asserts. Rather, due to the analytic difficulties in accounting for state regulations in the baseline scenario in the RIA, EPA broadly assumes that California and Colorado have equivalent or more stringent regulatory requirements to those in the November 2021 Proposal to avoid attributing emissions reductions in those states to the proposed action, as they would have happened regardless of any action taken by EPA. Thus, EPA's purpose in accounting for the California and Colorado requirements in the RIA baseline is to generate a more accurate estimate of the impacts of the rule rather than to use as a basis to evaluate other state programs.

Comment: Commenter (0824-Wyoming Department of Environmental Quality (WDEQ)) states that the November 2021 Proposal's expansion of the scope of affected facilities creates an unfunded mandate and infeasible resource burden upon the WDEQ. The commenter states that Wyoming's role as a nationally prominent producer of oil and natural gas means that the November 2021 Proposal places heightened burdens upon the Division's staff and financial resources compared to many other affected states in other parts of the country. As of August 2021, the commenter states Wyoming ranked eighth nationally in oil production and for the 2020 calendar year, Wyoming ranked ninth in marketed production of natural gas. Furthermore, the commenter adds that Wyoming has 16 of the nation's 100 largest natural gas fields, including the Pinedale and Jonah fields that rank among the top 10. Wyoming exercises air quality primacy and all areas in the State are meeting ambient air quality standards; through its Air Quality Division (AQD), it exercises substantial regulatory authority over the operations of Wyoming's extensive oil and gas industry. For example, the commenter reports that the WDEQ program covers over 18,000 operating single well sites and compressor stations. According to the commenter, while standing alone, the number of these sites is daunting, it barely begins to

---

<sup>5</sup> 87 FR 74844.

account for the massive increase in specific equipment subject to the November 2021 Proposal such as pneumatic pumps and controllers.

As such, the commenter (0824-WDEQ) reports that the November 2021 Proposal imposes compliance assurance costs on Wyoming without providing the funding to meet the additional federal regulatory burdens. For more than a decade, the commenter indicates that federal funds have only provided about 7 percent of the WDEQ's budget, with the rest coming from operator-paid fees or the State's General Fund. The commenter contends that, with the additional costs that will be imposed on Wyoming to implement the November 2021 Proposal, the proportion of federal funds will be further decreased, and the burden shifted to Wyoming's citizens and industry to shoulder the difference.

Commenter (0824-WDEQ) expresses that these costs would be of a magnitude that is simply unworkable for the Wyoming AQD (and likely other state regulatory agencies in the country) with no significant environmental outcomes. The commenter notes that the requirements pertaining to fugitive emissions monitoring and repair programs, including monitoring for fugitive emissions with OGI in accordance with 40 CFR part 60, Appendix K, would impose a massive reciprocal workload for state agencies. According to the commenter, conducting the compliance inspections, reports, and emissions inventories work commensurate with the requirements of the November 2021 Proposal places an overwhelming strain on agency staff and financial resources. The commenter contends that the skyrocketing workload would require hiring additional full-time employees (FTE), as well as training costs, equipment costs, and other associated costs.

The commenter (0824-WDEQ) presents potential state agency burdens that would be associated with the November 2021 Proposal but notes that it is impossible to pin down specific costs to the agency to fulfill the compliance demands of the November 2021 Proposal because EPA failed to provide specific regulatory language. However, the commenter notes that the increase in the number of facilities that would be affected, a general idea of some of the inspection requirements, and associated training costs, equipment costs, travel costs, and other costs, it is reasonable to assume the agency would have to hire significantly more staff. The commenter notes that the associated cost of hiring even five additional staff (one of whom would be at a senior level) would cost the agency \$585,458.67 annually. These estimates, according to the commenter, coupled with the costs identified above, would impose an immediate financial burden on the agency of about \$1,985,450, which does not account for recurring annual employee costs, recurring equipment maintenance and update costs, recurring future travel costs, *etc.*<sup>6</sup>

Commenter (0824-WDEQ) states that, despite proposing requirements that will certainly impact state agencies, EPA did not provide any information on anticipated implementation costs. The commenter contends that there is no way of providing a precise estimate for costs to WDEQ associated with the November 2021 Proposal. However, the commenter suggests that the financial demands placed on states under the November 2021 Proposal would require significant

---

<sup>6</sup> Cost statistics regarding FTE/additional FTE provided by WDEQ's Administration Division; cost-estimates regarding compliance duties associated with the November 2021 Proposal provided by AQD's Compliance Program.

additional funds. The commenter expresses concern that EPA has proposed no funding for the states to implement this expansive federal mandate. The commenter recommends that, if EPA expects the WDEQ to carry out these comprehensive compliance requirements, it is imperative that the federal government provide funding that would cover the entirety of the staffing and resource demands that they will experience. Otherwise, the commenter asserts that the November 2021 Proposal's requirements are unlawful, overly burdensome, and utterly impracticable.

Similarly, commenter (0580-Kentucky Division for Air Quality (KDAQ)) states that, as the delegated authority in Kentucky, the Division is responsible for the implementation and enforcement of both the new and existing rules once adopted into Kentucky law. The commenter reports that the Commonwealth has an estimated 60,000 sources that may become subject to the changes in the November 2021 Proposal. According to the commenter, the November 2021 Proposal creates an enormous unfunded mandate for the Division, as additional funding is not proposed to accommodate these additional responsibilities.

Commenter (0763-Texas Commission on Environmental Quality (TCEQ) and Railroad Commission (RRC)) asserts that the November 2021 Proposal constitutes an unfunded mandate that will dramatically impact oil and gas producing states. The commenter states that, for oil and gas producing states, costs will increase, while non-oil and gas producing states and the federal government will not see increases in regulatory or product cost. The commenter notes that, from a regulatory perspective these rules will significantly increase the permitting, investigation, and enforcement workload for the commenter (0763-TCEQ/RRC) as the delegated administrator. The rules will greatly increase the number of regulated facilities throughout the state and will also increase the number of records and reports that will be required to be reviewed to ensure compliance during an associated investigation. The commenter adds that the implementation of the November 2021 Proposal will dramatically increase the fiscal burden on Texas and will likely adversely affect delegated administrators across the nation with similar oil and gas production activity.

Response I-21-9: The new standards will work hand-in-hand with new resources and programs in the Inflation Reduction Act, which will incentivize early implementation of innovative methane reduction technologies and support methane mitigation and monitoring activities. These efforts will achieve greater methane emissions reductions more quickly. For more information on the IRA, the Administration has created a guidebook that provides an overview of the clean energy, climate mitigation and resilience, agriculture, and conservation-related tax incentives and investment programs, including who is eligible to apply for funding and for what activities. See <https://www.whitehouse.gov/cleanenergy/inflation-reduction-act-guidebook/>

EPA does intend on working with states to develop plans tailored to the factors concerning the states. The state-plan developing process, under which states establish performance standards for existing sources within their jurisdiction and have the discretion to consider remaining useful life and other factors, is one that Congress established through the text and structure of CAA section 111(d).

See the following proposed ICR Supporting Statements located at Document ID Nos. EPA-HQ-OAR-2021-0317-0144 (NSPS OOOO & OOOOa), EPA-HQ-OAR-2021-0317-1556 (NSPS

OOOOOb), EPA-HQ-OAR-2021-0317-1553 (EG OOOOOb) and the final ICR Supporting Statements for this rulemaking located in Docket ID No. EPA-HQ-OAR-2021-0317.

## **21.5 Executive Order 13132: Federalism**

Several commenters assert that the November 2021 Proposal does not provide sufficient respect to federalism considerations. Some of the specific concerns and comments received are presented in the following paragraphs.

Comment: Commenter (0573-Kansas Department of Health and Environment (KDHE)) argues that the November 2021 Proposal is flawed because it pertains to state implementation of the proposed EGs without adequately considering costs to the states to implement the guidelines for existing sources; adding that the preamble and the 2021 RIA for the November 2021 Proposal fail to correctly account state compliance costs. Furthermore, the commenter insists that the November 2021 Proposal by EPA to offer “aid and guidance” in an effort to correct for the anticipated “federalism implications” is not an acceptable substitute for adequate funding needed for this proposed federal initiative being imposed upon the state [86 FR 63260]. The commenter expresses concern that the proposed EGs would heavily impact their state of Kansas; pointing out, for example, that there are approximately 78,000 active oil wells and 28,000 active natural gas (including coal bed methane (CBM)) wells within the state and 93 of the 105 counties (in Kansas) have oil and gas well activity.

Commenter (0581-National Association of Clean Air Agencies (NACAA)) warns that state and local air pollution control agencies tasked with implementing and enforcing EPA’s rule will face a great variety of challenges – *e.g.*, increase their investments in personnel and technical capabilities, and urges the Agency to ensure that new burdens are paired with supplemental federal support and that they not come at the expense of resources already allocated for existing air programs. While the commenter recognizes agencies will be impacted differently – based on the number of sources within their authority – the commenter suggests that all agencies are presently facing resources and labor changes trying to meet their existing and emerging CAA responsibilities. The commenter warns that these resource and labor change issues will only increase unless agencies have federal support – *e.g.*, EPA ensures that agencies are appropriately funded.

Commenter (0581-NACAA) suggests that EPA can also help manage [federalism] implementation burdens by prioritizing and phasing its requirements under the rule to consider what the most resource-intensive actions are, and by balancing those actions with those that have the greatest demonstrated public health and environmental benefit. The commenter maintains that the speed and the order of the implementation steps must match the demonstrated availability of technologies and account for ongoing supply chain disruptions and labor issues. Additionally, the commenter points out that while sources such as pigging, truck unloading, small well sites are important and can have significant emissions, offering states flexibility for phasing in regulatory programs addressing them could potentially be valuable as a strategy to manage regulatory burdens. Although the commenter appreciates the November 2021 Proposal’s consideration of a number of new tools, programs and approaches, they note that those measures will take time to learn. Consequently, the commenter recommends that EPA should focus its

technical assistance efforts at addressing that learning gap. Additionally, the commenter writes, achieving shared goals for emission reductions may also be more successful if EPA prioritizes compliance assistance over example-setting enforcement in early years.

Response I-21-10: See Response I-21-9 of this Chapter. See also discussions on the timing of state plan submittals and compliance timelines in section V.D. of the December 2022 Supplemental Proposal Preamble,<sup>7</sup> and section XIII.E. of the final preamble.

Comment: Commenter (0946-Michigan Oil and Gas Association (MOGA)) expresses concern that associated costs from unfunded federal programs imposed on state agencies via “federalism” might be passed on to oil and gas producers in each state. The commenter supports EPA’s decision to allow individual state’s primacy over EGs. The commenter adds that wells are typically permitted, monitored, *etc.* on a local and/or state level, which, according to the commenter, allows for prompt changes, modifications, or community intervention, if needed, at these sites. The commenter notes that this is in contrast to federal inspections and correspondence.

Response I-21-11: Please see section IV.A of the final preamble discussing statutory background of CAA sections 111(b), 111(d), and general implementing regulations. Please see section XIII of the final preamble discussing the implementation framework of EG OOOOc.

Comment: Commenter (0797-NDDEQ/NDIC) notes that EPA solicited comment in the November 2021 Proposal on the costs associated with developing and submitting state plans for EG OOOOc. 86 Fed. Reg. at 63,261 (EO 13132 (Federalism)). However, the commenter contends that it is not reasonable to expect commenters to evaluate the cost of implementing a rule when EPA has not proposed rule text. Without the regulatory text of the rule itself (*i.e.*, what EPA proposes to publish in the Code of Federal Regulations), the commenter states that they do not know what it will have to do nor what it will cost. The commenter adds that, when EPA, consistent with its obligations under the Administrative Procedures Act (APA), publishes a proposed rule for comment, they will be able to evaluate the likely costs of the proposal.

Response I-21-12: See the proposed regulatory text for NSPS OOOOb at Document ID No. EPA-HQ-OAR-2021-0317-1551 and EG OOOOc at Document ID No. EPA-HQ-OAR-2021-0317-1552 in the public docket. See the following ICR Supporting Statements located at Document ID Nos. EPA– EPA-HQ-OAR-2021-0317-0144 (OOOO & OOOOa), HQ–OAR–2021–0317–1556 (OOOOb), EPA–HQ–OAR–2021–0317–1553 (OOOOc) for this action located at Docket ID No. EPA– HQ–OAR–2021–0317. See the final ICR Supporting Statements for this rulemaking located in Docket ID No. EPA-HQ-OAR-2021-0317.

Comment: Commenter (0790-West Virginia Office of the Attorney General (WV AG) *et al.*) asserts that the CAA expects that EPA’s regulatory efforts will show genuine respect for federalism and the role of the states. According to the commenter, the November 2021 Proposal does not.

---

<sup>7</sup> 87 FR 74831.

The commenter (0790-WV AG *et al.*) explains that states already regulate natural gas production and processing. They have an interest in reducing fugitive emission of gases from natural gas processing sites. States also ensure natural gas processors keep their facilities in good repair and engage in active efforts to make sure natural gas sites are safe. See, *e.g.*, W. Va. Code § 15-5C-2(a) (requiring pipeline and well operators to report safety incidents to West Virginia Division of Homeland Security). Further, the commenter adds that states already regulate greenhouse gas emissions through permitting and other regulations. See, *e.g.*, Col. Rev. Stat. § 25-7-102, Va. Code § 45.2-1706.1. The commenter recommends that EPA further discount the minimal benefits from federal methane regulations like those in the November 2021 Proposal given state efforts like these.

According to the commenter (0790-WV AG *et al.*), even more problematically, the November 2021 Proposal imposes a series of direct burdens on the states that neither the CAA nor any other existing law permits. The commenter notes that the November 2021 Proposal identifies only one potential implication for federalism—compliance costs. The agency dryly observes that the November 2021 Proposal “may” impose a burden on the States because of the “many hours of staff time” required to develop and implement the plans that the November 2021 Proposal requires. 86 Fed. Reg. at 63,261. The commenter explains that these costs will burden states. The commenter states that the November 2021 Proposal, however, does not contain any specific provisions explaining how EPA will help states bear these significant compliance costs. And these compliance estimates may well undershoot actual costs, as other aspects of the November 2021 Proposal — such as EPA’s choice to declare any unloading event a “modification” that subjects the facility to new-source performance standards—makes it difficult to evaluate accurately the true reach of the November 2021 Proposal.

The commenter (0790/0819-WV AG *et al.*) adds that the November 2021 Proposal otherwise ignores its own consequences for federalism. As an example, the commenter provides that section 111(d) of the CAA contemplates that states will have more latitude to implement standards of performance than when EPA takes up this task—as where the statute says that states may consider a facility’s “remaining useful life.” 42 U.S.C. § 7411(d)(1). In some public statements, the commenter notes that EPA touts how the November 2021 Proposal gives the states “room” to “adopt their own approaches.” See Fact Sheet for States, EPA (Nov. 2, 2021), <https://www.epa.gov/system/files/documents/2021-11/epas-proposed-oil-and-gas-rules-information-for-states.11.2.21.pdf>. The commenter states, however, that the November 2021 Proposal says otherwise, noting how “it would likely be difficult for States to demonstrate that the presumptive standards are not reasonable for the vast majority of designated facilities.” 86 Fed. Reg. at 63,251. The commenter suggests that, because EPA insists that the November 2021 Proposal will largely tether states to the agency’s “presumptive” standards, the states would have little choice but to implement the measures that comprise EPA’s BSER—lest EPA reject the states’ plans entirely. Even then, the commenter contends that EPA offers little reassurance to states, specifying that EPA still might not approve state plans that track the presumptive standards. *Id.* at 63,249.

Response I-21-13: EPA recognizes that some states currently regulate sources within the oil and gas industry. However, the comment is unclear regarding how this fact ought to influence EPA’s decision-making process for this rulemaking. It is unclear what the commenter is urging EPA to

do because EPA already carefully considered how states regulate these sources. Further, the need for the rule is explained in sections II and III of the final rule preamble.

The commenter claims that the proposal imposes burdens that the law does not permit, but the commenter does not identify any such burden or explain how such perceived burden conflicts with existing law. The commenter makes a broad unsupported claim. EPA has explained the legal basis for this rulemaking in sections IV and V of the final rule preamble.

EPA's statements about compliance costs came in the context of E.O. 12866.

The commenter claims that EPA's cost estimates may "undershoot" but they do not explain how or provide any details regarding costs that were unaccounted for. EPA explained its cost estimates in the final RIA and the final ICR Supporting Statements for this rulemaking located in Docket ID No. EPA-HQ-OAR-2021-0317 which are summarized in sections XVI and XVII.B of the final rule preamble, respectfully. The only example that commenters provide relates to uncertainty regarding the definition of modification for liquids unloading, but it's not clear to EPA how this would have impacts on costs to states (we are not looking at costs to industry for purposes of the Federalism EO).

Comment: Commenter (0819-WV AG *et al.*) states that the rational-basis approach set out in the November 2021 Proposal undermines the values of cooperative federalism embedded in the CAA. The commenter notes that Congress intended the Act to address air pollution while also maintaining the traditional division of authority between federal and state regulators. When Congress delegated authority to EPA to enact clean air rules, it also emphasized that "air pollution prevention ... is the primary responsibility of States and local governments." 42 U.S.C. § 7401(a)(3). This respect for state sovereignty is reflected in other parts of the statute, too. Congress assigned the critical ability to develop implementation plans for existing sources to the states—plans "which, after EPA approval, are published as regulations in the Federal Register." *People of State of Cal. ex rel. State Air Res. Bd. v. Dep't of Navy*, 431 F. Supp. 1271, 1274 (N.D. Cal. 1977), *aff'd*, 624 F.2d 885 (9th Cir. 1980). The commenter adds that the CAA repeatedly calls out the supremacy of States and local communities in controlling pollution. See, e.g., 42 U.S.C. § 7416 ("[N]othing in this chapter shall preclude or deny the right of any State or political subdivision thereof to adopt or enforce (1) any standard or limitation respecting emissions of air pollutants or (2) any requirement respecting control or abatement of air pollution."); *id.* § 7431 ("[N]othing in this chapter constitutes an infringement on the existing authority of counties and cities to plan or control land use, and nothing in this chapter provides or transfers authority over such land use.").

According to the commenter (0819-WV AG *et al.*), grafting rational basis onto the statute defies the stated principles of federalism. The commenter adds that, although the CAA imbues EPA with significant authority to set national performance standards, it is not boundless. The commenter explains that the demand to make and justify an endangerment finding for pollutants from a source category gives EPA meaningful guidelines—and preserves the states' roles while keeping the agency within its own. In short, the commenter states that a rational-basis standard gives EPA a blank check that Congress never wrote.

Response I-21-14: Please refer to RTC Volume I Chapter 3 on Significant Contribution Finding and the Congressional Review Act and final preamble section V.

Comment: Commenter (1381-Montana Petroleum Association (MPA)) reports that, at the state level in Montana, the Montana Department of Environmental Quality already has a facilities registration program in place with regular inspections using OGI cameras as well as enforcing leak detection and repair (LDAR). The commenter requests that EPA provide maximum flexibility under co-operative federalism to allow the individual states to manage the program and work with oil and gas operators on inspection technology and the related processes.

Response I-21-15: See discussions in section V.B.2.,<sup>8</sup> section V.B.3.,<sup>9</sup> and section IV.B.<sup>10</sup> of the December 2022 Supplemental Proposal. Please see sections X.A, X.B, XI.A, XI.B, and XIII.C.2 of the final preamble.

## **21.6 Executive Order 13175: Consultation and Coordination with Indian Tribal Governments**

Comment: Commenters (0391-Keweenaw Bay Indian Community (KBIC), 0605-Muscogee (Creek) Nation, 0781-National Tribal Air Association (NTAA)) recognize that while environmental justices (EJ) is an important issue disproportionately impacting, for example, minority and tribal communities, EPA must never usurp Tribal sovereignty and self-determination, nor should EJ be considered a substitute to government-to-government consultation directly with Tribes. More specifically, the commenters assert that EJ actions must treat Tribes as sovereign nations with self-determination first and part of the EJ community second. Furthermore, the commenters state that EPA's baseline assessment to determine if EJ concerns exist is not a sufficient analysis with respect to considering and addressing Tribal impacts. [See Chapter 6 (Environmental Justice (EJ) Implications and Stakeholder Outreach) for additional comments on EJ considerations.]

Commenter (0794-Mandan, Hidatsa and Arikara (MHA) Nation) recalls an opportunity for Tribes to consult with EPA officials on the November 2021 Proposal during a government-to-government consultation held on January 24, 2022, during which they were assured that engagement opportunities would be ongoing. The commenter states that, as part of the ongoing consultation promised to tribal representatives, EPA should meaningfully consider, and address concerns raised by tribes up until the rule is finalized and then throughout the rule implementation process.

Commenters (0391-KBIC, 0833-Environmental Programs Department, Ute Mountain Ute Tribe (Ute EPD)) state that while they support the provision requiring states to include community engagement for accepting program delegation for the new and modified sources and as part of the program approval for state plans for existing sources, this engagement is not equivalent to consultation and coordination with neighboring Tribal Governments. According to the commenters, requiring consultation and coordination between all government entities will

---

<sup>8</sup> 87 FR 74812.

<sup>9</sup> 87 FR 74816.

<sup>10</sup> 87 FR 74740.

provide more consistent understanding of the requirements, implementation, and enforcement across jurisdictions.

Commenters (0391-KBIC, 0781-NTAA, 0833-Ute EPD, 0943-Sault Ste. Marie Tribe of Chippewa Indians, Sault Tribe Environmental Department (Sault EPD)) disagree with EPA's conclusion that the November 2021 Proposal does not have Tribal implications; adding that the Agency decision is based on viewing the impacts of the Tribes with a lens of the EO alone. According to the commenters, the impacts and implications of oil and natural gas development, and the November 2021 Proposal, for Tribes are underestimated. In support, the commenters reference/cite the United Nations Declaration on the Rights of Indigenous Peoples, endorsed by the United States in 2011.<sup>11</sup>

Similarly, commenter (0605-Muscogee (Creek) Nation) states that EPA is only viewing the impacts of the November 2021 Proposal on Tribes with a lens of the EO alone. However, according to the commenter, the Agency's Indian policy and Treaty Rights policy require EPA to recognize Tribal rights, issues, and impacts beyond the EO.<sup>12</sup> The commenter notes that impacts include direct impacts to Tribal health and culture and impacts through climate change. Thus, the commenter asserts that it is important not to understate the impacts and implications of oil and natural gas development, and the November 2021 Proposal, for Tribes.

Commenter (1301-Northern Arapaho Tribe Business Council (NATBC)) states that the November 2021 Proposal has potentially significant impacts on the Tribe and requests continued government-to-government consultation regarding the Rule and any supplemental proposals pertaining to the November 2021 Proposal. The commenter also requests notification of related rules, policies, and opportunities.

Response I-21-16: See Volume I, Chapter 6 (Environmental Justice (EJ) Implications and Stakeholder Outreach), subsection 6.1.2 (Native American Environmental Justice Impacts ), Responses I-6-2 through I-6-4, for EPA's response to comments on EPA's EJ analyses.

On November 16, 2021, EPA sent a letter to all 574 Federally Recognized Tribes inviting Tribes to participate in Tribal Consultation on the November 2021 Proposal, "Standards of Performance for New, Reconstructed, and Modified Sources and Emissions Guidelines for Existing Sources: Oil and Natural Gas Sector Climate Review." Three tribes requested consultation. The following consultations were held: Tribal Consultation with MHA Nation (The Mandan, Hidatsa and Arikara Nation- Three Affiliate Tribes) on January 24, 2022; Tribal Consultation with the

---

<sup>11</sup> United Nations Declaration on the Rights of Indigenous Peoples, G.A. Res. 61/295, Annex, art. 32(2), UN. Doc. A/RES/61/295 (Sept. 13, 2007); Announcement of U.S. Support for the United Nations Declaration on the Rights of Indigenous Peoples, U.S. Dep't of State, <https://2009-2017.state.gov/documents/organization/154782.pdf>.

<sup>12</sup> Moreover, the United Nations Declaration on the Rights of Indigenous Peoples, endorsed by the United States in 2011, requires: "States shall consult and cooperate in good faith with the indigenous peoples concerned through their own representative institutions in order to obtain their free and informed consent prior to the approval of any project affecting their lands or territories and other resources, particularly in connection with the development, utilization or exploitation of mineral, water or other resources." United Nations Declaration on the Rights of Indigenous Peoples, G.A. Res. 61/295, Annex, art. 32(2), U.N. Doc. A/RES/61/295 (Sept. 13, 2007); Announcement of U.S. Support for the United Nations Declaration on the Rights of Indigenous Peoples, U.S. Dep't of State, <https://2009-2017.state.gov/documents/organization/154782.pdf>.

Northern Arapaho Tribe on January 24, 2022; Tribal Consultation with the Eastern Shoshone Tribe on January 25, 2022.<sup>13</sup> On November 14, 2022, EPA sent an additional letter to all 574 Federally Recognized Tribes inviting Tribes to participate in a follow up Tribal Consultation on the December 2022 Supplemental Proposal. Two tribes requested consultation. The following consultations were held: Tribal Consultation with MHA Nation on January 24, 2022, and Tribal Consultation with Ute Tribe on February 24, 2023.

EPA agrees that meaningful engagement is separate than tribal consultation. Additionally, EPA recognizes the rights of tribes as sovereign nations to self-determination and acknowledges the federal government's trust responsibility to tribes. EPA recognizes that some implications may be felt disproportionately across Indian country as well as in communities. To help resolve these, and specific to tribes, EPA provides programs, resources, financial assistance, technical assistance and training, consultation opportunities and dedicated engagement to help identify and mitigate perceived and tangible implications.

Consistent with previous actions affecting the Crude Oil and Natural Gas source category, the EPA understands there is continued significant tribal interest because of the growth of the oil and natural gas production in Indian country. In accordance with the EPA Policy on Consultation and Coordination with Indian Tribes, the EPA will continue to engage in consultation with tribal officials as these rules become implemented.

## **21.7 Executive Order 13211: Actions Concerning Regulations that Significantly Affect Energy Supply, Distribution, or Use**

Comment: Commenter (0802-Kraken Oil & Gas LLC (Kraken)) suggests that EPA's November 2021 proposed actions are significant energy actions (as defined under EO 13211); arguing that these actions are based on a fundamentally flawed cost-benefit analysis that compares global benefits of methane emissions reductions with domestic cost of compliance, thereby, according to the commenter overstating domestic GHG emissions and skewing the balance in favor of the benefits of the November 2021 proposed actions for NSPS OOOOa, NSPS OOOOb, and EG OOOOc – *e.g.*, more GHG emissions than would result in the absence of regulation. The commenter defines and recaps the intent of EO 13211 and maintains that EPA does not have any basis under the CAA that would allow GHG emissions to be compared as such. As additional support, the commenter notes that Western Energy Alliance submitted comments on "Technical Support Document: Social Cost of Carbon, Methane, and Nitrous Oxide Interim Estimates Under Executive Order 13990" (on June 21, 2021, via Regulations.gov) in which they present their position on the purpose of the CAA regarding determining the impact from November 2021 Proposal.

Response I-21-17: Please see appendix A, section A.6 of this RTC document for EPA's response to this comment.

---

<sup>13</sup> See Document ID No. EPA-HQ-OAR-2021-0317-1510.

## **21.8 Executive Order 12898: Federal Actions to Address Environmental Justice in Minority Populations and Low-Income Populations**

Comment: Commenter (0424-Division of Air Quality, West Virginia Department of Environmental Protection (WVDEP)) seeks clarification as to why EPA believes “that this action does not have disproportionately high and adverse human health or environmental effects on minority populations, low-income populations, and/or indigenous peoples, as specified in EO 12898 (59 FR 7629, February 16, 1994)” [86 Fed. Reg. 63262], and yet it is proposing additional meaningful engagement without specific guidance for the states.

Response I-21-18: The documentation for this assessment is contained in section 4 of the November 2021 RIA and in section 4 of the 2022 RIA for the Supplemental.<sup>14</sup> See discussion in section V.B.6. of the December 2022 Supplemental Proposal pertaining to meaningful engagement.<sup>15</sup> Also see the final rule RIA and section XIII.C.6 of the final preamble.

<sup>14</sup> See Document ID Nos. EPA–HQ–OAR–2021– 0317–0173 and EPA–HQ–OAR–2021– 0317–1566.

<sup>15</sup> 87 FR 74827.

## Chapter 22. Appendix K

The following sections provide a summary of comments received on 40 CFR part 60, appendix K (Appendix K), EPA's proposed protocol for the use of optical gas imaging (OGI) in the determination of leaks of volatile organic compounds (VOC), methane, and ethane.

### 22.1 General Support and Opposition for Appendix K

#### 22.1.1 Support for Appendix K

Comment: Several commenters (0414-Waterspirit, 0458-Maryland Department of the Environment (MDE), 0601-Connecticut Department of Energy and Environmental Protection (DEEP), 0756-Baker Hughes, 0808-American Petroleum Institute (API), 0834-Air Advocacy Coalition (A2C)) supported the development of Appendix K as a protocol for conducting OGI surveys. Commenters (0414-Waterspirit, 0458-MDE, 0756-Baker Hughes, 0834-A2C) supported the application of Appendix K for all oil and gas upstream and downstream sectors, or in specific sectors, such as gas processing and petroleum refining (0808-API). One commenter (0414-Waterspirit) urged EPA to broaden the scope to include all facilities within the oil and natural gas supply chains to provide a whole cycle assessment of methane reporting, from extraction through transmission and distribution. Another commenter (0601-DEEP) noted that Appendix K would greatly enhance the "consistency, predictability and enforceability of OGI leak detection and repair" and could serve as a model for state inspection staff to use when conducting OGI surveillance. This commenter generally supported the use of Appendix K as an alternative to EPA Method 21 monitoring and concurred that the alternative would be beneficial for states. A different commenter (0458-MDE) believes that OGI technology provides a more comprehensive survey of a facility's fugitive emissions.

Response I-22-1: EPA acknowledges the commenter's support for the development of Appendix K.

Comment: Several commenters (0749-Petroleum Association of Wyoming (PAW), 0794-Mandan, Hidatsa and Arikara Nation (MHAN), 0808-API, 0816-Montrose Environmental Group (Montrose), 0820-Pioneer Natural Resources USA, Inc. (Pioneer), 0831-American Exploration and Production Council (AXPC), 0911-North Dakota Petroleum Council (NDPC)) state that the goal of the proposed Appendix K protocol is to provide an equivalent, alternative, more technologically advanced method for leak detection and emissions reduction and a cost-effective alternative to standard EPA Method 21 leak detection and repair (LDAR) monitoring. The commenters agree that the use of OGI technology constitutes the Best System for Emission Reduction (BSER) because of its increased efficacy and because it is also cost effective, compared to traditional EPA Method 21. Further the commenters also agree that developing a protocol for OGI monitoring that includes training, survey methods, and auditing is a positive step. However, these commenters stress that the protocol requirements need to complement the technology and not inhibit the benefits.

Response I-22-2: EPA acknowledges the commenters support for the development of Appendix K.

## ***22.1.2 Opposition to Requiring Use of Appendix K***

### ***22.1.2.1 General Dissent for the Use of Appendix K in Upstream Oil and Gas***

Comment: Numerous commenters (0462/0564/0764-Arkansas Independent Producers and Royalty Owners (AIPRO), 0579-Chevron, 0743-Western Energy Alliance (WEA), 0777-Ascent Resources, LLC (Ascent), 0793-Permian Basin Petroleum Association (PBPA), 0807-BP America, Inc. (BP), 0808-API, 0817-GPA Midstream Association (GPA), 0820-Pioneer, 0831-AXPC, 0834-A2C) objected to or expressed concern regarding the use of Appendix K in upstream or midstream oil and gas facilities. Commenters (0462-AIPRO, 0579-Chevron, 0777-Ascent, 0808-API, 0817-GPA, 0820-Pioneer, 0831-AXPC) stated that the monitoring requirements in Appendix K are more aligned with downstream facilities such as refining and processing plants. Commenters (0462/0764-AIPRO, 0607-Arktos Environmental LLC (AENV), 0743-WEA, 0777-Ascent, 0786-Enerplus Resources (USA) Corporation (Enerplus), 0793-PBPA, 0808-API, 0810-Petroleum Alliance of Oklahoma (Petroleum Alliance-OK), 0817-GPA, 0820-Pioneer, 0831-AXPC, 0834-A2C, 0911-NDPC, 0938-Texas Oil & Gas Association (TXOGA)) stressed that the requirements are overly burdensome and not cost-effective for upstream facilities, including well pads, centralized production facilities, transmission compressor stations, or gathering and boosting stations. One commenter (0808-API) stated that Appendix K goes beyond the current NSPS OOOOa requirements concerning performance specifications, “operating envelope”, survey time, and records for leaking components and is impractical for operators to implement given the hundreds to thousands of well sites and compressor stations to monitor and the geographic dispersion of these facilities.

Some commenters (0564/0764-AIPRO, 0777-Ascent) state that the Appendix K protocol was principally designed to accommodate facility inspections in the downstream sector such as refining and processing plants. Commenters (0777-Ascent, 0808-API, 0817-GPA, 0834-A2C) noted that upstream facilities do not typically have dedicated staff or resources on-site to conduct monitoring surveys. Additionally, commenters (0786-Enerplus, 0808-API) stated that the Appendix K requirements do not account for the significantly different design, complexity, distribution, or operation of upstream production facilities; two commenters (0607-AENV, 0743-WEA) noted that the requirements do not accurately reflect the realities of conducting leak detection in rural, active oil field conditions and would dramatically reduce the ability and efficiency of operators to conduct leak inspections. One commenter (0808-API) stated that Appendix K would require several significant modifications to be effectively implemented across downstream oil and gas facilities, gas processing plants, or other process industries. Commenters (0786-Enerplus, 0793-PBPA, 0808-API, 0817-GPA, 0820-Pioneer, 0831-AXPC, 0834-A2C) specifically noted key differences between upstream and downstream facilities, including:

- (1) upstream and midstream facilities are smaller and less complex, with fewer regulated components (e.g., well sites contain tens to hundreds of components, and gathering and boosting stations have an average of 1,800 components - versus tens of thousands of components at a refinery; therefore the benefit of the economy of scale present at petroleum refineries is eliminated);
- (2) there are significantly more well sites and compressor stations;

(3) Upstream production operations are not steady-state process operations like a refinery, where the process flow is largely constant and consistent. Producers regularly have to adjust for variable conditions that can occur unpredictably from the formation or on the landscape, such as weather that can prevent or disrupt a planned monitoring activity;

(4) Because upstream facilities are located out on the natural landscape, rather than a large sited industrial location, they often have a different set of safety, environmental, or circumstantial issues to account for in the field, such as potential for H<sub>2</sub>S gas exposure, ecological considerations or even landowner limitations; and

(5) Downstream facilities have people onsite 24-hours a day, whereas most well sites, centralized production facilities, and compressor stations are unmanned sites in remote locations spread over large geographic areas requiring contractors to travel to perform OGI monitoring, often accompanied by operator personnel to provide access to the site. Unlike the larger sites, which have full-time personnel dedicated to one facility, most upstream companies assign one employee to multiple small sites, making on-site monitoring requirements particularly burdensome for small upstream producers.

Commenter (0817-GPA) specifically asserted that Appendix K is entirely unsuited for use at compressor stations. The commenter (0817-GPA) urged that if Appendix K is applied, EPA must revise elements of the protocol for midstream operations, notably: (1) excluding components with no detectable emissions; (2) excluding components below a certain VOC and methane threshold; (3) revising the senior OGI camera operator requirements; and (4) revising auditing requirements.

Another commenter (0462-AIPRO) stressed that Appendix K, as proposed, is not feasible for operators of upstream or midstream facilities to implement because the EPA is expanding the number of sites subject to OGI inspections while also making the inspection standards much more stringent. Commenters (0462-AIPRO, 0743-WEA, 0938-TXOGA) stated that the proposed standard would have a minimal impact on overall methane emissions and provide little environmental benefit, while substantially increasing operator costs. One commenter (0743-WEA) stated they support the continued use of OGI emissions detection in the production, gathering, boosting, transmission and storage segments, and its members are at the forefront of developing, implementing, and rigorously evaluating new technologies and approaches in the OGI space. However, as drafted, Appendix K outlines a set of additional recordkeeping, training, recording, and technical requirements that are largely impractical for use in upstream, midstream, transmission, and storage operations.

Several commenters (0793-PBPA, 0810-Petroleum Alliance-OK, 0814-Independent Petroleum Association of America (IPAA) et al., 0924-U.S. Small Business Administration (SBA), 0945/1373-JOFA Consulting (JOFA), 0959-Colt Midstream LLC (Colt)) expressed concern that the EPA has not considered the significant burden Appendix K will have on small businesses, small OGI operators, and particularly upstream companies. The commenters stated that they are concerned that this impact will disproportionately affect small businesses, which account for a large percentage of upstream operators. Commenters (0793-PBPA, 0959-Colt) noted that the field training, quality assurance and control, and the recordkeeping requirements create an

unnecessary burden on smaller to medium sized upstream and midstream oil and gas operators. For these requirements to have to be included with the facility records, the operator of the facility would potentially need to obtain these records from the contractor conducting the surveys for each survey performed at the facility. Further, one commenter (0793-PBPA) questioned if there will be adequate surveyors available to all operators, especially small oil and gas operators, when needed to meet the monitoring compliance requirements of NSPS OOOOa, NSPS OOOOb, and EG OOOOc. Another commenter (0810-Petroleum Alliance-OK) stated that EPA is making these survey compliance requirements too complicated and onerous for all operators, especially for small oil and gas operators that have marginal/low production wells. The commenter further stated the requirements will significantly extend survey timeframes beyond what is necessary to detect fugitive emissions, will likely require the use of contract surveyors, requires excessive electronic recordkeeping efforts, and increases costs excessively.

Response I-22-3: In response to the comments received on the November 2021 Proposal, EPA proposed a different regulatory approach for fugitive emissions from well sites, centralized production facilities, and compressor stations in the December 2022 Supplemental Proposal. For details, please see discussion in section IV.A.1.a.ii and IV.A.2.A of the December 2022 Supplemental Proposal related to fugitive emissions from well sites, centralized production facilities, and compressor stations.<sup>1</sup>

Comment: One commenter (0820-Pioneer) stated that based on their experience, a large horizontal tank battery takes 2.5 hours to survey. With the newly proposed requirements under Appendix K, they report it will take 5 hours and be done quarterly; and there are often safety concerns accessing the sites which could delay the process further. The commenter added that EPA is requiring surveys to be 60 days apart and this will be difficult to meet as each quarterly pass may take longer than expected and 60 days apart may not be feasible. The commenter stated that, if Appendix K remains in the rule, they recommend that EPA allow the surveys to be 30 days apart to allow more time to survey and help facilitate compliance with this new program.

Response I-22-4: In response to the comments received on the November 2021 Proposal, EPA proposed a different regulatory approach for fugitive emissions from well sites, centralized production facilities, and compressor stations in the December 2022 Supplemental Proposal. For details, please see discussion in section IV.A.1.a.ii and IV.A.2.A of the December 2022 Supplemental Proposal related to fugitive emissions from well sites, centralized production facilities, and compressor stations.<sup>2</sup>

Comment: Two commenters (0743-WEA, 0824-WDEQ) pointed out that there would be significant costs associated with meeting the requirements for the qualifications of the personnel operating OGI cameras in accordance with Appendix K. Operators will either have to undertake a costly training and certification process for their own staff or will have to hire qualified contractors to perform the work associated with the monitoring requirements. One commenter (0824-WDEQ) stated such costs are entirely prohibitive for many stripper well operators who would be subject to these requirements. As such, the commenter disagreed with EPA's assessment that it "no longer believes that production levels provide an appropriate threshold for

---

<sup>1</sup> 87 FR 74722-74736 and 74739 (December 6, 2022).

<sup>2</sup> 87 FR 74722-74736 and 74739 (December 6, 2022).

any exemption from fugitive monitoring.” Small operators are already voicing concerns that they will have to shut down operations demonstrating that EPA’s assessment is inaccurate.

Response I-22-5: In response to the comments received on the November 2021 Proposal, EPA proposed a different regulatory approach for fugitive emissions from well sites, centralized production facilities, and compressor stations in the December 2022 Supplemental Proposal. For details, please see discussion in section IV.A.1.a.ii and IV.A.2.A of the December 2022 Supplemental Proposal related to fugitive emissions from well sites, centralized production facilities, and compressor stations.<sup>3</sup>

Comment: One commenter (0793-PBPA) stated that should EPA include Appendix K in the forthcoming regulatory text, they recommend the following modifications be incorporated at a minimum:

- *Low Production Well Sites:* There should not be a one-size-fits-all approach to leak detection for low producing wells, such as requiring OGI surveys regardless of facility production levels. EPA acknowledges in the November 2021 Proposal that there is wide variability among low producing well sites with respect to methane emissions. Thus, EPA should not be overly prescriptive and should accommodate use of alternate technologies or even those that are yet to be developed and that may be economic for low production well sites as opposed to mandated OGI surveys that are likely to cause severe economic harm to the small business owners who primarily own these well sites.
- *Survey Frequency:* EPA’s cost justification is largely based on stale assumptions from old rulemakings and sources. EPA should collect updated information to create an adequate record that supports its proposal, as EPA has done for prior rulemakings. For example, in a 2020 rulemaking, EPA appropriately recognized varying emissions reductions based on type of site (low production site, gas well site, and oil well site) and monitoring frequency. But EPA didn’t account for those differences in its NSPS OOOOb/EG OOOOc proposal. EPA should start with LDAR applicability criteria from prior NSPS OOOO and NSPS OOOOa rulemakings and then inventory the types of facilities, well sites, and throughputs in order to craft a rule that avoids a “one-size-fits-all” approach applicable to millions of sites.

Response I-22-6: In response to the comments received on the November 2021 Proposal, EPA proposed a different regulatory approach for fugitive emissions from well sites, centralized production facilities, and compressor stations in the December 2022 Supplemental Proposal. For details, please see discussion in section IV.A.1.a.ii and IV.A.2.A of the December 2022 Supplemental Proposal related to fugitive emissions from well sites, centralized production facilities, and compressor stations.<sup>4</sup>

#### 22.1.2.2 Use of NSPS OOOOa Procedures in NSPS OOOOb and EG OOOOc

Comment: Several commenters (0462/0564/0764-AIPRO, 0607-AENV, 0743-WEA, 0802-Kraken Oil & Gas LLC (Kraken), 0807-BP, 0808-API, 0810-Petroleum Alliance-OK, 0831-AXPC, 0834-A2C, 0911-NDPC, 0938-TXOGA) stated that NSPS OOOOa OGI surveys are effective and sufficient to reduce methane emissions and recommended that EPA codify NSPS

---

<sup>3</sup> 87 FR 74722-74736 and 74739 (December 6, 2022).

<sup>4</sup> 87 FR 74722-74736 and 74739 (December 6, 2022).

OOOOa OGI procedures (with updates to streamline the method) for NSPS OOOOb and EG OOOOc OGI requirements for upstream facilities. The commenters noted that those rules have been implemented since 2015, and operators have designed processes and procedures to comply with those requirements over the last 7 years. The commenters noted that those requirements establish reasonable and appropriate OGI monitoring plan requirements that are likewise appropriate and reasonable to include in NSPS OOOOb and EG OOOOc. They added that those requirements have been functioning as a means of mitigating emissions in upstream operations and would be equally adequate for setting forth OGI requirements under a future NSPS OOOOb or EG OOOOc proposal.

One commenter (0808-API) stated that with respect to the proposal requirements for new (NSPS OOOOb) and existing (EG OOOOc) sources, the commenter generally supports, with recommended changes to Appendix K and its application, the provisions for fugitive emissions monitoring at well sites, compressor stations, and gas processing plants and remarked on the differences between the protocols and the types of sources that Appendix K and the NSPS OOOOa procedures are intended to address. The commenter asserted that EPA has not demonstrated that the more stringent requirements of Appendix K are more effective at detecting leaks at well sites, centralized production facilities, and compressor stations, whereas NSPS OOOOa camera specifications have been demonstrated as feasible through EPA testing and in the field. A different commenter (0579-Chevron) suggested that EPA reevaluate Appendix K for use in upstream facilities and craft applicable rules accordingly.

Response I-22-7: In response to the comments received on the November 2021 Proposal, EPA proposed a different regulatory approach for fugitive emissions from well sites, centralized production facilities, and compressor stations in the December 2022 Supplemental Proposal. For details, please see discussion in section IV.A.1.a.ii and IV.A.2.A of the December 2022 Supplemental Proposal related to fugitive emissions from well sites, centralized production facilities, and compressor stations.<sup>5</sup>

#### 22.1.2.3 Limit Use of Appendix K

A commenter (0808-API) recommended EPA limit Appendix K to refineries, gas plants, and similar larger process operations in other industries. The commenter stated that while the proposed Appendix K OGI protocol is not appropriate for use in the production and transmission sectors, where OGI monitoring specifications should continue to be based on NSPS OOOOa requirements, with the commenter's recommended modifications to Appendix K, the commenter generally supports its application for gas processing plants, petroleum refineries, and similar facilities. The commenter also proposed that EPA could strengthen the standards in OOOOa for using OGI in the production and transmission categories without applying Appendix K. Another commenter (0834-A2C) suggested that Appendix K should only be an optional alternative to EPA Method 21 for downstream natural gas processing plants and petroleum refineries in the oil and natural gas source category. The commenter stated that they wholly support the use of OGI as an alternative to leak detection using EPA Method 21 and that with appropriate applicability and adjustments as detailed by other commenters. The commenter also supported establishing Appendix K as a performance specification for OGI at complex process facilities. Yet another

---

<sup>5</sup> 87 FR 74722-74736 and 74739 (December 6, 2022).

commenter (0938-TXOGA) stated that Appendix K was developed and designed for downstream facilities (e.g., natural gas processing plants, natural gas liquids fractionation facilities, petroleum refineries). As the commenter understands it, the concept is that Appendix K is designed to provide a protocol for facilities to conduct OGI monitoring on difficult-to-monitor components at plants (e.g., elevated fugitive components), in combination with the current physical monitoring (e.g., EPA Method 21).

Several commenters (0607-AENV, 0743-WEA, 0748-American Fuel & Petrochemical Manufacturers (AFPM), 0777-Ascent, 0808-API) supported EPA in the development of Appendix K to establish appropriate protocols for complex downstream petroleum refineries with dedicated on-site staff to conduct fugitive monitoring surveys and at natural gas plants. However, these commenters asserted that significant modifications to Appendix K are necessary before it is implemented. The commenters recommended specific changes to the November 2021 Proposal (see specific recommended changes in the other sections of this chapter) to address their concerns that the proposed requirements would: 1) result in difficulty in finding and retaining adequate numbers of qualified senior OGI operators; 2) create training and quality assurance/quality control (QA/QC) requirements that are overly burdensome without leading to more effective leak detection; and 3) cause the ownership of various requirements, and particularly the recordkeeping requirements to be unclear and unnecessarily burdensome. The commenters also recommend that EPA include some clarifications and efficiency changes to Appendix K.

Response I-22-8: See responses to specific comments raised on Appendix K throughout the rest of this chapter.

In response to the comments received on the November 2021 Proposal, EPA proposed a different regulatory approach for fugitive emissions from well sites, centralized production facilities, and compressor stations in the December 2022 Supplemental Proposal. For details, please see discussion in section IV.A.1.a.ii and IV.A.2.A of the December 2022 Supplemental Proposal related to fugitive emissions from well sites, centralized production facilities, and compressor stations.<sup>6</sup>

#### 22.1.2.4 Appendix K Could Hinder Future Technology

Comment: One commenter (0782-Berkshire Hathaway Energy Company (BHE)) cautioned that the proposed Appendix K has the potential to negate future progress by introducing a substantial hindrance to the use of OGI technology; the commenter recommended retaining the standard LDAR provisions and not adding further requirements without first supporting/rationalizing the need for additional rigor, and suggested that EPA launch “a more inclusive and deliberate process to develop an OGI method that more thoroughly engages stakeholders.” Another commenter (0807-BP) expressed concern that emphasis on OGI could have the unintended consequence of mis-prioritizing LDAR resources. The commenter pointed out that OGI, unless supplemented by other higher frequency technologies, can leave the majority of calendar days unmonitored.

---

<sup>6</sup> 87 FR 74722-74736 and 74739 (December 6, 2022).

One commenter (1291-INGAA) stated issues with Appendix K go beyond stifling OGI. The commenter contended that the stringency and burdensome nature of Appendix K has implications for the adoption and implementation of other imaging or infrared-based technologies that are integral to the proposed rule (e.g., any new technologies such as remote or fence-line monitoring should have similar methods). The commenter noted that methods such as this would preclude technology deployment and is in direct conflict with EPA's desires to expand technologies available to both operators and communities. If EPA wants pathways to new technology that will offer more continuous monitoring or more transparency to communities, the commenter asserted that Appendix K is not the way to achieve those goals. Because these types of programs require some type of standardization, the commenter believed that Appendix K will preclude progress on these important issues. According to the commenter, it is incumbent on EPA to prepare methods that are simple, streamlined, easily replicated, and developed for all stakeholders.

One commenter (0782-BHE) observed that a highly prescriptive protocol could limit the ability of new lower cost and lower fidelity technologies. Further, as written, Appendix K may limit competition by reinforcing current IR monopolies, maintaining high camera prices, and working against the Agency's stated objective to identify and reduce meaningful leak emissions. This commenter provided an example of a lower cost long wave infrared uncooled microbolometer which can detect methane leaks and may be appropriately suited to identifying consequential leaks. However, this camera technology is currently incapable of visualizing propane at the concentration and mass rate specified in 40 CFR 60.5397a(c)(7)(i)(B). The commenter also recommended retaining EPA Method 21 as an acceptable method for test method alternatives; the commenters stated that due to the costs and limitations of OGI operator availability, alternative leak survey methods would likely be necessary to provide flexibility. The commenter posited that Appendix K holds operators to a much different strata of performance criteria, and that resource limitations may inadvertently force operators to "backslide" to EPA Method 21.

Response I-22-9: EPA disagrees that Appendix K will negate progress on future technologies and notes that there are many advanced technologies for leak detection currently being tested and implemented in different sectors. EPA has provided a pathway for use of advanced technologies in NSPS OOOOb and EG OOOOc. See Volume II, Chapter 5, and discussion in section X.B of the preamble to the final rule for information on advanced technologies. EPA has also retained the use of EPA Method 21 as an alternative to OGI for conducting monitoring of fugitive emissions and leaks.

EPA made substantial edits to Appendix K in response to comments on the November 2021 Proposal. See discussion in section VI of the December 2022 Supplemental Proposal.<sup>7</sup> In response to the comments received on the November 2021 Proposal, EPA proposed a different regulatory approach for fugitive emissions from well sites, centralized production facilities, and compressor stations in the December 2022 Supplemental Proposal. For details, please see discussion in section IV.A.1.a.ii and IV.A.2.A of the December 2022 Supplemental Proposal related to fugitive emissions from well sites, centralized production facilities, and compressor stations.<sup>8</sup>

---

<sup>7</sup> 87 FR 74837-74842 (December 6, 2022).

<sup>8</sup> 87 FR 74722-74736 and 74739 (December 6, 2022).

Comment: Many commenters (0458-MDE, 0558-Center for Climate and Energy Solutions (C2ES), 0759/0780-LongPath Technologies, Inc. (LongPath) et al., 0782-BHE, 0814-IPAA, 0844-Environmental Defense Fund (EDF) et al., 0935-Colorado Oil and Gas Association (COGA), 0954-Teledyne FLIR, LLC (FLIR), 1391-Interstate Natural Gas Association of America (INGAA)) expressed support for the inclusion and development of a wide variety of technologies and platforms for leak detection endeavors. Some commenters (0558-C2ES, 0954-FLIR) specifically referenced quantitative OGI while several others (0590-Honeywell, 0756-Baker Hughes, 0759/0780-LongPath, 0782-BHE, 0791-Airdar, Inc., 0808-API, 0844-EDF, 0944-Kuva Systems) discussed the various platforms that are applicable and currently in use at some facilities (most notably drones, sensor networks, and continuous monitoring). There was strong support from many commenters (0756-Baker Hughes, 0808-API, 0831-AXPC, 0911-NDPC, 1391-INGAA) encouraging EPA to change the definition for OGI to include drone-based and fixed, continuous applications at a minimum in order to allow for technology innovations and application flexibility. Other commenters (0760-Airdar et al., 0762-CleanConnect.AI et al., 0954-FLIR) proposed that EPA develop separate alternative work practices for the various alternative technologies and platforms.

Commenter (0782-BHE) identified seven categories of OGI technology for which EPA should consider broadening the Appendix K scope or developing new protocols:

- Portable handheld OGI (Appendix K);
- Fixed OGI;
- Methane sensors;
- Open path fence line air monitoring;
- Drone imaging;
- Fixed wing or helicopter remote surveillance; and
- Satellite imaging.

This inclusive technology-flexible approach was echoed by others as noted above. In cases where the leak source is intermittent, one commenter (0780-LongPath) recommended that another form of OGI (such as continuous monitors) be allowed for follow-up surveys/monitoring.

Response I-22-10: EPA removed the terminology “hand-held” from Appendix K in response to comments in the December 2022 Supplemental Proposal. We recognize that it is potentially possible to follow the requirements outlined in Appendix K while using an OGI camera mounted on a drone, and we did not intend to limit technology development. The use of OGI in other configurations would be dependent on the ability of the camera operator to follow the requirements outlined in Appendix K. For example, it is unlikely that a fixed-mount camera would be able to view components from multiple angles or that the operator of such a camera would be able to always adjust the view to account for interferences. Our intent was not to cover these types of applications in Appendix K, although EPA may update Appendix K or develop new protocols that do cover these applications in a future rulemaking.

EPA has also provided a pathway for use of advanced technologies in NSPS OOOOb and EG OOOOc. See Volume II, Chapter 5, and discussion in section X.B of the preamble to the final rule for information on advanced technologies.

#### 22.1.2.5 General Dissent

Comment: Commenters (0607-AENV, 0718-Tora Consulting, LLC (Tora), 0749-PAW, 0777-Ascent, 0793-PBPA, 0794-MHAN, 0816-Montrose) asserted that the onerous and overly prescriptive requirements proposed in the November 2021 Proposal of Appendix K may negate efficiencies gained from the use of OGI cameras (over other fugitive survey methods such as EPA Method 21) and would not always improve emissions reduction efficacy. Commenters (0749-PAW, 0938-TXOGA) contend that the regulatory constraints applied through Appendix K will significantly reduce, if not eliminate altogether, any advantages in efficiency or accuracy that OGI monitoring may provide over EPA Method 21. Another commenter (0911-NDPC) supported creating a protocol for OGI camera use and only referencing the protocol in the rule text but noted that there is little in Appendix K that they agree is appropriate.

Commenters (0749-PAW, 1291-INGAA) stated that the proposed requirements in Appendix K do not add any environmental benefits and are inordinately excessive and impractical and would preclude or severely hinder the ability of operators to conduct OGI leak surveys. Commenters (0607-AENV, 0718-Tora, 0938-TXOGA) noted that there would be a significant administrative burden to camera operators added by Appendix K that would result in activities which are not directly applied to leak identification and take time away from actual monitoring activity. The commenters stated that Appendix K negates the fundamental benefit of an OGI-LDAR program; specifically, the ability to safely and efficiently detect large leaks, which account for a majority of fugitive emissions (on a mass basis) at a facility. They asserted that excessive time spent on administrative activities does not support emissions reduction.

Commenters (0607-AENV, 0718-Tora) suggested that EPA should be improving the flexibility of OGI monitoring; for example, removing the annual EPA Method 21 requirement from the alternative work practice (AWP) in the part 60 General Provisions. Instead, the commenters stated that EPA is proposing to implement OGI monitoring, training, and auditing requirements that would make implementation nearly impossible. The commenters further stated that industry has adapted to the OGI provisions in 40 CFR 60.18 and 60.5397a. They suggested that any new method should be limited to those procedures which are already used in practice. The commenters added that Appendix K, as proposed in the November 2021 Proposal, would serve to discourage, not support, the use of OGI as a leak detection method.

According to the commenters (0607-AENV, 0718-Tora, 1291-INGAA), in no case should an OGI method be more stringent or burdensome than EPA Method 21, which has never contained the type of overreaching training, auditing, and monitoring requirements as are found in the proposed version of Appendix K, which could preclude or severely hinder the ability of operators to conduct OGI leak surveys. One commenter (1291-INGAA) stated that, as written, the Appendix K requirements will result in far less use of OGI technology for leak surveys, with operators being forced to opt for EPA Method 21 surveys instead. The commenter noted examples of issues with Appendix K related to training and operator certification hours, training cost (exceeding \$200,000), availability of experts and lack of qualification for existing staff, increase of survey time (by four-fold), and extensive recordkeeping, confusion regarding ownership of equipment requirements, inconsistencies in detection limits, rest break requirements, and weather data requirements.

One commenter (0820-Pioneer) questioned the reason for the extensive changes included in the Appendix K protocol. The commenter contended that the added burden, paperwork, and more stringent timelines are a product of EPA's skepticism and implication that operators are acting in bad faith. The commenter further stated that with the doubling of the survey frequency, they will need more thermographers. At the same time, the commenter contended, Appendix K imposes an additional burden on the thermographers time. Training, QA/QC, auditing, dwell time requirements, lengthy voluminous video clips, and recordkeeping requirements are unnecessary, unreasonably burdensome, and technologically infeasible. The combined requirements reduce the hours a camera operator can spend monitoring.

Another commenter (0817-GPA) expressed that Appendix K would impose a significant burden on the current use of OGI at compressor stations, due to its rigor. The commenter claimed that EPA provides no explanation as to why the current OGI practices require “such a significant overhaul.” The commenter considered the following to be “unwarranted burdens”: (1) the development of the operating envelope, (2) the requirement to take breaks to avoid fatigue at such a relatively small facilities, (3) the rigorous OGI camera operator training, and (4) the daily and quarterly audits. The commenter stated that these burdens eliminate much of the advantage that OGI provided over EPA Method 21. The commenter urged that EPA must definitively account for the additional costs and time that would now be required.

Response I-22-11: EPA made substantial edits to Appendix K in response to comments in the December 2022 Supplemental Proposal. See discussion in section VI of the December 2022 Supplemental Proposal for information related to the changes made to Appendix K.<sup>9</sup>

Additionally, in response to the comments received on the November 2021 Proposal, EPA proposed a different regulatory approach for fugitive emissions from well sites, centralized production facilities, and compressor stations in the December 2022 Supplemental Proposal. For details, please see discussion in section IV.A.1.a.ii and IV.A.2.A of the December 2022 Supplemental Proposal related to fugitive emissions from well sites, centralized production facilities, and compressor stations.<sup>10</sup>

See responses to specific comments raised on Appendix K throughout the rest of this chapter.

## **22.2 Scope and Applicability of Appendix K**

Comment: Some commenters (0604-Providence Photonics, LLC (Providence), 0748-AFPM, 0808-API, 0831-AXPC) urged that Appendix K should not be limited to the oil and gas sectors. Commenters (0604-Providence, 0748-AFPM, 0808-API, 0831-AXPC) stated that the protocol is technically applicable to other industries, such as organic chemical manufacturing plants and ethylene production units. Commenters (0604-Providence, 0748-AFPM, 0808-API) urged that a narrow applicability to the oil and gas sector would not serve any purpose, but would limit the beneficial applications of Appendix K. One commenter (0808-API) stated that because the proposed Appendix K clearly identifies in sections 6.1.1 and 6.1.2 that it applies where a particular OGI camera is sensitive enough to find leaks and rulemaking or Administrator approval would be needed to allow use of OGI for a process not covered by the current rulemaking, it would be counterproductive to limit Appendix K only to oil and gas source

---

<sup>9</sup> 87 FR 74837-74842 (December 6, 2022).

<sup>10</sup> 87 FR 74722-74736 and 74739 (December 6, 2022).

categories. Commenters (0604-Providence, 0808-API, 0831-AXPC) recommended that EPA remove the explicit exclusion for “chemical plants or other facility types outside of the oil and gas upstream and downstream sectors.”

Response I-22-12: EPA made substantial edits to Appendix K and the applicability of Appendix K in response to comments in the December 2022 Supplemental Proposal. See discussion in section VI.B.1. of the December 2022 Supplemental Proposal related to the scope of Appendix K.<sup>11</sup>

Comment: A commenter (0604-Providence) remarked that if there are specific provisions in Appendix K that are meant to apply specifically to the oil and gas sectors, the specificity should be clarified, and the technical criteria or specifications should be added to allow for broad applications. Another commenter (0750-Flogistix) critiqued that Appendix K already appears to be written for broader application than the oil and gas source category and suggested that future amendments to Appendix K intended for other sectors may have unintended consequences on upstream oil and gas sources. Yet another commenter (0911-NDPC) also encouraged EPA to work with OGI equipment manufacturers to develop section 1.0 of Appendix K to clarify the scope.

Response I-22-13: EPA acknowledges that Appendix K is written for broad applicability, as discussed in the November 2021 Proposal.<sup>12</sup> EPA also acknowledges that future changes to Appendix K will affect any sector that is required to use Appendix K, similar to how changes within test methods affect different sectors that are required to use those methods. Any future change to Appendix K will be subject to notice and comment rulemaking prior to implementing the change.

In response to comments received on the November 2021 Proposal, EPA updated the scope and applicability of Appendix K. For details, please see discussion in section VI.B.1. of the December 2022 Supplemental Proposal.<sup>13</sup>

Comment: Some commenters (0782-BHE, 0808-API) expressed that publishing an NSPS-specific OGI protocol would likely introduce a number of limitations or complications regarding applicability for other sectors or may preclude opportunities to supplant other EPA Method 21 applications. One commenter (0808-API) urged that EPA should also be specific in the referencing subpart as to the process chemistry that must be present to use OGI and Appendix K, or through the permit or Administrator review where it is requested, to be used for sources not covered by a referencing subpart. The commenter reiterated that the purpose of part 60 appendices is to provide generic methodologies that do not have to be amended each time they are referenced. Other commenters (0782-BHE, 1458-Innovative Environmental Solutions, Incorporated (IES)) specifically requested that OGI be broadly applicable and not tied to development of a specific NSPS; these commenters supported the development of an Air Emission Measurement Center stand-alone test method under 40 CFR part 60, Appendix A instead.

