<sup>91</sup> Petition for Reconsideration of Oil and Natural Gas Sector: National Emission Standards for Hazardous Air Pollutants Reviews; Final Rule, 77 Fed. Reg. 49,490 (Aug. 16, 2012), 40 CFR Part 63, Subparts HH and HHH, submitted by Earthjustice on behalf of California Communities Against Toxics, California Safe Schools, Clean Air Council, Coalition For A Safe Environment, Desert Citizens Against Pollution, Natural Resources Defense Council, and Sierra Club (Oct. 15, 2012) [hereinafter Reconsideration Petition], <https://www.regulations.gov/comment/EPA-HQOAR-2010-0505-4591>.

that EPA cannot adequately protect human health and the environment from the oil and gas industry's air toxics emissions without also updating the oil and gas NESHAP.

Commenter (0809-Earthjustice) states that in addition to this ongoing exposure, unreasonable delay in reconsideration, and missed deadline—which are reasons enough for EPA to act—the 2012 NESHAP rule contains a number of unlawful components that EPA has a clear duty to fix under intervening caselaw. These include, for example, an affirmative defense to civil penalties for malfunctions that the D.C. Circuit held to be illegal in 2014 and missing emission standards for certain pollutants known to be emitted by industry sources, which the D.C. Circuit held to be also illegal in 2020.<sup>92</sup> According to the commenter, EPA has improperly left these illegal loopholes in place, causing harm that should never have occurred or been extended this long.

Commenter (0809-Earthjustice) states that EPA's now-overdue section 112(d)(6) duty requires the agency to “review and revise as necessary” the emission standards for this source category, which includes making all changes that are “necessary” to bring standards into full compliance with the CAA, such as setting limits on all uncontrolled hazardous air pollutant emissions.<sup>93</sup> To satisfy this provision, the commenter asserts that EPA must review the NESHAP to assure it sets limits on all currently uncontrolled HAP emissions from the oil and gas source categories. As promulgated in the 2012 NESHAP rule, the standards allow uncontrolled emissions of from certain emission points—for example, glycol dehydrators, storage vessels without the potential for flash emissions (“PFE”), storage vessels in the transmission and storage sector, pigging, and equipment leaks—an issue commenters raised in the 2012 reconsideration process that remains uncompleted.<sup>94</sup> Under section 112(d)(6) and LEAN, the commenter contends that EPA must set emission limits that satisfy section 112(d)(2)-(3) in the overdue rulemaking.

Commenter (0809-Earthjustice) argues that additional measures to ensure proper performance of flares is an issue of critical importance with respect to the oil and gas NESHAP, especially due to the large amount of HAPs, VOCs, and other pollutants that flares can release- and to which nearby communities are exposed, such as the Wilmington neighborhood of Los Angeles-when flares are improperly operated and insufficiently monitored. The commenter adds that prompt EPA action is needed on NESHAP Rulemaking. The commenter asserts that oil and gas NESHAP categories incorporate by reference EPA's general flare standards under 40 C.F.R. § 63.11, which themselves are decades overdue for review. The commenter notes that on multiple occasions, EPA itself has stated that the general flare standards under 40 C.F.R. § 63.11 are outdated, lead to the operation of flares with poor destruction efficiency, and require revision.<sup>95</sup>

<sup>93</sup> See 42 U.S.C. § 7412(d)(2)-(3), (6); LEAN, 955 F.3d at 1096.

<sup>94</sup> See Reconsideration Petition, *supra*, at 7-25, app. tbl. 1.

<sup>95</sup> EPA published two documents in 2012 that acknowledged the shortcomings of the general flare standards. First, EPA published an Enforcement Alert regarding flaring violations, in which the agency recognized that certain needed parameters affecting the efficiency of flares are not captured within current standards, including maintaining the appropriate steam-to-vent-gas ratio and ensuring that the heating value of combustion zone gas is high enough to maximize combustion efficiency, neither of which are included in the General Flare Requirements. See EPA, EPA Enforcement Targets Flaring Efficiency Violations, Enforcement Alert (Aug. 2012), <https://www.epa.gov/sit> This

The commenter recommends that EPA revise the NESHAP to include strengthened flare standards for the oil and gas NESHAP categories. In doing so, the commenter states EPA should follow recent NESHAP rulemakings for chemical and petrochemical source categories, which set out improved flare operational and monitoring requirements (though without adding the unlawful exemptions EPA added in some of these rules).<sup>96</sup>

Commenter (0809-Earthjustice) asserts that without decisive action on air toxics standards, EPA will fail to fulfill its duties under the CAA to protect human health and the environment from air pollution caused by the oil and gas industry. Accordingly, the commenter urges EPA to ensure the aforementioned issues reach full and prompt resolution with all due speed through a full and comprehensive use of EPA's section 111 (NSPS) and section 112 (NESHAP) authorities, rather than continuing to delay its NESHAP duties indefinitely. In requesting such a comprehensive strategy, the commenter does not suggest that the agency should delay development of the agency's final NSPS rule—or, for that matter, further delay action on the NESHAP—but rather the agency should enhance its existing analysis and data collection process in furtherance of the NESHAP reconsideration and review as well.

Specifically, commenter (0809-Earthjustice) suggests EPA look carefully at how the two sets of standards address oil and gas industry sources, pollutants, local health risks, cumulative impacts assessment, and potential and known industrial and natural disaster risks in order to identify and eliminate any gaps in coverage. According to the commenter, of particular importance is the need for EPA to anticipate the information it requires for the NESHAP rulemaking, identify all known information deficits, and promptly begin a targeted ICR process as soon as possible.

Commenter (0809-Earthjustice) provides the example that EPA opted not to promulgate standards for storage vessels without potential flash emissions (PFE) on the basis that it did not have adequate data to do so.<sup>97</sup> This was a clear violation of the agency's duty to collect

---

comment regarding the NESHAP is outside the scope of this rulemaking; as such, no response is required. [es/production/files/documents/flaringviolations.pdf](https://www.epa.gov/production/files/documents/flaringviolations.pdf).

Second, following on the uniform emission standards rulemaking, EPA published a report in April 2012 entitled “Parameters for Properly Designed and Operated Flares”, which noted that reliance on the net heating value of the vent gas—the parameter that the General Flare Requirements use—“as an indicator of good combustion ignores any effect of steaming.” EPA, Parameters for Properly Designed and Operated Flares (Apr. 2012), <https://www3.epa.gov/airtoxics/flare/2012flaretechreport.pdf>.

<sup>96</sup> EPA has promulgated revised, stricter flare NESHAP standards for similar industries: petroleum refineries, miscellaneous organic chemical manufacturing, ethylene production, and organic liquids distribution facilities. See 80 Fed. Reg. at 75,178 (revising petroleum refinery flare standards to ensure better combustion efficiency); National Emission Standards for Hazardous Air Pollutants: Organic Liquids Distribution (Non-Gasoline) Residual Risk and Technology Review, 85 Fed. Reg. 40,740 (July 7, 2020); National Emission Standards for Hazardous Air Pollutants: Generic Maximum Achievable Control Technology Standards Residual Risk and Technology Review for Ethylene Production, 85 Fed. Reg. 40,386 (July 6, 2020); National Emission Standards for Hazardous Air Pollutants: Miscellaneous Organic Chemical Manufacturing Residual Risk and Technology Review, 85 Fed. Reg. 49,084 (Aug. 12, 2020). The record for these rulemakings demonstrates that flares operating under the general standards do not achieve their requisite destruction efficiency but rather a far lower percentage that fails to assure compliance with the emission standards. See, e.g., Memorandum from Andrew Bouchard to EPA, Dkt. No. EPA-HQ-OAR-2017-0357, Re: Control Option Impacts for Flares Located in the Ethylene Production Source Category, at 8 (Mar. 2019), <https://www.regulations.gov/document?D=EPA-HQ-OAR-2017-0357-0017>.

<sup>97</sup> See Oil and Natural Gas Sector: New Source Performance Standards and National Emission Standards for Hazardous Air Pollutants Reviews; Final Rule, 77 Fed. Reg. at 49,503.

information it needs to set emission limits and additional facility safety criteria, and it cannot make this mistake again. Nearly ten years have elapsed since EPA reached this conclusion and yet the agency has failed to conduct critical information gathering. As it stated in supporting documents for the NSPS rulemaking, the agency is already aware that it still lacks “detailed data” necessary for its section 112 review.<sup>98</sup> In 2016, the commenters state they noted several specific areas for which EPA should use information collection authority in order to improve its estimates of HAP emissions from oil and gas sources, including storage vessels, glycol dehydrators, fugitive emissions, and certain operational information.<sup>99</sup> The commenter asserts that EPA must start the process now to obtain this data.

Commenter (0809-Earthjustice) states that EPA now undoubtedly possesses data that it did not in 2012 and on which it could readily draw for the NESHAP reconsideration and new 112(d)(6) review. For example, the commenter provides that EPA has conducted NESHAP rulemakings for related source categories (*e.g.*, fence-line monitoring and improved flare standards in the refinery NESHAP, as discussed below), has conducted enforcement actions and reached consent decrees for oil and gas facilities (*e.g.*, pigging requirements in the 2018 consent decree discussed below), and has received data and information from oil and gas sources in compliance with the NSPS and other rules (*e.g.*, information on storage vessels and equipment leaks pursuant to NSPS OOOO and NSPS OOOOa). According to the commenter, EPA should quickly draw on this data that it already has in hand.

Response I-23-80: These comments regarding the NESHAP are outside the scope of this rulemaking; as such, no response is required.

Comment: Commenter (0789-PA DEP) recommends that EPA consider regulating natural gas emissions from glycol dehydration units and adding methanol to HAP thresholds for 40 CFR Part 63, Subparts HH and HHH.

Response I-23-81: This comment regarding the NESHAP is outside the scope of this rulemaking; as such, no response is required.

### ***23.17.10 Coordination with The International Community***

Comment: Commenter (0746-Methane Action) suggests that in the final rule or next proposal, EPA should incorporate section 115 of the CAA to begin the process of building cooperation with Mexico, Canada, and others whose air quality and public health are mutually affected by the methane releases of neighboring countries via climate change, ozone formation, and other means. The commenter also recommends that EPA work with state and U.S. Agency for International Development to develop model methane rules with cost effective options addressing all possible sources and assist other countries in reducing and removing methane

| <b>Chapter 5. Advanced Methane Detection Technologies.....</b>                                                        | <b>II-5-1</b> |
| 5.1 General Comments and Support .....                                                                                | II-5-1        |
| 5.1.1 Technology-Neutral/Matrix Approach/Flexibility.....                                                             | II-5-4        |
| 5.1.2 Incentivize Advanced Technology.....                                                                            | II-5-11       |
| 5.1.3 Industry Advancing Technologies .....                                                                           | II-5-15       |
| 5.2 Multi-Layer/Combination of Technologies .....                                                                     | II-5-21       |
| 5.3 Screening Frequency/Minimum Detection Threshold.....                                                              | II-5-26       |
| 5.4 Compliance Issues/Deviations Detected by Advanced Technologies.....                                               | II-5-28       |

|                                                               |          |
|---------------------------------------------------------------|----------|
| 5.5 Follow-up OGI.....                                        | II-5-31  |
| 5.6 Allow NSPS OOOOa Sources to Comply with NSPS OOOOb .....  | II-5-38  |
| 5.7 Recommended Changes/Clarifications .....                  | II-5-38  |
| 5.8 Alternative Periodic Screening .....                      | II-5-41  |
| 5.8.1 Matrix Approach.....                                    | II-5-41  |
| 5.8.2 Action Levels.....                                      | II-5-48  |
| 5.8.3 Screening Frequency/Minimum Detection Threshold .....   | II-5-50  |
| 5.8.4 Proposed Requirements .....                             | II-5-57  |
| 5.8.5 Follow-up OGI/Emissions Localization.....               | II-5-60  |
| 5.8.6 OGI Requirements are Duplicative .....                  | II-5-67  |
| 5.8.7 FEAST Modeling/Equivalency .....                        | II-5-73  |
| 5.8.8 Handheld Alternatives to OGI .....                      | II-5-83  |
| 5.8.9 Weather/Seasonal Considerations.....                    | II-5-84  |
| 5.9 Continuous Monitoring .....                               | II-5-90  |
| 5.9.1 General Comments .....                                  | II-5-90  |
| 5.9.2 Quantification .....                                    | II-5-94  |
| 5.9.3 Downtime .....                                          | II-5-97  |
| 5.9.4 Fenceline/Within Fenceline .....                        | II-5-100 |
| 5.9.5 Action Levels and Baselines.....                        | II-5-104 |
| 5.9.6 Probability of Detection.....                           | II-5-119 |
| 5.9.7 Matrix Approach.....                                    | II-5-127 |
| 5.9.8 FEAST Modeling .....                                    | II-5-129 |
| 5.9.9 Proposed Requirements Discourage Use.....               | II-5-142 |
| 5.9.10 Corrective Action/Timeline .....                       | II-5-144 |
| 5.9.11 Cost of Continuous Monitoring.....                     | II-5-145 |
| 5.9.12 Root Cause Analysis.....                               | II-5-146 |
| 5.9.13 Follow-up and Continuous OGI .....                     | II-5-149 |
| 5.9.14 Test Under Field Conditions.....                       | II-5-154 |
| 5.9.15 Consider Funding/Support of Continuous Monitoring..... | II-5-157 |
| 5.9.16 Recommendations and Text Changes.....                  | II-5-160 |
| 5.10 Alternative Test Method Approval.....                    | II-5-171 |

|                                                                               |               |
|-------------------------------------------------------------------------------|---------------|
| 5.10.1 General Comments/Support .....                                         | II-5-171      |
| 5.10.2 Overall Recommendations and Clarifications to Streamline Approval..... | II-5-172      |
| 5.10.3 Flexibility in Alternative Test Method (ATM) Process .....             | II-5-181      |
| 5.10.4 FEAST Model Results, Matrix Approach, and State CAA 111(d) Plans ..... | II-5-185      |
| 5.10.5 Minimum Application Requirements .....                                 | II-5-186      |
| 5.10.6 ATM Approval Process.....                                              | II-5-193      |
| 5.10.7 Inflation Reduction Act (IRA).....                                     | II-5-207      |
| <b>Chapter 6. Well Affected Facility and Associated Operations .....</b>      | <b>II-6-1</b> |
| 6.1 Well Affected Facility .....                                              | II-6-1        |
| 6.2 Oil Wells with Associated Gas.....                                        | II-6-3        |
| 6.2.1 Definition of Associated Gas.....                                       | II-6-3        |
| 6.2.2 Proposed BSER – NSPS OOOOb .....                                        | II-6-7        |
| 6.2.3 Proposed BSER - EG OOOOc .....                                          | II-6-26       |
| 6.2.4 Flaring.....                                                            | II-6-30       |
| 6.2.5 Beneficial Use/Useful Purpose.....                                      | II-6-73       |
| 6.2.6 Allowance for Venting of Emissions .....                                | II-6-82       |
| 6.2.7 Access to a Sales Line .....                                            | II-6-83       |
| 6.3 Well Completions.....                                                     | II-6-85       |
| 6.3.1 Applicability .....                                                     | II-6-85       |
| 6.3.2 Well Completions Requirements .....                                     | II-6-86       |
| 6.3.3 Technical Infeasibility Exception .....                                 | II-6-88       |
| 6.3.4 Definition of Hydraulic Fracturing - Well Completions.....              | II-6-90       |
| 6.4 Liquids Unloading Operations.....                                         | II-6-91       |
| 6.4.1 Applicability .....                                                     | II-6-91       |
| 6.4.2 Proposed Best System of Emission Reduction (BSER) .....                 | II-6-101      |
| 6.4.3 Liquids Unloading Definition.....                                       | II-6-111      |
| 6.4.4 Recordkeeping and Reporting Requirements.....                           | II-6-112      |
| 6.4.5 Existing State and Federal Requirements.....                            | II-6-116      |
| 6.5 Technical Infeasibility.....                                              | II-6-119      |
| <b>Chapter 7. Process Controllers.....</b>                                    | <b>II-7-1</b> |
| 7.1 NSPS OOOO and EG OOOOc Affected Facility Definition.....                  | II-7-1        |

|                                                                                                                                                          |         |
|----------------------------------------------------------------------------------------------------------------------------------------------------------|---------|
| 7.1.1 Support for EPA Proposed Affected Facility Definition.....                                                                                         | II-7-1  |
| 7.1.2 Request for Related Definitions/Other Clarifications .....                                                                                         | II-7-3  |
| 7.1.3 Modification/Reconstruction .....                                                                                                                  | II-7-5  |
| 7.1.4 Affected Facility - Collection of Controllers .....                                                                                                | II-7-14 |
| 7.1.5 Affected Facility-Natural Gas-Driven Controllers – Emissions Routed to a Process/<br>Self-Contained Natural-Gas Driven Pneumatic Controllers ..... | II-7-14 |
| 7.1.6 Exemptions .....                                                                                                                                   | II-7-16 |
| 7.1.7 Other .....                                                                                                                                        | II-7-22 |
| 7.2 NSPS OOOOb and EG OOOOc BSER Control Options .....                                                                                                   | II-7-22 |
| 7.2.1 General Support/Opposition of Proposed BSER.....                                                                                                   | II-7-22 |
| 7.2.2 Access to Reliable Electricity .....                                                                                                               | II-7-23 |
| 7.2.3 Solar.....                                                                                                                                         | II-7-30 |
| 7.2.4 Electric Controllers.....                                                                                                                          | II-7-32 |
| 7.2.5 Generators.....                                                                                                                                    | II-7-34 |
| 7.2.6 Instrument/Compressed Air Systems .....                                                                                                            | II-7-36 |
| 7.2.7 Self Contained/Route to Process .....                                                                                                              | II-7-37 |
| 7.2.8 Route to Control .....                                                                                                                             | II-7-39 |
| 7.2.9 Nitrogen-Powered Controllers.....                                                                                                                  | II-7-42 |
| 7.2.10 Regional Area Considerations .....                                                                                                                | II-7-43 |
| 7.2.11 Intermittent Vent Controllers .....                                                                                                               | II-7-45 |
| 7.2.12 Technology-Neutral Standard.....                                                                                                                  | II-7-48 |
| 7.2.13 Other .....                                                                                                                                       | II-7-48 |
| 7.3 NSPS OOOOb and EG OOOOc BSER Analysis/Emissions/Costs.....                                                                                           | II-7-49 |
| 7.3.1 Emissions/Emission Factors .....                                                                                                                   | II-7-49 |
| 7.3.2 Model Facilities .....                                                                                                                             | II-7-52 |
| 7.3.3 Costs .....                                                                                                                                        | II-7-53 |
| 7.3.4 BSER Based on Regional Considerations .....                                                                                                        | II-7-66 |
| 7.4 Low Production/Small Sites .....                                                                                                                     | II-7-67 |
| 7.5 Applicability and Compliance Date Considerations .....                                                                                               | II-7-69 |

## **Chapter 9. Inflation Reduction Act (IRA) and Methane Emissions and Waste Reduction**

### **Incentive Program (MERP) .....II-9-1**

|                                                                                |         |
|--------------------------------------------------------------------------------|---------|
| 9.1 Administrator’s Equivalency Determination .....                            | II-9-1  |
| 9.1.1 Temporal Elements of the IRA and MERP.....                               | II-9-1  |
| 9.1.2 Geographical Elements of Administrator’s Equivalence Determination ..... | II-9-9  |
| 9.1.3 Meaning of “Equivalent” Emissions Reductions .....                       | II-9-10 |
| 9.1.4 Calculation of Waste Emissions Charge.....                               | II-9-11 |
| 9.1.5 Compliance Determination.....                                            | II-9-12 |
| 9.1.6 Duration of the WEC .....                                                | II-9-14 |
| 9.2 Funding and Technical Assistance for Emissions Reductions Programs.....    | II-9-14 |
| 9.2.1 Assistance for Industry .....                                            | II-9-14 |
| 9.2.2 Assistance for Regulators (State/Local) .....                            | II-9-15 |
| 9.3 Target Setting and Tracking .....                                          | II-9-15 |
| 9.4 Synergy with other programs.....                                           | II-9-15 |
| 9.5 Miscellaneous .....                                                        | II-9-17 |

### **Chapter 10. Centrifugal Compressors .....II-10-1**

|                                                                                                    |          |
|----------------------------------------------------------------------------------------------------|----------|
| 10.1 New Source Performance Standard (NSPS) OOOOb Affected Facility/Definitions .....              | II-10-1  |
| 10.1.1 Affected facility .....                                                                     | II-10-1  |
| 10.1.2 Definitions .....                                                                           | II-10-3  |
| 10.2 NSPS OOOOb Proposed Best System of Emission Reduction (BSER) .....                            | II-10-7  |
| 10.2.1 Wet Seal Compressors .....                                                                  | II-10-7  |
| 10.2.2 Dry Seal Compressors .....                                                                  | II-10-18 |
| 10.3 Emission Guidelines OOOOc Designated Facility/Definitions.....                                | II-10-27 |
| 10.4 EG OOOOc Proposed BSER .....                                                                  | II-10-27 |
| 10.5 NSPS OOOOb and EG OOOOc Compliance Issues .....                                               | II-10-34 |
| 10.5.1 Subpart KKK Wet Seal Compressor Requirements .....                                          | II-10-34 |
| 10.5.2 Recommended Work Practice Standard Provisions (Apply to All Centrifugal Compressors).....   | II-10-34 |
| 10.5.3 Recommended Monitoring Provisions (Apply to All Centrifugal Compressors) .....              | II-10-40 |
| 10.5.4 Performance-Based Monitoring Alternative for Measurement of VOC and Methane Flow Rate ..... | II-10-45 |

|                                                                                          |                |
|------------------------------------------------------------------------------------------|----------------|
| <b>Chapter 11. Reciprocating Compressors .....</b>                                       | <b>II-11-1</b> |
| 11.1 New Source Performance Standard (NSPS) OOOOb Affected Facility/Definitions. II-11-1 |                |
| 11.2 NSPS OOOOb Proposed Best System of Emission Reduction (BSER) .....                  | II-11-3        |
| 11.2.1 Work Practice Standard vs Emission Limitation Standard .....                      | II-11-3        |
| 11.2.2 Clarification that Emissions Threshold is on a Per Cylinder Basis .....           | II-11-5        |
| 11.2.3 Other Comments on Proposed Standards .....                                        | II-11-10       |
| 11.2.4 Alternative Compliance Option .....                                               | II-11-19       |
| 11.2.5 BSER Analysis/Emissions/Costs .....                                               | II-11-21       |
| 11.3 NSPS OOOOb and EG OOOOc Compliance Issues .....                                     | II-11-23       |
| 11.3.1 Test Methods and Procedures (Apply to Both NSPS OOOOb and EG OOOOc) .....         | II-11-23       |
| 11.3.2 Clarification of Compliance Deadlines .....                                       | II-11-29       |
| 11.3.3 Timeline for Repair or Replacements (Apply to Both NSPS OOOOb and EG OOOOc).....  | II-11-30       |
| 11.4 EG OOOOc Proposed BSER .....                                                        | II-11-34       |
| 11.4.1 Applicability .....                                                               | II-11-34       |
| 11.4.2 Proposed Standards.....                                                           | II-11-34       |
| 11.5 Regulation Text Correction .....                                                    | II-11-35       |
| <b>Chapter 12. Equipment Leaks at Natural Gas Processing Plants.....</b>                 | <b>II-12-1</b> |
| 12.1 Monitoring Requirements .....                                                       | II-12-1        |
| 12.1.1 Inspection Frequency.....                                                         | II-12-1        |
| 12.1.2 Use of OGI vs. EPA Method 21.....                                                 | II-12-3        |
| 12.1.3 Use of Appendix K .....                                                           | II-12-6        |
| 12.2 Equipment Classification .....                                                      | II-12-8        |
| 12.3 Overlapping NSPS Applicability .....                                                | II-12-10       |
| 12.4 Request for Exemption .....                                                         | II-12-10       |
| 12.5 Closed Vent Systems and Equipment Designated as No Identifiable Emissions ..        | II-12-11       |
| 12.6 Leak Repair Timeline.....                                                           | II-12-12       |
| 12.7 Leaking Valve Replacement .....                                                     | II-12-12       |
| 12.8 Regulation Definitions .....                                                        | II-12-13       |
| 12.8.1 Definition of Natural Gas Processing Plant.....                                   | II-12-13       |

|                                                                                  |                |

## Chapter 1. Introduction

This document provides EPA’s responses to public comments on the proposed *Standards of Performance for New, Reconstructed, and Modified Sources and Emissions Guidelines for Existing Sources: Oil and Natural Gas Sector Climate Review* rulemaking published in the *Federal Register* on December 6, 2022, at 87 FR 74702 (hereinafter referred to as the December 2022 Supplemental Proposal).

Just over 517,400 public comments were received on the December 2022 Supplemental Proposal. The EPA Docket Center consolidated mass mail campaigns, form letters and petitions into single DCNs, resulting in over 2,200 posted comments, including late comments. (Note: Batches of substantially similar mass mail campaigns, form letters and petitions are considered as a single “unique” comment.). Each comment submitted to the Docket was reviewed and significant comments relevant to this action and submitted within the comment period (totaling just over 2,100 “unique” comments) have been summarized and included in this document.

Of the more than 2,100 “unique” comment letters received over 82 percent originated from individual private citizens, 6 percent are from industry (including industry associations), 4 percent are from environmental and public advocacy groups, 4 percent are mass mail campaigns/petitions (representing over 513,500 individuals), 3 percent are from state, local, federal, and tribal governments/representatives, 1 percent are from other advocacy groups, including financial companies, and less than 1 percent are from academia.

In addition to public comment submissions to the Docket, EPA held a virtual public hearing January 10, 2023, through January 12, 2023, to provide the public the opportunity to present comments and information on the Agency’s proposed updates to NSPS and EGs to reduce methane and other harmful pollution from the oil and natural gas industry. It is worth noting that the virtual public hearing was originally scheduled as a two-day hearing but due to the public’s overwhelming interest, EPA extended the hearing an additional day.

Roughly 300 speakers, from members of the public either representing themselves or speaking on the behalf of one or more organization or agency, provided oral testimony over the course of three days. Live, daily testimonies were recorded by a certified court reporter and documented in official transcripts. Emailed written copies of testimonies and other supporting information received were uploaded separately to the Docket.

The comment period for the December 2022 Supplemental Proposal closed on February 13, 2023. EPA received multiple requests to extend the public comment period (by 30-, 60-, and 90-days). The EPA did not grant an extension to the public comment period, however, as an outgrowth of stakeholder meetings, the EPA requested additional information from stakeholders that was reviewed and considered beyond the comment period closure date. As such, the EPA reviewed and considered all late comments up until and including September 20, 2023.

A general overview of all the comments received follows in Sections 1.1 through 1.4 of this Chapter. More-detailed comments provided by these commenters (some of which are highlighted in the general overview) on the December 2022 Supplemental Proposal have been summarized and included in Chapters 2 through 23, and Appendix A of this document.

## **1.1 Mass Mail Campaigns/Petitions**

More than 80 individual entries submitted to the Docket are categorized as mass mail campaign comments; representing roughly 508,500 of the more than 516,600 public submissions received by the Docket on the December 2022 Supplemental Proposal (> 98 percent).

Mass mail campaigns can be classified as either mailers/form letters or petitions. For the purposes of this Response to Comment (RTC) document, mailers and form letters (including postcards) are comment submissions submitted by separate, individual commenters, but present substantially similar (if not identical) remarks. These campaigns are typically sponsored by an organization/institution. Petitions are pre-written letters or statements (by a sponsoring agency/institution) requesting action that are signed by persons supporting what is stated in the pre-written letter or statement.

Under this proposal, mailers/form letters (including postcards) account for approximately 60 percent of the total number of mass mail campaign comments submitted to and identified by the Docket – representing more than 324,000 private citizens. Most contributors submitted templates provided by the known sponsoring organization(s) without change; however, it is worth noting that a few commenters customized the template(s) – e.g., to include statements describing personal experiences with deteriorating health. Petitions account for about 40 percent of the mass mail campaign comments identified and represent more than 183,000 private citizens.

Roughly 51 percent of mass mail campaign comments were prepared by an unknown sponsoring organization. The remaining campaigns were generated from various known groups and organizations comprised mostly of religion and environmental/public advocacy groups.

Approximately 62 percent of comments prepared by “Private Citizens” included one or more mass mail campaign arguments; however, these comments varied enough to be considered as a separate entry by the Docket. These comments are summarized in section 1.4.1 of this Chapter (as part of the private citizen summary). It is also worth noting that at least one mailer (representing more than 120 people) prepared and submitted remarks in Spanish. These remarks echo comments provided below.

Mass mail comment campaigns uniformly support the December 2022 Supplemental Proposal and applaud EPA’s efforts to reduce methane emissions from industrial sources (the oil and natural gas sector). Campaigns strongly believe that the December 2022 Supplemental Proposal is an essential step forward towards protecting public health and tackling/mitigating climate change, and often stress the point that methane is over 80 times more potent than carbon dioxide. Many of the campaigns cite or reference the amount of methane emissions generated from the oil and gas sector (16 million metric tons) and warn that without immediate

action, methane emissions and its impact on public health, primarily the health of vulnerable populations (e.g., children and communities located near oil and gas industry operations) and the environment will continue to worsen. Several campaigns (including one campaign representing over 350 health professionals and 50 individual health organizations) discuss the health risks and chronic conditions brought about and/or exacerbated by exposure to methane emissions (e.g., asthma, COPD, heart disease, Parkinson's disease, and low birth weight). A small number of petitions and mailers discuss state-specific concerns.

While campaigns agreed that, overall, the December 2022 Supplemental Proposal improves upon the November 2021 Proposal; nearly all the campaigns urge the Agency to further strengthen the final rule. Requests repeatedly made (which were also included under the November 2021 Proposal) include, for example:

- Ensure that operators at wells capture associated gas;
- End routine flaring (except in emergency situations);
- Strengthen the standards to address emissions from storage tanks by making the standards applicable to more tanks; and
- Provide a clear pathway for participation in the Super Emitter Response Program by ensuring communities and citizens can access data and technologies to help reduce methane and other pollutants in the areas where we live and work.

Other suggestions offered (by a few campaigns) include:

- Strengthen leak detection and repair (LDAR) requirements – e.g., require inspections at low-emitting/small wells with leak-prone equipment;
- Maintain zero-emitting controller and pump equipment requirements; and
- Require that abandoned wells are subject to inspections until closure.

A few mass mail campaigns (many of which were prepared by Black Church leaders and congregants) spoke directly on the issue of environmental justice. Largely these campaigns claim that the impacts from exposure to methane emissions (e.g., increases in methane emissions leads to the formation of smog and, consequently, an increase in asthma related events) disproportionately impact low-wealth communities and communities of color, particularly black communities.

At least one petition (with nearly 400 signatures) offers their support for recent science-based updates to the estimates for the social costs of greenhouse gases (SC-GHGs). Specifically, the petition expresses support for the incorporation of a broader range of climate impacts; a lower discount rate (from 3 percent to 2 percent); and the consideration of global estimates of climate damages. One mailer/form letter (representing over 230 people) discusses methane impacts as it relates to economy and market volatility. The petition maintains that businesses and supply chains are directly impacted by methane pollution and support the December 2022 Supplemental Proposal updates and strong methane regulations, which the petition claims will help reduce price uncertainty and stimulate private investment and foster greater innovation.

At least two mailers were deemed out of scope. One mailer/form letter (representing over 2,000

people) that expressed disagreement with EPA’s decision to include compressed natural gas and electricity derived from manure biogas in the proposed updates to the Renewable Fuel Standard (RFS) and urged the EPA to remove the sources as eligible fuels for the RFS and commit to protecting our communities and ecosystems from Concentrated Animal Feeding Operations (CAFOs) instead. The mailer recalls that the proposal claims that manure biogas production has low emissions and points out that the proposal fails to account for multiple highly emissive, intrinsic aspects of manure production, such as enteric fermentation, feed production, animal transport, and off-gassing of leftover manure solids, in its emissions calculations, in addition to addressing the environmental justice impacts of CAFOs on fenceline communities. The other mailer (representing over 3,700 people) called on EPA to “act quickly to address the backlog of judicial nominations currently before the Senate for consideration.”

A list of campaigns received is provided in **Appendix B** to this document. Examples of a few of the mass comment campaigns submitted can be found in **Appendix C** to this document.

## **1.2 General Support/Opposition**

### Support

An estimated 86 percent (or more than 1,800 submissions) of the unique written comments received support one or more of the updates made or the general intent of EPA’s December 2022 Supplemental Proposal. Support for the December 2022 Supplemental Proposal can be broken down by commenter type as follows: over 87 percent originated from individual private citizens (including mass mail campaign variations), 5 percent are from environmental and public advocacy groups, 2 percent are from industry (including industry associations), 4 percent are mass mail campaigns/petitions, 1 percent are from other advocacy groups (including financial companies), and less than 1 percent (combined) are from academia and state, local, federal, and tribal governments/representatives.

Supporters of the December 2022 Supplemental Proposal generally back EPA’s efforts to reduce methane emissions from the oil and gas sector and overwhelmingly believe that it’s a significant step forward to combating climate change (and its impacts on, for example, economic productivity and social welfare), as well as a significant step to improving air quality and protecting overall public health and the environment. These commenters urge the Agency to finalize and enact the strictest possible limits/safeguards to reduce (and eventually eliminate) methane pollution from the oil and natural gas industry. Many of which recap that methane is a potent greenhouse gas (GHG) (traps about 80 times as much as heat as carbon dioxide (CO<sub>2</sub>)) and point to the oil and gas industry as the biggest supplier (together with agriculture).

Several commenters suggest that the standard would achieve cost-effective methane emissions reductions and provide greater certainty about Clean Air Act (CAA) requirements for new, modified, and existing oil and natural gas activities, including the production, processing, transmission, and storage of natural gas and the production of oil. Other commenters highlight that they are working closely with impacted parties – non-governmental organizations (NGOs), unions, community leaders, etc. and other stakeholders – to develop/deploy technologies (e.g.,

continuous, near-continuous and non-continuous advanced methane detection technologies) and to advocate for policies that serve the goals of the Paris Agreement and support the ambitions of the Biden Administration to chart a path toward a legally durable and effective framework for regulating methane that encourages innovation and operational flexibility. At least one commenter suggests that the proposed updates/revisions will create a consistent, level playing field across production basins that span states, like the San Juan Basin, which crosses Colorado and New Mexico, and the Permian Basin, which crosses Texas and New Mexico.

Other commenters express particular concern over the health and wellbeing of communities of color and tribal communities – which they maintain are often disproportionately impacted by harmful air pollution from oil and gas operations – and agree that the December 2022 Supplemental Proposal could aid in addressing these environmental justice issues.

While commenters generally support the December 2022 Supplemental Proposal, many suggest that the proposed changes do not go far enough and called on the EPA to further tighten rules surrounding the release of methane emissions from the oil and natural gas industry. In such cases, commenters highlight instances where the rule could be improved upon (often pertaining to flaring, storage tanks, and the super emitter response program) and present one or more recommendations to further strengthen requirements. It is worth noting that many of these recommendations (and areas of concern) are similar as those offered in one or more mass campaign mailers received, as discussed under section 1.1 of this Chapter.

### Oppose

Approximately 8 percent (or more than 170 submissions) of the unique written comments received (largely from industry/trade association representatives, followed by private citizens, government officials/organizations, nonprofit organizations and other advocacy groups) generally oppose one or more of what was proposed in the December 2022 Supplemental Proposal. It is worth noting that a small number of commenters (comprised mostly of private citizens) outright refute climate change/global warming, and strongly object to the proposal.

While some commenters acknowledge that reducing methane emissions from the oil and gas industry is a necessary and important step towards mitigating climate change impacts, most assert that the proposed updates are unnecessary and unreasonable and an overreach. Many of these commenters contend that the December 2022 Supplemental Proposal does not adequately provide for (as required) cost-effective controls, nor does it ensure that the newly imposed requirements are not overly burdensome to the entire scope of the regulated community that are covered by the regulations, or the agencies that are required to implement these emission standards. Commenters urge the EPA to consider additional flexibilities that can minimize potential impacts (particularly impacts to small businesses) while accomplishing the goal of reducing methane emissions from oil and natural gas production.

Numerous commenters strongly oppose EPA’s approach to determine the “value of a statistical life” or social cost value; largely arguing that this approach is unjust and poses serious ethical concerns – as the value of life should not be determined/measured by their ability or “willingness to pay.” Moreover, commenters submit that the proposals are not in congruence

with environmental justice principles, due to its discrimination based upon wealth, and should be revised before finalization.

Several commenters express concerns that the December 2022 Supplemental Proposal will significantly impact oil and natural gas operations and costs, and unfairly and disproportionately impact small businesses and tribal communities, as well as significantly and negatively impact the economy (e.g., increases in gas prices and job losses). Overall, commenters disagree with EPA's decision to include marginal wells – or low production wells – which historically have been exempted; arguing that emissions from production operations are insignificant – marginal wells have a diminished capacity to emit methane and can become economically unviable for small independent drillers if new (inspection and repair) rules are too costly. These commenters believe that the EPA should maintain exemption status. Furthermore, commenters generally oppose EPA's one-size-fits all approach; calling it misguided and stress the importance of the oil and natural gas industry to state and local economies. Many of these commenters underscore the point that states, like Alaska heavily regulate oil and gas productions within their state, and therefore question whether the proposal would significantly reduce methane emissions as claimed.

A few commenters (representing tribal communicates) worry that the December 2022 Supplemental Proposal, as written, will have a direct financial impact on the tribal lands – i.e., tribal communities would be impacted by the rule both as a regulator and as an operator of oil and gas development facilities.

Some commenters ask that the Agency establish a realistic timeframe for compliance and implementation, and where possible streamline/simplify standards, including those pertaining to the state planning process (e.g., LDAR standards) to ensure prompt and efficient implementation of these new emissions guidelines (EGs).

#### Other Comment Types

Nearly 2 percent of the unique comments (approximately 33 comments, mostly from industry and government representatives) request that EPA extend the public comment period for the proposed rule; citing that the amount of time granted to prepare and submit remarks is insufficient.

Approximately 54 percent (roughly 100 comments, primarily from private citizens) of the unique comments received, conveyed general concerns about the environment and/or public health, but did not specifically comment on the proposed updates.

### **1.3 Summary of Public Hearing Comments**

As previously noted, the EPA held a virtual public hearing January 10, 2023, through January 12, 2023, to provide the public the opportunity to present comments and information on the Agency's proposed updates to NSPS and EGs to reduce methane and other harmful pollution from the oil and natural gas industry. It is worth noting that the virtual public hearing was originally scheduled as a two-day hearing but due to the public's overwhelming interest, EPA

extended the hearing an additional day. Over the course of three days, nearly 300 speakers (roughly 100 speakers per day), from members of the public either representing themselves or speaking on the behalf of one or more organization or agency, provided oral testimony. Testimonies can be broken down by commenter type as follows: Over 65 percent originated from environmental and public advocacy groups (including various nonprofits and faith communities), an estimated 30 percent originated from individual private citizens (including students, retirees, community members and volunteers), 3 percent originated from industry (including industry associations), and 1 percent originated from government agencies representatives and elected officials. It is worth noting that some speakers prepared and submitted to the Docket separate, more detailed comments. These remarks are discussed elsewhere in this document. The public hearing transcripts for the virtual public hearing are accessible at [regulations.gov](https://www.regulations.gov) (see EPA-HQ-OAR-2021-0317; search “2022 Supplemental Proposal Public Hearing”).

Environmental and public advocacy groups generally support EPA’s December 2022 Supplemental Proposal to reduce methane and other harmful pollution from the oil and natural gas industry. Many of the speakers remind that methane is a strong GHG – 86 more times potent than carbon dioxide, and a major contributor to climate change, as well as poses a hazard to human health. While speakers agree that the proposed updates would further protect public health and help mitigate climate change impacts, they urge the Agency to finalize the strongest most comprehensive rule, and offer as such, one or more recommendations aimed at strengthening the proposal. More specifically, speakers ask that the Agency to: 1) follow the lead of states like Colorado and New Mexico and prohibit the practice of routine flaring; 2) strengthen the standards to address emissions from storage tanks; and 3) supply a clear pathway for communities and individuals to take part and engage in the Super-Emitter Response Program.

Private citizens testimonies echo many of the remarks made by environmental and public advocacy groups – they generally support the proposed updates and applaud the Agency efforts to reduce methane from the oil and gas industry. Many of the speakers reiterate environmental (e.g., extreme weather) and public health concerns (e.g., low-birth weight) resulting from methane emissions from the oil and gas productions. Additionally, several speakers describe personal experiences and/or various health impacts which they believe are a result of exposure to air pollutants – methane, from oil and gas facilities. Some speakers also express concerns about the health of communities living near oil and gas facilities – who they maintain, pay a higher cost (disproportionally impacted) through increases in healthcare costs, a decrease in quality of life and other indirect costs. A few speakers express concern over relying on oil and gas industry volunteering efforts as the primary means to reduce methane emissions and address climate change and protect human health, and all call on the EPA to finalize the strongest most comprehensive rule.

Industry representatives are generally supportive of the December 2022 Supplemental Proposal; many reintegrating their commitment to supporting public policies that protect the environment while ensuring a safe, reliable, and resilient energy transmission system that provides affordable energy nationwide. Most speakers underscore the point that methane is harmful pollutant and acknowledge that the oil and gas industry is a large contributor. At least

one speaker (representing roughly 250,000 businesses spread throughout the U.S.) describes the negative impacts of methane emissions on local/state economies. For EPA’s consideration, several speakers testify to one or more of services and/or low-cost, innovative products/equipment/ technologies currently available (and manufactured/offered by them) that they contend are capable of efficiently reducing wasteful methane emissions. While many speakers agree with the overall intent of the December 2022 Supplement Proposal, some speakers express concern over one or more provision – e.g., on centrifugal compressors, at least one speaker feels that the new dry seal threshold should be revisited. At least one speaker warns against a lack of accountability for hydrocarbon waste streams.

Overall speakers representing governmental agencies/representatives (i.e., state and local/tribal governments) overwhelmingly support the December Supplemental Proposal and EPA’s overall intent to limit/reduce methane pollution from oil and gas operations; asking that the Agency finalize strong, comprehensive new and existing rules to cut methane pollution. While speakers identify several of the requirements which they agree-on – e.g., the use of zero-emitting technologies – they also maintain that more can be done – e.g., the December 2022 Supplemental Proposal can be further strengthened by banning the practice of routine flaring.

One speaker (a newly elected state representative) spoke specifically on the impacts of methane emissions on tribal communities and stated that the December 2022 Supplemental Proposal is an important step towards addressing the climate crisis and protecting public health.

## **1.4 Summary of General Positions by Commenter Type**

### ***1.4.1 Private Citizens***

#### **Support**

Most private citizens (nearly 92 percent of the “unique” comments received) generally support one or more requirements of the December 2022 Supplemental Proposal. Like public submissions included as part of mass mail campaigns, a number of these commenters feel that while the December 2022 Supplemental Proposal constitutes a major step forward in combating the climate crisis by reducing methane emissions from the oil and gas, many urge the Agency to go further and presented one or more recommendations to further strengthen requirements. It is worth noting that many of the recommendations presented – e.g., close existing loopholes and ban flaring, strengthen standards to address emissions from storage tanks, and provide a clear pathway for participation in the Super Emitter Response Program – duplicate those offered in one or more mass campaign mailer, as noted in the above section.

Several commenters reiterate that methane is a potent GHG (80 times the warming power of carbon dioxide). These commenters believe that global climate change poses a very serious threat and without immediate action, methane emissions from the oil and gas industry – leaks from a well, storage tank, pipeline, pump, compressor station or any other structure – and its impact on the environment and on public health, primarily the health of vulnerable populations (e.g., children and low-income and communities of color) will continue to worsen. Commenters presented examples of environmental (wildfires, droughts, severity of storms,

etc.) and public health impacts (asthma, chronic respiratory diseases, etc.), which they believe are a result of climate change and/or impacts from the air pollution emitted by the oil and gas industry. Plugging methane leaks, for many of these commenters, is considered a relatively low-hanging fruit – i.e., an efficient and effective way for oil and gas facilities to reduce methane emissions without having to pass shortfalls from unclaimed, leaked methane to consumers.

### Oppose

Approximately 4 percent of the “unique” comments received from private citizens generally oppose one or more requirements proposed in the December 2022 Supplemental Proposal. Overall, commenters believe that the December 2022 Supplemental Proposal imposes additional, unnecessary and burdensome regulations and standards on a large segment of the oil and gas industry, while doing little to improve environment conditions or address/consider potential economic impacts – increases in electricity rates – thus, unnecessarily hurting Americans.

Foremost, commenters largely object to EPA’s approach in calculating the “value of a statistical life” and strongly encourage the Agency to reconsider; arguing that quality of life should not be dependent on someone’s “willingness to pay”. At least one commenter suggests that if EPA were to consider all human lives as having equal value, regardless of what country or economic circumstances people live in, then the cost to the oil and natural gas industries will be sufficient to incentivize appropriate action. As currently framed, the commenter believes that the proposed changes will not result in necessary changes within these industries.

Similarly, commenters recommend that the EPA withdraw its External Review Draft “Report on the Social Cost of Greenhouse Gases,” and revise its analysis to correct the material deficiencies described in these comments. At least one commenter suggests that the peer review report is not comparable to a report with replicable data – the essential characteristic of the scientific method – and transparency – unfettered access to the assumptions, algorithms, software code, and data used. Another commenter briefly discusses the challenge to assigning and appropriate value of the social discount rate – the appropriate approach to social discounting depends on ethical judgments as well and argues that the Agency’s analysis fails to adequately grapple with these challenges, instead noting that the Agency uses a “descriptive approach,” which involves “inferring the discount rate from market rates of return.”

Some commenters believe the December 2022 Supplemental Proposal requirements are burdensome and unnecessary, with a few commenters questioning the validity of climate change claims. Commenters suggest that fossil fuels are a critical part of the economy and essential to keeping energy costs low, and warn that, if enacted as written, the proposal would lead to economic hardships. At least one commenter suggests that the oil and gas industry in their state (Michigan) does not warrant new regulations; arguing that negligible emissions generated by the sector within the state are not enough to justify inclusion and recommends that the EPA focus on large emitters of methane.

In some cases, commenters propose one or more changes (or considerations) to the December

2022 Supplemental Proposal aimed at minimizing potential regulatory and financial impacts on businesses and the general public, while still accomplishing the goal of reducing methane emissions from oil and natural gas production— e.g., provide an opportunity for operators to mitigate detected compliance issues instead of immediately classifying them as violations. In other cases, commenters feel that the December 2022 Supplemental Proposal, as written, fails to adequately protect human health and offer several suggestions/recommendations aimed at strengthening the Proposal.

### Other

Approximately 5 percent of the comments received from private citizens include broad remarks about the environment, public health, etc., but do not specifically comment on the proposed rule.

One private citizen requested an extension to the public comment period to ensure appropriate time to review new regulations and accompanying documents, as well as allow institutions a proper amount of time to conduct their own research and post their comments.

### ***1.4.2 Academia***

Comments received from academia unanimously (100 percent) support EPA’s December 2022 Supplemental Proposal that builds upon the November 2021 Proposal to control methane emissions from new and existing sources in the oil and gas industry. While commenters largely support the general intent of the rule, nearly all believe that the supplemental proposal, as written, does not go far enough, and in some cases, discuss specific areas in the rule where they believe further improvements, or additional clarification are warranted, and offered one or more recommendations aimed at toughening/clarifying EPA’s final rule (and its underlying analysis) and maximizing net benefits – e.g., in regard to strengthening the RIA, EPA should extend the timeframe of its analysis to quantify net benefits past 2035.

On the whole, commenters agree that the *Supplementary Material for the Regulatory Impact Analysis for the Supplemental Proposed Rulemaking, ‘Standards of Performance for New, Reconstructed, and Modified Sources and Emissions Guidelines for Existing Sources: Oil and Natural Gas Sector Climate Review – EPA External Review Draft of Report on the Social Cost of Greenhouse Gases: Estimates Incorporating Recent Scientific Advances* represent a significant advance and update on earlier social cost of GHG numbers put forward by the Interagency Working Group.

Several commenters, however, provide suggested changes for EPA to consider. For example, at least one commenter, who’s remarks centered around ‘dynamic discounting’ believes that the central numerical value for the Social Cost of Carbon (SCC) in the EPA report and the discounting methods used to reach this value have strong independent support from the academic literature – i.e., are consistent with academic findings and broader international policy guidance. While the commenter acknowledges that the numerical values for several of the underlying parameters are consistent with academic findings and broader international policy guidance, they

suggest that the EPA report is overly constrained by its purely positive framework and urge the Agency to put more weight on normative arguments. The commenter maintains that this approach/position would be clearly justified by the latest academic literature and would also make it easier for EPA to justify its modeling choices.

Similarly, another commenter offers additional technical observations – e.g., the EPA report would benefit from referring to its discounting approach as ‘risk-adjusted’ rather than ‘dynamic’ – concerning the summary statistics of the SCC, beyond the mean, that are given in the EPA report, and question whether these statistics/data provide information that is likely to be relevant for policy purposes. The commenter recommends that the EPA focus solely on the mean estimate of the SCC based on the central discount rate. Another commenter asserts that EPA’s discount rate range is too high based on the evidence presented by the Agency and recommends that the Agency shift down its short-run, risk-free discount rate range to 0.5%–2.5% with a central rate of 1.5%. While one commenter believes that EPA appropriately accounts for climate damages globally in the draft report, and that adopting a global value is economically sound and consistent with the approach EPA first developed under the George W. Bush administration, and in line with Circular A-4 (2003)’s recommendation that agencies report “effects beyond the borders of the United States”; the commenter asserts that this approach has sparked unmeritorious legal challenges claiming an inconsistency with standard administrative practice, and as a result, recommends that the EPA should situate its consideration of global climate damages in administrative precedent.

Another commenter expresses their appreciation and support for EPA’s proposed framework for enabling use of advanced technologies in the December 2022 Supplemental Proposal – reflecting how rapid advancements of such technologies can lead to greater emission reductions through earlier and more frequent detection of fugitive emissions as well as intermittent and persistent emission events. While the commenter agrees that the December 2022 Supplemental Proposal includes essential elements to incentivize the deployment of advanced technologies thereby securing larger methane emissions reductions more quickly, including the advanced technology matrix, they offered several comments that identify areas for EPA to align the matrix requirements to encourage owners and operators to use advanced technologies to ensure greater and more cost-effective emission reductions.

### ***1.4.3 Industry/Trade Association***

#### **Support**

Roughly 29 percent of comments received from industry representatives (including industry associations) on EPA’s supplemental action, *Standards of Performance for New, Reconstructed, and Modified Sources and Emissions Guidelines for Existing Sources: Oil and Natural Gas Sector Climate Review*, 87 Fed. Reg. 74,702 (December 6, 2022), generally support one or more requirements of the December 2022 Supplemental Proposal.

Most industry representatives prepared technical remarks of the December 2022 Supplemental Proposal based on factors that are unique to their members. Some commenters formally endorsed

or incorporate (by reference) one or more arguments made by other trade groups and industry stakeholders. While commenters support many aspects of the December 2022 Supplemental Proposal as drafted, nearly all the commenters agree that the EPA should continue to build on the progress in the December 2022 Supplemental Proposal and highlight specific areas in the proposal where they believe further improvements, or additional clarification are warranted. Specific areas of concern and/or recommendations made vary; however, two central themes or areas often discussed include: usage of advanced methane monitoring technologies and the allowance of states to leverage existing state programs.

A majority of industry/trade association commenters appreciate and support EPA's proposed framework for enabling use of advanced technologies in the December 2022 Supplemental Proposal (as an alternative to AVO, OGI, or Method 21) for methane LDAR, many also support efforts to further refine these frameworks to ensure that advanced methane monitoring technologies, including alternative periodic screening and continuous monitoring systems, can be successfully utilized by operators and that their ongoing development will be incentivized. These comments and recommendations generally centered around four (4) key points:

- Regulatory treatment of camera-based continuous monitoring systems under the supplemental proposal;
- Incentive for operators to utilize advanced technologies under the screening matrix;
- Alternative test methods application and use of FEAST modeling as part of an application Consideration of the intermittency of super-emitters in EPA's FEAST modeling simulations; and
- Use of cameras to comply with flare inspection under Method 22.

Some commenters reaffirm their commitment to reducing emissions and noted that they are proactively working with state regulatory agencies to develop reasonable requirements for the protection of air quality. These commenters underscore the point that many state agencies have already implemented regulations to reduce VOC and methane emissions from the same source categories included in NSPS OOOOb and EG OOOOc. In an effort to reduce administrative burdens and provide flexibility to states in the development and submittal of state plans (as intended by Congress), commenters requests that the EPA allow states to leverage existing state programs by submitting total program evaluations to demonstrate equivalency with EG OOOOc, which, according to at least one commenter is consistent with CAA section 111(d) and will promote, rather than disincentivize, future state efforts to adopt state programs for the control of emissions from the oil and natural gas industry, and other industry sectors.

It is worth noting that several commenters pitched company-owned methane reducing technologies, which they maintain are proven, scalable and cost-effective – e.g., Crusoe's Digital Flare Mitigation® (DFM) systems BSM's NIRview™, ZEVAC's Zero Emission Vacuum and Compressor, and Qnergy's Compressed Air Pneumatics, CAP3 system – emerging or currently available.

## Oppose

Roughly 51 percent of comments received from industry representatives (including industry associations) on EPA's December 2022 Supplemental Proposal, *Standards of Performance for New, Reconstructed, and Modified Sources and Emissions Guidelines for Existing Sources: Oil and Natural Gas Sector Climate Review*, 87 Fed. Reg. 74,702 (December 6, 2022), generally oppose one or more requirements of the Proposal.

Most industry representatives prepared individual, separate technical remarks – e.g., on record keeping and reporting requirements to processing of well plugging operations to encouraging community involvement that results in unqualified, unprotected residents visiting oil and gas production facilities – on the supplemental proposal based on factors that are unique to their members. However, many of the commenters express concerns regarding the supplemental proposal's (disproportional) impact on small oil and gas producers/businesses – many of which operate low production wells (i.e., wells with a production level less than 15 barrels per day [or equivalent gas production]) – and the states that rely on these producers/businesses for economic viability.

Commenters worry over their members' ability to implement and comply with regulations; stating that many of their members, for example, are limited in staffing and may not be able to manage day-to-day office activities and field maintenance work efficiently and effectively, without substantial support. Consequently, several commenters ask that the EPA maintain the low-production well exemption, which they contend would provide significant relief for small businesses without measurable environmental impacts.