---

<sup>11</sup> See 87 FR 74837 (December 6, 2022).

<sup>12</sup> See 86 FR 63172 (November 15, 2021).

<sup>13</sup> See 87 FR 74837 (December 6, 2022).

Response I-22-14: The proposed Appendix K was not intended to apply to one specific NSPS. As noted in the November 2021 Proposal, Appendix K is written for broad applicability.<sup>14</sup> It is not uncommon for test methods to also be published with a specific rulemaking, even though they may be used in other sectors in the future. For example, EPA Method 325A/B was originally published in the Refinery MACT RTR rulemaking, but this method was also proposed for use in chemical sector rules.<sup>15</sup> Appendix K is being treated in the same manner, in that it is being finalized in the first sector that is using it but may be applied to other sectors in future rulemakings.

However, that EPA may at some point in the future reference Appendix K in other subparts does not mean that Appendix K is immediately available to supplant EPA Method 21 applications in other subparts. Appendix K does not apply to any other sectors until it is referenced by a subpart through rulemaking that considers the cost of implementation and whether the incorporation of Appendix K, with or without supplemental requirements or leak detection alternatives, achieves the applicable standard for a specific industry sector. EPA does not anticipate that it will be necessary to update Appendix K each time that it is referenced in a new subpart but may do so if new information indicates that an update is necessary.

Comment: Some commenters (0750-Flogistix, 0756-Baker Hughes, 0954-FLIR) remarked that the use of the OGI camera is limited to hand-held surveys. One commenter (0756-Baker Hughes) supported the alternative fugitive emissions monitoring program with the caveat that EPA should revise Appendix K to modify the OGI equipment definition beyond hand-held applications and to include other platforms, such as drone-based OGI. Another commenter (0954-FLIR) requested clarity on what means of OGI technology outside of hand-held, if any, are applicable, and recommend non-handheld uses of the technology be separated from Appendix K.

Response I-22-15: EPA removed the terminology “hand-held” from Appendix K in response to comments in the December 2022 Supplemental Proposal. We recognize that it is potentially possible to follow the requirements outlined in Appendix K while using an OGI camera mounted on a drone, and we did not intend to limit technology development. The use of OGI in other configurations would be dependent on the ability of the camera operator to follow the requirements outlined in Appendix K. For example, it is unlikely that a fixed-mount camera would be able to view components from multiple angles or that the operator of such a camera would be able to always adjust the view to account for interferences. Our intent was not to cover these types of applications in Appendix K at this time.

Comment: One commenter (0808-API) stated that the applicability of Appendix K belongs in a referencing subpart, not in the protocol (section 1.3). The commenter also stated that the applicability does not reflect that the protocol addresses equipment leaks. The commenter recommended that section 1.3 be revised to “This protocol is applicable to equipment leak components at facilities when referenced by an applicable subpart.”

Response I-22-16: EPA made substantial edits to Appendix K and the applicability of Appendix K in response to comments in the December 2022 Supplemental Proposal. See discussion in

---

<sup>14</sup> See 86 FR 63172 (November 15, 2021).

<sup>15</sup> See 80 FR 75178 for the Refinery MACT RTR rulemaking. The use of Method 325A/B was proposed in technology reviews of the Hazardous Organic NESHA and Polymers and Resins I. See 88 FR 25080.

section VI.B.1. of the December 2022 Supplemental Proposal related to the applicability of Appendix K.<sup>16</sup>

## **22.3 Definitions and Terminology**

### ***22.3.1 Appendix K's Title***

Comment: Two commenters (0607-AENV, 0718-Tora) urged EPA to replace the term “Determination” in the title of Appendix K to “Identification” or “Detection”, asserting that the purpose of the protocol is to detect or identify leaks, not determine leaks.

Response I-22-17: EPA disagrees with the commenter. The purpose of Appendix K is to determine that a leak exists, which we recognize is the same as identifying and detecting leaks. We chose to use the word determination because it is the same word used in the title of EPA Method 21, which is similar in purpose to Appendix K.

### ***22.3.2 Regulated Components***

Comment: One commenter (0808-API) recommended that the term “regulated components” in Appendix K be changed to “equipment leak components regulated by the referencing subpart or permit.” The commenter (0808-API) stated that there are components regulated under other rules (e.g., a chemical process unit located within a refinery) or by non-equipment leak portions of the referencing rule or permit (e.g., process vents) that might be within an OGI camera’s operating envelope.

Response I-22-18: EPA agrees with the commenter. We have changed terminology from “regulated components” to “components regulated by the referencing subpart.”

### ***22.3.3 Fugitive Emission or Leak Definition***

Comment: One commenter (0808-API) questioned the definition of “fugitive emission or leak”, proposed as “any emissions observed using OGI.” The commenter stressed that the definition can only address emissions from equipment components identified in the referencing subpart or permit as being subject to OGI monitoring, as these are the only emission sources that were considered in the referencing subpart rulemaking or permitting process and are the only components that the referencing subpart or permit monitoring and repair provisions address. The commenter recommended the following definition: “Fugitive emission or leak means any emissions observed using optical gas imaging from any equipment component identified in the referencing subpart or permit as being subject to monitoring using this Appendix (Appendix K).”

Response I-22-19: EPA has updated the definition of fugitive emission or leak to mean “any emissions observed using OGI from components regulated by the referencing subpart.”

### ***22.3.4 Response Factor Definition***

Comment: Numerous commenters had questions related to the definition of response factor in section 3.0 of Appendix K. One commenter (0561-TRICORD Consulting, LLC (TRICORD))

---

<sup>16</sup> See 87 FR 74837 (December 6, 2022).

asked for clarity on the meaning of 10,000 parts per million-meter (ppm-m) basis. The commenter (0561-TRICORD) further stated that it appears that response factor determinations in the references are from a laboratory setting and recommended a combined EPA/industry group funded study to develop response factors for OGI. Another commenter (0782-BHE) noted that the current definition omits that the reference compound is propane and also ignores the fact that an optical path length-concentration measurement in ppm-m is typically associated with gas cell measurements specific to temperature differential and other optical window variables. The commenter requested the elimination of the performance measure requirement to estimate a ppm-m performance using ideal laboratory test conditions because it may result in uncertainty and the need for gas cell measurements to achieve this proposed performance specification has not been adequately established. The commenter provided an alternative: EPA should specify a signal to noise (S/N) ratio for a camera for a certain gas at a certain concentration under given radiant conditions. This analysis would be completed by the original equipment manufacturer (OEM) and specified in section 6.0 of Appendix K. The commenter provided an example specification: the camera shall produce a S/N ratio of 1 or greater when viewing a pure gas mixed homogeneously in nitrogen at atmospheric pressure while viewing a highly emissive, >96%, blackbody at 27°C when under laboratory conditions whose average ambient temperature is 22°C. Both the temperature difference ( $\Delta T$ ) and the absolute temperature are necessary to make this determination.

Response I-22-20: EPA revised the definition of response factor in the December 2022 Supplemental Proposal and added Annex 1 to Appendix K that details a procedure for determining the response factors for OGI Cameras. EPA notes that response factors vary between camera models, and as such, one study would not be enough to determine response factors for all current and future OGI camera models.

The commenter is correct that an S/N metric could be a potential measure of camera performance. However, with a midwave infrared (MWIR) cooled camera, it is anticipated that an extremely large S/N is required, and EPA does not currently have enough empirical data on what S/N range of the detector radiance output would be appropriate. As such we cannot integrate this approach at this time. If EPA conducts additional testing or receives additional information on this type of approach, such an approach could be incorporated into Appendix K in a future rulemaking.

Comment: One commenter (0719-Opgal Optronic Industries, Ltd. (Opgal)) stated that the current response factor definition proves that the response factor is a function (not a factor, Zeng et al., 2017) of concentration length and response sensitivity of a reference gas (i.e., propane in this protocol). The commenter stated that response factor criteria is manufacturer specific and therefore should not appear in this protocol. Another commenter (0604-Providence) agreed that the response factor is specific to a given OGI camera model and can vary between different camera models. The commenter recommended explicitly stating this in the definition to avoid improper use of response factors by operators who may not be aware that response factors are specific to OGI camera models.

Response I-22-21: The definition of response factor was modified in response to comments. Specifically, EPA has indicated that response factors are camera model specific. See discussion

in section VI.B.5 of the December 2022 Supplemental Proposal for more information related to response factors.<sup>17</sup>

Comment: Two commenters (0808-API, 0831-AXPC) raised issues with the second line of the response factor definition, which limits the response factors to those obtained from peer reviewed articles or developed according to procedures approved by the Administrator. The commenters explained the two main issues with this limitation as follows:

- The first issue is that there may be different response factors for different OGI cameras as technology changes and new response factors will be needed as additional applications of OGI are made. Such commercial information is not amenable to publication in peer reviewed articles, nor could such response factors be published in a timely manner. Thus, if anything is to be peer reviewed it must be the methodology used to develop the response factors. Given the specifics in the first sentence (a path-length of 10,000 ppm-m) and the specification in section 6.1.1 of propane as the reference compound, it seems unnecessary to require any review of the response factors themselves.
- Secondly, hundreds of response factors have been developed by camera manufacturers for current cameras. One commenter (0808-API) expressed concerns that those response factors, which are currently in widespread use, might not meet the criteria in the proposed definition. While these factors may have been peer reviewed, they were not necessarily “obtained from peer reviewed articles.” The commenter further pointed to the uncertainty involved in the procedures the Administrator might require and whether currently used factors will be found to be consistent with that yet undefined procedure.

The commenters believed that the criteria in the first sentence of the proposed definition and in section 6.1.1 of the proposed Appendix K are adequate to assure valid response factors and recommended deleting the second sentence of the definition. The commenters further recommended that if the Agency believes the response factor limitation is needed, it should focus the limitation on the methodology for developing response factors, propose the methodology they plan to require when the final Appendix K language is proposed, provide for automatic approval after 90 days of any response factor or response factor methodology submitted to the Administrator if no action is taken within that time, and grandfather response factors developed prior to the proposal of the Administrator’s methodology

Response I-22-22: In response to comments on the November 2021 proposed rule, as part of the December 2022 Supplement Proposal, EPA developed Annex 1 to Appendix K, which is a methodology for the development of response factors for OGI cameras. See discussion in section VI.B.5 of the December 2022 Supplemental Proposal for more information related to response factors.<sup>18</sup>

<sup>18</sup> 87 FR 74839 (December 6, 2022).

### ***22.3.5 Senior OGI Camera Operator Definition***

Comment: Several commenters raised concerns over various aspects of the definition of a senior OGI camera operator. One commenter (0561-TRICORD) considered the requirement for a senior OGI camera operator to have surveyed 500 sites to be unrealistic and burdensome. Other commenters (0607-AENV, 0718-Tora) agreed with this perspective and considered the site requirement to be arbitrary. Similarly, another commenter (0954-FLIR) argued that there are numerous severe challenges with the current definition of a senior OGI camera operator. Yet another commenter (0782-BHE) provided further agreement with this perspective and noted that the basis for requiring a senior OGI camera operator to complete a minimum of 500 site surveys is not supported or substantiated and is excessive. The commenter further argued that this criterion focuses less on demonstratable experience of an OGI camera operator and focuses more on the estimated number of surveys completed. Commenters (0814-IPAA, 0945/1373-JOFA) stated that EPA “needs to define a senior level operator more explicitly including qualifications and exemptions.”

A commenter (0916-Alaska Oil and Gas Association (AOGA)) focused on the “minimum of 500 sites, and 20 sites in the past 12 months” aspect of the senior OGI camera operator definition and stated that there are no camera operators in the state of Alaska who would meet this qualification threshold. Another commenter (1391-INGAA) concurred that the current definition results in very few people being qualified for this designation; including personnel that have consistently conducted quarterly LDAR surveys for three years. Another commenter (0750-Flogistix) finds the senior OGI camera operator definition to be restrictive, while a different commenter (0911-NDPC) argued that the definition does not consider the years of experience of a camera operator and their understanding of equipment or processes. One commenter (0817-GPA) believed that there is no justification for the 500-survey requirement and considered it to be excessive, especially for midstream operations. The commenter further justified that for midstream facility operators, which operate far fewer facilities that are frequently far apart from each other, it would likely take many years for in-house personnel to qualify as a senior OGI camera operator. This effectively prohibits the use of company personnel to conduct surveys for the foreseeable future, imposing a significant additional cost without a demonstrated benefit. Another commenter (0743-WEA) agreed with the perspective presented by the commenters above and stated that the requirement to complete 500 site surveys and 20 within the past year would be a very difficult standard to meet for operators. The commenter further stated that many operators do not have 500 sites to be surveyed within their organization.

Two commenters (0607-AENV, 0718-Tora) stated that qualification as a senior OGI camera operator could be based on multiple indices of experience (hours of OGI camera operation, number of OGI surveys, number of sites surveyed, etc.) not just the number of sites that the operator has surveyed. The commenters further argued that EPA should not dictate the minimum number of sites, hours, or surveys necessary to be a senior OGI camera operator but allow the operators to have discretion to qualify personnel as senior OGI camera operators. Another commenter (0954-FLIR) recommended that the qualification for a senior OGI camera operator be changed from number of sites to either the number of hours spent conducting OGI surveys, the number of surveys, or the number of components inspected. A third commenter (0782-BHE) agreed with the recommendation of changing the site survey criteria to hours of OGI operation and further recommended 500 operating hours as a reasonable requirement for skilled OGI

operators. A fourth commenter (0816-Montrose) agreed with the recommendation of changing number of surveys to hours of operation and further commented that their research indicates that 160 hours of training is sufficient as a requirement to be classified as a skilled OGI operator. Another commenter (0911-NDPC) provided further agreement to the requirement change from surveys to hours and recommended that the minimum level be changed to 40 hours of OGI operation per year including a minimum of 24 hours of in-field training.

One commenter (0561-TRICORD) suggested the following modified definition for a senior OGI camera operator *“A Senior OGI Operator is a camera operator with more than two years’ experience operating an OGI camera or an operator with more than one year experience who has also completed, developed or provided classroom camera operator training”*. A different commenter (0808-API) proposed a different revised definition for a senior OGI camera operator: *“A senior OGI camera operator is an OGI camera operator who has performed at least 100 hours of OGI monitoring (excluding their own initial and refresher training time) in the previous 12-months and has either 1) successfully completed the initial and field training specified in Section 10 of this Appendix and has completed any required refresher training or 2) is a certified thermographer. Previous 12-months means the 365-calender days prior to the day of the activity requiring a senior OGI camera operator.”*

The commenter (0808-API) further explained that the removal of career experience requirements is critical since they believe that this does not significantly add to the operator’s ability to train or audit other operators. The commenter believes that recent experience with current equipment and requirements at locations of the type currently being monitored is more critical to training and auditing others and hence recommends the 12-month criterion in the senior operator definition. The commenter goes on to provide an extensive description of how career experience is not of great importance by pointing to the results of operator experience testing reported in the Appendix K Technical Support Document (TSD). Another commenter (0831-AXPC) agreed with this commenter and suggested using 20 hours of recent monitoring as a requirement instead of number of sites. The commenter also agreed on the 12-month monitoring criterion recommendation.

One commenter (0817-GPA) suggested changing the senior operator experience requirement to 200 regulatory surveys rather than the currently stated 500 surveys. The commenter also recommended considering annual training as substitute for a certain number of surveys, referencing the EPA Method 9 smoke school methodology. Another commenter (0743-WEA) suggested that EPA require a senior operator be a certified thermographer, and field training for OGI camera operators consist of an hours-based training requirement. The commenter further recommended that as an alternative to Appendix K as currently drafted, EPA should require that operators establish a training and verification program but allow flexibility for operators to determine the requirements of that program based on the complexity and scope of their operations.

Response I-22-23: In response to comments on the November 2021 Proposal, the definition of Senior OGI camera operator was modified. See discussion in section VI.B.3 of the December 2022 Supplemental Proposal for more information.<sup>19</sup>

---

<sup>19</sup> See 87 FR 74838-47839 (December 6, 2022).

Comment: Numerous commenters sought clarification on the use of “Site/Sites” in the definition of a senior OGI camera operator. One commenter (0561-TRICORD) questioned whether a refinery or a single process unit would be considered as one site and stated that 500 sites would only be attainable at upstream facilities. Another commenter (0743-WEA) provided a similar argument, questioning whether a wellhead-only site survey would be equivalent to a large refinery. Other commenters (0607-AENV, 0718-Tora) agreed with this point of view and stated that since the term “site” is not defined and with no other qualification criteria included, Appendix K currently considers the experience gained from monitoring a single well site equivalent to the experience gained from monitoring a refinery. A different commenter (0719-Opgal) questioned whether 500 days at a site is only considered as one site. Yet another commenter (0954-FLIR) argued that the current definition of “site” is very ambiguous especially since the applicability is implied for both upstream and downstream sectors which vary greatly, both from each other and within each other. The commenter further stated that there are several OGI camera users with over 15 years of experience, but just at one site, which would not fulfill the 500-site requirement.

Other commenters (0816-Montrose, 0831-AXPC) noted that a site-based qualification standard is arbitrary since sites vary significantly by size, complexity and number of components. Commenters (0808-API, 0831-AXPC) found “site” to be a very imprecise term for the senior OGI camera operator definition. One commenter (0599-Marcellus Shale Coalition (MSC)) stated that it appears that the intent is for 500 different surveys, as stated at EPA's Optical Gas Imaging Stakeholder Workshop, November 9-10, 2020. The commenter suggested rewording the definition to agree with the findings of that presentation such that all references to sites be changed to survey.

Response I-22-24: In response to comments on the November 2021 Proposal, EPA removed the requirements for number of sites surveyed in the definition of Senior OGI camera operator. See discussion in section VI.B.3 of the December 2022 Supplemental Proposal for more information.<sup>20</sup>

Comment: One commenter (1425-Eclipse Environmental Services, LLC) questioned whether they needed to submit evidence of 500 inspections and 20 in the last 12 months to a point of contact in EPA.

Response I-22-25: In order to become a senior OGI camera operator, the operator does not need to submit a certification to EPA. The operator must maintain records demonstrating compliance with the experience and training requirements outlined in Appendix K. These documents must be made available for review upon request.

### ***22.3.6 Ambient Air Temperature Definition***

Comment: A commenter (0954-FLIR) recommended modifying the definition of ambient air temperature in section 3.0 of Appendix K to be more specific about the location. The commenter recommended that the current definition be modified to “the air temperature in the general

---

<sup>20</sup> See 87 FR 74838-47839 (December 6, 2022).

location where the leak is located by the OGI survey,” as there could be varying ambient air conditions at the site location.

Response I-22-26: EPA has updated the definition of ambient air temperature in section 3.0 of Appendix K to mean “the air temperature in the general location of the component being surveyed.”

#### ***22.3.7 Delta Temperature (delta-T) Definition***

Comment: A commenter (0561-TRICORD) contended that the assumption that emitted process gas temperature is equal to ambient air temperature as outlined in the definition of delta temperature in section 3.0 of Appendix K is not correct. The commenter noted that for an emitted gas to be detected by an OGI camera, a difference in temperature must exist between the emitted gas temperature and the background temperature.

Response I-22-27: The OGI process is influenced by three different temperatures: the temperature of the emission process gas, the temperature of the background, and the temperature of ambient air. The commenter is correct in stating that a delta-T must exist between the emission process gas temperature and the background temperature in order for the emissions to be detected by an OGI camera. However, the statement in section 3.0 of Appendix K is also correct since the practice of assuming the process gas temperature is equal to ambient air temperature (not background temperature) is an acceptable practice, as the temperature of the process gas when it is released will quickly equilibrate to the surrounding ambient air temperature.

#### ***22.3.8 Repair Definition***

Comment: Three commenters (0561-TRICORD, 0808-API, 0831-AXPC) recommended tweaks to the definition of repair or for the definition to be removed from Appendix K entirely because it will be addressed in the referencing subpart. One commenter (0808-API) further noted that while Appendix K appropriately requires identification of leaking components, it does not address repair.

Response I-22-28: EPA agrees that the definition of repair will be addressed in referencing subparts. We have removed the definition from Appendix K.

#### ***22.3.9 Survey Terminology***

Comment: A commenter (0463-Southern Ute Indian Tribe, Colorado (Southern Ute)) stated that throughout the proposed protocol EPA uses the term "survey" without defining exactly what constitutes a survey. The commenter stated that it's often unclear whether the term refers to the process of surveying an entire site or whether the survey of each distinct affected facility is itself considered one complete survey. The commenter further noted that the consequences of this definition are great because it affects the training requirements of section 10.0, which could be incredibly onerous or adequate depending on what a survey is. The commenter requested EPA define "survey" to provide clarity.

Response I-22-29: In response to comments on the November 2021 proposal, EPA updated the terminology used in Appendix K, including in the training requirements in section 10.0. EPA has updated the training criteria to be based on hours of surveying instead of numbers of surveys. EPA has maintained the terminology of survey as appropriate to refer to the process of using an OGI camera to determine if there are leaks. See discussion in section VI.B.2 of the December 2022 Supplemental Proposal for more information.<sup>21</sup>

## **22.4 OGI Camera Specifications**

### ***22.4.1 Manufacturer Certification***

Comment: Several commenters (0599-MSD, 0782-BHE, 0808-API, 0814-IPAA, 1391-INGAA, 1458-IES) requested clarification that the OEM is (or can be) responsible for designing equipment to the section 6.0 performance standards prior to sale of the equipment. Some commenters (0599-MSD, 0954-FLIR) noted that under NSPS OOOOa, the major camera manufacturers have published documents indicating compliance with the "initial verification" requirements of the rule following third-party testing.

One commenter (0782-BHE) noted that equipment operators should be responsible for daily instrument checks to verify operation according to the OEM specifications, while another commenter (1391-INGAA) requested that the obligations for OEM and ongoing operator requirements be clarified. One commenter (0782-BHE) suggested that most section 6.0 requirements can be satisfied under field conditions by a third-party study. The commenter recommended that the required series of operator performance testing is avoidable if the OEM performs testing and provides documentation of acceptable test results.

Response I-22-30: Regarding responsibilities for demonstrating compliance with the performance specifications outlined in section 6.0 of Appendix K, EPA has clarified that the initial testing to demonstrate compliance with the specifications can be performed by the owner or operator, the camera manufacturer, or a third party. See discussion in section VI.B.5 of the December 2022 Supplemental Proposal.<sup>22</sup>

Comment: A commenter (0814-IPAA) stressed that small businesses do not have access to advanced laboratories and/or the funding necessary to purchase, construct, operate, or maintain the proposed initial performance verification as required in section 6.1.2.

Response I-22-31: Regarding responsibilities for demonstrating compliance with the performance specifications outlined in Section 6.0 of Appendix K, EPA has clarified that the initial testing to demonstrate compliance with the specifications can be performed by the owner or operator, the camera manufacturer, or a third party. See discussion in section VI.B.5 of the December 2022 Supplemental Proposal.<sup>23</sup>

---

<sup>21</sup> See 87 FR 74837-47838 (December 6, 2022).

<sup>22</sup> See 87 FR 74839 (December 6, 2022).

<sup>23</sup> See 87 FR 74839 (December 6, 2022).

## ***22.4.2 Camera Configurations for Initial Certification***

Comment: A commenter (0808-API) stated that requiring the testing in section 6.2 for each individual camera is unnecessary since all cameras within a particular model are the same. The commenter stated that some camera configuration changes, as exemplified in the definition of camera configuration, can impact detectability (e.g., changes to sensitivity setting or camera lens) while others will not (e.g., whether camera is hand-held or mounted on a tripod) and the detection limit demonstration is only needed for each configuration that could impact the detection limit.

Response I-22-32: EPA agrees with the commenter that a particular camera model only needs to be tested once, and that each individual camera does not need to be tested. We have updated section 6.1 to indicate that each camera model must meet the specifications in section 6 and added section 8.3.1 to clarify that operating envelopes are specific to a camera model. EPA has further clarified in section 6.1 that the initial specification testing must be performed for each camera operating mode (e.g., standard versus high sensitivity or enhanced). In section 8.3.2 we have clarified that operating envelopes need to be developed for all potential configurations that could affect the detection limit.

## ***22.4.3 Detection Limits***

### ***22.4.3.1 Detection Limit Different from Previous Detection Limits***

Comment: Commenters (0808-API, 1391-INGAA) alleged that there are inconsistencies regarding detection limits. Two commenters (0607-AENV, 0718-Tora) pointed out that EPA previously established that bimonthly surveys, using a minimum detection sensitivity level of 60 grams per hour (g/hr), are equivalent to an EPA Method 21 based LDAR program at a leak definition of 500 ppmv.<sup>24</sup> Additionally, the commenters (0607-AENV, 0718-Tora, 0808-API) argued there is no reason for changing the minimum detection limit demonstration (and possibly having to replace some cameras), requiring new operating envelope determinations, and potentially requiring changing procedures and permits that already use the NSPS OOOOa requirements. One commenter (0808-API) suggested that the minimum detection limit requirement from §60.5397a(c)(7)(i)(B) be allowed as an alternative to the proposed section 6.1.2 minimum detection limit and that the operating envelope determination procedure in section 8.5 be revised accordingly. Similarly, another commenter (0782-BHE) contended the AWP Monte Carlo assessment determined that 60 g/hr was an adequate detection level for methane, but EPA has reduced this to 17 g/hr. This change appears to be based on Monte Carlo simulations and Colorado State University (CSU) testing; EPA has not rationalized the need for this level of detection even if the camera can achieve these lower detection levels.

Response I-22-33: EPA disagrees with the commenters. EPA acknowledges that the commenters are correct about the minimum detection sensitivity in the final rule for the Alternative Work Practice to Detect Leaks from Equipment.<sup>25</sup> Because OGI cameras do not measure in ppmv and the ability to observe leaks is greatly influenced by factors such as wind, thermal background, and distance, it can be difficult to determine the ppmv threshold that an OGI camera will be able

---

<sup>24</sup> This is the equivalence in the AWP of the General Provisions of part 60.

<sup>25</sup> 73 FR 78199 (December 22, 2008).

to see. EPA has continued to study OGI cameras since the time that the AWP was finalized, as reflected in the TSD for Appendix K, and the detection thresholds specified in Appendix K represent our best understanding of the capabilities of current MWIR OGI cameras.

EPA notes that it has made no changes to the OGI requirements in NSPS OOOOa, and as such, there should be no need to change procedures and permits for those sites. Additionally, based on testing conducted by EPA as part of the development of the Appendix K TSD, we expect that cameras that meet the threshold in NSPS OOOOa will also meet the requirements outlined in Appendix K.

#### 22.4.3.2 Detection Limit Compounds

Comment: Two commenters (0607-AENV, 0718-Tora) indicated that the inclusion of chemical-specific sensitivity thresholds limits the pool of acceptable OGI cameras. Another commenter (0782-BHE) declared that establishing a lower detection limit for methane than for butane is not justified by the MWIR absorption spectra or laboratory/field test data demonstrations. The first commenters (0607-AENV, 0718-Tora) encouraged EPA to provide additional data, discussion, and justification to support a significant change.

Response I-22-34: See discussion in section XIV.B.2 of the preamble to the final rule which details EPA's final standards related to OGI camera detection limits. More information on detection limits can also be found in the final TSD for Appendix K.

EPA notes that it has only included sensitivity thresholds for methane and either propane or butane. This is to ensure that OGI cameras used with Appendix K will be able to image leaks of both methane and VOCs. EPA also notes that sector-specific performance requirements can be considered on a regulation specific basis when EPA revises a subpart to reference Appendix K. Such sector-specific performance requirements would be defined in the referencing subpart and not in Appendix K.

Comment: Two commenters (0607-AENV, 0718-Tora) pointed out that for certain process streams with very low hydrocarbon content, the calculated mass flow rate may be too low to effectively utilize a hydrocarbon OGI camera. For example, some streams associated with an amine unit at a natural gas processing plant are very low in hydrocarbon content but relatively high in carbon dioxide content. For such streams, the use of an OGI camera capable of visualizing carbon dioxide (e.g., FLIR GF343) may be appropriate.

Response I-22-35: Appendix K was developed for determining leaks of VOCs and methane, and as such, the detection thresholds in Appendix K are specific to that effort. The spectral range of the filter of the FLIR GF343 is not appropriate for monitoring methane and a broad range of VOCs. While we acknowledge that this OGI camera may be a useful tool for monitoring carbon dioxide emissions, it falls outside the scope of Appendix K.

If an owner or operator has streams that cannot be monitored with an OGI camera meeting the requirements of Appendix K, the owner or operator may use EPA Method 21 or apply for alternative monitoring under §60.13(i).

Comment: One commenter (0954-FLIR) argued that while propane gas is referenced as a gas to be used for the daily verification test, it was not established as a gas to be imaged by OGI technology in any other sections of Appendix K. The commenter further noted that understanding that a camera developed around response factors will be able to image propane if it can detect methane, the inclusion of propane in this section supports the argument that a camera's detection capabilities and operating envelope requirements should be based only on the lower response factor gas. The commenter asked for clarification on the reasoning behind including propane and if including propane as a test gas will allow for testing of the "lowest response factor gas" in the operator envelope testing of the technology.

One commenter (0599-MS) questioned why EPA selected butane instead of propane for evaluation of performance, as propane will be the predominant constituent in natural gas compared to butane.

Two commenters (0782-BHE, 0954-FLIR) noted that in section 1.1 (Analytes), two gases are mentioned specifically, methane and ethane, along with general VOCs, while in various places within Appendix K, other gases are mentioned specifically including butane and propane in sections 6.1.1, 6.1.2, 6.2.2, 8.5.5, and 9.1.3. The commenters recommended adding these gases to the analyte list for clarity. One of the commenters (0782-BHE) noted that if the camera specification requires a minimum detection level of 18.5 g/hr yet butane is omitted as an analyte, this would indicate uncertainty and confusion regarding method development. The commenter further argued that Table 4-11 in the Appendix K TSD and Appendix K itself as written is misleading regarding compound applicability. The commenter referenced the December 14, 2021, Proposed Appendix K Webinar which expanded the analyte applicability to include hazardous air pollutants, which are not contained in Appendix K. The commenter also recommended removing ethane as an analyte, arguing that ethane had been specifically excluded from the definition of VOCs, has limited activity as a greenhouse gas, is much less abundant than methane, has a lifetime of only a few months, and is less efficient at absorbing radiation relative to mass.

The commenter (0782-BHE) argued that this supported the premise that an OGI protocol method should apply to all compounds having suitable absorbance in the MWIR spectrum and be performance based with criteria depending on the regulatory context.

Response I-22-36: EPA disagrees with the commenters. Appendix K is suitable for measuring a broad range of compounds with peaks in the MWIR spectrum. Propane is used as the reference gas in developing response factors. Propane is also a gas that can be visualized by OGI cameras with Appendix K because the response factor of propane, 1, would meet the criterion in section 6 of Appendix K. Additionally, methane and ethane are called out specifically in the analyte section because they are not VOC. EPA has not listed out individual VOC and has instead listed VOC generically, but the analytes covered by the term VOC include propane, butane, and other volatile organic compounds, including those hazardous air pollutants that are VOC. EPA does not think that it is necessary to list all individual VOC that can be imaged in Appendix K, as an OGI camera cannot differentiate between different compounds. EPA is retaining ethane as an analyte that can be monitored with Appendix K because OGI cameras covered by Appendix K can see leaks of ethane.

EPA notes that it has included sensitivity thresholds for methane and either propane or butane. This is to ensure that OGI cameras used with Appendix K will be able to image leaks of both methane and VOCs. While methane is less sensitive to detection for OGI cameras that operate in the 3.2-3.4 micron range, we have no empirical evidence to prove that the operating envelope for butane will always be better than the operating envelope for methane. Therefore, in the final rule EPA is maintaining the requirement to test both methane and either butane or propane during development of the operating envelope.

In response to comments received on the November 2021 Proposal, EPA updated Appendix K to allow the specification testing in section 6 and the development of operating envelopes in section 8 to be conducted with either butane or propane. See discussion in section VI.B.5 of the December 2022 Supplemental Proposal for more information related to response factors.<sup>26</sup>

#### 22.4.3.3 Detection Limit Levels

Comment: One commenter (1458-IES) acknowledged that the spectral range of infrared radiation measured by the OGI camera must overlap with an absorption peak for a chemical compound of interest. Another commenter (0782-BHE) maintained that OGI has application to different regulatory regimes (e.g., mitigation of greenhouse gases/methane, VOC, or hazardous air pollutants) and the protocol should consider different mass-based performance thresholds depending on the pollutant. The commenter also acknowledged that methane and greenhouse gases should not be subjected to the same leak threshold rate as VOC and hazardous air pollutants. The commenter requested that EPA establish Appendix K applicability with the corresponding analytes, minimum detection levels, response factors, or performance specifications.

Response I-22-37: EPA acknowledges that OGI has application to different regulatory regimes and notes that Appendix K is specific to the use of OGI in leak detection. The detection thresholds in Appendix K were developed based on common cooled MWIR OGI cameras, which can see both methane and VOCs. The detection level of these OGI cameras is not expected to vary much if the spectral filter remains in the same range (around 3.2-3.4 micron). Appendix K does not set different thresholds for different compounds other than noting what the OGI cameras need to be capable of detecting.

The emissions reductions achieved using an OGI camera are specific to each subpart where Appendix K is applied. The analysis for the individual subpart is where the emissions reductions for individual compounds based on the detection capabilities of the camera can be used to design the frequency of inspection using an OGI camera. EPA notes that sector-specific performance requirements can be considered on a regulation specific basis when EPA revises a subpart to reference Appendix K. Such sector-specific performance requirements would be defined in the referencing subpart and not in Appendix K.

Comment: Two commenters (0604-Providence, 1458-IES) acknowledged that if various subparts in 40 CFR parts 60, 61, 63, and 65 reference Appendix K then different detection limits (minimum emission rate detectable by an OGI camera model) may be needed. First, a different target compound will have different sensitivity even for the same OGI camera model. Second,

---

<sup>26</sup> 87 FR 74839 (December 6, 2022).

the objective of a particular subpart may be different (e.g., a subpart aimed at regulating air toxics may be more stringent than a subpart aimed at regulating methane). Therefore, the commenter suggested that EPA move the target compound (methane in this case, or methane and butane if the EPA would like to maintain both target compounds) and associated minimum emission rate to the regulation itself (e.g., NSPS OOOOb). This should not affect the content of Appendix K, but it will make it more generic and usable by future rulemakings (i.e., by other applicable subparts).

Response I-22-38: The detection thresholds in Appendix K were developed based on common cooled MWIR OGI cameras, which can see both methane and VOCs. The detection level of these OGI cameras is not expected to vary much if the spectral filter remains in the same range (around 3.2-3.4 micron). Appendix K does not set different thresholds for different compounds other than noting what the OGI cameras need to be capable of detecting. EPA notes that it has only included sensitivity thresholds for methane and either propane or butane, which are surrogates for other VOCs, as most VOCs have a peak in the same portion of the infrared spectrum. This is to ensure that OGI cameras used with Appendix K will be able to image leaks of both methane and VOCs.

The emissions reductions achieved using an OGI camera are specific to each subpart where Appendix K is applied. The analysis for the individual subpart is where the emissions reductions for individual compounds based on the detection capabilities of the camera can be used to design the frequency of inspection using an OGI camera. EPA notes that sector-specific performance requirements can be considered on a regulation specific basis when EPA revises a subpart to reference Appendix K. Such sector-specific performance requirements would be defined in the referencing subpart and not in Appendix K.

Comment: Commenters (0808-API, 0604-Providence, 0719-Opgal, 0831-AXPC) asserted that the detectability test for methane and butane emissions as specified in section 6.1.2 of Appendix K is not needed. One commenter (0719-Opgal) suggested that defining a criterion at one set of conditions is not sufficient to ensure a reasonable envelope of performance and proposed adding a higher emission rate requirement in another set of conditions to reflect more realistic conditions. Another commenter (0561-TRICORD) suggested that the detectability test for methane and butane be relaxed to a one-time or annual verification to reduce the burden on operators.

Another commenter (0604-Providence) recommended a different approach to minimum detection capability for OGI cameras, suggesting EPA replace the reference of “and butane” and the associated numeric minimum emission rate of “18.5 g/hr” with “or target compound and minimum emission rate if specified by an applicable subpart.” The commenter acknowledged that for the most commonly used cooled MWIR OGI cameras, the sensitivity for butane is significantly higher than methane, and that for the FLIR GF320 OGI camera model, the response factors are 0.297 and 1.011 for methane and n-butane respectively (indicating that butane is much easier to detect than methane).

Response I-22-39: EPA disagrees with the commenters that the detectability test in section 6.1.2 is not needed. It is important to ensure that each OGI camera model has a minimum detectability level before an owner or operator uses it for compliance with the survey requirements in a

subpart referenced by Appendix K. Additionally, EPA has only prescribed one set of conditions in section 6.1.2 because this is a performance specification confirmation of the particular camera model, which EPA notes is a one-time test to qualify the camera for use, and this testing can be performed by the manufacturer, the owner or operator, or a third-party. The testing in section 6.1.2 is not intended to dictate the full range of conditions a survey can be conducted under. The operating envelopes developed under section 8 of Appendix K is intended to set the range of conditions appropriate for conducting surveys.

EPA has only included sensitivity thresholds for methane and either propane or butane, which are surrogates for other VOCs, as most VOCs have a peak in the same portion of the infrared spectrum. This is to ensure that OGI cameras used with Appendix K will be able to image leaks of both methane and VOCs. sector-specific performance requirements can be considered on a regulation specific basis when EPA revises a subpart to reference Appendix K. Such sector-specific performance requirements would be defined in the referencing subpart and not in Appendix K.

EPA has reviewed the detection limits used in Appendix K. See discussion in section XIV.B.2 of the preamble to the final rule which details EPA's final standards related to OGI camera detection limits. More information on detection limits can also be found in the final TSD for Appendix K.

Comment: Commenters (0607-AENV, 0718-Tora) explained that the removal of the VOC concentration threshold from the definition of “in VOC service”, expands the population of components at a natural gas processing plant that would be subject to LDAR requirements.<sup>27</sup> The commenters indicated that this change requires Appendix K to be flexible and allow for the utilization of the OGI technology best suited for the streams being monitored. Specifically, EPA should remove the minimum detection criteria for specific hydrocarbon compounds (i.e., 17 grams per hour for methane and 18.5 grams per hour for butane) and instead retain the flexible performance criteria outlined in the current AWP. Under the AWP, the minimum concentration of detectable chemicals in a gas stream is multiplied by the selected detection sensitivity level (e.g., 60 grams per hour) to determine the mass flow rate for the performance of the daily instrument check.

Response I-22-40: Since the time that the AWP was finalized, EPA has continued to research and conduct studies on minimum detection sensitivity levels, and we have learned more about the detection capabilities of OGI cameras. Field conditions, especially delta-T, wind speed, and distance, play an important role in the ability of an OGI camera operator being able to observe leaks that are present. We have based Appendix K and the detection levels within Appendix K on the best available information.

EPA notes that it has only included sensitivity thresholds for methane and either propane or butane, which are surrogates for other VOCs, as most VOCs have a peak in the same portion of the infrared spectrum. This is to ensure that OGI cameras used with Appendix K will be able to image leaks of both methane and VOCs.

---

<sup>27</sup> Commenter cited to the November 2021 Proposed rule, 86 FR 63182 (November 15, 2021).

#### 22.4.3.4 Constituent Percent Criteria

Comment: Commenters (0607-AENV, 0718-Tora, 0782-BHE) declared that any minimum performance specification should be based on the concentration of detectable chemicals within the gas stream, not the count of such chemicals. The commenters provided similar example scenarios: a process gas stream has 10 constituents, where eight of the components are detectable by the OGI camera, but only account for 5-10% by weight of the overall gas stream. The OGI camera would meet the minimum performance specification for the process stream (>75% by count) but would not be effective at detecting leaks from the process stream.

Response I-22-41: Regarding the concentration of detectable chemicals within the gas stream as required in section 6.1.1 of Appendix K, EPA has clarified that 75 percent refers to the amount of constituents by volume. See section VI.C of the December 2022 Supplemental Proposal for clarification on this requirement.<sup>28</sup>

Comment: Commenters (0808-API, 0831-AXPC) advocated for the spectral range requirements in Section 6.1.1. One commenter (0808-API) called attention to refineries and other complex processes whose monitored components can contain many hydrocarbons with a range of individual response factors. The commenter stated that the OGI methodology should be feasible for these processes when there is a limited ability to precisely characterize stream compositions, and the methodology should balance both the camera's ability and the range of components that may be in an emission stream. The commenter contended that for upstream operations there is usually a dominant hydrocarbon in the streams being monitored and, therefore, the simpler, less burdensome requirement in §60.5397a(c)(7)(i)(A) is appropriate for those operations.

Response I-22-42: EPA acknowledges the support from the commenters on the approach taken in Appendix K. We recognize that some streams at refineries and within other sectors can be complex and difficult to characterize. However, it is imperative that an owner or operator ensure that any components monitored by an OGI camera be limited to those where an OGI camera can visualize any emissions from the streams in contact with the components.

In response to the comments received on the November 2021 Proposal, EPA proposed a different regulatory approach for fugitive emissions from well sites, centralized production facilities, and compressor stations in the December 2022 Supplemental Proposal, which is similar to the approach taken in NSPS OOOOa. For details, please see discussion in section IV.A.1.a.ii and IV.A.2.A of the December 2022 Supplemental Proposal related to fugitive emissions from well sites, centralized production facilities, and compressor stations.<sup>29</sup>

#### ***22.4.4 Calibrations and Non-Uniformity Correction***

Comment: Commenter (0561-TRICORD) called attention to an OEM design characteristic, the Non-Uniformity Correction (NUC).<sup>30</sup> The commenter attested that this characteristic was not properly acknowledged. The NUC is a required and routine calibration that is not acknowledged

---

<sup>28</sup> See 87 FR 74840 (December 6, 2022).

<sup>29</sup> 87 FR 74722-74736 and 74739 (December 6, 2022).

<sup>30</sup> NUC adjusts for minor detector drift that occurs as the scene and environment change.

in the proposed Appendix K section 7.1. Another commenter (0831-AXPC) supported section 7.0 in its current form.

Response I-22-43: EPA acknowledges that NUC can be important component of routine maintenance and calibrations for OGI cameras. While not specifically mentioned in Appendix K, EPA has revised the language in section 7.1 to state that operators should follow manufacturer recommendations regarding maintenance and calibration, as appropriate.

Comment: Commenters (0561-TRICORD and 0782-BHE) indicated that Appendix K Section 10.2.1.4 overstates the calibrations required for proper operation and maintenance. One commenter (0561-TRICORD) explained that no calibrations beyond the NUC and temperature calibrations are necessary.

Response I-22-44: EPA agrees that many OGI cameras do not need routine calibrations. The language in section 10.2.1.4 has been revised to remove the word calibration.

Comment: A commenter (0911-NDPC) stated that if a company conducts OGI surveys using company personnel, EPA should require that the camera calibration and maintenance be addressed in the facility's monitoring plan and should follow the manufacturer's recommendation.

Response I-22-45: EPA has revised the language in section 7.1 to state that operators should follow manufacturer recommendations regarding maintenance and calibration, as appropriate.

#### ***22.4.5 Equipment Needed for Certification Testing***

Comment: A commenter (0561-TRICORD) asked if the release orifice description in Section 6.2.3 refers to the outside or inside ¼ inch diameter.

Response I-22-46: The language in section 6.2.3 has been revised to specify the inner diameter.

Comment: A commenter (0561-TRICORD) suggested that an infrared thermometer should be an accepted alternative to the T-type surface skin thermocouple for measuring the background immediately behind the test gas as described in section 6.2.9. The commenter asserted that infrared thermometers are more accurate (0.3 °C vs. 1.0 °C) and have a slower response time.

Response I-22-47: EPA chose not to include infrared thermometers in section 6.2 of Appendix K, because an infrared thermometer is essentially the same technology as an OGI camera. Our intention was to verify the actual temperature using a method that would not be susceptible to the same interferences.

Comment: Commenters (0808-API, 0831-AXPC) suggested that the required National Institute of Standards and Technology (NIST) traceability accuracy of 5 percent required for the mass flow controller or rotameter in Section 6.2.4 seems unnecessary. NIST traceability is not specified for any other instrumentation.

Response I-22-48: In the final rule, EPA has removed the requirement for NIST traceability. Instead, we have changed this requirement to be “traceable to the International System of Units through an unbroken chain of comparisons” and have included this requirement on the distance measurement tool and thermocouples as well as the flow meter. We have also added calibration and standardization requirements for the meteorological station. These requirements are in place to minimize the error in the method and are critically important for producing accurate, reliable data.

Comment: Commenters (0808-API, 0831-AXPC) suggested that the requirement that the weather information described in Section 6.2.6 be obtained from a weather station within 1 mile of the test location seems unnecessary. Commenters (0808-API, 0831-AXPC) stated that in many cases National Weather Service stations will be the basis for this data, and the testing facility will not have ready access to the instrumentation specifications at that weather station or the ability to influence that equipment. The commenters (0808-API, 0831-AXPC) therefore recommend that weather data obtained from a National Weather Service Station located within 1 mile of the test location be allowed without requiring the information specified in Section 6.2.6.1 through 6.2.6.5 to be collected. Commenter (1391-INGAA) stated that the requirements limit the use of current equipment that satisfies existing NSPS OOOOa requirements.

Response I-22-49: The language in section 6.2.6 was revised in the December 2022 Supplemental Proposal to require a meteorological station at the test site. As this is a one-time requirement for each camera model, EPA does not consider an onsite meteorological station to be an onerous requirement. Because this demonstration is the basis for proving that the OGI camera model has the ability to meet the performance criteria specified in the rule, it is imperative that the data collected be accurate and of known quality, and it is important to know the sensitivity of the instrumentation used to collect the required data.

The requirements in section 6.2.6 of Appendix K do not limit the use of current equipment that satisfy existing NSPS OOOOa requirements. NSPS OOOOa does not require the use of Appendix K.

#### ***22.4.6 Response Factors***

Comment: One commenter (0782-BHE) questioned the selection of propane as the reference compound for response factor tests noting that natural gas can contain several or all alkanes that improve response. The commenter argued that since propane is one of the largest optical depth gases available, methane should be selected as the reference specification for this approach.

Response I-22-50: EPA disagrees with the commenter. Appendix K is meant to be more broadly applicable than for just finding leaks of methane and other compounds found in natural gas. Propane is an easily obtained gas that is neither a greenhouse gas nor a hazardous air pollutant, and therefore, it is a good candidate for testing relative responses of other gases. Additionally, there has already been work to date, as included in the Appendix K TSD, using propane as the reference gas.

Comment: One commenter (0954-FLIR) noted that the document commonly refers to the response factors of gases and recommends adding a table with response factor values for methane, ethane, and other analytes, such as the one available here: <https://www.tandfonline.com/doi/full/10.1080/10962247.2016.1244130>.

Response I-22-51: The definition of response factor was modified in response to comments. Specifically, EPA has indicated that response factors are camera model specific. See discussion in section VI.B.5 of the December 2022 Supplemental Proposal for more information related to response factors.<sup>31</sup> Because response factors are camera model specific, response factors cannot be included within Appendix K.

Comment: One commenter (0561-TRICORD) noted that most OGI cameras are qualitative rather than quantitative and questioned how response factors would be developed for qualitative cameras. The commenter further questioned that if a camera can image a propane leak at 40 feet distance, would the “other majority” of chemicals need to be imaged at a distance of 10 feet or more?

Response I-22-52: In response to comments on the November 2021 proposed rule, as part of the December 2022 Supplement Proposal, EPA developed Annex 1 to Appendix K, which is a methodology for the development of response factors for OGI cameras. See discussion in section VI.B.5 of the December 2022 Supplemental Proposal for more information related to response factors.<sup>32</sup>

EPA is clarifying that the operating envelope for the OGI camera model developed in accordance with section 8 is applicable to any compound being monitored. The operating envelope does not need to be adjusted for each individual compound in the emissions stream.

Comment: One commenter (0719-Opgal) believed section 6.1.1 should only need to state that the spectral range of infrared radiation measured by the OGI camera must overlap with a major absorption peak for the chemical target of interest. The commenter noted that if no sufficient overlap exists, the OGI camera will not be able to meet the performance-based requirements in 6.1.2. The commenter stated the 0.25 response factor requirement is not necessary and would be impossible to verify.

Response I-22-53: EPA disagrees with the commenter. While it is important for the target compound to have an absorption peak within the spectral range of radiation measured by the OGI camera, there are many emission streams that consist of a variety of compounds. It is important that Appendix K provide clarity on when it is appropriate to use an OGI camera to monitor emissions from these streams, and when the OGI camera is not expected to respond at appropriate levels. Therefore, we have maintained the specification that the majority (>75% by volume) of compounds in the emissions stream must have a response factor of at least 0.25, when compared to the response factor of propane.

<sup>32</sup> 87 FR 74839 (December 6, 2022).

## 22.5 Operator Training

### 22.5.1 General Opposition on Training Requirements

Comment: Commenters (0463-Southern Ute, 0607-AENV, 0718-Tora, 0749-PAW, 0782-BHE, 0831-AXPC) considered the OGI camera operator training requirements in section 10.2.2 of Appendix K to be expensive, prohibitive, and unnecessary. One commenter (0463-Southern Ute) stressed that the minimum field training elements for the initial OGI camera operator training are burdensome and will greatly increase the cost of the leak detection program. The commenter recommended lower minimum training requirements.

Several commenters suggested that the training requirements of Appendix K would result in numerous difficulties in implementation. One commenter (1458-IES) suggested that the stringent training requirements would result in significantly diminished stakeholder implementation of next generation technology, with many operators reverting to older leak detection techniques. Another commenter (0808-API) contended that the extensive training requirements could make implementation impractical and inefficient. The commenter noted that the significant overhead costs involved in completing the training requirements reduce the potential economic benefits of transitioning to OGI as an alternative leak detection technique.

Additionally, a commenter (0750-Flogistix) expressed reservations over feasibility for small oil and gas producers, while another commenter (0934-Leak Surveys, Inc. (LSI)) argued that while the length of training is important, the most important qualification of a successful OGI camera operator is the desire to find leaks. This implies that different trainees may have different training needs. A third commenter (0924-SBA) noted that several small businesses had expressed significant concerns about the extra burden Appendix K would place on their operations, and that training requirements for new operators would significantly reduce the capacity of the industry.

One commenter (0786-Enerplus) suggested that the training and qualification requirements currently outlined in Appendix K will limit the operator's ability to find qualified OGI operators, thereby restricting the pool of trained staff available to implement the method. Another commenter (0934-LSI) agreed that the stringent training requirements in Appendix K will result in disqualification of field technicians, thereby reducing the number of qualified OGI operators available to conduct surveys. The commenter stated that this would result in operators reverting to older technology like EPA Method 21. A third commenter (0808-API) indicated that the extensive training requirements of Appendix K will increase the dependence of operators on third-party OGI camera operators, and since third party operators may not be trained or allowed by operators to attempt a first repair upon leak detection (as under NSPS OOOOa programs), the leak repair will be delayed resulting in more emissions.

Response I-22-54: In response to comments received on the November 2021 Proposal, EPA updated the training requirements for Appendix K in the December 2022 Supplemental Proposal. See discussion in section VI.B.2 of the December 2022 Supplemental Proposal related to operator training.<sup>33</sup>

---

<sup>33</sup> See 87 FR 74837-74838 (December 6, 2022).

### ***22.5.2 Site Survey Criterion***

Comment: Commenters (0782-BHE, 0808-API, 0831-AXPC, 0954-FLIR) requested clarification on the definition of a site survey and indicated that the duration of a site survey varies depending on the complexity of the site to be monitored. Thus, monitoring a “site” can take a brief time for one OGI operator (minutes or hours) or require many fulltime OGI operators and take months to complete. One commenter (0749-PAW) stated that Appendix K does not define a site survey adequately and suggested that site surveys can vary widely for upstream, midstream and downstream facilities. Further, the commenter suggested a hybrid training system of in-field and classroom training would be the ideal for OGI trainees.

Commenters (0808-API, 0814-IPAA) indicated a lack of clarity on whether site surveys require sites with a variety of equipment sets or to be significantly different from each other. One commenter (0599-MSC) stated that the training requirements will be difficult and costly for smaller companies that don't have multiple cameras/camera operators to comply, and the number of site surveys conducted in tandem with a senior operator seems arbitrary and overly onerous. The commenters (0599-MSC, 0808-API, 0814-IPAA) suggested replacing the number of surveys criterion with a set number of survey hours for each training phase because a survey may vary greatly in duration depending on the type of facility being surveyed. Another commenter (0916-AOGA) recommended that the term site be defined to mean a single wellhead or single piece of equipment.

One commenter (0561-TRICORD) proposed quantifying new trainee requirements on the time spent using the OGI camera, with 100 hours as a training requirement rather than 100 surveys.

Response I-22-55: In response to comments received on the November 2021 Proposal, EPA removed the site survey terminology in the training requirements for Appendix K in the December 2022 Supplemental Proposal. See discussion in section VI.B.2 of the December 2022 Supplemental Proposal related to operator training.<sup>34</sup>

### ***22.5.3 Recertification Requirements***

Comment: Commenters (0607-AENV, 0718-Tora, 0814-IPAA) found the OGI operator recertification requirements in section 10.5 of Appendix K to be unnecessary and excessive, with the recommendation that the recertification for an experienced OGI operator be limited to the final site monitoring survey test and the annual refresher training, thereby eliminating the repetition of full classroom training.

A commenter (0782-BHE) questioned the basis for the retraining requirements outlined in section 10.5 and expressed concern on the time spent by experienced OGI camera operators in completing lengthy repeat training sessions. The commenter considered these issues to be significant enough to prevent the implementation of OGI as a viable alternative to existing leak detection methodologies.

One commenter (0463-Southern Ute) also found the operator recertification process to be onerous and expressed concern over the potential expenditure. Another commenter (0561-

---

<sup>34</sup> See 87 FR 74837-74838 (December 6, 2022).

TRICORD) did not object to the retraining requirements of section 10.5 but suggested extending the period of inactivity from 12 months to 24 months.

Response I-22-56: In response to comments received on the November 2021 Proposal, EPA has updated the recertification criteria of Section 10.5 in the training requirements for Appendix K in the December 2022 Supplemental Proposal. See discussion in section VI.B.2 of the December 2022 Supplemental Proposal related to operator training.<sup>35</sup>

#### ***22.5.4 Initial Training Requirements for Experienced Camera Operators***

Comment: Commenters (0808-API, 0831-AXPC) questioned the requirement for experienced OGI camera operators to go through the entire initial training program to meet Appendix K requirements. The commenter recommended that an OGI camera operator with at least 24 hours of OGI monitoring experience in the previous 12 months, but no previous Appendix K experience, only be required to go through the refresher level of training rather than the full initial training and then pass the field training final test.

Response I-22-57: In response to comments received on the November 2021 Proposal, EPA proposed to allow previous experience to be substituted for certain initial training requirements in the December 2022 Supplemental Proposal for Appendix K. See discussion in section VI.B.2 of the December 2022 Supplemental Proposal related to operator training.<sup>36</sup>

#### ***22.5.5 Classroom Training***

Comment: Commenters (0750-Flogistix, 0793-PBPA, 0814-IPAA, 0924-SBA, 0945/1373-JOFA) indicated that the annual classroom training refresher for OGI camera operators is an excessive requirement. Some commenters (0793-PBPA, 0808-API) recommended that the refresher training be required every 3 years. Another commenter (0599-MSD) stated that while they generally support refresher training, camera operators should be exempted from the annual refresher training requirement if the operator is conducting frequent surveys throughout the year and pass all performance audits.

Response I-22-58: In response to comments received on the November 2021 Proposal, EPA updated the training requirements for Appendix K in the December 2022 Supplemental Proposal. See discussion in section VI.B.2 of the December 2022 Supplemental Proposal related to operator training.<sup>37</sup>

Comment: Several commenters (0782-BHE, 0802-Kraken, 0808-API, 0814-IPAA, 0911-NDPC, 0954-FLIR, 0945/1373-JOFA) requested clarification on the references to classroom training in sections 10.2 and 10.3 of Appendix K. Commenters (0808-API, 0831-AXPC, 0954-FLIR) recommend that virtual or online training sessions be allowed as viable substitutes for in-person classroom training. A commenter (0954-FLIR) also requested further information on the

---

<sup>35</sup> See 87 FR 74837-74838 (December 6, 2022).

<sup>36</sup> See 87 FR 74837-74838 (December 6, 2022).

<sup>37</sup> See 87 FR 74837-74838 (December 6, 2022).

classroom training elements outlined in section 10.2.1, including guidance on the teaching time per element, content per element and classroom testing for efficacy.

Response I-22-59: EPA does not intend to prescribe the time or content of the required classroom training beyond the outline provided in Appendix K. While we recognize that the theory behind the operation of OGI cameras is important and should be covered in any comprehensive training program, we believe that the final field test and performance audits will be the true demonstration of an operator's ability. Therefore, we are providing flexibility for people to design their own classroom programs, as long as each program covers the topics outlined in section 10.0 of Appendix K.

Additionally, in response to comments received on the November 2021 Proposal, EPA clarified the classroom training requirements for Appendix K in the December 2022 Supplemental Proposal. See discussion in section VI.B.2 of the December 2022 Supplemental Proposal related to operator training.<sup>38</sup>

### **22.5.6 Field Test**

Comment: A few commenters raised objections over the requirement to be 100% accurate during the final monitoring survey field test. One commenter (0911-NDPC) noted that Appendix K in its current form requires the camera operator to be 100% accurate during training, which does not account for human error and situational factors. Another commenter (0782-BHE) raised the same point and referenced studies performed at Colorado State University where experienced OGI camera operators did not have 100% leak detection. Other commenters (0808-API, 0831-AXPC) recommended that the accuracy criterion be revised to at least 90% agreement or a difference of no more than 1 persistent leak if less than 10 persistent leaks are identified. One of the commenters (0808-API) also recommended that if 90% agreement is not achieved, the senior operator should work with the trainee on the reasons for the failure followed by a repeat test. In the case of a second failure, the trainee should be required to go through the refresher level of training prescribed in section 10.3 of Appendix K before retaking the final test. Another commenter (0599-MSD) noted that the requirement to achieve zero missed persistent leaks is higher than the amount achieved by all levels of experience in the studies presented at EPA's Optical Gas Imaging Stakeholder Workshop in November 2020. The commenter suggested that the threshold be revised to an allowable percentage of missed persistent leaks rather than an arbitrary number. Other commenters (0607-AENV, 0718-Tora) stated that determination of suitability for independent monitoring should be based on observations and comparative monitoring, as determined by the senior OGI camera operator.

Commenters (0808-API, 0831-AXPC) also expressed concern over the length of the final field test and recommended that the final test be reduced to one hour in duration.

Response I-22-60: In response to comments received on the November 2021 Proposal, EPA updated the training requirements for Appendix K in the December 2022 Supplemental Proposal.

---

<sup>38</sup> See 87 FR 74837-74838 (December 6, 2022).

See discussion in section VI.B.2 of the December 2022 Supplemental Proposal related to operator training.<sup>39</sup>

### ***22.5.7 Performance Audits for Camera Operators***

#### **22.5.7.1 Performance Audit Opposition**

Comment: Multiple commenters (0463-Southern Ute, 0561-TRICORD, 0607-AENV, 0718-Tora, 0749-PAW, 0750-Flogistix, 0782-BHE, 0786-Enerplus, 0808-API, 0814-IPAA, 0831-AXPC, 1458-IES) questioned or opposed the proposed performance audit specifications for OGI camera operators. One commenter (1458-IES) argued that performance audits are unnecessary. Some commenters (0786-Enerplus, 1458-IES) stated that audits provide no additional assurances of enhanced leak identification or effectiveness. Commenters (0749-PAW, 1458-IES) stated that performance audits are not typically supported by precedence in other reference methods, and that the proposed requirements of Appendix K would make the method significantly more onerous than EPA Method 21 or other reference methods. A commenter (0814-IPAA) reiterated that other similar work practice programs, such as EPA Method 21 LDAR monitoring, have been in service for more than 40 years without a similar audit requirement.

Several commenters (0750-Flogistix, 0782-BHE, 0786-Enerplus, 0814-IPAA, 0924-SBA) remarked that the requirements were overly burdensome. One commenter (0782-BHE) objected to the substantive changes from the AWP, inconsistency with EPA Method 21, and “arduous” criteria. Commenters (0782-BHE, 1391-INGAA) supported either significantly streamlining the process or providing additional justification and support for the rationale for the added audit, training, and certification requirements. One commenter (0782-BHE) specifically expressed concern that the cost-effectiveness analysis may not adequately reflect the time required to complete the audits or the impacts to survey personnel.

Other commenters (0463-Southern Ute, 0817-GPA, 0916-AOGA) stated that the proposed audit requirements of Appendix K would effectively require facilities to use contractors instead of in-house personnel. One commenter (0463-Southern Ute) stated that because the audits require senior OGI camera operator surveys to be audited, many companies would be forced to either have two senior OGI operators on staff or rely on third party contractors for each survey. The commenter (0463-Southern Ute) added that if third party contractors are required, this could result in potential delays and would add travel and lodging expense costs. A commenter representing Alaskan production facilities (0916-AOGA) noted that the quarterly requirements would force them to displace their local staff observers with consultants from the Lower 48. The commenter (0916-AOGA) explained that due to the short summer window in Alaska, the risk of assigning local staff who last conducted an OGI survey during the previous summer to first pass a performance audit and then complete the OGI monitoring program at a series of facilities within the summer window would be too great (i.e., if the staff did not pass the audit). The commenter (0916-AOGA) also indicated that the availability of qualified consultants willing to spend the summer conducting OGI surveys at these facilities may be problematic. Another commenter (0814-IPAA) asserted that this would be particularly costly for compressor stations, as services for fugitive emission surveys using OGI are not readily available in many areas of the country, and the cost to bring in equipment from other areas would be prohibitive. The

---

<sup>39</sup> See 87 FR 74837-74838 (December 6, 2022).

commenter (0814-IPAA) provided a cost of \$13,400 per year per compressor station. A commenter (0463-Southern Ute) recommended that EPA allow the performance audits being conducted by a third-party qualified OGI camera operator as sufficient for the performance audit requirement. The commenter also suggested that EPA should allow companies to implement their own leak detection training programs internally, without reliance on third party contractors.