Several commenters acknowledge that reductions in emissions from the oil and gas sector are needed to mitigate the predicted impacts of global climate change. To that end, commenters describe existing voluntary efforts and those currently underway by industry leaders to address methane emissions and improve air quality. Moreover, many of these commenters strongly object the proposal's one-size-fits all approach, which they believe fails to adequately account for impacts to small businesses – proposal largely ignores the fact that different wells have different production and emission characteristics. At least one commenter proclaims that EPA never revised the LDAR technology requirements to reflect inclusion of low production wells, which according to the commenter is significant, because the cost-effectiveness of an LDAR program is very different for large well sites compared to small business low production wells. A few commenters worry about compliance and implementation impacts on wells located in predominantly rural areas and have limited access to power.

In addition, some commenters assert that EPA's December 2022 Supplemental Proposal fails to consider the third-party U.S. DOE study titled, "Quantification of Methane Emissions from Marginal (Small Producing) Oil and Gas Wells," on low-production well emission profiles. Many of the commenters suggests that the Agency review and consider data presented in the study when developing a baseline that shows distinctions between large wells and low

production wells and the difference that exist between types of wells – when developing low production well regulations. At least one commenter suggests that the EPA reconstruct the regulation to provide that as wells decline to the low production well threshold, these wells would move into the low production well requirements.

Other commenters formally endorsed or incorporate (by reference) one or more arguments made by other trade groups and industry stakeholders.

### Other

Approximately 12 percent of the industry comments respectfully request an extension of the public comment period (anywhere from 60- to 90-days, with one commenter requesting a 30-day extension) for EPA's *Standards of Performance for New, Reconstructed, and Modified Sources and Emissions Guidelines for Existing Sources: Oil and Natural Gas Sector Climate Review (Supplemental Proposed Rule)*; citing, in general, insufficient time to respond adequately and appropriately – to fully review the December 2022 Supplemental Proposal, the supporting material, and provide meaningful comments. Several commenters specifically point to the breadth (number of pages) and depth of the issues in the proposal, as well as the estimations of significant cost implications.

Many of these commenters question the timing of the proposal as its publication date coincide with several other recently release draft rules – as lengthy and complicated, including BLM's Waste Prevention, Production Subject to Royalties and Resource Conservation rule; proposed revisions to CAA section 111(d) regulations [published in the *Federal Register* on December 27, 2022]; proposed revisions to the definition of “waters of the United States” (WOTUS), and public comment period spans extending over three (3) holidays, ultimately reducing the amount of time stakeholders must respond.

At least one commenter (representing a professional trade association located in Alaska) explains that several of the proposed rules sweeping changes to the performance standards and monitoring methods that oil and gas producers must deploy to control and monitor methane emissions in multiple operational sectors may not be feasible in the harsh climatic conditions, nor realistic or practical for Alaska's North Slope operations. Due to Alaska unique conditions, the commenter appreciates a deadline extension to allow for meaningful comments.

Furthermore, less than 9 percent of commenters submitted separate supportive documents, including copywritten materials (in addition to their primary comments).

### ***1.4.4 State/Local/Tribal/Federal Governments***

#### Oppose

Roughly half (approximately 55 percent, made up exclusively of state and tribal agencies) of the comments submitted by government agencies and representatives generally opposed, as written,

*EPA's Supplemental Notice of Proposed Rulemaking: Standards of Performance for New Reconstructed, and Modified Sources and Emissions Guidelines for Existing Sources: Oil and Natural Gas Sector Climate Review: Published 87 Fed. Reg. 74702 (December 6, 2022).*

Specific concerns vary by commenter. In some cases, commenters restate or incorporate by reference concerns outlined in their initial comments submitted on the original proposal.

While most commenters appreciate EPA's work in drafting the December 2022 Supplemental Proposal and appreciate the underlying goal to protect public health, safety, and the environment, many believe the proposed EGs are redundant (due to existing oil and natural gas state-level laws and regulations) and create unnecessary confusion and regulatory burdens –e.g., making implementation infeasible given the massive increase of affected facilities and the corresponding mountain of additional requirements pertaining to compliance, permitting, emissions inventories, the development of State plans, and other air quality aspects. Furthermore, commenters maintain that the December 2022 Supplemental Proposal also lays out unrealistic assumptions and artificially high metrics to estimate the climate benefits of the rule. In general, commenters urge the EPA to reconsider the proposed EGs and consolidate existing applicable regulations and streamline proposed requirements for new and existing sources in the oil and natural gas industry.

Commenters maintain that EPA's "one-size-fits-all" approach does not adequately consider or reflect how rulemakings may affect certain states differently than others. One commenter asserts that the December 2022 Supplemental Proposal has an outsized impact upon states whose economies are resource dependent; adding that many of these states have significantly smaller staffing and less funding available compared to other state agencies. At least one commenter claims that the EPA has not performed a proper Unfunded Mandate Reform Act (UMRA) analysis because the proposal and its analysis fails to represent potential costs that state-level regulatory agencies will have to bear to meet the implementation requirements of the supplemental proposal. In similar remarks, some commenters express their concerns over the December 2022 Supplemental Proposal requirements (i.e., EG OOOOc) for state-level agencies to justify and apply for an alternative standard that takes into consideration the remaining useful life (RULOF) of a designated facility and other factors outlined in the proposed regulatory text; arguing that these requirements would create impractical workloads and resource burdens – on state regulatory agencies due to the sheer volume of affected sources that should be considered for remaining useful life and other factors. Commenters agree that the Agency must provide sufficient funding to offset or lessen the burden placed on states under the proposed rule and any resultant supplemental actions, as well as provide adequate time for states to meaningfully consider EPA final action and develop an implementation plan accordingly.

Regarding the super emitter program, at least one commenter asserts that the program is unlawful. The commenter further expresses their concerns over the redundancy or conflict with established state delegated programs, the lack of clear communication to delegated authorities of super-emitter events, the potential time-lag present in third-party monitoring systems, the lack of

established ground truthing protocol and the perception these third-party monitors will have some fashion of non-delegated regulatory authority, to name a few.

A few commenters (including one commenter representing a coalition of local governments) express their concerns that the proposal exceeds EPA's statutory authority under the CAA and will significantly limit domestic energy supply. Many of the commenters underscore that the oil and gas industry is currently heavily regulated by state agencies – i.e., they currently comply with a number of state-specific emission guidelines, monitoring requirements, and technical requirements for existing storage tanks, separation vessels, dehydration units, pumps and controllers, and compressor stations, and warn against additional regulations – during a time where energy supply is fluctuating as a result of international conflict – that could result in result in unpredictability and ambiguity for industry operators (particularly on small businesses in the oil and gas production sector) as well as state regulators.

At least one commenter asserts that the December 2022 Supplemental Proposal does not account for increased costs for alternate sources of energy due to loss of natural gas production if the wells are plugged rather than implementing emission control equipment and contends that a large amount of oil and gas would be removed from the marketplace, increasing costs to the public.

Several commenters suggest that the Agency streamline regulatory requirements (e.g., for various source categories, including storage vessels, controllers, pumps, etc.) by allowing both the industry and state regulators to determine regulatory applicability based on a singular date; adding that this approach would enable states then streamline their regulations for the oil and gas industry when submitting their state implementation plans (SIPs) to comply with the emission guideline. At least one commenter requests that the EPA add the following sources – glycol dehydration units, pigging operations threshold for multiple sources controlled by a single device – to the existing proposed regulatory requirements.

Several other commenters (including tribal groups) suggests that the December 2022 Supplemental Proposal lacks transparency. Commenters suggests that a lack of consultation and simultaneous comment periods on multiple significant proposed rules prevents meaningful engagement and completely disregards cooperative federalism. Commenters strongly recommend that the Agency conduct meaningful engagement with state/tribal co-regulators before promulgating a final rule. One commenter (representing tribal businesses and community) reminds that their members rely on oil and natural gas production as a revenue source instead of a tax base. The commenter adds that while there are parts of the proposed rule which would impose more stringent regulation that they are in support of, the commenter cautions the EPA against overregulation and ask that the Agency defer to tribal law. Moreover, one commenter states that the program is a direct attack on tribal sovereignty.

Commenters express additional concerns over the proposed timeframe for compliance and implementation and strongly believe that the supplemental proposal has the potential to disproportionately impact tribal regulatory agencies and urge the Agency to ensure funding

mechanisms for tribal entities that implement these regulations. At least one tribal agency commented on applicability as it relates to facilities located in Alaska recommends that any requirement, or exemption, that is written specifically as applicable to those facilities also include language allowing for a similarly relaxed requirement or exemption for any facility located elsewhere that can show just cause as determined by the Administrator.

### Support

Roughly 21 percent of states, federal and tribal representatives generally support one or more of the requirements in the December 2022 Supplemental Proposal and encourage the quick adoption of *Standards of Performance for New, Reconstructed, and Modified Sources and Emissions Guidelines for Existing Sources: Oil and Natural Gas Sector Climate Review* rulemaking.

Commenters prepared and submitted individual, separate remarks on the proposed rule based on factors that are unique to their state or tribal community. Some commenters restate or incorporated by reference remarks outlined in their initial comments submitted on the November 2021 Proposal. Specific areas of support vary by commenter and commenter type – e.g., support for closure plans and super emitter response program requirements.

While commenters largely support the proposal as written, a few commenters offered technical comments and/or one or more recommendations aimed at further strengthening the supplemental proposal/rules. Some concerns expressed (i.e., surrounding compliance implementation, meaningful engagement, and the need for the Federal agency to provide states/local/tribal governments with adequate funding support) mimic those expressed by non-governmental representatives (including private citizens, environmental groups, etc.).

In addition, a number of commenters (including a Trustee of state employees) share recommendations that are identical to or resemble recommendations proposed by non-governmental representatives (including private citizens, environmental groups, etc.) – such as, ban and/or limit flaring to emergencies situations only, strengthen requirements for storage tanks, provide a clear pathway for communities and individuals to participate and engage in the Super Emitter Response Program, expand routine monitoring (increase frequency), transitioning to zero-emitting technologies for controllers.

At least one comment letter (representing multiple Members of Congress) requests that EPA consider consultation with small, family-owned businesses/producers who are impacted by the rule; adding that while many larger entities can comply with new regulations, smaller companies may struggle to adopt technologies mandated by EPA, thus further highlighting the importance of technology flexibility.

Commenters applaud the EPA's efforts, in general, in creating a more comprehensive approach to reducing methane – a potent GHG – from the oil and natural gas industry; adding an action that will help the U.S. meet its climate change mitigation goals. At large, commenters believe that the

implementation of the supplemental proposal (and its adjoining rule) will result in significant climate benefits as well as direct health benefits to communities harmed by local and regional emissions, including low-wealth, communities of color (including tribal communities).

Overall commenters believe that the December 2022 Supplemental Proposal (and its adjoining rule) will ensure innovation is encouraged in the private sector and maximize emission reductions at the least cost to consumers as well as ensure accountability and reliability in, for example, identifying methane and VOC leaks through the use of advance monitoring technologies. Commenters urge EPA to work together with states to promulgate regulations that comply with the CAA and allow for the broadest variety of methane emissions detection technologies, or combinations of technologies, while driving towards the use of best available technologies to measure actual site-level emissions.

One commenter (representing over 150 principal member Tribes) appreciates EPA's public outreach efforts and expressed desire to collect input from a broad range of stakeholders; however, the commenter requests that these efforts not only continue, but that they be expanded, particularly with respect to coordination and consultation with Indian Tribes; noting that each tribe's unique circumstances must be evaluated. The commenter stresses the importance of addressing environmental justice implications of the proposed action and seek to advance equity for all; however, they underscore the point that that concern for environmental justice cannot replace government-to-government consultation with Tribes. The commenter (along with separate tribal organization) underscores the point that tribes are sovereign nations with self-determination, as such, one of the commenters adds that they cannot be treated like EJ communities.

At least one commenter urges the EPA to reconsider its proposal to solely rely on the use of audio, visual and olfactory (AVO) monitoring techniques at wellhead-only or small well sites.

Another commenter's (representing a federal lobbying group) remarks primarily focus on vulnerabilities and the methane proposal's use of the Interagency Working Group's (IWG) social cost of greenhouse gas (SC-GHG) estimates and on EPA's External Review Draft of Report on the Social Cost of Greenhouse Gases: Estimates Incorporating Recent Scientific Advances ("External Review Draft"). The commenter identifies one or more areas of concern – e.g., EPA's decisions to include the External Review Draft in the Methane Proposal also hinders the credibility of the External Review Draft and urges the Agency to withdraw the External Review Draft from this rulemaking and defer to the IWG's process for updating the SC-GHG values. In a similar but contrasting comment, one commenter (representing a bipartisan coalition of governors) applauds the inclusion and utilization of updated estimated values for the SC-GHG in the proposal's accompanying draft report, *The Social Cost of Greenhouse Gases: Estimates Incorporating Recent Scientific Advances*. According to the commenter, these estimates are informed by the latest science, account for global damage estimates, and include an appropriate range of discount rates, and is particularly timely as action from the IWG remains unfinished.

## Extension

Remaining comments (approximately 24 percent, predominately state representatives) ask that the EPA extend the public comment period (anywhere from 30- to 60-days); citing, in general, insufficient time to respond adequately and appropriately. Nearly all commenters reference the length and complexity of EPA's proposal (hundreds of pages and multiple supportive documents to review) as the primary reason for requesting an extension and insist that an extension will lead to a more robust and comprehensive set of comments that will ultimately lead to a stronger final rule. At least one commenter suggests that an extension shouldn't be a problem since there is no statutory or court ordered deadline associated with the proposed rule.

### ***1.4.5 Environmental and Public Advocacy Groups***

## Support

Comments (about 90 percent) from environmental and public advocacy groups overwhelmingly support (one or more requirements found) the December 2022 Supplemental Proposal and appreciate the Agency's efforts to reduce methane emissions from oil and gas operations and urge the Agency to swiftly adopt the strongest possible rules.

Several commenters briefly discuss climate change impacts, including its effect on public health (especially on families living near gas wells, and the safety and livelihoods of indigenous and low-income communities/communities of color), and in some cases, even offer state-specific examples of violations or air quality. Commenters agree that the December 2022 Supplemental Proposal (and its adjourning rule) is one of the best opportunities to help slow the rate of climate change and protect our health.

While supportive of the Agency's efforts to reduce emissions, many of the commenters also echo feelings noted by other commenter types (including private citizens, academia, industry, etc.) that the proposed rule does not go far enough.

Consequently, many of these commenters' support and reiterate one or more proposed regulatory changes (many of which have been discussed already) also supported by non-environmental and public advocacy groups – e.g., banning/limiting flaring to emergency events only, requiring a zero-percent leak rate from controllers, addressing leaks from storage tanks, providing a clear pathway for communities and individuals to participate in the Super Emitter Response Program. Regarding the proposed timeline, at least one commenter, recommends that the EPA offer states and gas companies' incentives for the early adoption of these necessary public health standards while also increasing air monitoring at oil and gas facilities to identify malfunctioning equipment prior to enforcement deadlines.

At least one commenter disagrees with industry concerns that the proposed rule would be overly costly/burdensome with little benefits; stating that the EPA systematically underestimates methane emissions from oil and gas drilling and transport activities, the benefits of controlling

those emissions also have been underestimated (according to Institute for Energy Economics and Financial Analysis finding) and as a result, the oil and gas industry margins will be greater—not smaller—if the new EPA methane rules are implemented.

One commenter refers to research done by the University of Cincinnati in southeastern Ohio, that suggests wells that produce less than a barrel of oil per day leak into the atmosphere more than 100 percent of their reported gas production. According to the commenter, gas wasted by these low-producing wells could meet the heating and cooking needs of nearly every home in the State of Ohio.

A small number of comments (approximately 6 percent) prepared and submitted are written copies of verbal testimonies presented at the January 2023 public hearing and/or copies of supporting documents referenced in verbal testimonies.

### Oppose

Roughly 5 percent of commenters generally opposed the December 2022 Supplemental Proposal, as written; suggesting it is flawed and lacks transparency, and requests that the Agency withdraw the rule. Specific concerns vary by commenter. Several of the commenters suggest that the EPA's December 2022 Supplemental Proposal (and its adjoining rule) overstep EPA's authority. At least one commenter asserts that the Agency continues to ignore/arbitrarily disregard the principles and regulatory analysis established in Circular A-4 (2003) – a guidance document to federal agencies on developing regulatory analyses required by Executive Order 12866, and the requirement of a 7 percent discount rate. At least one commenter questions the accuracy of EPA's data and stress the need for physical evidence verse speculation or theories. In a similar comment, after thoroughly reviewing EPA's draft new methodology, one commenter finds that the methodology and estimates are not yet scientifically reliable and robust for policy use – i.e., contains multiple significant technical issues and does not satisfy the National Academies of Sciences, Engineering, and Medicine (NASEM) recommendations. The commenter maintains that key issues – e.g., increase transparency, justification, scientific basis, and incorporation of uncertainty should be addressed before the estimates are deployed to inform policy, for this rule and otherwise. Another commenter objects to the SCC model used for the rule's cost-benefit analyses; moreover, ask that EPA revise its supporting documents – e.g., Fact Sheet and TSD to account for/consider rises in sea-level.

### Other

Remaining commenters (about 6 percent) requested an extension of the public comment period (by an additional 90-days) or an additional day to the scheduled January 2023 public hearings. At least one commenter, cited insufficient time to respond to requests adequately and appropriately as a reasoning. Another commenter (interested in extending the public hearing) suggests that interest to participate in scheduled hearings was high and as a result, registration slots to provide

verbal testimonies filled nearly a month before the hearing was scheduled to take place, leaving out remaining interested participants.

#### ***1.4.6 Other/Other Advocacy Groups***

##### **Support**

Most comments (over 80 percent) received from other advocacy groups (comprised mostly of private equity/investment firms and union organizations) support the proposed updates to the NSPS and EG (under the December 2022 Supplemental Proposal). Overall, commenters commend EPA's efforts to adopt commonsense, cost-effective regulations that reduce transition risks to oil and gas investments, while addressing/reducing methane emissions from oil and gas operations – the largest source of industrial methane emissions in the U.S. At large, commenters encourage EPA to continue to build on the progress in the December 2022 Supplemental Proposal and move swiftly to finalize the strongest, most comprehensive rules and standards possible.

Commenters (representing investors/investment management firms) stress their commitment to integrating environmental, social, and governance (ESG) factors into investment management decisions, and ask that the Agency establish a transparent, credible, and empirically based methane emissions reporting framework to improve the accuracy and credibility of reported methane emissions data that would allow investors (i.e., investment management firms) to clearly differentiate between “leaders” – enterprises with strong financial underpinnings, sustainable business models, prudent management practices, and a governance structure that supports these objectives – and “laggards”.

Various commenters remind EPA that methane is a GHG and agree that the rule is an important step in identifying sound investments needed to reduce methane emissions – the cheapest and easiest means of reducing the industry's GHG footprint – tackle climate change, and help address public health issues, while also offering economic opportunities – support quality, family-sustaining jobs and a way to meet air quality goals outlined in, for example, the Paris Agreement.

While commenters applaud EPA's effort to strengthen and broaden the NSPS and EGs, most commenters believe that it does not go far enough and call on the EPA to further tighten rules surrounding the release of methane emissions from the oil and natural gas industry. In these cases, commenters often highlight specific areas in the rule where they believe further improvements, or additional clarification are warranted, and offer one or more recommendations aimed at toughening/clarifying EPA's final rule (and its underlying analysis) and maximizing net benefits. Several of the recommendations provided mimic those offered in one or more mass campaign mailer – e.g., strengthen leak monitoring requirements to include low-production wells, transition to zero-emitting technologies for pumps/controllers, ban/limit flaring to only cases of emergency.

A few commenters expressed concern over the health and wellbeing (safety risks) of workers and local communities – vulnerable populations located near oil and gas facilities, which commenters argue are disproportionately impacted. While commenters agree that the proposed updates to the rule could aid in addressing environmental justice issues, they also agree that critical changes to the rule are still needed to address EJ concerns effectively and efficiently – i.e., continue to allow communities the ability to monitor pollution, reduce the timeframe between high level of pollution notification and responses, adequately reward notifiers, and strengthen documentation requirements.

At least one commenter states that they support EPA’s analytical proposal to put the social cost of carbon equivalents (SC-CO<sub>2e</sub>) at \$190/mTon based on extensive research and analysis, and also suggests that this proposed baseline for damage costs is most likely overly conservative due to what they believe are several omissions in EPA’s analysis which probably justify the higher of the three benchmark pricing points of \$340/mTon.

### Oppose

Approximately 16 percent of commenters (including one leasing management company) oppose the proposed rule as written. Technical commenters and remarks covering specific areas of concern vary from commenter to commenter. Some commenters question, in general, the quality (and accuracy) of the data used in developing proposed requirements, and techniques used to accept, reject or qualify data. One commenter (representing a management company) asserts that the supplemental proposal (and its adjourning rule) is based on dated information – pulled from large producers in operations in 1974, and therefore, not valid for current operations, particularly operations of small, marginal producers. The commenter states that ignoring difference between large 1974 operations and 2023 small operations is totally unacceptable and should never be used for proposing new rules, and instead urges the Agency, in finalizing this rule, to utilize recent data generated and made available by the Department of Energy (DOE).

Another commenter maintains that if implemented, the proposed standards will impose real and significant compliance costs in the pursuit of illusory climate benefits. The commenter further states that EPA’s reliance on the Interagency Working Group’s (IWG) deeply flawed social cost of greenhouse gases (SC-GHG) methodology to estimate the proposal’s net benefits renders the entire exercise vulnerable to challenge as arbitrary and capricious, and therefore, should be withdrawn.

One commenter (West Virginia Surface Owner's Rights Organization) (comprised of roughly 800 members) that represents West Virginia’s surface owners expresses concern about limiting inspections to only AVO inspections in some instances. The commenter questions the adequacy of AVO inspections to effectively detect methane leaks and its overall purpose/need considering the availability of lost-cost alternative methane detection technologies – e.g., Amazon results in a wide choice of meters capable of detecting methane appearing starting at a price of only \$32.

## Chapter 2. Legal Basis for Rulemaking

### 2.1 EPA's Statutory Authority under the Clean Air Act

#### *2.1.1 Supplemental Proposal Exceeds EPA's Statutory Authority Under Section 111(d) of the CAA*

Comment: Commenters (2237-NDIC, 2241-UDNR, 2252-PAW, 2254-PBPA, 2292-WV AG et al, 2428-API) contend the supplemental proposal exceeds EPA's statutory authority under the Clean Air Act (CAA). Specific comments are provided in the following paragraphs.

Commenter (2237-NDIC) contends that this EPA proposal to impose a national one-size-fits-all best system of emission reduction (BSER) as the default baseline requirement for state plans violates section 111 of the CAA. The commenter notes that the EPA states that a "state plan needs to include a demonstration that the state requirements for designated facilities achieve the same or greater emissions reduction as the designated facility presumptive standards."<sup>1</sup> EPA's claimed performance for BSER technologies are not just estimates of the costs in tons per year (tpy) of emission reductions but are rather emission reduction targets that EPA demands the states to implement and achieve for each BSER source in order to have an "approvable" state plan. The commenter asserts that such an EPA dictate violates section 111 of the CAA and the cooperative federalism enshrined in the CAA by Congress. The commenter asserts that EPA must withdraw the unlawful supplemental proposal or substantially rework it to remedy this unlawful approach.

Additionally, the commenter (2237-NDIC) provides that EPA is unlawfully imposing a national presumptive emission limitation for all state plans. The commenter contends that EPA's presumptive national emission limitation standards for existing sources deprives states of their authority and discretion to control emissions through state plans and are unlawful under section 111(d) of the CAA. Described as an "experiment in federalism," *Michigan v. EPA*, 268 F.3d 1075, 1078 (D.C. Cir. 2001) (quotation omitted), the CAA assigns to the states the primary sovereign role in air pollution prevention and control. According to the commenter, one of the states' principal authorities and responsibilities under the Act is to implement and enforce standards of performance for existing sources of air pollution under CAA section 111(d), using the states' expertise in applying source-specific considerations and factors to establish achievable emission limitations controlling air emissions from those sources.

Commenter (2237-NDIC) also notes that CAA section 111(d) directs EPA's Administrator to "prescribe regulations which shall establish a procedure ... under which each State shall submit to the Administrator a plan which (A) establishes standards of performance for any existing source for any air pollutant . . . and (B) provides for the implementation and enforcement of such standards of performance." 42 U.S.C. section 7411(d)(1). The commenter states that this text reflects the federal-state balance of the cooperative federalism framework created by Congress: EPA is to establish national guidelines (i.e., BSER) for the states to follow in creating their CAA section 111(d) plans, and it is the states, through the state plans, that establish the specific

---

<sup>1</sup> 87 Fed. Reg. at 74,814.

standards of performance (i.e. achievable emission limitations) for the existing sources in their states. The commenter notes that the primary "regulatory authority" and decisionmaker in setting standards of performance for specific individual existing sources under CAA section 111(d) is therefore the state and CAA section 111(d) does not grant EPA the authority to establish nationwide mandatory emission limitations such as the presumptive and fixed standards of performance masquerading as "BSER" in the supplemental proposal, thereby forcing the states to achieve these emission limitations through the state plans. The commenter states that this deprives states of their authority expressly protected under CAA section 111(d), reducing the states' roles to mere extensions of federal authority.

Furthermore, the commenter (2237-NDIC) asserts that EPA wrongly justifies its unlawful extension of its authority by claiming that in *West Virginia et al. v. EPA*, 142 S. Ct. 2587 (2022) "[t]he Supreme Court made clear that CAA section 111 authorizes the EPA to determine the BSER and the amount of emission limitation that state plans must achieve."<sup>2</sup> In fact, the commenter notes that the Supreme Court in *West Virginia* gave no such blessing for EPA to set a BSER that operates as a presumptive national standard of performance, imposing binding emission limitations on the states:

We have no occasion to decide whether the statutory phrase "system of emission reduction" refers exclusively to measures that improve the pollution performance of individual sources, such that all other actions are ineligible to qualify as the BSER. To be sure, it is pertinent to our analysis that EPA has acted consistent with such a limitation [e.g. only choosing BSER measures that could be applied at individual sources] for the first four decades of the statute's existence. But the only interpretive question before us, and the only one we answer, is more narrow: whether the "best system of emission reduction" identified by EPA in the Clean Power Plan as within the authority granted to the Agency in Section 111 (d) of the Clean Air Act. For the reasons given, the answer is no."<sup>3</sup>

According to the commenter (2237-NDIC), the Supreme Court was clear that the general question the scope of EPA's authority under CAA section 111(d) was not before it, and that the only issue it was deciding was EPA's authority to promulgate the BSER in the Clean Power Plan. The commenter notes that the Supreme Court decided that BSER, which sought to impose one-size-fits-all national emission standards on the states, was unlawful and that EPA's claim in this supplemental proposal is incorrect. The commenter also contends that EPA's "position that CAA section 111(d) authorizes the EPA to allow states, in particular rules, to achieve the requisite emission limitation through the aggregate reductions from their sources, and the EPA is accordingly proposing to authorize states to leverage their state programs to satisfy their CAA section 111(d) state plan obligations pursuant to emission guidelines (EG) OOOOc, subject to requirements discussed in the following sections,"<sup>4</sup> is incorrect for several reasons. First, the commenter states EPA must select BSER that can be applied at the source, and not on an aggregate level. Second, the commenter notes that under the cooperative federalism framework of the CAA, EPA is not authorized under section 111(d) to set national emission limitations for

---

<sup>2</sup> 87 Fed. Reg. at 74,812.

<sup>3</sup> 142 S. Ct. at 2615-2616.

<sup>4</sup> 87 Fed. Reg. 74,813.

existing sources. Instead, EPA sets the BSER, based on a technology applicable at a particular existing source, and then the states create their own respective CAA section 111(d) plans with source-specific emissions limitations that the states establish using the BSER guidelines selected by EPA.

Under CAA section 111(d)(1), the commenter (2237-NDIC) asserts EPA does not have the authority to establish and impose presumptive national emission limitations for existing sources, with the sole remaining role of the states being the requirement to implement the national standards through local rules. According to the commenter, EPA is only authorized to "establish a procedure" (42 U.S.C. section 7411(d)(1)) for states to follow when they create state plans containing performance standards established by states applying EPA's BSER. The commenter adds that the EPA's BSER are only to be guidelines (see the title of the supplemental proposal, characterizing the proposed rule as creating "Emission Guidelines for Existing Sources" 87 Fed. Reg. at 74,702), not binding overarching national emission standards for the states or existing sources. According to the commenter, section 111(d) of the CAA is explicit that it is the states, not EPA, that establish the binding standards of performance for existing sources.

Finally, the commenter (2237-NDIC) concludes that EPA's proposed BSER technologies intended as presumptive national binding emission limitations for existing sources exceed EPA's authority under the CAA and deprive states of their authorities protected by the CAA. The commenter argues that EPA must withdraw these presumptive overreaching national standards and instead propose BSER technology guidelines, from which the states can then adroitly create CAA section 111(d) plans for existing sources that set the actual and better tailored localized standards of performance and required emission limitations.

Commenter (2241-UDNR) provides that in the immediate wake of the Supreme Court's decision in *West Virginia v. EPA*, 142 S. Ct. 2587 (2022), the EPA's obligation to identify clear, express statutory authority for rulemaking is heightened.<sup>5</sup> In *West Virginia*, the EPA's rulemaking authority under the sections 111(b) and (d) of the CAA came under scrutiny. It is precisely these same sections that the EPA relies on to promulgate the proposed rule and supplemental proposal that are the subject of this current comment letter. In *West Virginia*, the Supreme Court found that the EPA's Clean Power Plan had exceeded their authority, and "had applied too broad an interpretation of 'best system of emission reduction.'"<sup>6</sup> In light of this holding, the commenter encourages the EPA to review the November 2021 proposed rule and December 2022 supplemental proposal to ensure that the current rulemaking process does not also apply too broad an interpretation of "best system of emission reduction" and/or exceed its statutory rulemaking authority under the CAA.

Commenter (2252-PAW) asserts that EPA is overstepping Congress's authority granted to states through the CAA to develop a compliance program for existing sources. The commenter states

---

<sup>5</sup> Tina Van Bockern, Here We Go Again: BLM Issues Another Methane Rule, Holland & Hart, available at: <https://www.hollandhart.com/here-we-go-again-blm-issues-another-methane-rule> (2022); citing *Wyoming v. U.S. DOI*, 493 F. Supp. 3d 1046 (D. Wyo. 2020).

<sup>6</sup> Grace Olson, Understanding the US Supreme Court's Decision in *West Virginia v. EPA*, Great Plains Institute, available at: <https://betterenergy.org/blog/understanding-the-us-supreme-courts-decision-in-west-virginia-v-epa/> (2022).

that the resulting December 2022 proposal imposes \$2.8 billion in annual compliance costs to the oil and gas industry, with most of these costs being borne on existing facilities. The commenter states that this is because the EPA is proposing that the emission controls it will require of new oil and gas facilities are also cost-effective for existing sources, which should instead tier off the EPA's requirements for new sources.

The commenter (2292-WV AG et al) adds that the proposed "presumptive" standards are presumptuous. The commenter asserts that CAA empowers states, not the agency, to create their own implementation plans to reduce methane emissions from existing sources under EPA's supervision. This flexibility includes the right to "establish[] standards of performance for designated facilities" reflecting the EPA-derived emission limits that are achievable through the BSER. The commenter asserts that EPA is trying to squash state agency discretion by channeling it into EPA-drafted "presumptive" plans.

Commenter (2254-PBPA) contends that neither Congress nor (until recently) EPA envisioned CAA section 111(d) being used, as here, to regulate whole sectors of the economy. When EPA first established procedures and requirements for submittal of state plans for control of pollutants from existing facilities under CAA section 111(d), the commenter notes that the EPA stated that under CAA section 111(d) "extensive control strategies are not required," State plans would "be much less complex," and "the number of designated facilities per State should be few." Indeed, the commenter adds that the EPA has only rarely promulgated CAA section 111(d) standards and only for industry-specific pollution issues like acid mist emissions from sulfuric acid plants. According to the commenter, the EPA's infrequent and narrow use of CAA section 111(d) confirms that this provision was understood to allow limited regulation of existing sources and that the provision was a secondary part of the overall statutory scheme. The commenter states that this also applies to the EPA's remaining useful life and other factors (RULOF) proposal, which they believe inappropriately constrains states in contravention of EPA's prior practice and the flexibility Congress provided in CAA section 111(d). The commenter asserts that this goes too far, and EPA has failed to adequately explain or justify its departure from prior practice.

Response II-2-1: The commenters raise a series of issues related to EPA's authority to establish the BSER for existing sources. These comments lack merit. First, the commenters argue that EPA's determination of the BSER for emission sources improperly sets nationwide mandatory emission limits for these sources. Contrary to commenter's assertions, EPA's emission guidelines do not include a prescriptive "one-size-fits-all" BSER analysis. Rather, the emission guidelines are based on aggregate information that represents what EPA believes to be the BSER for an "average" existing source, taking into account the statutory criteria in section 111. EPA agrees with the commenters assertion that the CAA allows state to set standards of performance for existing sources. However, EPA also has a role to play in that process. Under EPA's longstanding regulations in subpart Ba (and the predecessor subpart B), along with the newly promulgated revisions to subpart Ba, EPA's emission guidelines include information to assist states with developing their standards of performance, including the degree of emission limitation achievable through application of that BSER. A fuller discussion of the role of EPA in identifying the BSER, and of the role of States in establishing standards of performance for existing sources is including in the record for the separately finalized Subpart Ba rulemaking.

The comments addressing the Subpart Ba rulemaking are addressed in the record for that rulemaking.

Next, the commenters contend that EPA lacks authority to determine what emission limitations are achievable by existing sources, and that EPA's determination of the BSER usurps the role of the States. That is incorrect. Unless EPA specifies "the degree of emission limitation achievable through application of" the BSER, under section 111(a)(1), States would lack meaningful guidance on what plans EPA would find "satisfactory," section 111(d)(2)(A). EPA's regulations therefore require the agency to specify the degree of emission limitation achievable. 40 C.F.R. 60.22a(b)(5). The Supreme Court's decision in *West Virginia* is consistent with the EPA's understanding. For a discussion of the factors that the EPA considered in establishing the BSER and degree of emission limitation for existing sources in the EG, as well as the states' role in establishing standards of performance implementing this EG (including the authority to establish less stringent standards), see section XIII of the preamble for this final rule.

Lastly, the EPA recognizes that it has promulgated fewer emission guideline rules than New Source Performance Standards. This does not undermine the EPA's authority to establish the emission guidelines here. The EPA's authority to establish emission guidelines for this source category is discussed at length in section IV of the preamble for this rule.

### ***2.1.2 EPA Does Not Have Authority to Modify the CAA***

Comment: Commenters (2200-NuEnergy, 2257-MOGA) question the authority of EPA to make modifications to the CAA without congressional approval.

Commenter (2200-NuEnergy) states that the CAA was originally written and authorized by the federal government through the House of Representatives and approved by the Senate in the early 1970's. The commenter contends that revisions, additions, and changes that have been authored and approved solely by the EPA without elected congressional input or voting for approval is likely illegal. According to the commenter, this does not allow the people of the U.S. to have a voice and questions whether EPA is only listening to non-governmental organizations (NGOs) to create regulations.

Commenter (2257-MOGA) refers to a previous request that they made to EPA to provide clarification of the validity of arguments made by the EPA in the "2020 Methane Rollback Rule" published in the *Federal Register* regarding the ability of the EPA to regulate methane under the CAA based on the premise that Methane was not listed as a known chemical detrimental to human health and the environment. The commenter inquired at that time whether Congressional modification to the CAA was necessary to add methane to the CAA. Since the EPA referenced the Methane Rollback regulations in the December 6, 2022, proposed regulations, the commenter believes that the EPA provided argument to the validity to the Methane Rollback rule and should provide explanation as to why EPA now believes it has legal authority to regulate methane without Congressional modification to the CAA. According to the commenter, without Congressional approval from both the Federal House of Representatives and the U.S. Senate, additions, removals, or edits to the CAA are not considered binding. Also, the commenter is requesting clarification from the EPA regarding the permissible time allotments between any rule

changes to the CAA. The commenter notes that review of the 1970 rule suggests significant modifications to the rule may not be more frequent than 7-year cycles without Congressional approvals.

Response II-2-2: As the EPA explained in the 2016 rule, CAA section 111 authorizes the EPA to regulate GHG emissions, including methane, from the oil and gas source category after determining that it is rational to do so or, in the alternative, after making a GHG-specific significant contribution finding. The EPA made those findings and therefore is authorized to regulate GHG emissions in the form of methane from the oil and gas source category. The 2016 rule and this action are fully consistent with CAA section 111, for the reasons explained in the preamble and in the various chapters of this Response to Comment document. The EPA has received input and comments from numerous entities, including industry and states, and has responded to those comments.

### ***2.1.3 Proposals are Consistent with West Virginia v. EPA Court Decision***

Comment: Commenter (2433-EDF et al) addresses the impact of the Supreme Court’s June 2022 decision in *West Virginia v. EPA*.<sup>7</sup> In that case, the Court considered EPA’s authority under CAA section 111(d) to establish CO<sub>2</sub> EGs for existing fossil fuel-fired power plants. Specifically, the Court held that in designating the “best system of emission reduction” for such sources, EPA lacked authority to include emission reduction measures based on generating-shifting—that is, measures reflecting the opportunity for grid-level shifts away from existing fossil-fired electricity generation like coal and gas plants and toward new renewable energy like wind and solar generators.<sup>8</sup> According to the Court, a generation-shifting approach for the electric power sector entailed a “transformative expansion” of its section 111(d) authority<sup>9</sup> and effected a “fundamental revision of the statute.”<sup>10</sup> Thus, under the “major questions doctrine,” a section 111(d) rule based on generation-shifting required explicit authorization in the CAA, which the Court found lacking.<sup>11</sup>

According to the commenter (2433-EDF et al) the NSPS OOOOb and EG OOOOc proposals are fully consistent with the Court’s decision in *West Virginia*. In reaching its decision, the court contrasted generation-shifting—which reduces the emissions of the “overall power system” by requiring dirtier sources to operate less often in favor of cleaner, non-regulated sources—with traditional “technology-based” CAA section 111 standards, which focus “on improving the emissions performance of individual sources.”<sup>12</sup> The commenter states that EPA’s proposed NSPS OOOOb and EG OOOOc rules fall squarely within the latter category: they achieve pollution reductions entirely through the use of source-based technologies that improve the emissions performance of individual pieces of equipment. Furthermore, the Court in *West Virginia* deployed an interpretive principle—the major questions doctrine—that is reserved for “extraordinary cases ” involving agency actions that, among other unusual characteristics, reflect

---

<sup>7</sup> *West Virginia v. EPA*, 142 S. Ct. 2587 (2022).

<sup>8</sup> *Id.*

<sup>9</sup> *Id.* at 2610.

<sup>10</sup> *Id.* at 2612.

<sup>11</sup> *Id.* at 2614–16.

<sup>12</sup> *Id.* at 2611.

a “transformative expansion [of the agency’s] regulatory authority” and that are purported to have “vast economic and political significance” for the country.<sup>13</sup> The commenter adds that the NSPS OOOOb and EG OOOOc rules reflect the use of readily available technology options that many oil and gas operators already use and support, will allow companies to defray costs and even earn profits in some instances through sale of captured gas, and will have an effectively negligible impact on consumer energy spending. The commenter contends that this is exactly the kind of “ordinary” regulation that simply does not implicate the concerns at issue in *West Virginia*.<sup>14</sup>

Additionally, the commenter (2433-EDF et al.) states that *West Virginia*’s holding confirms EPA’s regulatory authority in one important respect. In particular, the commenter notes that the state of North Dakota previously argued that EPA’s role under CAA section 111(d) was merely an advisory one, and that states, not EPA, were primarily responsible for determining the substantive emission reduction requirements to be achieved by existing sources.<sup>15</sup> The commenter rebutted this position in their comments on the 2021 proposal,<sup>16</sup> and the Supreme Court definitively foreclosed it in *West Virginia*. Even while it ruled against EPA in that case, the Court explained that “[a]lthough the States set the actual rules governing existing [sources], EPA itself still retains the primary regulatory role in Section 111(d)” and “[t]he Agency, not the States, decides the amount of pollution reduction that must ultimately be achieved.”<sup>17</sup> Accordingly, state plans under CAA section 111(d) are “*not to exceed the permissible level of pollution established by EPA*.”<sup>18</sup> The commenter believes that the agency is thus acting firmly within the scope of its authority by issuing EGs for oil and gas methane emissions that establish binding emission reduction requirements to which state plans must adhere.

Response II-2-3: The EPA agrees with the commenters that this rulemaking is consistent with the Supreme Court’s decision in *West Virginia*.

### ***2.1.4 EPA Has the Authority Under the CAA to Establish State Plan Requirements***

Comment: Commenter (2355-Constellation Energy) asserts that EPA has the authority under the CAA to establish minimum requirements, approve state plans that are more stringent than EGs, and allow trading and averaging in state plans. The commenter provides justification for their assertions in the following paragraphs.

Firstly, the commenter (2355-Constellation Energy) agrees with EPA’s interpretation of CAA section 111(d) that the Agency must determine the “degree of emission limitation achievable” by existing sources through application of the BSER and then must translate the degree of emission limitation achievable into minimum standards of performance that states may use in their state

---

ID No. EPA-HQ-OAR-2021-0317-0797), [https://downloads.regulations.gov/EPA-HQ-OAR-2021-0317-0797/attachment\\_1.pdf](https://downloads.regulations.gov/EPA-HQ-OAR-2021-0317-0797/attachment_1.pdf).

<sup>16</sup> See 2022 Joint Environmental Comments, at 211–14.

<sup>17</sup> *West Virginia*, 142 S. Ct. at 2601–02.

<sup>18</sup> Id. at 2602 (emphasis added).

plans. The commenter states that any EGs developed under CAA section 111(d) should establish minimum requirements that are binding, sufficiently stringent, and comply with the statute.

The commenter (2355-Constellation Energy) notes that section 111(d)(1) of the CAA directs EPA to establish a procedure similar to section 110 of the Act for states to submit plans that establish “standards of performance” for air pollutants that are not regulated under section 112 and for which no national ambient air quality standard has been established under section 108(a), from existing sources which would be subject to standards of performance under section 111(b) if they were new sources.<sup>19</sup>

The commenter (2355-Constellation Energy) asserts that this statutory structure contemplates a complementary regulatory approach in which both EPA and the states have a role.

The commenter (2355-Constellation Energy) suggests that the most logical interpretation of CAA section 111(d)(1) when read with the definition of “standard of performance” in CAA section 111(a) is that EPA must determine the “degree of emission limitation achievable” through application of the BSER. “Standard of performance” is defined as:

a standard for emissions of air pollutants which reflects the degree of emission limitation achievable through the application of the best system of emission reduction which (taking into account the cost of achieving such reduction and any nonair quality health and environmental impact and energy requirements) the Administrator determines has been adequately demonstrated.<sup>20</sup>

The commenter (2355-Constellation Energy) believes that the natural reading of this definition supports the conclusion that the “Administrator determines” both the “best system of emission reduction” and the “degree of emission limitation achievable” through that system of emission reduction. This interpretation also would avoid the anomalous result of interpreting or applying the same defined term—“standard of performance”—differently for purposes of CAA section 111(b) and CAA section 111(d)(1). The commenter agrees that CAA section 111(b) directs EPA to establish standards of performance for new sources in listed source categories and does not expressly contemplate a role for states in establishing those standards, whereas CAA section 111(d) directs EPA to develop a procedure for states to submit plans that establish standards of performance. But in both cases, the commenter notes that the statute requires the development of “standards of performance” as defined in CAA section 111(a)(1), and it makes sense for EPA to apply the same interpretation of the definition of “standard of performance” in CAA section 111(d) as in CAA section 111(b).

The commenter (2355-Constellation Energy) reports that the U.S. Supreme Court endorsed this approach as recently as last year, explaining that “ The Agency, not the States, decides the amount of pollution reduction that must ultimately be achieved. . . . The States then submit plans containing the emission restrictions that they intend to adopt and enforce in order not to exceed the permissible level of pollution established by EPA.”<sup>21</sup> The commenter asserts that this

---

<sup>19</sup> 42 U.S.C. § 7411(d)(1).

<sup>20</sup> 42 U.S.C. § 7411(a)(1).

<sup>21</sup> *West Virginia v. EPA*, 142 S. Ct. 2587, 2601–02 (2022).

approach is also consistent with EPA’s previous rulemakings under section 111(d)(1), and with EPA’s general regulations that were in place for more than 40 years.<sup>22</sup> Nothing suggests the Agency has erred for more than four decades in its understanding of the respective roles of EPA and the states in implementing section 111(d)(1).

In the EGs in the December 2022 supplemental proposal, the commenter (2355-Constellation Energy) notes that EPA proposes to translate the degree of emission limitation achievable through application of the BSER into presumptive standards for specific designated facilities. If a state chooses to adopt the presumptive standards as the standards of performance in a state plan and the plan meets all other applicable requirements, EPA would approve the plan as meeting the requirements of CAA section 111(d) and the EGs. The commenter agrees with this approach and suggests EPA finalize presumptive standards for all designated facilities.

The commenter (2355-Constellation Energy) believes that including presumptive standards of performance that represent a minimum level of control in the EGs is critical to the meaningful success of a GHG regulatory regime. This approach would create administrable criteria against which EPA can measure the adequacy of a state plan. The commenter reports that the statute expressly directs EPA to establish a procedure similar to CAA section 110 for the submission and review of state plans, and thus assigns to EPA the responsibility to approve or disapprove state plan submissions. Where the state has failed to submit an approvable plan, the statute mandates that EPA develop one.<sup>23</sup> The commenter states that EPA has long recognized that this approach makes sense only if “Congress intended the [s]tates to prescribe standards on some substantive basis” and intended that substantive criteria—not just procedural criteria—govern EPA’s review of state plans.<sup>24</sup> The commenter asserts that in the absence of any EPA-developed minimum standards, EPA would be unable to review state plans against reasonable, substantive criteria.

The commenter (2355-Constellation Energy) contends that providing minimum standards also substantially eases the administrative burdens on states. Without minimum standards, the state would have to translate, for each affected facility, the degree of emission limitation achievable into a standard of performance, taking into account source-specific features. The commenter believes that where EPA provides presumptive standards, it is less time-consuming and resource intensive for states to develop their plans, submit their plans for review and approval more quickly, and enabling faster implementation of pollution reduction measure.

In addition, the commenter (2355-Constellation Energy) states that providing minimum standards that, if included in a state plan would render the plan presumptively approvable, also provides affected facilities with greater certainty of what will be required. Certainty is necessary

---

<sup>22</sup> Since 1975, when EPA promulgated general regulations governing the establishment of standards under section 111(d) and state plans, EPA has interpreted section 111(d) to require the Agency to set minimum substantive requirements for state performance standards. *State Plans for the Control of Certain Pollutants From Existing Facilities*, 40 Fed. Reg. 53,340, 53,342–343 (Nov. 17, 1975). Indeed, that is the approach EPA has taken every time it has regulated under section 111(d). See 82 Fed. Reg. 65,507, 61,512 n.11 (Dec. 28, 2017) (listing section 111(d) emission guidelines for other categories of sources).

<sup>23</sup> 42 U.S.C. § 7411(d)(2).

<sup>24</sup> *State Plans for the Control of Certain Pollutants From Existing Facilities*, 40 Fed. Reg. at 53,342.

for facilities to plan for investment that achieves the emission reduction goals of the regulation.

Secondly, the commenter (2355-Constellation Energy) agrees that EPA has the authority to approve state plans that are more stringent than required by the EGs, and to render the state plan federally enforceable. The commenter notes that state authority to address air pollution extends to include measures that are not inconsistent with or less stringent than federal law.<sup>25</sup>

Cooperative federalism principles in the CAA demand that EPA protect states' authority to establish requirements and to pursue reductions that exceed minimum federal standards, allowing states to achieve their own goals and initiatives to address air pollution. The commenter reports that the CAA carves out a critical role for states to address air pollution,<sup>26</sup> and the Act does not preempt state authority to exceed the minimum requirements established by the statute or by EPA in regulations promulgated under the statute. The commenter asserts that an interpretation of the Act, including CAA section 116, that EPA does not have discretion to approve state plans that are more stringent than required by the Emissions Guidelines would unlawfully strip states of their authority to establish air pollution measures that exceed minimum federal standards. Once EPA approves such a state plan, the state plan becomes federally enforceable by operation of CAA section 111(d).<sup>27</sup>

Thirdly, the commenter (2355-Constellation Energy) believes that EPA has the authority to allow trading and averaging in state plans. The commenter reports that trading and averaging are familiar mechanisms employed by EPA and states in a variety of programs as powerful tools to achieve cost-effective and meaningful air pollution reductions. The commenter has long supported such market-based programs as enabling an industry to achieve meaningful emission reductions at lower overall cost.

In the December 2022 supplemental proposal, the commenter (2355-Constellation Energy) states that the EPA interprets the CAA to allow the Agency to permit states to include trading and averaging in their plans where permitted by EPA in sector-specific CAA 111(d) EGs. The commenter notes that EPA adopted a more restrictive interpretation in the Affordable Clean Energy rule (ACE Rule)<sup>28</sup> that the U.S. Court of Appeals for the District of Columbia found was inconsistent with the Act.<sup>29</sup> That portion of the D.C. Circuit's decision in *American Lung Association v. EPA* was not disturbed by the U.S. Supreme Court's decision in *West Virginia v. EPA*.<sup>30</sup> The commenter reports that the only question before the Supreme Court was: "whether the 'best system of emission reduction' identified by EPA in the Clean Power Plan was within the authority granted to the Agency in Section 111(d) of the Clean Air Act."<sup>31</sup> In the Clean Power Plan, EPA determined that "generation shifting" is considered part of the "best system of emission reduction" for power plants, and used that "system" to determine "the degree of

---

<sup>25</sup> 42 U.S.C. § 7416 (retention of state authority).

<sup>26</sup> See, e.g., 42 U.S.C. § 7407(a) (providing that states have "primary responsibility for assuring air quality" within the geographic area comprising the state by submitting implementation plans to achieve and maintain national ambient air quality standards).

<sup>27</sup> 42 U.S.C. § 7411(d)(2).

<sup>28</sup> Repeal of Clean Power Plan; Emission Guidelines for Greenhouse Gas Emissions From Existing Electric Generating Units; Revisions to Emission Guidelines Implementing Regulations, 84 Fed. Reg. 32,520 (July 8, 2019).

<sup>29</sup> *American Lung Ass'n v. EPA*, 985 F.3d 914, 957–58 (D.C. Cir. 2021).

<sup>30</sup> *West Virginia*, 142 S. Ct. at 2614-15.

<sup>31</sup> *Id.* at 2615-16.

emission limitation achievable through the application” of that system. The *West Virginia* decision applied the major question doctrine to conclude that EPA did not have legal authority to “set an emissions cap at the level ‘which reflects the degree of emission limitation achievable through the application of [a cap-and-trade] system[.]’”<sup>32</sup> Notably, what the U.S. Supreme Court did not do is impair EPA’s ability to authorize states to develop section 111(d) state plans that include cap-and-trade systems for sources to comply with standards of performance established under those plans.<sup>33</sup> In other words, while the *West Virginia* decision may preclude EPA from using the generation shifting that results from a cap-and-trade system to derive the standards of performance, the commenter contends that the decision does not preclude EPA from allowing state cap-and-trade programs as a means of complying with standards of performance.<sup>34</sup>

Though the statute provides EPA with authority to allow trading in state plans, the commenter (2355-Constellation Energy) suggests that a state plan that integrates trading will not necessarily meet the requirements for environmental equivalence with a CAA section 111(d) EG. Where EPA exercises its discretion to permit trading, the Agency must do so in a manner that will result in standards of performance that will yield the necessary aggregate emission reductions from the units covered by the state plan. This should be an obvious and uncontroversial point. By expressly requiring that a standard of performance reflect “the degree of *emission limitation*” achievable through the “best system of *emission reduction*,” the definition of “standard of performance” unambiguously requires that such standards actually result in emission reductions.<sup>35</sup> This plain language interpretation, according to the commenter, is consistent with the overall purpose of the Act: to promote “pollution prevention,” i.e., “the reduction or elimination . . . of the amount of pollutants produced or created at the source.”<sup>36</sup> Therefore, any emission guidelines established under CAA section 111(d) and any state plan developed pursuant thereto must ensure that standards of performance actually compel covered sources to reduce their emissions in the aggregate, and that any compliance mechanisms using trading or averaging are appropriately designed to achieve that result.

Response II-2-4: The EPA generally agrees that the EPA has authority to establish minimum requirements for state plans, approve state plans that are more stringent than the emission guidelines, and that trading and averaging may be appropriate as part of state plans. The EPA notes that we have finalized the Agency’s interpretations regarding the states’ ability to establish more stringent standards and the authority to rely on trading in averaging in the separately finalized subpart Ba rulemaking. A detailed discussion of States’ role in the state plan process is included in the preamble, and discussed at further length in the Subpart Ba rule.

### 2.1.5 Regulation of Methane Under the CAA

Comment: Commenters (2355-Constellation Energy, 2410-CA AG et al, 2433-EDF et al) state that EPA has the authority, and in some cases the obligation, to regulate methane under the CAA.

Commenter (2355-Constellation Energy) believes that the EPA's duty to regulate greenhouse gas (GHG) emissions from the Crude Oil and Natural Gas source category is well-established and that EPA is correct not to reopen its conclusion from the 2016 Oil and Natural Gas Sector rule (2016 Rule)<sup>37</sup> that the Agency is not required to make an additional pollutant-specific finding that GHG emissions from the source category contribute significantly to dangerous air pollution.

The commenter (2355-Constellation Energy) states that the Supreme Court confirmed that GHGs are air pollutants under the CAA.<sup>38</sup> Thereafter, in 2009, EPA made an endangerment finding under section 202(a)(1) of the Act, confirming through "a large body of robust and compelling scientific evidence"<sup>39</sup> that the level of GHGs in the atmosphere may reasonably be anticipated to endanger human health and the environment.<sup>40</sup> The endangerment finding and EPA's regulation of greenhouse gas emissions from mobile sources has been upheld in court.<sup>41</sup> The commenter contends that strong scientific evidence linking anthropogenic GHG emissions to threats to human health, welfare, and the environment has only grown stronger since this finding and remains irrefutable.<sup>42</sup> Thus, the commenter provides that there is no reasonable dispute at this point that EPA can and must regulate GHG emissions under the CAA, an obligation confirmed by the Supreme Court in 2011.<sup>43</sup>

Additionally, the commenter (2355-Constellation Energy) asserts that methane must be addressed in regulatory programs addressing the oil and gas sector, and that EPA's first meaningful step to this end was in 2016 when it promulgated a rule regulating emissions of greenhouse gases (in the form of limitations on methane emissions) from new, modified, and reconstructed sources in the production, processing, transmission, and storage segments. The commenter notes that, as EPA properly recognized at the time, a new endangerment finding was not a prerequisite to that regulation. The commenter contends that section 111 of the Act does not require a separate endangerment finding when EPA establishes standards of performance

for emissions of a pollutant for which EPA already made an endangerment finding, from a source category already listed under section 111.<sup>44</sup>

Commenter (2355-Constellation Energy) points out that EPA listed the Crude Oil and Natural Gas Production source category for regulation under CAA section 111 in 1979.<sup>45</sup> By virtue of that listing, the commenter states that the EPA determined that the source category “causes, or contributes significantly to, air pollution which may reasonably be anticipated to endanger public health or welfare,” pursuant to CAA section 111(b)(1)(A). This “endangerment finding” included both the “causes or contributes significantly” component and the “endanger public health or welfare” component of the determination. In subsequent rulemakings, for which the period available for judicial review has long since passed, EPA refined the scope of this source category.<sup>46</sup> For example, in 2012, EPA established NSPS for VOC emissions from numerous emission sources in the production, processing, transmission, and storage segments of the oil and gas sector.<sup>47</sup> Additional sources in those segments were included in the 2016 Rule.<sup>48</sup> The commenter notes that the 2016 Rule also added standards for GHG emissions—in the form of methane standards—for those sources. The commenter asserts that EPA did not, and was not, required to make a new endangerment finding regarding the Oil and Natural Gas Sector to establish standards of performance for GHG emissions from those sources.