Commenters (0749-PAW, 0808-API) pointed out that requiring senior OGI camera operators to also be audited is not a productive use of time. One commenter (0749-PAW) argued that the proposed approach would require senior OGI camera operators to spend more of their time reviewing other operators' work than in the field completing surveys. The commenter (0749-PAW) asserted that if senior OGI camera operators have the training and experience to audit others, they should be excluded from the auditing process. The other commenter (0808-API) stated that because senior OGI camera operators will automatically review monitoring requirements frequently and have an opportunity to identify and correct issues of their own, they should not be required to undergo performance audits.

Several commenters (0561-TRICORD, 0750-Flogistix, 0782-BHE, 0814-IPAA, 0817-GPA, 0916-AOGA) questioned the retraining requirements for OGI camera operators who missed detecting leaks during the performance audit. Commenters (0599-MSC, 0749-PAW, 0808-API, 0817-GPA, 0831-AXPC, 0924-SBA) questioned the requirement that the survey test require a trainee to be 100% accurate. Commenters noted that this level of accuracy is unrealistic, unreasonable, or inconsistent with other aspects of Appendix K. Other commenters (0607-AENV, 0718-Tora, 0750-Flogistix) emphasized that the retraining requirements would include five additional side-by-side comparative surveys and ten additional supervised surveys if one small leak was missed, which is excessive, punitive and burdensome. One commenter (0817-GPA) stressed that there is always some subjectivity to using an OGI camera and that even experienced observers may disagree on whether they recognize a leak. The commenter suggested that EPA require trainee operators to be at least 75% accurate to qualify for independent survey work. Other commenters (0749-PAW, 0808-API, 0831-AXPC) recommended that the criteria be based on 90% accuracy or a difference of no more than one persistent leak if less than ten persistent leaks are identified. One commenter (0561-TRICORD) urged that if a leak is missed by the camera operator being audited, the camera operator ought to be informed that they missed a leak in a specific area and given the opportunity to re-image; the commenter noted that if the operator consistently missed the leak, only then should retraining be required.

One commenter (0808-API) emphasized that failures to observe a leak or to follow some aspects of the monitoring procedure are situation specific, and that general retraining dilutes the focus on the real problem(s) and uses monitoring time and senior resources on issues that are not a problem. Instead, the commenter suggested the requirement should be to specify that retraining is required to address monitoring aspects observed to be an issue during the audit. The commenter also recommended the word "site" be deleted from the retraining requirements in sections 10.4.1.2 and 10.4.2.2 ("required number of site surveys") and recommended, instead, that the monitoring requirements be expressed on a time basis. Another commenter (0718-Tora) similarly insisted that recertification should be based on a reasonable duration of supervised surveys (e.g., 40 hours).

One commenter (0817-GPA) stated that Appendix K is not clear as to what occurs if the comparative monitoring reveals that the senior OGI camera operator performed poorly. A separate commenter (0718-Tora) also noted a scenario where the senior OGI camera operator could erroneously identify missed leaks during video review and recommended that section 10.4.2 should provide that any leaks identified during video review by the senior OGI camera operator as being allegedly missed are not considered leaks for regulatory compliance purposes.

Commenters (0916-AOGA, 1458-IES) noted that the proposed requirements would likely reduce the number of available personnel to conduct surveys. One commenter (0916-AOGA) asserted that the proposed retraining requirements would potentially complicate the scheduling of annual LDAR surveys. The commenter noted that operators try to schedule surveys ahead of planned shutdowns to accommodate the repair of any leaks discovered; the commenter stated that if a camera operator is found to have missed a leak during the quarterly performance audit, the same operator would likely be disqualified from conducting the annual LDAR survey during that year.

One commenter (0599-MSD) was also concerned about a potential shortage of qualified senior OGI camera operators and stated that any qualified OGI camera operator should be able to conduct an audit on another camera operator. Other commenters (0808-API, 0831-AXPC) requested that EPA clarify that the audits may be performed by the OGI camera operator employer or a site owner or operator and there is no requirement for additional audits as the camera operator moves from one site to another or from employer to employer.

Several commenters (0750-Flogistix, 0814-IPAA, 0924-SBA, 0945/1373-JOFA) remarked that the performance verification requirements are particularly complicated and burdensome for small facilities, such as small oil and gas producers. Two commenters (0814-IPAA, 0945/1373-JOFA) stated that the proposed requirements would cause many small businesses to close because they cannot meet the financial, time, staffing, data storage or management obligations of the proposed requirements. Another commenter (0924-SBA) stated that, as proposed, these requirements would “practically preclude sole proprietors or businesses with a small number of employees because of the numerous requirements that require two people to do the job of one during initial training and quarterly auditing”. The commenter added that proposed operational requirements will also significantly increase the time and burden of OGI site visits.

Response I-22-61: EPA disagrees that senior OGI camera operators should be exempt from performance audits. As commenters pointed out, even senior OGI camera operators may perform poorly; as such it is important that the performance of all OGI camera operators be audited regularly to ensure that all OGI camera operators, even senior OGI camera operators, maintain the ability to see leaks. This is similar to how EPA Method 9 observers must be recertified every six months, regardless of how long the observer has been conducting EPA Method 9. A robust training and auditing program is necessary to ensure operators can see leaks that are present.

If a senior OGI camera operator performs poorly during comparative monitoring of an auditee, the owner or operator should consider whether it is appropriate for the senior OGI camera operator to continue to conduct senior OGI camera operator duties and the appropriate next steps based upon the specifics of the situation. Such next steps could include conducting a performance audit of the senior OGI camera operator, retraining the senior OGI camera operator,

or noting whether there were extenuating circumstances for the performance. The auditee would pass the audit if the auditee found more leaks than the senior OGI camera operator. EPA disagrees that Appendix K should provide that any leaks identified during video review by the senior OGI camera operator as being allegedly missed are not considered leaks for regulatory compliance purposes; the owner or operator must decide in each individual case whether a leak exists.

EPA recognizes that OGI camera operators that miss leaks during a performance audit need to be retrained following the audit and may not be available during a scheduled LDAR survey. EPA maintains that it is important that the OGI camera operators performing surveys can find leaks that are present and an OGI camera operator who fails an audit may not be able to find leaks that are present.

Audits of OGI camera operators must be performed by a senior OGI camera operator; OGI camera operators who are not senior OGI camera operators do not have the level of experience necessary to oversee other OGI camera operators. Additionally, the owner or operator of a site cannot perform this function, as the owner or operator may not have any experience with an OGI camera. However, EPA agrees that if an OGI camera operator changes employers, as long as the OGI camera operator maintains adequate records of past training and auditing, there is no need to repeat the training and auditing requirements.

In response to comments received on the November 2021 Proposal, EPA updated the OGI camera operator audit requirements for Appendix K in the December 2022 Supplemental Proposal. See discussion in section VI.B.2 of the December 2022 Supplemental Proposal related to operator training.<sup>40</sup>

In response to the comments received on the November 2021 Proposal, EPA proposed a different regulatory approach for fugitive emissions from well sites, centralized production facilities, and compressor stations in the December 2022 Supplemental Proposal. For details, please see discussion in section IV.A.1.a.ii and IV.A.2.A of the December 2022 Supplemental Proposal related to fugitive emissions from well sites, centralized production facilities, and compressor stations.<sup>41</sup>

See additional responses related to the final requirements for OGI camera operator audit requirements in Volume II, Chapter 22, Section 22.4.6.

#### 22.5.7.2 Performance Audit Frequency

Comment: Several commenters (0561-TRICORD, 0718-Tora, 0750-Flogistix, 0808-API, 0814-IPAA, 0831-AXPC, 0916-AOGA) opposed the quarterly frequency of the audits. Commenters (0561-TRICORD, 0718-Tora, 0814-IPAA) remarked that quarterly audits are unreasonable, costly, and overly burdensome. Some commenters (0463-Southern Ute, 0786-Enerplus, 0817-GPA) pointed out the audits require two operators every quarter, one being a senior OGI camera operator, which would impose additional overhead at significant cost. Many commenters (0561-TRICORD, 0599-MSD, 0718-Tora, 0749-PAW, 0808-API, 0831-AXPC, 0916-AOGA) recommended an annual audit or, alternatively, biennial audits. One commenter (0718-Tora)

---

<sup>40</sup> See 87 FR 74837-74838 (December 6, 2022).

<sup>41</sup> 87 FR 74722-74736 and 74739 (December 6, 2022).

noted that an annual audit would align with typical performance review frequencies. Another commenter (0808-API) urged that annual audits would reduce the demand on senior OGI camera operator time, allowing more time for senior OGI camera operators to do monitoring and training, while a commenter (0599-MSD) similarly raised concerns about quarterly audits placing additional obligations on the limited number of qualified camera operators. An additional commenter (0782-BHE) also stated that performance audits should be conducted no more frequently than annually. One commenter (0561-TRICORD) recommended that EPA could begin by requiring quarterly audits but then decrease in frequency to semiannual if no problems are present and could return to a quarterly frequency if a leak is found to have been missed during a semiannual audit. The commenter also noted that leaks could occur after a viewing is performed, therefore, EPA could consider designating the frequency of audits by the number of leaks found (e.g., a facility conducting annual audits that found 5-10 leaks would return to quarterly performance audits, but a facility that only found 1-4 leaks would return to semiannual audits).

Response I-22-62: In response to comments received on the November 2021 Proposal, EPA updated the OGI camera operator audit requirements for Appendix K in the December 2022 Supplemental Proposal. See discussion in section VI.B.2 of the December 2022 Supplemental Proposal related to operator training.<sup>42</sup> See additional responses related to the final requirements for OGI camera operator audit requirements in Volume II, Chapter 22, Section 22.4.6.

#### 22.5.7.3 Performance Audit Length

Comment: Commenters (0599-MSD, 0749-PAW, 0808-API, 0831-AXPC, 0916-AOGA) asserted that four hours is an excessive length for the performance audit; most commenters recommended one hour as adequate to assess if the auditee is following procedures and monitoring correctly. One commenter (0599-MSD) stated the 4-hour survey is arbitrary and may not be applicable if the site being audited is a small compressor station or a well pad where the original survey would not meet that time requirement. Another commenter (0808-API) stated that a 4-hour requirement is not a reasonable use of resources, stating that the proposed requirements would tie up an OGI camera operator and auditor for more than a day and a third person (taking the video) for more than half a day. The commenter requested that if the requirement is maintained, it should allow for a senior operator to simply observe the auditee and not have to record a video, to eliminate the need for a third person.

Response I-22-63: EPA notes that if it takes less time to survey a site than the length of time required for a performance audit, surveys of multiple sites can be used to achieve the required audit time. Additionally, EPA is clarifying that we did not propose, nor are we finalizing, a requirement for a third person to video the audit, and as such, there is no need for a third person to be involved in a performance audit.

In response to comments received on the November 2021 Proposal, EPA updated the OGI camera operator audit requirements for Appendix K in the December 2022 Supplemental Proposal. See discussion in section VI.B.2 of the December 2022 Supplemental Proposal related

---

<sup>42</sup> See 87 FR 74837-74838 (December 6, 2022).

to operator training.<sup>43</sup> See additional responses related to the final requirements for OGI camera operator audit requirements in Volume II, Chapter 22, Section 22.4.6.

#### 22.5.7.4 Performance Audit Approaches

Comment: One commenter (0561-TRICORD) specifically questioned the proposed performance audit by video review. The commenter contended that a 4-hour imaging video is not an effective audit technique and suggested removing this as an audit option or significantly reducing the number of hours of video to be reviewed. Alternatively, video reviews could be conducted for three quarters, with a site audit conducted annually. Another commenter (0599-MSD) stated that Appendix K shows a lack of understanding for how OGI camera programs and surveys work in real life, because reviewing video footage collected by another surveyor is useless from an auditing standpoint. The commenter stated that video review forces the auditor to only utilize data collected via the methods and procedures of the surveyor, not utilizing their own skills to compare results. The commenter additionally noted that the video clips captured via OGI cameras are generally poor when compared to the way that the live screen image appears through the viewfinder or LCD screen during the survey.

Some commenters (0808-API, 0831-AXPC) supported alternative audit approaches, since there will be many variants in monitoring organizations, monitoring schedules, senior OGI camera operator availability, and facilities. The commenters requested that EPA require that the performance audit methodologies be included in the monitoring plan and that the two currently proposed approaches in sections 10.4.1 and 10.4.2 be cited as examples. One of the commenters (0808-API) further suggested other alternative approaches, including visual observation by a senior OGI camera operator (as opposed to their reviewing a video), observation by a monitoring supervisor, or review of results from monitoring at a test facility.

Response I-22-64: EPA provided an option to conduct audits by video review to assist small companies who may not have the resources to schedule comparative monitoring of each OGI camera operator. We think this is a viable alternative to comparative monitoring, as a senior OGI camera operator can watch the video to determine if the OGI camera operator looked at the scene for an appropriate amount of time and from multiple angles, whether the background was considered, and whether interferences were dealt with appropriately.

EPA disagrees that owners and operators should be allowed to create their own auditing procedures in the monitoring plan, as it could lead to auditing techniques that do not appropriately monitor the capabilities of the OGI camera operator. While the techniques suggested by the commenter will provide information on the OGI camera operator's ability, EPA disagrees that the suggested techniques provide adequate information for an audit. For example, knowing that an OGI camera operator can perform well at a test facility is good information about the operator's ability, but it is not as good as knowing that the OGI camera operator can see leaks under actual field conditions. Likewise, visually observing someone conducting a survey will provide information on aspects of survey technique like dwell time and angles, but it will not provide information on whether the OGI camera operator missed any leaks. Therefore,

---

<sup>43</sup> See 87 FR 74837-74838 (December 6, 2022).

EPA is retaining, as proposed, two options for OGI camera operator audits, comparative monitoring and video review.

In response to comments received on the November 2021 Proposal, EPA updated the OGI camera operator audit requirements for Appendix K in the December 2022 Supplemental Proposal. See discussion in section VI.B.2 of the December 2022 Supplemental Proposal related to operator training.<sup>44</sup> See additional responses related to the final requirements for OGI camera operator audit requirements in Volume II, Chapter 22, Section 22.4.6.

#### 22.5.7.5 Performance Audit Repair Requirements

Comment: One commenter (0718-Tora) stated that since comparative monitoring would not be performed simultaneously, it would be possible for a leak to commence in between the auditee and senior OGI camera operator monitoring events. The commenter recommended that section 10.4.1 provide that the leak repair timeline for regulatory compliance purposes starts on the date that the leak allegedly missed by the trainee is found by the senior OGI camera operator.

Response I-22-65: Leak repair timelines are defined by the referencing subpart and are not defined in Appendix K. Generally, leak repair timelines are based upon the date that a leak is first found.

#### ***22.5.8 Senior OGI Camera Operators***

Comment: Various commenters raised issues with the burden associated with the senior OGI camera operator requirements and expressed concern over a limited supply of qualified senior OGI camera operators. Commenters (0599-MSA, 0782-BHE, 0924-SBA) stated that the current definition of senior OGI camera operator coupled with their involvement in training and auditing requirements of other OGI operators would greatly limit the availability of qualified senior OGI camera operators to conduct audit surveys. Further, this limited supply of operators would result in increased costs, logistical challenges, potential non-compliance due to capacity issues, and backsliding to older technologies such as EPA Method 21. One commenter (0782-BHE) further argued that the criteria for training, auditing, and annual survey requirements outlined in section 10.5 of Appendix K appears to rely on research done at a Colorado State University research site and does not account for real-world operating conditions. Another commenter (0463-Southern Ute) found the definition of senior OGI camera operator overly stringent, which would significantly affect the ability of owners and operators to dedicate qualified staff for OGI surveys, possibly necessitating the use of external third-party contractors resulting in increased costs and delay in leak repairs. Commenters (0808-API, 0831-AXPC) outlined all the senior OGI camera operator requirements from sections 3.0, 10.2.1, and 10.2.2 of Appendix K and noted that the overall burden these requirements would place on senior OGI camera operators would result in a very limited supply of senior OGI camera operators and very limited time available for conducting audit surveys. The commenters further argued that the implementation of OGI as an alternative to EPA Method 21 can only succeed if the supply of senior OGI camera operators exceeds the demand. Another commenter (0743-WEA) noted that requiring 50 surveys be done under a senior OGI camera operator's supervision, 10 surveys to be observed by a senior OGI camera operator, and 40 surveys to be verified by a senior OGI camera operator does not

---

<sup>44</sup> See 87 FR 74837-74838 (December 6, 2022).

adequately account for the staffing limitations already faced by several operators. A commenter (0817-GPA) noted that the 500-survey qualification requirement would rule out the use of in-house personnel at compressor stations which would cause operators to rely on a relatively limited number of contractors, increasing rates due to the increased demand and relatively small supply of qualified OGI camera operators and senior OGI camera operators.

Response I-22-66: In response to comments received on the November 2021 Proposal, EPA updated the requirements for senior OGI camera operators in Appendix K in the December 2022 Supplemental Proposal. See discussion in section VI.B.3 of the December 2022 Supplemental Proposal related to senior OGI camera operators.<sup>45</sup>

In response to the comments received on the November 2021 Proposal, EPA proposed a different regulatory approach for fugitive emissions from well sites, centralized production facilities, and compressor stations in the December 2022 Supplemental Proposal. For details, please see discussion in section IV.A.1.a.ii and IV.A.2.A of the December 2022 Supplemental Proposal related to fugitive emissions from well sites, centralized production facilities, and compressor stations.<sup>46</sup>

See additional responses related to the final requirements for senior OGI camera operators in Volume II, Chapter 22, Section 22.4.7.

Comment: Commenters (0808-API, 0831-AXPC) noted that some OGI camera operators are certified thermographers. The thermographic certification requirements for a Level 2 thermographer parallel the initial and refresher OGI training requirements that would apply under Appendix K. The commenters recommended that certified thermographers be considered as senior OGI camera operators and that they be exempted from the initial training requirements in proposed sections 10.1 through 10.3. One commenter (0808-API) further recommended adding a definition of a certified thermographer as follows: *Certified Thermographer for the purposes of this Appendix, means a thermographer who has successfully completed the requirements for a Level 2 or higher thermography certificate compliant with ASNT-TC-1A or ISO 18436-7.*

Response I-22-67: EPA disagrees that there is a need to add this requirement to Appendix K. If the established training for certified thermography program parallels the training requirements in Appendix K, the owner or operator will be able to use that documentation to show that the senior OGI camera operator meets the requirements outlined in Appendix K.

#### ***22.5.9 Miscellaneous Training Comments***

Comment: One commenter (0463-Southern Ute) requested that OGI camera operator experience be documented based on a calendar year rather than a rolling 12-month period to reduce administrative burden. A different commenter (0808-API) recommended that 12-month be clarified to mean the 365-calendar days prior to the day of the activity.

---

<sup>45</sup> See 87 FR 74838-74839 (December 6, 2022).

<sup>46</sup> 87 FR 74722-74736 and 74739 (December 6, 2022).

Response I-22-68: In the December 2022 Supplemental Proposal, EPA clarified that previous 12 months means the 365-calendar days prior to the day of the activity that requires a senior OGI camera operator.

Comment: A few commenters had recommendations on developing training programs that could be implemented by all operators. One commenter (0959-Colt) suggested that EPA consider developing an OGI Surveyors Certification Program with corresponding initial and annual training and field exams. Successful trainees would then use their certificate of completion as proof of competency and certification. Commenters (0814-IPAA, 0945/1373-JOFA) added that EPA should consider providing short online OGI training seminars for experienced OGI operators to enhance their skills with latest tips and techniques.

Response I-22-69: At this time, EPA is not developing OGI training programs. OGI camera operators can develop their own program or to attend programs developed by third-party providers.

Comment: One commenter (0911-NDPC) agreed with the requirement for training but requested flexibility on whether the training is manufacturer, third-party, company-specific, or EPA content.

Response I-22-70: EPA notes that it has not specified who must perform the training. The training can be performed by anyone qualified to instruct operators in optical gas imaging fundamentals and applications. Such entities may include camera manufacturers, company personnel, or third-party vendors.

Comment: A commenter (0808-API) recommended that the following sentence be deleted from section 10.1: “If the facility does not perform its own OGI monitoring, the facility must ensure that the training plan for the company performing the OGI surveys adheres to this requirement.” The commenter stated that any company contracting for OGI monitoring services has a responsibility to assure that those services meet any applicable requirements. The commenter further noted that a training plan is not more critical than any of the other requirements of Appendix K and questions how individual facilities would “ensure” compliance with the training plan requirements.

Response I-22-71: EPA disagrees with the comment. The training plan is crucial to the success of an OGI operator’s ability to find leaks. If an owner or operator chooses to use another company to perform monitoring services, it should request documentation from that company that the operator performing the services were trained in accordance with the requirements of Appendix K.

## **22.6 Operating Envelope**

### ***22.6.1 Party Responsible for Envelope Development***

Comment: Commenters (0463-Southern Ute, 0719-Opgal, 0782-BHE, 0808-API, 0814-IPAA, 0831-AXPC, 0911-NDPC, 0945/1373-JOFA, 1458-IES) requested clarification on who is responsible for developing OGI camera operating envelopes. Some commenters (0463-Southern Ute, 1458-IES) suggested that EPA clearly assign these responsibilities to the camera

manufacturers and stated that these requirements can even be set apart in their own section. One commenter (0945/1373-JOFA) recommended that EPA place any requirements for testing, laboratory, or funding on the manufacturers of OGI cameras as “certifications prior to point of sale” of the equipment, with another commenter (0911-NDPC) requesting EPA to issue certifications to companies whose OGI technology complies with this protocol, like the certification provided under NSPS OOOOa. Yet another commenter (0954-FLIR) suggested that third-party accreditation conducted by an independent camera manufacturer or a third-party, like National Physical Laboratory, could define an operating envelope and ensure compliance with Appendix K and allow operators to avoid an independent assessment. Still another commenter (0743-WEA) suggested that EPA allow for a generalized operating envelope to be developed for an entire operational area and note where an individual operating envelope might be necessary for a specific type of component or situation.

Response I-22-72: EPA notes that it did not issue any certifications for OGI cameras under NSPS OOOOa. Certain camera manufacturers had models of their OGI cameras tested independently and provided certifications that the cameras met the requirements outlined in NSPS OOOOa, but EPA was not involved in this process. Similarly, EPA does not intend to certify OGI cameras for Appendix K.

Section 8.0 was updated in the December 2022 Supplemental Proposal to specify that owners, operators, camera manufacturers or third parties may develop operating envelopes for OGI cameras. We note that operating envelopes must be developed initially, prior to conducting surveys with the OGI camera, but that the operating envelope may be updated or expanded at any time, even on a site-specific basis, following the procedures in section 8.0. See discussion in section VI.C of the December 2022 Supplemental Proposal related to operating envelopes.<sup>47</sup> Additionally, see discussion in section XIV.B.3 of the preamble to the final rule which details EPA’s final standards related to daily field checks in lieu of an operating envelope.

Comment: One commenter (0945/1373-JOFA) stated that the state of Michigan had indicated limited interest in working together to meet Appendix K performance verification and on-going annual auditing because of a “conflict of interest.” This leads the commenter to question what EPA proposes to allow as an equal playing field for small businesses with regard to section 8.0 of Appendix K.

Response I-22-73: Section 8.0 was updated in the December 2022 Supplemental Proposal to specify that owners, operators, camera manufacturers or third parties may develop operating envelopes for OGI cameras. This should relieve some of the burden for individual OGI operators. See discussion in section VI.C of the December 2022 Supplemental Proposal related to operating envelopes.<sup>48</sup>

---

<sup>47</sup> See 87 FR 74839-74842 (December 6, 2022).

<sup>48</sup> See 87 FR 74839-74842 (December 6, 2022).

### ***22.6.2 Operating Envelopes for Camera Models***

Comment: Commenters (0561-TRICORD, 0604-Providence, 0808-API) requested that the language in Appendix K be changed to designate operating envelope development is specific to camera model and configuration rather than to “each OGI camera” as proposed.

Response I-22-74: Section 8.3.1 of Appendix K was updated to specify that operating envelopes are developed for each model of OGI camera and each configuration.

### ***22.6.3 Configuration Concerns***

Comment: Two commenters (0954-FLIR and 0604-Providence) challenged the necessity of developing an operating envelope for every camera configuration. One commenter (0954-FLIR) argued that if configurations are similar, but one is more challenging than the other, developing an operating envelope for the more challenging configuration should satisfy both configurations; for example, developing an envelope for 10 meters would satisfy the 10-meter configuration and a 5-meter configuration. The commenter also challenged that there exist too many different configurations for OGI cameras and being asked to develop an operating envelope for each is unreasonable. The commenter stated that testing every color palette, manual level, and span mode would create too many configurations to test.

Similarly, another commenter (0808-API) believed that certain variables which could constitute a different configuration do not impact the detection ability of the OGI camera and therefore should not be considered when determining testable configurations. The commenter stated as an example that whether a camera is hand-held verses tripod-mounted verses drone-mounted is an irrelevant variable so long as the other conditions of the configuration are consistent.

Response I-22-75: In the December 2022 Supplemental Proposal, section 8.3.2 of Appendix K was revised to indicate that operating envelopes needed to be developed for any camera configuration that could impact the detection limit. EPA cannot provide a complete list of configurations that will affect the detection limit because each OGI camera model is different. The owner or operator should work in concert with the OGI camera manufacturer to determine which configurations will impact detection limits.

EPA notes that the distance example provided by the commenter is not a camera configuration, but an operating envelope parameter. While in a camera configuration, at a set delta-T and wind speed, the entity developing an operating envelope should determine the distance from which an OGI leak is visible.

See additional responses related to the final requirements for developing operating envelopes for OGI camera configurations in Volume II, Chapter 22, Section 22.5.3.

### ***22.6.4 Methane and Butane***

Comment: Several commenters (0604-Providence, 0782-BHE, 0954-FLIR) stated that the requirement to develop an operating envelope for both methane and butane is unnecessary because an operator can use documented response factors to develop the operating envelope for

one gas once an operating envelope has been developed for the other gas. The commenters suggested that an operating envelope should only need to be developed for methane as it has the lower response factor, compared to butane.

Another commenter (0808-API) requested flexibility in the requirement to test both methane and butane to develop the operating envelope. The commenter argued that in NSPS OOOOa, EPA currently requires that a camera's minimum detection be obtained using a methane/propane mixture. The commenter therefore requested that Appendix K allow for the use of either approach (methane and butane separately or a methane/butane mixture) to be acceptable for determining the operating envelope in Appendix K.

Response I-22-76: EPA notes that the development of operating envelopes is likely to be a one-time requirement for each camera model, although owners and operators do have the ability to adjust these envelopes at any time by doing further testing. Therefore, we do not consider it onerous to test for both butane and methane. While methane is less sensitive to detection for OGI cameras that operate in the 3.2-3.4 micron range, we have no empirical evidence to prove that the operating envelope for butane will always be better than the operating envelope for methane. Therefore, in the final rule EPA is maintaining the requirement to test both methane and either butane or propane during development of the operating envelope.

Additionally, in Appendix K, the gas release rates for developing the operating envelope are based on pure gases, not a mixture. Because Appendix K applies more broadly than NSPS OOOOa, it is important to verify the conditions under which an OGI camera can be used to determine leaks of methane and VOC individually, to ensure that leaks of both methane and VOC are able to be determined and that the inability to detect one compound is not masked by the ability to detect the other. Therefore, we are not adjusting the operating envelope requirement to allow a mixture of methane and butane.

#### ***22.6.5 Temperature-Controlled Background***

Comment: One commenter (0570-Konica Minolta) expressed concern over the requirement to use a temperature-controlled background encompassing approximately 50% of the field of view for the development of an acceptable operating envelope. The commenter contended that based on that requirement, if the camera was operated from a long distance, the temperature-controlled background size would need to be unreasonably large to fulfill the requirement. The commenter provided the following example: when the angle of view of the OGI camera is 24 degrees and the distance is 65 feet, then a 13-foot by 10-foot temperature-controlled background will be required.

Response I-22-77: EPA acknowledges the commenter's concern. In general, leak surveys conducted with Appendix K should not be conducted from far distances, due to the need to view components from multiple angles and the tight grouping of components in the types of units where Appendix K will be applied. OGI camera operators should optimize camera optics when surveying from a distance so that the component(s) being observed fills a large portion of the field of view; if this is done, the temperature-controlled background should not need to be unusually large. If an OGI camera operator needs to increase distance beyond the distance of the standard operating envelope to occasionally view components, EPA has updated Appendix K to

add section 8.7, which allows expansion of the operating envelope to determine a daily viewing distance under site-specific conditions.

While EPA acknowledges the commenter's concern, no solutions were offered by the commenter on how this issue could be resolved while maintaining a controlled background such that the OGI camera's span remains steady. If an owner or operator has an alternative to this requirement for use in developing operating envelopes, the owner or operator may request an alternative test method. If appropriate, Appendix K may be amended in a future rulemaking to incorporate approved alternatives.

## **22.7 Conducting OGI Surveys**

### ***22.7.1 Interferences***

Comment: One commenter (0463-Southern Ute) requested that determinations of whether a monitoring survey is of "acceptable quality", especially determinations regarding hot backgrounds, be left to the OGI camera operator's best judgment. The commenter noted that site-specific conditions may restrict a camera operator to a limited number of observation locations due to safety considerations or physical access limitations, which may require a camera operator to survey components with a relatively hot background. The commenter further noted that leaks can still be identified in hot backgrounds with staff trained to operate the OGI camera. Another commenter (0599-MSD) stated that although interferences from atmospheric conditions such as fog, mist, rain, and solar glint may have an impact on an OGI camera operator's ability to detect leaks, they do not fully eliminate the OGI camera operator's ability to determine the presence and location of emission points. Consequently, OGI surveys should not be prohibited during such periods of non-ideal atmospheric conditions.

Response I-22-78: EPA has not restricted camera operators from performing OGI surveys in any conditions. In section 4.0 of Appendix K, we note that there are certain conditions that may impact the quality of a survey. We maintain that this is true and recommend that these conditions be avoided to the extent possible.

### ***22.7.2 Daily Verification Check***

Comment: A commenter (0719-Opgal) remarked on the requirement in section 9.1.3 of Appendix K, stating that there is no need to use a cylinder of gas for the daily verification check because a clear thermal focus on the palm of a hand demonstrates sensitive gas detection.

Response I-22-79: Section 9.1.3 of Appendix K requires that a monitoring plan include confirmation that the OGI camera produces a live IR image using a known emissions source, such as a butane lighter or a propane cylinder. The monitoring survey protocol requires confirmation of both an emission source and temperature. Although imaging sweat evaporation off the palm of a hand is a powerful sensitivity demonstration, butane lighters are easily obtained, and a demonstration of a specific gas emission is more applicable.

Comment: Commenters (0463-Southern Ute, 0750-Flogistix, 0782-BHE, 0814-IPAA, 0911-NDPC) remarked that the monitoring plan requirements for daily verification checks and video

recording were overly burdensome. One commenter (1391-INGAA) cited video recordkeeping requirements as onerous, due to requiring multiple storage cards to save and upload footage without clear benefit. Another commenter (0782-BHE) questioned whether EPA had accurately accounted for the burden of video recordings in its cost analysis.

Some commenters generally supported the daily initial verification check (0808-API, 0831-AXPC), however, commenters (0808-API, 0814-IPAA, 0816-Montrose) objected to the requirement in proposed section 9.1.4 of Appendix K to record a video of the camera imaging a butane lighter or other validation sources as overly burdensome, costly, and unnecessary. Commenters (0808-API, 0814-IPAA) stated that it is more than adequate to simply have confirmed that the camera sees the butane lighter image as part of confirming the entire set of daily instrument requirements. One commenter (0816-Montrose) requested that EPA instead reference the daily instrument check requirements outlined for the use of OGI in the AWP; the commenter urged that removing sections 9.1 through 9.1.5 would also eliminate potential confusion from having two different daily check/verification requirements that are associated with the same activity. The commenter further expressed confidence that the manufacturer's proven daily instrument check requirements are the superior approach because they can be modified to suit new equipment without the process of redefining regulations.

One commenter (0954-FLIR) stated that daily verification checks are unnecessary for certain types of camera equipment. Specifically, the commenter asserted that if the camera used in the survey is engineered with a cold filter built onto the detector, there is no need to confirm that the OGI camera produces a live image using a known emission source, provided the camera loads successfully without error. The commenter provided a general instrument check process that can be used to ensure the camera can detect the intended compounds with the same sensitivity as when originally manufactured, including: (1) making sure that the camera powers on; (2) making sure that the camera completes the cool-down process and produces a live infrared image; (3) making sure that the camera does not report any error messages on startup; (4) making sure that the camera focuses properly, and (5) making sure that the camera is able to engage High Sensitivity Mode. The commenter requested that EPA clarify the need to emit gas during the daily verification check if the camera is engineered such that the filter cannot be removed.

Finally, one commenter (1458-IES) stated EPA should revise section 9 of Appendix K to clearly define the daily operator camera verification check.

Response I-22-80: EPA agrees it is unnecessary to record the daily verification check, as there is no requirement to record the survey itself. In the December 2022 Supplemental Proposal, EPA revised section 9.1 of Appendix K to remove the requirement to record the daily verification check.

EPA disagrees that the daily verification check is not well defined. EPA also disagrees that the daily instrument check in the AWP should be referenced in Appendix K. The approach to conducting OGI surveys is different in the AWP and Appendix K. For surveys conducted using Appendix K, because the OGI camera operator will already have established operating envelopes, there is no need to create an obligation to perform a daily distance check. EPA does not believe that having different daily checks in the AWP and Appendix K will cause confusion because the AWP and Appendix K will not both be used during the same survey. Additionally, other requirements between the AWP and Appendix K are vastly different, and as such, there is

no need to conform the daily check between the AWP and Appendix K. Furthermore, because there is nothing in the daily verification check in section 9.1 of Appendix K that is OGI camera specific and this check is only aimed at ensuring that an OGI camera is functioning as expected, EPA does not anticipate a need to revise the daily verification check in the future to suit new equipment.

EPA notes that the alternative daily verification check outlined by the commenter is similar to the daily verification check in Appendix K. Appendix K does not specify engaging particular operating modes because Appendix K is written to be generic and not all OGI cameras have the same operating modes. Additionally, because Appendix K is written generically, it is prudent to include a check that the camera can image a known emission source. Butane lighters are easily obtained and emit very little gas, and as such EPA does not consider the requirement to image a butane lighter to be burdensome or environmentally detrimental, especially when compared to the environmental consequences of conducting surveys with an OGI camera that will not be able to detect large leaks.

### ***22.7.3 delta-T Monitoring***

#### **22.7.3.1 Continuous Monitoring of delta-T**

Comment: One commenter (0604-Providence) focused on the importance of continuous monitoring of delta-T, considering this to be the fundamental element of all OGI measurements. The commenter asserts that the most important changing condition during a survey will be delta-T and recommends that Appendix K prescribe a method for continuous monitoring of delta-T throughout each OGI monitoring survey. The commenter presented an example on how the maximum detection distance for a methane leak will change considerably based on delta-T if both the leak rate and wind speed are consistent. The commenter further contended that delta-T will change with changes in both background and ambient temperatures and should thereby be recorded continuously. The commenter proposed two options for continuously monitoring delta-T.

In the first option presented by the commenter, the operating envelope can presume a minimum delta-T. That minimum delta-T will determine a maximum distance (camera model, wind speed, and other factors held constant) which can be applied throughout the survey. The operator can then conduct the survey in that operating envelope by ensuring that the minimum delta-T is met for each component surveyed while staying within the maximum distance established in the operating envelope for that delta-T. In the second option presented by the commenter, the operating envelope can consider delta-T as a variable, allowing the operator to determine the maximum distance for each component throughout the survey. In other words, the maximum distance will not be a fixed number for the entire survey. Instead, it will be determined by the delta-T based on the background for each view of the component. Components with a higher delta-T can be surveyed from a farther distance, provided the operator can determine the delta-T for each component as part of the survey. The commenter noted that the first option is simpler to implement but more restrictive than option 2, while option 2 would require implementation of the delta-T determination for each component, which could be demanding. The commenter also submitted an Excel workbook of “Data for OGI operating envelope based on the proposed minimum emission rate for methane and butane”.

Response I-22-81: EPA agrees with the commenter that delta-T is a fundamental component of OGI monitoring. In order to provide flexibility to OGI camera operators and ensure an adequate delta-T exists during surveys, the operating envelope treats delta-T as a variable. During development of the operating envelope, delta-T is varied to determine the boundaries of wind speed and distance where a trained OGI camera operator can observe a leak at a specific delta-T condition.

Comment: One commenter (0719-Opgal) noted the importance of taking the process gas temperature measurement at the correct location. The commenter emphasized that the emission gas temperature measurement should be taken near the source in the OGI frame but not right at the source. The commenter further contends that the emitted gas temperature at the point of release can be colder due to the expansion process while the temperature of the emitted gas will equalize to the ambient temperature a few centimeters away from the point of release (source).

Response I-22-82: EPA agrees with the commenter. As noted in the definition of delta-T, it is an acceptable practice in the field to assume that the emitted process gas temperature is equal to the ambient air temperature. This is due to the fact that process gas will quickly equilibrate to the ambient temperature once released. However, the commenter is correct that this does not happen immediately at the release point.

Comment: One commenter (0599-MSD) stated that when surveying in high sensitivity mode (the primary mode of many camera operators), plume movement is much more important than large delta-Ts - and plume movement is always present in a gas leak scenario due to the high-pressure gas escaping to atmosphere. The commenter contended that proper training, experience, and general operating principles are much more important and aid in effectively finding leaks.

Response I-22-83: Appendix K is written for broad applicability; it is not intended to apply only to cameras with particular operating modes. Additionally, OGI camera operators generally use more than one mode when conducting surveys, switching to the most appropriate mode based on the site conditions.

EPA disagrees with the commenter that all leaks occur at high pressure, although plume movement is an important indication of a leak. EPA agrees that proper training, experience, and knowledge of operating principles are all important elements for developing an OGI camera operator's ability to locate leaks that exist; Appendix K includes requirements for training and experience due to the importance of these elements. However, delta-T is also a fundamental concept in OGI monitoring, and as such, EPA is retaining the requirement to monitor delta-T during OGI surveys.

#### 22.7.3.2 delta-T Check Function

Comment: A few commenters (0561-TRICORD, 0719-Opgal) expressed concern over the use of a built-in delta-T check feature of OGI cameras or the use of a background temperature reading as an effective way for the operator to ensure that an adequate delta-T is present for viewing emissions. One commenter (0561-TRICORD) argued that collecting a background reading would require a second person constantly in the field to check the background each time the camera operator moves, which would make all cameras without the delta-T function too

expensive to use. The other commenter (0719-Opgal) considered the built-in camera delta-T function as manufacturer/camera specific and recommended providing more guidance to OGI camera operators who would be using a background temperature reading to ensure an adequate delta-T is present. The first commenter (0561-TRICORD) provided an example by suggesting that the background temperature reading be taken on a known and universal temperature spot like the human body.

Response I-22-84: Section 9.2.2 of Appendix K outlines the requirement for a description of how the operator will ensure an adequate delta-T is present to view potential gaseous emissions. The use of the built-in delta-T check function of OGI cameras is mentioned as an example of one way of ensuring an adequate delta-T is present. Operators may use and document other ways of ensuring an adequate delta-T is present, including using a background temperature reading in the OGI camera field of view. EPA is not limiting the methods that an OGI camera operator can use to determine an adequate delta-T exists; however, due to the importance of delta-T in OGI monitoring, the OGI camera operator must have some method for determining that an adequate delta-T exists.

Comment: Commenters (0719-Opgal, 0782-BHE) raised concerns over delta-T checks being included in the daily OGI camera functionality check. One commenter (0719-Opgal) considered the delta-T check to be a scene check and recommended not having a requirement for a delta-T check function or thermometry in the OGI camera. The other commenter (0782-BHE) suggested that thermography checks are not required for camera performance assurances and is a separate function within the camera and recommended eliminating the requirement to assess delta-T from monitoring plans.

Response I-22-85: EPA disagrees with the commenters. EPA notes that checking the delta-T check function is only required if the delta-T check function will be used to monitor delta-T during the survey. EPA considers a check of the delta-T check function as appropriate, considering the importance of delta-T in OGI monitoring.

Appendix K does not require that an OGI camera have a delta-T check function. The OGI camera operator may monitor delta-T in ways other than a delta-T check function, as long as the method for determining the delta-T is included in the monitoring plan. EPA is retaining the requirement to describe how the delta-T will be assessed in the monitoring plan, as delta-T is a fundamental component of OGI monitoring.

Comment: One commenter (0599-MSD) stated there is only one way to monitor delta-T and one camera which can do it. The commenter further stated that to fulfill this proposed requirement, an OGI camera operator must continuously concentrate on viewing a calculated number on the screen instead of focusing on visually interpreting the screen images to find potential leaks. Extensive field testing using a method which focuses on extreme delta-T limitations has led to finding less leaks, which negates its perceived advantages.

Response I-22-86: EPA disagrees with the commenter that there is only one way to monitor delta-T. Appendix K provides examples of two ways to monitor delta-T (using a delta-T check function built into the features of the OGI camera or using a background temperature reading in

the OGI camera field of view), and we acknowledge that an OGI camera operator may have additional ways of determining the delta-T.

EPA disagrees that monitoring delta-T will require the OGI camera operator to focus on a calculated number instead of interpreting the screen images to find leaks. Because delta-T is a fundamental component of OGI monitoring, the OGI camera operator must first determine that an adequate delta-T exists in the scene. Once the OGI camera operator determines that an adequate delta-T exists, the OGI camera operator does need to continuously focus on the delta-T; instead, the OGI camera operator should dwell on the scene for the required amount of time to determine if a leak is present.

#### ***22.7.4 Maximum Viewing Distance***

Comment: One commenter (0561-TRICORD) objected to the proposed requirement in section 9.2.1 of Appendix K to determine the camera operator's maximum viewing distance from surveyed components based upon wind speed and expected delta-T. The commenter questioned how the expected delta-T would be determined since delta-T varies from component to component depending on the temperature of the background and temperature of the leaking gas. Another commenter (0599-MSD) concurred, stating that delta-T is highly variable even at a single facility, and it is not possible to have a single "expected delta T".

Response I-22-87: EPA agrees with the points made by the commenters and has revised Appendix K to remove this requirement, except where an OGI camera operator will be using section 8.7 of Appendix K to establish a maximum viewing distance using a daily field check.

#### ***22.7.5 Dwell Time***

##### ***22.7.5.1 Length of Dwell Time***

Comment: Some commenters (0463-Southern Ute, 0599-MSD, 0718-Tora, 0814-IPAA, 0916-AOGA, 0954-FLIR) stated that a 5 second required dwell time per component is unnecessary or too long and pointed to both operator experience and increased survey time and cost with no corresponding benefit as reasons for this stance. One commenter (073-WEA) noted that this dwell time is especially inappropriate in an upstream setting. Commenters (0743-WEA, 0749-PAW, 0924-SBA) stated that Appendix K's dwell time and required rest requirements would increase the time to complete a survey or its cost by 2 or 3 times. Commenters (0749-PAW, 0814-IPAA) argued that OGI monitoring is valuable because of its time savings, cost savings, and rapid leak detection characteristics and the Appendix K requirements would nullify these characteristics. Another commenter (0570-Konica) concurred that in practical use, it is often possible to identify the leak source in a shorter amount of time, even in a larger monitoring area, and the commenter was concerned the new requirement might hinder an OGI camera operator's efficiency. The commenter requested EPA review the dwell time conditions, considering the current usage of OGI camera and its performance.

Commenters (0743-WEA, 0749-PAW) maintained that dwell times can be highly variable and prescribing exact requirements is not feasible. Another commenter (0817-GPA) agreed, arguing that viewing components individually from at least two different angles for a total of ten seconds at a model site of 1,800 components would result in the survey time for a single facility being

five hours. The commenter warned that time spent on OGI monitoring will increase substantially when all additional factors of Appendix K (including an additional break time, calibration time, travel time, audit requirements, and increased frequency of monitoring) are considered. Two commenters (0808-API and 0814-IPAA) suggested the prescriptive dwell time is overly restrictive and rigid and dwell time should be left to the discretion of the operator. One of the commenters (0808-API) further argued that experienced operators know how much dwell time is appropriate for each situation and guidance is unnecessary. Other commenters (0599-MS, 0743-WEA, 0831-AXPC) pointed out that EPA has not provided any explanation for the dwell time requirement or that implementing this requirement would result in the identification of more leaks, reduction of more emissions, or improvement of OGI camera operator performance.

Once commenter (0743-WEA) believed the dwell time would end up having unintended negative consequences that are contrary to the Administration's objectives. The commenter is working to continuously improve facility designs, including adding automation, eliminating tanks where they are not necessary, and designing separation stages to capture as much gas as possible most efficiently. The commenter noted that many of these modern designs require the installation of additional components (valves, controllers, gauges, connectors), and by requiring facilities with many components to include extended dwell times for each component, EPA is inadvertently disincentivizing innovation in facility design and emissions mitigation. The commenter suggested that EPA clarify that the dwell time for multiple components can be completed concurrently.

One commenter (0816-Montrose) supported another commenter's (0954-FLIR) view that the dwell times proposed in section 9.4 are very arduous and contradict the reasoning for ensuring operators are trained, as detailed in section 10 of Appendix K. The commenter (0816-Montrose) further stated that experienced operators only need 3 seconds per scene to evaluate for leaks. This commenter stated the Texas Council on Environmental Quality recently agreed that a three second dwell time is acceptable. The commenter pointed out that requiring a minimum dwell time of 5 seconds and requiring operators to view components from a minimum of 2 angles would considerably increase survey times which could in turn make surveying more expensive. The commenter provided the following example: a technician following current industry standards and utilizing dwell times of 3 seconds per scene with multiple angles can finish a 7,000-component facility in an average time of 5.5 hours; by comparison, Appendix K would require 70,000 seconds or 19.4 hours of dwell time, which is estimated to increase survey cost from \$1,265 to over \$5,000. Another commenter (0599-MS) provided a different example: an average Pennsylvania well pad may include 2,500 fugitive components, which can be effectively imaged using NSPS OOOOa procedures in approximately 1.5 hours; by comparison, Appendix K would require seven hours to complete the same survey (not counting any additional time for initial procedures or leak repair efforts). The commenter recommended removing the dwell time requirement.

Other commenters also supported the concept of dwell time on a scene basis. One commenter (0782-BHE) stated that if the dwell time provision or any part is retained the requirement should be scene-based and not component based. Other commenters (0816-Montrose, 0954-FLIR) recommended that dwell time be on a scene basis, not a per component basis, and it should account for the level of operator as a factor. Another commenter (0599-MS) stated the burdensome nature of requirements related to "dwell time" cannot be overstated; common

practice is to find a single leaking component within a cluster of components and then locate the actual egress point by simply moving closer at various points within the area until the leak is identified. A different commenter (0561-Tricord) also stated that imaging on a component-by-component basis is impractical and takes more time than EPA Method 21. The commenter stated that the 5-second dwell time ought to apply to all the components in the camera's field of view.

Response I-22-88: In the December 2022 Supplemental Proposal, section 9.4.1 of Appendix K was amended to reflect a 2 second dwell time per component in the field of view instead of 5 seconds per component in the field of view. See discussion in section VI.B.4. and VI.C. of the December 2022 Supplemental Proposal.<sup>49</sup>

Additionally, in response to comments received on the December 2022 Supplemental Proposal, EPA has continued to refine the dwell time requirements in Appendix K. See discussion in section XIV.B.1 of the preamble to the final rule, which details EPA's final standards related to dwell time.

Also, in response to the comments received on the November 2021 Proposal, EPA proposed a different regulatory approach for fugitive emissions from well sites, centralized production facilities, and compressor stations in the December 2022 Supplemental Proposal. For details, please see discussion in section IV.A.1.a.ii and IV.A.2.A of the December 2022 Supplemental Proposal related to fugitive emissions from well sites, centralized production facilities, and compressor stations.<sup>50</sup>

#### 22.7.5.2 Table 14-1

Comment: One commenter (0817-GPA) stated that section 9.4 of Appendix K requires camera operators to survey each component for five seconds per viewing angle, providing an example of five components requiring 25 seconds of dwell time; Table 14-1, however, states that five components would be monitored in 10–20 seconds, depending upon the monitoring area, which is much more reasonable. The commenter stated that in view of this apparent inconsistency, the EPA should clarify the dwell time it is proposing and explain the basis for the proposed dwell time so stakeholders may assess the rationale, as no explanation is provided in the proposal.

Response I-22-89: In the December 2022 Supplemental Proposal, section 9.4.1 of Appendix K was amended to reflect a 2 second dwell time per component in the field of view instead of 5 seconds per component in the field of view. See discussion and rationale in section VI.B.4. and VI.C. of the December 2022 Supplemental Proposal.<sup>51</sup>

Additionally, in response to comments received on the December 2022 Supplemental Proposal, EPA has continued to refine the dwell time requirements in Appendix K. See discussion in section XIV.B.1 of the preamble to the final rule, which details EPA's final standards related to dwell time.

---

<sup>49</sup> See 87 FR 74839-74841 (December 6, 2022).

<sup>50</sup> 87 FR 74722-74736 and 74739 (December 6, 2022).

<sup>51</sup> See 87 FR 74839-74841 (December 6, 2022).

Comment: One commenter (0604-Providence) suggested that the monitoring area requirement for the field of view be removed, and dwell time be determined by the number of components alone. The commenter pointed out that requiring a specific viewing area would be overly restrictive and does not account for practical considerations like the type of camera lens used or the complexity of the scene. The commenter stated the requirements for the operating envelope would likely guide operators to establish suitable distances from components, thus rendering the required viewing areas to be redundant and possibly in conflict with the operating envelope. The commenter further noted the intention of Table 14-1 is to increase dwell time when the scene is more complex and/or contains more components and recommend that EPA consider simply specifying dwell time based on the number of components regardless of the size of the monitoring area. The commenter stated that this could be further refined by defining the scene as “simple” or “complex” with dwell time increased for “complex” scenes; example of a simple scene may include a tank with a minimum number of pipes while an example of a complex scene may include a highly congested area with many pipes and components.

Another commenter (0782-BHE) noted that EPA has not defined the term “monitoring area” and as written, the following footnote in Table 14-1 may arbitrarily restrict the viewing distance from a source to approximately 10.5 feet using a 25-millimeter lens. The commenter argued this may eliminate the distinct OGI advantages for screening leaks from elevated sources or vents irrespective of the number of components in the scene. The commenter suggested test data and the basis for this restriction of the largest monitoring area to less than one square meter irrespective of the number of components in the subsection may be lacking and unfounded. The commenter further noted the term subsection is not defined and confusing in this context.

Response I-22-90: In the December 2022 Supplemental Proposal, section 9.4.1 of Appendix K was amended to reflect a 2 second dwell time per component in the field of view instead of 5 seconds per component in the field of view. See discussion and rationale in section VI.B.4. and VI.C. of the December 2022 Supplemental Proposal.<sup>52</sup>

Additionally, in response to comments received on the December 2022 Supplemental Proposal, EPA has continued to refine the dwell time requirements in Appendix K. See discussion in section XIV.B.1 of the preamble to the final rule, which details EPA’s final standards related to dwell time.

Comment: One commenter (0604-Providence) found Table 14-1 to be unrealistic in its definition of monitoring areas. The commenter believed that the table outlines unrealistic scenarios where the number of components to the specified areas would never occur in real world environments, thus rendering the table unusable. Other commenters (0782-BHE, 0814-IPAA, 0911-NDPC) disputed the necessity of Table 14-1, arguing that it is arbitrary, does not have a credible source attributed to it, and therefore seems inappropriate to require. One commenter (0782-BHE) stated that if the table is retained, this table and the one paragraph of discussion that follows it would likely be more suitable for inclusion and expanded upon in section 9 of Appendix K.

Another commenter (0718-Tora) argued that Table 14-1 establishes an effective maximum viewing area of 1 square meter, which would make OGI monitoring impossible, and requiring

---

<sup>52</sup> See 87 FR 74839-74841 (December 6, 2022).

operators to consult Table 14-1 during surveying would be technically infeasible. The commenter critiqued the depth of components requirement for the use of Table 14-1 to be arbitrary and unnecessary and possibly unsafe since it requires operators to have to navigate complex component systems to establish the appropriate depth.

One commenter (0782-BHE) recommended the elimination of Table 14-1 as it presents requirements that will be an unenforceable and inefficient burden on the leak survey process. The commenter contended that Table 14.1 is not referenced or discussed elsewhere in Appendix K and contains unintended OGI restrictions for screening leaks. A second commenter (0599-MSD) supported elimination of Table 14.1 because the requirements are inconsistent with what experienced camera operators would do and not technically feasible due to the requirement to continuously measure distance and count components to determine the applicability of the table. Another commenter (0561-TRICORD) recommended EPA change the title of Section 14 because this protocol does not include any Diagrams of Flow Charts.

Response I-22-91: In the December 2022 Supplemental Proposal, section 9.4.1 of Appendix K was amended to reflect a 2 second dwell time per component in the field of view instead of 5 seconds per component in the field of view. See discussion and rationale in section VI.B.4. and VI.C. of the December 2022 Supplemental Proposal.<sup>53</sup>

Additionally, in response to comments received on the December 2022 Supplemental Proposal, EPA has continued to refine the dwell time requirements in Appendix K. See discussion in section XIV.B.1 of the preamble to the final rule, which details EPA's final standards related to dwell time.

#### 22.7.5.3 Other Dwell Time Comments

Comment: One commenter (0599-MSD) stated that holding the camera "steady" is often a poor practice for finding leaks with an OGI camera, particularly in high sensitivity mode. It is often much better to "pan" or slowly move the camera across a scene, to avoid screen flickering and aid in seeing plume movement.

Response I-22-92: EPA disagrees with the commenter. While initially panning a scene can provide detection of certain leaks quickly, to see movement on the screen and ensure all leaks are found, the scene on the screen needs to be held steady, even in an enhanced or high sensitivity mode.

#### **22.7.6 Rest Breaks**

Comment: Several commentors (0599-MSD, 0718-Tora, 0749-PAW, 0750-Flogistix, 0782-BHE, 0808-API, 0814-IPAA, 0816-Montrose, 0817-GPA, 0954-FLIR, 0945/1373-JOFA) believed a prescribed break schedule is unnecessary and should not be defined in Appendix K. These commenters pointed out that OGI camera operators do not look through their cameras for 20-minute stretches and therefore do not require section 9.5 to outline breaks for eye fatigue. Commenters stated that rest breaks should be left up to the OGI camera operator's discretion. One commenter (0599-MSD) noted that operator fatigue is unique to each OGI camera operator

---

<sup>53</sup> See 87 FR 74839-74841 (December 6, 2022).

and survey situation. The commenter stated that generally, the OGI camera operator is not continuously surveying from a fixed location for an extended period, thus the OGI camera operator has frequent small survey breaks moving from location to location. One commenter (0831-AXPC) stated that there is no generic or efficient approach for avoiding operator fatigue that would not interfere with the execution of the survey and recommend that all but the first sentence of section 9.5 be deleted.

One commentor (0749-PAW) argued that proper field training, which is required in Appendix K, would already include discussions about operator fatigue and rest break frequency. Other commentors (0793-PBPA, 0945/1373-JOFA) stated experienced camera operators know when to take breaks without Appendix K guidance, and the decision to take a break should be left to the OGI camera operator, with one commenter (0793-PBPA) pointing out that a 20-minute break requirement is arbitrary. A third commenter (0814-IPAA) noted that prescribed rest breaks are unjustified and insulting to small businesses and individuals that purchased OGI cameras, suggesting that senior level camera operators are not capable of defining specific rest intervals based on experience, training, and physical conditioning and implying that all OGI camera operators have similar operating limitations. Two commentors (0749-PAW, 0782-BHE) stated that requiring frequent breaks would add to the time needed to perform surveys, leading to greater costs.

Two commenters (0814-IPAA, 0945/1373-JOFA) further questioned how EPA is proposing to level the playing field for sole proprietorship companies that cannot meet the proposed requirement of having 2 camera operators, as proposed in Section 9.5, when engaged in continuous monitoring. The commenters stated this requirement is highly discriminatory and would likely prohibit senior level certified small business camera operators from conducting large facility inspections. Another commenter (0793-PBPA) noted that having 2 camera operators for a survey is not always feasible and will be cost prohibitive for small operators.

Two commenters (0561-TRICORD, 1391-INGAA) argued that 20 minutes between breaks is too short of a time window. One commenter (0561-TRICORD) recommended a 30-minute interval instead of 20 minutes. Another commenter (0814-IPAA) stated EPA does not define what constitutes a "break." The commenter noted that on most occasions, OGI camera operators survey for leaks at 1-3 minutes intervals from a fixed location prior to moving to another fixed location to scan the same components from a second angle; the commenter questioned whether this constitutes a break.

Response I-22-93: In the December 2022 Supplemental Proposal, EPA revised section 9.5 of Appendix K to increase the surveying interval prior to taking a break to 30 minutes. See discussion in section VI.B.5 of the December 2022 Supplemental Proposal.<sup>54</sup>

EPA notes that section 9.5 allows performing other survey related tasks besides "actively imaging components" as a break, such as documenting leaks found. This would also allow operators to stay productive during their break and would not impede the overall survey length.

---

<sup>54</sup> See 87 FR 74839 (December 6, 2022).

EPA disagrees that a mandated rest break is unnecessary. The language for rest breaks that was put into the November 2021 Proposal was derived from EPA Method 9, which is another visual observation method. EPA determined it was appropriate to add a similar requirement for Appendix K because both mental and eye fatigue are known issues that occur with prolonged viewing of components with an OGI camera. Such fatigue may be a safety hazard, and it may also prevent the OGI camera operator from finding leaks that are present.

EPA acknowledges natural breaks will occur at regular intervals when an OGI camera operator moves between process units or process levels and notes that rest breaks are only required if these natural breaks do not occur frequently enough such that the OGI camera operator is continuously surveying for more than 30 minutes. EPA encourages OGI camera operators to take longer or more frequent rest breaks as needed to reduce the incidence of fatigue.

### ***22.7.7 Monitoring Plans***

Comment: Commenters (0718-Tora, 0782-BHE, 0808-API, 0831-AXPC) questioned the requirements for each “site” to prepare monitoring plans and procedures. One commenter (0782-BHE) noted that requiring individual site monitoring plans is overly burdensome and encouraged EPA to permit operators to develop a single monitoring plan for components at multiple locations. Similarly, commenters (0718-Tora, 0808-API, 0831-AXPC) requested that the requirements not be based on a site or be site-specific. One commenter (0808-API) stated that EPA should clarify that a copy of the plan is not required to be maintained at every site; the commenter pointed out that a monitoring plan is developed centrally and would be available electronically to operators when monitoring a specific site.

Response I-22-94: In the December 2022 Supplemental Proposal, EPA added clarification that a monitoring plan can encompass multiple sites, as long as the relevant information for each site is included in the monitoring plan. EPA also updated other wording in section 9 to refer to the monitoring plan instead of to the site.

EPA notes that Appendix K does not require that records be kept at a particular site; instead, Appendix K states that these records must be retained and easily accessible.

Comment: One commenter (0782-BHE) requested EPA eliminate the monitoring plan reference and requirement from section 9.8 of Appendix K or reword it to state that the survey should follow the monitoring plan QA/QC procedures in conformance with section 11.0.

Response I-22-95: EPA disagrees with the commenter. Section 9.8 is part of what is required in a monitoring plan, so the reference to the monitoring plan cannot be removed from this requirement. Section 9.8 requires the monitoring plan to describe the QA/QC process that will be used to ensure valid monitoring data. EPA does not agree that there is a need to reword this requirement.

### ***22.7.8 Daily QA Videos***

Comment: Several commenters (0463-Southern Ute, 0561-TRICORD, 0599-MSD, 0604-Providence, 0782-BHE, 0808-API, 0814-IPAA, 0816-Montrose, 0817-GPA, 0831-AXPC,

0945/1373-JOFA, 0954-FLIR) specifically posed that the 5-minute quality assurance video required by the monitoring plan is an unnecessary burden and requested that EPA remove this requirement. Commenters (0599-MSD, 0808-API, 0954-FLIR) asserted the training, daily check, and audit requirements within the rule would ensure survey quality, making the QA video requirement unnecessary and redundant. One commenter (0750-Flogistix) remarked that the verification check requirements are too complicated and burdensome for small facilities, such as small oil and gas producers. A third commenter (0463-Southern Ute) noted that for many simple well sites, the QA video could take longer than the actual monitoring survey, and a simple confirmation that the requirements of section 9.1 are met should be sufficient.

Commenters (0808-API, 0831-AXPC) stated that is unclear how a video clip would show compliance with the procedures that Appendix K specifies (e.g., dwell times, angles, distances, backgrounds), the camera configuration, or the operating envelope criteria. Other commenters (0814-IPAA, 0945/1373-JOFA) noted the documentation of specific procedures used for the QA verification video monitoring requirements (e.g., dwell times, angles, distances, backgrounds) in the monitoring plan will change based on individual site-specific requirements. One commenter (0808-API) further contested that video of OGI camera operators who know they are being videoed is unlikely to be representative. Commenters (0911-NDPC, 0954-FLIR) noted that a daily video requirement has not been required for prior technologies, including EPA Methods 9, 21, and 22.

One commenter (0782-BHE) pointed out a conflict between the requirements on the amount of time for daily QA videos in section 9.7.3 (five minutes) versus section 11.2 (5-10 seconds of video). Commenters (0782-BHE, 0954-FLIR) noted that if the QA video requirement is retained, the shorter time of 5-10 seconds is adequate.