Furthermore, the commenter (2355-Constellation Energy) reports that CAA section 111(b)(1)(B) does not specify what pollutants should be the subject of standards from a source category once the source category is listed for regulation.<sup>49</sup> In the 2016 Rule, EPA applied its well-settled rational basis test: EPA may exercise its discretion to regulate particular pollutants under CAA section 111(b) as long as EPA provides a rational basis for doing so.<sup>50</sup> EPA had then—and continues to have now—a rational basis for regulating greenhouse gas emissions from these sources. In fact, the commenter states that the scientific support forming EPA’s rational basis has only gotten stronger since the 2016 Rule. As noted above, the commenter believes that EPA has ample evidence that GHG emissions cause or contribute to air pollution that is reasonably

<sup>48</sup> Oil and Natural Gas Sector: Emission Standards for New, Reconstructed, and Modified Sources, 81 Fed. Reg. 35,824 (June 3, 2016).

<sup>49</sup> 42 U.S.C. § 7411(b)(1)(B).

<sup>50</sup> 2016 Rule, 81 Fed. Reg. at 35,842.

anticipated to endanger public health and the environment, and this determination has been upheld against legal challenge.

According to the commenter (2355-Constellation Energy), once EPA established standards of performance for new sources under CAA section 111(b), the Agency was legally obligated to establish EGs under CAA section 111(d)(1) for existing sources that would be subject to the new source standards if they were new.<sup>51</sup> In turn, the EGs must require states to promulgate standards of performance for the existing sources.<sup>52</sup> Methane emissions from new, modified, and reconstructed sources in the Crude Oil and Natural Gas source category, including in the production, processing, transmission, and storage segments, have been regulated under section 111 of the CAA since 2016. The commenter contends that EPA has had a duty to develop EGs for methane emissions from existing sources in those segments that would be subject to the new source standards if they were new for the past seven years. The commenter applauds the Agency for initiating that regulation with the November 2021 original proposal and continuing it with the December 2022 supplemental proposal and encourages the Agency to proceed swiftly to promulgate final EGs.

Commenter (2355-Constellation Energy) asserts that state regulation of methane emissions and voluntary methane emission reduction programs and measures are not enough to address the increasingly dangerous impacts of climate change on public health and welfare. While some states have their own regulations for methane emissions at existing oil and gas sources, these regulations vary widely in terms of sources covered, emissions limits, testing frequency, and flexibility to use new leak detection and repair technologies.<sup>53</sup> The commenter agrees with EPA that direct federal regulation of methane from new sources combined with the approved state plans that are consistent with the EGs for existing sources is necessary. The commenter believes that doing so will “level the regulatory playing field, help promote technological innovation, and reduce both climate- and other health-harming pollution from a large number of sources that are either currently unregulated or where additional cost-effective reductions can be obtained.”<sup>54</sup>

Commenter (2410-CA AG et al) similarly states that the oil and natural gas sector contributes significantly to air pollution that may reasonably be anticipated to endanger public health or welfare and EPA remains statutorily obligated under CAA section 111 to regulate emissions—including methane emissions—from new and existing sources in the oil and natural gas source category. Further, the commenter contends that in 2016, EPA correctly determined that it had legal authority to regulate methane from the oil and natural gas source category under CAA section 111(b)(1)(B).<sup>55</sup> The commenter notes that EPA relied on overwhelming record evidence regarding the adverse impacts of methane to public health and welfare and the high quantities of

<sup>54</sup> Original Proposal, 86 Fed. Reg. at 63,137.

<sup>55</sup> 81 Fed. Reg. at 35,841; *id.* at 35,842–43 (“When considered in total, the facts presented in . . . this preamble, along with prior EPA analysis, . . . provide a rational basis for regulating GHG emissions from affected oil and gas sources by expressing GHG limitations in the form of limits on methane emissions.”).

methane emissions from the oil and natural gas source category, including existing sources.<sup>56</sup> The commenter adds that EPA explicitly made an endangerment and significant contribution finding with respect to GHG emissions from the oil and natural gas source category. Thus, EPA properly concluded that methane emissions must be directly addressed through standards of performance under CAA section 111(b)(1).<sup>57</sup> And since at least 2016, when EPA began to regulate methane from new oil and natural gas sources under section 111(b) of the CAA, EPA has been required to promulgate EGs to regulate methane from existing oil and natural gas sources under section 111(d) of the CAA.<sup>58</sup>

Commenter (2433-EDF et al.) also provides that EPA’s authority under the Clean Air Act to establish source-based technology requirements for individual pieces of equipment, and thus achieve these reductions, is clear. The commenter notes EPA’s authority and obligation to regulate methane from this source category have only been bolstered by Congress through the passage of two items: the Congressional Review Act (CRA) resolution on June 30, 2021, to Disapprove EPA’s Oil and Gas Policy Rule<sup>59</sup> and the passage of the Inflation Reduction Act (IRA), including the Methane Emissions Reduction Program (MERP), on August 16, 2022.<sup>60</sup>

Response II-2-5: The EPA explained its authority to regulate methane emissions in the preamble and in Volume I, Chapter 3 of the RTC. These comments are generally consistent with those explanations, and no further response is necessary.

Comment: Commenter (2254-PBPA) states that as a predicate to promulgating an NSPS, Congress directs EPA to find that a source category “contributes significantly” to air pollution which may reasonably be anticipated to endanger public health or welfare before promulgating

---

<sup>56</sup> See, e.g., 81 Fed. Reg. at 35,833–43 (citing to, among other things, EPA’s 2009 endangerment finding for GHGs, including methane, 74 Fed. Reg. 66,496 (Dec. 15, 2009), and subsequent assessments validating and lending additional credence to such finding; the fact that the oil and natural gas source category is the largest industrial emitter of methane in the United States; and the high global warming potential of methane, which is 28 to 36 times greater than that of carbon dioxide); cf. *Coalition for Responsible Regulation, Inc. v. EPA*, 684 F.3d 102, 120 (D.C. Cir. 2012) (“The body of scientific evidence marshaled by EPA in support of the [2009] Endangerment Finding is substantial.”).

<sup>58</sup> 81 Fed. Reg. at 35,833–43.

<sup>59</sup> Joint resolution providing for congressional disapproval under chapter 8 of title 5, United States Code, of the rule submitted by the Environmental Protection Agency relating to “Oil and Natural Gas Sector: Emission Standards for New, Reconstructed, and Modified Sources Review,” Pub. L. No. 117–23, 135 Stat. 295 (2021); See also Env’t Protection Agency, Congressional Review Act Resolution to Disapprove EPA’s 2020 Oil and Gas Policy Rule, Questions and Answers (Jun. 30, 2021), [https://www.epa.gov/system/files/documents/2021-07/qa\\_cra\\_for\\_2020\\_oil\\_and\\_gas\\_policy\\_rule.6.30.2021.pdf](https://www.epa.gov/system/files/documents/2021-07/qa_cra_for_2020_oil_and_gas_policy_rule.6.30.2021.pdf).

<sup>60</sup> See generally 42 U.S.C. §7436. While MERP establishes a number of incentives for operators to reduce methane emissions, Joint Environmental Commenters note that the source-specific standards discussed below are reasonably cost-effective independent of the MERP incentives. EPA should focus the implementation of MERP on achieving reductions of methane beyond those that will be achieved by the standards and guidelines that are finalized. See Comments of Clean Air Task Force et al., Comments in Response to Request for Information – Methane Emissions Reduction Program, (Doc. ID No. EPA-HQ-OAR-2022-0875-0031) (Jan. 18, 2023), <https://www.regulations.gov/comment/EPA-HQ-OAR-2022-0875-0031>.

an NSPS.<sup>61</sup> The commenter notes that roughly two years before EPA’s current proposal, EPA in the 2020 Policy Rule acknowledged two statutorily-mandated threshold questions that necessarily flow from this language of the CAA that must be answered before issuance of CAA section 111 standards:

- *Methane-Specific Endangerment Finding.* First, as a predicate to promulgating new source performance standards, the commenter states that the EPA must determine that methane emissions from the oil and gas sector contribute significantly to endangerment.<sup>62</sup> That is, a pollutant-specific endangerment finding for the source category requires EPA to determine that methane emissions from the oil and gas sector have a significant effect on global surface temperatures. After all, according to the commenter, Congress unambiguously applied the significant contribution finding requirement not only to the source category (here, the oil and gas sector), but also to the “air pollution” (here, methane) that actually causes the endangerment.<sup>63</sup> As EPA previously (and rightly) reasoned, “because Congress limited EPA to regulating only stationary sources in a category that the Administrator must first determine to cause or contribute significantly to dangerous pollution, it is not reasonable to read ‘air pollutants’ to refer to any of the source category’s air pollutants for which EPA has not made a [significant contribution finding].”<sup>64</sup>
- *Meeting Articulated Criteria for Judging Significance of Contribution.* Second, the commenter notes that the EPA should articulate criteria for distinguishing between a “contribution” and a “significant contribution” to dangerous pollution and, before regulating under CAA section 111, must conclude that the pollutant and source category being assessed meet the test for the latter.<sup>65</sup> The commenter contends that the EPA has sensibly pronounced that without articulated criteria, “it is impossible to evaluate whether

<sup>63</sup> *Id.* at 57,035 (“It follows that the air pollutants for which the Administrator must establish standards must, or at least may reasonably, be limited to those air pollutants which contribute to this dangerous air pollution.”); see *Motor and Equip. Manufacturers Ass’n of the United States, Inc. v. NYSDEC*, 627 F.2d 1095, 1113 (D.C. Cir. 1979) (“Congress was certainly capable of adding the phrase ‘accompanying enforcement procedures’ wherever the word ‘standards’ appeared if it desired the statutory findings to apply to both. We see no reason to assume that its failure to do so is attributable to sloppy draftsmanship.”); see also *U.S. v. Menasche*, 348 U.S. 528, 538-39 (1995) (“[E]very clause and word of a statute” must be given effect.).

<sup>64</sup> 85 Fed. Reg. at 57,037.

<sup>65</sup> 84 Fed. Reg. 50,244, 50,268 (Sep. 24, 2019) (“Congress has made it clear that in order to be subject to regulation, the emissions must have a greater impact than a simple contribution.”); 85 Fed. Reg. at 57,038 (“[T]he EPA concludes that the failure to identify any such standard or any established set of criteria for the 2016 Rule’s SCF for methane emissions from the source category is unreasonable ....”; cf. *Catawba Cty. v. EPA*, 571 F.3d 20, 39–40 (DC Cir. 2009) (holding that in determining whether an area “contributes” to downwind ozone air quality problems, the EPA, “[t]o be reasonable . . . must . . . define and explain the criteria the agency is applying”; explaining that the EPA adopted a set of nine criteria that it defined and explained “in spades”).

[a significant contribution finding] is well reasoned.”<sup>66</sup> In the absence of articulated criteria, the commenter states that any prior or present-day determination of significant contribution or “rational basis” EPA may claim is arbitrary.<sup>67</sup>

The commenter (2254-PBPA) asserts that EPA has answered neither of these questions. The commenter states that EPA provides that a prior CAA section 111 rulemaking “establishe[s] the agency’s authority to regulate these methane emissions.”<sup>68</sup> The commenter notes that rulemaking relies on the 2009 endangerment finding (specific to GHGs, not methane) and a 1979 listing of the general oil and gas source category, and primarily focuses on emissions of sulfur dioxide (SO<sub>2</sub>), volatile organic compound (VOC), and GHGs (not specifically methane). The commenter maintains the EPA also asserts that “in the legislative history of the CRA resolution, Congress made clear its intent that CAA section 111 did not require or authorize a pollutant-specific significant contribution finding, and the EPA confirmed that it agreed with that interpretation,”<sup>69</sup> and that “[t]he legislative history of the CRA joint resolution rejected the position that a standard or criteria is necessary for determining significance.”<sup>70</sup> The commenter provides that legislative history embodied in a House Committee Report or in Senate floor statements is not the law.<sup>71</sup>

Although Congress disapproved the 2020 Policy Rule under the CRA, the commenter (2254-PBPA) states EPA is still obliged to follow the express terms of the statute and answer these questions. The commenter provides that EPA’s proposal “broaden[s] the types of sources” subject to regulation and requires, “for the first time[,] regulation of hundreds of thousands of existing sources across the country.”<sup>72</sup> The commenter also notes that EPA projects that the rule as proposed would result in an annual domestic oil production decline of 21 million barrels,<sup>73</sup> which will likely cause another country—undoubtedly with relatively less stringent emission control requirements—to seize the opportunity to increase production (and methane emissions) accordingly.<sup>74</sup> The commenter states that the EPA should analyze how lowering production in the U.S. affects the world and whether such reductions will lead to increased production and increased emissions in other countries.

Response II-2-6: The EPA addressed these comments in the preamble and in Volume I, Chapter 3 of this RTC.

<sup>74</sup> As just one example, if the proposed rule is finalized PBPA projects a 9 percent increase in global methane emissions were Turkmenistan to incrementally replace our lost domestic oil production.

## 2.2 Zero-Emission Standard as BSER for Range of Operations

Comment: Commenter (2202-TXOGA) reiterates their objections to the presumptive standards on specific technical or other grounds. For example, in its initial comments, the commenter had noted EPA’s proposal to “issue a zero-emission standard as achievable by BSER for certain new and existing sources.”<sup>75</sup> The commenter expressed “fundamental concerns” with the approach EPA was describing, given that that approach began with a determination of BSER that was “not achievable across the range of operations that are necessary for the source category.”<sup>76</sup> The commenter explained that this would result in a structure under which companies would be required to “demonstrate that they qualify for an exception from a general rule,” thereby shifting the “burden of proof from EPA to the source, on a case-by-case basis.”<sup>77</sup> But, legally, it was EPA’s own obligation to “define BSER based on the statutory definition” – i.e., EPA is required in the first instance to “establish the BSER based on the expected operational situation” of the facilities being regulated.<sup>78</sup> In other words, the commenter states that it was incumbent on EPA to tailor any zero-emissions standard only to those facilities “for which it is adequately demonstrated to be consistent with the statutory definition.”<sup>79</sup>

The commenter (2202-TXOGA) states that EPA seemed to be suggesting that it could set zero-emission standards as BSER even in those circumstances where it knew and acknowledged that the chosen BSER was not feasible in many circumstances. As EPA stated it, such standards were allowable on the basis that “[a]n ‘adequately demonstrated’ system need[] not be one that can achieve the standard ‘at all times and under all circumstances.’” But the commenter pointed out that this “misconstrues the scope of *Essex Chemical*,” insofar as the court “was simply articulating the well-established principle, first enunciated in *Portland Cement Ass’n v. Ruckelshaus*, 486 F.2d 375 (D. C. Cir. 1973), that CAA ‘[s]ection 111 looks toward what may fairly be projected for the regulated future, rather than the state of the art at present.’”<sup>80</sup>

This observation of the court in *Portland Cement*, according to the commenter (2202-TXOGA), is particular pertinent here, where, in its December 2022 supplemental proposal, EPA proposes to find for purposes of EG OOOOc that (i) the BSER for the designated facility pneumatic controllers: Natural gas-driven that Vent to the Atmosphere” to be the “use of zero-emissions controllers”; and (ii) the BSER for the designated facility pneumatic pumps to be the “[u]se of zero-emission pumps that are not powered by natural gas.” In setting presumptive standards of performance for designated facilities under CAA section 111(d), the commenter asserts that EPA must be especially cognizant of the fact that deriving a “best system of emission reduction” for a

---

<sup>75</sup> TXOGA January 2022 Comments at 19.

<sup>76</sup> Id. at 20.

<sup>77</sup> Id.

<sup>78</sup> Id.

<sup>79</sup> Id.

<sup>80</sup> TXOGA January 2022 Comments at 21 (quoting *Portland Cement Ass’n v. Ruckelshaus*, 486 F.2d at 391. In *Portland Cement*, the court began its analysis by “rejecting the suggestion of the cement manufacturers that the Act’s requirement that emission limitations be ‘adequately demonstrated’ necessarily implies that any cement plant *now in existence* be able to meet the proposed standards.” 486 F.2d at 391 (emphasis added). As the court noted, “Section 111 looks toward what may fairly be projected for the regulated future, rather than the state of the art at present, since it is addressed to standards for *new plants*.” Id. (emphasis added). Under the CAA, the court noted, emissions from existing sources were to be “controlled through other regulatory authority.” Id.

particular category of *existing sources* can involve fundamentally different considerations than when the Agency is looking to determine BSER for the same category of new sources. In the specific case here, where EPA has proposed to set zero-emission standards for pneumatic controllers and pneumatic pumps, the commenter notes that EPA has not even suggested that such standard is “achievable across the range of operating conditions” of those existing sources, nor does the proposal “attempt to limit it to the conditions for which it might be achievable.”<sup>81</sup>

Response II-2-7: To the extent that the commenter is suggesting that zero emission standards are never permitted under section 111(b) of the CAA, EPA disagrees. There is nothing within the text of CAA section 111 that supports such a position. As a general matter, EPA’s BSER analyses for promulgating NSPS are often based on aggregate information and assumptions that EPA has reason to believe would hold true for the vast majority of affected facilities. This aggregate approach is evident by examining EPA’s use of model plants in the BSER analysis. EPA was especially reasonable to utilize such an approach here for the oil and natural gas industry because the industry includes a wide variety of sources in different configurations and the NSPS is establishing industry-wide standards of performance for sources across the country. EPA did acknowledge the possibility that the aggregate information used for the BSER analysis may not be true and entirely accurate for all affected facilities (that there may be outliers). Commenters had two opportunities to provide input on EPA’s aggregate information and analysis. Further, EPA’s acknowledgment regarding the possibility of outliers does not render the BSER analysis insufficient or EPA’s approach contrary to the CAA. In this situation, it is reasonable for EPA to fulfill the requirements of the CAA by basing decisions on representative industry information. It is unreasonable, and perhaps even impossible, for EPA to consider the unique circumstances of each source, of which there could be thousands or hundreds of thousands in this industry, when setting industry-wide standards. Where EPA found that certain characteristics, or circumstances, were present in a sizable portion of the industry and such facts were relevant to the BSER analysis (the facts related to the elements or “inputs” that EPA examines for the BSER analysis), EPA’s final NSPS includes subcategories based on those facts. One example of this are the final standards for pumps which includes a subcategory with a different standard for sites without access to grid electricity that have less than 3 diaphragm pumps. Another example is the subcategory with a different standard for process controllers at sites in Alaska without access to grid electricity.

Where the final NSPS includes zero emissions standards, the EPA has demonstrated in each of those cases that this “degree of emission limitation [is] achievable through the application of the best system of emission reduction which...the Administrator [has] determine[d] has been adequately demonstrated.” CAA 111(a)(1). For EPA to demonstrate that the best system of emission reduction has been “adequately demonstrated,” EPA does not need to prove beyond any doubt that each and every affected facility is capable of utilizing the system that EPA examined in the Agency’s BSER analysis. Imposing such an onerous requirement, as commenters suggest, would put EPA in an absurd position such that promulgating any standard of performance for this source category would be nearly impossible. Lastly, EPA does not agree with commenter that the Agency misconstrued *Essex Chemical*. As stated in the 2021 Proposal, an “adequately demonstrated system” is one that “has been shown to be reasonably reliable, reasonably efficient, and which can reasonably be expected to serve the interests of pollution control without

---

<sup>81</sup> TXOGA January 2022 Comments at 22.

becoming exorbitantly costly in an economic or environmental way.” *Essex Chemical*, 486 F.2d at 433.

Further, the fact that some zero emissions standards included in the final NSPS allow sources to comply via means other than the primary control method assessed for the BSER analysis does not render the BSER analysis flawed. When EPA’s standards in a NSPS can be expressed as numerical limitations, sources are free to choose how they comply with those standards. To the extent that EPA acknowledged that certain control options evaluated might not be feasible or preferable for certain sources, and where EPA specifically discussed other methods of compliance, it was done so to highlight that sources have options. In many, if not all, situations where the NSPS requires compliance with a zero emission standard sources have options such that if one compliance method does not work for them for some reason, they can choose another method of compliance. EPA’s proposal preambles highlight the degree of flexibility that sources have when complying with zero emissions standards. EPA does not agree with the commenter’s implication that allowing alternatives to achieve equivalent emission reduction somehow renders the BSER analysis flawed. Lastly, EPA does not agree that including limited exemptions for specific technical and safety reasons renders the BSER analysis flawed. For EPA’s full response to those comments, see Response II-2-13.

To the extent that the commenter is claiming that EPA erred in including presumptive standards in the final EG that are similar to the finalized standards in the NSPS (commenter is relying on *Portland Cement*), see section XIII.C.1 of the preamble. That section explains EPA’s position on this subject and is responsive to this portion of the comment.

To respond to the comments regarding the presumptive standards in the final emission guidelines (OOOOC) for process controllers and pumps, see sections XI.D and XI.E of the final rule preamble.

## **2.3 Legal Basis – Certification of Technical Infeasibility**

Comment: Commenter (2428-API) notes that applicability of several elements of the proposed rule depends on a certification of technical infeasibility that must be executed by a professional engineer or other qualified individual. Examples include the use of an emissions control device to handle associated gas (see, e.g., proposed 40 CFR 60.5377b(b)(2)), the continued use of pneumatic pumps driven by natural gas (see, e.g., 40 CFR 60.5393b(c)), and the use of emitting gas well unloading methods (see, e.g., 40 CFR 60.5376b(c)(2)(ii)(B)(2)). The commenter provides that the EPA imposes these certification requirements out of concern about the possible “abuse” of these provisions such that they might open a “loophole” in the regulations (87 FR 74776). EPA stresses that it, “wants to make it clear that in the case that such a certification is determined by the Agency to be fraudulent, or significantly flawed, not only will the owner or operator of the affected facility be in violation of the standards, but the person that makes the certification will also be subject to civil and potentially criminal penalties.” *Id.* Thus, the commenter states that the proposal raises the serious prospect of individual, personal liability, not only for fraudulent certification, but also for technically erroneous (i.e., “significantly flawed”) certifications. The commenter supports these opt out provisions as a practical matter. The commenter agrees that non-emitting measures and methods should be used where they are

technically feasible and cost effective, but EPA rightly understands that non-emitting approaches are not always practicable and that imposing an absolute requirement would constitute an unwarranted prohibition on necessary operations, such as liquids unloading, in many situations. The proposed alternative measures are a common-sense solution to the commenter.

However, the commenter (2428-API) does not believe that EPA has asserted an adequate legal basis for identifying non-emitting techniques as BSER and establishing them as a standard, but at the same time creating opt outs. The commenter points out in their comments on the original November 2021 proposal that the need to allow for technical infeasibility exceptions to the proposed non-emitting standards indicates that the non-emitting standards are not permissible under CAA section 111 because non-emitting standards are not “adequately demonstrated” if opt outs are needed to make them feasible and workable.

The commenter (2428-API) reiterates those concerns about the legal basis for EPA’s opt-out approach because onerous and potentially punitive certification requirements make the opt out approach even more legally tenuous. The commenter contends that such certification requirements will significantly limit the situations where an opt out can be employed. As a result, what otherwise might be a reasonably viable alternative to an unworkable zero-emissions standard is unnecessarily complicated by strict certification requirements tied to an undefined standard that will be difficult to apply and limit the usefulness of the alternative. According to the commenter, that heightens the concern that creating an opt out is unlawful circumvention of the obligation to demonstrate that BSER and the corresponding standards of performance are adequately demonstrated and cost effective.

Response II-2-8: See Response II-2-7 for responses to portions of this comment that discuss EPA’s BSER analysis and the concept of “adequately demonstrated” under CAA section 111. In addition, EPA does not agree that including certain provisions providing exceptions from the general standard, which the commenter terms “opt outs,” in the final NSPS renders zero emissions standards inadequate. First, the final NSPS does not include some iterations of certain exceptions that EPA had proposed. For example, the final new source standards for Associated Gas, after the phase-in period for compliance, no longer allow for technical infeasibility determinations. Next, the oil and natural gas industry includes a wide variety of sources in a wide variety of configurations. The exceptions that commenter takes issue with were generally designed to account for the possibility that legitimate safety, operational, and/or technical reasons may exist at some sources that could render compliance with the final standards a hazard to human safety or technically impossible from an engineering perspective. Such circumstances are the exception and not the norm. Put another way, the vast majority of the industry will not need to use any exceptions included in the final NSPS because they will be able to meet the standards.

The exceptions are only to be used in very limited and specific circumstances, and EPA does not expect them to be used often. For reasons explained within each BSER analysis for each relevant affected facilities where this issue is presented, EPA has explained how and why the best system has been “adequately demonstrated.” The fact that EPA sometimes allows very limited exceptions does not render that demonstration invalid, but rather is consistent with EPA’s authority under CAA section 111(b)(2) to distinguish sources with different characteristics

(“classes, types, and sizes”) when establishing such standards. EPA has also explained how and why certain exceptions are included in the final NSPS. The reasoning for including, or not including, a particular exception is fact-specific to the affected facility and the related standard and is therefore located within the discussion for the relevant affected facility. As explained in the context of each exception, EPA has reason to believe that a very limited set of sources may present unique characteristics such that a variation of the final standard is warranted to account for those situations. EPA has a history of allowing these kinds of limited variations in the oil & gas source category, and in other NSPS, because of the many different configurations in the field.<sup>82</sup>

We disagree with commenter's characterization of the certification requirement as 'onerous and potentially punitive.' Certification is appropriate to ensure any reliance on the exception is legitimate and based on a sound engineering analysis, and that the exception does not become a compliance loophole. Flaws in the certified engineering analysis may result in the exception being inapplicable and a related enforceable violation of the standards. Fraudulent or significantly flawed certifications may result in both civil and criminal liability and penalties for the owner, operator, and the person that makes the certification. These consequences are consistent with, and no more "punitive" than, those for any other violation or certified, fraudulent statement submitted to EPA.

---

<sup>82</sup> Allowances for technical infeasibility have been included in prior EPA rules for this and other industries. For example, technical infeasibility is a factor to consider within the gas well standards in 40 CFR Part 60 Subpart OOOO: “[r]oute the flowback into one or more well completion vessels and commence operation of a separator unless it is technically infeasible for a separator to function.” 40 CFR § 60.5375(f)(2). By way of another example where the assertion of technical infeasibility must be certified, see the standards for pumps within Subpart OOOOa found at 40 CFR § 60.5393a(b)(5).

## Chapter 3. Effective, Applicability and Compliance Dates/Definitions

### 3.1 New, Modified, or Reconstructed Source for Purposes of the Proposed NSPS OOOOb Applicability Date

Comment: Commenters (2157-Tennessee Department of Environment & Conservation (TNDEC), 2202-Texas Oil & Gas Association (TXOGA), 2221-Texas Pipeline Association (TPA), 2227-Western Energy Alliance (WEA), 2238-Southeastern Ohio Oil and Gas Association, 2240-Rose Rock Environmental Services, LLC (RRES), 2247-Ohio Environmental Protection Agency (OHEPA), 2248-North Dakota Petroleum Council (NDPC), 2252-Petroleum Association of Wyoming (PAW), 2254-Permian Basin Petroleum Association (PBPA), 2292-West Virginia Office of the Attorney General *et al.*, 2294-Ohio Oil & Gas Association (OOGA), 2326-American Exploration and Production Council (AXPC), 2354-Business Roundtable, 2360-Devon Energy, 2399-GPA Midstream Association (GPA), 2428-American Petroleum Institute (API), 2483-Interstate Natural Gas Association of America (INGAA), Others) state that the November 2021 proposal lacked regulatory text or sufficient factual and technical basis and therefore should not be used to define new sources for purposes of New Source Performance Standards (NSPS) OOOOb. Some of the specific comments provided are included in the following paragraphs.

Commenter (2326-AXPC) recommends that EPA extend implementation timelines – particularly for sources that became NSPS OOOOb affected facilities prior to the date of final rule publication. The commenter urges that EPA provide additional time for certain affected facilities to come into compliance following the final rule’s effective date if those facilities that became new, modified, or reconstructed after the NSPS OOOOb “new” facility trigger date (*i.e.*, November 15, 2021, as proposed by EPA; and December 6, 2022, as requested by the commenter) and before the final rule’s *Federal Register* publication date. The commenter explains that until the effective date of NSPS OOOOb, some of these facilities would be unregulated under an existing NSPS or would begin operating as NSPS OOOOb affected facilities and may then need to complete retrofits to comply with newly applicable NSPS OOOOb standards. By way of example, the commenter explains that NSPS OOOOb pneumatic controllers and pumps are not subject to a zero emissions standard but would be subject to zero emissions standards under NSPS OOOOb, requiring retrofit within 60 days of the final rule’s publication in the *Federal Register*. The commenter states that this is not enough time to acquire retrofit equipment that will be in high demand, and likely short supply, as operators across the country place orders for equipment to meet the zero emissions standard. In addition, the commenter notes that operators must acquire engineering resources to engineer the installation of zero emissions pneumatic controller systems and that these engineering resources, too, are likely to be in high demand and short supply.

Commenter (2157-TNDEC) believes that new sources should be based on the publication date of the December 2022 supplemental proposal rather than the November 2021 proposal because the November 21, 2021, proposal did not contain sufficient factual and technical basis for meaningful comments to be developed. The commenter states that the D.C. Circuit has noted:

An . . . important component of the process of reasoned decision-making is the agency's own explanation for the rules it adopts. While an agency need not justify the rules it selects in every detail, it should explain the general bases for the rules chosen.<sup>1</sup>

The commenter (2157-TNDEC) requests that EPA consider the practical implications of giving sources and state regulators time to understand new federal rules and implement actions necessary to comply with new federal rules. The commenter contends that without regulatory language it was difficult, if not impossible, for potentially regulated sources to determine if they would be subject to the proposed regulation. Furthermore, the commenter states that the December 2022 supplemental proposal included sources that were not addressed in the November 2021 proposal. According to the commenter, the goal of the Clean Air Act (CAA) is not to drive reductions in ways that harm business, and the commenter believes that by defining new sources by the date of the December 2022 supplemental proposal, the rule will provide a pathway for reductions but will also give businesses and regulators time to understand what implementation for compliance will entail.

Commenter (2202-TXOGA) notes that the initial November 2021 proposal, effectively without discussion or explanation, includes an applicability date for new, modified, and reconstructed sources subject to NSPS OOOOb of November 15, 2021, which they assert was not legally permissible as the CAA defines a “new source” as “[a]ny stationary source, the construction or modification of which is commenced after the publication of regulations (or, if earlier, proposed regulations) prescribing a standard of performance under this section which will be applicable to such source.”<sup>2</sup> The commenter states that EPA seeks to codify this date despite the comments to the contrary on the November 2021 proposal.

Based on the preamble of the December 2022 proposal, the commenter (2202-TXOGA) notes EPA had not utilized the stated flexibility by the Administrative Procedures Act (APA) previously, instead providing regulatory text in all prior NSPS proposals.<sup>3</sup> According to the commenter, soliciting comment on “whether CAA section 111(a) provides the agency discretion to define ‘new sources’ based on the publication date of a supplemental proposal”<sup>4</sup> and “[i]f so,” the preamble asks whether “there are any unique circumstances here that would warrant the exercise of such discretion in this rulemaking,”<sup>5</sup> turns the proper inquiry on its head. The question the commenter raises is not whether Congress gave EPA the “discretion” to set some date other than November 15, 2021, as the applicability date trigger for Quad Ob for new sources. Instead, the commenter urges EPA, before the Agency takes final action here, to

---

<sup>1</sup> *Conn. Light & Power Co. v. Nuclear Regulatory Com.*, 673 F.2d 525, 528 (D.C. Cir. 1982).

<sup>2</sup> CAA §111(a)(2); 42 U.S.C. §7411(a)(2)

<sup>3</sup> And this was the case even though the Agency had been facing increasing costs from the Office of the *Federal Register* and was under pressure to reduce such costs. Had EPA considered non-publication a legal option previously, it is reasonable to conclude that the budget pressures of the past decade would have prompted this action, but they did not.

<sup>4</sup> 87 Fed. Reg. at 87,716.

<sup>5</sup> *Id.* First, as the commenter (2202-TXOGA) pointed out in its January 2022 comments, the language of CAA section 111(a)(2), defining “new source” for purposes of the NSPS program, reveals no evident ambiguity: a “new source” is “[a]ny stationary source, the construction or modification of which is commenced after the publication of regulations (or, if earlier, proposed regulations) prescribing a standard of performance under this section which will be applicable to such source.”

evaluate whether EPA has authority under the CAA to set November 15, 2021, as the applicability date in the first place and believes the statute does not grant such authority.

Instead, the commenter (2202-TXOGA) notes that the preamble simply asserts that nothing in CAA section 307(d)(3) requires that a “notice of proposed rulemaking” proposing regulations under CAA section 111 requires that the proposal contain “proposed regulatory text.”<sup>6</sup> As has been noted, however, under the plain language of CAA section 111(a)(2), a “new source” for NSPS applicability purposes is defined in relation to the date when EPA has published – either in final or proposed form – “regulations . . . prescribing a standard of performance.” The commenter contends that even if EPA were permitted under CAA section 307(d)(3) to withhold proposed regulatory language at the time it publishes a notice of proposed rulemaking (which, as is argued below, it is not), such publication, sans regulatory text, would not constitute the “publication of... proposed regulations” within the meaning of CAA section 111(a)(2).

The commenter (2202-TXOGA) states that the proposal’s reliance on the language of APA, 5 U.S.C. section 553, which explicitly provides that a notice of proposed rulemaking may contain “either the terms or substance of the proposed rule” or a “description of the subjects and issues involved,” ignores the fact that the “promulgation of revision of any standard of performance under” CAA section 111 is conducted pursuant to the more elaborate procedures and requirements set forth in CAA section 307(d), not the APA.<sup>7</sup> The commenter contends that CAA section 307(d) requires more than a “description of issues.” It requires disclosure of the “factual data on which the proposed rule is based” and the “legal and policy considerations underlying the proposed rule.” According to the commenter, a rule must be a part of a CAA section 307(d) proposal in order to disclose its factual, legal, and policy basis. They add that they believe that there is simply no footing on which to moor a claim that providing a “description of the subjects and issues involved” in a notice of proposed rulemaking would satisfy the disclosures required under CAA section 307(d) with respect to “the proposed [CAA section 111] rule,” much less that

---

<sup>6</sup> 87 Fed. Reg. at 87,716. The Proposal’s reliance on the language of APA, 5 U.S.C. section 553, which explicitly provides that a notice of proposed rulemaking may contain “either the terms or substance of the proposed rule” or a “description of the subjects and issues involved,” ignores the fact that the “promulgation of revision of any standard of performance under” CAA section 111 is conducted pursuant to the more elaborate procedures and requirements set forth in CAA section 307(d), not the APA.

<sup>7</sup> Some 40 years ago (and just six years after Congress had first enacted CAA section 307(d) as part of the CAA Amendments of 1977), the U.S. Court of Appeals for the District of Columbia Circuit had occasion in *Small Refiners Lead Phase-Down Task Force v. EPA*, 705 F.2d 506 (D.C. Cir. 1983) to point out that there were “basically two major differences between APA § 553(b) and Clean Air Act §307(d)(3).” *Id.*, 705 F.2d at 519. The first of these “major differences,” the court explained, is that the “Clean Air Act, unlike the APA, requires EPA to issue a ‘proposed rule.’” *Id.* The court acknowledged that while “§307(d)(3) does not explicitly require EPA to issue a proposed rule,” that section of the CAA does “refer[] to the agency’s duty to explain ‘the factual data on which the proposed rule is based’ and ‘the major legal interpretations and policy considerations underlying the proposed rule.’” *Id.* (emphasis in original). Also, the court continued, “at the final rule stage, §307(d)(6) requires EPA to explain ‘any major changes in the promulgated rule from the proposed rule.’” *Id.* In the court’s view, “EPA cannot comply with these statutory requirements unless it issues a ‘proposed rule.’” *Id.* The court added that it, in observing the evident need for a notice of proposed rulemaking to include a “proposed rule,” it “express[ed] no view on whether the ‘proposed rule’ must take any particular form,” save that it must be “specific enough to comply with § 07(d).” *Id.* at 519 n. 27.

such a “description” is equivalent to the “publication of . . . proposed regulations” within the meaning of CAA section 111(a)(2).<sup>8</sup>

Moreover, prior to enactment of the CAA Amendments of 1977, and the introduction of more prescriptive rulemaking requirements applicable to specified EPA actions (including the promulgation of standards of performance under CAA section 111), the commenter (2202 - TXOGA) provides that rulemakings to establish standards under CAA section 111 were governed by the less prescriptive requirements of the APA, 5 U.S.C. §553. They note that this fact, in turn, provides an explanation for what, at first glance, may seem an odd formulation in CAA section 111(a)(2), in which Congress defined a “new source” as a source whose construction or modification is commenced after the “publication of [final] regulations (or, if earlier, proposed regulations) prescribing a standard of performance . . . .” . Since the promulgation of a final standard of performance under CAA section 111(b) will always be preceded by a notice of proposed rulemaking, they believe that Congress’s use of the term “proposed regulations” in CAA section 111(a)(2) can only be construed as being a reference to proposed regulatory text and not to any other contents (such as the preamble) in the notice of proposed rulemaking. Otherwise, the commenter suggests that CAA section 111(a)(2)’s invocation of the words “if earlier” would be rendered nonsensical. When Congress first enacted CAA section 111 in 1970, the commenter provides that it recognized that, as EPA itself has pointed out, the agency was not compelled by the then-governing provisions of the APA, 5 U.S.C. Section 553, to publish proposed regulatory text in the *Federal Register*, and that the agency had the option under the APA to provide instead in the notice of proposed rulemaking simply a description of the “subjects and issues involved.” The commenter explains that in keeping with Congress’s intent at the time that rulemakings to prescribe standards of performance under CAA section 111 were to be conducted expeditiously, and that regulated entities would be prompted to take account of, and comply with, those standards as soon as was practicable, Congress allowed that the applicability date for standards adopted for a “new source” could be fixed at the time “proposed regulations” were published, but only if EPA had embraced the first of the APA’s two listed options and had included with the notice of proposed rulemaking the “terms or substance of the proposed rule” – *i.e.*, proposed regulatory text – so as to ensure that regulated entities had adequate notice of the specific terms of what EPA was proposing.

According to the commenter (2202-TXOGA), it is not exactly clear what argument is being advanced in support of the position that EPA is authorized, or compelled, to set November 15, 2021, as the applicability date for NSPS OOOOb. The commenter provides that EPA seeks to suggest, without ever saying as much – again, in addressing this point in its December 2022 supplemental notice, the preamble never engages the pertinent language of CAA section 111(a)(2) – that, by having met the requirement under CAA section 307(d)(3) to publish what it considers to be a sufficiently detailed “statement of basis and purpose” (*i.e.*, the preamble that constituted the November 15, 2021 notice), the Agency has, in effect, published a “proposed

---

<sup>8</sup> The commenter does not agree that section 307(d) bears EPA’s reading of it. Under EPA’s interpretation, it seems that no regulatory language would ever need to be published, even language setting forth final regulations – since EPA’s reasoning for not publishing the proposed regulatory text is based on statutory language in section 307(d) that is identical for final rules – nothing in section 307(d) refers to publishing final rule language, yet we are aware of no situation in which EPA failed to provide final rule language when issuing a rule.

regulation” within the meaning of CAA section 111(a)(2), and that the Agency was under no further obligation to publish or make available any regulatory text. The commenter does not consider this approach sustainable. In effect, the position appears simply to be a claim that the preamble to a notice of proposed rulemaking is (or, at least, can be) equivalent to a “proposed regulation.” The commenter notes that it is true that the term “regulation,” while used throughout the CAA (including, most significantly for present purposes, in CAA section 111(a)(2)), is nowhere defined in the CAA, or, for that matter, in the APA (where the operative defined term is “rule”), nor is the term “regulation” defined in the Federal Register Act (FRA).<sup>9</sup> In the commenter’s view, the Proposal seems to suggest that the preamble to a notice of proposed rulemaking can itself be viewed as a proposed “regulation” generally, or even that the publication of a notice of proposed rulemaking without any accompanying proposed regulatory text, can constitute the publication of “proposed regulations . . . prescribing a standard of performance” within the meaning of CAA section 111(a)(2). While the FRA contains no definition of “regulation,” the commenter states that the FRA’s own implementing rules do specify that the terms “regulation” and “rule” “have the same meaning” and that the terms can be used interchangeably.<sup>10</sup> Elsewhere, they note that the FRA’s implementing rules provide that, “[p]ursuant to chapter 15 of title 44, United States Code, the Director of the *Federal Register*” is to “publish periodically a special edition of the *Federal Register* to present a compact and practical code called the ‘Code of Federal Regulations,’ to contain each Federal regulation of general applicability and legal effect.”<sup>11</sup> The commenter contends that since a preamble that accompanies a notice of final rulemaking is itself never published in the Code of Federal Regulations, such a preamble can never be characterized as being a “regulation.”<sup>12</sup> As such, the commenter explains that it follows that the preamble to a notice of proposed rulemaking can never be characterized as a “proposed regulation” – much less a “proposed regulation . . . prescribing a standard of performance” within the meaning of CAA section 111(a)(2) – no matter how much EPA may wish it to be so. The commenter requests that EPA reconsider its position, repropose the rule with regulatory text, and, in the final rule, establish the applicability date for

---

<sup>9</sup> The FRA is the federal statute that authorizes the Administrative Committee of the *Federal Register* to prepare and publish “in special or supplemental editions of the *Federal Register*” the “complete codifications of the documents of each agency of the Government having general applicability and legal effect, issued or promulgated by the agency by publication in the *Federal Register*,” which “complete codifications” are to be “designated as the ‘Code of Federal Regulations.’” See 44 U.S.C. § 1510(a), (b). The FRA specifically defines “document,” as used therein, to mean a “Presidential proclamation or Executive order and an order, regulation, rule, certificate, code of fair competition, license, notice, or similar instrument, issued, prescribed, or promulgated by a Federal agency.” 44 U.S.C. § 1501. But the FRA itself provides no definition of the term “regulation” or, for that matter, the term “rule.”

<sup>10</sup> See 1 C.F.R. § 1.1.

<sup>11</sup> 28 See 1 C.F.R. § 8.1. Notably, the phrase “each Federal regulation of general applicability and legal effect” tracks in certain significant respects the APA’s definition of the term “rule.” As is relevant here, the APA defines “rule” to mean the “whole or a part of an agency statement of general or particular applicability and future effect designed to implement, interpret, or prescribe law or policy.” See 5 U.S.C. § 551(4). Hence, that FRA’s implementing rules equates the terms “regulation” and “rule” makes sense.

<sup>12</sup> Cf. *Brock v. Cathedral Bluffs Shale Oil. Co.*, 796 F.2d 533 (D.C. Cir. 1986). While the D.C. Circuit had no occasion in *Cathedral Bluffs* to address the precise point at issue here, then-judge Scalia, in assessing the status of a policy statement adopted by the Secretary of Labor – which policy statement the Labor Department had formally published in the *Federal Register* – took pains to note that the “real dividing point between regulations and general statements of policy is publication in the Code of Federal Regulations, which the statute authorizes to contain only documents ‘having general applicability and legal effect,’ 44 U.S.C. § 1510 (1982), and which the governing regulations provide shall contain only ‘each Federal regulation of general applicability and current or future effect,’ 1 C.F.R. § 8.1 (1986).” *Id.* 796 F.2d at 539 (emphases in original).

new sources subject to NSPS OOOOb no earlier than the date that EPA finally publishes in the *Federal Register* proposed regulatory text according to the CAA.

Additionally, the commenter (2202-TXOGA) suggests that even if this interpretative approach to CAA section 307(d) in general were supported, the special applicability structure of CAA section 111 means that, for purposes of NSPS, the publication of the proposed regulatory text is required. In enacting CAA section 111, the commenter states that Congress determined that, in those circumstances where regulated entities had been provided adequate notice of the specific contents of EPA's proposed standard – *i.e.*, by being afforded the proposed regulatory text at the time of proposal, which they could evaluate and comment upon, setting the final standard's applicability date on the basis of the date on which the standard had been proposed would not result in any prejudicial retroactive application. The commenter notes that such retroactivity “is not favored in the law.”<sup>13</sup> To this end, the commenter asserts that this is why Congress mandated that final rules must quickly follow proposal under CAA section 111, in essence taking steps to minimize any possible prejudicial retroactivity. The commenter adds that CAA section 111 thus requires EPA to “afford interested persons an opportunity for written comment on . . . proposed regulations” to establish a standard of performance, and then, “[a]fter considering such comments,” to promulgate the final standard “within one year after such publication . . . with such modifications as [the Administrator] deems appropriate.”<sup>14</sup> The commenter states that this “one year” promulgation deadline reflects a change made to CAA section 111(b)(1)(B) by the CAA Amendments of 1990. Prior to that time, CAA section 111(b)(1)(B) had specified that “[a]fter considering such comments, [EPA] shall promulgate within 90 days after such publication, such standards with such modifications as he deems appropriate.”<sup>15</sup>

According to the commenter (2202-TXOGA), the extraordinarily abbreviated time that Congress has allotted to EPA to take final action on a proposed standard of performance underscores Congress's intent that a proposed standard should reflect well (if perhaps not fully) developed thinking on the Agency's part at the outset of the rulemaking process, thus minimizing the risk that setting the applicability date as the date of publication of the proposed regulation will have unacceptable retroactive effect, while balancing that concern with congressional desire that standards of performance be adopted as expeditiously as possible. The commenter asserts that the position in the proposal runs directly afoul of congressional intent in that respect. Due to the time that has passed since EPA published the November 2021 notice; the commenter states that for EPA to set the applicability date based on that publication date would conflict with the Agency's statutory obligation to have finalized the standard within one year (as set out in CAA section 111(b)(1)(B)).

The commenter (2202-TXOGA) maintains that this point is illustrated very well by the current proposed action. The commenter explains that the discussion of potential standards did not fully reflect what was proposed to be required of affected sources, such that an entity completing new installations between November 15, 2021, and release of the regulatory language would be able to sufficiently design its operations to comport with the new standards. The commenter continues that if an affected source is “new” under CAA section 111, it is not afforded the lead time that is

---

<sup>13</sup> See *Bowen v. Georgetown University Hosp.*, 488 U.S. 204, 208 (1988).

<sup>14</sup> See CAA §111(b)(1)(B); 42 U.S.C. §7411(b)(1)(B).

<sup>15</sup> See, *e.g.*, CAA 111(b)(1)(B); 42 U.S.C. §1857c-6(b)(1)(B) (1970).

associated with normal project planning to comply with a final rule.<sup>16</sup> The commenter contends that as the November 2021 notice did not contain essential elements such as methods including averaging times, test methods, and the like, affected facilities did not have the “notice” needed to design their new, reconstructed, or modified facilities for compliance in accordance that date being the new source trigger date.

Similarly, commenter (2221-TPA) states that basing the applicability date of the proposed new NSPS OOOOb on the prior publication date, November 15, 2021 - a date over a year before regulated parties were able to see the actual rule language, they may have to comply with is inappropriate. According to the commenter, the provisions of Part 60, including any new or revised performance standard promulgated under section 111(b) of the CAA, apply to “an affected facility, the construction or modification of which is commenced after the date of publication in this part of such new or revised standard (or, if earlier, *the date of publication of any proposed standard*) applicable to that facility.”<sup>17</sup> The commenter contends that the “proposed standard” -is the actual rule language, not EPA's prefatory description and explanation - and in some cases, EPA's mere prediction - as to what that rule language might ultimately look like. In the world of complex regulations emission limits, and compliance, details are everything.<sup>18</sup> The commenter provides that a company determining whether, and to what extent, a particular operation is covered by a performance standard may gain some insight or coloration from a preamble, but in the last analysis it is the precise rule language itself that is always carefully scrutinized in order to resolve questions of applicability and required compliance. The commenter states that the key is what the formal rule text says. However, the commenter notes that it was not until December 2022 that companies finally had the benefit of seeing the actual proposed rule language with which they might ultimately be required to comply. The commenter believes that the prior proposal was more in the nature of an advance notice of proposed rulemaking than a rule proposal, and as such it is inappropriate to base the applicability date on the November 15, 2021, publication date.

Additionally, the commenter (2221-TPA) contends that the extended preamble-only publication on November 15, 2021, gave companies no ability to proceed with confidence as to how the rules might ultimately read. For example, they note that the control device monitoring, testing, and recordkeeping requirements, which encompass multiple affected source categories, could not have been determined based on the November 2021 preamble text, as that preamble text only suggested that the requirements should be strengthened while failing to state what the new requirements would be. According to the commenter, merely stating an emission limitation or work practice standard is not sufficient notice, because monitoring, recordkeeping, and reporting requirements are also part of a standard and it is therefore imperative that owners and operators have knowledge of these requirements at the time of construction to be certain that full compliance can be achieved. In short, the commenter asserts that requiring compliance based on

---

<sup>16</sup> The commenter maintains that the provision of only 60 days after publication for sources that were constructed, reconstructed, or modified since proposal to comply and demonstrate compliance is unreasonable and unrealistic and it should be revised.

<sup>17</sup> 40 CFR § 60.1(b) (emphasis added).

<sup>18</sup> EPA previously referred to November 15, 2021, as “the date of publication of the proposed revisions to the NSPS,” 86 Fed. Reg. 63117 (Nov. 15, 2021), when that is the date of EPA's description of the upcoming proposed revisions, which would only be revealed over a year later.

a construction or modification date that is months earlier than the publication of actual proposed rule language - *i.e.*, the “proposed standard” described by 40 CFR 60.1(b) - would be unfair and contrary to EPA's own rules, and to proceed in this way would potentially trigger future litigation. The commenter urges EPA to base the applicability dates in these rules on the date of *Federal Register* publication of actual rule language, December 6, 2022, as it has traditionally done, not a preamble description of what such language might look like in the future.

Commenter (2227-WEA) provides that the CAA section 111(a)(2) definition of “new source” uses the term “proposed regulations” in defining the new source applicability date. The commenter contends that the November 2021 publication alone, which was at most a lengthy preamble, cannot constitute proposed regulations or “rules,” the two terms being essentially synonymous, any more than a final rule that is unaccompanied by regulatory text could qualify as a “rule.” Although the November 2021 preamble described the types of regulatory requirements that EPA was considering promulgating, the commenter finds that the preamble was not in and of itself a document “prescribing a standard of performance under this section [111]....” A “prescribed standard” would be established only by the proposed regulatory text, which was not provided until the December 2022 supplemental proposal.

The commenter (2227-WEA) adds that, as required in the CAA, under 42 U.S.C. section 7411(b)(1)(B), requirements for new sources are required to be finalized within one year of the publication of proposed regulations. The commenter states that a final rule was not finished for the sources listed in the 2021 proposal by November 15, 2022, and this provides even more evidence that the initial proposal should never have been classified as a proposed rule. The commenter recognizes that reclassifying the previous publication as an advanced notice of proposed rulemaking (ANPR) would be difficult, if not impossible retroactively; however, they suggest that the EPA has the deference and indeed is required to base the applicability date on this supplemental proposal, *i.e.*, the publication date of the “proposed rules”. Considering also the supplemental rule is the first instance where regulated sources were given fair notice of proposed regulatory language, the commenter contends that it is a more appropriate date for future applicability of the final rule. The commenter contends that this alone would qualify as a “unique circumstance” to justify a change to the proposed applicability date.

Commenter (2240-RRES) states that the first version of the proposed rule did not include regulatory language, a major departure from all other proposed rules previously published by the EPA. Regulatory language, which an operator might reasonably be expected to follow, were not published until December 6, 2022. As such, the commenter believes that the applicability date of the rule should be December 6, 2022.

Commenter (2247-OHEPA) is concerned about the applicability date for the NSPS sources. The commenter notes that historically, when the EPA issues a new NSPS, they first issue draft rules with a comment period. After the comments are reviewed, the final rules are issued. The date the draft rules are published is then used as the applicability date for the NSPS. The commenter states that, in this case, EPA took an additional step where they issued a pre-draft package simply asking for suggestions and comments before drafting rules. This pre-draft package was issued in late 2021. The commenter notes that EPA chose to set the NSPS applicability date based on the pre-draft package, not the official draft rule package.

According to the commenter (2247-OHEPA) the problem with doing this is it adds another year's worth of new or modified facilities that are instantly not in compliance when the final rule comes out. This means companies will have to scramble to modify their facilities and permitting agencies will need to work through more old installation permits to update them to the newly issued NSPS. The commenter recommends that EPA stick to past practices and assign the applicability date to when the draft rules were issued in late 2022. Those new or modified sources installed during 2022 will then fall into the emission guideline (EG) rules which, because of the rule writing process, will allow more time for permittees and permitting agencies to update their systems for the new EG rules.

Commenter (2252-PAW) states that under this Administration, the first iteration was issued on November 15, 2021, and that that iteration was all preamble – no proposed regulatory text was provided. The commenter compares this iteration to an ANPR rather than a proposed rule. The commenter asserts that companies cannot be required to be compliant with a regulation for which there is no text. In the December 6, 2022, supplemental rule proposal, extensive revisions were made demonstrating that companies are not able to make capital investment decisions until regulation certainty. The commenter states that the industry does not know the extent to which EPA will revise this proposed rule on the path to finalization and that EPA should change the effective date to align with the date of issuance of a final regulation. The commenter notes that the CAA requires this in section 111(b)(1)(B): “Standards of performance or revisions thereof *shall* become effective upon promulgation.” (emphasis added) The commenter adds that “promulgate” is defined as “formally putting it into effect” and that this regulation will not be in effect until the EPA issues a final regulation. Further, the commenter states that the EPA is barred from requiring industry compliance until that time, as well.