One commenter (0911-NDPC) explained that video recordings may be infeasible; the commenter stated that companies with multiple sites generally have one monitoring plan that covers all sites, with separate site-specific information (e.g., walking paths) included, and many companies prohibit walking while viewing through a camera due to safety considerations. The commenter urged that companies should be allowed to define their own QA/QC procedure in their monitoring plans. Another commenter (0814-IPAA) proclaimed that the 5-minute video requirement would substantially reduce the life of the camera and require unnecessary and costly maintenance and replacement. The commenter further stated that section 9.7.3 would require massive amounts of data storage over the 5-years of recordkeeping requirements, and the necessary documentation of procedures the OGI camera operator uses will change based on individual specific site requirements.

One commenter (0808-API) further asserted that the QA video would require extensive video records that are difficult to reliably store, provide no useful information, are unlikely to ever be reviewed, and would be overly burdensome. Another commenter (0911-NDPC) stated that the videos would provide no value to the operator and will be a great burden to retrieve, review, and transfer if requested by state agencies or EPA. Commenters (0814-IPAA, 0945/1373-JOFA, 0954-FLIR) expressed concern that EPA has underestimated the burden of storing video files; one commenter (1391-INGAA) specifically stated the QA video would require multiple SD cards to save and upload footage, without clear benefit. Another commenter (0954-FLIR) noted the 5-minute video would require approximately 75 megabytes of storage; assuming an OGI

camera operator works five days a week for forty weeks or more a year, this would result in over 15 gigabyte of storage capacity for a single operator annually. One commenter (0808-API) provided as evidence examples of data storage issues associated with 40 CFR part 63, subpart CC, which requires recordkeeping of photos taken of a flare every 15 seconds. The commenter noted that for at least one company operating several refineries, the flare images are not stored on a cloud, but are saved locally on a server, primarily for security. The commenter pointed out that facilities could experience data loss due to power outages or other technical issues associated with handling the sheer volume of images.

Some commenters (0561-TRICORD, 0604-Providence) recommended that in lieu of a 5-minute video, EPA adopt a 1-minute video to record the imaging procedure to alleviate storage concerns; one commenter (0561-TRICORD) suggested that this could be taken quarterly instead of daily. Another commenter (0816-Montrose) supported recordings of surveys and suggested language for retaining a video of surveys (including documentation of fugitive emissions or found leaks) for a minimum of three years; the commenter suggested that three years of bimonthly OGI surveys from a typical facility could be stored on a 2-terabyte external hard drive (costing approximately \$50) and would eliminate the need for a five-minute QA video.

Response I-22-96: EPA considers the requirement for a daily QA video a reasonable alternative to requiring full survey videos. While we agree that it is not necessary to keep a full video of a monitoring survey, it is important to be able to assess each OGI camera operator's technique when reviewing survey records, as the ability to find leaks that are present is dependent on the camera operator's technique. The daily QA video allows someone who is not present for the survey to determine whether an OGI camera operator uses proper technique on a day-to-day basis. This documentation is especially important for a delegated agency to have available in their review of OGI survey records and to assess whether Appendix K is being properly implemented. EPA notes that if an OGI camera operator does keep a video of the full survey, this can also be used to satisfy the requirement for a daily QA verification video.

EPA acknowledges that there is no video requirement in EPA Methods 9, 21, and 22. However, there are no requirements involving a camera in those EPA methods, and as such, it would not make sense to require a recording of the instrumentation. OGI surveys are performed with a camera, and an operator only needs to hit the record button to record a survey. This is analogous to writing down the readings taken with an EPA Method 21 analyzer or noting the opacity read by the observer's eye in EPA Method 9.

EPA disagrees that video recordings are infeasible. EPA does not encourage OGI camera operators to survey or record video during times when they are walking, and we are only requiring video to be taken when an OGI camera operator is actively conducting a survey. EPA also disagrees that recording video reduces the lifespan of an OGI camera; no data was submitted to substantiate this claim. Recording some or all footage of an OGI survey is a practice used by many OGI camera operators and is a requirement for those owner and operators complying with the AWP. OGI camera operators performing surveys under the AWP have not provided EPA with any evidence that the recording requirement has reduced the lifespan of their OGI cameras.

EPA does not consider a 5-minute video clip cost prohibitive, even if the video clip is taken daily. According to one commenter, the average size of a 5-minute OGI video clip is 75 megabytes; if a clip is taken each business day of the year, this will equate to just under 20

gigabytes of data. Cloud storage of files generally runs in the range of \$5-\$10 for a terabyte of storage, or as one commenter noted, a 2-terabyte external hard drive costs approximately \$50. EPA does not consider these storage costs to be cost prohibitive. EPA notes that data loss is a potential issue for any recordkeeping requirement, and it not unique to the recordkeeping requirements within Appendix K.

Regarding the suggestion to change the duration of this video requirement, EPA disagrees with the commenters. The intent of the QA video is to evaluate the OGI camera operator's survey process, not to document that the QA verification tasks in section 9.1 of Appendix K have been completed. Nor is there conflict between the video requirements for documenting leaks and the QA video requirement. The QA video requirement is meant to document the OGI camera operator's survey technique, and should include periods where there are no leaks, not just periods where there leaks. Additionally, we do not consider 1 minute of video enough time to assess the technique of an OGI camera operator. As one commenter implied, OGI camera operators who know the survey is being recorded are likely to change their survey technique during that period; however, it is more difficult to maintain a different technique for 5 minutes than for just 1 minute. Requiring a longer QA video will encourage the OGI camera operator to maintain the proper technique throughout the survey and is more likely reveal instances where an OGI camera operator does change techniques for the QA video. As such, we are retaining the length of the QA video as 5 minutes.

Also, in response to the comments received on the November 2021 Proposal, EPA proposed a different regulatory approach for fugitive emissions from well sites, centralized production facilities, and compressor stations in the December 2022 Supplemental Proposal. For details, please see discussion in section IV.A.1.a.ii and IV.A.2.A of the December 2022 Supplemental Proposal related to fugitive emissions from well sites, centralized production facilities, and compressor stations.<sup>55</sup>

### ***22.7.9 Monitoring Regulated Components***

Comment: One commenter (0782-BHE) urged that all three options for demonstrating the entire facility is included in the survey in section 9.3 of Appendix K are overly onerous, unjustified, and unsupported; the commenter pointed to EPA Method 21, noting that the standard does not place a restriction on route path or GPS tracking. The commenter explained that the requirement to include GPS route tracing to track survey paths would be burdensome and may further complicate path corrections or adjustment due to facility activities (e.g., safety, access during unit maintenance, etc.) or weather events. The commenter also questioned whether the costs and labor for this provision was adequately considered.

Two commenters (0808-API, 0831-AXPC) suggested that section 9.3 be replaced in its entirety with the language in NSPS OOOOa. One commenter (0808-API) explained that the three proposed approaches appear to be written for larger operations with multiple monitoring locations and significant resources. The commenter remarked that many locations subject to the current rule are smaller facilities or portions of a facility, where monitoring would require one pair of observations or at the most a few observations, and the current requirements would

---

<sup>55</sup> 87 FR 74722-74736 and 74739 (December 6, 2022).

impose burdensome and repetitive route maps, maintenance of location markers, or identification of GPS coordinates for these smaller sources.

Other commenters (0814-IPAA, 0945/1373-JOFA) urged that the survey techniques should have the flexibility to meet the needs of the producer and should allow for modifications for business size and staff, communication ability (in remote areas), availability of on-site maintenance staff, and fluctuations in daily operational agendas.

Some commenters (0808-API, 0814-IPAA) recommended an additional fourth option that could apply to facilities where less than 25 monitoring observations points are needed to monitor all components regulated by a referencing subpart or permit. The option would allow the monitoring plan to include a description of the approach used (e.g., monitoring all components from two views at least 90 degrees apart) and a list of the facilities or facility locations to which the option applied. Another commenter (0831-AXPC) supported the same option but applied it to facilities where less than 10 monitoring points are needed to monitor all components.

Commenters (0808-API, 0831-AXPC) implored that EPA should at least allow a mix of the current options provided all components are monitored; the commenters asserted that for larger facilities or facilities with a mix of densely located components and remote locations, a mix of the options would be most efficient.

Commenters (0808-API, 0831-AXPC) also asserted that the route maps, GPS coordinates, and site lists required by section 9.3 are laborious and requested that these records be allowed to be kept in electronic form and not “included as part of the monitoring plan”. One commenter (0831-AXPC) suggested including a description of the walking path instead of specific observation paths. Conversely, another commenter (0561-TRICORD) stated that it would not be sufficient to simply have a map with observation locations marked on it, but that there would have to be corresponding markers (e.g., signage) as suggested in section 9.3.2, placed in the field to accurately align the camera operator with the map’s observation points.

Commenters (0808-API, 0831-AXPC) also requested that EPA should clarify that a component database is not required. One commenter (0599-MSC) noted the use of a component database for an OGI-based LDAR program is inappropriate and negates one of the major advantages of OGI.

Response I-22-97: EPA disagrees that the three options presented in section 9.3 of Appendix K are overly burdensome and unnecessary. The purpose of section 9.3 is to ensure that the OGI camera operator will image all regulated components; this is especially important as there is no requirement for a video record of the survey. In an EPA Method 21 based LDAR program, owners and operators generally note the reading for each component, thus showing that each component is monitored; there is no analogous requirement for an OGI survey unless a video record is stored. In lieu of requiring video records in Appendix K, EPA is requiring a choice of different approaches that must be implemented to ensure all regulated components are monitored.

EPA disagrees that the language from NSPS OOOOa should be written into Appendix K. NSPS OOOOa applies to well sites and compressors stations. These are generally small sites with few regulated components, making it easier to ensure that all regulated components are imaged by

the OGI camera during a survey. Appendix K is intended to apply to a range of sites, including very large industrial facilities with hundreds of thousands of regulated components, where it will be much more difficult to view all regulated components without prior planning on how this will be accomplished. As such, EPA has determined that it is important that owners and operators choose from a set of prescribed techniques to show they are viewing all regulated components.

Commenters did not provide information on why smaller sites (with less than 10 or 15 monitoring points) could not use one of the approaches already listed in section 9.3 of Appendix K or why these approaches are burdensome for a small site. Additionally, commenters did not provide information on what type or approach these sites might use instead of the approaches listed in section 9.3. Commenters also did not provide information on why a description of a walking path is less burdensome than providing the specific observation path with observation points marked. EPA considers this alternative less desirable to achieving the desired goal of ensuring all regulated components are imaged, as an OGI camera operator may not know all the required observations points from a written description of a walking path. Additionally, it is much easier and quicker for an OGI camera operator to look at a map than to read a written description.

EPA disagrees that having a map with observation locations marked on it is not sufficient for determining that an OGI camera operator has viewed all regulated components. If an owner or operator also has corresponding markers in the field to accurately align the camera operator with the map's observation points, we encourage these extra measures, as well as any other extra measures taken by the owner or operator to ensure all regulated components are monitored.

In the December 2022 Supplemental Proposal, EPA clarified in section 9.3 that owners and operators may use a combination of the listed methodologies. Additionally, EPA clarified in section 12.1 that records (including the monitoring plan) may be kept in hard copy or electronic form. EPA agrees with commenters that Appendix K itself does not require a component database; reference to a component database was removed from section 9.3 in the December 2022 Supplemental Proposal.

EPA acknowledges that EPA Method 21 does not place restrictions on a route path or GPS tracking. However, LDAR programs that use EPA Method 21 generally have intensive recordkeeping requirements, including component databases. Section 9.7.3 of Appendix K is meant to replace this requirement while still ensuring that all regulated components are imaged by the OGI camera.

EPA is not currently aware of another approach that would effectively ensure an owner or operator monitors all components regulated by a referencing subpart. If an owner or operator develops a new methodology that can achieve this goal, the owner or operator may submit a request for alternative monitoring procedures under 40 CFR 60.13(i) or 40 CFR 63.8(f), as applicable. Additionally, when Appendix K is applied to a specific subpart through a rulemaking, commenters may request that additional methodologies be added for use of Appendix K in that subpart.

Also, in response to the comments received on the November 2021 Proposal, EPA proposed a different regulatory approach for fugitive emissions from well sites, centralized production facilities, and compressor stations in the December 2022 Supplemental Proposal. For details, please see discussion in section IV.A.1.a.ii and IV.A.2.A of the December 2022 Supplemental Proposal related to fugitive emissions from well sites, centralized production facilities, and compressor stations.<sup>56</sup>

Comment: One commenter (0945/1373-JOFA) included a 10-step guide for survey techniques. The steps provided by the commenter include the camera operator performing beginning-of-day and field calibration verification using Eastern Research Group, Inc's "Disposable Lighter Mass Emissions Study" to confirm the OGI camera's operational capability; identification of leaks using the high sensitivity mode with the correct temperature alignment to control ambient background temperature interference; flagging and marking the exact component leak location and date of detection; documentation of leaks via digital OGI photograph and specifics of the leak (e.g., component type, location of the leak) in a field book; communicating the field notes to the operations or maintenance manager at the end of each facility survey or survey day; where no leak is found, documenting via high-quality photograph with the OGI camera that a survey was completed; conducting end-of-day field calibration verification; and creation of a detailed report capturing location, weather conditions, found leaks, repair dates, etc.

Another commenter (0814-IPAA) noted that EPA commissioned the Eastern Research Group, Inc. a couple of years ago to develop a quick calibration field protocol meant to allow quick calibration and verification of the camera. The resulting "Disposable Lighter Mass Emissions Study" was approved by the EPA for use and required the calibration and verification technique be conducted at the beginning and end of each survey day. The technique involved a 13 to 19 second video using a butane lighter to capture a video using each camera setting. The commenter stated this technique is efficient and effective, and a senior level certified OGI operator member of the group indicated that EPA field staff stated this methodology was created because EPA inspectors often fly to various areas and couldn't find the necessary equipment to conduct the original calibration and verification requirements. Allowing this technique to continue would allow EPA inspectors and private OGI camera operators to fly, rental car, stop at any gas station, buy a lighter, and easily conduct a calibration and verification in the field. The proposed regulations in Appendix K will create a similar situation which would complicate both the EPA's field staff ability to meet their own rules and prohibit private OGI camera operators from completing EPA required monitoring for oil and gas facilities.

Response I-22-98: EPA acknowledges the information provided by the commenters. The daily field verification check in Appendix K can be performed with a butane lighter, and as such, we disagree that the procedure complicates the ability of EPA field staff or OGI camera operators to meet the requirements in Appendix K nor does this field check vary significantly from current field practice.

---

<sup>56</sup> 87 FR 74722-74736 and 74739 (December 6, 2022).

EPA made substantial edits to Appendix K in response to comments in the December 2022 Supplemental Proposal. See discussion in section VI of the December 2022 Supplemental Proposal for information related to the changes made to Appendix K.<sup>57</sup>

## **22.8 Records and Reporting**

### ***22.8.1 Excessively Burdensome and Costly Requirements***

Comment: Several commenters (0749-PAW, 0750-Flogistix, 0777-Ascent, 0782-BHE, 0808-API, 0831-AXPC, 0911-NDPC, 1391-INGAA) stressed the importance of carefully evaluating the amount of additional recordkeeping burden required in Appendix K, especially regarding small businesses and the current NSPS OOOOa requirements. Commenters stated that additional monitoring plan, recordkeeping, performance auditing, and prescriptive OGI camera operating requirements would add unnecessary cost and nearly eliminate the advantages of using OGI cameras over EPA Method 21. One commenter (1391-INGAA) stated that the viewing and recordkeeping requirements should be simplified and streamlined. Another commenter (0749-PAW) noted that facilities will incur other indirect costs due to the need for additional monitoring plan and recordkeeping requirements to implement Appendix K; the commenter urged EPA to address this additional documentation in evaluating the burden and cost-effectiveness of the rule. A commenter (0777-Ascent) asserted that the additional requirements of Appendix K will require that owners, operators, and OGI contractors dedicate significantly more time away from actual monitoring surveys.

Response I-22-99: EPA made substantial edits to Appendix K in response to comments in the December 2022 Supplemental Proposal, including revisions to the recordkeeping requirements. See discussion in section VI of the December 2022 Supplemental Proposal for information related to the changes made to Appendix K.<sup>58</sup>

### ***22.8.2 Ownership of Records***

Comment: Multiple commenters (0463-Southern Ute, 0782-BHE, 0808-API) raised concerns regarding ownership of various records and requested flexibility in who, where, and how records are maintained. Some commenters (0808-API, 0831-AXPC) asserted that, as written, the ownership of various requirements was unclear; one commenter (0808-API) asserted that the information required is not site-specific and may be generic for a particular camera or monitoring approach. Commenters (0808-API, 0831-AXPC) requested that EPA either reconsider assigning requirements to the site or provide flexibility to allow facilities to assign responsibility to reduce unnecessary or duplicative requirements.

Commenters (0808-API, 0831-AXPC) stated that there are requirements assigned to the site that could fall under the responsibility of a contract monitoring organization and therefore could apply at multiple sites. These commenters (0808-API, 0831-AXPC) provided as an example the development of procedures that describe how components will be viewed with the OGI camera (section 9.4) and the requirement to have a plan for avoiding camera operator fatigue (section

---

<sup>57</sup> 87 FR 74837-74842 (December 6, 2022).

<sup>58</sup> 87 FR 74837-74842 (December 6, 2022).

9.5). One commenter (0808-API) suggested that to reduce confusion rather than trying to list who should be responsible for each procedure in section 9, the requirements should be reworded to simply identify the monitoring plan content without specifying who is responsible.

Several commenters (0808-API, 0831-AXPC) contended that records should not be kept on a “facility” basis. The commenters stated that many of the required records would be developed by the camera manufacturer, while others could be maintained in owning or operating company central repositories, or, in other cases, handled by the OGI camera operator’s employer (e.g., a monitoring company). The commenters pointed out that many cameras will be used at multiple facilities and may not be owned by the facility or even the facility owner. One commenter (0808-API) asserted that a site monitoring plan would be the responsibility of an OGI camera owner or monitoring contractor. The commenters (0808-API, 0831-AXPC) recommended the word “facility” be deleted from section 12 and the appropriate entity (e.g., OGI camera owner, facility owner or operator, OGI camera operator employer) be substituted, or that no specific entity be identified as having to maintain the record.

One commenter (0808-API) recommended that the recordkeeping requirements be revised to require the OEM or other entity that performs the section 6.1.2 evaluations to maintain the records showing compliance with the minimum detection limits and that such a record not be required to be kept by the OGI camera owner or at each location where the camera is used.

Commenters (0782-BHE, 0808-API, 0831-AXPC) noted that records of data supporting development of the operating envelope should be kept by the camera manufacturer, records applicable to OGI camera operators kept by the OGI camera operator’s employer, and records of actual surveys maintained by the owner/operator of the monitored site. One commenter (0782-BHE) specifically expressed concerns with the requirement to retain all data supporting development of the operating envelope, which, the commenter asserted, “could include thousands of site-specific components at each camera and atmospheric test condition over the myriad of facility configurations”. The commenter suggested that these requirements, and other OEM specification criteria, are best addressed by the OEM initial performance testing, and the owner or operator should only address anything outside of these test conditions in the monitoring plan. The commenter further stated that several requirements in the summary table in section 11.3 of Appendix K (e.g., spectral bandpass range and initial performance verification) should not be the responsibility of the operator.

Commenters (0808-API, 0831-AXPC) additionally stated that EPA should clarify that not everyone that has to records of the development of the operating envelope. One commenter (0808-API) discussed the necessary documentation and recordkeeping requirements specified in section 8.1 for each OGI camera. The commenter called attention to the fact that these cameras will be used at multiple, separate facilities owned by different entities, and it would be difficult for every entity that uses the camera to maintain a copy of that documentation. The commenter recommended that records required under section 8.1 should be relocated to section 6 of Appendix K and maintained by the organization doing the demonstration.

Commenters (0808-API, 0831-AXPC) requested that records of operating training activities, including training surveys performed to locate leaks, be maintained with the training and

monitoring records under sections 12.4.3 and 12.5 of Appendix K. The commenters also stated that the requirement that the records in section 12.5 of Appendix K be made available to technicians executing repairs is overly burdensome, asserting that most items are not associated with repairs or locating the leak.

One commenter (0463-Southern Ute) stated that it is often not feasible for records to be kept on site at a facility due to storage limitations or environmental considerations such as lack of electricity (such as at well sites). The commenter requested the option to keep records readily available at an alternative location.

Response I-22-100: EPA made substantial edits to Appendix K in response to comments in the December 2022 Supplemental Proposal, including revisions to the recordkeeping requirements. These revisions included clarifying which records need to be kept by the owner or operator and which records need only be accessible to an owner or operator (and available to the Administrator for review upon request). Where an owner or operator must maintain records, Appendix K does not require that records be kept at a particular site; instead, Appendix K states that these records must be retained and easily accessible.

EPA also clarified in the December 2022 Supplemental Proposal that the initial OGI camera specification testing and development of the operating envelope can be performed by the owner or operator, camera manufacturer, or a third-party. However, regardless of who performs the testing, the owner or operator must have access to these records in order to ensure that the OGI camera meets the requirements of Appendix K, as it is the ultimate responsibility of the owner or operator to conduct surveys meeting the requirements in Appendix K, if a subpart requires the use of Appendix K.

EPA made changes to the records in proposed section 12.5 (now section 12.6) of Appendix K in the December 2022 Supplemental Proposal. EPA notes that the records in this section are records of the initial survey. EPA does not consider the requirement to make the initial survey records available to the person who will be conducting repairs overly burdensome. We consider it appropriate to make the initial survey records available to the person making repairs, as the person making repairs may need additional information to complete the repairs, especially if the initial inspection misidentifies the component that is leaking or if there are multiple components in a grouping that are leaking.

Comment: One commenter (0599-MS) questioned why records are required to be retained for the lifetime of equipment, when the survey records themselves are only required to be kept for 5 years (or as otherwise required by a regulation or permit).

Response I-22-101: EPA made substantial edits to Appendix K in response to comments in the December 2022 Supplemental Proposal, including revisions to the recordkeeping requirements. These revisions included clarifying the length of time different types of records need to be kept to better align the OGI camera records with the OGI survey records.

### ***22.8.3 Survey Records***

Comment: Several commenters (0599-MSD, 0718-Tora, 0782-BHE, 0808-API, 0814-IPAA, 0831-AXPC, 0911-NDPC, 0945/1373-JOFA) objected to the requirement to maintain 10-second OGI video clips of leaking components. Commenters (0782-BHE, 0808-API, 0814-IPAA, 0945/1373-JOFA) expressed that the requirement is unnecessary, overly burdensome, and would require massive amounts of storage space. Commenters (0782-BHE, 0808-API, 0814-IPAA) proclaimed that EPA did not consider the additional cost of data storage for the 10-second video clips for a minimum of five years. One commenter (0782-BHE) noted that the added burden of maintaining video records from site surveys would add to the time to complete the surveys, require modifications to existing field programs and data collection practices, and would add to the labor resources required to complete the leak surveys. The commenter requested additional justification for these requirements and that the requirements be accurately reflected in the cost-effectiveness analysis. Commenters (0718-Tora, 0814-IPAA) stated that the quality of OGI video clips is poor and would not be useful for maintenance personnel. A different commenter (0599-MSD) noted that in a proficient LDAR program, surveys are conducted with appropriate staff so that detected leaks are repaired simultaneously when possible, and that a color still image serves the same purpose and provides a clearer and more detailed image while enabling more efficient use of survey time. One commenter (0808-API) requested that EPA allow either a video or a digital picture and only impose the requirement where a leak is not immediately repaired or tagged, and that only a written record of the leak information be required otherwise. Another commenter (0831-AXPC) supported removing any requirements related to digital photograph or videos related to OGI.

One commenter (0814-IPAA) noted that EPA originally supported OGI inspections as a quick and efficient alternative to EPA Method 21, allowing companies to survey thousands of components quickly and allowing efficient communication to staff for repair. The commenter urged that a 10-second video for each leak would be impossible to quickly communicate necessary repairs, due to file size and video quality. The commenter asserted that the low-quality video would make an accessory, high-quality digital photograph also necessary to document and communicate a leak. Commenters (0814-IPAA, 0945/1373-JOFA) stated that high-quality digital images are small and easier to communicate and pointed out that OGI camera videos may be easily corrupted.

Other commenters (0463-Southern Ute, 0808-API) noted that a digital photograph allows for identification of leaking components without tagging and is preferred when physical tagging may not always be possible due to safety considerations (e.g., hot equipment, where no safe access is available, or where toxics may be present). Commenters (0463-Southern Ute, 0808 API) specifically requested that EPA allow the same alternative provided in NSPS OOOOa to use a digital photograph in lieu of tagging. One commenter (0463-Southern Ute) pointed out that such photographs clearly identify locations, are easily shared, and allow for gathering of appropriate resources without requiring a trip to the site. The commenter also stated that a high-quality digital photograph can help target repairs of leaks where the exact source cannot be identified and are preferred to physical tagging that is susceptible to failure due to weather exposure.

Some commenters (0718-Tora, 0814-IPAA) asserted that the requirements for tagging and notation of date, time, and location should be sufficient for leak documentation. One commenter (0718-Tora) urged that documentation that the OGI camera operator remained within the operating envelope and followed the procedures of the monitoring plan can be achieved through an affirmative statement made by the OGI camera operator, with periodic auditing.

Several commenters (0782-BHE, 0808-API, 0831-AXPC) specifically supported the exclusion of video-recordings for non-leaking components in section 9.7.2 of Appendix K, which they cited as a large improvement from the AWP.

Response I-22-102: In response to comments on the November 2021 Proposal, EPA updated the survey documentation requirements to require either a short video clip or a photograph of each leak in the December 2022 Supplemental Proposal.

EPA disagrees that there should not be a video or photograph documentation of all leaks. EPA acknowledges that the requirement to keep video clips or photographs is different from other LDAR programs. However, LDAR is generally performed using EPA Method 21, and during an inspection, the operator documents the EPA Method 21 reading when a leaking component is found. Taking a photograph of a visual OGI image is analogous to documenting the instrument reading when using EPA Method 21.

The requirement to tag a component for repair is only applicable if the repair cannot be made immediately. A photograph of the component may not be enough to identify the component if there are multiple components in the vicinity of the leak. EPA notes that tagging components is a requirement in most leak detection programs and provides an easy way for a technician to locate the correct component in the field. As such, we are retaining the requirement to tag components that cannot be immediately repaired at the time of inspection.

#### ***22.8.4 Documentation of Ambient Weather Changes***

Comment: Several commenters (0718-Tora, 0808-API, 0814-IPAA, 0831-AXPC, 0945/1373-JOFA) questioned requirements to document weather conditions at the beginning of each survey, when transitioning between process areas, and at the end of each survey. Some commenters (0808-API, 0814-IPAA, 0831-AXPC) contended that the requirements apply to an undefined and ambiguous “monitoring survey”, noting that the length of a survey of a single site or even a single process can take between an hour and several days to complete. One commenter (0599-MSD) noted that major process area is not defined, nor should it be defined or included. Commenters (0808-API, 0817-GPA, 0831-AXPC) saw no value in documenting weather data when monitoring moves from one process unit to another at the same location or at the end of the day, urging that weather does not change significantly due to location changes within a facility. One commenter (0718-Tora) expressed that the weather conditions recorded would not necessarily be indicative of conditions throughout a survey (e.g., a wind speed record generated during a calm period on a gusty day), therefore, such requirements would not serve to demonstrate whether conditions are within the OGI camera operating envelope. Commenters (0808-API, 0831-AXPC) added that end of day weather information is of no use in assuring operating envelope requirements are being met, since monitoring has concluded for the day. One

commenter (0599-MSD) stated that recording conditions at the end of the survey only serves to collect data which would be used to scrutinize or invalidate collected survey data, although if the OGI camera operator utilized proper technique, the data could not be invalidated. The commenters (0599-MSD, 0808-API, 0831-AXPC) requested that the requirement to record survey identifying information, including weather conditions, be revised to so that information is only required at the start of the monitoring day or whenever there is a change in facility. Another commenter (0817-GPA) suggested that, at most, EPA should require new conditions be recorded if weather conditions change substantially during the survey, while a different commenter (0718-Tora) urged that an affirmative statement by the OGI camera operator should be sufficient to document that conditions are appropriate.

Some commenters (0814-IPAA, 0945/1373-JOFA) requested that EPA clarify the time intervals of weather documentation. These commenters noted that for small marginal wells, an OGI survey may only take 15 minutes to observe all components, as opposed to a full day or more for large processing facilities. The commenters questioned whether operators would be required to document weather changes in intervals of less than 15 minutes and remarked that this would be impractical and time consuming.

Response I-22-103: In the December 2022 Supplemental Proposal, EPA updated the requirements in section 9.6.2 of Appendix K concerning recording weather conditions to remove ambiguity. Weather conditions must be recorded at the beginning and end of the monitoring survey, and if the monitoring survey is greater than four hours, at least once every two hours. EPA disagrees with the commenters that it is unnecessary to record weather conditions at regular intervals. EPA notes that the weather conditions are a relevant component of how a survey is conducted. Wind speed and temperature are directly related to how an OGI camera operator uses the camera's operating envelope, and as such, an operator needs to be always aware of these parameters and any changes in these parameters. Sky conditions are important to understanding the types of backgrounds that may be present during the survey, which is related to the OGI camera operator's ability to find a suitable delta-T. Understanding the conditions of a survey are crucial to anyone who is reviewing the results of a survey, as well as to the person conducting the survey.

## **22.9 Other Comments**

### ***22.9.1 Section 5.0 - Safety***

Comment: Three commenters (0808-API, 0831-AXPC, 0911-NDPC) discussed the applicability of safety requirements in Appendix K. Two commenters (0808-API) and (0831-AXPC) recommended that EPA remove the last sentence of section 5.1, while the other commenter (0911-NDPC) urged EPA to remove the section on safety in its entirety.

Response I-22-104: EPA disagrees with the commenters. Safety is a topic covered in most EPA test methods, and EPA used similar language in Appendix K. EPA does not prescribe particular safety protocols that must be followed in Appendix K. Appendix K only recommends that the user be aware of the hazards that may exist at the site and with prolonged use of an OGI camera. EPA sees no reason why this information should not be included within Appendix K.

### ***22.9.2 QA/QC Requirements in Section 11.0***

Comment: One commenter (0808-API) provided recommended revisions in the redline version of section 11.3 of Appendix K, as well as suggested improved wording and addition of specific references in the frequency column of the table where the commenter indicated it is unclear as to who is responsible and how often and on what basis the QA/QC activity is required.

Response I-22-105: EPA acknowledges the input provided by the commenter. Some of the suggested changes were incorporated in the December 2022 Supplemental Proposal.

### ***22.9.3 Solicitation of Input***

Comment: Commenters (0814-IPAA, 0945/1373-JOFA) are concerned that EPA only solicited input from OGI camera manufacturers before designing the proposed requirements. The commenters noted that manufacturers have a vested interest and desire to maximize camera use in order to expedite the failure rate and drive-up maintenance and new sales revenue from the excessive camera use outlined throughout the proposed Appendix K. One of the commenters (0945/1373-JOFA) requested that EPA divulge who EPA solicited comments and input from before designing the proposed requirements and requested, and for transparency, whether EPA solicited comments and advice from very small businesses and sole proprietorships prior to publishing the proposed Appendix K.

Response I-22-106: On November 9 and 10, 2020, EPA held a virtual stakeholder workshop to gather input on development of a protocol for the use of OGI. This workshop was open to the general public and attended by approximately 300 people. The workshop had two components. Half of the workshop was dedicated to presentations from a variety of stakeholders, including OGI camera manufacturers, regulated industry, researchers, LDAR contractors, universities, an independent laboratory, and a state environmental agency. The second half of the workshop was an open forum on specific topics where everyone present was given an opportunity to speak and provide input. The workshop findings are summarized in a report available in the docket for this rulemaking.<sup>59</sup>

EPA also provided a list of meetings held prior to the development of Appendix K in the docket for this rulemaking.<sup>60</sup> This included meetings with regulated industry and different camera manufacturers. Additionally, as noted in the Appendix K TSD, EPA conducted extensive literature searches and performed its own studies of OGI cameras. The TSD is the basis of the development of Appendix K.

### ***22.9.4 Separate Appendix K Final Rule***

Comment: Commenters (0793-PBPA, 0794-MHAN, 0749-PAW, 0816-Montrose, 1291-INGAA) recommended that EPA re-write Appendix K and engage with stakeholders and operators with experience in OGI to do so. In addition, commenters recommended that EPA separately propose

---

<sup>59</sup> EPA-HQ-OAR-2021-03017-0077.

<sup>60</sup> EPA-HQ-OAR-2021-03017-0078.

Appendix K's OGI requirements on a standalone basis for industry-wide review and comment and drop the proposed requirement in the context of this regulatory proceeding.

Response I-22-107: In order to finalize the BSER for gas processing plants in NSPS OOOOb and EG OOOOc, which is OGI monitoring according to Appendix K, EPA must finalize Appendix K either before or in conjunction with NSPS OOOOb and EG OOOOc. As such, we are not separating the finalization of Appendix K from this rulemaking.

As part of the development of appendix K, EPA conducted an extensive literature review on the technology development as well as observations on current application of OGI technology. EPA also commissioned multiple laboratory studies and OGI technology evaluations. Additionally, on November 9 and 10, 2020, EPA held a virtual stakeholder workshop to gather input on development of a protocol for the use of OGI. The information obtained from these efforts was used to develop the TSD for appendix K, which provides technical analyses, experimental results, and other supplemental information used to evaluate and develop standardized procedures for the use of OGI technology in monitoring for fugitive emissions of VOC and methane from industrial environments. EPA initially proposed Appendix K in the November 2021 Proposal and took comment on that proposal. EPA provided an overview of the proposal during a webinar on December 14, 2021, and responded to clarifying questions during the webinar. Based on comments received on the initial proposal, EPA developed a revised Appendix K, which was proposed as part of the December 2022 Supplemental Proposal, and we took comment on the revised version of Appendix K. EPA has provided substantial notice of the requirements in Appendix K and multiple opportunities for stakeholders to provide input.

#### ***22.9.5 Focus Appendix K***

Comment: One commenter (0782-BHE) argued that Appendix K should focus on the ability of the technology to detect leaks that materially contribute to emissions. The commenter stressed that EPA Method 21, which relies on concentration, is a poor surrogate for leak rate mass emissions, and in some cases, a concentration can result in more leaks being tagged and subsequently repaired than necessary. The commenter contended that EPA should develop a decision-basis for leak repair or a tier-based programs that considers leak size and that EPA has not accounted for the cost of tracking and repairing small leaks. The commenter further requested that EPA ensure that the primary focus of an OGI program is to locate and eliminate “meaningful” or significant leaks that account for a large proportion of overall emissions. The commenter criticized the Appendix K criteria as “pursuing perfection”, highlighting the contrast between Appendix K and the actual performance of EPA Method 21 surveys, noting that facilities continue to achieve significant emissions reductions with OGI that would be ignored by EPA Method 21 under the current methodology. The commenter stated that the costs of tagging, tracking and repairing components under Appendix K may not be justifiable and cautioned against trying to identify *all* small immaterial leaks because it may have limited impact, add significant costs, or deplete available qualified technicians and resources that might better be applied elsewhere. The commenter cautioned that adding unnecessary “rigor” to the requirements may add time and cost to an approach that has proven to be more advantageous over conventional EPA Method 21-based LDAR.

Response I-22-108: EPA made substantial edits to Appendix K in response to comments in the December 2022 Supplemental Proposal. See discussion in section VI of the December 2022 Supplemental Proposal for information related to the changes made to Appendix K.<sup>61</sup>

EPA notes that the commenter is correct that EPA Method 21 relies on concentration. However, we note that the ability of an OGI camera to image a leak relies on concentration-pathlength, not on mass emissions. For this reason, it can be difficult to determine if an OGI camera is seeing a large leak or small leak, which makes creating a tiered program impossible. EPA disagrees that it is pursuing perfection with Appendix K. EPA is providing requirements within Appendix K to help ensure that OGI camera operators find leaks that exist to ensure that LDAR programs that use OGI are equivalent to LDAR programs that use EPA Method 21, as effective OGI surveying is highly dependent on OGI camera operator training and experience, as well as site conditions (such as wind speed).

#### ***22.9.6 Editorial Changes***

Comment: A commenter (0808-API) noted a typographical error where section 10.4.2.2 was labeled as 10.4.2.3 in the proposed Appendix K.

Response I-22-109: EPA has made the correction to paragraph labeling in the final rule.

#### ***22.9.7 Burden and Cost***

Comment: Several commenters (0814-IPAA, 0935-COGA, 945/1373-JOFA, 1391-INGAA) urged EPA to re-evaluate the financial implications of implementing Appendix K, especially for small businesses who may not have more than one OGI camera operator and remote or difficult to access facilities, as these new practices may prove fiscally devastating and force these smaller businesses to close.

Response I-22-110: EPA made substantial edits to Appendix K in response to comments in the December 2022 Supplemental Proposal. See discussion in section VI of the December 2022 Supplemental Proposal.<sup>62</sup>

Additionally, EPA notes that Appendix K does not on its own apply to any sources. Each rule that implements Appendix K will evaluate the cost of implementation and provide any appropriate leak detection alternatives.

Comment: One commenter (0808-API) stressed that existing cameras have not been tested and certified to meet the proposed Appendix K specifications. The more stringent Appendix K requirements will require retesting of existing OGI cameras and if the camera does not meet these requirements, operators could be required to purchase a new OGI camera, which is an additional cost not considered in EPA's cost analysis.

Response I-22-111: EPA acknowledges the statement of the commenter. Based on the work that was done in support of the TSD for Appendix K, we are confident that cooled MWIR OGI

---

<sup>61</sup> 87 FR 74837-74842 (December 6, 2022).

<sup>62</sup> 87 FR 74837-74842 (December 6, 2022).

cameras currently on the market and currently be used for inspection of VOC and methane leaks will be able to meet the specifications outlined in Section 6.0 of Appendix K.

## 22.10 Incorporations by Reference

In some cases, commenters incorporated by reference all or part of a comment letter submitted by another commenter. Rather than repeat the associated comment excerpts for each commenter, the EPA has listed the comment excerpt only once and provided a list of all the commenters who otherwise incorporated the comments by reference in the table below.

**List of Comment Letters Incorporated by Reference**

| Commenter                 | Commenter Affiliation                                     | Incorporations by reference                           | IBR'd DCN                                                                       |

## Chapter 23. Miscellaneous Other Comments

### 23.1 Statutory Basis for Proposed Rules

Comment: Commenter (0734-ATS) states that under the CAA, the EPA has the authority to regulate the GHG emissions and volatile organic compound (VOC) emissions, which is critical to protecting public health and mitigating the harmful impacts of climate change.

Similarly, commenter (0735-CBF), states that under the CAA, EPA is tasked with “protect[ing] and enhance[ing] the quality of the nation’s air resources so as to promote the public health and welfare and the productive capacity of its population.”<sup>1</sup> They add that section 111 of the CAA requires EPA to identify standards of performance for new categories of stationary air pollution sources if the pollutants they emit cause or contribute significantly to air pollution that may endanger public health or welfare.<sup>2</sup> In 2016, the commenter notes that the EPA promulgated new source performance standards (NSPS) for methane and VOC emissions from oil and gas sources after recognizing the public health and welfare risk caused by methane, a GHG, and a major contributor to climate change.<sup>3</sup>

Response I-23-1: The EPA received similar supporting comments on the December 2022 Supplemental Proposal regarding EPA’s statutory authority under the CAA to regulate GHG and VOC emissions. See Volume II, Chapter 2 (Legal Basis for Rulemaking), subsection 2.1.4 (EPA Has the Authority Under the CAA to Establish State Plan Requirements). These comments are supportive comments; as such, no response is required.

See also, discussions in sections IV (Statutory Background and Regulatory History) and V (Legal Basis for the Final Rule Scope) of the final rule preamble for the basis and scope of the final NSPS OOOOb and EG OOOOc rules.

### 23.2 Applicability of Requirements Under the Proposed Rules

Comment: Several commenters (0810-Petroleum Alliance of Oklahoma (Petroleum Alliance-OK), 0457-Southeastern Ohio Oil and Gas Association (SOOGA), 0722-Missouri Department of Natural Resources, Air Pollution Control Program (MDNR), 0743-Western Energy Alliance (WEA), 0755-Texas Pipeline Association (TPA), 0777-Ascent Resources, LLC (Ascent), 0782-Berkshire Hathaway Energy Company (BHE), 0793-Permian Basin Petroleum Association (PBPA), 0808-American Petroleum Institute (API), 0814-Independent Petroleum Association of America (IPAA) *et al.*, 0817-GPA Midstream Association (GPA), 0820-Pioneer Natural Resources USA, Inc. (Pioneer), 0831-American Exploration and Production Council (AXPC), 0911-North Dakota Petroleum Council (NDPC), 0921-U.S. Chamber of Commerce (USCC), 0929-NSWA National Stripper Well Association (NSWA), 0938-Texas Oil & Gas Association (TXOGA), 1289-Atmos Energy Corporation (Atmos), 1391-Interstate Natural Gas Association of America (INGAA), 1421-DePuy Oil and Gas Co. (DePuy)) express that the

---

<sup>1</sup> 42 U.S.C. § 7401(b)(1).

<sup>2</sup> 42 U.S.C. § 7411, Standards of Performance for New Stationary Sources.

<sup>3</sup> 40 C.F.R. pt., 60, subpt. OOOOa.

effective/applicability date of requirements for new and existing sources under the November 2021 Proposal needs to be based on the date of the proposal of the regulatory text (with the supplemental proposal) and not based on the November 2021 Proposal date. Some of the examples of comments submitted by commenters are presented in the following paragraphs.

Commenter (0810-Petroleum Alliance-OK) states that since EPA's publication of the November 2021 Proposal did not include any proposed regulatory language, the November 2021 Proposal should not be characterized as a "proposed rule" in which the publication date of November 15, 2021, becomes the applicability date for methane and VOC emissions from sources that commenced construction, modification, or reconstruction. The commenter requests EPA revise the applicability date to align with a forthcoming proposed supplemental rule publication date that contains actual text.

Commenter (0793-PBPA) believes it would be inappropriate for EPA to treat its November 15, 2021, publication as "proposed regulations," as that phrase is used in CAA 111(a)(2) for purposes of establishing an applicability date to distinguish between new and existing sources. By applying the proposed NSPS to sources that are new, modified, or reconstructed after November 15, 2021, as opposed to after whatever date EPA actually publishes proposed regulatory text, the commenter states that EPA will effectively impose a retroactive applicability date that brings in sources as new and subject to NSPS requirements when they should be treated as existing and subject to EG requirements, which are implemented by the states. The commenter notes that the November 15, 2021, publication should be considered an Advanced Notice of Proposed Rulemaking (ANPR).

Commenter (0743-WEA) believes that EPA's classification of the publication in 86 FR 63110 as a proposed rule is inappropriate. They explain that under 42 U.S.C. § 7411(a)(2), "New Source" is defined as "any stationary source, the construction or modification of which is commenced after the publication of regulations (or, if earlier, proposed regulations) prescribing a standard of performance under this section which will be applicable to such source." For a typical NSPS, the commenter notes that this generally means that compliance is required for those sources that are either modified or constructed after a particular trigger date, based on when regulations are proposed. Within this publication, the commenter notes that EPA states that the types of sources discussed in the document would be required to meet the yet undefined standards in a forthcoming final rule if their construction or modification occurred after November 15, 2021. In the view of the commenter, this approach conflicts with 42 U.S.C. § 7411(a)(2) as there has yet to be a publication of regulations, or proposed regulations.

Commenter (0743-WEA) suggests that EPA recognizes that no publication of proposed regulations or regulatory text has been made, noting that "EPA plans to issue a supplemental proposal and supplemental RIA [Regulatory Impact Analysis] for the supplemental proposal to provide regulatory text for the November 2021 proposed NSPS OOOOb and EG OOOOc." This is reiterated in EPA's supporting fact sheet on the rule proposal: "EPA intends to issue a supplemental proposal in 2022 that will provide proposed regulatory text and may expand on or modify the 2021 proposal in response to public input." The commenter states that EPA is clear in the publication that the actual proposed regulations are forthcoming, and therefore the current

publication would not trigger new source requirements for sources discussed in the publication at the date of its publication.

Commenter (0743-WEA) states that, in addition, EPA intimates that the supplemental proposal could include sources, requirements, and information based on comments received that aren't mentioned in the current publication. If that were to happen, based on EPA's asserted date in the publication of November 15, 2021, the commenter states that the NSPS OOOOb rule could end up having two separate compliance dates based on this current publication and the supplemental proposal, needlessly complicating regulatory compliance for impacted companies.

Instead of proposed regulations and regulatory text, the commenter (0743-WEA) states that the publication in 86 FR 63110 is a lengthy set of information that would typically be included in either the preamble to a rulemaking, or in an ANPR, and some questions that would typically appear in an Information Collection Request (ICR). Given that EPA does identify some potential themes or ideas around what potential regulations in the rule could look like, the commenter suggests that EPA should have classified this publication as an ANPR, as EPA has done with previous rulemaking efforts. That said, according to the commenter, a mere description of potential regulatory requirements that may be proposed in a supplemental proposal is not enough to inform the regulated public how they are to comply with a rule. In this instance, there is yet to be a rule to actually comply with.

Commenter (0743-WEA) notes that by publishing the November 2021 Proposal with a purported compliance date of November 15, 2021, EPA is expecting operators to begin to track facilities that may or may not ultimately be regulated, with regulatory requirements that have not yet been proposed, and are expected to do so in addition to expecting more sources that could potentially be included in the future, all of which could impact compliance budgets, planning, and design. Absent clear guidance, EPA should not expect operators and the regulated public to anticipate the intentions of what a proposed rulemaking would look like in the future when developing plans for facility design, control technologies, and approaches. The commenter recognizes that it would be difficult to reclassify the publication as an ANPR at this stage. As such, to remedy the conflict the publication has with CAA section 111(a)(2), (42 U.S.C. 7411(a)(2)) the commenter encourages EPA to clarify in the supplemental proposal that the compliance date is triggered with the publication of the regulations and regulatory text in the supplemental proposal, whenever that is ultimately published in the *Federal Register*. Going forward, the commenter hopes EPA will avoid publishing documents titled as a proposed rule under the NSPS absent formal regulatory text. The commenter contends that this practice does not allow for sufficient public input and comment when the regulated public has a mere 75 days to comment on only the limited information that would normally be provided in a preamble. The commenter also requests the supplemental proposal to come later this year include a robust comment period for regulated entities to adequately evaluate the impacts of the proposed rule.

Similarly, commenter (0938-TXOGA) states that since the *Federal Register* publication on November 15, 2021, did not contain "proposed regulations," the date of this publication cannot be used to determine applicability of the NSPS that will eventually be codified in NSPS OOOOb. The commenter provides that the CAA does not define the term "regulations" (in section 111 of the CAA or elsewhere), but it is commonly accepted in administrative law that agency

regulations promulgated pursuant to statutory authority are “rules” within the meaning of the Administrative Procedures Act (APA), and the two terms are used interchangeably. Under the APA, an agency “rule” is defined (in relevant part) as “the whole or a part of an agency statement of general or particular applicability and future effect designed to implement, interpret, or prescribe law or policy.”

Commenter (0938-TXOGA) asserts that the congressional intent in establishing the proposal date as the trigger date for applicability is based on the actual proposal of rule language. Congress established a rigorous schedule for establishing NSPS, in which standards are to be finalized within a year of proposal. At the same time, the commenter states that the NSPS are intended to support economic growth by being demonstrated and achievable. Thus, Congress reasonably concluded that companies evaluating investments would be in a position to design their facilities to accommodate pending standards at the time of modification if they were on notice of how the regulations would apply. The commenter adds that Congress contemplated that sources should be “on notice” of what would be required of them for the consequence of a proposal to trigger applicability. While it is true that requirements can change from proposal to final, that fact does not undo the fundamental requirement that the level of detail in a proposal that puts the source on notice of requirements be provided in the first instance. Congress’s requirement that NSPS proposals be finalized within a year supports this conclusion. Sources would not reasonably be subjected to an applicability date where the rulemaking is not completed expeditiously. Here, the commenter notes that EPA has called the November 2021 *Federal Register* notice a “proposal” which they say would bring with it necessarily that the rule would need to be finalized by November 15, 2022. Given that EPA must publish and seek comment on regulatory language, and given that the proposed language is unlikely to be available in the *Federal Register* for public review until at least March of 2022, with at least a 30-day comment period, and taking into account that this proposal will require at least 90 days for Office of Management and Budget (OMB) review, the commenter believes it seems improbable at best that this rule could issue within the statutorily required time frame. On this basis alone, the commenter asserts that EPA would need to consider the publication of the proposed regulatory language as the trigger date for applicability.

In sum, commenter (0938-TXOGA) states that for sources to trigger applicability of the NSPS, under CAA section 111, they must be provided reasonable prior notice of the standards that will apply at the time they make the decision to undertake construction, modification, or reconstruction. Publication of the November 2021 Proposal in the *Federal Register* does not provide this information and thus, applicability must be tied to the date an adequate proposal is published. The commenter concludes that releasing a description of what EPA may propose as regulatory text does not satisfy the statutory standard.

Commenter (0938-TXOGA) states that if EPA sought to enforce the conceptual NSPS standards set forth in the November 2021 Proposal against sources that undertook construction or modification between November 15, 2021, and publication of the to-be-issued supplemental proposal (supplying regulatory text), this would raise significant due process concerns under the “fair notice” line of cases in several Circuit Courts of Appeal. The commenter explains that a number of these courts have held that due process precludes enforcement penalties where a regulation is not sufficiently clear to put a regulated party on notice of what is expected of it.

These cases align with the fundamental principle articulated by the U.S. Supreme Court that that “agencies should provide regulated parties ‘fair warning of the conduct [a regulation] prohibits or requires.’” In the analogous context of CAA section 112 maximum achievable control technology (MACT) standard applicability, the Fifth Circuit has determined that a source may not be held, after the fact, in violation of a standard that did not apply at the time that the facility allegedly triggered it (*e.g.*, by commencing a modification). The commenter suggests that EPA keep in mind these commonsense principles and revise the trigger date for NSPS OOOOb applicability when it issues its supplemental proposal.

Commenter (0921-USCC) states that EPA proposed the applicability date of the NSPS OOOOb, as the date of publication of the November 2021 Proposal (November 15, 2021), not from the date of the planned supplemental proposal. If this proposed applicability date is included in a final rule, new, modified, or reconstructed sources built after that date would have to comply with the new standards despite the November 2021 Proposal’s lack of any proposed regulatory text. The commenter contends that EPA’s approach here does not align with the CAA’s definition of a “new source.” Specifically, the CAA defines a “new source” as “any stationary source, the construction or modification of which is commenced after the publication of regulations (or, if earlier, proposed regulations) prescribing a standard of performance under this section which will be applicable to such source.” Since EPA has not yet issued any “proposed regulations,” applicability for NSPS OOOOb cannot lawfully start on November 15, 2021. At the earliest, applicability could start from the date EPA publishes the proposed regulatory text, presumably in the planned supplemental proposal.

Commenter (0921-USCC) states that owners and operators of sources that trigger applicability under the rule must have reasonable prior notice and a clear understanding of the standards prior to commencement of construction, modification, or reconstruction. The commenter states that the November 2021 Proposal without the text of proposed regulations cannot provide adequate guidance to prospective owners and operators of would-be new sources. The commenter notes that EPA did not provide any text that describes with the necessary particularity the requirements with which source owners and operators should plan to comply if they are currently contemplating owning or operating a new, modified, or reconstructed source. The commenter asserts that that EPA should not put new or modified unit owners and operators in a position to guess at these uncertain requirements based on preamble text only. The commenter adds that the practice of issuing NSPS that lack any regulatory text and invoking them as an applicability trigger is arbitrary policy, sets a negative precedent for other NSPS, and is inconsistent with the CAA.

Commenter (0921-USCC) states that one final reason why EPA should not use the November 2021 Proposal’s date of publication as the applicability trigger for NSPS OOOOb is to avoid creating serious enforceability issues by raising due process and fair notice problems. The commenter explains that the fair notice doctrine stands for the principle that a regulated source cannot be enforced against for a standard that did not apply under then-applicable regulations. In *Sierra Club v. Sandy Creek Energy Associates*, for example, the Fifth Circuit articulated this doctrine in the CAA context, finding that new facilities covered by a vacated standard must obtain a case-by-case MACT determination under CAA section 112(g). Likewise, they add that

courts have held that due process would preclude enforcement of standards against a source the owner or operator of which had no prior notice of the standards.

For the stated legal, policy, and enforceability reasons, commenter (0921-USCC) suggests that EPA should amend the applicability date for the NSPS to the publication date of the anticipated supplemental proposal, which will presumably include regulatory text sufficient to trigger applicability.

Commenter (0929-NSWA) expresses concern that EPA states that “methane and VOC emissions from sources that commenced construction, modification, or reconstruction after November 15, 2021” will be required to comply with the proposed “requirements.” Typically, the commenter states that the effective date of NSPS is the date the performance standards are proposed and published in the *Federal Register*. As indicated above, the commenter states that the November 15, 2021, publication in the *Federal Register* contains no proposed regulatory language at all.

Commenter (1289-Atmos) recommends that EPA extend the November 2021 Proposal’s applicability date to the date the agency publishes specific rule language. Because the unique two-step approach EPA is employing for this rulemaking, doing so would be consistent with and better effectuate the purpose of the Part 60 implementing regulations. The commenter states that currently, the November 2021 Proposal would apply requirements under NSPS OOOOb to sources that are new or have been modified or reconstructed after November 15, 2021—the date EPA published the Proposal in the *Federal Register*. However, the commenter notes that EPA’s regulations state that any new or revised performance standard promulgated under CAA section 111(b) applies to “an affected facility, the construction or modification of which is commenced after the date of publication in this part of such new or revised standard (or, if earlier, the date of publication of any proposed standard) applicable to that facility.” While EPA has described different potential regulations in the November 2021 Proposal, the commenter notes that it has yet to publish specific rule language, which they state is understandable, as the agency seeks in-depth feedback on many aspects of the November 2021 Proposal. The commenter encourages EPA to release specific proposed rule language for comment, for which the public can then provide additional feedback. This process will give interested parties a chance to fully analyze the details of the rule, which affects complex industries and involves a highly technical body of regulations from both a legal and operational perspective. Specifically, the commenter recommends that EPA extend the Proposal’s applicability date to the date the agency publishes specific rule language.

Commenter (0777-Ascent) appreciates that EPA has already acknowledged that the November 15, 2021, *Federal Register* notice does not constitute a complete proposed rule, as evidenced by EPA’s stated commitment to issuing a supplemental proposal that will contain the proposed regulatory text for new subparts NSPS OOOOb and EG OOOOc. The commenter strongly supports the issuance of a supplemental proposal, and respectfully urges EPA to make the scope of that supplemental proposal, and the subjects on which it solicits comment, as broad as possible.

Because the regulated community has not yet had a chance to review and comment on proposed rule language, the commenter (0777-Ascent) urges EPA in its supplemental proposal to change

the proposed applicability date for sources that will be subject to the new NSPS OOOOb from November 15, 2021 (the date of publication in the *Federal Register* of the November 2021 Proposal) to the date of publication of the supplemental proposal that includes actual proposed rule language. CAA section 111(a)(2), 42 U.S.C. § 7411(a)(2), provides that a “new source” is any source whose construction or modification begins “after the publication of . . . proposed regulations prescribing a standard of performance under this section which will be applicable to such source.” The CAA does not define the term “proposed regulations.” It is at best doubtful whether, with respect to the proposed new NSPS OOOOb and EG OOOOc, the November 15, 2021, publication constitutes “proposed regulations” within the meaning of the statute, as that publication does not propose any regulatory text with respect to these proposed new subparts. The commenter states that the approach EPA has taken, under which it proposes to subject new sources (*i.e.*, those that commence construction or modification after November 15, 2021) to regulatory requirements whose regulatory text it has not yet proposed, creates considerable uncertainty for companies that may wish to construct or modify sources but cannot reasonably predict what specific requirements such sources will be subject to under the proposed new subparts.

For this reason, the commenter (0777-Ascent) states that EPA should in the supplemental proposal propose an applicability date for proposed new NSPS OOOOb and EG OOOOc that is the date of publication of the supplemental proposal (assuming that the supplemental proposal contains proposed regulatory text for these subparts). Failing to do so may render the eventual final rule legally vulnerable in this regard. Should EPA decide not to delay NSPS OOOOb applicability to the date that the proposed regulations are published, the commenter urges EPA at a minimum to account for the gap that failing to change this date would create between the “trigger” date for new sources and the date at which regulated companies see proposed regulatory text by providing a longer period to come into compliance, to include a phasing-in of regulatory requirements through a series of compliance dates, similar to the approach taken in the 2016 adoption of NSPS OOOOa.

Commenter (0814-IPAA *et al.*) states that the 154 pages of *Federal Register* text contained no proposed regulatory language. The commenter asserted that the “proposed rule” is not a proposed rule and is at best an ANPR. The commenter notes that the applicability date (the requirements of the NSPS apply to any sources constructed or modified after a certain date) is the date the NSPS are proposed and published in the *Federal Register*. As indicated above, however, the November 15, 2021, publication in the *Federal Register* did not contain proposed regulatory language. Thus, the commenter contends that, for EPA to require all new or sources modified after November 15, 2021, as subject to drafted regulations that were not yet drafted is arbitrary and capricious.

Commenter (0808-API) states that the November 2021 Proposal cannot set the new source trigger date under NSPS OOOOb because regulatory text is missing. EPA proposes that the new source trigger date for NSPS OOOOb is November 15, 2021, the date the Proposal was published in the *Federal Register*. The commenter appreciates EPA’s promise to make proposed regulatory text available in an upcoming supplemental proposal, but they assert that such a promise is not sufficient to set the new source trigger date at November 15, 2021.

Commenter (0808-API) states that the lack of proposed regulatory text creates an insurmountable practical problem. Affected facilities cannot know with certainty what regulatory requirements EPA has proposed and are thus unable to reasonably plan to comply with the final rule. Affected facilities can only surmise what the rule would require based on the description and explanation provided in the preamble. But affected facilities cannot know with sufficient clarity what would be required under the Proposal because they cannot see the part of the proposal that matters most – the regulatory text that would establish the binding legal obligations that would be imposed under the proposal.

Commenter (0808-API) suggests that the lack of regulatory text means that the November 2021 Proposal does not give fair notice to potentially affected facilities of what requirements they might be required to meet upon the effective date of the final rule. Fair notice is only achieved when EPA provides regulated entities with sufficient detail of what exactly will be required, which it has not done here.

Commenter (0808-API) also states that the publication date of the November 2021 Proposal does not set the trigger date because it is not a proposed “regulation.” CAA section 111(a)(2) defines “new source” to mean “any stationary source, the construction or modification of which is commenced after the publication of regulations (or, if earlier, proposed regulations) prescribing a standard of performance under this section which will be applicable to such source.” CAA section 111(a)(2) (emphasis added). Thus, only a proposed “regulation” may set the new source trigger date.

Commenter (0808-API) states that the preamble alone cannot constitute a proposed rule any more than a final rule that is unaccompanied by regulatory text could be declared a “rule.” Although the current preamble describes the type of regulatory requirements that EPA proposes to eventually promulgate, the preamble is not in and of itself a document that establishes the “agency statement of general or particular applicability and future effect.” That type of required statement would be established only by the proposed regulatory text, which is absent here. Thus, the November 2021 Proposal cannot establish the new source trigger date because it does not include a proposed rule. The new source trigger date is tied to the date proposed regulatory text is published in the *Federal Register*.

As a last note, the commenter notes that CAA section 307(d) administrative rulemaking procedures do not expressly require a proposed rule to include proposed rule text. Commenter (0808-API) does not opine on the question of whether a proposed rule subject to CAA section 307(d) provides adequate public notice and an opportunity to comment if it does not include or make available proposed rule text. But that issue, according to the commenter, is beside the point here because the new source trigger date is defined in CAA section 111(a)(2) and not in CAA section 307(d). So, even if the current proposal satisfies the procedural requirements of CAA section 307(d), the commenter states it does not set the new source trigger date for the reasons they explained above.

Commenter (0722-MDNR) states that the November 2021 Proposal does not include any proposed regulatory text. The preamble and the RIA for the November 2021 Proposal provide some level of specificity in what EPA is proposing. However, without seeing the regulatory

requirements or the EGs as they are proposed to appear in the Code of Federal Regulations, it hinders the commenter's ability to review the impact of the November 2021 Proposal and provide meaningful comments during the public participation process. The November 2021 Proposal indicates EPA is planning to submit a supplement to this proposed rule, and the commenter encourages strong state/federal engagement as the requirements are further refined and specified. The commenter recommends EPA reach out to states to conduct webinars and workshops to offer information and gather input on the contents of the supplement before it is proposed. Then once EPA proposes the supplement, it should allow adequate time for the public review and comment period, with a minimum of 60 days, but preferably longer depending on the complexity and scope of the supplement.

Commenter (0831-AXPC) urges EPA, in its supplemental proposal, to change the applicability date for sources that will be subject to the new NSPS OOOOb from November 15, 2021 (the date of publication in the *Federal Register* of the November 2021 Proposal) to the date of publication in the *Federal Register* of the supplemental proposal, which will, apparently, also be the date on which EPA will first propose regulatory text for the new NSPS OOOOb and EG OOOOc.

The commenter's (0831-AXPC) position is that EPA does not have authority under CAA section 111 to define a "new source" for a standard other than by reference to the date of publication of proposed regulatory text for that standard. Additionally, the commenter states that even if EPA had legal authority to proceed in this manner, the commenter believes there are strong policy and equity reasons why it is not appropriate for EPA to do so (arguments provided below):

First, as regards EPA's legal authority to proceed in this manner: Clean Air Act (CAA) Section 111(a)(2) (42 United States Code (U.S.C.) § 7411(a)(2)), provides that a "new source" is any source whose construction or modification begins "after the publication of . . . proposed regulations [] prescribing a standard of performance under this section which will be applicable to such source." The CAA does not define the term "proposed regulations." However, with respect to the new subparts OOOOb and OOOOc, the Initial Methane Notice does not appear to constitute "proposed regulations . . . prescribing a standard" within the meaning of the statute, as that publication does not propose regulatory text with respect to these new subparts.