Commenter (2254-PBPA) expresses that EPA's failure to propose rule text in the November 2021 publication and then selecting November 2021 as the “new source” applicability date departs from decades of NSPS rulemaking practice. According to the commenter, the November 2021 preamble text should be considered an ANPR as the December 2022 proposed rule is generally more stringent than the November 2021 preamble, both in terms of actual prescribed standards that go beyond what was earlier described (“EPA is issuing this supplemental proposal to update, strengthen, and expand the standards ....”<sup>19</sup>), impact (EPA is now projecting annual reductions in crude oil production of 21 million barrels compared to its November 2021 projection of 12 million barrels), and scope (e.g., well head monitoring regardless of relative size). Additionally, the commenter states that although Congress referred to NSPS OOOOb (in reference to a methane fee) in the Inflation Reduction Act (IRA), nothing in the IRA alters or overrides the CAA's applicability date provision or EPA's longstanding implementation of it. Had Congress wanted to, the commenter notes that it could have spoken directly to this issue in the IRA and specified November 2021 as the trigger date for NSPS OOOOb applicability, but it did not do so.

Furthermore, commenter (2254-PBPA) recommends EPA should instead use December 6, 2022, as the new source applicability date. According to the commenter, EPA's reliance on section

---

<sup>19</sup> See, e.g., Standards of Performance for New, Reconstructed, and Modified Sources and Emissions Guidelines for Existing Sources; Oil and Natural Gas Sector Climate Review, 87 Fed. Reg. 74, 705 (Dec. 6, 2022).

553(b) of the APA, which only requires notice of a proposed rule to include a description of the subjects and issues involved, is misplaced as follows:

- This is a CAA rulemaking, and the NSPS statutory text sets the applicability date based on proposed rules that “prescrib[e]” a standard of performance that “will be applicable” to the source. Indeed, EPA has proposed that the applicability date for dry seal centrifugal compressors be December 2022 because “standards for dry seal centrifugal compressors were not proposed in the November 2021 proposal.”<sup>20</sup> This is true for all sources covered by the December 2022 proposal, as EPA in November 2021 didn’t prescribe any standards that “will be applicable.”
- The CAA’s NSPS applicability date provision requires publication of “proposed regulations.” NSPS-specific provisions supersede the CAA’s and APA general rulemaking provisions in an NSPS rulemaking. Mere description of the “subjects and issues involved” therefore does not suffice. The CAA section 307(d)(3) language EPA cites is intended to describe what must accompany a proposed rule, not what comprises a proposed rule. The very existence of requirements concerning what must accompany the proposed rule confirms the expectation that there is a proposed rule. EPA’s November 2021 proposal failed to include an actual proposed rule, which eliminates meaningful notice and comment because regulated entities, in practice, do not have the luxury of waiting to see what EPA ultimately finalizes. The importance and potential economic impacts of this rulemaking only further serve to justify a December 2022 applicability date.
- EPA cites a Ninth Circuit decision for the proposition that failure to propose in advance the actual wording of a rule does not make the final rule invalid. See *Rybachek v. EPA*, 904 F.2d 1276, 1287 (9th Cir. 1990). That case is distinguishable. First, the subject matter: That case dealt with wastewater discharge regulations promulgated pursuant to a different statute and for which an applicability date wasn’t set by a rule proposal, which has nothing to do with whether a final rule is invalid. Second, the impact: That case dealt with regulations that applied to permits covering a discrete industry (Alaskan placer mining), whereas the NSPS OOOOb regulations would affect millions of new sources across the U.S.

Commenter (2294-OOGA) objects to U.S. EPA’s proposed compliance date of November 15, 2021, particularly given that regulatory text was unavailable as of the proposed compliance date. The commenter contends that EPA maintaining the November 15, 2021, compliance date is unwarranted and will result in companies having a large backlog of new and modified sources that may be subject to NSPS OOOOb. For example, the storage vessel affected source was expanded from individual tanks to tank batteries under the supplemental proposal. If such new/modified storage vessel sources dating back to November 15, 2021, are subject to NSPS OOOOb, companies will need additional time to meet the initial compliance requirements. The commenter also notes that applicable compliance date of November 15, 2021, will likely result in supply chain shortages.

---

<sup>20</sup> See, e.g., Standards of Performance for New, Reconstructed, and Modified Sources and Emissions Guidelines for Existing Sources; Oil and Natural Gas Sector Climate Review, 87 Fed. Reg. 74,702, 74,707 & 74,716 (Dec. 6, 2022).

Commenter (2326-AXPC) believes that EPA should set the demarcation date for new, modified, and reconstructed NSPS OOOOb as December 6, 2022. Briefly, the commenter believes:

- The November 2021 Notice did not meet the bare minimum requirements under CAA section 307(d) and APA section 553(b) to constitute a “proposed regulation” because a preamble without regulatory text is not a “regulation;” and
- Because the November 2021 notice was not a “proposed regulation,” it could not define a “new source” trigger date under CAA section 111(a)(2).

Commenter (2360-Devon Energy) encourages EPA to establish December 6, 2022, as the appropriate applicability date for new sources subject to NSPS OOOOb. The commenter contends that the initial proposal provided a general framework for regulating methane and volatile organic compounds (VOC) from new and existing sources but lacked the regulatory text necessary to provide the reasonable regulatory certainty necessary for oil and gas operators to be able to make operational and contractual decisions and procure the equipment necessary for compliance. The commenter states that contracts for services and equipment are often finalized months or years in advance, and without the benefit of regulatory certainty in the initial proposal, as evidenced by the numerous changes between the initial and supplemental proposals, operators are left to surmise what the final regulations will entail. The commenter notes that it is actively working toward operational practices and facility designs that meet or exceed the proposed standards, including the phase-out of gas-driven pneumatic controllers, but notes it is necessary that the proposed regulations allow for appropriate “new” and “existing” source designations (*i.e.*, when regulatory text is proposed) and allow for appropriate compliance timelines and control strategies (*e.g.*, routing gas-driven pneumatic controllers to combustion devices) that acknowledge the resource, supply chain, and time constraints that exist when modifying facilities and wells that are already producing in accordance to newly enacted standards.

Commenter (2399-GPA) requests that EPA revise the applicability date for NSPS OOOOb to be, at the earliest, December 6, 2022—the date EPA published the supplemental proposed rule in the *Federal Register*. The commenter asserts that EPA did not in fact propose the actual “regulations” when it provided an initial proposal in 2021 and that, without any actual rules to guide, as a matter of law and basic fairness, EPA should not seek to make November 15, 2021, the effective date for NSPS OOOOb.

First, the commenter (2399-GPA) argues that the CAA does not authorize EPA to make the effective date of NSPS OOOOb a year before it published the actual regulations. The commenter recognizes that in CAA section 111(a)(2) the definition of “new source” suggests that EPA may apply a “standard of performance” to a new source as of the date of “proposed regulations.”<sup>21</sup> However, the commenter states that the EPA did not publish a clear “standard of performance” in “proposed regulations” in November 2021 – it provided preamble language, requested comment on the numerous suggestions it outlined in that preamble, and promised to publish the actual regulatory text. The preamble, however, does not set a “standard of performance” and is not the governing “regulations,” but is designed to inform the public about the meaning of the

---

<sup>21</sup> A “new source” is “any stationary source, the construction or modification of which is commenced after the publication of regulations (or, if earlier, proposed regulations) prescribing a standard of performance under this section which will be applicable to such source.” 42 U.S.C. §7411(a)(2); CAA §111(a)(2).

regulations that are codified in the Code of Federal Regulations.<sup>22</sup> According to the commenter, it has long been understood that those explanatory statements are distinct from the actual rules – and would be used by the courts and the public “in the interpretation of the agency’s rules.”<sup>23</sup>

Second, the commenter (2399-GPA) notes that in putting together the supplemental proposed rule and preparing the regulatory text, EPA has added to and changed the approach it described in the November 2021 preamble.<sup>24</sup> The commenter states it would be grossly unfair and unsound policy for the agency to make a proposal retroactive, when sources and permit writers could not know even a general description of what EPA intended, let alone the regulatory text that would in fact govern. The commenter points to areas where EPA did not set suggested outcomes, such as the requirements for control devices on combustion sources. The commenter asserts that the general request for comments for additional monitoring for control devices does not mean that flow meters and net heating value measurements and other requirements would be required, as EPA has now proposed. Moreover, the commenter contends that unilaterally applying new regulatory text retroactively does not consider the practical implications, costs or burdens associated with retrofitting controls or monitoring equipment on existing controls in the segment.

Third, the commenter (2399-GPS) contends that EPA’s proposed November 2021 effective date runs counter to the U.S. Supreme Court’s long settled rule against applying law retroactively.<sup>25</sup> According to the commenter, nothing in the Act expressly provides EPA the authority to take the wholly unprecedented act of saying its preamble is sufficient. As such, by making NSPS OOOOb effective a year before EPA provided the public the regulatory text, it should be viewed as an impermissible retroactive application.<sup>26</sup>

Fourth, even assuming for the sake of argument that EPA had the authority to apply its December 6, 2022, proposed regulations to sources that commenced construction after November 11, 2021, the commenter (2399-GPA) believes EPA should not do so. The commenter

<sup>25</sup> *Bowen v. Georgetown University Hospital*, 488 U.S. 204 (1988) (“Retroactivity is not favored in the law.”). Congress must convey “the power to promulgate retroactive rules” “in express terms.” *Id.*

<sup>26</sup> *E.g.*, *Marrie v. S.E.C.*, 374 F.3d 1196, 1207 (D.C. Cir. 2004) (“In the administrative context ... ‘a rule is retroactive if it ‘takes away or impairs vested rights acquired under existing law, or creates a new obligation, imposes a new duty, or attaches a new disability in respect to transactions or considerations already past.’”).

states that good policy should afford affected facilities fair notice of the actual regulations – the regulatory text – before potentially being subject to those requirements considering the extraordinary complexity of the proposed regulations – layered onto the already confusing history surrounding the past decade of regulation of oil and natural gas production, midstream, transmission and storage. Moreover, the commenter contends that in the supplemental proposal EPA has proffered no actual justification for adopting this unprecedented approach, making no effort to consider the impracticality, burdens and costs imposed on sources that had no actual regulatory text to consider – and to weigh those against any purported benefits of this harsh retroactive approach.

Commenter (2428-API) states that the new source trigger date should be December 6, 2022, the date the Supplemental Proposal was published in the *Federal Register*. The commenter believes that not only does CAA section 111(a) allow EPA to define the new source trigger date based on the publication date of the supplemental proposal, but also in fact requires it. The commenter reiterates their comments on the original NSPS OOOOb and EG OOOOc proposed rule that the original proposal was fundamentally incomplete because no proposed regulatory text was published or otherwise made available at the time of proposal. As a result, they believe that proposal could not serve to set the new source trigger date for new requirements described in the proposed rule. The commenter provides that EPA’s analysis on the applicability date indicates that EPA believes the CAA and the APA provide the flexibility to select November 15, 2021, as the trigger date for new sources, but nothing in EPA’s analysis specifically concludes or determines that it must use the November 15, 2021, date. The commenter therefore believes that EPA’s rationale for using November 15, 2021, remains flawed for three reasons.

First, the commenter (2428-API) states that the CAA section 111(a)(2) definition of “new source” uses the term “proposed regulations” in defining the new source trigger date. The commenter notes that a preamble unaccompanied by regulatory text is not a “regulation.” Here, the preamble to the original proposal was simply a description of the proposed regulations, but by itself did not constitute a proposed regulation because nothing in the preamble was intended by the Agency to constitute an enforceable legal obligation. The commenter asserts that it could not, as EPA co-proposed multiple concepts for singular facility types in the November 2021 proposal and requested comment that informed the November 2022 supplemental proposal’s regulatory text. The commenter provides that, for example, in the November 2021 proposal, EPA co-proposed quarterly and semi-annual fugitive emissions surveys for well sites with baseline emissions of 3 or more and less than 8 tons per year of methane. The commenter states that the EPA then abandoned the baseline emissions approach in the November 2022 supplemental proposal in favor of an equipment threshold. In another example, EPA co-proposed to define affected well facilities in two ways for purposes of the liquids unloading standards. Under one approach, every well that undergoes liquids unloading would be an affected facility; under the other approach, the affected facility would be limited to wells that undergo liquids unloading that is not designed to eliminate venting. The commenter states that these co-proposals, while limited to a subset of the affected facilities, provides evidence that EPA intended the November 2021 proposal to be conceptual and a means of informing the November 2022 regulatory text. The commenter contends that the November 2022 proposal is complex and requires affected facilities to parse complicated standards that will inform significant capital expenditures and expensive compliance programs. The commenter asserts that the absence of proposed regulatory text in the

original proposal prevents such affected facilities from knowing with reasonable certainty the precise requirements that might apply, and thus prevents them from adequately planning for compliance.

Second, the commenter (2428-API) states that EPA's interpretation of CAA section 307(d) and APA section 553(b) is unreasonable and does not make sense in the broader context of these provisions. For example, the commenter notes that the EPA argues that the required content of a proposed rule specified in CAA section 307(d)(3) does not expressly require regulatory text, but the corresponding content requirements for a final rule (specified in CAA sections 307(d)(4)(B)(i), (6)(A), and (6)(B)) similarly do not expressly require regulatory text. By EPA's reasoning, that means that the Agency is not required to provide regulatory text as part of a final rule. The commenter asserts that is nonsensical because the record for judicial review is limited to the materials prescribed by CAA sections 307(d)(3), (d)(4)(B)(i), (6)(A), and (6)(B). CAA section 307(d)(7)(A). The commenter argues that if proposed and final rules do not need to include regulatory text, then regulatory text would not be subject to judicial review, which is contrary to reason and the clear intent of the law. The commenter summarizes that it is simply not plausible to argue that because CAA section 307(d) does not expressly require a proposed rule to include regulatory text; EPA is not required to make proposed regulatory text available at the time of the 2021 "proposal". The commenter maintains that when considered as a whole, CAA section 307(d) plainly requires rule text to be available.<sup>27</sup>

Third, and more broadly, the commenter (2428-API) contends that the rush issuance of the original proposed rule was politically motivated as a facet of the administration's climate change regulatory agenda, and it was deemed expedient to issue the proposed rule in conjunction with the 2021 Conference of the Parties to the United Nations Framework Convention on Climate Change in Glasgow, Scotland.<sup>28</sup> While the commenter recognizes that every administration has the right to set and implement its regulatory agenda they believe that this Administration's desire to expedite issuance of the original proposed rule led to compromises in the usual regulatory procedures, including the decision not to make proposed regulatory text available. The commenter states that it would be unreasonable for affected facilities to bear the burden of those compromises. The commenter considers it arbitrary and capricious for EPA to decide to issue an admittedly incomplete proposed rule to satisfy political objectives, and, at the same time, assert that it is somehow complete enough to constitute a "proposed rule" that sets the new source trigger date.

As shown in the analysis above, the commenter (2428-API) provides that nothing allows or requires EPA to utilize the November 15, 2021, date. Further, commenter states that the failure

---

<sup>27</sup> EPA cites *Rybachek v. USEPA*, 904 F.2d 1276, 1297 (9th Cir. 1990) as supporting its position that proposed regulatory text is not necessary. That case is inapposite because the court relies on APA § 553(b)(3). While that provision applies to this rulemaking, the more specific requirements of CAA § 307(d) control here.

<sup>28</sup> EPA's press release for the original proposal is available at U.S. to Sharply Cut Methane Pollution that Threatens the Climate and Public Health | US EPA ("As global leaders convene at this pivotal moment in Glasgow for COP26, it is now abundantly clear that America is back and leading by example in confronting the climate crisis with bold ambition," said EPA Administrator Michael S. Regan. "With this historic action, EPA is addressing existing sources.")

of EPA to provide regulatory text in the November 15, 2021, proposal is reason enough for EPA to “warrant exercising” any discretion it does have with respect to the deadline.

Additionally, the commenter (2428-API) contends that by utilizing November 15, 2021, as the relevant demarcation date, EPA will be including a significant number of sources that were new, modified, or reconstructed between November 15, 2021, and December 6, 2022. The commenter explains that, for a significant number of the affected facilities, operators will be required to retrofit those new, modified, or reconstructed sources to comply with the regulations, including regulations not known to operators at the time of construction, modification, or reconstruction. Many of these requirements described by the commenter involve either: (1) substantial capital expenditures for equipment (*e.g.*, instrument air skids and/or generators for use of non-emitting pneumatic controllers); (2) engineering design (*e.g.*, storage tanks, design for any covers and closed vent systems, among others); (3) acquisition (along with all other operators) of a substantial number of part and equipment (*e.g.*, flow meters, calorimeters; and (4) substantial in-field resources for retrofits. The commenter asserts that not knowing with reasonable certainty what the final rule would require would significantly complicate implementation of compliance measures, causes the rule to be much more costly for such sources than EPA predicts, and frustrates the regulatory purpose of setting the new source trigger date at the date of proposal (which they say clearly is intended to provide reasonable notice of the ultimate requirements so that planning can be done at the time of construction, reconstruction, or modification). The commenter also indicates the supply chain disruptions since the onset of the COVID pandemic and that the November 15, 2021, trigger date would only compound this issue.

Commenter (2483-INGAA) argues that application dates for NSPS OOOOb regulations governing new, modified, and reconstructed sources that commence construction after the date of the November 15, 2021, partial proposal, and that proposed EG OOOOc will govern existing sources that commenced construction on or before November 15, 2021, even for new sources subject to a previous NSPS (*i.e.*, NSPS OOOOa) are incorrect as a matter of law. The commenter notes that section 111(a) of the CAA defines a “new source” as “any stationary source, the construction or modification of which is commenced after the publication of regulations (or, if earlier, proposed regulations) prescribing a standard of performance under this section which will be applicable to such source.”<sup>29</sup> The commenter describes that EPA takes the position in the supplemental proposed rule that a notice of proposed rulemaking need not contain proposed regulatory language in order to trigger the applicability provision of CAA section 111(a). For support, EPA notes that a “notice of proposed rulemaking” is required to contain certain items under section 307(b) of the CAA and section 553(b)(3) of the APA, but neither explicitly requires regulatory language. The commenter contends that EPA ignores the text of section CAA 111(a), which does not refer to a “notice of proposed rulemaking” (the term used in section 307(b) to set minimum information that is required in such a notice) and instead 111(a) refers to “regulations ... or ... proposed regulations[] prescribing a standard of performance under this section.” (Emphasis added). The commenter adds that what the statute is referring to is plainly the actual rules – language that would become law and would be included in the Code of Federal Regulations once finalized – setting forth the standard of performance. According to the

---

<sup>29</sup> CAA §111(a)(2), 42 U.S.C. §7411(a)(2).

commenter, if there is any doubt, the term “prescribing” dispels it: this term requires a level of specificity that cannot be set forth without regulatory text.

Moreover, commenter (2483-INGAA) highlights that section 111(a) of the CAA states that, after considering comments on the published “proposed regulations,” EPA “shall promulgate, within one year after such publication, such standards with such modifications as [EPA] deems appropriate.” This tight deadline for promulgating the final regulations that would legally prescribe conduct by the regulated entity reflects the highly unusual regime of regulation under section 111 – namely, that there may be some change between the date of the proposal and the final rule that may impose slightly different requirements on sources constructed in the interim, retroactively. The commenter states that it is unrealistic for EPA to be able to finalize regulatory language – which surely it must include in the final regulation – within one year of publishing a notice of proposed rulemaking that contains no proposed regulatory language whatsoever. The commenter considers this further evidence that EPA’s interpretation of the applicability date under section 111(a) is incorrect and unreasonable. According to the commenter, the date *should* be that of publication of specific proposed rules that prescribe a standard of performance, *not* that of a notice that generally describes a possible standard without prescribing it in detail. For these reasons the commenter contends that the application date for NSPS OOOOb is the date of the Supplemental Proposed Rule – December 6, 2022 – not the date of a notice of proposed rulemaking that contained no proposed regulations prescribing a standard of performance.

Commenter (2354-Business Roundtable) asserts that the EPA may define “new sources” based on the publication date of the supplemental notice, (*i.e.*, December 6, 2022). The commenter believes EPA is required to do so by the text of CAA section 111(a)(2). That section provides that new sources are those that were constructed, reconstructed or modified “after the publication of regulations (or, if earlier, proposed regulations) prescribing a standard of performance under this section that will be applicable to such source.”<sup>30</sup> According to the commenter, the November 2021 proposal in this rulemaking contained no proposed “regulations” – *i.e.*, proposed regulatory text – it was simply a preamble.<sup>31</sup> The commenter notes that it is well-established in administrative law that “regulations” are the regulatory text that will appear in the Code of Federal Regulations. In *Perez v. Mortgage Bankers Ass’n*, for example, the Supreme Court declared that an interpretive rule cannot “amend” a “regulation” because a regulation is “text” in the CFR that can only be amended by notice and comment rulemaking.<sup>32</sup> “Regulations” are “agency statement[s] of general applicability and future effect, which the agency intends to have the force and effect of law.”<sup>33</sup> The commenter provides Justice Kavanaugh’s explanation, “[by] the 1980s, the words ‘regulation’ and ‘substantive’ ... carried a special meaning in the context of administrative law ... A ‘substantive rule,’ often promulgated pursuant to specific statutory authority, is a rule that ‘bind[s]’ the public or has ‘the force and effect of law.’”<sup>34</sup> By contrast, the commenter states that regulatory preambles do not appear in the CFR, and ordinarily are not legally binding.

---

<sup>30</sup> 42 U.S.C. §7411(a)(2)

<sup>31</sup> See 86 Fed. Reg. 63110 (Nov. 15, 2021), referring repeatedly to “this preamble” (*e.g.*, at 63115, 63116).

<sup>32</sup> *Perez v. Mortgage Bankers Ass’n*, 575 U.S. 92, 103-105 (2015).

<sup>33</sup> See E.O. 12866 (Sept. 30, 1993) at § 3(d).

<sup>34</sup> *Azar v. Allina Health Services*, 139 S.Ct. 1804, 1818 (2019) (Kavanaugh, J., concurring)

According to the commenter (2354-Business Roundtable), because CAA section 111(a)(2) specifically refers to proposed “regulations,” the November 2021 proposal did not trigger it, and the applicability date for this rulemaking is therefore December 6, 2022, the date of publication of the supplemental notice, which does include proposed CFR text, albeit still not in the *Federal Register*.<sup>35</sup> The commenter states that EPA contends that CAA section 307(d)(3) enumerates all the required elements of a notice of proposed rulemaking (*e.g.*, factual data), and that these do not include proposed regulatory text.<sup>36</sup> In fact, this statutory enumeration spells out what belongs in the statement of basis and purpose, which is to “accompan[y]” the notice of proposed rulemaking.<sup>37</sup> Section 307(d)(6)(A) of the CAA sets almost exactly the same requirement for final rules, too,<sup>38</sup> which obviously must contain the CFR text of the final rule. The commenter concludes that Congress assumed EPA would publish the text in both cases.

Based on this analysis, the commenter (2354-Business Roundtable) believes CAA sections 111(a)(2) and 307(d) require EPA to set December 6, 2022, as the applicability date for this rulemaking. In addition to the statutory basis that establishes the applicability date on December 6, 2022, the commenter adds that the Agency has good reasons, rooted in the purpose of section 307(d) of the CAA, to exercise its discretion to do so due to the complexity and coverage of the rule. The commenter provides that EPA has recognized the sheer number of facilities to which the proposed regulations will apply and the complexity of the regulations.<sup>39</sup> The commenter contends that unnecessary complexity and regulatory confusion not only waste resources but also make it more difficult to comply with regulations designed to reduce methane emissions. By applying the definition of “new source” consistent with the CAA and setting the applicability date for NSPS OOOOb as December 6, 2022, EPA would clarify regulatory applicability to the benefit of both sources and the Agency. Additionally, the commenter states that sources affected by applying the correct applicability date (new, modified, or reconstructed sources between November 21, 2021, and December 6, 2022) would still be regulated. They would first be subject

---

<sup>35</sup> The Agency argues that neither Section 307(d) of the Clean Air Act nor Section 553 of the Administrative Procedure Act (APA) requires EPA to publish the proposed C.F.R. text in a notice of proposed rulemaking. In fact, the D.C. Circuit has held that Section 307(d) does require EPA to publish proposed regulatory text. *Small Refiner Lead Phase-Down Task Force v. EPA*, 705 F. 2d 506 (D.C. Cir. 1983) involved a CAA rulemaking where, as here, EPA did not include the proposed regulatory text in its notice of proposed rulemaking. The court began by noting that, “[i]n 1977, Congress—concerned that the [APA] did not provide procedures adequate for the complex scientific issues involved in EPA rulemaking—created new procedures for most rulemaking under the CAA, [ones that] require[] a much more detailed notice of rulemaking.” *Id.* at 518. The court explained that one of the two major differences between APA §553(b) and CAA §307(d)(3) [is that] the CAA, unlike the APA, requires EPA to issue a “proposed rule.” Although CAA §307(d)(3) does not explicitly require EPA to issue a proposed rule, it refers to the agency’s duty to explain “the factual data on which the proposed rule is based” and “the major legal interpretations and policy considerations underlying the proposed rule.” *Id.* at 519.

<sup>36</sup> 87 Fed. Reg. 74716.

<sup>37</sup> 42 U.S.C. §7607(d)(3) (emphasis added)

<sup>38</sup> *Id.* §7607(d)(6)(A).

<sup>39</sup> Supplemental Notice, *supra* note 1 [87 Fed. Reg. 74702 (Dec. 06, 2022).], at 74833 (“The EPA understands that EG OOOOc for the Crude Oil and Natural Gas source category will apply to an extraordinary number of designated facilities and for many designated facilities the standards are complex compared to other EG. For example, in the U.S., the EPA has identified over 15,000 oil and gas owners and operators, around 1 million producing onshore oil and gas wells, about 5,000 gathering and boosting facilities, over 650 natural gas processing facilities, and about 1,400 transmission compression facilities.”).

to existing NSPS OOOOa, and then in a few years, EPA's proposed EGs for existing sources under EG OOOOc, thus eliminating any potential regulatory gap.

Finally, the commenter notes that many thousands of wells and other equipment will become subject to the new source performance standards. The commenter contends it will be an enormous challenge for owners and operators to purchase and install the required equipment, establish record-keeping and reporting protocols, and train personnel needed to comply with these regulations just 60 days after the final regulations are published in the *Federal Register*. The commenter urges EPA to incorporate extended implementation timelines that phase-in compliance with the standards.

Commenter (2248-NDPC) reiterated their January 31, 2022, comments, where they commented that they do not believe this action (*i.e.*, the proposed rule in Docket EPA-HQ-OAR-2021-0317) meets the legal or ethical requirements of a proposed rule for rulemaking and the proposed applicability date for sources that will be subject to the new subpart NSPS OOOOb should not be November 15, 2021, but rather the date the actual proposed rule text is finally published. The commenter reports that several state agencies and other industry trades made the same comment. In addition, the commenter notes that the additional information requests in this supplemental proposal have put a large burden on state agencies, the public, and the industry to provide meaningful comments on such a moving target. The commenter contends that this is setting a dangerous precedent for future regulation development and public participation. The commenter is requesting the EPA rethink its position on calling this a proposed rule and not set the effective date until all stakeholders have a chance to review a complete, well-written proposal.

Response II-3-1: Section IX (Interaction of the Rules and Response to Significant Comments Thereon) of the preamble to the final rule responds to these comments.

Comment: Commenter (2218-Texas Commission on Environmental Quality and Railroad Commission to Texas) notes that the new NSPS has different applicability and modification definitions than the NSPS OOOOa rule. The commenter suggests that creating separate classifications within the NSPS based on dates of construction or modification will create additional burdens when reviewing authorizations within the specified legislatively mandated time frames. In the preamble, the commenter reports that the EPA provided different scenarios to demonstrate how applicability under the different rules would work. The commenter appreciates the examples EPA provided in the preamble demonstrating how applicability under the different rules would work, however, they assert that the fact that the provided examples are needed demonstrates the complexity of these overlapping requirements.