The approach EPA has taken, under which it purports to subject new sources (*i.e.*, those that commence construction or modification after November 15, 2021) to regulatory requirements whose regulatory text it has not yet proposed, creates considerable uncertainty for companies that may wish to construct or modify sources but cannot reasonably predict what specific requirements such sources will be subject to under the new subparts. For this reason, EPA should, in the supplemental proposal, propose an applicability date for new subparts OOOOb and OOOOc of the date of publication of the supplemental proposal (assuming that the supplemental proposal, unlike the November 2021 Proposal, contains proposed regulatory text for these subparts).

Second, even if EPA had legal authority to proceed in this manner, it is unsound as a matter of policy, and inequitable. The plain purpose of Congress defining a new source as one whose construction or modification begins after proposal of regulations is that this

sequence allows owners and operators to understand their proposed regulatory obligations when they make decisions whether to break ground on new facilities or modify existing facilities—so that they know, not only whether a source constructed or modified after a date certain will be treated as a new source, but also the details of the regulatory obligations that will be incurred by a source deemed new. Because EPA has not yet proposed regulatory text for new subpart OOOOb, Congress’s purpose is not fulfilled if EPA deems sources to be new whose construction or modification begins after November 15, 2021.

In addition to EPA’s approach not fulfilling Congress’s purpose in enacting 111(a)(2), it also threatens to unjustly penalize owners and operators who have been making and will continue to make choices in good faith as to whether and how to construct or modify their facilities without the benefit of proposed regulatory text.

Finally, even if EPA does not in its supplemental proposal change the date defining a new source from November 15, 2021 to the date of publication in the *Federal Register* of the supplemental proposal and proposed regulatory text—which, for the reasons given above, it should—AXPC urges EPA at a minimum to account for the gap that failing to change this date would create between the “trigger” date for new sources and the date at which regulated companies see proposed regulatory text by providing a longer period to come into compliance, to include a phasing-in of regulatory requirements through a series of compliance dates, similar to the approach taken in the 2016 [NSPS] OOOOa rule.

Commenter (0911-NDPC) states that reviewing and developing meaningful comments is difficult and inefficient when EPA does not include the actual proposed rule text. The commenter adds that EPA should not consider the November 2021 publication a proposed rule without the rule text. The commenter adds that they do not believe the November 2021 action meets the requirements of a proposed rule for rule making, and the proposed applicability date for sources that will be subject to the new NSPS OOOOb and EG OOOOc should not be November 15, 2021, but rather the date the actual proposed rule text is published.

Commenter (0817-GPA) states that the November 2021 Proposal does not include proposed regulatory language. This deprives regulated industries of fair notice regarding what EPA is actually proposing and inhibits their ability to effectively comment on the Proposal. Further, it raises significant concerns regarding the effective date. EPA should clarify that, as there are no proposed regulations, the effective date should be, at the earliest, when EPA publishes a supplemental proposed rule that includes proposed regulatory text.

As an initial matter, the commenter (0817-GPA) suggests EPA make clear that the NSPS OOOOb regulations shall not be effective before EPA publishes the regulatory text. Without proposed regulatory text, no stakeholder can provide complete comments on the proposed NSPS OOOOb (or EG OOOOc) regulations. The commenter provides that EPA’s November 2021 Proposal only includes preamble language describing what EPA intends to propose, but states that it “plans to propose the regulatory language for NSPS OOOOb and EG OOOOc through a supplemental action.” 86 Fed. Reg. at 63,124. Although the preamble provides basic concepts, the commenter cannot understand or comment fully on the details of EPA’s proposed regulations

until EPA publishes the actual regulatory language. According to the commenter, such details are absolutely essential for understanding what will be a highly technical rule. Given the absence of such details, and EPA's stated plans to provide regulatory language through a supplemental notice, the November 2021 Proposal must be considered, in effect, an ANPR for a yet to be proposed NSPS OOOOb, with the actual proposal – and a separate public comment period that provides a full and fair opportunity for public comment – to come sometime in the future.

Commenter (0817-GPA) states that any other approach would be inconsistent with the explicit direction of Congress. Under 42 U.S.C. § 7411, a “new source” is defined as one where construction or modification commences “after the publication of regulations (or, if earlier, proposed regulations) prescribing a standard of performance....” (emphases added). Thus, the statutory trigger is clearly “regulations,” not a general preamble discussion lacking the actual regulatory text but, instead, promising that the regulatory text will be forthcoming. This correction is necessary, as the commenter asserts that the November 2021 Proposal erroneously suggested that NSPS OOOOb would be applicable after November 15, 2021.

Even aside from the express statutory requirement, the commenter (0817-GPA) suggests that imposing an effective date before regulatory text is presented would be wholly impractical and grossly unfair to regulated parties. Without regulatory text, owners and operators cannot know how to design and construct “new” sources in accordance with the rule. A preamble cannot, and does not, provide the technical details required to design and construct compliant sources or to properly structure the monitoring and recordkeeping programs required. Further, owners and operators do not know when new sources must be constructed. Hence, the commenter states that, at the earliest, a source could become “new,” and subject to new regulations, only upon EPA's publication of the “regulations.” The commenter urges EPA to tie the effective date to any final rule, given the extraordinary complexity and scope of the new regulatory scheme that EPA apparently expects to publish in its supplemental proposal. Deferring the effective date would allow the public comment process to be completed and provide parties with a greater degree of certainty before triggering the investments a new NSPS OOOOb would entail. Regardless, EPA must—at the very least—make clear that the “new source” effective date will not occur until, at the earliest, it publishes a supplemental proposed rule that includes the proposed regulatory language.

Commenter (0921-USCC) requests that EPA amend the applicability date for the NSPS OOOOb to the publication date of the anticipated supplemental proposal, which will presumably include regulatory text sufficient to trigger applicability.

Commenter (0755-TPA) suggests that the applicability date of new NSPS OOOOb be extended to the publication date of the proposed rule language. EPA has chosen in this instance to pursue an unusual rulemaking process: issuing a proposal that does not include the actual rule language that would be contained in the Code of Federal Regulations. Specifically, EPA's November 15, 2021, *Federal Register* notice consists of 154 pages of preamble and no formal regulatory text.

EPA nonetheless proposes to base the applicability date of the new NSPS OOOOb on the November 15, 2021, preamble publication date. Commenter (0755-TPA) believes that this approach to rulemaking is inappropriate. The provisions of Part 60, including any new or revised

performance standard promulgated under CAA section 111 (b), apply to “an affected facility, the construction or modification of which is commenced after the date of publication in this part of such new or revised standard (or, if earlier, the date of publication of any proposed standard) applicable to that facility.” The “proposed standard” is the actual rule language, not EPA's prefatory description and explanation- and in some cases, EPA's prediction- as to what that rule language might ultimately look like. In the world of complex regulations, emission limits, and compliance, the details are everything. The commenter suggests that a company determining whether, and to what extent, a particular operation is covered by a performance standard may gain some insight or coloration from a preamble, but in the last analysis it is the precise rule language itself that is always carefully scrutinized in order to resolve questions of applicability and required compliance. The key is what the formal rule text says. Yet the commenter states that they currently do not have the benefit of the actual proposed rule language with which their members must ultimately comply. Indeed, the commenter notes that EPA indicates that additional rulemaking, clarifications, modifications are still to occur. The commenter contends that the current NSPS OOOOb proposal is more in the nature of an ANPR than a rule proposal, and as such it is inappropriate to base the applicability date on the November 15, 2021, publication date.

In this setting, the commenter (0755-TPA) states that a company cannot proceed with any sort of confidence as to how the rules might ultimately read. Requiring compliance based on a construction or modification date that is months earlier than the publication of actual proposed rule language - *i.e.*, the “proposed standard” described by 40 CFR 60.1(b)- would be unfair and contrary to EPA's own rules, and to proceed in this way would potentially trigger future litigation. The commenter urges EPA to base the applicability dates in these rules on the date of *Federal Register* publication of actual rule language, as it has traditionally done, not a preamble description of such language.

Commenters (0599-Marcellus Shale Coalition (MSC), 0739-Citation Oil & Gas Corp. (Citation), 0787-Atmos Energy Corporation (Atmos), 0802-Kraken Oil & Gas LLC (Kraken), 0820-Pioneer) request that the effective date for the proposed regulation not be established until the actual draft regulatory text is proposed and published for public review. Commenter (0599-MSC) states that the November 2021 Proposal provides varying degrees of detail describing what EPA plans to propose in a supplemental regulatory action, which not only makes commenting on the regulation extremely difficult, but also places an effective date on new construction and modifications which are in various stages of implementation, such as having a completed design or being ready to commence construction imminently. Commenter indicates that many of these projects will have to wait for this supplemental proposal to determine if they include an affected source and applicable NSPS requirements and notes that regulatory language for these determinations will not be available for at least several months, possibly after implementation.

Commenter (0802-Kraken) requests that EPA align the rule applicability dates with the publication of the supplemental proposal and actual proposed rule language to minimize duplicative requirements and conflicts with compliance dates. The commenter states that there is a chance this rule could have multiple compliance dates based on both the November 2021 Proposal and on the supplemental proposal. The commenter asserts that if the applicability

compliance date is not associated with the proposed supplemental rule, affected facility determinations would be based on a rule proposal and not actual proposed rule language, bringing into question the rule's interpretations and compliance under the CAA.

Commenter (0820-Pioneer) notes that CAA section 111(a)(2) provides that a “new source” is any source whose construction or modification begins “after the publication of . . . proposed regulations [] prescribing a standard of performance under this section which will be applicable to such source.” The commenter states that the CAA does not define the term “proposed regulations,” but the commenter asserts that with respect to the proposed new NSPS OOOOb and EG OOOOc, the November 2021 publication does not appear to constitute “proposed regulations ... prescribing a standard” within the meaning of the statute, as that publication does not propose any regulatory text with respect to these proposed new subparts. The commenter believes that the approach EPA has taken, under which it proposes to subject new sources (*i.e.*, those that commence construction or modification after November 15, 2021) to regulatory requirements whose regulatory text it has not yet proposed, creates considerable uncertainty for companies that may wish to construct or modify sources but cannot reasonably predict what specific requirements such sources will be subject to under the proposed new subparts. For this reason, the commenter states, EPA should, in the supplemental proposal, propose an applicability date for proposed new NSPS OOOOb and EG OOOOc of the date of publication of the supplemental proposal. The commenter believes that failing to do so may render the eventual final rule legally vulnerable. If EPA does not do this, the commenter urges EPA to account for the gap between the “trigger” date for new sources and the date at which regulated companies see proposed regulatory text by providing a longer period to come into compliance, to include a phasing in of regulatory requirements through a series of compliance dates, similar to the approach taken in the 2016 NSPS OOOOa rule.

Response I-23-2: See discussion in section IX.A (What date defines a new, modified, or reconstructed source for purposes of the final NSPS OOOOb?) of the Final Rule preamble related to applicability of the requirements under the proposed rules.

Comment: Commenter (0424-Division of Air Quality, West Virginia Department of Environmental Protection (WVDEP)) asks two questions regarding applicability:

- For affected existing sources constructed on or before November 15, 2021, that will be designated facilities under the EG of 40 CFR part 60, subpart OOOOc, will they continue to also be subject to the NSPS of 40 CFR part 60, subparts OOOO or OOOOa, as applicable?
- Will designated existing facilities under 40 CFR part 60, subpart OOOOc (EG) continue to be subject to 40 CFR part 60, subpart KKK? Please clarify if both the 40 CFR part 60, subpart KKK VOC standards will apply and the 40 CFR part 60, subpart OOOOc (EG) presumptively approvable methane standards will apply to these facilities, or if 40 CFR part 60, subpart KKK will no longer apply, and these sources will be regulated by the state under 40 CFR part 60, subpart OOOOc. If the sources will be subject to regulation under both subparts, has the EPA reviewed these subparts such that the sources will not be subject to conflicting requirements and that the requirements are streamlined?

Similarly, commenter (0924-U.S. Small Business Administration (SBA)) states that small entities have expressed significant confusion and concern about how sources that were new, modified, or reconstructed between August 23, 2011, and November 15, 2021, will be regulated because these sources are subject to direct EPA regulation under prior NSPS, subparts OOOO or OOOOa, and these same sources would be covered by the proposed EG subpart OOOOc to be regulated under state law. The commenter indicates that this situation has the potential to create duplicative regulatory requirements, multiple enforcement authorities, and significant unnecessary costs for small businesses. The commenter recommends that EPA propose that states can obtain an explicit exemption for existing sources from the prior NSPS subparts; under this exemption, states would incorporate the performance standards of NSPS OOOO and OOOOa for these sources into their performance standards under the EG. The commenter notes that such an exemption would reduce the number of different regulatory provisions to which they are subject and clearly identify the regulatory authority for their sources.

Response I-23-3: See discussion in sections IX.A (What date defines a new, modified, or reconstructed source for purposes of the final NSPS OOOOb?), IX.B (What date defines an existing source for purposes of the final EG OOOOc?), and IX.C (How will the final EG OOOOc impact sources already subject to NSPS KKK, NSPS OOOO, or NSPS OOOOa?) of the Final Rule preamble.

Comment: Commenter (0922-National Association of Manufacturers (NAM)) states that EPA should take steps to reduce the likelihood that efforts to comply with the final EG independently trigger requirements under the CAA's New Source Review provisions for any air pollutant.

Response I-23-4: See discussion in section XV (Prevention of Significant Deterioration and Title V Permitting) of the preamble to the final rule regarding the applicability of permitting requirements.

### **23.3 Lack of Regulatory Text**

Comment: Several commenters (0193-National Federation of Independent Business (NFIB), 0599-MSC, 0743-WEA, 0750-Flogistix, 0793-PBPA, 0802-Kraken, 0824-Wyoming Department of Environmental Quality (WDEQ), 0836-Domestic Energy Producers Alliance (DEPA), 0910-Attorney General of Louisiana (AG LA) *et al.*, 0929-NSWA, 0938-TXOGA, 0946-Michigan Oil and Gas Association (MOGA), 0957-Wyoming Coalition of Local Governments (WYCLG), 1391-INGAA, 1341-PGCC *et al.*, 375-Kinder Morgan, 1391-INGAA) express that the November 2021 Proposal, because it did not contain proposed regulatory text for NSPS OOOOb and EG OOOOc, and/or did not meet the requirements as a proposed rule under the APA, does not represent a proposed rule. Several of these commenters (0193-NFIB, 0836-DEPA) recommended that EPA withdraw the November 2021 Proposal. Examples of some of the comments received are provided in the following paragraphs.

Commenter (1391-INGAA) suggests that the lack of regulatory text makes comment on certain aspects of the November 2021 Proposal difficult, if not impossible, because it is unclear what EPA intends to do. For example, the commenter states that in numerous places in the November 2021 Proposal, EPA discusses the regulation of emissions from wells, but it is unclear whether

EPA intends to regulate production wells, storage wells, or both. In Table 2 of the November 2021 Proposal, EPA lists “well liquids unloading” as an affected source and proposes a best system of emissions reduction (BSER) of zero methane or VOC emissions. This BSER can be applied only at hydraulically fractured wells. According to the commenter, it is possible that EPA understands this and intends that this performance standard apply only to hydraulically fractured wells, but without the proposed regulatory text, the commenter’s members have no way of confirming that. The commenter adds that the issue of what type of wells certain proposed standards of performance apply to is a core, fundamental issue, and without knowing this with certainty, the commenter’s members cannot evaluate the proposal and provide EPA with meaningful feedback. Without clear definitions being provided, the commenter argues that it is impossible to understand the scope of the November 2021 Proposal. The commenter provides several examples where it was necessary for them to have greater detail in the form of regulatory text to properly comment (*e.g.*, NSPS and EG proposed compliance timelines, EG state plan requirements).

Commenter (0750-Flogistix) states that they support the Agency's utilization of performance-based standards. However, they note that, by not publishing regulatory text to support the “standards of performance,” EPA demonstrates that these rules have not been fully developed and require significant additional work. By indicating that EPA will later publish a “supplemental proposal” with regulatory text, the commenter contends that the Agency is creating confusion and uncertainty.

Commenter (0193-NFIB) states that the 153-page notice is all preamble and no proposed rule; the notice fails to contain the text of proposed rules. Nevertheless, to the extent the notice describes or refers to proposed rules, the commenter recommends that EPA withdraw them.

Commenter (0836-DEPA) agrees with the Producers Associations comments that the November 2021 proposed rule is at best a notice of proposed rulemaking as a data gathering exercise. The commenter states that the 153 of *Federal Register* text contains no proposed regulatory language. The commenter notes that the comments provided by Producers Associations stated that, “[t]here is no statutory deadline forcing a truncated comment period.

Commenter (0938-TXOGA) suggests that the November 2021 Proposal contains no regulatory language specifying the requirements that would apply to these sources under NSPS OOOOb. To be sure, this approach creates significant uncertainty for regulated sources, but it also is inconsistent with the CAA “new source” definition and Congress’s underlying intent in creating this definition in the statute. The CAA defines a “new source” as “[a]ny stationary source, the construction or modification of which is commenced after the publication of regulations (or, if earlier, proposed regulations) prescribing a standard of performance under this section which will be applicable to such source.” Under this statutory definition, it is clear that application of “new source” standards occurs only where a source undertakes construction or modification after the publication of “regulations” or “proposed regulations” prescribing a standard of performance applicable to the source.

Commenter (0938-TXOGA) suggests the November 2021 Proposal cannot be reasonably construed as a “proposed regulation” (or a proposed “rule,” to use the APA term) because the

Proposal lacks sufficient specificity to reflect any “design to implement, interpret, or prescribe law or policy.” In the Proposal, EPA sets forth conceptual standards that it is considering for affected facilities under NSPS OOOOb but notes that more specific requirements will be issued in a supplemental proposal to “provide regulatory text.” This forthcoming proposed “regulatory text” will constitute the “proposed regulations” for NSPS OOOOb; thus the publication date of the supplemental proposal would be the earliest triggering date for NSPS OOOOb applicability allowed under CAA section 111. The commenter contends that this conclusion is further supported by statements in the preamble that indicate EPA may be regulating beyond that which is identified in the Proposal. For example, EPA states in Section II.A, “Does this action apply to me?” that for regulated entities to determine if they are covered by the regulation, “you should carefully examine the applicability criteria found in the final rule.” But commenters need to examine the applicability in the proposed rule to provide comment. The commenter asserts that is the purpose of a proposed rule.

Commenter (1375-Kinder Morgan) notes that that EPA has advanced its NSPS OOOOb and EG OOOOc proposals without rule language. In this way, the commenters states that the proposals are more akin to an ANPR, making fulsome comment on the proposals at this time, difficult. The APA requires that an agency’s proposed rule must provide “either the terms or substance of the proposed rule or a description of the subjects and issues involved.” EPA states that it “plans to issue a supplemental proposal and supplemental [RIA] for the supplemental proposal to provide regulatory text for the proposed NSPS OOOOb and EG OOOOc.” At present, however, the commenter states that the November 2021 Proposal has been issued without regulatory text, leaving much of the “terms [and] substance” open to interpretation. The commenter, therefore, reserves the right to supplement and modify these comments upon review of any subsequently published proposed regulatory text. Given the significant nature of these preliminary proposals, the commenter encourages EPA to continue dialogue with operators to ensure adequate opportunity for review and comment on any draft rule language is afforded.

Commenter (0824-WDEQ) states that the November 2021 Proposed Rule does not meet the notice requirements of § 4 of the APA. 5 U.S.C. § 553(b). The commenter adds that section 553 of the APA requires agencies to provide public notice of a proposed rulemaking in a way that is “adequate to afford interested parties a reasonable opportunity to participate in the rulemaking process.” *Florida Power & Light Co. v. United States*, 846 F.2d 765, 771 (D.C. Cir. 1988); see also SENATE JUDICIARY COMMITTEE, ADMINISTRATIVE PROCEDURE ACT, S. REP., No. 752, 77th Cong., 1st Sess. 14 (1945) (“Agency notice must be sufficient to fairly apprise interested parties of the issues involved, so that they may present responsive data or argument relating thereto”). The commenter explains that this notice requirement is designed (1) to ensure that agency regulations are tested via exposure to diverse public comment, (2) to ensure fairness to affected parties, and (3) to give affected parties an opportunity to develop evidence in the record to support their objections to the rule and thereby enhance the quality of judicial review. *Small Refiner Lead Phase-Down Task Force v. EPA*, 705 F.2d 506, 547 (D.C. Cir. 1983), *MCI Telecomm. Corp. v. FCC*, 57 F.3d 1136, 1142 (D.C. Cir. 1995).

Commenter (0824-WDEQ) adds that here (under the November 2021 proposal), the agencies have not actually proposed a rule. The commenter states that the proposal lacks any regulatory language or specific requirements, which made it impossible for the commenter to fairly

comment on the substance of the proposal or to assess the scope of its impacts. According to the commenter, the lack of proposed regulatory language, coupled with EPA's 31-page comment solicitation requests about preamble language, is unfair and unlawful. The commenter asserts that EPA must provide substantive and specific regulatory language for comment in conjunction with the preamble in a future proposed rulemaking before it attempts to promulgate a final rule.

Commenter (0824-WDEQ) states that the proposed rule's ambiguity and lack of specific, binding requirements - as well as its solicitation of additional comments on emissions sources and definitions that are not even addressed in the proposed rule, such as abandoned wells, pigging operations and related blowdown activities, and control device efficiency and operation, prevents a full assessment of the complete scope of its impacts. It is quite clear to the commenter, however, that the revised requirements pertaining to NSPS OOOOa, and especially the newly introduced NSPS requirements in NSPS OOOOb and EG OOOOc, would significantly impact Wyoming.

Commenter (0824-WDEQ) states that the proposed rule is opaque, expansive, and lacks specific requirements. The commenter adds that the fact that EPA is soliciting comment on extended areas to regulate in effect transforms a single proposed rule into several different rulemakings; it is far too broad in its scope for a complete assessment. The commenter believes that the document, as written, more closely resembles an ICR or an ANPR than a proposed rule - and a formal period of assessment was not provided. The commenter states that EPA should have performed more outreach with individual oil and gas producing states, such as Wyoming, before promulgating the proposed rule. By not doing so, the commenter believes that EPA missed out on obtaining AQD's extensive knowledge and practical experience on the control and management of methane and other emissions and controls for the oil and gas sector.

Commenter (0824-WDEQ) believes this overarching concern applies to all of the subsequent concerns that are raised. Simply put, the commenter provides that states like Wyoming that will experience significant impacts and cumbersome requirements as a result of the proposed rule cannot reasonably assess the rule in its entirety. In turn, they assert that EPA should have directly engaged with states and given states significantly more time and input by way of an ANPR or ICR, followed by a proposed rule containing more regulatory specificity. According to the commenter, EPA's failure to follow this procedure not only jeopardizes the legal defensibility of the rule, but it represents a missed opportunity for valuable collaboration.

Commenter (0957-WCLG) states that the APA requires that a NPRM include "either the terms or substance of the proposed rule or a description of the subjects and issues involved." 5 U.S.C. § 553(b)(3). The commenter goes on to say that EPA is asking for comments on the potential for establishing standards for abandoned and unplugged wells, pipeline pigging and related blowdown activities, and tank truck loading operations. 86 Fed. Reg. at 63240. The commenter notes that EPA admits that it does not have enough information to quantify and evaluate BSER or NSPS for these systems and, therefore, is not proposing NSPS or EG at this time. This commenter continues by stating that the solicitation of comments is not appropriately included within this notice of proposed rulemaking because it fails to provide an adequate description of the issues involved or terms or substance of a proposed rule. The commenter argues that this

request for additional information on other sources of emission should instead be its own separate rulemaking, starting with an ANPRM to obtain the necessary information.

Commenter (0793-PBPA) states that the November 2021 Proposed Rule does not contain regulatory text. The commenter notes that the proposal indicates that EPA will later publish a “supplemental proposal.” The commenter suggests that, by publishing this proposal without providing the regulated community any regulatory text, EPA has demonstrated that the proposal has not been fully developed and requires significant additional work. Instead of providing the regulated community with proper notice of how it will be regulated, the commenter states that EPA provided a proposal—covering hundreds of thousands of sources—that lacks clarity and creates uncertainty.

Commenter (0793-PBPA) recommends that once EPA publishes the proposed regulatory text, the public should have a minimum of 90 days to review it. The commenter states that they would oppose efforts to promulgate the rule in such a way as to circumvent public input and comment (e.g., through publication of an interim final rule).

Commenter (0802-Kraken) states that EPA published these actions as a “proposed rule” without actual proposed rule language. The commenter sees the November 2021 proposed rule as more of an ANPR in that the published document is soliciting feedback on topics and emission sources with specific associated issues in the same manner as previous EPA rulemaking information collection requests. The commenter posits that publishing proposed actions not yet defined, along with a solicitation for feedback on the addition of regulated sources, creates regulatory and financial uncertainty for the regulated community.

Commenter (0910-AG LA *et al.*) believes that just as other commenters have noted, the Methane Notice is not a NPRM. Despite its length, the so-called “proposed rule” contains no proposed regulatory text. Nor does it put parties on notice of what the final rule will contain. Without such specific and clear proposed regulatory text, the Notice must be considered an ANPR; it does not adequately provide notice to the public of what precisely is being proposed. See 5 U.S.C. §553(b) (“The notice shall include ... either the terms or substance of the proposed rule or a description of the subjects and issues involved.”). Accordingly, before a final rule can be promulgated, the commenter argues that EPA must publish a full notice of proposed rulemaking that includes specific, clear proposed regulatory text.

Commenter (0946-MOGA) believes that the proposed regulations on November 15, 2021, did not offer a specific regulatory framework or text. Small business entities with minimal staff and limited resources need direct, well-defined, and easily understood proposed regulations to evaluate for impacts and provide meaningful comment. Further, approximately 1000 pages of preamble and technical service documents were published by EPA with a limited response time of 77 days encompassing two major holidays. The commenter asserts that this significantly prevented many of the commenter’s constituents from fully deciphering and commenting on the potential short-term and long-term implications of proposed regulations.

Commenter (0929-NSWA) states that the 153 pages of *Federal Register* text contains no proposed regulatory language. The commenter asserts that the “proposed rule” is not a proposed

rule, at best, it should be considered in the form of what experienced observers of federal regulatory practices would view as an ANPR. The commenter believes that it is particularly concerning that the released preamble language – without regulatory text included as mentioned previously – is not well-formed and yet the agency is still seeking a significant number of comments. The commenter states that this is occurring in the context of a demonstrated lack of full input from regulated parties about how the regulations will impact their business and the challenges with implementing EPA’s proposals, both operationally and financially. For example, they note that small business operators will disproportionately realize the impact of short development time of this regulation due to fewer available resources to digest and translate the requirements into actionable programs.

Commenter (0929-NSWA) believes EPA should have been collecting additional input from stakeholders which most likely would have reduced the number of times that EPA solicited input in the proposed regulation and would have provided the regulated community with more certainty in what the final regulation will look like.

Thus, the commenter (0929-NSWA) suggests it is likely the regulatory text, whenever it is issued, will leave efforts to address methane and improve the environment in a weaker, not stronger, position. The commenter states that one very tangible example of this likely outcome in the forthcoming rule is reflected in the preamble, where EPA stated that they are considering including additional sources as affected facilities that would be regulated for methane emissions. These sources include standards for abandoned and unplugged wells, pipeline pigging and related blowdown activities, and tank truck loading operations. The commenter is concerned that EPA has not spent sufficient time developing the regulation to determine if these operations should be included in the regulation or should be omitted. The commenter believes that there is currently insufficient data to support developing new regulations for the proposed sources. The commenter asserts that EPA needs to collect an appropriate volume of data and engage industry stakeholders prior to developing new regulations for the sources.

Commenter (1391-INGAA) states that the absence of proposed regulatory text makes it difficult to provide meaningful comments on November 2021 proposed NSPS OOOOb and proposed EG OOOOc. They add that EPA’s failure to provide the proposed regulatory text is unusual and is inconsistent with the intent of the APA. The commenter urges EPA to follow through on its plan to issue a supplemental proposal with the proposed regulatory text. The commenter states that they will submit comments on the supplemental proposal and the proposed regulatory text and asks EPA to allow sufficient time (*i.e.*, at least 90 days) for preparation of comments on that proposal. In the absence of the regulatory text, commenting on certain aspects of the Proposed Rule is difficult—if not impossible. For example, the commenter states that it is unclear in several places what type of wells EPA intends to regulate in certain situations.

Commenter (1391-INGAA) asserts that EPA’s failure to provide the proposed regulatory text is unusual and is inconsistent with the intent of the APA. As EPA notes in the Proposed Rule, it “plans to issue a supplemental proposal and supplemental [regulatory impact analysis (RIA)] for the supplemental proposal to provide regulatory text for the proposed [NSPS] OOOOb and ... [EG] OOOOc.” EPA states that it views this “[a]s a further step in the rulemaking process” and will be “solicit[ing] additional public input” at that time. As a result, these portions of the

Proposed Rule do not include rule language and are more akin to an ANPR, and as discussed further below, it makes meaningful comment on certain aspects of the Proposed Rule impossible.

Commenter (1391-INGAA) states that it is highly unusual for an agency to purposefully exclude proposed regulatory language in a proposed rule, especially one of this magnitude. The commenter adds that the APA requires that an agency's proposed rule must provide "either the terms or substance of the proposed rule or a description of the subjects and issues involved." Courts have interpreted the notice requirement of the APA to require that a final rule be a "logical outgrowth" of the proposed rule. The commenter notes that the issue of whether or not mere vague discussion of the issues involved is sufficient to satisfy the logical outgrowth test has not yet been decided by the courts.

Commenter (1391-INGAA) urges EPA to follow through on its plan to issue a supplemental proposal and supplemental RIA along with the proposed regulatory text for NSPS OOOOb and EG OOOOc and further urges EPA to allow sufficient time for comment on these important documents. In particular, seeing the regulatory text is imperative as the specific words matter. As EPA knows, the commenter states that how a statute or a regulation is interpreted by courts and by EPA can be affected by such benign things as the placement of a comma or a word as seemingly innocuous as "any." The commenter provides several examples where they note that it was essential for them to see the regulatory text in order to be able to provide comment. The commenter states that they look forward to reviewing the proposed regulatory text once it becomes available and asks the Agency to provide a reasonable amount of time for comment on that text and all related aspects of the Proposed Rule as it will likely give rise to many new issues that cannot be identified now in the text's absence.

Response I-23-5: The EPA has responded to concerns about proposed regulatory text, and applicability in the preamble for the final rule. The December 2022 Supplemental Proposal included proposed regulatory text for both the NSPS OOOOb and EG OOOOc.<sup>4</sup> Similar comments were also provided on the December 2022 Supplemental, see Volume II, Chapter 23 (Miscellaneous Other Comments), subsection 23.6 (Regulatory Text), Response II-23-26 for response to those comments.

### **23.4 Request for Clarification of the Applicability/Requirements of the Differing NSPS OOOOa/OOOOb/OOOOc Rules**

Comment: Commenter (0820-Pioneer) recommends that EG OOOOc be relative to NSPS OOOOa and as such, the applicability date for EG OOOOc be pre-2015 instead of pre-2021. As this rule is proposed, the six or so years of "new sources" under NSPS OOOOa (applicability date of September 2015), will now potentially be captured under EG OOOOc as "existing sources". The commenter notes that this would result in individual affected facilities such as compressors, certain pneumatic controllers, and fugitive emission components, among others, to be considered both a "new" and "existing" source under the CAA.

---

<sup>4</sup> For the proposed NSPS OOOOb regulatory text, see Docket ID Number EPA-HQ-OAR-2021-0317-1551; for the proposed EG OOOOc regulatory text, see Docket Number EPA-HQ-OAR-2021-0317-1552.

Commenter (0820-Pioneer) states that notwithstanding the fact that these source categories and individual affected facilities within the source categories are covered under the same statute and covered under two separate, seemingly mutually exclusive sections, CAA 111(b) and 111(d), the definition and use of the term "existing source" in the CAA seems to clearly differentiate these sections. In 111(a)(6), EPA defines "existing sources" as "*any stationary source other than a new source,*" and CAA 111(d)(1)(A)(ii) provides that state plans for existing sources establish standards of performance for "any existing source for any air pollutant... to which a standard of performance under this section would apply *if such existing source were a new source.*" (emphasis added). The commenter asserts that the plain text of CAA 111, therefore, repeatedly draws a binary distinction between new and existing sources. According to the commenter, there is no sign that Congress intended EPA to regulate any source for the same pollutant simultaneously as both a new source under CAA 111(b) and an existing source under CAA 111(d).

Commenter (0820-Pioneer) requests that EPA explain the process and precedent for imposing two separate provisions that apply to two different categories of the same sources per definitions on 111 of the CAA.

Commenter (0820-Pioneer) requests clarification on how compliance would work in this scenario. For example, would there still be federal requirements under NSPS OOOOa to comply with as well as the EG OOOOc requirements that will presumably be developed under the state plan? The commenter suggests that would seem to result in duplicative record keeping a great deal of confusion. EPA should work to ensure that there is not duplicative reporting and recordkeeping requirements. For example, if a source is subject to both NSPS OOOOa and EG OOOOc, the source should be allowed to submit information to the state under EG OOOOc and be able to meet the reporting requirements for NSPS OOOOa. Please clarify.

Further, the commenter (0820-Pioneer) states that the vast majority of operators have taken extensive measures to comply with NSPS OOOOa in good faith and the EG OOOOc rules will likely impose more stringent requirements in the same sources which may require replacement and/or retrofitting certain equipment. The commenter explains that operators across the country have made certain decisions in well site and tank battery designs and equipment, and capital investments in reliance of NSPS OOOOa and in will potentially have to readdress and change these same sources for EG OOOOc. The commenter urges EPA to keep in mind that regulatory certainty is of vital importance to the oil and gas business functioning well economically and in an environmentally sound and compliant manner. The commenter adds that constant changes can result in a great deal of confusion, disrupt operations, such as delaying production and causing wells to be shut in prematurely, and even emission events while replacing and/or retrofitting, and impose an undue burden.

Response I-23-6: The EPA responded to concerns about applicability, including the potential for overlapping requirements in section IX (Interaction of the Rules and Response to Significant Comments Thereon) of the final rule preamble.

Furthermore, the EPA disagrees with commenters that the EPA's definition of a "new" and "existing" source for purposes of this rulemaking is at odds with the statutory definitions. In this

final action, pursuant to CAA section 111(b)(1)(B), the EPA is promulgating new and updated standards in NSPS OOOOb that will apply to sources that construct after December 6, 2022, consistent with the statutory definition of “new sources” at CAA section 111(a)(2) which ties the applicability of an NSPS to the date of the proposed regulations prescribing the standards of performance. The term “existing source” is defined at CAA section 111(a)(6) in direct contrast as “*any stationary source other than a new source.*” Thus, relative to NSPS OOOOb being finalized in this rulemaking, an existing source is *any* source that would not be subject to NSPS OOOOb, i.e., any source constructed on or before (rather than after) December 6, 2022. This is further reinforced by the terms of 111(d)(1), which state that an EG promulgated under that provision applies to “*any existing source for any air pollutant . . . to which a standard of performance under this source would apply if such existing source were a new source.*” Consistent with this text, the EPA is promulgating OOOOc to apply to the same facilities that would have been subject to NSPS OOOOb if they had been constructed after December 6, 2022.

Moreover, the fact that some of these facilities may have been subject to the previously promulgated NSPS OOOOa does not undermine the EPA’s definition of an existing source relative to NSPS OOOOb. Nothing in the text of section 111 bars the EPA from regulating sources that complied with previous new source performance standards as “new sources” when newly constructed as “existing sources” after the EPA has promulgated updated new source standards after the source’s construction. Such sources meet the definition for an “existing source,” which broadly is defined as “any stationary source other than a new source.” Such sources are not, as the commenters contend, both “new sources” and “existing sources” of the same pollutant at the same time. Rather, after an emission guideline is issued, and a state or federal plan setting forth standards of performance is finalized, these sources are only existing sources. The commenters contend that their reading of section 111 means that any source that complied with a new source performance standard as a new source would never have to apply updated emission controls—they would only ever have to comply with the new source performance standard in place when they were newly constructed. That reading is untenable, and inconsistent with both the plain meaning of section 111 read as a whole, as well as with the broader purpose of the CAA. *See* CAA §101(b)(1) (The primary goal of the CAA is: “[T]o protect and enhance the Nation’s air resources so as to promote the public health and welfare and the productive capacity of its population.”). Application of that approach could have the perverse approach of permitting source that constructed decades prior consistent with now-outdated performance standards to avoid updating pollution controls even when more advanced and cost-effective control measures have become available, which cannot be reconciled with the statutory mandate to review standards every 8-years. This would frustrate the core purpose of section 111(b) and (d), which is intended to ensure that the standards of performance reflecting the “best system of emission reduction” are implemented for all sources (both new and existing). Further, regulating a source that complied with a new source performance standard when newly constructed as an “existing source” at a later point in time after the new source standards are updated is consistent with past agency practice. In the 2016 emission guideline for methane emissions from landfills, EPA likewise regulated landfills as existing sources even where those landfills had complied with a new source performance standard when constructed.

In response to comment that EPA keep in mind that constant changes can result in confusion, and disrupt operations, such as delaying production and causing wells to be shut in prematurely,

and even emission events while replacing and/or retrofitting, can impose an undue burden, the EPA acknowledges the commenter's concerns. The EPA has engaged with pertinent stakeholders regarding their concerns throughout the rulemaking process. Stakeholders have included, but are not limited to, industry, small businesses, tribal nations, and communities most affected by, and vulnerable to, the impacts of the rule. See discussion section VII (Summary of Engagement with Pertinent Stakeholders) in the final rule preamble. Input from all stakeholders were considered in the development of the final rule requirements, including industry concerns regarding the burden. See section X of the final rule preamble for a summary of the final NSPS OOOOb and EG OOOOc requirements.

Comment: Commenter (0831-AXPC) is concerned that, under EPA's Initial Methane Notice, proposed in November 2021 some sources would be deemed both "new" and "existing" with respect to CAA 111 standards for methane. Specifically, sources whose construction or modification begins after September 18, 2015, and before November 15, 2021, would be "new" in that they are covered by NSPS OOOOa, and "existing" in that they will also be covered by new EG OOOOc. 86 Fed. Reg. at 63,117, Table 1 (Applicability Dates for Proposed Subparts Addressed in This Proposed Action). The commenter asserts that EPA does not have authority to take this approach under the statute. Even if it did, there is no environmental benefit to "pancaking" multiple layers of regulation on the same source, and there are compelling reasons of policy why EPA should not do so—in fact, doing so could be environmentally counterproductive (please note that this is separate and apart from commenter's position, as expressed elsewhere in these comments, that EPA cannot define a "new source" as one that begins construction or modification after the publication of the Initial Methane Notice, and that it should instead, in the supplemental proposal, set the determining date for new-source status at the eventual date of publication of that supplemental proposal, to include proposed regulatory text for new NSPS OOOOb and EG OOOOc).

First, the commenter (0831-AXPC) provides that CAA 111(d)(1)(A)(ii) provides that state plans for existing sources establish standards of performance for "any existing source for any air pollutant . . . to which a standard of performance under this section would apply if such existing source were a new source" (emphasis added). And CAA 111(a)(6) defines "existing source" as "any stationary source other than a new source" (emphasis). The commenter adds that the plain text of CAA 111, therefore, repeatedly draws a binary distinction between new and existing sources. The commenter states that there is no sign that Congress intended EPA to regulate any source for the same pollutant simultaneously as both a new source under CAA 111(b) and an existing source under CAA 111(d).

Second, the commenter (0831-AXPC) notes that even if EPA did have authority to proceed in this fashion, they believe that it would be either pointless or environmentally counterproductive to do so. Layering multiple sets of regulation to control the same pollutant does not provide enhanced environmental benefits, but it does create a highly confusing situation for owners and operators wishing to understand their compliance obligations. In fact, this "pancake" approach could actually lead to worse environmental outcomes. If owners and operators subject to a new-source regulation are faced with the prospect that EPA, at any future time, may also subject their new-source facilities to an existing source rule, that uncertainty will deter the owners and operators from innovating to comply with, and even do better than, the standards contained in the

new source regulation. The commenter states that CAA 111(b) is supposed to identify the best performance or work-practice standards and encourage their adoption to generally further the performance of the fleet of new sources. That purpose is thwarted under a duplicative, confusing, and extra-statutory approach like the one EPA suggests in the Initial Methane Notice.

Fortunately, commenter (0831-AXPC) suggests there is a way to avoid this negative scenario, which is both in keeping with the statute and good policy. In its supplemental proposal, the commenter recommends that EPA revise the Initial Methane Notice in the following regard: It should, in the supplemental proposal, propose that new EG OOOOc will only apply to pre-NSPS OOOOa sources, *i.e.*, those sources that did not begin construction or modification before September 18, 2015. This will ensure that new sources subject to NSPS OOOOa are not subject to duplicative methane regulation under that standard as well as the existing-source methane rule in new subpart EG OOOOc. By taking this approach, the commenter states that EPA can avoid both the conflict with the statutory text and design, and the policy problems noted above.

Response I-23-7: See Response I-23-6 of this Chapter.

Comment: Commenter (0810-Petroleum Alliance-OK) states that it is very confusing as to how the Proposed Rule will function collectively. For example, they suggest that it is unclear how the effective dates, requirements, new definitions, *etc.* overlap and/or are triggered pushing an operator into different rule requirements. The commenter encourages EPA to provide clarity as to how each rule (NSPS OOOOa/b/c) will work together, separately or be superseded.

Commenter (0911-NPDC) suggests that EPA should seek to create rules that are easy to understand and implement. The constant amendments, additions, and deletions to the Oil and Natural Gas Sector NSPS have made it difficult for industries and agencies to interpret. The commenter has heard that interpretations between EPA regions and states with primacy vary significantly. The commenter suggests EPA address this by developing regulations and guidance that can be universally understood by agencies and regulated industries.

Commenter (0577-KIOGA) requests clarification regarding affected existing sources constructed on or before November 15, 2021, that will be affected facilities under the EGs of 40 CFR 60, subpart OOOOc, will they continue to also be subject to the NSPS of 40 CFR 60, subparts OOOO or OOOOa, as applicable?

Commenter (0921-USCC) states that the applicability of NSPS OOOO, OOOOa, and OOOOb, and EG OOOOc is unclear. The commenter explains that some preamble language, however, suggests that EPA believes a source can be covered concurrently by requirements for both new and existing sources, and that there will be some sort of yet-to-be-explained process based on the stringency of individual provisions to establish which provisions control. The commenter contends that this view is incorrect as a matter of law and unworkable administratively. In the forthcoming supplemental proposal, the commenter requests that EPA explain how it views the relative applicability of these Subparts.

Commenter (0921-USCC) requests that EPA make clear the following in the supplemental proposal. First, if a source is currently regulated as a “new source” under NSPS OOOO,

OOOOa, or OOOOb, it cannot be regulated as an “existing source” under NSPS OOOOc. Second, EG OOOOc would apply only to those sources not covered by NSPS OOOO or OOOOa on the date of the NSPS OOOOb applicability, which should occur no earlier than the publication date of a supplemental proposal with proposed regulatory text. Third, in the future, sources covered by NSPS OOOOc will transition to Subpart Ob if they undergo a modification or reconstruction. The commenter suggests that this approach is grounded in the statute, eliminates the ambiguity of the current Proposal, prevents unnecessary duplicative regulatory requirements, and also would be workable by the regulated parties and EPA.

Commenter (0727-OK DEQ) states that once the rules are final, there will be four NSPS rules applicable to the oil and gas sector (NSPS OOOO, OOOOa, OOOOb, and OOOOc/State Plan), all of which could potentially be applicable at a single facility, albeit for different components/affected facilities. Because of this, each subpart needs to be clear in the rule text as to where one rule supersedes the other and where applicability of each rule starts and stops for each affected facility. No single component/affected facility should be subject to more than one NSPS or emissions guideline at any given time. The commenter asserts that, without clear rule text, there will be confusion among owners/operators as well as regulators about the applicability of each subpart. Regulatory clarity and certainty pertaining to the applicability of each potential future rule are necessary for effective programs, and the commenter requests EPA pay close attention to this matter when finalizing any future rules.

Response I-23-8: See Response I-23-6 of this Chapter.

Comment: Commenter (0742-ADEC) requests clarification on several aspects of the Proposed Rule. NSPS OOOOa (and presumably, the final NSPS OOOOb proposal will replicate) states: “You are subject to the applicable provisions of this subpart if you are the owner or operator of one or more of the onshore affected facilities ... for which you commence construction, modification, or reconstruction after November 15, 2021...”. Also “Each well affected facility, which is a single well that conducts a well completion operation following hydraulic fracturing or re-fracturing...” and “Each pneumatic controller affected facility...” and “For well sites, each pneumatic pump affected facility, which is a single natural gas-driven diaphragm pump...” The confusion begins when there are affected facilities (*e.g.*, pneumatic controller) at affected facilities (*e.g.* well-site) including some non-affected facilities that are comprised of many small emissions units (*e.g.* other identical pneumatic controllers) alongside wells that may be affected facilities or not. According to the commenter, tracking the entire affected and non-affected universe of facilities list as well as the applicable requirements can lead directly to compliance risk and concerns. The commenter recommends that EPA propose a simpler and more robust system of compliance tracking that is more readily adaptable to the constant changes due to plant repair and upkeep requirements, especially on the Alaska North Slope, where the repair and replacement maintenance season may be severely limited.

Response I-23-9: In response to comments on the need to provide a rule that is simpler than NSPS OOOOa, the structure of applicability of requirements to affected facilities under the final NSPS OOOOb rule is similar. The definition of affected facilities and the applicability of requirements are affected facility-specific and while the commenter may find compliance tracking challenging, many of the differences are needed to account for specific emissions

mechanisms, technologies, data and feedback from commenters providing support for those differences.

The EPA considered these and other comments when developing the NSPS OOOOb and EG OOOOc regulatory text proposed with the December 2022 Supplemental Proposal.<sup>5</sup> Based on comments on the December 2022 Supplemental Proposal, the EPA made changes and clarifications to the final rules. See section X of the final rule preamble for a summary of the final NSPS OOOOb and EG OOOOc requirements.

Comment: Commenter (0740-UPA) requests that EPA include a provision in NSPS OOOOb and EG OOOOc regulations such that sites may comply with the most stringent applicable set of requirements between the Federal Implementation Plan (FIP)<sup>6</sup>, NSPS OOOOb, or state regulations adopted under EG OOOOc to meet the EGs, or that a source may voluntarily comply with a more stringent set of regulations in lieu of the FIP, without an obligation to continue to show compliance with the applicable but less stringent set of requirements. The commenter states that such a provision will simplify compliance with recordkeeping, reporting and other regulatory details, and could potentially encourage some operators to voluntarily meet a more stringent standard as a means to harmonize and simplify their overall compliance obligations.

Response I-23-10: While the EPA did not include a provision in NSPS OOOOb and EG OOOOc stating that sites may comply with the most stringent applicable set of requirements between the NSPS OOOOb, state regulations adopted under EG OOOOc and the FIP, the EPA clarified the stringency and applicability of the differing federal rules/requirements under the NSPS and EG in the final rule preamble, including at section IX (Interaction of the Rules and Response to Significant Comments Thereon), as well as in the discussion of individual emission sources.

See also section XIII.C.2 (State flexibilities) of the final rule preamble for a discussion regarding the specific criteria that states need to meet in determining whether a state plan meets the level of stringency required under the final EG.

Comment: Commenter (0577-KIOGA) inquires whether designated existing facilities under 40 CFR 60, Subpart OOOOc will continue to be subject to 40 CFR 60, Subpart KKK. The commenter requests clarification on whether both the NSPS KKK VOC standards will apply and the EG OOOOc presumptively approvable methane standards will apply to these facilities, or if NSPS KKK will no longer apply, and these sources will be regulated by states under EG OOOOc. The commenter further asks whether sources will be subject to regulation under both subparts, and whether EPA has reviewed these subparts such that the sources will not be subject to conflicting requirements and that the requirements are streamlined.

Response I-23-11: The EPA responded to this concern in the preamble for the final rule in addressing applicability.

---

<sup>5</sup> For the proposed NSPS OOOOb regulatory text, see Docket ID Number EPA-HQ-OAR-2021-0317-1551; for the proposed EG OOOOc regulatory text, see Docket Number EPA-HQ-OAR-2021-0317-1552.

<sup>6</sup> Federal Implementation Plan for Managing Emissions From Oil and Natural Gas Sources on Indian Country Lands Within the Uintah and Ouray Indian Reservation in Utah.

## 23.5 NSPS OOOOb Compliance Timeline

Comment: Commenter (0831-AXPC) suggests that EPA provide a considerably longer time for compliance with the provisions of new NSPS OOOOb after finalization than it otherwise might, or than it has in prior section 111 rulemakings. The commenter believes that a longer time for compliance is specifically appropriate here for three main reasons. First, the subject matter involved in this rulemaking is considerably more complex than it was in most or all prior rulemakings under this section, in terms of, *e.g.*, factors including the scope and types of equipment covered, and the number of sources covered, and the variability from site to site. Second, ongoing supply-chain issues, including but not limited to, the impact of the ongoing pandemic, make it more difficult for companies to prepare for compliance. Third, because the Initial Methane Notice did not include proposed regulatory text for new NSPS OOOOb, companies are even more hindered in their ability to prepare for their eventual compliance options.

Commenter (0831-AXPC) states that they look forward to reviewing the proposed regulatory text for new NSPS OOOOb in the forthcoming supplemental proposal. Based on their review of that proposed regulatory text and the information and analysis that the supplemental proposal will provide, they anticipate that they will be able to provide more detailed comments and suggestions with respect to compliance dates in their comments on the supplemental proposal.

Commenter (0740-Utah Petroleum Association) suggests that EPA provide three years for existing new facilities to come into compliance with NSPS OOOOb.

Response I-23-12: With regards to the compliance timeline for NSPS OOOOb, the EPA has not granted the three-year extension for existing new facilities to come into compliance with NSPS OOOOb. Nonetheless, the EPA has concluded that only sources constructed, modified, or reconstructed after the date of the Supplemental Proposal (December 6, 2022) should be considered new sources for the purposes of NSPS OOOOb. Changing this date to December 6, 2022, from the November 15, 2021, reduces the number of existing new sources that will need to comply with NSPS OOOOb. For details, please see discussion in section IX (Interaction of the Rules and Response to Significant Comments Thereon), subsection A (What date defines a new, modified, or reconstructed source for purposes of the final NSPS OOOOb?) of the final rule preamble. The EPA also provided an alternative compliance timeline in the final rule for process controllers and pumps required to meet a zero-emission standard (*i.e.*, final rule allows up to one year from the publication date of the final rule). See section XI.D.4 (Compliance dates) of the final rule preamble for a discussion on the compliance dates finalized for process controllers (which also applies for pumps). Additionally, the EPA has included several provisions in the NSPS OOOOb final rule that address supply chain issues (*e.g.*, delay of repair provisions for when parts are unavailable for repair).

Comment: Commenters (1085-Small Operator Society LLC, 0847-Mull Drilling Company, Inc.) suggest that EPA should provide a longer implementation period of the rule for small businesses.

Commenter (0598-Countrymark Energy Resources, LLC) recommended providing relief to small entity representatives by including an extended compliance period. For reference, the

commenter notes that EPA did not provide this benefit in the final release of NSPS OOOOa in 2016. At the time of this particular implementation, all companies were required to develop and implement compliance programs within 60 days. The commenter states that EPA has a history of granting small entity representatives an extended compliance period. For example, small business refiners were granted three additional years to implement solutions to reduce the sulfur in their gasoline products (Tier III gasoline standard). In this case, the commenter asserts that EPA recognizing constraints on many small businesses, and granting an additional twelve months for compliance would be meaningful relief.

Response I-23-13: See Response I-23-12 of this Chapter.

## **23.6 General Opposition to the Proposed Rule(s)**

### ***23.6.1 General Opposition***

Comment: Commenters (0321-Hoosier House Furnishing LLC, 0219-Mullet Battery Inc., 0910-AG LA *et al.*, 1300-Public Land Solutions) generally oppose the proposed regulations.

Commenter (0425-Darrah) believes the rule unfairly singles out the oil and gas industry, when the agriculture industry is essentially equal in methane emissions according to EPA. The agriculture industry can voluntarily implement programs and are paid to do so while the oil and gas industry is mandated and subject to burdensome costs. The commenter suggests that the EPA rule is not an equitable station.

Other commenters (0465-Jordan Development, 0572-West Bay Production Company, 0739-Citation, 0790-West Virginia Office of the Attorney General, 0803-OH OG, 0946-MOGA, 1102-TDR Construction, 1155-Bean Ridge Resources) express opposition to the rule(s) based on what they assert will result in impractical, unnecessary and costly burdens associated with requirements under the rule for an industry that is already controlling its emissions:

- Many of the proposed requirements are not practical, such as the monitoring of wells that are plugged, as the supervision and authority for well plugging is vested with the state. (0572-West Bay Production Company)
- The Proposed Rule's emission controls, monitoring, and recordkeeping requirements are burdensome and will stifle the continued development of oil and natural gas resources in Ohio. Such a result will have a substantial negative impact on homeowners, farmers, and small businesses, particularly in underserved rural communities in Ohio. The commenter suggests that EPA should revise the Proposed Rule by providing more regulatory flexibility and less stringent emissions control requirements where practical realities dictate as much. (0803-OH O&G)
- The cost of the implementation, especially the monitoring and compliance, will devastate small businesses. The commenter is also uncomfortable with the liability insurance and risk of having untrained personnel on their oil lease. There is also not a clear amount of emissions per bbl of oil [barrel of crude oil] to determine if you have to implement the monitoring. (1102-TDR Construction, Inc.)

- The potential reporting burden from the inclusion of existing facilities could be very large. The commenter requests the reporting requirements for any existing facilities be removed or minimized. (0739-Citation)
- The proposed regulations appear to unfairly penalize companies who have been reducing emissions since implementation of Subpart OOOO. The commenter questions how the purchase and financing of existing wells is different than drilling new wells. The commenter asks for clarity on how costs will change when considering new regulations. Lastly, the commenter questions how EPA's emission reduction goals can be met when the proposed regulations are changed every 2 to 4 years. It doesn't appear that production decline is even considered. The commenter urges EPA to reconsider and instead to work with industry to develop a plan that allows small companies to continue to profit and move forward. (1155-Bean Ridge Resources)

Commenter (0946-MOGA) questions EPA's use of 2019 emission data to justify the current proposed regulations. Based on historic rulemaking efforts, if the full implementation of NSPS OOOOa did not begin until roughly 2018 (considering the 2-year & 90-day court stay), the commenter inquires how can EPA determine the effectiveness of the NSPS OOOOa regulations and justify the new proposed regulations? The commenter states that, as shown in the emissions reduction table in Comment number "2" of their comment letter (regarding Pragmatic and Economic Viability Concerns), Michigan producers have been successful in reducing emissions through NSPS OOOO and OOOOa regulations. [Emission reduction table shows reductions show a range of 40 to 90 percent reduction in methane emissions from 2011 to 2020 for 3 companies, with an average reduction in methane emissions of around 65 percent). The commenter notes that the three small businesses included in the emission reduction table have invested significant capital to achieve emission reductions without EPA allowing enough time to recover costs. Based on this data, the commenter believes that EPA should allow more time to evaluate current regulations applied to new sources and future modifications of previously non-regulated sources before amending regulations resulting in another substantial economic burden on small business producers.

Similarly, commenter (0465-Jordan Development) argues that existing regulations for new wells including NSPS OOOO and NSPS OOOOa combined with natural production formation depletion will facilitate EPA's emission reduction goals. The commenter evaluated their 40 CFR Part 98, Subpart W annual reported Carbon Dioxide (CO<sub>2</sub>), Methane (CH<sub>4</sub>) and Nitric Oxide (NO<sub>x</sub>) emission over the 9-year reporting period from 2011 through 2020. From the data, Jordan observed an average annual methane reduction of 4.8% and a total methane emission reduction of 43.20% to date. EPA indicated that they used 2019 emission data to justify the current proposed regulations. If the full implementation of NSPS OOOOa did not begin until 2018 (considering the 2-year & 90-day stay), the commenter asks how can EPA determine the effectiveness of the current regulations and justify the new proposed regulations? The commenter states that their efforts to implement NSPS OOOO and OOOOa regulations has resulted in significant capital investment for their small business to reduce emissions without EPA allowing enough time to recover costs. The commenter believes that EPA should allow more time to evaluate current regulations applied to new sources and future modifications of previously non-regulated sources before amending regulations resulting in another substantial economic burden on small business producers.

Response I-23-14: The oil and natural gas industry is the United States' largest industrial emitter of methane. Human emissions of methane, a potent GHG, are responsible for about one third of the warming due to well-mixed GHGs, the second most important human warming agent after carbon dioxide. The EPA is finalizing the actions as outlined in the preamble to the final rule accordance with its legal obligations and authorities following a review directed by EO 13990, "Protecting Public Health and the Environment and Restoring Science to Tackle the Climate Crisis," issued on January 20, 2021.

In response to comments that state that industry has already been effective at reducing emissions under the NSPSs OOOO and OOOOa, the EPA agrees. However, greater emissions reductions of VOC and methane emissions are needed. As discussed in the final rule preamble, these final actions stem from the EPA's authority and obligation under CAA section 111 to directly regulate categories of new stationary sources that cause or contribute to endangerment from air pollution and to promulgate EG for states to follow in regulating existing sources (designated facilities) in the source category. See section II (Executive Summary), subsections A (Summary of the Major Provisions of this Regulatory Action) and B (Purpose of the Regulatory Actions), and section IV (Statutory Background and History) of the final rule preamble for support for the development of the NSPS OOOOb standards and EG OOOOc presumptive standards.

As discussed in section VIII.B (How does EPA evaluate control costs in this final action?) of the final rule, the final standards will impose some new costs on industry (including small businesses). Many of the standards, however, reflect control mechanisms and measures that many companies and sources around the country are already implementing – again, without deleterious effect on industry as a whole – which shows not only that such controls are "adequately demonstrated" but also underscores their reasonableness from a cost perspective. The EPA provides the cost effectiveness estimates for reducing VOC and methane emissions for various control options considered in the November 2021 Proposal and the December 2022 Supplemental Proposal, as well as in section XI of this preamble and associated TSDs. See also Volume II, Chapter 4 (Fugitive Emissions from Well Sites, Centralized Production Facilities, and Compressor Stations), section 4.3.4 (Small Business/Cost Concerns) comments and responses on small business/cost concerns related to fugitive emissions requirements.

Also, the revised Initial Regulatory Flexibility Analysis (IRFA) and Final Regulatory Flexibility Analysis (FRFA) provides an extensive discussion of regulatory flexibility alternatives and notes key areas where options were chosen to reduce regulatory burden on small businesses that will also, in many cases, reduce regulatory burden for many large businesses. In addition to providing several compliance alternatives for affected facilities under NSPS OOOOb and designated facilities under EG OOOOc, the EPA has also considered issues such as lingering supply chain issues and increased demand for equipment and services when establishing compliance, and repair and delay of repair provisions included in the final NSPS OOOOb and EG OOOOc rules to account for parts not being available.

With respect to EPA using 2019 emissions data, when the EPA developed the November 2021 Proposal, the most up to date emissions data was for the Year 2019, and the EPA has maintained this baseline in subsequent analyses in support of these actions for consistency. Note that the present value (PV) and equivalent annual value (EAV) of costs, benefits, and net benefits of this

rulemaking is in 2019 dollars; and the Regulatory Impacts Analysis (RIA) estimated the cost, emissions, and benefit impacts for the 2024 to 2038 period.

### ***23.6.2 Interaction with State Regulations***

Comment: Commenter (0957-WY CLG) asks EPA to approach this area with caution and first determine what if any role should EPA play. This proposed rulemaking greatly expands the regulatory reach over the oil and gas industry by proposing more stringent VOC and GHG emission standards and monitoring requirements for new sources, subjecting more equipment and processes to the standards, and proposing EGs for existing sources. The commenter provides that western states have developed rules that link environmental protection, land use and production. The EPA top-down rules will only interfere with the current system with the goal of reducing emissions at great cost to the industry and the states. The over regulation of the oil and gas industry will only lead to continued production declines and increased reliance on imports to meet the nation's energy demands.

Response I-23-15: In response to the comment that the November 2021 Proposal greatly expands regulation, and that over regulation of the oil and gas industry will only lead to continued production declines and increased reliance on imports to meet the nation's energy demands, we disagree. There are a lot of variables influencing production and demand that extend beyond regulations impacting the oil and gas industry. See Volume I, Chapter 20 (Emissions and Regulatory Impacts), section 20.2.6 (Energy Impacts), Responses I-20-25 and I-20-26 for EPA's response to comments on the expected impacts of the final NSPS OOOOb and EG OOOOc regulations on domestic oil and natural gas production.

See also sections IV (Statutory Background and Regulatory History) and V (Legal Basis for the Final Rule Scope) of the final rule preamble for the basis and scope of the final NSPS OOOOb and EG OOOOc rules.

### ***23.6.3 Domestic/Global Oil and Natural Gas Resource Demand Considerations***

Comment: Commenter (0921-USCC) suggests that the Proposed should consider the importance of maintaining the nation's energy security and continuing the development of our natural resources to maintain comparatively low energy prices. The commenter also suggests that EPA consider and support the availability and growth of good-paying jobs in the oil and gas sector.

Commenter (0921-USCC) states that while crafting a methane regulation that will be durable and cost-effective, it is critical that EPA maintain and not undercut the energy security that the shale revolution has provided for the nation. In 2019, the U.S. enjoyed its best energy security since 1970.<sup>7</sup> In addition, the U.S. became a net energy exporter in 2019 for the first time since 1952.<sup>8</sup> After achieving a record high risk score in 2011 of 100.[9], the total U.S. energy security risk

---

<sup>7</sup> See Global Energy Institute ("GEI"), U.S. Chamber of Commerce, "Index of U.S. Energy Security Risk – 2020 Edition" Table 1, [https://www.globalenergyinstitute.org/sites/default/files/2020-10/024036%20Global%20Energy%20Institute%20US%20Index\\_Web.pdf](https://www.globalenergyinstitute.org/sites/default/files/2020-10/024036%20Global%20Energy%20Institute%20US%20Index_Web.pdf).

<sup>8</sup> U.S. Energy Information Administration ("EIA"), "U.S. Energy Facts Explained" <https://www.eia.gov/energyexplained/us-energy-facts/imports-and-exports.php>.

score fell in seven of eight years, achieving a record low of 70.1 in 2019 (a 5.5 percent decrease from 2018.).<sup>9</sup> This record achievement in reduced energy security risk is a direct result of the increased energy production and usage made possible by advanced hydraulic fracturing technology.<sup>10</sup>

Importantly, commenter (0921-USCC) states that the increased energy security in the U.S. due to production of oil and gas from shale occurred while the U.S. maintains one of the lowest methane intensity measures in the world associated with its energy production.<sup>11</sup> In addition, largely as a result of natural gas fueling an ever increasing portion of electricity generation, overall CO<sub>2</sub> emissions from fossil fuel combustion decreased by 896.8 million metric tons of CO<sub>2</sub> equivalent (MMT CO<sub>2</sub>e) from 2005 levels to 2019, a decrease of approximately 15.6 percent.<sup>12</sup> From 2018 to 2019, emissions decreased by an additional 134.7 MMT CO<sub>2</sub>e (2.7 percent).<sup>13</sup>

Commenter (0921-USCC) states that the decreases in emissions and reduced methane intensity from energy production were achieved while natural gas production rose to a record level in 2019, climbing 10.6 percent to 40.7 trillion cubic feet (tcf).<sup>14</sup> The U.S. led the world in natural gas production in 2019. Increases in Texas (1.3 tcf) and Pennsylvania (0.8 tcf) accounted for most of the increase.<sup>15</sup> Colorado, Louisiana, New Mexico, North Dakota, Ohio, Oklahoma, and West Virginia also contributed increased output. This data underscores the abundance of natural gas throughout the country and its comparative value in enabling reductions in both energy security risk and emissions.

Moreover, when it comes to prices, Commenter (0921-USCC) believes America's households and industrial consumers benefit greatly from our energy advantage. The U.S. pays two to six times less than counterparts in Europe and other industrialized nations.<sup>16</sup> With natural gas stocks at historically low levels, prices breaking records, and several weeks of potential winter demand spikes still to come, many European leaders are concerned that a firm response to Russian aggression could lead to energy supply disruptions. It's a stark reminder that energy security is national security, and as Europe looks to diversify its supplies, the United States is poised to help.

Commenter (0921-USCC) states that since 2005, annual consumption of natural gas in the United States has increased by nearly 41 percent or 9 tcf. Electric power (up 60 percent) and

<sup>12</sup> U.S. EPA, "Inventory of U.S. Greenhouse Gas Emissions and Sinks 1990-2019" EPA 430-R-21-005, pp. ES-11 and 2-13, available at <https://www.epa.gov/sites/default/files/2021-04/documents/us-ghg-inventory-2021-maintext.pdf?VersionId=yu89kg1O2qP754CdR8Qmyn4RRWc5iodZ>.

<sup>13</sup> Id.

<sup>14</sup> See GEI "Index of U.S. Energy Security Risk – 2020 Edition," supra note 3.

<sup>15</sup> Id.

<sup>16</sup> See Daniel Byers, "U.S. Natural Gas Exports Deliver More Than Just Energy," GEI, U.S. Chamber of Commerce (Jan. 27, 2022), <https://www.globalenergyinstitute.org/us-natural-gas-exports-deliver-more-just-energy>.

industrial sector use (up 28 percent) comprise nearly 90 percent of the increase.<sup>17</sup> Thus, natural gas has displaced other power generation sources to become the primary fuel for electric power generation over the past 10 years.<sup>18</sup> This has led to drastic reductions in national carbon emissions since 2005.<sup>19</sup> Natural gas also now provides almost a third of the energy to the U.S. industrial sector.<sup>20</sup> It is used for on-site electricity generation (fueling boilers and turbines); process heat to melt glass, process food, preheat metals, and dry various products; and combined heat and power (CHP) systems.<sup>21</sup> Natural gas is also used as a material input itself—as a feedstock as opposed to being combusted—to make products such as fertilizers, chemicals, and plastics. All economic sectors consume natural gas.<sup>22</sup> This is in part due to the low cost of production of natural gas driven by the shale revolution.<sup>23</sup>

Commenter (0921-USCC) believes that, in the development of its supplemental proposal to regulate new, modified, reconstructed, and existing sources, EPA will be able to meet its GHG reduction goals and incorporate critical aspects of energy security into its deliberations. As demonstrated by the reductions in overall carbon emissions and methane intensity from energy production over the last decade, EPA can drive down GHG emissions without undermining the continued economic security that oil and gas production provides. As EPA designs its regulatory framework, it should be careful to avoid creating a structure that would disincentivize domestic energy production. With market and technological innovations in the oil and gas sector, combined with smart regulations and protocols, EPA can build a certain, predictable, and environmentally effective compliance regime.

Response I-23-16: See Volume I, Chapter 20 (Emissions and Regulatory Impacts), section 20.2.6 (Energy Impacts), Responses I-20-25 and I-20-26, for EPA’s response to comments on the expected impacts of the final NSPS OOOOb and EG OOOOc regulations on domestic oil and natural gas production.

Comment: Commenter (0595-Consumer Energy Alliance) urges EPA to balance the economic welfare of the nation’s energy consumers as well as current progress toward emission reductions, as it contemplates actions related to greenhouse gases and overall environmental stewardship. America has demonstrated we can accomplish both of these critical objectives at the same time.

Response I-23-17: See Volume I, Chapter 20 (Emissions and Regulatory Impacts), section 20.2.6 (Energy Impacts), Responses I-20-25 and I-20-26 for EPA’s response to comments on the

<sup>23</sup> See Daniel Byers, “More Gold Medals for America’s Energy Producers,” GEI, U.S. Chamber of Commerce (Jul. 28, 2021), <https://www.globalenergyinstitute.org/more-gold-medals-americas-energy-producers>.

expected impacts of the final NSPS OOOOb and EG OOOOc regulations on domestic oil and natural gas production.

Comment: Commenter (0951-Ridgeling Energy LLC) states that Europe is in critical need of our exported frozen gas (liquefied natural gas (LNG)) and that even our annual production of natural gas is not enough to support their needs. Due to Russia using natural gas to split European support for NATO, the U.S. cannot give up 10 percent to 12 percent of their natural gas.

Commenter (0334-Gas and Oil Association of WV, Inc.) requests that EPA pause and recognize the critical role energy plays in the lives of all Americans. The stark reality is natural gas produced here must remain a key component of the U.S. energy portfolio. It's use as a heating fuel, in manufacturing processes, and for low-emission power generation should be embraced and encouraged by the Biden Administration. Natural gas produced in West Virginia is done so under the most stringent regulatory and environmental standards in the nation; and U.S. standards far surpass those of other nations.

Commenter (0334-Gas and Oil Association of WV, Inc.) states that natural gas is a global commodity and in great demand throughout the world. Domestically, we have the capability to be energy dominant. Shifting this energy production to distant countries that fail to adhere to the standards followed by American companies will not provide the positive global emission reductions that will lead to better air quality nor achieves global climate goals.

Commenter (0861-Discovery Operating, Inc.) has been in upstream oil and gas production for 60 years and has learned that any rule such as the proposed EPA Methane Rule, that would handicap production from thousands of low producing oil and gas wells would greatly damage America's best strategic petroleum reserve. The proposed rule could cause many of our stripper wells to be plugged and abandoned. The commenter contends that any rule that jeopardizes the oil and gas industry and long-lasting oil and gas reserves reduces the security of the nation.

Commenter (0599-MSC) suggests that any final rules should have a reasonable and cost-effective pathway to compliance. The commenter states that American natural gas and liquids are critical to both missions: providing affordable, clean energy to heat and power American homes, schools, businesses, and other facilities while fueling American manufacturers, including pharmaceuticals, as evidenced by the role natural gas liquids are playing in the health care arena, from medical equipment to vaccine development and deployment.

Response I-23-18: In response to comments that state that the rule would handicap production from thousands of low-producing oil and gas wells and would cause many of their stripper wells to be plugged and abandoned, the EPA developed a financial analysis of marginal oil and natural gas wells in Chapter 6 of the final rule TSD. EPA finds that marginal wells may continue to operate at low or negative profits rather than be shut-in and plugged due to a variety of reasons, including low operating costs, high plugging costs, low state bonding requirements, accounting practices, and tax credits available to the oil and gas industry.

See also Volume I, Chapter 20 (Emissions and Regulatory Impacts), section 20.2.6 (Energy Impacts), Responses I-20-25 and I-20-26, for EPA's responses to comments on the expected

impacts of the final NSPS OOOOb and EG OOOOc regulations on domestic oil and natural gas production.

Comment: Commenter (0800-Utah Public Lands Policy Coordinating Office and Utah Division of Air Quality) supports natural gas energy production and related development, as “Utah is an ‘all-of-the-above’ energy state” meaning “there is room for all types of energy production and distribution”<sup>24</sup> both conventional and renewable. To date, this all-of-the-above energy policy has served Utahns well,<sup>25</sup> and the state supports all reasonable forms of energy development and generation available within its borders.

Commenter (0800-Utah Public Lands Policy Coordinating Office and Utah Division of Air Quality) states that as evidence of the success of this policy, Utah currently generates more electricity than it consumes, and the state is a net supplier of power to other states.<sup>26</sup> As of 2020, coal fueled 61% of Utah's total electricity net generation, down from 75% five years earlier, and natural gas accounted for 25%. Almost all of the rest of Utah's in-state electricity generation came from renewable energy sources, primarily solar power.<sup>27</sup> This trend is expected to continue, and Utah's Strategic Energy Plan anticipates natural gas-fired generation will replace coal and will back up intermittent renewables like wind and solar power.<sup>28</sup> In fact, no new coal-fired generators have been built in the state since 1993, but about 60 natural gas-fired units have been put into service since then.<sup>29</sup> As part of its overarching policy, the State is committed to continuing to diversify its energy portfolio and has adopted a voluntary goal of obtaining 20 percent of its adjusted retail electric sales from renewable energy resources by 2025.<sup>30</sup> In fact, about 97% of Utah's electric generating capacity added since 2015 is powered by solar energy.<sup>31</sup>

However, the commenter (0800-Utah Public Lands Policy Coordinating Office and Utah Division of Air Quality) states that due to the intermittent characteristics of some forms of renewable energy (wind, solar, &c.), there is still a need for electricity generation that can be available to the electricity grid 24/7, regardless of weather conditions. This need for

<sup>29</sup> Id. citing U.S. EIA, Preliminary Monthly Electric Generator Inventory (based on Form EIA-860M as a supplement to Form EIA-860), Inventory of Operating Generators as of December 2020, Plant State: Utah, Technology: Natural Gas.

<sup>30</sup> Id.; citing NC Clean Energy Technology Center, DSIRE, Utah, Renewable Portfolio Goal, updated July 3, 2018.

<sup>31</sup> Id. citing U.S. EIA, Preliminary Monthly Electric Generator Inventory (based on Form EIA-860M as a supplement to Form EIA-860), Inventory of Operating Generators as of December 2020, Plant State: Utah, Technology: Select All.

“dispatchable” energy - meaning energy that can be ramped up or down quickly to make up for intermittency caused by other renewable energy resources - is highlighted by current events.

Commenter (0800-Utah Public Lands Policy Coordinating Office and Utah Division of Air Quality) states that with recent actions taken by the Biden Administration<sup>32</sup> (and subsequent litigation)<sup>33</sup> there is a push by the current President to “tackle” climate change by shifting away from traditional energy sources such as oil and gas. As the United States tackles climate change by transitioning to low-carbon energy resources, it is imperative that baseload and dispatchable energy sources (such as natural-gas) remain viable and online. If fossil-fueled energy systems are retired at a pace that is greater than renewable projects are brought online, then our nation almost certainly will experience a host of adverse effects due to insufficient energy – rolling blackouts or system failures causing death by exposure to extreme temperatures, and exorbitant energy bills which unfairly burden individuals, businesses, and local governments.

With this expectation in mind, the commenter (0800-Utah Public Lands Policy Coordinating Office and Utah Division of Air Quality) believes it is critical to remember that if we reduce our reliance on fossil fuel energy systems at a pace that is greater than renewable projects are developed, and without the necessary baseload and dispatchable energy sources (such as natural gas) remaining viable and online, then we must expect these extreme weather events to wreak even more havoc on the environment and human life. Energy, regardless of its source, plays a significant role in ameliorating the deleterious effects of severe meteorological phenomena on human life. Unfortunately, the possibility of energy shortfalls is conceivable as our Nation and some of its states attempt to aggressively cut fossil fuel use by, among other things, pulling permits for crude oil pipelines,<sup>34</sup> denying access to state lands for interstate natural gas pipelines,<sup>35</sup> and pausing oil and gas lease sales on public lands and in offshore waters.<sup>36</sup> In light of these potential energy shortfalls, Utah remains committed to its “all-of- the-above” energy approach, and asserts that it remains imperative that any future regulatory changes (such as the current Proposal) not inhibit fossil fuel development to a point where it becomes unviable. The State has adopted specific policies in furtherance thereof.

Response I-23-19: The EPA acknowledges and commends Utah in their support for natural gas energy production and related development, both conventional and renewable. The EPA also agrees that while addressing climate change by transitioning to low-carbon energy resources, it is important that baseload and dispatchable energy sources (such as natural-gas) remain viable and online. See Volume I, Chapter 20 (Emissions and Regulatory Impacts), section 20.2.6 (Energy Impacts), Responses I-20-25 and I-20-26 for EPA’s responses to comments on the expected

impacts of the final NSPS OOOOb and EG OOOOc regulations on domestic oil and natural gas production.

## 23.7 General Support for the Proposed Rule(s)

Comment: Several commenters (*e.g.*, 0201-Lone Star Chapter of the Sierra Club, 0317-National Affairs and Legislation Committee and The Garden Club of America, 0339-Cheyenne Area Landowner's Coalition, 0385-Silent Spring Institute, 0387-Climate Writers, 0391-Keweenaw Bay Indian Community (KBIC), 0398-US House of Representatives, 0401-Mercy Investment Services, 0405-Prostate Citizen, 0406-Boone and Crockett Club, 0427-Private Citizen, 0434-Pax World Funds, 0435-Wespath Benefits and Investments, 0437-State of NY Comptroller, 0443-SGI, 0444-Damascus Citizens for Sustainability, 0455-Radio Drama Network, 0460-Trinity Health, 0538-Change Finance, 0560-Legal & General Investment Management America, 0569-Wellington Management Company, 0579-Chevron, 0581-NACAA, 0583-Harvard Management Company, Inc, 0584-EIG Global Energy Partners, 0586-Navajo Nation Environmental Protection Agency, 0587-US Well Services Inc, 0589-NEI Investments, 0600-PIMCO, 0592-Citizens United for Responsible Energy Development, 0601-CT DEEP, 0605-Muscogee Creek Nation, 0610-Occidental, 0715-Dayenu Circle of Jewish Silicon Valley, 0721-Moms Clean Air Force, 0723-Ceres, 0725-National Grid USA, 0733-CVNM, 0734-American Thoracic Society, 0735-Chesapeake Bay Foundation, 0737-Clarke Valve, 0738-Exxon Mobil Corporation, 0752-AF&PA, 0753-IGSD, 0754-National Religious Partnership for the Environment, 0757-Private Equity Stakeholder Project, 0761-Exelon Corporation, 0769-CARB, 0770-Northern Plains Resource Council, 0781-NTAA, 0785-John Crane, 0786-Enerplus Resources Corporation, 0795-Allergy & Asthma Network, 0807-BP, 0809-Earthjustice, 0821-Xcel Energy, 0828-Union of Concerned Scientists, 0830-Devon Energy, 0832-NMED, 0833-UMUT EPD, 0838-TRIDO, 0839-Continental Resources, 0840-Navajo Nation, Counselor Chapter House, 0917-Our Children's Trust, 0918-CO CCA, 0919-TEP Rocky Mountain LLC, 0920-We Act for Environmental Justice, 0921-USCC, 0926-Austin Energy, 0927-Interfaith Center on Corporate Responsibility, 0931-Essential Information Inc, 0943-Sault Ste. Marie Tribe of Chippewa, 1160-Uinter Methodist Women of the Desert Southwest Conference, 1271-Lee Memorial AME Church, 1301-Northern Arapaho Tribe Business Council, 1302-Wyoming Outdoor Council, 1322-Lone Star Chapter of the Sierra Club, 1330-Catskill MK, 1337-Boston Catholic Climate Movement, 1350-EOS at Federated Hermes, 1377-Lander Climate Action Network, 1383-Interfaith Power & Light New Mexico, 1384-Louisiana Environmental Action Network, 1387-350 Bay Area Action, 1388-Private Citizen, 1389-VERIS Wealth Partners, 1423-US Congress, 1434-US Senate) generally support efforts from EPA and other federal agencies to reduce emissions from the entire oil and gas industry. This includes extraction and production, processing, transmission, and distribution. Most commenters are asking for a rapid promulgation of the final rule in order to achieve the estimated emission reductions so that citizens can experience the health and environmental benefits. Examples of some of the reasons that commenters provided as support include the following:

- The climate crisis requires urgent action by the federal government in order to reduce air pollution and the associated human health consequences.
- The standards will be especially helpful in protecting communities of color and other vulnerable communities (*e.g.*, children, the elderly, immunocompromised, persons with

asthma/cardiovascular issues, lower socio-economic communities) which are hit hard by climate change and air pollution.

- The application of the proposed standards to more new and existing sources than in the past.
- Affordable, domestically produced natural gas has been one of the primary driving forces behind significant reductions in carbon emissions achieved over the past decade, most notably from the power generation sector.
- Targeting the wasted methane emissions from the oil and gas sector is a largely cost-effective and low-hanging solution among a much longer list of policy actions that are needed to mitigate the most severe impacts of climate change later this century.<sup>37</sup>
- Direct federal regulation of methane emissions from the oil and gas industry are more effective than most state or voluntary efforts.
- The cost of compliance with the proposed standards would be relatively low.<sup>38</sup>
- The proposed rules would encourage the use of innovative methane detection technologies and other cutting-edge solutions, many of which are being developed and utilized by small businesses providing robust jobs in the United States.
- The proposed rule(s), once implemented and enforced, will result in significant and meaningful reductions of air pollutants that negatively impact public health and the environment, including a significant reduction in ozone precursor pollutants which will result in lower ozone concentrations, a significant reduction of methane, a potent GHG that contributes to climate change, and a significant reduction in both toxic and hazardous air pollutants, including carcinogens such as benzene.
- The proposed standards will establish a baseline set of requirements that apply nationwide and will help to align the varying approaches by states to address emissions from the O&G sector, especially where emissions from one state may impact affected areas in another state.
- Methane reduction in oil and gas production is an immediate and cost-effective opportunity to reduce the rate of climate warming.
- It is essential these sources of methane emissions are addressed adequately to meet the commitments of the Global Methane Challenge and President Biden's nationally determined contribution (NDC) to at least halve economy wide GHGs below 2005 levels by the end of the decade.
- Strong regulations are needed to level the playing field and accelerate industry-wide methane reduction and the energy transition.
- Strong methane regulation and regulatory certainty is essential to the success of companies in both the oil and gas industries, as well as companies that may be affected by climate change in other ways.
- Ambitious methane regulations can assist investors to better execute a more effective transition risk-mitigation strategy, as a predictable regulatory landscape is likely to lead to increasingly dependable capex guidance and improved data transparency.
- Robust regulation would quicken and streamline emissions reduction, providing assurance of the lower-emissions profile of US-produced natural gas.

---

<sup>37</sup> International Energy Agency: Curtailing Methane Emissions from Fossil Fuel Operations. Oct. 2021.

<sup>38</sup> Investor Guidance on EPA Proposed Standards for Oil and Natural Gas Methane Emissions, EDF, December 2, 2021.

- An effective regulation, which broadly limits emissions across hard-to-abate sectors such as oil and natural gas, is essential to advance mitigation and meet climate goals.
- Reduction of VOCs nationally will help reduce local emissions of ozone and ozone precursor transport from states with significant oil and gas production.
- The Texas Commission of Environmental Quality (TCEQ), the Texas Railroad Commission (which governs fossil-fuel extraction, NOT railroads), and the Texas State legislative and executive branches is not doing enough to make a difference in the battle against climate change.

Response I-23-20: Comments are supportive comments for EPA’s proposals; as such, no response is required.

Comment: Commenter (1340-Citizens United for Responsible Energy Development) agrees that the proposed methane reduction rules will minimize methane into the atmosphere and reduce its explosive impact as a GHG. The commenter has never fought energy development in the Upper Green as they recognize the substantial positive economic effect that natural gas production has in the Basin; the commenter just insists that it be done responsibly. The new rules can be a step in this direction. Development must include a clean and healthy environment and a quality of life where humans don’t contend with “ozone days” -- those with compromised lungs aren’t hospitalized, and schools don’t need to prohibit children from going outside for recess in January, or February, or March. Commenter urges EPA to move quickly and decisively in adopting standards that will accomplish this.

Response I-23-21: Comments are supportive comments for EPA’s proposals; as such, no response is required.

Comment: Commenter (0761-Exelon Corporation) strongly supports EPA’s Proposal and offers comments focused on the following points:

- EPA is legally obligated to regulate methane emissions from the crude oil and natural gas category under the Clean Air Act (CAA).
- In the EGs for existing sources, EPA must identify the “degree of emission limitation achievable” through application of the “best system of emission reduction.”
- The EGs should include presumptive standards of performance for all designated facilities that, if adopted in a state plan, would make the plan presumptively approvable by EPA.
- EPA has authority to approve a state plan that requires measures that are more stringent than the EGs.
- The social cost of methane should guide Agency decision-making.
- A consideration of costs and benefits of an Agency action should include consideration of all quantifiable and unquantifiable, direct and indirect, costs and benefits.
- A final rule should include meaningful measures to protect disadvantaged and overburdened communities from the effects of air pollution.
- All contents of regulatory Docket ID No. EPA-HQ-OAR-2021-0295 should be included in the record for Docket ID No. EPA-HQ-OAR-2021-0317.

Response I-23-22: For comments that are supportive comments for EPA's proposals; no response is required. The EPA, in the development of the final NSPS OOOOb standards and EG OOOOc presumptive standards considered these and other comments on the November 2021 Proposal and December 2022 Supplemental Proposal in the development of the NSPS OOOOb and EG OOOOc rule requirements.

With regards to the request that the contents of non-rulemaking Docket ID No. EPA-HQ-OAR-2021-0295 be included in the rulemaking Docket ID No. EPA-HQ-OAR-2021-0317, the EPA has not granted that request. The EPA opened the non-rulemaking docket (Docket ID No. EPA-HQ-OAR-2021-0295) for public input on the Agency's efforts to reduce emissions of methane and other air pollutants from new and existing sources in the oil and natural gas sector in order to further the Administration's policies as described in Executive Order 13990, "Protecting Public Health and the Environment and Restoring Science to Tackle the Climate Crisis." The goal of this non-rulemaking docket and other public engagement efforts was to gather perspectives from a broad group of stakeholders for the oil and natural gas sector, including individuals and communities that experience disproportionate adverse health and environmental impacts as a result of oil and natural gas operations.

Comment: Commenter (0752-AF&PA) generally supports the proposed rules because they aim to reduce emissions from natural gas pipelines, which the commenter asserts will reduce their costs and may increase safety from detection of leaks, the commenter is not taking a position on the legal rationales or CAA interpretations underlying the Proposed Action. In general, commenters are supportive of the need for common sense regulations that do not impose unnecessary administrative burdens and cost on regulated parties. As EPA develops the rule, the commenter recommends the agency provide compliance flexibility and consider cost effectiveness. As noted above, due to methane leaks from natural gas pipelines the commenter is paying for natural gas that does not reach their facilities. Moreover, following natural gas pipeline incidents, the commenter has incurred very significant costs in terms of curtailment, lost production, and increased gas and power costs. The pulp and paper industry and certain PGC members alone are estimated to have paid at least \$50 million for fuel and lost gas in 2018.

Response I-23-23: This comment is a supportive comment for EPA's proposals; as such, no response is required. Please also see section VIII.B (How does the EPA evaluate control costs in this final action?) of the final rule preamble for a discussion on how the EPA evaluates control costs, and section X of the final rule preamble for a summary of the final NSPS OOOOb and EG OOOOc requirements. Specifically, see section X.C (Super Emitter Program) of the final rule preamble on EPA's Super Emitter Program to ensure that the final rulemaking comprehensively addresses the widespread problem of abnormally large emissions events known as super-emitters.

Comment: Commenter (0339-Cheyenne Area Landowner's Coalition) is supportive of the new methane standards from the Proposal. The commenter has learned from multiple state examples, that most oil and gas operators respond to that which is required by rule or law.

Commenter (0339-Cheyenne Area Landowner's Coalition) believes that the new methane requirements for the oil and gas industry have the potential to significantly improve air quality in

Laramie County, as well as the rest of the State. DEQ's Air Quality Division has demonstrated a propensity to do only that which will keep the agency in compliance with EPA requirements. Here are three examples:

1. Air quality in the Upper Green River Basin has experienced ozone pollution severe enough that the area has been determined to be a nonattainment area. As such DEQ strengthened the air quality standards in this area. DEQ missed the opportunity to improve air quality in Wyoming when it determined it would not implement these stricter standards statewide, despite local urging that it do so. What is good enough for EPA is viewed as good enough for Wyoming.
2. The Air Quality Division of DEQ is required to demonstrate that it is monitoring air quality in Wyoming, including in Laramie County. A couple of years ago, the Air Quality Division placed a mobile air monitoring station in eastern Laramie County. The problem was in the location of this mobile unit. Instead of placing the unit in an area where there was significant oil and gas development, DEQ placed the unit at a very rural fire station miles and miles from the nearest well pad. The Cheyenne Area Landowner's Coalition recommended that the unit be relocated to a place where meaningful results could be anticipated. DEQ ignored our concerns, and the results were meaningless as expected. DEQ then decided to move the mobile unit out of Laramie County and relocate it in distant Fremont County. Another missed opportunity to demonstrate the impact of oil and gas operations on the quality of the air local residents breathe.
3. In November 2020, the Cheyenne Area Landowner's Coalition in partnership with the Powder River Basin Resource Council, hired a professional to photograph methane and other VOC emissions from a number of existing well sites in Laramie County, using a FLIR camera. The results were reported to DEQ's Air Quality Division, with a request that it follow up with the appropriate oil and gas operators. Part of the response from DEQ was that since these emissions were not visible with the naked eye, there was no violation of EPA (Section 22) standards. Hence there was no corrective action needed. Methane of course is not visible to the naked eye.

Commenter (0339-Cheyenne Area Landowner's Coalition) suggests the creation and implementation of new methane standards will result in Wyoming' DEQ being required to do a better job of monitoring and improving air quality in Wyoming. And these improved standards will contribute to the overall objective of slowing the pace of global warming. Thanks for the opportunity to comment.

Response I-23-24: This comment is a supportive comment for EPA's proposals; as such, no response is required.

Comment: Several industry commenters generally support the proposed actions (0808-API, 0817-GPA, 0820-Pioneer, others) with comments that provide corrections, improvements, concerns. These comments are provided in the relevant Chapters of this document.

Commenter (0839-Continental Resources) applauds EPA's effort to move forward to reduce emissions of GHG and other harmful air pollutants from the Crude Oil and Natural Gas source category, although they do not agree with all the methods or presumptions provided by

the proposal. The commenter issues this broad endorsement to the industry groups it supports because all the comments being submitted show consistency not only in the objections they raise to the proposal, but in acceptance of those rational recommendations made by EPA.

Commenter (0738-Exxon Mobil Corporation) explains that while voluntary efforts by individual companies are important, they only capture a fraction of industry's overall emissions. Full industry participation is required to maximize the benefits to society. Accordingly, based on their experience and expertise, the commenter supports EPA's proposal to strengthen its current LDAR methodologies and programs and expand the scope of regulation to cover all sources not currently included (*e.g.*, liquids unloading, pneumatic pumps and associated gas from oil wells). The commenter also recognizes the importance of technical expertise, training, documentation, and related requirements. The commenter looks forward to further discussions on the best means to meet EPA's goals to enhance upstream monitoring performance.

Commenter (0807-BP) supports reducing methane emissions as a key lever in efforts to combat climate change. Methane currently accounts for around one-fifth of man-made global GHG emissions. In the United States, the oil and natural gas industry is the second largest aggregate source of anthropogenic methane emissions after the agriculture sector (including livestock and manure emissions).<sup>39</sup> The Intergovernmental Panel on Climate Change estimates that the global surface temperature was 1.09-degrees Celsius higher in 2011-2020 than in 1850-1900, with methane emissions contributing about one-half (0.5-degrees Celsius) of that warming.<sup>40</sup> As EPA stated, methane has an estimated 100-year global warming potential value of 25, which “indicates that one ton of methane has approximately as much climate impact over a 100-year period as 25 tons of carbon dioxide.” 86 Fed. Reg. at 63,130. Since methane has a shorter lifetime than carbon dioxide, “the emissions of a ton of methane will have more impact earlier in the 100-year timespan and less impact later in the 100-year timespan relative to the emissions of a 100-year GWP equivalent quantity of carbon dioxide.” *Id.* Therefore, curbing methane emissions from oil and gas can have meaningful near-term impacts—both on climate warming and the world's ability to meet net zero by 2050 or sooner.

Commenter (0807-BP) states that for these reasons, the Biden Administration has understandably made reducing methane emissions a key priority. The U.S., along with the U.K. and other nations, was instrumental at the 26th Conference of the Parties<sup>41</sup> in securing a Global Methane Pledge to collectively cut methane emissions across all sectors by at least 30 percent below 2020 levels by 2030.<sup>42</sup> Over 110 countries, representing nearly 50 percent of the sources of global methane emissions, have joined the pledge. President Biden's U.S. Methane Emissions

---

<sup>39</sup> Overview of Greenhouse Gas Emissions, EPA, <https://www.epa.gov/ghgemissions/overview-greenhousegases#methane> (last visited Jan. 25, 2022).

<sup>40</sup> IPCC, 2021: Summary for Policymakers. in: CLIMATE CHANGE 2021: THE PHYSICAL SCIENCE BASIS. CONTRIBUTION OF WORKING GROUP I TO THE SIXTH ASSESSMENT REPORT OF THE INTERGOVERNMENTAL PANEL ON CLIMATE CHANGE (Valerie Masson-Delmotte, et al. eds., 2021).

<sup>41</sup> The 26th United Nations Climate Change Conference (COP26).

<sup>42</sup> Joint US-EU Press Release on the Global Methane Pledge, THE WHITE HOUSE (Sept. 18, 2021), <https://www.whitehouse.gov/briefing-room/statements-releases/2021/09/18/joint-us-eu-press-release-on-the-global-methane-pledge/>; Fast Action on Methane to Keep a 1.5°C Future Within Reach, GLOBAL METHANE PLEDGE, <https://www.globalmethanepledge.org/> (last visited Jan. 4, 2022).

Reduction Action Plan focuses on a whole-of government approach “to identify and cost-effectively reduce methane emissions from all major sources.”<sup>43</sup>

Commenter (0807-BP) supports these methane emissions goals and agrees with the importance of EPA taking regulatory action now. See 86 Fed. Reg. at 63,152 (“The importance of taking action at this time, in accordance with the requirements of CAA section 111, to reduce the enormous amount of methane emissions from oil and gas sources, in light of the impacts on the climate of this pollution, cannot be overstated.”).

Commenter (0807-BP) continues to support the direct federal regulation of methane emissions. A uniform federal regulatory framework, which establishes consistent minimum standards and nationally applicable guidelines, is necessary for the industry. This can increase consumer and regulator confidence that natural gas producers are acting responsibly, and that natural gas production is both safe and efficient. Voluntary actions by energy companies, although significant, are not enough to solve the methane problem and federal regulations help to level the playing field among companies and incentivize action. Moreover, a federal framework helps support the global competitiveness of American natural gas as pressure for more stringent regulations on methane grows outside the U.S. While state regulations are also still important to achieve methane emission reduction goals, an overarching national regulatory framework for methane emissions is preferable to a patchwork of state-by-state approaches.

Commenter (0919-TEP Rocky Mountain LLC) supports and commends the mutual pursuit to reduce emissions and continue to produce current and future clean energy needs of the nation. As EPA establishes guidelines and standards of performance, the commenter implores EPA to do so in an evidence-based and goal-oriented approach that is built to be flexible and allow for creativity. The commenter reminds EPA that an evidence-based approach includes the positive effects of reliable, clean, and affordable energy sources that propel economies and provide the mechanism for the innovation that future generations will employ. Few public health advances rival the advances made possible by clean and local energy.<sup>44</sup>

Commenter (0766-Cheniere Energy, Inc.) believes understanding and improving the environmental performance of our LNG is not just an environmental imperative, but a business one as well, for the commenter and the supply chain partners. To this end, since 2018, the commenter has pursued a climate strategy focused on data-driven scientific and transparent collaboration along the supply chain to better understand the emissions profile and identify strategic and cost-effective mitigation opportunities, including foundational support for the Collaboratory to Advance Methane Science and a Quantification, Monitoring, Reporting, and Verification collaboration.

---

<sup>43</sup> Fact Sheet: President Biden Tackles Methane Emissions, Spurs Innovations, and Supports Sustainable Agriculture to Build a Clean Energy Economy and Create Jobs, THE WHITE HOUSE (Nov. 2, 2021), <https://www.whitehouse.gov/briefing-room/statements-releases/2021/11/02/fact-sheet-president-bidentackles-methane-emissions-spurs-innovations-and-supports-sustainable-agriculture-to-build-a-cleanenergy-economy-and-create-jobs/>.

<sup>44</sup> See, e.g., World Health Organization, About the Health and Energy Platform of Action, <https://www.who.int/initiatives/health-and-energy-platform-of-action/about-the-health-and-energy-platform-ofaction>.

Commenter (0766-Cheniere) believes that quantifying, monitoring, and reducing methane emissions across the U.S. natural gas supply chain are vital to ensure that natural gas and LNG continue to accelerate the global transition away from more polluting fuels and towards a lower-carbon future. Federal regulations on methane can help drive emissions reductions and ensure the long-term sustainable role of U.S. LNG in helping countries meet their climate goals through verifiably lower methane emissions — something the commenter supports and has been proactively working to advance.

Response I-23-25: These comments are supportive comments for EPA’s proposals; as such, no response is required.

Comment: Several commenters (0199-Allergy & Asthma Network, 0216-Montana Health Professionals for a Healthy Climate, 0317-Essential Information, Inc, 0340-Mothers & Others for Clean Air, 0401-Mercy Investment Services Inc, 0402-Cancer Free Economy Network, 0440-Holy Spirit Missionary Sisters, 0414-Waterspirit, 0421-Big Thicket Biosphere Reserve, 0443-Seventh Generation Interfaith Inc, 0444-Damascus Citizens for Sustainability, 0458-MDE, 0559-State of Texas, 0578-Grand Canyon Trust, 0720-Miller/Howard Investments, Inc, 0721-Moms Clean Air Force, 0724-Boston Trust Walden, 0728-Calvert, 0734-American Thoracic Society 0735-Chesapeake Bay Foundation, 0746-Methane Action, 0796-Asthma and Allergy Foundation of America – Michigan Chapter, 0812-Ohio Farmers Union, 0828-Union of Concerned Scientists, 0837-Clean Water Action, 0840-Navajo Nation, Counselor Chapter House, 0920-We Act for Environmental Justice, 0947-23 Different Advocacy Groups, 0949-Liveable Arlington, 1247-Healthy Air and Water Colorado, 1267-The State of California, 1283-Green Arlington Foundation, 1372-General Capital, 1338-Lexington Climate Action Network, 1383-Interfaith Power & Light New Mexico, 1388-William Limpert, 1389-VERIS Wealth Partners, PBC,) support EPA’s proposed rules as a first step towards cutting methane emissions, and generally ask EPA to strengthen the proposal and any further rules involving methane and the oil and gas industry. Examples of some of the comments provided are included in the following paragraphs. Any detailed comments on support for recommended specific changes to the proposed requirements for emission sources provided by these commenters are provided in the relevant Chapters of this document.

Commenter (0578-Grand Canyon Trust) suggests EPA strengthen the rule by consulting directly with Native Americans, strengthening inspection requirements of oil and gas wells, eliminating the wasteful practice of routine flaring at oil and gas sites, and expanding these requirements to abandoned and orphaned oil gas wells. The commenter states that this would help reduce waste and improve the collection of royalties.

Commenters (0216-Montana Health Professionals for a Healthy Climate, 0421-Big Thicket Biosphere Reserve) suggest eliminating loopholes for older, grandfathered operations and end flaring from oil and gas facilities.

Commenter (0947-23 Different Advocacy Groups) suggests strong methane protections like those adopted in Colorado and those adopted or set to be adopted in New Mexico. The commenter notes that these national-leading protections include a prohibition on routine flaring, frequent inspections for all well sites regardless of emission thresholds, increased inspections to

protect disproportionately impacted communities and those living closest to well sites, and strong requirements to retrofit existing oil and gas well sites with zero-bleed or zero-emission pneumatic devices.

Commenter (0734-American Thoracic Society) believes that EPA needs to go further on this rulemaking to tackle environmental injustice, mitigate the disproportionate emissions from small companies, “super-emitters,” abandoned wells and mines, and flaring, and increase monitoring networks and citizen science initiatives.

Commenter (0578-Grand Canyon Trust) urges EPA to heed the warnings of climate experts around the world and to consult directly with Native American tribes and nations regularly to do everything that it can to reduce dangerous methane and other GHG emissions across the country. In the context of this proposed rulemaking, the commenter asserts that EPA must conduct quarterly monitoring at all facilities, including those where site-level baseline methane emissions are below 3 tons per year (tpy), prohibit routine flaring at oil and gas sites, and require monitoring and plugging at abandoned and improperly plugged oil and gas wells.

Commenter (0840-Navajo Nation, Counselor Chapter House) supports the Federal EPA's efforts to cut methane and other harmful pollutants and calls on EPA to strengthen its final oil and gas air pollution rules by enacting a ban on routine flaring and eliminating loopholes that allow certain wells to forgo any regular inspections and requiring monitoring at smaller, leak prone wells.

Commenter (1388-William Limpert) finds that the proposed rule does not go far enough in reducing methane and pollutant emissions from the oil and gas industry. The commenter would like to see more stringent controls resulting in far less emissions, and with those emissions being completely prohibited in the very near future. The commenter adds that testing soil, groundwater, and air should be conducted on a routine basis near compressor stations.

Commenter (0317-Essential Information, Inc) supports the proposed rule, but also suggests that there are several aspects that should be changed or improved. Wells that emit less than 3 tpy of methane should be subject to twice-a-year OGI monitoring. EPA should mandate bonding requirements for each new oil and gas well, of an amount sufficient to cover periodic monitoring, the full future costs of plugging and dismantling wells, and the complete restoration of the well site. Owners/operators should be required to plug wells that are non-producing for four years. EPA should significantly restructure its proposed complaint mechanism. Finally, as a policy matter, the commenter recommends that the Biden Administration assess how the use of natural gas could be totally phased out in order to greatly reduce methane and carbon dioxide emissions to prevent climate change.

Response I-23-26: While these commenters generally support the development of the NSPS OOOOb and EG OOOOc rules, they urge EPA to do more to reduce methane and VOC emissions from the oil and natural gas industry. As discussed in section II.A (Purpose of the Regulatory Actions) of the final rule preamble, the final rulemaking takes a significant step forward in mitigating climate-destabilizing pollution and protecting human health by reducing GHG and VOC emissions from the oil and natural gas industry, specifically the Crude Oil and

Natural Gas source category. These mitigations are based on proven, cost-effective technologies already required by prior EPA regulations or states' regulations or deployed by industry leaders to reduce this dangerous pollution. The final rules will also encourage the deployment of innovative technologies that currently exist to rapidly and cost-effectively detect and reduce methane pollution and promote further innovation that is already under way to find even more efficient and effective ways to mitigate this pollution. Because methane is the main component of natural gas, the rules also result in more saleable product. The oil and natural gas industry is the United States' largest industrial emitter of methane. Human emissions of methane, a potent GHG, are responsible for about one third of the warming due to well-mixed GHGs, the second most important human warming agent after carbon dioxide. The EPA is finalizing the actions described in the preamble to the final rule in accordance with its legal obligations and authorities following a review directed by EO 13990, "Protecting Public Health and the Environment and Restoring Science to Tackle the Climate Crisis," issued on January 20, 2021.

In response to comments that the EPA should end wasteful flaring, the EPA, as a result of information provided through the public comment process, is finalizing revisions to the proposed requirements to limit routine flaring of associated gas. During the comment period, the EPA received extensive information regarding the availability and cost-effectiveness of alternatives to routine flaring, state-level requirements to limit or prohibit routine flaring, and commitments that owners and operators have already made voluntarily to phase out routine flaring in the near future. Based on this information and the EPA's updated BSER analysis, the EPA is finalizing requirements to prohibit routine flaring of associated gas from newly constructed wells that are developed after the effective date of the final rule.

Comment: Commenter (0753-IGSD et al) applauds EPA for taking this first step, expresses general support for the proposed standards and guidelines, and offers here a set of recommendations to make this regulation even more effective and better aligned with existing best practice and ambition for achieving critically necessary methane emissions reductions. The commenter also recognizes the current administration for leading global efforts to achieve methane reductions in numerous sectors, as witnessed by the U.S. promoted Global Methane Pledge announced in Glasgow at COP26, to work to reduce global methane emissions by at least 30 percent below 2020 levels by 2030. In this spirit and because methane emissions reductions are the single most effective pathway to slow the rate of warming over the next two decades, the commenter urges EPA to issue a strengthened final rule that will lead to even greater methane reductions. Finalizing more stringent regulations will meet EPA's CAA mandates<sup>45</sup> and related obligations to protect public health, safeguard the environment, and tackle climate change with the urgency warranted, including as expressed in Executive Order 13,990.<sup>46</sup>

Commenter (0753-IGSD) focuses on provisions for which the commenter urges EPA to act on the best available science and adopt the best available and tested practices, technology, and policies, to ensure that the final rule—provides the most reduction of methane emissions practicable; achieves the U.S.'s international methane goals; and protects communities and ecosystems from the severe impacts of methane and associated pollutants. Specifically, the commenter makes three priority recommendations for the supplemental proposal and final rule:

---

<sup>45</sup> E.g., Clean Air Act § 101(b)(1), 42 U.S.C. § 7401(b)(1); Clean Air Act § 111(a)(1); 42 U.S.C. § 7411(a)(1).

<sup>46</sup> Exec. Order. No. 13,990, 86 Fed. Reg. 7037.

(1) to require effective monitoring of all sources; (2) to ban routine flaring; and (3) to use EPA's broad authority in CAA §111 to promulgate strong standards for abandoned and unplugged wells.

Commenter (0753-IGSD) restates the goals of the Global Methane Pledge, including the reduction of methane by 30 percent by 2030, which would reduce warming by 0.2°C by 2050 and keep the 1.5°C target within reach.<sup>47</sup> According to the Proposed Rule's RIA, average annual reductions between 2023–2030 would be 2.75 million short tons of methane.<sup>48</sup>

The commenter (0753-IGSD) believes that while this is a good start, it is likely too low to meet the US's commitment under the Global Methane Pledge. Because the largest extent of methane abatement can occur within the oil and gas sector, sectoral emissions must be reduced by over 50 percent to ensure overall methane emissions are reduced by 30 percent. As a co-lead with the EU and signatory to the Global Methane Pledge, and because climate actions by the US can influence other large emitter countries, the U.S.'s domestic actions must align with reducing global emissions by 30 percent.

Commenter (0753-IGSD) suggests that the U.S. should reduce oil and gas methane emissions to the greatest extent possible, particularly when low- or no cost technology and best practices are available. Methane emissions reduction potential in the sector are estimated to be around 65% below 2012 levels,<sup>49</sup> and even greater when additional sources like abandoned wells are included. Promulgating stringent oil and gas methane emissions reductions requirements—as part of the Biden Administration's larger agenda on methane<sup>50</sup>—will set the world on the path to achieving the Global Methane Pledge's goals.

Commenter (0753-IGSD) points out that on many occasions, the U.S. has taken a bold stance to reduce methane emissions. In the North America Climate, Clean Energy, and Environment Partnership, the United States committed to a 40–45 percent reduction in methane emissions from oil and gas by 2025.<sup>51</sup> At the 2021 North American Leaders' Summit, the United States, Canada, and Mexico pledged to create a North American Strategy on Methane and Black Carbon, targeting all sectors and especially oil and gas.<sup>52</sup>

Commenter (0753-IGSD) believes that EPA's Proposed Rule does not appear to put the U.S. on track to meet the original 40–45 percent goal. By 2025, the commenter notes that the RIA projects that the Proposed Rule would reduce methane emissions by only 13.5 MMTCO<sub>2</sub>e cumulatively. The commenter notes that stricter measures by EPA, complemented by other

<sup>49</sup> Clean Air Task Force (December 2020) Reducing Methane from Oil and Gas.

<sup>50</sup> See generally White House Office of Domestic Climate Policy (2021) U.S. Methane Emissions Reduction Action Plan.

<sup>51</sup> The White House (29 June 2016) Leaders' Statement on a North American Climate, Clean Energy, and Environment Partnership, Press Release.

<sup>52</sup> The White House (18 November 2021) FACT SHEET: Key Deliverables for the 2021 North American Leaders' Summit.

actions outside of the scope of this rulemaking, are needed to decrease emissions from this sector to meet the 40–45 percent reduction target by 2025.

Similarly, commenter (0788-350 Seattle) states that more than 100 countries signed the Global Methane Pledge at COP26, agreeing to cut their methane emissions by 30 percent. While EPA’s Proposed Rule to reduce methane emissions from the oil and natural gas sector is an important step towards meeting this pledge, the rule does not go far enough, and must be strengthened in order to protect communities on the frontlines of oil and gas development and confront the climate crisis head-on.

Commenter (0864-Dayenu Circle of Jewish Silicon Valley) states that the U.S. and the rest of the world are already far behind in halting the climate crisis. Halting methane emissions is an important step in having a livable planet. The commenter notes the pledges to eliminate methane emissions at COP26. They state, however, that methane can hold 86 times more heat in the atmosphere than CO<sub>2</sub>. But methane lasts only about a decade, while CO<sub>2</sub> can remain for 100 years. By eliminating methane emissions, it can positively impact the climate crisis more quickly.

Response I-23-27: See Response I-23-26 of this Chapter.

Comment: Commenter (1295-Public Land Solutions) recommends that EPA strengthen its proposed methane rule. While this proposed rule is a great start, it can be improved by ending the wasteful and dangerous practice of routine flaring at oil and gas facilities, as states like Colorado and New Mexico have done already. Routine flaring burns natural gas as a waste product, emitting a host of climate and health-harming pollutants. Routine flaring should only be allowed in emergency situations. In addition, EPA’s Methane Rule should require regular monitoring at all smaller, high-polluting and leak-prone wells, and work to incorporate emission monitoring results generated by community groups and other third parties to help address major leaks. Cleaning up oil and gas methane pollution is critical for improving air quality, protecting public health, and ensuring that communities across the country retain the opportunity to diversify their economies and pursue economic benefits that result from protected landscapes and the outdoor economy.

Commenter (1295-Public Land Solutions) applauds EPA’s draft rule and urges the agency to set even stronger standards, eliminate loopholes for smaller operations, and end venting and flaring from oil and gas facilities. Finally, EPA should finalize this methane rulemaking as quickly as possible as climate change is an emergency, and our planet cannot afford further delay.

Response I-23-28: See Response I-23-26 of this Chapter.

Comment: Commenter (1160-United Methodist Women of the Desert Southwest Conference) urges EPA to strengthen the rules that reduce toxic air pollution. The commenter asks for rules written to encourage a transition to clean, renewable energy that can reach a target of 70 percent renewable energy by 2030 and 100 percent by 2050, based on 2010 levels. The rule should encourage the modernization of crumbling infrastructure and support the decarbonization of transportation. The rule should also support a just transition for disproportionately impacted

workers and communities. The end goal is 100 percent renewable energy, clean transportation, and a just transition. Thank you for writing rules that cut fracking's climate and toxic air pollution. Thank you for writing and strengthening rules so that our goal of Just Energy for All will become a reality.

Response I-23-29: See Response I-23-26 of this Chapter.

Comment: Commenter (0877-Embankment Preservation Coalition) asks EPA to support the reduction of methane emissions in the natural gas and oil supply chains and require methane measurement from all components of each supply chain. Reporting methane emissions as 100-year carbon dioxide emissions equivalency should be discontinued. All measurements across the entire oil and natural gas supply chains should be required to be provided in actual methane emissions (in pounds and or in tons). The rule should also include all methane emissions, including the unburned methane emitted from the exhaust smokestacks from natural gas-fired compressor units, generators, and boilers located at many compressor station facilities.

Commenter (0877-Embankment Preservation Coalition) states that methane and all hazardous air pollutants emitted from natural gas and oil facilities must be fully reported. Regardless of claimed reported methane emissions, facilities should be required to perform actual baseline methane measurements annually during peak load periods. Reducing methane pollution is one of the most effective things we can do to mitigate climate change in the short run. The commenter urges EPA to make these critical rule improvements and enforce stronger reporting of methane emissions.

Response I-23-30: With regards to suggestions to (1) require methane measurement from all components of each supply chain in actual emissions, and (2) require methane and all hazardous air pollutants emitted from natural gas and oil facilities be fully reported, the reporting of emissions, methane emissions information is reported under the GHGRP and hazardous air pollutants information is included in the National Emissions Inventory (NEI) and is not within the scope of this rulemaking.

The GHGRP requires reporting of GHG data and other relevant information from large GHG emission sources, fuel and industrial gas suppliers, and CO<sub>2</sub> injection sites in the United States. Approximately 8,000 facilities are required to report their emissions annually, and the reported data are made available to the public in October of each year.<sup>53</sup>

The NEI is a comprehensive and detailed estimate of air emissions of criteria pollutants, criteria precursors, and hazardous air pollutants from air emissions sources. The NEI is released every three years based primarily upon data provided by State, Local, and Tribal air agencies for sources in their jurisdictions and supplemented by data developed by the US EPA. The NEI is built using the [Emissions Inventory System](#) (EIS) first to collect the data from State, Local, and Tribal air agencies and then to blend that data with other data sources.<sup>54</sup>

---

<sup>53</sup> <https://www.epa.gov/ghgreporting>.

<sup>54</sup> <https://www.epa.gov/air-emissions-inventories/national-emissions-inventory-nei>.

In response to comment that reporting methane emissions as 100-year carbon dioxide emissions equivalency should be discontinued, see Volume I, Chapter 20 (Emissions and Regulatory Impacts), section 20.2.2 (Global Warming Potential (GWP) of Methane), Response I-20-8, for EPA's response supporting the use of the 100-year GWP value.

Comment: Commenter (0789-Pennsylvania Department of Environmental Protection (PDEP)) supports EPA's efforts to significantly reduce GHG emissions, particularly methane, and other harmful air pollutants from the Crude Oil and Natural Gas source category. When finalized, the proposed rule will support state efforts to meaningfully address the harmful impacts of climate change and further protect human health and welfare and the environment. In particular, the proposed rule will assist Pennsylvania in achieving its goal of reducing net GHG emissions from 2005 levels by 26 percent by 2025 and 80 percent by 2050.<sup>55</sup> Pennsylvania's climate change goal is aligned with the reduction targets under the Paris Agreement aimed at keeping global temperature rise below the 2-degree Celsius threshold.

Commenter (0789-PDEP) reiterates that as noted by EPA, the Oil and Natural Gas Industry is the United States' largest industrial emitter of methane. Methane is a potent GHG with a global warming potential more than 28 times that of carbon dioxide over a 100-year period. As methane is the main component of natural gas, it is crucial to address emissions from this source category. Reducing human-caused methane emissions, such as controlling natural gas leaks and releases as proposed by EPA, would contribute substantially to global efforts to limit temperature rise, aiding efforts to remain well below the 2-degree Celsius threshold.

Commenter (0789-PDEP) states that Pennsylvania has been a leader since 2013 in establishing protective and cost-effective conditions for oil and natural gas sources. As such, the commenter supports EPA's efforts to significantly reduce methane emissions from the Crude Oil and Natural Gas source category

Response I-23-31: The EPA acknowledges and commends Pennsylvania in establishing protective and cost-effective conditions for oil and natural gas sources. These comments are supportive comments for EPA's proposals; as such, no response is required.

Comment: Commenter (0574-Consumers Energy Company) would like to highlight two specific issues. First, the commenter supports and reasonable regulation of methane and VOC emissions from the upstream oil and natural gas sector. Clear and reasonable regulation helps keeps natural gas affordable for our ratepayers. In addition, the commenter supports reducing methane emissions in accordance with the recommendations from scientific bodies like the Intergovernmental Panel on Climate Change (IPCC) and their own publicly announced methane reduction goal of net-zero methane by 2030. Under this goal, the commenter has made significant progress in reducing methane emissions from their natural gas delivery system and will continue to support methane reduction efforts from the upstream natural gas sector.

---

<sup>55</sup> Executive Order 2019-01, Commonwealth Leadership in Addressing Climate Change and Promoting Energy Conservation and Sustainable Governance, codified at 4 Pa. Code §§ 5.1001—5.1009.

Response I-23-32: The EPA commends the commenter for making significant progress in reducing methane emissions. The EPA considered this and other comments.

Comment: Commenter (0186-Environmental and Natural Resources Department, Snoqualmie Indian Tribe) supports sharply reducing pollution as proposed, by expanding and strengthening NSPS for methane and VOCs from new, modified, and reconstructed oil and natural gas sources, and by establishing the first EGs requiring regulation of methane from hundreds of thousands of existing sources nationwide. These existing sources include significant industrial and commercial sources which have been left unregulated for far too long. Industrial and commercial sources of pollution must be required to pay for mitigating their own impacts, which should be built into their own business structures, and this should occur without perseveration or delay.

Response I-23-33: These comments are supportive comments for EPA's proposals; as such, no response is required.

Comment: Commenter (0751-Pennsylvania Environmental Council (PEC)) urges EPA to advance strong, comprehensive rules to address methane emissions from the oil and gas sector. It is critical that EPA promptly implement effectual standards to address these emissions; this includes regular leak detection and repair requirements for smaller, leak prone wells. As noted above, these lower-producing wells constitute a significant percentage of methane emissions in Pennsylvania and the nation, and the number of these wells is growing every single year. This is an emissions problem that will continue to get worse if not properly addressed. Under the current EPA proposal, operators that calculate lower potential emissions (less than 3 tons per year of methane) could avoid all monitoring after just one initial inspection. This situation is untenable. Rigorous monitoring and repair requirements that reduce emissions by 80 to 90 percent (consistent with EPA's estimates for quarterly to monthly inspections) must apply comprehensively across all facilities. Without regular inspections, these smaller sites could emit pollution into the atmosphere and nearby communities undetected.

Response I-23-34: These comments are supportive comments for EPA's proposals; as such, no response is required.

Comment: Commenter (0741-United Methodist Women) states that monitoring, reporting, and verification standards have a crucial role in providing accurate data on methane leakages and dictating where action needs to be taken. EPA should develop community monitoring programs that engage with frontline communities, educate and certify community members and require immediate follow up on complaints filed by those certified community members. EPA must strengthen the proposed rule to protect public health and the climate and use all its authority under Clean Air Act § 111(d) to cut methane pollution from oil and gas development by 65 percent by 2025. It is common knowledge that methane pollution increases the threat of climate change and negatively impacts air quality. Black, Indigenous, Latino, Asian, and low-wealth communities, will be forced to deal with the worst impacts of both climate change and methane pollution. The commenter urges EPA to act urgently to address this climate injustice to ensure that the health of God's creation and God's people is protected.

Response I-23-35: In response to comments that EPA should develop community monitoring programs that engage with frontline communities, educate and certify community members and require immediate follow up on complaints filed by those certified community members, while the EPA did not develop the community monitoring program that the commenter envisioned, the EPA developed the Super Emitter Program under the final rule.

Please see section X.C of the final rule preamble for a summary of the final requirements under the Super Emitter Program. As described in section IV.C of the December 2022 Supplemental Proposal preamble, the EPA proposed the Super Emitter Program to ensure that this rulemaking comprehensively addresses the widespread problem of abnormally large emissions events known as super-emitters. The EPA is including the Super Emitter Program in this final rulemaking, previously proposed as the Super Emitter Response Program in the December 2022 Supplemental Proposal. The EPA has developed this program in response to recent studies, which indicate that a small portion of sources contribute almost 50 percent of the methane emissions in the oil and gas sector, and on a global scale, the largest of these emissions sources may represent as much as 12 percent of global methane emissions from oil and gas production. For purposes of this rule, a super-emitter event is one that has a quantified emission rate of 100 kg/hr of methane or greater. As described in the final rule preamble, this program is designed to provide a transparent, reliable, and efficient mechanism by which the EPA will provide owners and operators with timely notifications of super-emitter emissions data collected by the EPA-certified third parties using the EPA-approved remote sensing technologies (*e.g.*, satellites). Where such an event is attributable to a source regulated under CAA section 111 (NSPS OOOO, OOOOa, or OOOOb, or a state or Federal plan implementing EG OOOOc), the responsible owner or operator will take action in accordance with the applicable regulation.

Lastly, as discussed in section II.A (Purpose of the Regulatory Actions) of the final rule preamble, the final rulemaking takes a significant step forward in mitigating climate-destabilizing pollution and protecting human health by reducing GHG and VOC emissions from the oil and natural gas industry, specifically the Crude Oil and Natural Gas source category. These mitigations are based on proven, cost-effective technologies already required by prior EPA regulations or states' regulations or deployed by industry leaders to reduce this dangerous pollution. The final rules will also encourage the deployment of innovative technologies that currently exist to rapidly and cost-effectively detect and reduce methane pollution and promote further innovation that is already under way to find even more efficient and effective ways to mitigate this pollution. Because methane is the main component of natural gas, the rules also result in more saleable product. The oil and natural gas industry is the United States' largest industrial emitter of methane. Human emissions of methane, a potent GHG, are responsible for about one third of the warming due to well-mixed GHGs, the second most important human warming agent after carbon dioxide. The EPA is finalizing the actions described in the preamble to the final rule in accordance with its legal obligations and authorities following a review directed by EO 13990, "Protecting Public Health and the Environment and Restoring Science to Tackle the Climate Crisis," issued on January 20, 2021.

Comment: Commenter (0444-Damascus Citizens for Sustainability (DCS)) urges the adoption of modifications that would aid in adequately protecting our air resources. Most important is to establish at least a mile and a half, better [would] be two mile geographic area around a facility

seeking a permit within which there is an addition of total accumulation - aggregation - of air pollutant emission sources must be taken into account, as opposed to just permitting each site based on the emissions of that single-point source of pollutants. The point source approach avoids the area designation of 'major sources' and then the avoidance of proper modifications to reduce emissions - or not allow the facility's placement. Protection of public health and environmental health must be the paramount reasoning for regulations. Climate impacts must also be recognized which can only be done if all emissions in an area are added together.

Commenter (0444-DCS) provides the example that in Pennsylvania: Due to the topography of PA, many areas have poor air quality. With the increasing presence of the gas industry, a change for the worse is certainly headed our way. A variety of emissions are emitted at compressor sites: NO<sub>x</sub>, CO<sub>2</sub>, VOC, Formaldehyde, PM<sub>10</sub>, Ethane, Methane, Propane, I-butane, n-butane, Non-Methane Hydrocarbons, Heavy Non-Methane and Non-Ethane Hydrocarbons, etc. Compressors, pits, pipelines, gas wells emit a mix that can create ground level ozone that will regularly be held in place by the air inversion factor we see in our valleys and hollows where we live.

Commenter (0444-DCS) suggests that total toxic accumulation - aggregation - of air emission sources must be taken into account, as opposed to just permitting each site based on the emissions of that single-point source of pollutants. What might this mean to our family, especially children, the elderly and those with respiratory challenges is that the materials emitted in the exploration and development of gas and oil wells have profound health effects. The health effects of air pollution - asthma in children and adults, other forms of compromised lung function, all the effects of absorbed and ingested contaminants that produce multiple health effects - must be of prime importance in considering this legislation.

Commenter (0444-DCS) asks EPA to take a look at this paper and take the information in it into account PEER REVIEWED ARTICLE: Natural Gas Operations from a Public Health Perspective attached as AIR-H24263Colborn2011.

With these considerations in mind, Commenter (0444-DCS) urges the following additions to the rule:

1. EPA cannot continue to determine air quality impacts in piecemeal fashion. There needs to be a policy that informs the public and the drillers that EPA will examine multiple sources of all pollution in the aggregate. This policy must cover a single new source of emissions and all potential related sources in the local area. Failure to do so will jeopardize air quality. The commenter urges mile and a half or better 2-mile areas.
2. EPA needs to notify municipalities and the public when new sources of air pollution are installed, even if they are temporary installations. Large pieces of equipment, such as generators, compressors, and pumps generate noise and air pollution that affects local communities.
3. EPA cannot issue exemptions from source permitting requirements where best available control technology is available to control emissions. Flaring to complete gas wells should no longer be exempt. Green or flareless completion is routinely performed in the gas industry and the installation of these should be required and not exempt such emissions.

4. All possible air emissions capture mechanisms must be used in gas and oil drilling - no exceptions - as Best Management Practices.

Commenter (0444-DCS) suggests that the concerns of citizens must be addressed in EPA's air pollution policy. These concerns highlight the need for community-driven, local air monitoring. Gas drilling companies should be required to regularly report pollution levels, as well as equipment malfunctions, leaks, repairs, and the quantity of collected gas that would have otherwise been emitted to the atmosphere. Residents impacted by the oil and gas industry deserve accurate, publicly available real-time air monitoring and to know what nearby industrial facilities are doing to protect public health.

Response I-23-36: The EPA considered these and other comment in developing the final NSPS OOOOb and EG OOOOc rules. As discussed in section II.A (Purpose of the Regulatory Actions) of the final rule preamble, the final rulemaking takes a significant step forward in mitigating climate-destabilizing pollution and protecting human health by reducing GHG and VOC emissions from the oil and natural gas industry, specifically the Crude Oil and Natural Gas source category. These mitigations are based on proven, cost-effective technologies already required by prior EPA regulations or states' regulations or deployed by industry leaders to reduce this dangerous pollution. The final rules will also encourage the deployment of innovative technologies that currently exist to rapidly and cost-effectively detect and reduce methane pollution and promote further innovation that is already under way to find even more efficient and effective ways to mitigate this pollution. Because methane is the main component of natural gas, the rules also result in more saleable product. The oil and natural gas industry is the United States' largest industrial emitter of methane. Human emissions of methane, a potent GHG, are responsible for about one third of the warming due to well-mixed GHGs, the second most important human warming agent after carbon dioxide. The EPA is finalizing the actions described in the preamble to the final rule in accordance with its legal obligations and authorities following a review directed by EO 13990, "Protecting Public Health and the Environment and Restoring Science to Tackle the Climate Crisis," issued on January 20, 2021.

Methane emissions information is reported under the GHGRP and hazardous air pollutants information included in the National Emissions Inventory (NEI) and is not within the scope of this rulemaking. The GHGRP requires reporting of GHG data and other relevant information from large GHG emission sources, fuel and industrial gas suppliers, and CO<sup>2</sup> injection sites in the United States. Approximately 8,000 facilities are required to report their emissions annually, and the reported data are made available to the public in October of each year. The NEI is a comprehensive and detailed estimate of air emissions of criteria pollutants, criteria precursors, and hazardous air pollutants from air emissions sources. The NEI is released every three years based primarily upon data provided by State, Local, and Tribal air agencies for sources in their jurisdictions and supplemented by data developed by the US EPA. The NEI is built using the Emissions Inventory System (EIS) first to collect the data from State, Local, and Tribal air agencies and then to blend that data with other data sources.

Permitting is not within the scope of this rulemaking. See, however, EPA's discussion in section XV (Prevention of Significant Deterioration and Title V Permitting) of the preamble to the final rule regarding the applicability of permitting requirements.

Comment: Commenter (1388-Private Citizen) asks for the help from EPA in reducing the negative health impacts, and climate change impacts from existing polluting facilities. The commenter believes that EPA should extend many of these rules to existing facilities. If that is not possible EPA should quickly set new rules to substantially reduce GHG and other pollutant discharges from existing facilities within the next 2 years.

Commenter (1388-Private Citizen) provides one example, which is the Mountain Valley natural gas pipeline. This facility is currently approved to transport up to 2 billion cubic feet of natural gas per day. Mountain Valley has stated that they hope to get approval to increase the volume to 2.5 billion cubic feet per day. Allowing Mountain Valley Pipeline and other facilities under facilities that are currently under construction to emit GHGs and other pollutants under current rules is unacceptable. The Mountain Valley Pipeline may still be operating 50 years from now. Best available science tells us that natural gas transmission lines, like the Mountain Valley Pipeline generally discharge 0.3 percent to 0.35 percent of their volume through leaks and intentional discharges. That would mean emissions of 6 to 7 million cubic feet per day while transporting 2 billion cubic feet of natural gas per day, and emissions of 7.5 to 8.75 million cubic feet per day while transporting 2.5 billion cubic feet per day. Over the next 50 years total emissions from the Mountain Valley Pipeline could come close to 160 billion cubic feet if it is allowed to operate under today's insufficient rules. These are only emissions from the pipeline itself, and do not consider upstream emissions through exploration, extraction, and production that this pipeline will enable, or the very large downstream emissions from combustion of the natural gas.

Commenter (1388-Private Citizen) suggests that today's rules are what got us into our climate crisis, and contributed to so many negative health impacts, including childhood asthma, from this industry. They need to be changed now. Although the industry might argue that it is not fair to change rules for a facility that is currently under construction, because it will cost the, more to complete the project. The commenter is arguing that not to do so will cost many lives and untold suffering in the future.

Response I-23-37: See Response I-23-26 of this Chapter.

Comment: Commenter (0882-New Mexico Public Health Association (NMPHA)) states that oil and gas producers should not be allowed to burn, vent or leak methane. Not only is methane a major driver of the climate crisis and a toxic pollutant that poses public health problems, but this practice is also a big waste of natural resources that should be captured and sold. Natural resources belong to the people, and the state should receive the royalties from them that their people are due. These royalties should be going to schools and hospitals instead of going up in flames.

Response I-23-38: See Response I-23-26 of this Chapter.

Comment: Commenter (0832-NMED) suggests the proposed rule supports New Mexico's efforts to reduce VOC and GHG emissions that contribute to unhealthy ozone levels and contribute to climate change.

Commenter (0832-NMED) points out that several ozone monitors in New Mexico show that air quality is approaching or exceeding the 2015 ozone NAAQS. The Sunland Park area in southern New Mexico is currently designated as in nonattainment of the 2015 ozone NAAQS, with an additional seven counties in the state monitoring ozone concentrations at or above 95 percent of the standard. Monitored ozone concentrations increased throughout New Mexico over the last several years, including both of New Mexico's oil and natural gas producing regions in the San Juan and Permian Basins. According to EPA's latest National Emissions Inventory (EPA, 2014 NEI version II), over 80 percent of the emissions in these areas are from oil and natural gas sources. The Carlsbad ozone air monitor (AQS ID # 35-015-1005) in the Permian Basin, which is an area of rapid growth in oil production, serves as a prime example of the air pollution problems facing New Mexico. The design value for ozone at this monitor has elevated from 68 ppb in 2016 to 78 ppb in 2020. 2021 data show some of the highest monitored ozone concentrations recorded in the past decade, indicating this upward trend will continue throughout the state.

To improve air quality in these areas, the commenter (0832-New Mexico Environmental Department) developed the Ozone Attainment Initiative (OAI) and joined EPA's Ozone Advance program. As part of the OAI, the commenter is currently researching options for control measures for all source sectors. EPA's proposed rule will be fundamental to reducing emissions from the oil and gas sector. Without these important reductions, additional counties in New Mexico and other states may exceed the 2015 ozone NAAQS, resulting in additional nonattainment area designations and nonattainment permitting requirements.

Commenter (0832-New Mexico Environmental Department) states that recent photochemical modeling indicates that interstate transport contributes to high ozone concentrations in New Mexico. As a result, New Mexico faces nonattainment designations and increased nonattainment permitting requirements, while many states contributing to these exceedances have taken no action to address their contributions. This further emphasizes the need for strong, federally enforceable emissions standards for the O&G sector to ensure fair and equitable requirements in basins that span state lines.

Response I-23-39: These comments are supportive comments for EPA's proposals; as such, no response is required.

Comment: Commenter (0746-Methane Action) suggests that in the final rule or next proposal, EPA sets out a process for backing methane out of most of its current level of use, production lease sales, and permitting, while retaining sufficient capacity in the mid-term to help provide essential services for those who have no short term options or alternatives in the U.S. or allied countries such as Germany, while at the same time assisting them in making the transition to climate protection and restoration and via renewables, storage, and efficiency. As noted in section 5 above, the scientific and legal basis for this has been established and confirmed by the studies released in just the past few weeks, showing harm throughout the life cycle of oil and gas produced by fracking and related unconventional methods. Thus, for EPA to do anything other than to begin a phase-out, starting with oil and gas produced with these methods within a kilometer of human residences, is to allow by permit unnecessary disease and death of significant proportions.

Response I-23-40: See Volume II, Chapter 2 (Legal Basis for Rulemaking), subsection 2.1.4 (EPA Has the Authority Under the CAA to Establish State Plan Requirements). See also, discussions in sections IV (Statutory Background and Regulatory History) and V (Legal Basis for the Final Rule Scope) of the final rule preamble for the basis and scope of the final NSPS OOOOb and EG OOOOc rules. The EPA does not have the authority to phase-out natural gas production/use.

## **23.8 Scope of NSPS/EG Oil and Natural Gas Sector Requirements**

Comment: Commenter (0815-AGA) appreciates and supports the proposal to retain the exclusion of local natural gas utility operations from the crude oil and natural gas source category. The commenter urges that this exclusion be clearly stated in the regulatory text for OOOOa, OOOOb, and OOOOc.

Commenter (0928-APGA) requests that clarify that local distribution companies are not subject to the proposed rule. The commenter notes that EPA’s 2016 final rule for NSPS OOOOa (2016 NSPS)<sup>56</sup> defined the “crude oil and natural gas source category” to include “natural gas production, processing, transmission, and storage, which include the well and extend to, *but do not include, the local distribution company custody transfer station.*”<sup>57</sup> However, they suggest that the language of the 2016 NSPS did not make it immediately apparent that LDCs are excluded from the scope of the rule.

Commenter (0815-AGA) suggests that to avoid confusions, EPA should clarify in Section 60.5365a and the corresponding provisions of new NSPS OOOOb and EG OOOOc that the listed types of facilities are subject to the rule only if they are located within the Crude Oil and Natural Gas Production Source category.

Commenter (0815-AGA) states that there is no proposed regulatory text in EPA’s “notice of proposed rulemaking,” and the scope of the existing rule is not clearly described in the current, 2016 version of 40 C.F.R. Part 60, Subpart OOOOa, §60.5365a. That scope provision is intended to answer the question: “Am I subject to this subpart?” A small gas utility or cooperative that does not have an environmental lawyer on staff may not understand that the rule applies only to facilities that are located within the Crude Oil and Natural Gas Production source category as defined in §60.5430a, and that they should turn to the definitions section toward the end of the rule to discover that the source category does not include operations inside and including the LDC custody transfer station, and then understand that the subpart only applies to facilities in the defined source category. Clarifying language was added to section 60.5365a in 2020. At a minimum, the commenter recommends that clarifying language be restored in NSPS OOOOa and should be included in the new scope provisions of NSPS OOOOb and EG OOOOc so that it is clear to anyone asking “am I subject to this subpart” that facilities inside and including the LDC custody transfer station are not subject to the subpart.

---

<sup>56</sup> Oil and Natural Gas Sector: Emission Standards for New, Reconstructed, and Modified Sources, Final Rule, 81 Fed. Reg. 35823 (Jun. 3, 2016), available at <https://www.federalregister.gov/documents/2016/06/03/2016-11971/oiland-natural-gas-sector-emission-standards-for-new-reconstructed-and-modified-sources>.

<sup>57</sup> Id. at 1931 (emphasis added).

The commenter (0815-APA) urges EPA to include the following text in section 60.5365a and the analogous scope sections of NSPS OOOOb and EG OOOOc:

You are subject to the applicable provisions of this subpart if you are the owner or operator of one or more of the onshore affected facilities listed in paragraphs (a) through (j) of this section, that is located within the Crude Oil and Natural Gas Production source category, as defined in §60.5430a. Facilities located inside and including the LDC custody transfer station are not subject to this subpart.

Response I-23-41: The EPA agrees that, while the definitions section clearly defines the boundaries of the source category, additional clarification in the applicability section of the subpart, in particular with respect to LDC custody transfer, would further help sources to identify if they might be subject to any of the requirements in NSPSs OOOOa and OOOOb and EG OOOOc. Therefore, these rules have been revised to include the following introductory language at 40 CFR 60.5365a and 60.5386c, as well as 40 CFR 60.5365a:

You are subject to the applicable provisions of this subpart if you are the owner or operator of one or more of the onshore affected facilities listed in paragraphs (a) through (j) of this section, that is located within the Crude Oil and Natural Gas source category, as defined in §60.5430b [or 40 CFR 60.5430a and 60.5430c, as relevant], for which you commence construction, modification, or reconstruction after September 18, 2015, and on or before December 6, 2022. Facilities located inside and including the Local Distribution Company (LDC) custody transfer station are not subject to this subpart.

Comment: Commenter (0813-Black Hills Energy) states that they are currently investigating opportunities to help customers transport their renewable natural gas to consumers. The commenter explains that natural gas produced from renewable sources such as landfills, livestock operations, and wastewater treatment plants is generally accepted as a lower carbon fuel than geologically produced natural gas. The commenter asks that EPA clarify when renewable natural gas could become subject to the requirements of the proposed rule for the natural gas transmission and storage segment. The commenter recommends that the custody transfer point between the natural gas transportation company (NAICS codes 221210 or 486210) and the renewable natural gas producer, be the delineation between the two. They also recommend that any equipment upstream of that custody transfer point, not be considered in the proposed rule for the applicable facility.

Response I-23-42: Renewable natural gas from sources such as landfills, livestock operations, and wastewater treatment plants is not subject to the natural gas transmission and storage segment requirements of the final NSPS OOOOb or EG OOOOc. See the definition of the crude oil and natural gas source category included in both of these rules [40 CFR 60.5430b; 40 CFR 60.5430c]:

*Crude oil and natural gas source category means:*

(1) Crude oil production, which includes the well and extends to the point of custody transfer to the crude oil transmission pipeline or any other forms of transportation; and

(2) Natural gas production, processing, transmission, and storage, which include the well and extend to, but do not include, the local distribution company custody transfer station.

Also note that the introductory text to 40 CFR 60.5365b [and parallel language in 40 CFR 60.5386c (without sentence regarding centrifugal compressor facilities)] states:

You are subject to the applicable provisions of this subpart if you are the owner or operator of one or more of the onshore affected facilities listed in paragraphs (a) through (i) of this section, that is located within the Crude Oil and Natural Gas source category, as defined in §60.5430b, for which you commence construction, modification, or reconstruction after December 6, 2022. Centrifugal compressor affected facilities listed in paragraph (b) of this section that use dry seals are subject to the applicable provisions of this subpart if construction, modification, or reconstruction are commenced after December 6, 2022. Facilities located inside and including the Local Distribution Company (LDC) custody transfer station are not subject to this subpart.

Comment: Commenter (0742-ADEC) requests clarification of the definition of “onshore”. The commenter notes that, assuming EPA uses the same definitions from NSPS OOOO and OOOOa, as the proposal contains no new definitions to review, the current regulations define “onshore” as:

*Onshore* means all facilities except those that are located in the territorial seas or on the outer continental shelf.

The commenter (0742-ADEC) would like EPA to confirm that no new extensions to the definition of “onshore” are being proposed, and that no expansion of regulated stationary sources to State waters is proposed because this proposal directly uses the term “onshore” without definition.

Response I-23-43: The NSPS OOOOb and EG OOOOc final rules define “onshore” as follows:

*Onshore* means all facilities except those that are located in the territorial seas or on the outer continental shelf.

## **23.9 Recordkeeping and Reporting**

### ***23.9.1 Rule-Related Recordkeeping and Reporting Requirements***

#### **23.9.1.1 Electronic Reporting**

Comment: Commenters (0391-KBIC, 0781-NTAA, 0605-Muscogee (Creek) Nation, 0943-Sault Ste. Marie Tribe of Chippewa Indians, 0833-UMUT EPD) support the use of electronic reporting of performance test reports, annual reports, and semiannual reports and requests that EPA make sure this information, along with other relevant information, is organized and easily accessible to the public. The commenters believe that information on large emissions events should be made public sooner than the annual reporting period.

Commenter (0461-BHE) supports electronic reporting through Compliance and Emissions Data Reporting Interface (CEDRI). Public access to these reports could be addressed through EPA systems using periodic reports submitted to EPA by operators – *i.e.*, EPA could provide the conduit for information to be made available to the public. Without regulatory text or program elements defined, it is unclear what EPA may be considering programmatically to maintain parity between differing optical imaging technologies with different performance objectives and the need for regulatory test methods. EPA also solicits comment on what elements, if any, are appropriate for more frequent reporting. For example, EPA envisions a program where leak size is distinguished (rather than just leak detection) with tiered reporting criteria potentially applying and larger leaks reported sooner than in an annual report. EPA requests feedback on what mechanism would be appropriate for the collection and public dissemination of this information. Again, it is premature to offer specific recommendations until such technologies are in place with standards for their use. However, the commenter recommends operators reporting through EPA (CEDRI) with public access to the data through EPA systems.

Other commenters (0797-NDDEQ and NDIC) suggest that EPA allow any required documentation to be first sent to the states delegated by EPA with the implementation and enforcement authority for the 2021 NSPS Proposal.

The commenters (0797-NDDEQ and NDIC) note that EPA proposes requiring electronic reporting of performance test reports, annual reports, and semiannual reports through the CEDRI. 86 Fed. Reg. at 63,185. For states that have been delegated authority by EPA to oversee the implementation and enforcement of NSPS OOOO and OOOOa, the commenter states that it is currently burdensome to require owners and operators to solely submit documents through CEDRI. The commenter notes that states with delegated authority have no control over CEDRI, and cannot implement state automation, tracking, and other processes for these reports without first either retrieving the data from CEDRI themselves and then uploading the data into their own systems, or by requiring the owner or operators to resubmit the data directly to the state.

Nonetheless, the commenters (0797-NDDEQ and NDIC) support the use of electronic reporting and agree with EPA “that the electronic submittal of these reports in the proposed NSPS OOOOb will increase the usefulness of the data contained in those reports, is in keeping with current trends in data availability, will further assist in the protection of public health and the environment, and will ultimately result in less burden on the regulated community.” 86 Fed. Reg. at 63,185. The commenters also agree that “[e]lectronic reporting can also eliminate paper-based, manual processes, thereby saving time and resources, simplifying data entry, eliminating redundancies, minimizing data reporting errors, and providing data quickly and accurately to the affected facilities, air agencies, EPA, and the public.” However, the commenters assert that requiring those reports to be controlled solely through CEDRI undermines many of those goals, requiring states that are supposed to be helped by electronic reporting to instead be burdened by a system over which they have no control of or input into. The commenters agree with the intent of CEDRI but disagree with its implementation.

Commenters (0797-NDDEQ and NDIC) state that CEDRI allows owners and operators to meet their annual NSPS OOOOa reporting obligations by uploading a single report containing all their affected facilities in the U.S. rather than breaking up the report by state, county, etc. The

commenters provide that this creates challenges for North Dakota, which includes several federally recognized Indian Nations, including the Mandan, Hidatsa, and Arikara Nations, which have substantial oil and gas development. The commenters state that they do not have CAA delegation for those areas, and that there is no current way in CEDRI to differentiate locations within tribal boundaries without manually locating each facility suspected to be within those boundaries. In addition, they state that the public cannot generally access reports within CEDRI and instead must wait until such reports have been sent to EPA's WebFIRE repository which is available to the public. WebFIRE itself has a general disclaimer that "[t]hese records and any related attachments may or may not have been reviewed by the state, local, or tribal air pollution agency or delegated authority." As CEDRI reports do not require the commenter's review before being sent to WebFIRE, the commenters suggest that the public may not be certain over the accuracy of the data or if the commenter has even had the chance to review the data beforehand.

Lastly, the commenters (0797-NDDEQ and NDIC) recognize that EPA acknowledges that CEDRI or even EPA's Central Data Exchange itself may suffer outages. 86 Fed. Reg. at 63,185. While most outages are expected to be short-lived, the commenter notes that those related to a shutdown of the federal government may be considerably longer based on the recent historical record. If CEDRI access was cutoff during a prolonged shutdown, this would severely disrupt the work of a delegated state such as North Dakota. The commenters state that WebFIRE (if still online) would be a sufficient backup for past data, however as a shutdown progresses, the more out of date it becomes. According to the commenters, this is especially concerning for CAA compliance work, as air pollution does not stay at a site and allow itself to be cleaned up later.

Commenters (0797-NDDEQ and NDIC) recommend that the proposed rule be simplified to require owners and operators to submit their reports "to the Administrator", as is the general requirement in many other regulations (*e.g.*, NSPS Subpart Kb), and for CEDRI to be the initial point of submission where EPA, not the state, is implementing the program. Should EPA insist on explicitly requiring CEDRI, the commenter suggests that language referencing or based on section 60.4(a) (All requests, reports, applications, submittals, and other communications to the Administrator pursuant to this part shall be submitted in duplicate to the appropriate Regional Office of the U.S. Environmental Protection Agency...) be included instead, to include wording requiring the duplicate be submitted through CEDRI. In this manner, the delegated state can immediately receive the required report independent of CEDRI's status, and EPA will receive the duplicate for their own use. The commenters contend that this flexibility is vital in allowing the commenter and other delegated entities to continue the implementation and enforcement work that is required and expected, both by EPA and the public.

Response I-23-44: EPA acknowledges the commenters' support for electronic reporting. See section X.N (Electronic Reporting) of the final rule preamble for a discussion on EPA's final electronic reporting requirements to increase the ease and efficiency of data submittal and data accessibility. The EPA is finalizing a requirement that owners and operators submit electronic copies of performance test reports, natural gas processing plant semiannual reports, annual reports, and notifications of well closure activities through the EPA's Central Data Exchange (CDX) using CEDRI.

Regarding making information public on large emissions events sooner than the annual report, see section X.C of the preamble to the final rule for a discussion on the final standards for super emitter events.

As noted in the November 2021 Proposal, a description of the electronic data submission process is provided in the memorandum Electronic Reporting Requirements for New Source Performance Standards (NSPS) and National Emission Standards for Hazardous Air Pollutants (NESHAP) Rules, available in the docket for this rulemaking. As described in that memo, data flows to EPA from owners and operators through CEDRI. Data then flow from CEDRI to WebFIRE. WebFIRE is the public access portal for information that is submitted to CEDRI. Data submitted to CEDRI is not immediately available in WebFIRE; it goes through a processing period, which allows delegated air agencies time to review reports to reduce any errors that may be in the reports before they are made available to the public. Additionally, although there is a statement in WebFIRE that indicates the data may not have been reviewed by the delegated authority, this should not create certainty over the accuracy of the data. EPA notes that the owner or operator is ultimately responsible for the accuracy and completeness of data contained in the report. The owner or operator or their delegated representative must attest to the report's completeness and accuracy when they electronically certify the report in the CEDRI submission process.

EPA disagrees that reports should first be sent to the delegated air agency before it is sent to CEDRI. Reports that are not submitted electronically are required to be sent to the appropriate EPA regional office concurrently with the delegated air agency, not after the delegated air agency reviews the report. EPA is not changing this requirement; we are merely changing the format in which the report is sent. EPA also notes that even without the addition of specific regulatory text in NSPS OOOOb, the requirement to report electronically to CEDRI does not relieve an owner or operator of the obligation in 40 CFR 60.4(b) to submit a copy of the report to a delegated air agency, if the delegated air agency does not wish to receive the report through CEDRI. However, EPA understands that many delegated air agencies do want to receive reports through CEDRI due to the volume of reports expected with this rulemaking (see the next comment as one example) and because it simplifies the reporting process for owners and operators by allowing a single submission for both the EPA regional office and delegated air agency.

Since the development of CEDRI,<sup>58</sup> EPA has worked with delegated air agencies to develop a system that meets their needs as well as the needs of reporting entities. EPA is committed to continuing to find ways to improve CEDRI and the electronic reporting process, and we continue to provide training to delegated air agencies on CEDRI and our other electronic reporting systems. We are continuing to investigate the integration of delegated air agency reporting systems with multiple EPA reporting systems, including CEDRI, and we are investigating tools to help delegated air agencies review submitted data more easily and quickly.

---

<sup>58</sup> During the development of CEDRI, EPA initiated a multi-disciplinary, cross-functional integrated project team that included EPA personnel from various offices and representatives from delegated air agencies.

EPA acknowledges that currently there is no way to filter facilities within Indian Nations within CEDRI. This need has been expressed by users, and we are currently investigating the addition of such a filter within CEDRI.

EPA acknowledges that CDX and CEDRI have experienced short outages, which is why we have included provisions for owners and operators to seek reporting period extensions for narrow circumstances. However, we note these outages are not related to government shutdowns. EPA's electronic reporting systems, both CEDRI and WebFIRE, continue to operate, even in the event of a government shutdown.

Comment: Commenter (0763-TCEQ) states that throughout the proposal, EPA is requiring additional components and additional affected facilities to provide annual reporting. The commenter contends that most states will not be able to accommodate this new amount of paper copies. Therefore, investigators must be able to access the reports through EPA's reporting system. The commenter recommends that EPA ensure that their system (CEDRI) is capable of handling this increase in activity.

Response I-23-45: The EPA acknowledges the commenter's recommendation. See also Response I-23-44.

Comment: Commenter (0560-LGIM America) encourages EPA to adopt a reliable reporting framework that investors and other stakeholders can utilize. The commenter contends that easy and reliable access to data is one of the best methods to achieve EPA's goal of empowering stakeholders to assist in identifying and stopping large emission events. As an investor, the commenter reports that they have the ability to leverage their suite of stewardship tools and capital allocation options in order to encourage positive change at laggard companies. But the commenter contends that this can only be done if the data is there to make the initial evaluation.

Response I-23-46: The EPA agrees that having access to data is useful for investors and stakeholders. See Response I-23-44 of this Chapter related to Electronic Reporting required under the NSPS OOOOb and EG OOOOc. Investors and stakeholders can also access methane emissions information from the Greenhouse Gas Reporting Program (GHGRP). The GHGRP requires reporting of greenhouse gas (GHG) data and other relevant information from large GHG emission sources, fuel and industrial gas suppliers, and CO<sub>2</sub> injection sites in the United States. Approximately 8,000 facilities are required to report their emissions annually, and the reported data are made available to the public in October of each year.<sup>59</sup>

Comment: Commenters (0401-Mercy Investment Services Inc, 0434-Pax World Funds, 0435-Wespath Benefits and Investments, 0443-SGI, 0455-Radio Drama Network Inc, 0460-Trinity Health, 0538-Change Finance, 0723-Ceres) urge EPA to ensure strong methane emission performance standards by crafting a regulation that establishes a transparent, credible, and empirically based methane emissions reporting framework to improve the accuracy and credibility of reported methane emissions data, and enable us, as investors, to clearly differentiate between leaders and laggards.

---

<sup>59</sup> <https://www.epa.gov/ghgreporting>.

Response I-23-47: The NSPS OOOOb and EG OOOOc requirements do not establish a methane emissions reporting framework. See section II.A (Purpose of the Regulatory Actions) of the final rule preamble for a discussion regarding the purpose of the regulatory actions. See also, discussions in sections IV (Statutory Background and Regulatory History) and V (Legal Basis for the Final Rule Scope) of the final rule preamble for the basis and scope of the final NSPS OOOOb and EG OOOOc rules.

Investors and stakeholder can access methane emissions information from the Greenhouse Gas Reporting Program (GHGRP). The GHGRP requires reporting of greenhouse gas (GHG) data and other relevant information from large GHG emission sources, fuel and industrial gas suppliers, and CO<sub>2</sub> injection sites in the United States. Approximately 8,000 facilities are required to report their emissions annually, and the reported data are made available to the public in October of each year.<sup>60</sup>

#### 23.9.1.2 Streamlined Recordkeeping and Reporting Requirements

Comment: Commenter (0598-CER) agrees with EPA's proposal to maintain the reduction in reporting requirements included in the 2020 Technical Rule Revisions. The commenter notes that the preamble did not include regulatory text for the commenter to validate the reporting requirements under the newly proposed rules in order to evaluate if any additional reductions will be beneficial to industry and EPA. The commenter encourages EPA to evaluate the data that is being provided to determine what additional reporting requirements may be eliminated. The commenter suggests that eliminating reporting requirements be based on the data that EPA is using or not using from the large volume that is submitted by obligated parties.

Commenter (0831-AXPC) urges EPA to minimize any unnecessary recordkeeping and reporting requirements that overlap with those of other state, local, or federal agencies. To the extent that one or more other agencies already require companies to record and report identical or substantially similar information, the commenter suggests that EPA deem that recordkeeping and reporting sufficient for purposes of this rulemaking. The commenter notes that this should guide EPA's approach both in its retention of the reforms of NSPS OOOOa from the 2020 Technical Rule, and in its design of new NSPS OOOOb and EG OOOOc.

Commenter (0831-AXPC) believes streamlining recordkeeping and reporting allows for the oil and natural gas industry to continue to comply with the intent of EPA's regulations, while removing unnecessary burdens that do not result in increasing emissions reductions. The commenters suggest that recordkeeping and reporting reforms become even more important as this regulation adds another form of new source (NSPS OOOOb) and will eventually result in state plans for all existing sources (EG OOOOc). As there are multiple regulations that will apply to EG OOOOc sources, the commenters believe that there is the potential for duplication and unnecessary reporting to multiple regulators.

Also, while the commenter (0831-AXPC) states that they will provide suggestions after seeing the proposed regulatory text in EPA's future actions. The commenter notes that they are currently supportive of the recordkeeping and reporting reforms that EPA has implemented since

---

<sup>60</sup> <https://www.epa.gov/ghgreporting>.

the development of the NSPS OOOOa program. According to the commenter, it is currently unclear without regulatory text what other recordkeeping and reporting reforms may be necessary to harmonize the multiple overlapping federal and state regulations, but state that they will provide comments within the supplemental proposal comment period.

Response I-23-48: The EPA acknowledges the concerns raised by the commenter. The EPA considered this and other comments received when developing the proposed regulatory text for the NSPS OOOOb and EG OOOOc included under the December 2022 Supplemental Proposal.<sup>61</sup> Based on comments received on the December 2022 Supplemental Proposal rule language and requirements, we reviewed the notification, recordkeeping and reporting requirements in the NSPS OOOOb and EG OOOOc rules to assure that these requirements are the minimum necessary to assure compliance and properly notify regulatory agencies.

Comment: Commenter (0598-CER) suggests that one method to reduce the burden for small businesses is to reduce the documentation requirements for the small businesses. A few suggestions provided by the commenter are presented below:

The commenter (0598-CER) suggests reducing the inspection requirements to AVO and soap bubble inspections will also reduce some of the documentation burden for small businesses. Digital photos or videos and supporting documents for the inspector or OGI camera will not be required.

The commenter (0598-CER) states that EPA could reduce the number of data points that need to be reported each year. For example, the commenter notes that EPA asks if each tank facility has been removed from service or returned to service each year. The commenter states that an operator could only report on the few that changed status instead of reporting on every facility every year. The commenter adds that EPA also asks if a site became an affected facility during the reporting period. According to the commenter, this is another case where the operator should be able to report on the exceptions instead of reporting “yes” or “no” for every site in the report.

Lastly, the commenter (0598-CER) suggests reducing the time period for small business entities to store and maintain records from five years to two years. The commenter explains that document storage, physical or digital, can be time consuming and expensive. As this revision will impact many more small business entities than the 2016 NSPS OOOOa, the commenter believes that maintaining historic records for five years will result in a greater impact.

Response I-23-49: The EPA has not developed different compliance documentation requirements for owners or operators of affected facilities/designated facilities in the final rule requirements established under NSPS OOOOb and EG OOOOc. However, as discussed in Response I-23-48, we reviewed the notification, recordkeeping and reporting requirements in the NSPS OOOOb and EG OOOOc rules to assure that these requirements are the minimum necessary to assure compliance and properly notify regulatory agencies.

---

<sup>61</sup> For the proposed NSPS OOOOb regulatory text, see Docket ID Number EPA-HQ-OAR-2021-0317-1551; for the proposed EG OOOOc regulatory text, see Docket Number EPA-HQ-OAR-2021-0317-1552.

We also note that some fields in the reporting form are not required, but are meant to aid in walking users through the entirety of the form.

### ***23.9.2 Other Recordkeeping and Reporting Requirement Suggestions***

Comment: Commenter (0782-BHE) states that they believe the current recordkeeping and reporting requirements in NSPS OOOOa are extensive and adequate, and suggests additional recordkeeping is not warranted for NSPS OOOOb or EG OOOOc.

Commenter (0782-BHE) notes that EPA requested feedback on public access to reporting information, including use of information from and for communities and others. The commenter recommends retaining the extensive and complete reporting and recordkeeping requirements in the current regulation, NSPS OOOOa. Other programmatic approaches that may be under consideration require significant programmatic development before adoption in a rulemaking and implementation. The current reporting and recordkeeping requirements are extensive and adequate and would be effective if retained. The commenter supports developing programs associated with reporting large leaks, developing community programs, and other elements contemplated in the proposed rule via a transparent process that engages operators and other stakeholders, with any additional reporting and recordkeeping criteria as an outgrowth of that process. While it is premature to offer specific recommendations until program elements are formulated, some general comments from the commenter are provided at this time.

The commenter (0782-BHE) notes that EPA solicits comment on what “community use of information” guidelines should entail and whether specific protocols (*e.g.*, permissible detection technologies, data analytics, operator training, data reporting, public access, and data preservation) should govern the collection of such data and whether such data should conform to any type of certification. The commenter recommends ensuring that any technologies or analytics implemented be vetted through a peer review process with standards or methodologies adopted to ensure data quality. The commenter states that the proposed Appendix K criteria likely present unnecessary hurdles for optical imaging technology, but the commenter supports rational performance metrics and training criteria reflected in methods or standards (*e.g.*, EPA test method, ASTM method). Such standards must apply to all users, whether an operator or a third party in the community. The commenter discourages EPA from implementing community-based programs without standardization and quality control criteria in place to ensure data integrity.

At this time, the commenter (0782-BHE) suggests additional or more frequent reporting for NSPS OOOOb and EG OOOOc may not be necessary, and the costs and benefits associated with significant departure from NSPS OOOOa recordkeeping and reporting requirements have not been developed or considered. The commenter supports development and integration of new detection and measurement technologies, but the commenter suggests that all elements of those programs be developed through a systematic, transparent process that engages stakeholders. Reporting and recordkeeping criteria are just one of the many elements of such programs that require additional, thoughtful consideration.

Response I-23-50: The EPA included similar recordkeeping and reporting requirements as included under NSPS OOOOa under NSPS OOOOb and EG OOOOc where the standards /presumptive standards were similar. Otherwise, the EPA considered this and other comments received when developing the proposed regulatory text for the NSPS OOOOb and EG OOOOc included under the December 2022 Supplemental Proposal. Based on comments received on the December 2022 Supplemental Proposal rule language and requirements, we reviewed the notification, recordkeeping and reporting requirements in the NSPS OOOOb and EG OOOOc rules to assure that these requirements are the minimum necessary to assure compliance and properly notify regulatory agencies.

In response to the comment discouraging EPA from implementing a community-based program without standardization and quality control criteria in place to ensure data integrity, see section X.C of the final rule preamble for a summary of the final requirements under the Super Emitter Program. As described in section IV.C of the December 2022 Supplemental Proposal preamble,<sup>62</sup> the EPA proposed the Super Emitter Program to ensure that this rulemaking comprehensively addresses the widespread problem of abnormally large emissions events known as super-emitters. The EPA is including the Super Emitter Program in this final rulemaking, previously proposed as the Super Emitter Response Program in the December 2022 Supplemental Proposal. The EPA has developed this program in response to recent studies, which indicate that a small portion of sources contribute almost 50 percent of the methane emissions in the oil and gas sector, and on a global scale, the largest of these emissions sources may represent as much as 12 percent of global methane emissions from oil and gas production. For purposes of this rule, a super-emitter event is one that has a quantified emission rate of 100 kg/hr of methane or greater. As described in the final rule preamble, this program is designed to provide a transparent, reliable, and efficient mechanism by which the EPA will provide owners and operators with timely notifications of super-emitter emissions data collected by the EPA-certified third parties using the EPA-approved remote sensing technologies (e.g., satellites). Where such an event is attributable to a source regulated under CAA section 111 (NSPS OOOO, OOOOa, or OOOOb, or a state or Federal plan implementing EG OOOOc), the responsible owner or operator will take action in accordance with the applicable regulation.

Comment: Commenters (1389-VERIS Wealth Partners, 1372-General Capital, PBC, 0728-Calvert, 0724-Boston Trust Walden, 0720-Miller/Howard Investments) urge EPA to ensure strong methane emission performance standards by crafting a regulation that establishes a transparent, credible, and empirically based methane emissions reporting framework to improve the accuracy and credibility of reported methane emissions data, and enable investors to clearly differentiate between leaders and laggards.

Commenter (0437-State of NY Comptroller) believes the 2021 November Proposed Rule only partially meets investors' expectations for a robust rule that fully addresses methane emissions. The commenter urges EPA to establish an empirically-based methane emissions reporting framework based on the actual measurement of emissions. Field studies have estimated that EPA's current factor-based methods may undercount methane emissions by as much as 60

---

<sup>62</sup> 87 FR 74722.

percent.<sup>63</sup> The commenter suggests that EPA require empirically founded, measurement-based methods for reporting methane emissions, which enables us as investors to better assess methane-related risks.

Response I-23-51: See Response I-23-47 of this Chapter.

Comment: Commenter (0329-350 Colorado) suggests rules that rely on industry self-reporting of emissions give too much responsibility to an industry with a horrendous track record of complying with reporting requirements. The commenter recommends that EPA require real-time, third party monitoring that is made available to community-based organizations, as well as regular, frequent aerial monitoring surveys.

The commenter (0329-350 Colorado) claims that Colorado’s oil and gas operators have a horrendous track record of complying with data reporting requirements. The commenter notes that their claim is evidenced by two performance audits that the state has conducted in recent years:

1. A 2020 Severance Tax Audit found that-
  - 316 of 416 active operators from the period of 2016 to 2018 were found to potentially be in violation for over 51,000 missing or incomplete reports.
  - The Colorado Oil and Gas Conservation Commission could have levied penalties totaling \$308 million for just 30 days of delinquency, and much more if violations exceeded 30 days. However, it failed to collect these penalties.
2. A 2021 Performance Audit of oil and gas production reporting found that-
  - As of 2021, “about 215,000 of the more than 280,000 reports (77 percent) that COGCC listed as delinquent—and intended to follow up on with operators— were more than 5 years old, with some dating back to 1999.”

[The commenter (0329-350 Colorado) includes an attachment to their comments that includes highlight sheets from both of these reports.]

Response I-23-52: The EPA appreciates the commenter’s information. The EPA has not granted the commenter’s request that EPA require real-time, third-party monitoring be made available to community-based organizations, as well as requiring regular, frequent aerial monitoring surveys. However, the EPA has established a Super Emitter Program in the final action. See section X.C of the final rule preamble for a summary of the final requirements under the Super Emitter Program. As described in section IV.C of the December 2022 Supplemental Proposal preamble, the EPA proposed the Super Emitter Program to ensure that this rulemaking comprehensively addresses the widespread problem of abnormally large emissions events known as super-emitters. The EPA is including the Super Emitter Program in this final rulemaking, previously

---

<sup>63</sup> Alvarez, Ramon A. et al. “Assessment of Methane Emissions from the U.S. Oil and Gas Supply Chain,” Science, Vol. 361. No. 6398, 2018.

proposed as the Super Emitter Response Program in the December 2022 Supplemental Proposal. The EPA has developed this program in response to recent studies, which indicate that a small portion of sources contribute almost 50 percent of the methane emissions in the oil and gas sector, and on a global scale, the largest of these emissions sources may represent as much as 12 percent of global methane emissions from oil and gas production. For purposes of this rule, a super-emitter event is one that has a quantified emission rate of 100 kg/hr of methane or greater. As described in the final rule preamble, this program is designed to provide a transparent, reliable, and efficient mechanism by which the EPA will provide owners and operators with timely notifications of super-emitter emissions data collected by the EPA-certified third parties using the EPA-approved remote sensing technologies (e.g., satellites). Where such an event is attributable to a source regulated under CAA section 111 (NSPS OOOO, OOOOa, or OOOOb, or a state or Federal plan implementing EG OOOOc), the responsible owner or operator will take action in accordance with the applicable regulation.

Comment: Commenter (0941-350 Silicon Valley) requests that EPA's National Emissions Inventory (NEI) figures for methane be improved and made publicly available in a timely way. The Energy Information Administration (EIA) at the U.S. Department of Energy (DOE) produces monthly oil and gas production estimates based on a monthly survey (Form EIA 914) of the major oil and gas producers in the country. This form specifies that flared and vented gas be excluded from the survey. The commenter recommends that EPA request that these amounts be included in the survey. This could easily be done by adding 3 questions to Form EIA 914, requesting separate estimates for the amount of natural gas (1) flared, (2) vented and (3) leaked. Initially most of the answers to these questions will probably be emission factor estimates, but over time they could improve. They would at least start providing timely estimates for both methane and carbon dioxide emissions from the production of oil and gas.

The commenter (0941-350 Silicon Valley) also recommends that the proposed NSPS and EG rules clarify in the final rule that all facilities are required to report separately the quantity of all the methane they flare, vent and leak. The commenter adds that all these emissions whether they are considered to be "unavoidable" due to an emergency or upset, "avoidable" or routine should be reported monthly. The commenter suggests a deadline for reporting these 3 types of emissions for existing facilities, if possible should be January 2025, but no later than January 2026.

Response I-23-53: The request that EPA's NEI figures be improved and made publicly in a timely way is outside of the scope of this rulemaking; as such, no response is required.

With regards to the recommendation that the proposed NSPS and EG rules clarify that all facilities are required to separately report the quantity of methane they flare, vent, or leak, this is not within the scope of EPA's rulemaking. See section II.A (Purpose of the Regulatory Actions) of the final rule preamble for a discussion regarding the purpose of the regulatory actions. See also, discussions in sections IV (Statutory Background and Regulatory History) and V (Legal Basis for the Final Rule Scope) of the final rule preamble for the basis and scope of the final NSPS OOOOb and EG OOOOc rules.

Methane emissions information is reported under the GHGRP. The GHGRP requires reporting of GHG data and other relevant information from large GHG emission sources, fuel and industrial

gas suppliers, and CO<sub>2</sub> injection sites in the United States. Approximately 8,000 facilities are required to report their emissions annually, and the reported data are made available to the public in October of each year.<sup>64</sup>

## **23.10 Requests for Extension of the 2021 November Proposal/Information Collection Request Comment Period**

### ***23.10.1 Initial Requests for Extension of the Comment Period for the 2021 November Proposal***

Comment: Several commenters (0184-OK Alliance, 0189-API, 0190-NACAA, 0191-GPA, 0192-AXPC, 0200-ODEQ, 0214-U.S. Senate, 0291-AOGA, 0324-CenSARA, 0334-WV Oil and Gas, 0348-IPAA, 0358-KDHE, 0360-ADEC, 0361-WDEQ, 0408-U.S. Congress, 0412-AGA, 0415-INGAA, 0417-NDDEQ, 0418-Railroad Commission of Texas, 0419-TCEQ, 0580-KY Division of Air Quality, 0825-Montana Department of Air Quality, 0829-U.S. Congress, 0936-U.S. Congress) requested that EPA extend the comment period for the November 2021 proposed rule. These commenters suggested that the comment period be extended anywhere from 30 days to 90 days. Examples of some of these requests are presented in the following paragraphs.

Commenter (0190-NACAA) requested that EPA extend the public comment period by at least 30 days and notify the public of the extension as soon as possible and well in advance of the January 14 deadline so commenters may make full use of the additional time. The commenter (0190-NACAA) stated that the provisions contained in EPA's proposal are complex and have significant ramifications. Indeed, the commenter noted that EPA has requested comment and information on a long list of issues that may require modeling or other analyses to understand. Performing these analyses will necessitate longer than the comment period currently allows. The commenter reported that air quality agencies need a minimum amount of time to review the extensive background materials, gather data, consider the impacts of the proposed changes, and prepare comments, and the intervening holiday season will introduce obstacles to the ability of our respective organizations to coordinate and convene discussions for members. To ensure that state and local agencies have an adequate opportunity to review and respond to the proposal, the commenter stated that additional time beyond the 60-day comment period is necessary.

In light of the considerations discussed above, and because there is no statutory or court-ordered deadline associated with the proposed rule, the commenter (0190-NACAA) requested that EPA extend the comment deadline by a minimum of 30 days, to February 14, 2022 (or later) to allow state and local agencies and others to fully consider and respond to the proposal.

Commenter (0189-API) respectfully requested a minimum 30-day comment period extension for the Proposed Rule. The commenter stated that they will be directly affected by the proposed regulations which are a substantial departure from the current regulations and will have significant impacts on our industry's operations. Considerable effort will be required to analyze and understand rule implications, and to develop constructive comments. Further, the commenter noted that EPA has explicitly solicited feedback on over 200 items, all of which will necessitate

---

<sup>64</sup> <https://www.epa.gov/ghgreporting>.

sufficient time to analyze, collect any necessary data, and develop thoughtful responses. The commenter also notes that the comment period encompasses the holidays, which can limit available personnel resources during those holiday periods.

Commenter (0189-API) supported the direct regulation of methane for new and existing sources and remains committed to working with EPA and the Administration to identify emission control opportunities that are cost effective, facilitate innovation and further the progress made in reducing emissions. However, trade associations and operators, including the commenter, have resource limitations and it's imperative that they are allowed sufficient time to fully analyze the impact of these regulations.

Commenter (0415-INGAA) requested that the deadline be extended an additional 30 days, allowing interested parties a total of 90 days to comment following *Federal Register* publication. The commenter contended that this extension is necessary because it raises issues arising for the first time. Specifically, the commenter noted that the proposed rule sets forth emissions guidelines for existing sources under section 111(d) of the CAA. The Crude Oil and Natural Gas source category (which is the source category at issue in the proposed rule) has never been regulated under section 111(d) before. Because this is a complex issue of first impression, the commenter stated that an extension of time is needed to ensure all concerned parties have an opportunity to develop meaningful comments on these important issues.

Commenter (0412-AGA) requested that EPA extend the comment period by an additional 30 days, to allow interested parties a total of 90 days to comment following *Federal Register* publication.

As INGAA and API have noted in their similar extension requests, the commenter (0412-AGA) contended that considerable effort will be required to analyze the proposal, evaluate rule impacts, collect, and analyze any necessary data, develop thoughtful responses to the more than 200 questions EPA has posed for stakeholder feedback and develop constructive comments. The commenter reported that many of the same subject matter experts at the association and in their member companies that will be called on for this effort are also working on myriad other agency rulemakings and initiatives relating to GHG reductions and reporting. With this constraint on our resources, they stated that it is critical to be allowed a minimum 30-day comment period extension on the proposed standards.

Commenter (0191-GPA) requested that EPA provide a 30-day extension of the comment period on EPA's Proposed Rule. The commenter noted that the November 2021 proposal provided only a 60-day comment period. According to the commenter, the timeframe is insufficient to permit stakeholders to provide meaningful comment, especially in view of the expansive set of issues for which EPA has explicitly asked for comment. The commenter stated that EPA's own compilation of just the items on which it explicitly solicits input spans 30 pages and includes some 186 separate requests for comment.<sup>65</sup> The commenter noted that the agency must allow stakeholders an adequate opportunity to provide comments, and this includes sufficient time to

---

<sup>65</sup> EPA, Proposed Rule Summary of Comment Solicitations (Nov. 1, 2021), available at <https://www.regulations.gov/document/EPA-HQ-OAR-2021-0317-0028>.

actually consider the extensive discussion in the Proposal and addressing the expansive list of specific requests for input.

Commenter (0191-GPA) stated that, in addition, while not offering regulatory text, the Proposal discussed a wide range of contemplated regulatory changes across the newly redefined Crude Oil and Natural Gas source category. Moreover, they added that EPA's proposal discussed new approaches for regulating emissions from both new, reconstructed, and modified sources and the hundreds of thousands of existing sources across the sector not previously regulated by EPA requirements. This included significant new approaches to addressing emissions, as well extensive associated new monitoring, recordkeeping, and reporting requirements. To assess fully, they stated that stakeholders will need to review the record proffered by EPA in support of its Proposal governing different categories and types of equipment across EPA's source category – including the 390-page Technical Support Document (TSD) and associated materials<sup>66</sup> - and attempt to assess the feasibility of the approaches to both new and existing sources, which often present different and complex scientific and economic analyses.

Commenter (0192-AXPC) requested a minimum of 60 additional days for the public to provide comment on the proposal. The commenter stated that EPA would be justified in granting additional time for public comment both in keeping with precedent of significant air rules and to enhance the quality of public comments and thus support the durability of EPA's final product. The commenter stated that the breadth and depth of the issues in the proposal, as well as the estimations of significant cost implications, necessitate additional time to adequately consider and respond to EPA's ask for feedback on how aspects of the proposal enable final regulations, consistent with section 111 of the CAA and that “achieves the greatest possible reductions in methane and VOC emissions while remaining achievable, cost effective, and conducive to technological innovation.” They added that EPA's own summary of just the solicitation requests for comment in the proposal is 30 pages long. The commenter also noted that these are just a small excerpt of the more than a thousand pages that make the proposal package presently subject to a standard 60-day comment period spanning two of the most significant holiday periods of the year.

The commenter (0192-AXPC) stated that for previous NSPS, and other rules of this size and estimated impact, EPA has often granted extended timeframes to allow for more thorough public comment. For example, the commenter noted that the original NSPS OOOO proposal<sup>67</sup> comment period in 2011 was extended to 90 days. Similarly, they added that the later proposal in 2015 to revise the NSPS again and add NSPS OOOOa<sup>68</sup> also had a comment period that was extended to 90 days. In one of the few similar examples of the agency also proposing existing source guidelines under CAA 111(d), the Clean Power Plan (CPP)<sup>69</sup> first proposed in 2014 initially provided for 120 days of public comment, which was extended to nearly six months. The commenter noted that the CPP and EPA's current methane proposal had similar estimated cost

---

<sup>66</sup> Background Technical Support Document for the Proposed New Source Performance Standards (NSPS) and Emissions Guidelines (EG) (Oct. 2021), available at <https://www.regulations.gov/document/EPA-HQ-OAR-2021-0317-0166>.

<sup>67</sup> EPA-HQ-OAR-2010-0505-0002.

<sup>68</sup> EPA-HQ-OAR-2010-0505-4776.

<sup>69</sup> EPA-HQ-OAR-2013-0602-0001.

impacts of roughly \$15 billion and \$13 billion respectively. The methane rules estimate a 74 percent reduction in its targeted emission of methane over year 2005 versus the CPPs estimated 30 percent reduction in its target of carbon dioxide (CO<sub>2</sub>). Just as EPA correctly recognized the cost and emission impacts of the CPP rule warranted additional time for public comment, the commenter believed the same reasoning holds true for the comparable methane proposal. Indeed, the commenter noted that the proposed EG could cover orders of magnitude more sources than the CPP did, which justifies another reason why EPA should afford at least as much time to comment here as it did there.

Commenter (0192-AXPC) stated that further challenging the timeline for developing sufficient public comment is the possibly unprecedented absence of regulatory text accompanying the narrative description that EPA put forth as its Notice of Proposed Rulemaking (NPRM). Absent the ability to clearly see how envisioned requirements will be written into the Code of Federal Regulations, it is considerably difficult for stakeholders to determine with confidence the impacts of the proposal, any unintended consequences, or opportunities to improve the practicality of the rules. Without actual text, the commenter stated that the public is forced to consider the range of options based on assumptions which expands the scenarios that must be analyzed and, at a minimum, requires more time to consider than the standard 60-day timeframe provided.

Commenter (0192-AXPC) pointed out that there are other unprecedented approaches included in EPA's proposal that present a sizeable challenge for the affected industry to understand and the public to comment. For example, the commenter provided that there are multiple vintages of NSPS OOOO that each come with an applicability date for what constitutes "new sources" versus "existing sources" based on the date of proposed regulatory text. EPA's plan revises the earlier vintage NSPS OOOOa for "new and modified sources" under that rules' effective date, while creating a new NSPS OOOOb for "new and modified sources" and a new EG OOOOc for what will be considered an "existing source" under this rule. Thus, the commenter noted that EPA is proposing a dynamic matrix of compliance requirements and applicability dates where the exact same source would be considered both "new" under NSPS OOOOa within CAA 111(b) and at the same time "existing" under EG OOOOc within CAA 111(d). Without precedent for our industry sector or regulatory text to rely on, the commenter stated that the affected industry and the public will struggle to respond with meaningful comment for situations like this one described. For this situation, in addition to extended time for comment on the NPRM, the commenter supported the need for a supplemental rule that includes reopening the current proposed requirements, without being limited to only new potential areas of regulation, and with a comment period that should also be at least 90 days, if not longer, in alignment with other similar rulemakings.

In addition, commenter (0192-AXPC) stated that EPA in its published proposal and during its recent webinars, has emphasized a need for public comment to include a host of information on new and emerging technologies as well as topics not well studied such as emissions from low producing wells. The commenter provided that detailed analysis of the kind EPA is interested in takes considerable time and availability of third-party vendors and analysts.

Commenter (0825-Montana Department of Air Quality) requested that EPA extend the public comment period by at least another 60 days. The commenter noted that the provisions contained in EPA's proposal are complex and could have significant policy and economic implications for the State of Montana.

Commenters (0418-Railroad Commission of Texas, 0419-TCEQ) requested that EPA extend the November 2021 proposal comment period for 60 days or to the end of the yet to be determined 2022 supplemental proposal comment period to allow for states to provide meaningful feedback on the significant amount of information in the proposal, technical support documents, appendices, and regulatory impact analysis.

Commenter (0358-KDHE) requested that EPA extend the public comment period by at least 60 days and preferably through the end of the yet to be determined 2022 supplemental proposal comment period. The provisions contained in EPA's proposal are complex and have significant ramifications for our sources. The commenter's preliminary review indicated to them that the current proposal does not contain enough specific detail while the supplemental proposal may include more details on which the commenter can provide meaningful comment. According to the commenter, the current limited 60-day comment period does not provide the commenter an adequate opportunity to review the information for the Proposed Rule and provide meaningful and fully informed comments on the requested topics given the breadth and complexity of the issues raised.

Commenter (0200-ODEQ) requested a 60-day extension of the deadline to comment on the November 2021 proposed rules. The commenter provided that the proposal requested comment on a wide range of complex and technical issues. To provide time for meaningful review and response to this proposed rule, the commenter requested that the deadline to comment be extended.

Commenter (0200-ODEQ) stated that the challenges posed by the limited comment period are due not only to complexities inherent in the rule proposal, but also to the potential repercussions in the commenter's approach to permitting, compliance monitoring, regulatory enforcement, and emissions inventory reporting. In short, the commenter contended that the proposed rule, if adopted, would have extreme impacts on all aspects of the commenter's program because it will dramatically affect workload, allocation of resources, and budgeting. The commenter added that the reason the proposal poses such an extraordinary challenge is that the commenter's air program is grounded on the assumption that facilities with emission sources are best addressed when the owner or operator of the facility obtains an air quality permit. Currently, the commenter reported that their program covers approximately 13,000 facilities with air quality permits. The commenter noted that Proposed Oil and Gas Methane Rule has the possibility of increasing that number by an order of magnitude if permits are ultimately determined to be necessary for all designated facilities.

Commenter (0200-ODEQ) added that, notwithstanding the complexity of the rule and the substantive requests EPA is making for feedback, the number of facilities in Oklahoma that could be subject to applicable requirements is vast. They explained that states like Oklahoma with such a high potential for extreme changes to their programs need extra time to assess the

true nature of the potential impacts of the rule to the environment, state programs, and to industry. The commenter suggested that, without extension, the comment period does not allow states adequate time to analyze the voluminous background materials compiled in the docket, much less the proposed rule itself. According to the commenter, this lack of adequate review time is compounded by the fact the comment period overlaps with the winter holiday season.

Commenter (0291-AOGA) requested a 60-day extension of the January 14, 2022 deadline for submittal of comments on the performance standards and guidelines proposed for comment at 86 Fed. Reg. 63110 (November 15, 2021). The commenter stated that the proposed rules include sweeping changes to the performance standards and monitoring methods that oil and gas producers must deploy to control and monitor methane emissions in multiple operational sectors. The commenter stated that they had determined that several of the proposed emission limits assume the application of control strategies that may not be feasible in the harsh climatic conditions of the Alaska North Slope. Similarly, the commenter reported that some of the monitoring requirements in the rule may not be realistic or practical for North Slope operations. To the extent that the proposed rules present engineering challenges, the commenter sought to provide to EPA focused and documented comments, including suggestions for alternate compliance strategies that offer high control efficiencies with fewer feasibility constraints. To do so, they intended to bring to bear our members' vast engineering expertise. They asserted that a comment deadline of January 14, 2021, spanning the holiday season, does not provide enough time to marshal the resources necessary to fully develop meaningful comments that will inform EPA's judgment.

Commenter (0184-OK Alliance) requested EPA extend the public comment period for 60 additional days for the Proposed Rule. The commenter suggested that the current limited 60-day comment period did not provide our members an adequate opportunity to review the information and rationale for the Proposed Rule and provide meaningful and fully informed comments on the requested topics given the breadth and complexity of the issues raised. In addition, they noted that the upcoming holiday season limited their members availability to review and provide beneficial information to EPA. The commenter added that the requested extension of time will not cause hardship to EPA. On the contrary, the commenter contended that it would assist in EPA's decision-making process, and noted that there is ample precedent for EPA to provide an extension of time.

Commenters (0359-NDPC, 0802-Kraken) also requested additional time for stakeholders to thoughtfully consider and respond to EPA's Proposed Rule. The commenters acknowledged EPA's desire to advance the public process; however, given the extent of the proposal (*i.e.*, revisions to one existing rule, two new rules, and comment on a future rule), and the many equipment related and technical feasibility challenges that will need to be considered by multiple interrelated stakeholders (*e.g.*, companies within the oil and gas sector and equipment manufacturers), and its timing, they requested a minimum of 60 additional days for the public to be able to provide comment on the proposal.

Commenter (0214-U.S. Senate) urged EPA to extend the public comment period by 60-days for EPA's proposed rule to directly regulate methane emissions from the oil and gas sector. The commenter asserted that the complexity of EPA's proposal, coupled with the holiday season

falling within the comment period, provided ample justification for a 60-day extension of the comment period to March 15, 2022.

Commenter (0324-CenSARA) requested that EPA extend the public comment period by at least 60 days and preferably through the end of the yet to be determined 2022 supplemental proposal comment period. The commenter also requested that EPA notify the public of the extension as soon as possible and well in advance of the January 14 deadline so commenters may make full use of the additional time. The commenter supported their request by noting that the provisions contained in EPA's proposal are complex and have significant ramifications for our members. They added that their preliminary review indicates that the November 2021 proposal does not contain enough specific detail while the supplemental proposal may include more details on which we can provide meaningful comment.

Commenter (0324-CenSARA) added that in this proposal, EPA has requested comment and information on a lengthy list of issues that may require modeling or other analyses to be performed before these issues can be fully understood. The commenter noted that performing these analyses will necessitate a longer comment period than currently proposed. Air quality agencies need a minimum amount of time to review the extensive background materials, gather data, consider the impacts of the proposed changes, and prepare comments. To ensure that state and local agencies have an adequate opportunity to review and respond to the proposal, the commenter provided that additional time beyond the 60-day comment period is necessary.

Commenter (0408-U.S. Congress) urged EPA to grant an extension of time on the initial 60-day comment period for the Proposed Rule. The commenter noted that the implications of the Proposed Rule which applies to both new and existing sources, will expand across the entire oil and natural gas industry. The commenter reported that Wyoming ranks 8th in the nation in oil production and 9th in natural gas production, and as such, Wyoming constituents and the state will be directly affected by the Proposed Rule which represents a significant change to the current regulations. Specifically, the commenter noted that the proposals for existing sources will be difficult to review due to the immediate and broad impacts they will create. As such, they explained that it will require a substantial amount of time and effort to determine the mechanics associated with the Proposed Rule, as well as to gauge the overall impact to the industry. The commenter requested that EPA grant a 60-day extension of the comment period to allow for the time it will take to fully analyze and understand the implications of the proposed rule and to provide meaningful comments.

Commenter (0417-NDDEQ) requested an extension of the comment period for the November 2021 proposed rules to allow sufficient time to review and comment on the complex proposed new rules and guidance. The commenter requested an extension of the public comment period of a minimum of 60 days. The commenter reported that they are the primary state regulatory agency responsible for the protection of North Dakota air quality and for the implementation of the numerous federal and state environmental protection programs. The commenter stated that the proposed new regulations are technically complex. The current comment period does not provide sufficient time to adequately evaluate the impact the proposed new regulations will have on the state of North Dakota, including estimating financial impacts, reviewing for conflicts with

existing state regulation(s), and determining impacts if the state does not agree to implement the rules (*i.e.*, direct EPA implementation).

Commenter (0829-U.S. Congress) stated that the proposed rule includes sweeping changes to the performance standards and monitoring methods that energy producers will need to implement in order to control and monitor methane emissions from new and existing sources, while burdening producers with acute financial burdens. The commenter suggested that EPA has failed to provide a fully developed, well-defined, and easily understandable regulation that can be clearly understood by small businesses and individuals. The commenter asserted that it is necessary to extend the public comment period for an additional 60 days to give the American people more time to comment.

Commenter (0361-WDEQ) requested a 60-day extension of the deadline to submit comments on EPA's proposed rule. The commenter and the State of Wyoming have significant interests in the proposed rule. As of August 2021, the commenter reported that Wyoming ranked eighth nationally in oil production<sup>70</sup> and for the 2020 calendar year, Wyoming ranked ninth in marketed production of natural gas.<sup>71</sup> The commenter noted that they exercise substantial regulatory authority over the operations of Wyoming's extensive oil and gas industry. For example, the commenter stated that their program covers over 18,000 operating single well sites and compressor stations. The commenter stated that the proposed rule introduced a variety of complex technical requirements and revisions that could have significant policy and economic implications for the State of Wyoming, and the current public comment period does not provide nearly enough time for meaningful review and response. The commenter asserted that they needed more time to assess the impacts of the proposed rule and the potentially dramatic increase in permit applications and reviews it could impose on the commenter's staff. In the limited time the commenter has had to review the rule, they expressed that they already had significant concerns regarding the heavy burden the proposed rule would place upon the agency. Rather than reinforce the commenter's efficient, expedient permitting process, the commenter noted that it appears the proposed rule will exacerbate the resource challenges their agency already faces.

Commenter (0361-WDEQ) expressed that EPA is also seeking comment and information on an extensive additional list of subjects, essentially conflating the proposed rule with an ANPR. The commenter noted that the current public comment period does not provide sufficient time to review both the requirements within the proposed rule, and the additional areas that could inform decisions on a final rule or other potential related future rulemakings. For example, on November 1, 2021, EPA released a memo with a 27 page-long Excel table outlining 186 topics and issues for which EPA is soliciting comment and information. The commenter asserted that this places a tremendous burden on states like Wyoming in addition to the work necessary to review the proposed rule itself. The commenter noted that states can provide EPA with important and valuable feedback on these information solicitations, but only if they have significant time for review and develop meaningful feedback. Similarly, the commenter added that the 214-page RIA for the proposed rule is massive/technical and requires additional time for review.

---

<sup>70</sup> U.S. Energy Information Administration, <https://www.eia.gov/state/rankingsfillseries/46>.

<sup>71</sup> U.S. Energy Information Administration, <https://www.eia.gov/state/rankingsfillseries/47>.

Finally, the commenter (0361-WDEQ) suggested that the timing of the proposed rule is challenging. It is troublesome that the public comment period for a rule with such significant policy implications, and requiring such extensive review, falls almost entirely during the winter holiday season and the closing weeks of the fourth quarter of 2021. They asserted that there are already staff resource burdens involved with completing required end-of calendar-year reports and other work. Moreover, the commenter reported that staff availability is diminished as a result of the holiday season.

Commenter (0348-IPAA) stated that the proposal document characterized as a proposed rule did not contain proposed regulatory language. The commenter noted that EPA provided 60 days for comments. The commenter added that a 60-day comment period for a true "proposed rulemaking" of one "distinct" regulatory action with proposed regulatory text, is probably typical, with more complex regulatory action providing three to six months to provide comment.<sup>72</sup> The commenter provided that EPA even stated in the first sentence of the "proposed rule" that "this document comprises three distinct groups of actions under the Clean Air Act." According to the commenter, each of these three distinct regulator actions under the CAA warrant at least a separate, non-concurrent 60-day comment period. The notice and comment procedures of the APA are intended to provide "for the public to comment on notices of proposed rulemaking."<sup>73</sup> The APA was designed to provide stake holders adequate time to analyze and provide comment on each and every proposed rule. The fact a proposed regulatory action may be interrelated, and overlap does not justify a typical or ordinary 60-day comment period. To the contrary, according to the commenter, the interrelatedness and complexity of proposing three distinct regulatory actions simultaneously, justify at least a 120-day comment period.

Commenter (0348-IPAA) stated that, in addition to the concerns associated with the "procedural" shortcomings of a 60-day comment period, a 60 day comment period truncates EPA's and stakeholder's ability to adequately and appropriately evaluate a \$1,496,987 taxpayer funded study by the DOE that will provide the most comprehensive data set on emissions from low production wells created to date. Finally, after ten years of effort to have the government gather representative data on low production wells, the DOE is poised to publish its Quantification of Methane Emissions from Marginal (Small Producing) Oil and Gas Wells (DE-FE0031702) at the end of this month/early 2022 (the government contractors are to provide their final draft report on or about December 23, 2021 and DOE to release the report in early 2022). The commenter contended that it makes no sense to arbitrarily provide a 60-day comment period effectively precluding adequate review of the best data set yet to be created/released. The commenter stated that the additional 60 days will be meaningless in terms of when certain sources will be regulated and the amount of additional methane that will be released to the environment will be inconsequential. However, for the small businesses relying on low production wells for their livelihood, it could mean their very existence.

Commenter (0360-ADEC) stated that the proposed rule included sweeping changes to the performance standards and monitoring methods that oil and gas producers in Alaska will need to

---

<sup>72</sup> American Exploration & Production Counsel Request for Extension of Public Comments (November 23, 2021), EPA-HQ-OAR-2021-0317-0192.

<sup>73</sup> <https://www.epa.gov/laws-regulations/summary-administrative-procedure-act>.

institute to control and monitor methane emissions from non-traditional emission sources. The commenter stated that due to the wide-ranging and deeply technical scope of the proposal, including a period over an extended holiday season, the commenter believed it would be beneficial for all stakeholders if the comment period for the Proposed NSPS Emissions Guidelines for Control of GHG Emissions from the Oil and Natural Gas Sector be extended a minimum of 60 days beyond the original January 14, 2022, deadline.

Commenter (0936-U.S. Congress) stated that EPA's own press release established the extraordinary scope of this proposed rule, as it applied to "existing sources nationwide."<sup>74</sup> The commenter noted that the November 2021 proposal was unprecedented in its scope and breadth. The commenter suggested that EPA expand the comment period no less than 90 days beyond January 31, 2022.

Commenter (0334-WV Oil and Gas) urged EPA to extend the current 60-day public comment period by an additional 90 days. The commenter expressed that the Administration may have moved too quickly in its effort to release the proposed rule in advance of the Glasgow Climate Conference. As such, the commenter stated that the proposed timeframe does not allow adequate time to appropriately review hundreds of pages of new proposed regulations and accompanying documents. Given the importance of this review, the commenter believed it is prudent to allow more time to assess and comment.

Commenter (0580-KY Division of Air Quality) asked for an extension of time due to the extensive nature of this proposal and reduced staffing levels caused by the recent COVID-19 pandemic, the Division recommended a minimum extension of the comment period of at least ninety (90) days is requested.

Commenter (0946-MOGA) asserted that a condensed response time to facilitate an adequate response to EPA and Small Business Administration (SBA) was too short. The commenter reported that, during previous NSPS OOOO and NSPS OOOOa rulemaking events under the Obama and Trump administrations, the duration of response time was much longer and allowed a more in-depth analysis and comprehensive response.

Commenter (0946-MOGA) argued that more time is necessary to address the concerns and comments of the participating Small Entity Representatives (SERs) submitted on July 13, 2021, and following the initial Small Business Advocacy Review (SBAR) panel discussion. The commenter reported that the follow-up SBAR panel needed 2 separate meetings (July 29, 2021 & August 3, 2021) to discuss SER comments. The commenter believed that time constraints limited EPA's response to SER comments and required skipping through material. The commenter expressed that they would have preferred that adequate time would have been provided to address the various comments and concerns and to individually address each source category as it pertains to proposed changes.

Response I-23-54: After consideration of comments received on the November 2021 proposal from industry and states to extend the comment period due to the lengthy and complex nature of

---

<sup>74</sup> U.S. EPA Press Office, <http://www.epa.gov/newsreleases/us-sharply-cut-methane-pollution-threatens-climate-and-public-health>, January 31, 2022.

the action, EPA extended the public comment period from January 14, 2022, to January 31, 2022. This extension was provided to allow additional time requested by the public to review the proposal and gather and provide information to the Agency.<sup>75</sup>

### ***23.10.2 Follow-Up Requests for Additional Extension of the Comment Period for the 2021 November Proposal/More Time Being Allowed Under the Supplemental Proposal***

Comment: Several commenters (0383-U.S. SBA, 0585-Kentucky Oil & Gas Association, 0598-Countrymark Energy Resources, 0758-Ovintiv Inc, 0778-U.S. Congress, 0788-U.S. Congress, 0810-Petroleum Alliance-OK, 0923-Lambda, 1422-U.S. Congress) requested that EPA extend the comment period for the November 2021 proposed rule beyond the 15-day extension period that EPA provided. Examples of some of these requests are presented in the following paragraphs.

Commenter (0814-IPAA *et al.*) stated that, at the request of the Producer Associations (the commenter) and other stake holders, EPA provided roughly an additional 14 days for comments. While the commenter appreciates the additional time, the commenter asserted that the comment period is still inadequate. The commenter argued that there is no statutory deadline forcing a truncated comment period. Additionally, at the commenter pointed out in their request for additional time to comment, the DOE is poised to produce a study on emissions from low production wells that needs to be reviewed and considered by EPA as it intends to withdrawal certain exemptions for low production wells.<sup>76</sup> The commenter therefore expressed that that they believe the truncated comment period, when EPA is aware of the pending DOE study, was arbitrary and capricious.

Commenter (0585-Kentucky Oil & Gas Association) requested that the original comment period be extended by 45 to 60 days. They reported that EPA granted an extension from January 14, 2022 to January 31, 2022. While they appreciated the additional time, they noted that it is not the 45 to 60 days that was requested.

Commenters (0810-Petroleum Alliance-OK) suggested that the 60-day comment period along with the 15-day comment extension is unreasonable for such a complex rulemaking. The commenter noted that it does not allow our members adequate opportunity to review the information and rationale for the Proposed Rule, and to provide meaningful and fully informed comments on the requested topics given the breadth of the issues raised.

Commenter (0778-U.S. Congress) asked EPA to withdraw this proposed rule pending further environmental and economic study. Barring that, the commenter requested an extension of the comment period beyond the 15 days that EPA extended the comment period, of not less than 60 days, to give the public, regulated community, and other stakeholders the time necessary to analyze the proposal and fully participate in the rulemaking process. The commenter suggested that, as the country continues to recover from the COVID-19 pandemic the U.S. needed to be

---

<sup>75</sup> 86 FR 71603.

<sup>76</sup> Quantification of Methane Emissions from Marginal (Low Production Rate) Oil and Natural Gas Wells - Draft Final Project Report, US DOE NETL Award Number DE-FE0031702 (Dec. 31, 2021) - "Attachment C".

working to strengthen American energy production, not burdening the industry with unnecessary and costly regulation.

Commenter (0923-Lambda) asserted that the short review period of 77 days (including two major holidays) did not allow sufficient time for companies to read, evaluate the potential impacts and provide adequate comments regarding the feasibility of the proposed rule. Applicability of new regulations to assets is always challenging but is even more so with vague references to what might be regulated in the future with regards to NSPS OOOOa, NSPS OOOOb, EG OOOOc. The commenter recommended that EPA provide a clear and more concise set of proposed rules and revise the nearly 1000 pages of text that were introduced. Again, the commenter noted that the 577-page preamble and 390-page technical document did not provide specific text or proposed regulations for consideration, leaving companies such as the commenter guessing on what may be required with a lot of gray areas in potential impacts to our small business. The commenter added that providing the commenter's staff the time to read and interpret this depth of information in such a short amount of time is also a hurdle for a small business such as the commenter.

Commenter (0758-Ovintiv) requested additional time to review and comment on what they stated was a complicated rulemaking. The commenter expressed that the 15-day extension provided by EPA is insufficient to provide the public with an adequate opportunity to participate as required under the APA. Moreover, the commenter added that since no regulatory text has been provided in this initial proposal, the commenter's assessment of the proposed standards will likely change once the requirements are clarified in EPA's supplemental proposal.

Similarly, commenter (0788-U.S. Congress) welcomed EPA's decision to extend the comment period but expressed that the extra 16 days provided is not sufficient for relevant stakeholders to provide the substantive comments necessary for a thorough rulemaking process. On top of the inadequate amount of time provided for public comment, the commenter added that the 154-page proposed rule is devoid of rule text and the kind of specificity that the public and regulated community are due.

Commenter (0598-Countrymark Energy Resources) pointed out that EPA granted a comment period extension from January 14, 2022, to January 31, 2022. While the commenter expressed appreciation for the additional time, they noted that it is not the full 60 days that was requested. From the quality of the comments presented, the commenter stated that the proposal was read, and comments were developed for EPA's review. The commenter complained that completing this work in the given time period was a substantial burden on a small team during the end of year holidays and beginning of the year start-up activities.

Commenter (0383-U.S. SBA) believed that the comment period was unreasonably short for the scale and scope of the proposed rule. The commenter suggested that EPA extend the comment period by 45 days (noting that an extension of the comment period by only 17 days was insufficient).

Commenter (0383-U.S. SBA) stated that small businesses and trade associations that represent their interests have expressed their concern that the complexity of the EPA proposal, the open-

ended nature of some of the requests for comments, ambiguities in the proposal due to a lack of regulatory text, and the large number of previously unregulated sources that might be subject to the rule have made it extremely difficult to fully understand and comment on the rule. The commenter provided that small businesses want to contribute to EPA's understanding of the oil and natural gas production industry, correct potential errors in EPA's calculations, and project the unintended negative consequences of this proposal, to industry participants, to their suppliers and customers, and to the environment. However, the commenter stated that this was not possible given the short time frame.

Commenter (0383-U.S. SBA) reminded EPA that there have already been requests for an extension of the comment period from trade associations representing a range of oil and natural gas producers, large and small, and the two major associations representing state clean air regulators. The commenter added that small businesses face the additional challenge that their operations are generally very lean, with regulatory compliance staff already overburdened. The commenter provided that the same staff is being asked to also work on this complicated and voluminous proposal; at the same time the comment period both overlaps with the major holiday season and with a range of end-of-the-year compliance activities. The commenter contends that EPA's extension of the comment period by 17 days ameliorates some of this impact but does not fully address the difficulty that small businesses are having understanding this complex rulemaking.

The commenter (0383-U.S. SBA) suggested that further extension of the public comment period would allow for small businesses to incorporate the results of the highly anticipated study sponsored by the DOE, "Quantification of Methane Emissions from Marginal (Small Producing) Oil and Gas Wells." During the Small Business Regulatory Enforcement Fairness Act (SBREFA) panel, SERs strongly recommended that EPA delay the proposed rule until EPA could incorporate results of the study into its findings. The U.S. SBA Office of Advocacy (Advocacy) understands that this study should be released by the end of this calendar year. The commenter asserted that a further extension would give small businesses an opportunity to relate the results to their operations.

The commenter (0383-U.S. SBA) expressed that the prospect of a supplemental proposed rule and subsequent comment period are not a substitute for a further extension of this comment period. The commenter stated that EPA has put forward this proposal as is, with the extensive request for comments and complex technical supporting documents. They asserted that EPA should allow for a full consideration of these issues as they are now presented and respond to this public input in the supplemental. They argued that it does not serve the public interest for EPA to work on a supplemental proposal with incomplete information. Similarly, they added that EPA should not rely on future comment periods to justify a decision to not further extend this comment period; any supplemental proposal that does not benefit from the full and considered input of affected small entities is bound to be flawed.

Commenter (1422-U.S. Congress) welcomed EPA's decision to extend the comment period, but the commenter contended that the extra 16 days provided is not sufficient for relevant stakeholders to provide the substantive comments necessary for a thorough rulemaking process. On top of the inadequate amount of time provided for public comment, the commenter stated that

the proposed rule is devoid of rule text and the kind of specificity that the public and regulated community are due.

The commenter (1422-U.S. Congress) noted the environmental and economic implications of this rule and requested that EPA withdraw the proposed rule pending further studies. Barring that, the commenter called for a further extension of the comment period, of not less than 60 days, to give the public, regulated community, and other stakeholders the time necessary to analyze the proposal and fully participate in the rulemaking process. The commenter stated that, as the country continued to recover from the COVID-19 pandemic the U.S. needed to be working to strengthen American energy production, not burdening the industry with unnecessary and costly regulation.

Response I-23-55: As noted in Response I-23-54 of this Chapter, after consideration of comments received on the November 2021 proposal from industry and states to extend the comment period due to the lengthy and complex nature of the action, EPA extended the public comment period from January 14, 2022, to January 31, 2022. (86 FR 71603, December 17, 2021.)

The EPA also notes that while many commenters wanted additional time to provide comment on the November 2021 Proposal beyond the extra 15 days provided, the public also had the opportunity to provide comments on the December 2022 Supplemental Proposal and had access to pre-publication versions of the preambles for both the November 2021 Proposal and December 2022 Supplemental Proposal on EPA's website.

While the prospect of a supplemental proposed rule and subsequent comment period may not have been a substitute for an extension of this comment period beyond the 15 days provided on the November 2021 Proposal, the EPA is appreciative of the significant number of thoughtful and constructive comments provided by the public for EPA to review and consider in the development of the December 2022 Supplemental Proposal.

As for the suggestion that the EPA withdraw the rule, the EPA has not granted the commenter's request. While COVID-19 is still present, the pandemic has ended. See also sections XVI.C (What are the cost impacts?) and D (What are the economic impacts?) of the final rule preamble where the EPA presents a summary of the results of the cost and economic impact and distributional analyses conducted.

### ***23.10.3 Unable to Provide Comprehensive Comments on the November 2021 Proposal Because of Insufficient Time***

Comment: Commenter (0729-EWTC) submits general examples of technologies that can meet the proposed goals; however, they contend that the short initial 60-day comment period, and the two-week extension, have limited the detailed analysis crucial to a regulation of this magnitude. The commenter states that EPA has announced plans to issue a supplemental proposal containing the regulatory text in 2022. The commenter respectfully requests that EPA offer a full and extended public comment period for the supplemental rule to ensure our companies can deliver a

comprehensive analysis of the proposed regulations and the potential implications for our industry.

Commenter (0911-NDPC) acknowledges EPA's desire to advance the public process. However, the commenter states that given the extent of the proposal (*i.e.*, revisions to one existing rule, two new rules, and comment on a future rule) and the lack of detailed rule text, the comments are limited in scope and detail due to the condensed public comment period and the lack of rule text to review. The commenter asks that future rulemakings not be bundled with multiple proposed regulatory actions to give the public and regulated industry the time to participate efficiently and effectively. Silence on any part of this proposal should not be interpreted as our agreement or support. According to the commenter, time constraints have impacted our ability to respond to every piece of this proposal.

Commenter (0742-ADEC) feels that the scope and expanse of this rulemaking proposal, including the widely varying and disparate topics require more than the short initial 60-day comment period, including this meager extension. Oil and gas producers within Alaska are extremely burdened to attempt a highly technical response to this proposal under the current deadline. The commenter hopes that in the next phase of this rulemaking process, EPA will provide adequate time for review so that additional supporting data can be provided for consideration.

Commenter (0810-Petroleum Alliance-OK) requested EPA's forthcoming proposed supplemental rule provide at least a 120-day comment period.

With the short period of time, commenter (0585-Kentucky Oil & Gas Association) reported that they were not able to review all the documents provided by EPA and develop more data driven comments. With the workload that was before them, the commenter added that they were not able to develop the data driven responses to EPA as if the 60-day extension were granted. The commenter asserted that this lack of time to respond with quality feedback is detrimental to their industry. The commenter expresses that several times in prior years, EPA has informed industry that a position was taken on a proposed regulation because of the lack of information provided by industry. The commenter noted that they are submitting this feedback to EPA that the quality of feedback is not available due to the timeline that was granted by EPA.

Response I-23-56: See Response I-23-55 of this Chapter.

#### ***23.10.4 Extension of Comment Period to Review Information Collection Request***

Comment: Commenter (0416-GPA) requested that the OMB provide a minimum of a 30-day extension of the comment period on its review of the ICR in the Proposed Rule. The commenter noted that the ICR component includes detailed reporting and recordkeeping and associated cost information and assumptions.<sup>77</sup> According to the commenter, EPA must allow stakeholders an adequate opportunity to provide comment, and this includes sufficient time to consider the expansive Proposal and related ICR demands.

---

<sup>77</sup> E.g., ICR at 5-16; EPA-HQ-OAR-2021-0317-0144\_attachment\_1.

Response I-23-57: The comment period for review of the Information Collection Requests (ICRs) developed in support of the November 2021 Proposal was not extended.

### **23.11 Other Recommendations for Reducing Impacts from Methane Emissions**

Comment: Commenter (0912-Shell) states that the regulatory framework authorized under the CAA provides EPA and states with considerable latitude to establish credible and reliable protocols for determining compliance with methane intensity standards. One such option is Oil and Gas Methane Partnership 2.0 (OGMP 2.0), which establishes a greatly improved set of measurement, reporting and verification (MRV) protocols that have been under development since 2019 by the United Nations Environment Program (UNEP) and the Climate and Clean Air Coalition (CCAC) in partnership with the European Union Commission, the Environmental Defense Fund, and major industry players. The MRV protocols focus on establishing best practices for quantifying methane emissions from all segments of the oil and gas sector where material quantities of methane emissions can be released. OGMP 2.0 effectively increases the accuracy and granularity of methane emission monitoring, reporting, and verification for oil and gas assets.

In the recently proposed methane legislation, the European Union uses the OGMP 2.0 as the basis for its mandatory MRV protocols under methane regulatory program that it now has under development. The commenter (0912-Shell) believes that OGMP 2.0 sets a necessary new standard for credible and transparent methane emissions reporting, while recognizing the outstanding technological, commercial, and cost challenges to improved emissions reporting. In the current legislative proposal, these MRV protocols would likely also apply to all imports of natural gas into the European Union, including LNG and pipeline natural gas imported from other countries. Adoption of the OGMP2.0 protocols by natural gas/LNG exporters into the European Union and natural gas producers in the country of origin, satisfies MRV data transparency requirements in the European Union methane legislation.

For these reasons, the commenter (0912-Shell) urges EPA to develop robust MRV protocols for demonstrating compliance with the methane emissions standards and determining methane emission intensity across the natural gas value chain. In so doing, EPA should work to ensure that MRV protocols being developed for the U.S. regulatory program are fully consistent and generally equivalent to the version of OGMP 2.0 now being developed for use in the European Union. This equivalence will provide a simple mechanism for demonstrating that LNG from the U.S. meets the performance standards that could be established in the future for importing LNG into the European Union.

The commenter (0912-Shell) states that once control levels have been set for a subcategory based on BSER would EPA establish statewide targets that achieve an equivalent level of methane reductions based on the application of emission controls for each subcategory. One important advantage of setting statewide intensity targets is that it accounts for the great diversity of sources and operations within the oil and gas source category. Instead of just focusing on only certain specific types of sources for achieving the mandated methane reductions, the regulations would provide the most cost-effective way to achieve methane reductions by setting methane

emission intensity targets that would apply at the asset level for each company. This approach will ensure all methane sources are managed and allow companies to focus its control efforts on those sources that are most impactful and cost-effective to reduce methane emissions.

Similarly, commenter (0912-Shell) points out that there are advantages of setting one statewide intensity standard for both new and existing oil and gas sources. The combination of new and existing sources into one intensity standard provides companies with important flexibility to meet their existing source control requirements by installing new innovative control technologies and measures that can cost-effectively exceed the new source control levels mandated by NSPS OOOOa. Those surplus reductions for a company could then be used for meeting its existing source control obligations that would be established through the implementation of the state emission guidelines. According to the commenter, this approach also provides important flexibility for states, whose environmental regulatory agencies are most familiar with the unique characteristics of regional oil and gas production and the varying characteristics of producing basins.

In addition, the establishment of an intensity standard could greatly simplify the process for demonstrating the regulatory equivalence of LNG imported from the U.S. into the European Union. Commenter (0912-Shell) believes the best way to position U.S. gas exports to the European Union is based on regulatory equivalence between the trading blocks. The commenter states that this eliminates the formidable technical challenges with tracing gas molecules from individual producers along complex gas delivery chains. The commenter suggests that such a framework for demonstrating such equivalence could help to preserve U.S. competitiveness and export opportunity.

Response I-23-58: The EPA appreciates the commenter's recommendation. However, creating the recommended intensity standards and measurement, reporting and verification (MRV) protocols similar to what is required under OGMP 2.0 is not supported by CAA sections 111(b) and 111(d), which is the basis for the NSPS OOOOb standards and EG OOOOc presumptive standards. See sections IV (Statutory Background and Regulatory History) and V (Legal Basis for the Final Rule Scope) of the final rule preamble for the basis and scope of the final NSPS OOOOb and EG OOOOc rules.

Comment: Commenter (0807-BP) supports EPA's use of CAA section 111(d) to regulate methane emissions from existing oil and natural gas sources. The commenter encourages EPA to design the 111(d) rule to promote flexibility and efficiency in compliance and drive technology innovation. The commenter suggests that one way to provide this flexibility is through a methane intensity standard. The commenter recommends that EPA consider soliciting input on the potential for incorporating methane intensity standards into its EG OOOOc rules. The commenter notes that EPA could solicit this feedback either in the context of the forthcoming supplemental regulatory proposal, or through convening a technical workshop or other forum to facilitate a dialog among experts from all sectors.

On September 20, 2021, commenter (0807-BP) submitted supplemental comments in advance of EPA issuing this proposal, which encouraged EPA to consider quantifying the "degree of emission limitation achievable" in the form of emission performance rates, and for EPA to

consider using a “methane intensity” standard.<sup>78</sup> By “methane intensity”, the commenter explains that they are referring to the volume of methane emissions from a source’s operated upstream oil and gas assets as a percentage of the total gas that goes to market from those operators.

Commenter (0807-BP) points out that states are beginning to use a methane intensity approach. For example, the commenter reports that the Colorado Air Quality Control Commission (“AQCC”) recently established a GHG intensity target for the upstream segment. 5 Colo. Code Regs. § 1001-26(IV) (2021). The AQCC defines “greenhouse gas intensity” as CO<sub>2</sub> equivalent emissions from pre-production and production as a percentage of hydrocarbon liquids and gas production. The regulation sets greenhouse gas intensity targets starting in 2025.

In order to implement a methane intensity standard, the commenter (0807-BP) recommends EPA consider gathering additional information, identifying different standards for different segments, and evaluating the impact of using methane emissions data derived from measurement, as opposed to emissions factors. EPA could solicit input or form a working group to determine how methane intensity standards may be used and best defined, specifically with regard to 111(d) emissions guidelines. The commenter suggests that EPA could identify different methane emission performance rates – with different methane intensity standards – tailored to various segments of the oil and gas industry. Additionally, EPA could evaluate how transitioning to actual methane emissions data, as opposed to data calculations using emissions factors, may change or increase the reported methane emissions from certain sources and how to factor that into what baseline year to use. In any event, the commenter recommends that EPA consider and seek stakeholder input on how best to take advantage of methane intensity standards as a regulatory tool that could be incorporated into the EGs, whether in the context of its supplemental proposal in this rulemaking or through other complementary mechanisms.

Response I-23-59: See Response I-23-58 of this Chapter.

Comment: Commenter (0602-Business Roundtable) believes the U.S. should adopt a more comprehensive, coordinated and market-based approach to reducing emissions. While a market-based climate strategy should apply broadly across the economy, the commenter expresses that no one policy or approach can fully address climate change across such a diverse economy and such diverse sources of GHG emissions. In unique circumstances, the commenter provides that nonduplicative, tailored policies may be more effective or administratively feasible. Targeted, smart methane regulation would help meaningfully address climate change and could present one such circumstance. Moreover, the commenter reports that smart methane regulation is immediately actionable, given the high cost-effectiveness of many technologies and methods for preventing, monitoring, and mitigating emissions.

Response I-23-60: The EPA appreciates the commenter’s recommendation. However, adopting a market-based approach to reducing emissions is not supported by CAA sections 111(b) and 111(d), which is the basis for the NSPS OOOOb standards and EG OOOOc presumptive standards. See sections IV (Statutory Background and Regulatory History) and V (Legal Basis

---

<sup>78</sup> See Letter from Downey Magallanes, *supra* note 8, at 4.

for the Final Rule Scope) of the final rule preamble for the basis and scope of the final NSPS OOOOb and EG OOOOc rules.

## **23.12 Clarification of What Constitutes a Reconstruction**

Comment: Commenter (0742-ADEC) requests clarification on the definition of “reconstruction”. The commenter provides that “reconstruction” is usually defined as “[t]he fixed capital cost of the new components exceeds 50 percent of the fixed capital cost that would be required to construct a comparable new source”. The commenter adds that the term “reconstruction” is nowhere used to define changes or repairs to many of the affected facility emissions units in the proposal. A well that has been fractured becomes a modified well, and refracturing the well doesn’t change its status as a modified affected facility. The commenter inquires: (1) what constitutes a “reconstructed” well or well-site; and (2) what constitutes a “reconstructed” natural-gas operated diaphragm pump, where the low fixed capital cost would support replacement as the primary option to reconstruction. Likewise, the commenter adds that tracking the cost of repair to justify whether an individual piece of equipment was “reconstructed” is beyond the emissions value gained or economic sense realized for many of these extremely low-cost portable units. The commenter notes that the same argument can be advanced as regards a single natural gas operated pneumatic controller, as well as many other of these small emissions units that become affected facilities. The commenter explains that the low fixed-capital cost of many of these individual emissions units supports replacing the on-site unit with a pool or stock replacement that can be repaired off-line as time permits the owner or operator. Tracking pools of small, portable equipment that may change status from a non-affected facility to an affected facility simply through field repair and upgrade off-site has no emissions-reduction value and simply exposes an owner/operator to compliance risk. According to the commenter, it will be essentially impossible to monitor and track the compliance status of huge numbers of portable units that may get moved from an exploratory well-site to another without informing compliance personnel.

Response I-23-61: The EPA considered this and other comments received related to what constitutes a “reconstruction” when developing the proposed and final regulatory text for the NSPS OOOOb and EG OOOOc included under the December 2022 Supplemental Proposal.

Under 40 CFR 60.15, “Reconstruction” means the replacement of components of an existing facility to such an extent that:

- (1) The fixed capital cost of the new components exceeds 50 percent of the fixed capital cost that would be required to construct a comparable entirely new facility, and
- (2) It is technologically and economically feasible to meet the applicable standards set forth in this part.

For the final rule, the EPA also allows owners and operators of natural gas-driven process controllers and pumps to choose an alternative definition of what constitutes a “reconstruction” which would allow reconstruction to be defined based on the number of natural gas-driven process controllers or pumps in the affected facility. Owners and operators may choose which

definition of reconstruction to apply and whether to comply; they do not need to apply both. If owners and operators choose to comply with the latter option, they may demonstrate compliance with 40 CFR 60.15(b)(1) by showing that more than 50 percent of the number of natural gas-driven process controllers in the affected facility is replaced. That is, if an owner or operator meets the definition of reconstruction through the “number of controllers” or “number of pumps”, they will have shown that the “fixed capital cost of the new components exceeds 50 percent of the fixed capital cost that would be required to construct a comparable entirely new facility,” as required in 40 CFR 60.15(b)(1).

Additionally, the final rule defines “reconstruction” of a tank battery when any of the following occurs and result in the potential for VOC or methane emissions to meet or exceed either of the thresholds specified in the rule. (1) At least half of the storage vessels are replaced in the existing tank battery that consists of more than one storage vessel; or (2) the provisions of 40 CFR 60.15 are met for the existing tank battery that consists of a single storage vessel.

### **23.13 Other General Requests for Clarification/Requests/Comments**

Comment: Commenter (0946-MOGA) recommends EPA provide clear, well-defined, and easily understood proposed regulations that can be understood by small businesses. This would include clear definitions of major equipment, calculation methodologies with samples, well-defined source definitions aligned with the 1979 CAA and clarification of exemptions.

Response I-23-62: The EPA considered this and other comments received when developing the proposed regulatory text for the NSPS OOOOb and EG OOOOc included under the December 2022 Supplemental Proposal. Based on comments received on the December 2022 Supplemental Proposal rule language and requirements, the EPA made further changes to the rule to improve clarity. Please also see section X of the final rule preamble for a summary of EPA’s final NSPS OOOOb standards and EG OOOOc presumptive standards.

Comment: Commenter (0539-AOGCC) states that having different requirements for the North Slope and Cook Inlet could make compliance by the operators that work in both regions more complicated.

Response I-23-63: Where the EPA has finalized different requirements for the North Slope and the Cook Inlet, it is because commenters have provided information to support differences in technologies and conditions on the Alaska North Slope. For example, under the NSPS OOOOb and EG OOOOc, owners or operators of wet seal centrifugal compressors on the Alaska North Slope that are equipped with a seal oil recovery system (*i.e.*, centrifugal compressors equipped with sour seal oil separator and capture system, such as a seal oil gas separation system that separates gas from the sour seal oil exiting the compressor seal assembly, upstream from the degassing drum) have the option to comply with the rule by meeting a performance-based volumetric flow rate at or below 9 scfm (in operating or standby pressurized mode) per seal. In lieu of complying with this alternative compliance option, an owner or operator can comply by meeting the requirements for other compressors with wet seals (including those located on the Cook Inlet). Please also see section XI.G.6 (Wet seal compressors equipped with a seal oil gas separation system utilized on the Alaska North Slope (ANS)) of the final rule preamble.

## 23.14 Enforcement

Comment: Commenter (0592-Citizens United for Responsible Energy) states that enforcement of the rules is the only way to assure that reductions to emissions actually occur. In this case, the commenter suggests that producers must have an expectation that they will be held accountable for loss of resources by excess emissions. According to the commenter, fines will not be enough, and shutdowns may be necessary in order to protect our air and planet. The commenter recommends that EPA's Self-Audit program should be stringently examined and re-assessed in this regard.

Commenter (0941-350 Silicon Valley) further suggests that penalties, proportional to the environmental damage inflicted by failure to comply with performance standards rules, must be a tool available to EPA. The commenter contends that no company should benefit economically by not complying with methane emissions standards. Failure to replace damaged components, failure to inspect equipment and make necessary repairs, failure to use flare stacks as intended, failure to demonstrate that flaring was necessary for emergency purposes and failure to report venting and flaring episodes, especially routine flaring, are some examples of incidents that should be subject to penalties once new rules and target dates become enforceable. The commenter adds that the supplemental methane emissions rule includes descriptions of penalties to be imposed on companies that fail to implement required performance standards.

Response I-23-64: Violations of the final rules may be subject to civil enforcement under Section 113 of the Clean Air Act, 42 U.S.C. § 7413. Under Section 113, EPA may pursue administrative or civil enforcement actions to restrain violations, order compliance, and assess or seek the assessment of penalties consistent with the statutory penalty limits, as modified by the Federal Civil Penalties Inflation Adjustment Act of 1990, 28 U.S.C. § 2461, the Debt Collection Improvement Act of 1996, 31 U.S.C. § 3701, and most recently by the Federal Civil Penalties Inflation Adjustment Act Improvements Act of 2015, Pub. L. No. 114-74 § 701, 129 Stat. 584, 599-601. In determining the amount of penalty in an administrative or judicial civil enforcement matter, EPA or a court may consider factors set forth in Clean Air Act ~~ion~~ section 113(e), 42 U.S.C. § 7413(e), including the economic benefit of noncompliance.

Knowing violations of the final rules may also be subject to criminal enforcement under Section 113(c) of the Clean Air Act, 42 U.S.C. § 7413(c). In addition, regarding reporting and monitoring required by the rule, knowing false statements, material omissions, failure to report, and/or tampering with monitoring devices or methods can also be prosecuted under Section 113(c). Upon conviction, a criminal violation may result in a fine pursuant to title 18 or imprisonment, or both.

EPA has not proposed and is not finalizing separate civil or criminal enforcement or penalty provisions applicable to the methane emission standards. EPA's Audit Policy is beyond the scope of this rulemaking.

## 23.15 Administrative Record

Comment: Commenter (0761-Exelon) suggests that all contents of regulatory Docket ID No. EPA-HQ-OAR-2021-0295 should be part of the record for Docket ID No. EPA-HQ-OAR-2021-0317. The commenter states that EPA opened a docket for stakeholders to submit early input on issues informing the Proposal, and that docket was assigned Docket ID No. EPA-HQ-OAR-2021-0295. According to the Proposal, the contents of Docket ID No. EPA-HQ-OAR-2021-0295 are not automatically part of the Proposal rulemaking record, and in order for information submitted to that docket to be considered in the Proposal rulemaking, it must be resubmitted to Docket ID No. EPA-HQ-OAR-2021-0317. According to the commenter, that approach risks excluding information and material that informed EPA's Proposal from the administrative record. Instead, the commenter requests that all contents of Docket ID No. EPA-HQ-OAR-2021-0295 be automatically incorporated into and considered part of the rulemaking docket for this Proposal, Docket ID No. EPA-HQ-OAR-2021-0317.

Response I-22-65: See Response I-23-22 of this Chapter.

## 23.16 One-Size Fits All Approach

Comment: Commenter (0740-Utah Petroleum Association) supports the appropriate regulation of methane and VOC emissions. Yet Utah's oil and gas operations have several unique aspects that EPA must consider in proposing rule language and finalizing the new source performance standards (NSPS) OOOOb and EG OOOOc regulations. Most notably, they report that their operations on Tribal lands and within an ozone nonattainment area, their unique waxy crude oils, their remote operations that do not lend themselves easily or within reasonable cost to electrification, their labor shortage more acute than elsewhere in the country, and their small operators all require consideration in the final rulemaking. These considerations will help to ensure promulgation of a practical and cost-effective rule for all and that will not drive small operators out of business.

Response I-23-66: The EPA, when developing the final NSPS OOOOb and EG OOOOc requirements, considered these and other comments that expressed concern that the uniqueness of their oil and natural gas operations be considered. The revised Initial Regulatory Flexibility Analysis (IRFA) and Final Regulatory Flexibility Analysis (FRFA) provides an extensive discussion of regulatory flexibility alternatives and notes key areas where options were chosen to reduce regulatory burden on businesses. In addition to providing several compliance alternatives for affected facilities under NSPS OOOOb and designated facilities under EG OOOOc, the EPA has also considered issues such as lingering supply chain issues and increased demand for equipment and services when establishing compliance, and repair and delay of repair provisions included in the final NSPS OOOOb and EG OOOOc rules to account for parts not being available.<sup>79</sup>

Additionally, both NSPS OOOOb and EG OOOOc include provisions that could be pursued for an alternative but equivalent compliance option under NSPS OOOOb or equivalent or less

---

<sup>79</sup> See sections XI.A.1.e (Delay of repair due to parts unavailability) of the final rule preamble for example.

stringent requirements considering remaining useful life and other factors (RULOF) under EG OOOOc under a state plan. 40 CFR 60.5399b (What are the alternative means of emission limitations for GHG and VOC emissions from well completions, liquids unloading operations, centrifugal compressors, reciprocating compressors, fugitive emissions components, and process unit equipment affected facilities; and what are the alternative fugitive emissions standards based on state, local, and tribal programs?) of NSPS OOOOb provides procedures for the submittal and approval of alternative means of emission limitation for GHG and VOC based on work practices for well completions, liquids unloading operations, centrifugal compressors, reciprocating compressors, fugitive emissions components and process unit equipment affected facilities. See section XIII.C (Establishing Standards of Performance in State Plans) of the final rule preamble for state plan requirements and sub-section XIII.C.3 (Remaining useful life and other factors (RULOF)) of the final rule preamble for a summary of the RULOF provisions that have been finalized in the subpart Ba rulemaking (codified at 40 CFR part 60, subpart Ba).

Comment: Commenter (0732-Panhandle Producers and Royalty Owners Association/Remnant Energy) supports the presumed objective of these rules, but it would be their recommendation to set objectives and allow the industry to innovate to meet these objectives of emission reduction. Production methods vary greatly as required by various reservoirs. A natural gas stream that is high in water vapor has different issues than a natural gas liquid (NGL) rich gas stream. One size fits all solutions will prove counterproductive and defeat the improvements that all desire.

Response I-23-67: These final actions stem from the EPA's authority and obligation under CAA section 111 to directly regulate categories of new stationary sources that cause or contribute to endangerment from air pollution and to promulgate EG for states to follow in regulating existing sources (designated facilities) in the source category. See section II (Executive Summary), subsections A (Summary of the Major Provisions of this Regulatory Action) and B (Purpose of the Regulatory Actions), and section IV (Statutory Background and History) of the final rule preamble for support for the development of the NSPS OOOOb standards and EG OOOOc presumptive standards.

See also Response I-23-66 of this Chapter.

Comment: Commenter (0793-PBPA) states that in both the NSPS and the EG, EPA has applied a one-size fits all approach to the regulation of an incredibly diverse industry. The commenter asserts that the regulations applied in the Marcellus Shale may not be appropriate for the Haynesville Shale and what works in the Bakken may not work in the Permian Basin. There are even intra-basin differences. For example, the commenter explains that within the upstream segment of the Permian Basin, the Midland Basin varies significantly from the Eastern Shelf, which varies significantly from the Central Basin Platform. Sub-basin variations are also material. The Midland Basin Trend Area fields are quite different than Grayburg fields.

Commenter (0793-PBPA) points out that similarly, the emissions for a site producing 10,000 barrels a day are not the same as a stripper well site producing 10 barrels a day; and yet EPA's one-size-fits-all approach would effectively treat them the same. In fact, in some instances, the required emission controls for low producing sources actually generate more emissions than the regulated facility itself. The proposal also does not recognize that many upstream and midstream

sources are spread out over a wide geographic area, located in remote regions, and do not have dedicated onsite staff.

Commenter (0793-PBPA) states that with regard to EPA's proposed repair requirements, for example, operators of such facilities must coordinate the delivery of new equipment, the arrival of repair contractors, and then for a separate contractor to come and perform the resurvey. Simply put, the commenter recommends that EPA develop a more nuanced approach that considers the location, basin, reservoir, remaining useful life (including of reserves), product, throughput, and age of a particular facility (among other things) before mandating a set of performance standards.

Response I-23-68: See Response I-23-66 of this Chapter.

Comment: Commenter (0946-MOGA) questions EPA's justification of proposing new regulations and capital investments to reduce emissions every 2 or 4 years? How can EPA justify new regulations without a baseline to determine whether previous rules 40 CFR Part 60, Subpart OOOO and the current rule 40 CFR Part 60, Subpart OOOOa have been successful?

Commenter (0946-MOGA) argues that existing regulations for new wells including NSPS OOOO and OOOOa combined with natural production depletion (or Production Decline) will facilitate EPA's emission reduction goals. The commenter evaluated three Michigan Basin producers reported 40 CFR Part 98, Subpart W annual reported Carbon Dioxide ("CO<sub>2</sub>"), Methane ("CH<sub>4</sub>") and Nitric Oxide ("NO<sub>x</sub>") emission over the 9-year required reporting period from 2011 through 2020. The commenter attached a table that shows the initial 2011 reported data, the 2020 reported data and the percent change over 9 years.

From the data provided in the attached table, commenter (0946-MOGA) observed an average annual CO<sub>2</sub> reduction of 5.0%, an average annual methane reduction of 7.1% and an average annual NO<sub>x</sub> reduction of 6.19% for the three companies, in aggregate. Further, the commenter observed a total CO<sub>2</sub> emission reduction of 45.03%, a total CH<sub>4</sub> emission reduction of 64.59% emission reduction and a total NO<sub>x</sub> emission reduction of 55.70%, to date. The above stated emission reductions will likely continue on the current annual rate of decline as more facilities have modifications and become subject to the existing NSPS OOOOa regulations.

Given the above data, the commenter (0946-MOGA) believes EPA must justify the current proposed regulations by explaining why the current NSPS OOOOa regulations are not sufficient to meet emission reduction goals. At minimum, MOGA believes EPA must justify a "one-size-fits-all" approach to emission reductions when many producers are currently employing effective techniques and technologies from previous rulemaking efforts.

Response I-23-69: See Responses I-23-14, I-23-66 and I-23-67 of this Chapter.

## **23.17 Out of Scope Comments**

### ***23.17.1 Memorandum of Understanding***

Comment: Commenter (0792-IOGCC) provides a forum for states and EPA to work together to address issues of mutual concern. This year marks the twentieth anniversary of the establishment of a Memorandum of Understanding (MOU) between EPA and the commenter regarding communication and cooperation related to environment regulation of oil and natural gas exploration and production activities. EPA and the commenter have reviewed and renewed this MOU every few years, most recently in 2019. The MOU and the Task Force it creates have provided an effective forum for the exchange of information and ideas on oil and gas regulation.

Before publishing the referenced proposal late last year, the commenter (0792-IOGCC) states that EPA did not avail itself of the mechanisms for communication and cooperation established in the MOU. Under the MOU, the EPA Administrator designates the EPA Co-Chair of the Task Force and up to five additional members. Because the EPA Co-Chair and other EPA members have not yet been designated in the new administration, the Task Force did not meet in 2021 in accordance with the MOU. The commenter state that they expected and understood the change in administration might produce a brief delay in the scheduling of Task Force meetings. Now that a full year has passed, however, the EPA members should be appointed immediately, especially as EPA is moving forward with significant proposals within the scope of the MOU. The commenter suggests that the November 2021 proposal is a prime example of the kind of issue the MOU Task Force should address. The add that the proposal would have benefited from the communication and coordination that has traditionally occurred when EPA and the commenter work together in accordance with the MOU.

Response I-23-70: This comment on the referenced MOU is outside the scope of this rulemaking; as such, no response is required.

### ***23.17.2 NEPA and CAA Section 309***

Comment: Commenter (0781-NTAA) believes that, as stated in the Agency's draft strategic plan, EPA should use its review authority under NEPA and CAA section 309 to actively review new oil and natural gas leasing particularly in Indian country. The commenter believes that EPA should use this authority to help coordinate and facilitate proper evaluation of new oil and natural gas production, particularly in Indian country. The commenter suggests that EPA work with other federal agencies to fully evaluate the climate impacts of proposed oil and natural gas actions, including by considering the costs with the use of the social cost of methane.

Response I-23-71: This comment on NEPA and CAA section 309 is outside the scope of this rulemaking; as such, no response is required.

Comment: Commenter (0438-Private Citizen) has reviewed NEPA and feels that FERC has full authority on how FERC executes the Natural Gas Act. It also appears that FERC is meant to use NEPA as a basis of the review with states. According to the commenter, this would suggest that FERC can make policy and regulations taking into consideration NEPA, which is broad and

where natural gas expansion has already undermined many of NEPA's stated provisions (highlighted in an appendix to their comment letter).

Response I-23-72: This comment on NEPA is outside the scope of this rulemaking; as such, no response is required.

### ***23.17.3 U.S. Securities and Exchange Commission (SEC) and Greenhouse Gas Reporting Program (GHGRP) Regulations***

Comment: Commenter (0588-Project Canary) states the U.S. Securities and Exchange Commission (SEC) is planning to propose several regulations and other administrative actions relating to environmental, social, and governance (ESG) factors and climate risk disclosure, in a parallel track to EPA's development of this rule. These actions will significantly impact the oil and natural gas sector – and those interested in investing in that sector. Regulations the SEC is considering over the next six months, include but are not limited to: mandatory climate change disclosures; shareholder proposals in proxy statements; rules relating to investment companies and investment advisors to address matters relating to ESG; and climate stress testing for large asset managers and large investment companies.

The commenter (0588-Project Canary) states one of the main issues relates to the U.S GHGRP that is run by EPA. The onshore oil and natural gas sector is required to submit information under subpart W of 40 CFR part 98 for the GHGRP. Both environmental groups and the oil and natural gas industry do not believe that subpart W accurately captures the emissions from the oil and natural gas sector – whether it be underreported or overreported. The commenter explains that part of the reason for issues with capturing accurate data comes from subpart W using over 100 emissions factors for determining how much is emitted from the oil and natural gas sector. The commenter states that continuous monitoring can help eliminate the need for the use of emission factors as it can provide real information on emissions. This will also help bridge the gap on what a company may report to the SEC under its forthcoming regulations and what is being provided under the EPA GHGRP.

The commenter (0588-Project Canary) notes it is key that the SEC and EPA communicate to avoid unnecessary reporting burden or duplicative or conflicting requirements. Luckily, continuous monitoring can help bridge the gap between the two regulations by providing a compliance alternative for EPA, while also serving as a mechanism to allow for compliance with SEC's upcoming regulations. Continuous monitoring provides a way to ensure that companies are providing the reductions that they are claiming on their SEC filings with respect to climate change.

Response I-23-73: The comments on the GHGRP are outside the scope of this rulemaking, as such, no response is required. The EPA finalized the NSPS OOOOb and EG OOOOc rules with consideration of minimizing or eliminating duplicative reporting with what is required under the GHGRP. As an example, the EPA specifically does not require owners or operators conducting liquids unloading at their gas well affected facilities to estimate, record and report estimates of vented emissions during events because this information is already being reported under the

GHGRP. See section X of the final rule preamble for a summary of the final NSPS OOOOb and EG OOOOc requirements.

With regards to the EPA and SEC communicating to avoid unnecessary reporting burden or duplicative or conflicting requirements, the SEC oversees securities exchanges, securities brokers and dealers, investment advisors, and mutual funds in an effort to promote fair dealing, the disclosure of important market information, and to prevent fraud. It is unlikely that the information EPA requires to demonstrate compliance with an EPA rule developed under the CAA would overlap to any significant degree with what would be required by the SEC.

#### ***23.17.4 Ethane Cracker Plant***

Comment: Commenter (1322-Lone Star-Sierra Club) provides an example where the largest ethane cracker plant in the world (a facility that turns methane into the precursor for single-use plastic bags) is almost completed on Corpus Christi Bay. The infrastructure has required many, many miles of gas pipeline. The commenter reports that when the factory applied for a TCEQ permit to release VOCs, the TCEQ itself looked at the numbers, and said they were too high and suggested instead that the company build two plants right next to each other, which would allow each facility to release half of the original requested amounts. The commenter notes that this plant is surrounded by a minority community. At a TCEQ meeting the commenter attended, they stated that community members requested that the company put benzene (a known carcinogen VOC) monitors around the perimeter of the facility. The commenter reports that the company responded by saying, “You do not require any other Texas facility to do that.” According to the commenter, this is despite the fact that the company operates another such facility in New Jersey, where they have benzene monitors around the plant. The commenter reports that they were not required to put up any benzene monitors.

Response I-23-74: This comment on air emissions monitoring at ethane cracker plants is outside the scope of this rulemaking; as such, no response is required.

#### ***23.17.5 Radioactive Substances***

Comment: Commenter (1388-Public Citizen) does not find radioactive substances listed as pollutants carried in the natural gas stream in EPA’s proposed rule. Naturally occurring radioactive substances are found deep in the earth, including areas of shale where hydraulic fracturing (fracking) is used to extract natural gas. Fracking extracts and concentrates these substances. They are brought from deep underground, where they are safe, to the surface, where they are dangerous to the public health and the environment. Under a 1980’s federal exemption to the Resource Conservation and Recovery Act (RCRA), streams of waste from oil and gas wells, including radioactive waste, are not required to be handled as hazardous wastes. Radioactive substances cannot not be fully separated from the gas stream, and they are carried downstream through gas transmission pipelines, and compressor stations.

Commenter (1388-Public Citizen) states that due to significant volumes of leakage, and intentional releases from these pipelines, and compressor stations, persons, wildlife, and the environment in proximity to them are at risk for radiation contamination. Radioactive radon-222

is carried in the natural gas stream. A compilation of studies indicated an average concentration of 40 - 60 pico-curies per liter in natural gas transmission lines. This is 100 to 150 times higher than ambient air levels, which are 0.4 pico-curies per liter. They are also much higher than the 4 pico-curie per liter threshold for homes, where EPA advises that remedial action must be taken to reduce the health risk.

Commenter (1388-Public Citizen) points out that EPA has determined that radon-222 causes 21,000 lung cancer deaths per year in our country. Many locations near compressor stations are already high in naturally occurring radioactive radon-222. Leaks and intentional discharges from compressor stations could further increase the risk of radon contamination for citizens along the routes. Radioactive scales and sludges containing radioactive lead-210 and radioactive polonium-210, which are decomposition products of radon-222, are also deposited as scales along the inside of the pipes, and in filtering materials at compressor stations, and other structures.

Commenter (1388-Public Citizen) states that studies conducted by the Louisiana Department of Environmental quality, the Pennsylvania Departments of Environmental Protection, and the Oil and Gas Journal found an average of over 40,000 pico-curies per gram in these scales. Lead-210 is also present inside the pipes as particulate matter in dust, or black powder, which can also be released through leaks and intentional discharges. Filtering devices in the pipes and compressor stations cannot filter all of the particulate matter, and it is likely that lead-210, and possibly polonium-210 are discharged from compressor stations and along natural gas transmission lines through leaks, venting, blowdowns, and compressor station combustion discharges.

The threat to public health, wildlife, and the environment from these radioactive substances has not been adequately studied, regulated, or mitigated. These threats are significant. They must be fully taken-into-account, and mitigated in order to protect the public health, and the environment.

Commenter (1388-Public Citizen) suggests that EPA should include comments in the proposed rule that consider the public health and environmental threat from these radioactive substances. EPA should also act to eliminate this threat.

Response I-23-75: This comment on threats from radioactive substances from the oil and natural gas industry is outside the scope of this rulemaking; as such, no response is required.

### ***23.17.6 AERMOD Modeling***

Comment: Commenter (1388-Private Citizen) finds that the proposed rule does not go far enough in reducing methane and pollutant emissions from the oil and gas industry. The commenter would like to see more stringent controls resulting in far less emissions, and with those emissions being completely prohibited in the very near future. The commenter suggests that AERMOD should not be used for compressor station air pollution air modeling because AERMOD models may not accurately predict pollutant deposition, distribution, or concentration from variable state discharges from compressor stations.

According to the commenter (1388-Private Citizen), most of the pollutants from compressor stations are heavier than air, and much heavier than methane pollutants in the combustion exhaust emissions, in the blowdown emissions, and in leaks from compressor stations, and may drop out of the discharge plumes, and be deposited in, and accumulate near the compressor station. The commenter adds that pollutants may also react with each other, and form solid particulate matter which may drop out of the plume. The commenter states that the entire pollutant discharge plume may also come into contact with the ground near the compressor station during certain weather conditions, including air inversions.

Commenter (1388-Private Citizen) states that AERMOD is what is referred to as a Gaussian model. There are a number of scientific articles that indicate that AERMOD modeling systems are not suitable to predict pollutant concentration, deposition, or distribution from compressor stations.<sup>80</sup>

Commenter (1388-Private Citizen) shows that section 2.1 (i) of Appendix W to Part 51—Guideline on Air Quality Models, states Gaussian plume models use a steady-state approximation, which assumes that over the model time step, the emissions, meteorology and other model inputs, are constant throughout the model domain, resulting in a resolved plume with the emissions distributed throughout the plume according to a Gaussian distribution. This formulation allows Gaussian models to estimate near-field impacts of a limited number of sources at a relatively high resolution, with temporal scales of an hour and spatial scales of meters. However, this formulation allows for only relatively inert pollutants, with very limited considerations of transformation and removal (*e.g.*, deposition), and further limits the domain for which the model may be used. Thus, Gaussian models may not be appropriate if model inputs are changing sharply over the model time step or within the desired model domain, or if more advanced considerations of chemistry are needed.

Commenter (1388-Private Citizen) explains that emissions from compressor stations would not be steady state emissions. The commenter adds that they would vary widely over time. The commenter notes that they would vary during startup and shut down procedures, during variable air temperatures, during venting and blow down, during variable turbine use, during variable combustion load scenarios, and as the quantity of natural gas passing through the station varies, including the amount that is leaking from the facility.

Commenter (1388-Private Citizen) suggests that deposition of pollutants near the facility is a significant concern from compressor station emissions. The commenter reports that most of the pollutants carried in the gas stream, that would be discharged during blowdowns, venting, and leaks, and in combustion emission discharges are heavier than air, and much heavier than the methane in which they are initially entrained. They may deposit out of the emission plume near the compressor station due to their significantly higher molecular weight.

Commenter (1388-Private Citizen) also suggests that chemical reactions in the discharge plumes could also result in gaseous substances like sulfur dioxide and nitrous oxides reacting, and being

---

<sup>80</sup> In Volume 82, Number 10 of the Federal Register, dated January 17, 2017, under 40 CFR Part 51 EPA issued a final rule revising guidelines on air quality models. (EPA-HQ-OAR-2015-0310; FRL-9956-23-OAR) RIN 2060-AS54.

reduced to solid, particulate matter that would also tend to drop out of the plume. AERMOD does not account for this change in the discharge plume. The commenter states that AERMOD only allows for inert, non-reactive plume components in the air dispersion analysis.

Commenter (1388-Private Citizen) suggests that air modeling for natural gas compressor stations be completed using a model that accurately predicts the deposition, distribution, and concentration of pollutants discharged during variable discharges scenarios, and under all weather conditions. The commenter believes there may be other air models that would be more accurate than an AERMOD model.

Response I-23-76: This comment is about AERMOD modeling and why it should not be used for air modeling for natural gas compressor stations and is outside the scope of this rulemaking; as such, no response is required.

### ***23.17.7 Clean Water Act (CWA) or Safe Drinking Water Act (SDWA)***

Comment: Commenter (0414-Waterspirit) states that natural gas drilling's process as it is done today uses not only copious amounts of fresh water but also undisclosed toxic chemicals which have never been subject to the CWA or SDWA, per the Halliburton loophole<sup>81</sup>.

Response I-23-77: This comment regarding the CWA or SDWA is outside the scope of this rulemaking; as such, no response is required.

### ***23.17.8 Toxic Substances Control Act (TSCA)***

Comment: Commenter (0746-Methane Action) recommends that EPA, in the final rule or your next proposal, incorporate and use the tools EPA has been given in the Toxic Substances Control Act (TSCA), as amended only a few years ago, to determine the extent to which methane presents not only the hazards that warrant its removal under TSCA, and not only a clear and present danger, but on-going harm that TSCA requires the EPA to in turn require the emitters to reduce, remove and/or retrieve. The commenter states that, as Inside Climate News put it, in their story entitled, "Gas Stoves in the US Emit Methane Equivalent to the Greenhouse Gas Emissions of Half a Million Cars":

Cooking with gas is heating up the climate and filling some homes with hazardous nitrogen oxides in excess of EPA safety standards for outdoor air concentrations. The study found that:

Running gas ovens and stove top burners in small kitchens with poor ventilation resulted in emissions that within a few minutes surpassed the Environmental Protection Agency's safety standards for outdoor air concentrations of nitrogen dioxide, an irritant that can aggravate asthma and may contribute to the development of the disease. The agency does not have a separate safety standard for indoor air concentrations of nitrogen dioxide.

<sup>81</sup> <https://www.statnews.com/2021/04/26/end-fracking-exemptions-a-threat-to-maternal-and-public-health/>.

Meanwhile, the commenter (0746-Methane Action) reports that an EPA-funded study<sup>82</sup> by the Harvard Chan School of Public Health, reveals the people over 65 who live within a kilometer of a fracking or directional drilling site have a higher rate of death than those who do not. As Harvard put it: "Living near or downwind of unconventional oil and gas development linked with increased risk of early death."<sup>83</sup> According to the commenter, the presumption of toxicity, hazard and on-going harm to health is established and warrants EPA's invocation of TSCA.

Response I-23-78: This comment regarding TSCA is outside the scope of this rulemaking; as such, no response is required.

### ***23.17.9 National Emission Standards for Hazardous Air Pollutants (NESHAP)***

Comment: Commenter (0809-Earthjustice) recommends the critical importance that EPA does not ignore communities exposed to toxic air pollution. The commenter provides that there are 57 million people living within 50 kilometers of oil and gas facilities, according to EPA data.<sup>84</sup> Residents of rural communities like Eagle Ford, Texas, and of urban neighborhoods such as Wilmington in the city of Los Angeles, are surrounded by oil production operations and oil refineries operating near their homes, public schools, and recreational parks.<sup>85</sup> Overburdened by pollution, the commenter states that individuals in these and other communities have for years complained of trouble breathing, neurological problems, and concerns about increased risk for other health threats. The commenter asserts that EPA must act now to protect these communities, as it is required to do under section 112 of the CAA. See 42 U.S.C. § 7412(d), (f)(2).

Commenter (0809-Earthjustice) points out that the oil and gas sector emits thousands of tons of harmful compounds each year, including organic HAPs such as benzene.<sup>86</sup> Benzene is a known human carcinogen that EPA has identified as a major contributor to cancer risk nationwide in the most recent National Air Toxics Assessment (NATA).<sup>87</sup> The commenter notes that EPA's 2011 draft residual risk assessment showed that individuals living in close proximity to oil and gas sources endure substantial cancer, chronic non-cancer, and acute health threats from being exposed daily to emissions from nearby oil and gas facilities.

<sup>87</sup> 2014 NATA Summary of Results, at 4, [https://www.epa.gov/sites/default/files/2020-07/documents/nata\\_2014\\_summary\\_of\\_results.pdf](https://www.epa.gov/sites/default/files/2020-07/documents/nata_2014_summary_of_results.pdf).

Commenter (0809-Earthjustice) states that in the regulatory impact analysis for the NSPS proposal, EPA estimates, based on 2017 NEI data, that approximately 6.8 million people have a cancer risk of more than one-in-one-million, more than 142,000 people have a cancer risk of equal to or more than 50-in-one-million, and more than 38,000 people have a cancer risk of equal to or more than 100-in-one-million.<sup>88</sup> While these risk levels only reflect cancer risk and no other chronic and acute health risks, these risk levels are unacceptable and cannot be fully addressed under the NSPS alone. First, EPA admits that a “majority of the estimated risk is likely being driven by sources not impacted by this proposed regulation.”<sup>89</sup> Second, while continuing revision of the NSPS standards under section 111 is important and necessary, the section 112 requirements most directly address human health risk due to emissions of air toxics. NESHAP rulemaking is therefore necessary to mitigate both cancer risk “driven by sources not impacted by” the NSPS proposal, as well as the unaddressed non-cancer risk associated with inhalation of hazardous air pollutants.

Commenter (0809-Earthjustice) points out that EPA’s last revision of the NESHAP for the oil and gas sector was in 2012.<sup>90</sup> It has not completed any review or revision since then, even though several groups—including undersigned organizations—filed a petition seeking EPA’s reconsideration of the 2012 standards.<sup>91</sup> The commenter complains that the reconsideration petition has been pending over nine years, a length of delay so long that a subsequent eight-year review deadline under section 112(d)(6) has come and gone. See 42 U.S.C. § 7412(d)(6). The commenter contends that EPA’s inaction has left in place illegal and arbitrary standards that fail to regulate or that insufficiently regulate hazardous air pollution from oil and gas sources.

Response I-23-79: This comment regarding the NESHAP is outside the scope of this rulemaking; as such, no response is required.

Comment: Commenter (0809-Earthjustice) urges EPA to complement this important work on methane and VOC emissions from the oil and gas sector with a renewed focus on controlling the sector’s air toxics emissions via revised NESHAP.

Namely, the commenter (0809-Earthjustice) urges EPA to act on the outstanding reconsideration petition regarding the 2012 NESHAP rule for the oil and gas sector, as well as the now overdue duty under section 112(d)(6) to review and, if necessary, revise those standards. While EPA’s proposed updates to the NSPS proposal are a needed key step forward, the commenter asserts