Response II-3-2: Section IX (Interaction of the Rules and Response to Significant Comments Thereon) of the preamble to the final rule responds to these comments.

Comment: Commenter (2337-Kansas Department of Health and Environment) indicates that there were significant changes and updates made to the November 15, 2021, original rule proposal. These include different designated (affected) facility categories, their corresponding proposed BSER/EG (and frequency and methods of monitoring), and most importantly, the basis for such amendments (*e.g.*, assumptions, modeling approach, analysis) in such a way that the

SNPR proposal is almost a complete overhaul of the original rule proposal. The commenter believes it makes sense that the definition of "new source" be based either on the date after the publication of the SNPR or, since the EPA is still in the process of soliciting comments on all important aspects of the supplemental proposal, to wait until after the publication of a final draft of the rule.

Response II-3-3: Section IX (Interaction of the Rules and Response to Significant Comments Thereon) of the preamble to the final rule responds to these comments.

### **3.2 Existing Source for Purposes of the Proposed EG OOOOc**

Comment: Commenter (2483-INGAA) agrees with EPA's definition of "existing source" and states that the statutory text is unambiguous, and therefore a source cannot be both "new" and "existing" at the same time. The commenter notes that even so, EPA insists that the applicability date of EG OOOOc for existing source methane standards is for sources that commenced construction on or before November 15, 2021 (*i.e.*, the applicability date after which the NSPS OOOOb new source standards apply). Recognizing that under this regime a source that was constructed after September 18, 2015 (the applicability date for the NSPS OOOOa new source standards) would be subject simultaneously to NSPS OOOOa and EG OOOOc, EPA goes on to explain how it believes the two standards would interact and which standard would govern for which type of source. Thus, according to EPA – though the commenter notes the Agency never says it explicitly – such sources are both "new" because they were constructed after the applicability date of NSPS OOOOa and "existing" because they were constructed before the applicability date of NSPS OOOOb. The commenter contends that the statutory text cannot bear such an interpretation.

The commenter (2483 - INGAA) states that the statute defines "new source" as "any stationary source, the construction or modification of which is commenced after the publication of regulations (or, if earlier, proposed regulations) prescribing a standard of performance under this section which will be applicable to such source."<sup>40</sup> Sources whose methane emissions were subject to NSPS OOOOa are "new sources" under section 111 – and thus they cannot be existing sources – because those sources are already subject to "a standard of performance" for methane under section 111. As a result, "existing sources" for the purpose of proposed EG OOOOc are those sources that commenced construction on or before September 18, 2015, which is the date that NSPS OOOOa was proposed. According to the commenter, any source that commenced construction after that date was a "new source" and complied with the standards of performance set forth in NSPS OOOOa.

The commenter (2483-INGAA) believes that this makes sense within the context of section 111(d) of the CAA, which is to ensure that certain pollutants (those like methane that are not regulated under the national ambient air quality standard (NAAQS) program or the hazardous air pollutants (HAP) program) are regulated either as new sources under CAA section 111(b) or as existing sources under CAA section 111(d).<sup>41</sup> The commenter holds that there is no need to

---

<sup>40</sup> CAA §111(a), 42 U.S.C. §7411(a).

<sup>41</sup> See *id.* §111(d), 42 U.S.C. §7411(d).

regulate sources that commenced construction after September 18, 2015, under the existing source program of CAA section 111(d) because those sources have already complied with NSPS under CAA section 111(b). For these reasons, the commenter recommends EPA change the applicability date for EG OOOOc to sources that commenced construction on or before September 18, 2015.

Response II-3-4: Section IX (Interaction of the Rules and Response to Significant Comments Thereon) of the preamble to the final rule responds to these comments.

Comment: Commenter (2254-PBPA) states that existing source standards should not be “co-proposed” with new source standards, as EPA has done here, but should instead be informed by already-finalized new source standards and made less stringent as necessary to accommodate “other factors,” such as the remaining useful life of existing sources.<sup>42</sup> The commenter notes that EPA has previously proposed to require that existing source standards be proposed simultaneously with new source performance standards, but EPA ultimately declined, in part because “proposing (or publishing) an emission guideline after promulgation of the corresponding standard of performance” would allow “the Agency [to] benefit from the comments on the standard of performance in developing the emission guideline.”<sup>43</sup> If EPA proceeds as proposed, the commenter suggests that the opportunity to have the EG informed by the process of developing and implementing the NSPS would be lost. According to the commenter, this would have material consequence because EPA would be left to take a one-size-fits-all approach through enacting existing source standards that largely mirror its new source standards. The commenter states this is particularly important because EGs will have a far greater impact on the oil and gas sector because there are far more existing sources than there are new sources subject to the NSPS program.

Additionally, commenter (2254-PBPA) provides that EPA should wait and later propose EGs that are less stringent than the proposed NSPS under NSPS OOOOb because there are a fundamentally different set of considerations when regulating existing sources for the first time. Existing sources must retrofit equipment without the benefit of incorporating emission controls into pre-operational design, resulting in added costs. For example, the commenter provides that in the Permian and many other areas, many existing well sites are low producing wells that could be close to production cycle end-of-life. The complete retrofit of a low-producing facility is likely cost prohibitive based on well economics, which may result in many low production or stripper well sites shutting in production. These costs will likely accelerate the abandonment of many older existing well sites by fundamentally altering the costs associated with their operations and ongoing compliance. The commenter states that the economics of EPA’s proposed EGs are therefore fundamentally different and more burdensome to the industry than new source standards, and EPA needs to revise its economic analysis accordingly.

Response II-3-5: EPA disagrees with commenters that the Agency was required to first promulgate final NSPS before proposing to promulgate Emission Guidelines. Nothing in CAA

---

<sup>42</sup> 42 U.S.C. §7411(d)(1). EPA should not, as it has proposed, require states to demonstrate as a threshold matter that a designated facility cannot reasonably apply BSER before the states account for remaining useful life and other factors (RULOF) in order to set a less stringent standard. See 87 Fed. Reg. at 74,820-21.

<sup>43</sup> See, e.g., 40 Fed. Reg. at 53,345.

section 111(d) requires that the EPA take these actions consecutively rather than concurrently. Rather, CAA section 111(d)(1) provides that the Administrator “prescribe regulations” pursuant to which states develop plans that “establish[] standards of performance for any existing source for any air pollutant ... (ii) to which a standard of performance under this section would apply if such existing source were a new source.” For each existing emission source addressed by the final Emission Guideline, the EPA is also finalizing an NSPS that would apply “if such existing source were a new source.” Accordingly, EPA has satisfied the requirements of CAA section 111(d). For EPA’s response to comment regarding the different factors that may affect the EPA’s identification of the BSER for existing sources, see section XIII.C.1 of the final rule preamble.

Comment: Commenter (2391-Chesapeake Energy Corporation) recommends that if the final rule does not authorize compliance by routing natural-gas driven pneumatic controllers and pumps to control devices, EPA should define “new sources” based on the December 6, 2022, publication date of the supplemental proposal to allow them and other similarly situated operators more time to plan for and attain the zero emission standards proposed for existing sources under EG OOOOc. Alternatively, the commenter suggests EPA employ any available authority it has to provide operators like them who may need to comply with standards for modified or reconstructed sources a more reasonable and feasible amount of time to determine applicability and implement the final regulation.

Response II-3-6: Section IX (Interaction of the Rules and Response to Significant Comments Thereon) of the preamble to the final rule responds to these comments.

### **3.3 EG OOOOc Impact on Existing NSPS KKK, NSPS OOOO, or NSPS OOOOa**

Comment: Commenters (2180-Pennsylvania Department of Environmental Protection (PADEP), 2222-Wisconsin Department of Natural Resources (WIDNR), 2301-U.S. Chamber of Commerce (USCC)) recommend that EPA streamline requirements in consideration of the complex implementation requirements of this rule compounded with existing regulation requirements.

Commenter (2180-PADEP) requests that EPA consolidate existing applicable regulations and streamline the proposed requirements for new and existing sources in the oil and natural gas industry. The commenter contends that with multiple regulations, operators could miss important requirements, which would consequently increase the burden on state regulators in determining and enforcing compliance. The commenter notes that the regulatory framework becomes even more complex when considering state regulations that were promulgated to comply with the State Implementation Plan (SIP) requirements for the 2016 Control Techniques Guidelines for the Oil and Natural Gas Industry (2016 CTG).

The commenter (2180-PADEP) states that, because EPA intends to promulgate a NSPS and an EG for existing sources in the oil and natural gas sector, the proposed rules should be modified to include all applicable existing requirements and replace NSPS KKK, LLL, OOOO, and OOOOa, while also establishing appropriate VOC and methane requirements for existing sources. The commenter maintains that streamlining the regulatory requirements by allowing both the industry and state regulators to determine regulatory applicability based on a singular date would be an

efficient approach that would enable states to then streamline their regulations for the oil and natural gas industry when submitting their SIPs to comply with the EG.

Commenter (2222-WIDNR) indicates that the complexity of determining applicability of multiple CAA section 111 standards to the same group of equipment at a facility is burdensome for affected sources and permitting authorities and ultimately leads to inconsistencies in rule implementation. The commenter contends that for certain designated facilities, the presumptive standards that will apply to existing facilities under the proposed EG are less stringent than standards that apply to those facilities under existing NSPS KKK, OOOO, or OOOOa. The commenter suggests that for designated facilities that are subject to a more stringent NSPS limit than the limit proposed in the EG, EPA should include in the EG (or at the very least in the federal plan implementing the EG) a limit equivalent to the NSPS limit for designated facilities constructed within the applicability time frame of the NSPS. Additionally, the commenter provides that for certain designated facilities, EPA proposes in its preamble that compliance with the EG will satisfy compliance with the existing NSPS. The commenter also states that EPA should ensure rule language to this effect is included in the EG so this decision is clear and enforceable, and that EPA should revise the titles and applicability conditions in the existing NSPS KKK, OOOO, and OOOOa to clarify which rules facilities must comply with.

Commenter (2301-USCC) provides that EPA must avoid complex and difficult-to-follow layering of multiple NSPS regimes atop one another, particularly for equipment located at the same site. EPA must ensure that the regulatory regime does not require extensive time and resources to track differing compliance requirements for equipment across these facilities and should aim instead to align any new requirements with those already in place under the existing regime or continue to clearly state in the final regulatory text that compliance with any NSPS or EGs finalized under this rulemaking will also constitute compliance with the older NSPS standards.

In particular, the commenter (2301-USCC) notes that sources already subject to NSPS OOOOa as of EPA's proposed November 15, 2021, applicability date,<sup>44</sup> also become existing sources on that date, and therefore subject to EG OOOOc requirements.<sup>45</sup> The commenter notes that adding to this already complicated structure, different pieces of equipment at the same facility would be subject to different versions of the NSPS based on whether the individual component was replaced or modified after a particular trigger date, which would require extensive tracking for operators to determine which regime applies to each piece of equipment if EPA does not make compliance with the new standards equate to compliance with NSPS OOOO and OOOOa. However, the commenter asserts that EPA's Methane Proposal would not fully abrogate NSPS OOOO and NSPS OOOOa, indicating only that "[f]or most designated facilities," compliance with an implementing state or federal plan consistent with EG OOOOc would constitute compliance "with the older NSPS," presumably meaning NSPS OOOO and OOOOa.<sup>46</sup> The commenter contends that this would not provide sufficient regulatory certainty for regulated

---

<sup>44</sup> Although, as noted in other sections of the comment letter, the commenter contends that the proper applicability date for any final rule should be the date of this proposed Methane Proposal—December 6, 2022—not that of the November 2021 Notice.

<sup>45</sup> See 87 Fed. Reg. at 74,707 (Table 1 providing applicability dates for NSPS OOOOa and EG OOOOc).

<sup>46</sup> Id. at 74,707.

sources under the Methane Proposal. The commenter asserts that regulated entities should not be left to guess whether they will be found in compliance with the proposed layering of requirements—particularly given the potential to incur high administrative and civil penalties on a per-day, per-violation basis in the event of an enforcement case. According to the commenter, the resulting web of regulatory requirements would not only be arbitrary and capricious and unduly burdensome but would also raise serious due process concerns. The commenter recommends EPA simplify the application of these layered provisions to remedy these due process and CAA concerns.<sup>47</sup>

Response II-3-7: In this action the EPA is finalizing amendatory text to NSPS KKK, OOOO, and OOOOa to state that those rules continue to be in effect until an affected facility begins complying with a more stringent requirement, that applies to the same affected facility, in an approved, and effective, state or federal plan that implements EG OOOOc, or modifies or reconstructs to become subject to NSPS OOOOb. With the exception of sweetening units at onshore natural gas processing plants, all affected facilities under NSPS KKK, OOOO, and OOOOb have corresponding designated facilities under EG OOOOc, however, the emissions standards for sweetening units remain unchanged from NSPS LLL to NSPS OOOO, OOOOa, OOOOb or OOOOc. For further information, see section IX.C of the final rule preamble.

Comment: Commenters (2326-AXPC, 2428-API) question the legality of simultaneous designations as a “new” and “existing” source under multiple standards.

Commenter (2326-AXPC) states EPA must clarify that where overlapping NSPS requirements apply to a source, the source needs to comply with only one set of requirements. The commenter notes that generally, EPA suggests that one must conduct a line-by-line comparison of the requirements from each of the multiple applicable regulations to determine which is most stringent, and EPA will consider compliance with the most stringent to be compliance with the other applicable regulations. The commenter provides that there will of course be uncertainty as to whether one requirement is more stringent than another. For example, if a similar standard requires methane and VOC reductions on the one hand and only methane reductions on the other, which is more stringent? In addition to this uncertainty, the commenter provides that the EPA does not explain how operators must sort through the reporting and recordkeeping requirements under multiple standards that would apply simultaneously. Must the operator report under both standards? The commenter further states that EPA provides no legal analysis for why it believes a source could be subject to multiple, conflicting performance standards as a “new” source under one standard and an “existing” source under another. The commenter is not aware that EPA has ever taken the position that a source could continue to be subject to a previously applicable new source performance standard after triggering the applicability of a subsequent standard. And here, EPA proposes that EG OOOOc will apply to existing sources regardless of whether the source is subject to NSPS OOOO or OOOOa. The commenter requests that EPA clearly identify that only one NSPS OOOO/a/b/c standard can apply to a source at any given time. The commenter recommends EPA provide detailed affected facility-by-affected-facility guidance, on

---

<sup>47</sup>*Cf. Sessions v. Dimaya*, 138 S. Ct. 1204, 1212 (2018) (“‘The prohibition of vagueness in criminal statutes’ . . . is an ‘essential’ of due process, required by both ‘ordinary notions of fair play and the settled rules of law.’ The void-for-vagueness doctrine, as we have called it, guarantees that ordinary people have ‘fair notice’ of the conduct a statute proscribes.... And the doctrine guards against arbitrary or discriminatory law enforcement.”).

a requirement-by-requirement basis, that clearly identifies the applicable compliance standard, along with guidance on recordkeeping, reporting, and notification requirements should the current proposal be finalized.

Commenter (2428-API) expresses that the explanation provided at 87 FR 74716 does not provide sufficient detail on key legal questions of this application. For example, EPA does not explain how the law requires or can be interpreted to require a source to be regulated as a “new” source under a prior NSPS and, at the same time, be regulated as an “existing” source under a subsequent CAA section 111(d) program. The commenter contends this is how EPA considers the law to work, but that the supplemental proposal does not explain why this outcome (applicability of both new and existing source standards to the same affected/designated facility) must or may be prescribed under the law.

The commenter (2428-API) notes that EPA has never taken the position that previously applicable NSPS continue to apply to an affected facility that triggers the applicability of a subsequent standard. For example, VOC emissions from storage vessels are regulated under both NSPS OOOO and OOOOa. It is easily conceivable that a given storage vessel might have triggered NSPS OOOO because it was constructed one month after that standard was proposed and then subsequently triggered NSPS OOOOa because the storage vessel was modified two months after that standard was proposed. It is well understood that, in such a circumstance, the NSPS OOOO storage vessel requirements cease to apply after the corresponding NSPS OOOOa requirements are triggered. The commenter asserts that the approach to reconciling applicability suggested in the supplemental proposal cannot be reconciled with EPA’s historic practice.

More broadly, the commenter (2428-API) provides that EPA fails in both the original and supplemental proposals to explain how the law must or can be construed to determine what standard applies to a given source when: (1) the source is regulated as a new source under a prior version of an NSPS (such as NSPS OOOO) and then triggers a subsequent version of that new source standard (such as NSPS OOOOa); (2) the source is regulated as a new source under an existing new source standard (such as NSPS OOOO or OOOOa) and is in existence when a subsequent CAA section 111(d) existing source standard is proposed (such as EG OOOOc) and subsequently take effect; and (3) a source is regulated as an existing source under a CAA section 111(d) standard (such as EG OOOOc) and is subsequently modified or reconstructed such that it triggers a corresponding new source standard (such as NSPS OOOOb). In sum, the commenter believes EPA fails to acknowledge the complexities and ambiguities as to how the law applies to this situation and fails to provide relevant legal analysis on these points. Unless EPA corrects these problems, the final rule will be both procedurally flawed (for failure to satisfy the CAA section 307(d)(3) obligation for EPA to address in the proposed rule that major legal interpretations underlying the proposed rule and to provide an opportunity for public comment) and arbitrary and capricious (for failure to address key factors underlying applicability of the various subparts). The commenter notes the legal basis for the applicability scheme for these rules is an issue of central relevance because the scope of applicability is fundamental to proper implementation and coordination of these rules.

Response II-3-8: Section IX (Interaction of the Rules and Response to Significant Comments Thereon) of the preamble to the final rule responds to these comments.

Comment: Commenter (2177-Southern Ute Indian Tribe) states that the current set of proposed regulations, EG OOOOc do not directly impose requirements on existing sources. Rather, states must submit plans for the EPA's approval that are at least as effective as the presumptive standards in EG OOOOc. The commenter explains that many states already have oil and gas emission control programs in place, and the EPA has outlined criteria to assist those states in determining whether those existing programs are equivalent to EG OOOOc. The commenter contends that this approach leaves sources located in Indian country in uncertainty as these sources are not under state regulation. The commenter suggests EPA consider developing reservation specific Federal Implementation Plans (FIP) or assist tribes with developing Tribal Implementation Plans (TIP) for sources located within Indian country. The commenter notes EPA proposes to require states to submit their methane plans for review within 18 months of publication of the final EG and to require compliance by existing sources within 36 months after the state plan is due to the EPA. The commenter suggests EPA should consider the timeliness of FIP and/or TIP development to coincide with state plans.

Response II-3-9: See the discussion in Section I.A (General Information/Does this action apply to me?) ((of the preamble to the final rule. Tribes are not required to develop plans to implement the EG under CAA section 111(d) for designated existing sources. The EPA notes that this final rule does not directly impose specific requirements on designated facilities, including those located in Indian country. Before developing any standards for sources on tribal land, the EPA would consult with leaders from affected tribes.

Comment: Commenter (2286- Colorado Department of Public Health and Environment, Air Pollution Control Division) appreciates EPA's narrative discussion comparing the older NSPS to the proposed presumptive standards but requests that EPA include the described more stringent provisions in the proposed presumptive standards directly or by reference, should EPA prefer those requirements continue to be implemented instead of the proposed presumptive standards once finalized. Specifically, the commenter requests that EPA put forth a singular standard for gas plant leak detection and repair (LDAR) to streamline oversight and reduce uncertainty in the various applications of portions of federal rules. The commenter appreciates the goals that EPA is pursuing with this proposal. However, the commenter requests that EPA not err on the side of being overly prescriptive and allow states flexibility in determining appropriate criteria on these issues to allow for the continued implementation of effective plans.

Response II-3-10: See the discussion in Section IX.C (How will the final EG OOOOc impact sources already subject to NSPS KKK, NSPS OOOO, or NSPS OOOOa) of the preamble to the final rule.

Comment: Commenter (2393-Oklahoma Office of the Secretary of Energy and Environment) indicates that EPA has made a few notable exceptions for when the existing standards may functionally be more stringent than the new EGs and therefore must continue to be followed. Namely, EPA mentions that NSPS KKK is more stringent than the presumptive standard in EG OOOOc for centrifugal compressors and reciprocating compressors.<sup>48</sup> The commenter states that this would mean that some facilities could be subject to requirements of both NSPS KKK and EG OOOOc. In addition, EPA's change from regulating a single storage vessel in NSPS OOOO

---

<sup>48</sup> 87 Fed. Reg. 74717.

and OOOOa to regulating a tank battery in EG OOOOc and from a pneumatic controller in NSPS OOOO and OOOOa to a collection of pneumatic controllers in EG OOOOc further complicates the determination of what facilities are subject to which regulations.<sup>49</sup> The commenter asserts that regulations need to be clear as to which subpart equipment was subject to along with when and how a source became subject to a different regulation.

Response II-3-11: See the discussion in Section IX.C (How will the final EG OOOOc impact sources already subject to NSPS KKK, NSPS OOOO, or NSPS OOOOa) of the preamble to the final rule.

Comment: Commenter (2428-API) states that EPA must consider the cumulative burden imposed to the regulated community of numerous and onerous provisions in the supplemental proposal, especially due to the unprecedented number of sources that will be subject to the rule given the proposed November 2021 applicability date for new, modified, and reconstructed sources. The commenter notes EPA must also consider the overlapping applicability of NSPS OOOO, OOOOa, OOOOb, and EG OOOOc and the difficulty the industry has faced to fully understand the impacts of this rule without a comment extension. The commenter contends that these difficulties for the regulated community have been compounded by other rules that impact the same sources (*e.g.*, Bureau of Land Management's (BLM's) Waste Prevention Proposal). Specifically, the commenter requests EPA be clear on the disposition of NSPS OOOO and OOOOa applicable sources if and when they become subject to EG OOOOc.

Response II-3-12: Regarding the applicability date, see the discussion in Section IX.A. (What date defines a new, modified, or reconstructed source for the purposes of the final NSPS OOOOb?) of the preamble to the final rule. Regarding requests for comment extensions, see Responses II-23-20 and II-23-22 of Volume II, Chapter 23 (Miscellaneous Other Comments), subsection 23.4.1 (Public Comment Period Adequacy (*i.e.*, Request for Extension, Inadequate Time Provided) of the RTC. For the disposition of NSPS OOOO and OOOOa applicable sources if and when they become subject to EG OOOOc, see the discussion in Section IX.C (How will the final EG OOOOc impact sources already subject to NSPS KKK, NSPS OOOO, or NSPS OOOOa) of the preamble to the final rule.

### **3.4 Feasibility of Applicability and Compliance Dates for New and Existing Sources**

Comment: Commenters (2200-NuEnergy Operating, Inc. (NuEnergy), 2227-WEA, 2252-PAW, 2255-Ovintiv Inc. (Ovintiv), 2428-API) express concerns with the ability to immediately implement the necessary changes within the proposed timeframes.

Commenter (2200-NuEnergy) states that implementation would not be feasible if a November 15, 2021, application date is set. The commenter indicates they would need many months' time for their company to comply with the new regulations. The commenter recommends an alternative scalable implementation timeline instead as they have no doubt that resources,

---

<sup>49</sup> Id.

services, and equipment will not be immediately available to be able to comply with the new regulations.

Commenter (2227-WEA) recommends a phase-in period of three years for new and modified facilities to install equipment required to meet a non-emitting standard, and a longer period of seven years for existing facilities to retrofit equipment with low-bleed, intermittent bleed, or non-emitting controllers. The commenter states that EPA has not adequately considered the impacts of the current supply chain interruptions on the ability for operators to comply with the rule. The commenter notes that specialized equipment, such as air compressors, electric controllers, and equipment needed to retrofit facilities have been particularly hard-hit by supply chain constraints related to COVID-19. According to the commenter, the industry has experienced delays of several months in acquiring equipment to retrofit facilities, all prior to this publication being made. The increased demand for equipment, given the potential rule requirements, would only exacerbate the challenges associated with acquiring that equipment.

Commenter (2252-PAW) states that the CAA suggests compliance for NSPS sixty days following the final rule publication in the *Federal Register*, or sixty days after becoming an affected facility. The commenter does not believe this timeline is feasible for several emission source categories, including pneumatic controllers and pneumatic pumps. According to the commenter, nearly fifty percent of Wyoming surface and two-thirds of its mineral estate is federally managed. Most of the companies operating in Wyoming operate with a federal nexus, which in part include BLM wildlife stipulations including for sage grouse, burrowing owl, and ferruginous hawk. These stipulations restrict companies from conducting various construction activities due to disturbance thresholds such as noise. The commenter adds that during colder winter months, there could be weeks with temperatures below freezing when companies are unable to safely disconnect production facility equipment to retrofit with the necessary upgrades without wells and equipment freezing. With the existing supply chain and labor shortages, they note that it is expected that challenges will continue with both contractor availability and equipment availability. This necessitates a longer duration compliance timeline than currently being offered. The commenter requests that a location have a minimum of 18 months to bring a facility into compliance once rule applicability has been triggered.

Commenter (2255-Ovintiv) emphasizes the importance of providing adequate implementation time-periods in the final regulation. The commenter provides that it is already experiencing noticeable delays in the supply chain for various equipment required by the proposed rules including, but not limited to, control devices, flow monitoring equipment, and instrument air systems. The commenter asserts that these and other realities should be reflected in the implementation schedule in the final rule.

Commenter (2428-API) provides that NSPS OOOOb and EG OOOOc will apply to hundreds of thousands of sites when implemented. The commenter notes that the industry is already experiencing a noticeable delay in the supply chain for equipment required by the proposed rules including (but not limited to) control devices, flow monitoring equipment, instrument air systems, solar panels, etc. Control devices are currently experiencing delays of 3 to 4 months, while flow monitors are on backorder for a minimum of 6 to 8 months from suppliers. Instrument air systems (including the air compressor and associated equipment) are nearly 1 year

on backorder, and recently ordered solar panels are delayed between 18 to 24 months. As more facilities become subject to proposed requirements in NSPS OOOOb and EG OOOOc, the commenter expects that the above timelines will be exacerbated before the market experiences a correction to meet these new levels of demand. The commenter requests EPA consider these challenges prior to finalization of certain provisions within these rules to allow operators the ability to acquire and install the required equipment. Additionally, the commenter recommends EPA allow more time for new, modified, and reconstructed sources to come into compliance with NSPS OOOOb if it maintains the current applicability date of November 15, 2021.

Response II-3-13: The EPA considered these and other comments when establishing applicability and compliance dates in the final NSPS OOOOb and EG OOOOc rules. has revised the applicability and compliance dates.

For the NSPS OOOOb, the EPA has concluded that only sources constructed, modified, or reconstructed after the date of the Supplemental Proposal (December 6, 2022) should be considered new sources for the purposes of NSPS OOOOb. Changing this date to December 6, 2022, from the November 15, 2021, reduces the number of existing new sources that will need to comply with NSPS OOOOb, thereby allowing more time to plan for compliance and supply chain issues. The EPA believes that the adjustment to the applicability date from November 15, 2021, to December 6, 2022, gives sources an additional almost 13 months to plan and obtain equipment necessary to comply with the final rule . For details, please see discussion in section IX (Interaction of the Rules and Response to Significant Comments Thereon), subsection A (What date defines a new, modified, or reconstructed source for purposes of the final NSPS OOOOb?) of the final rule preamble. The EPA has also provided an alternative compliance timeline in the NSPS OOOOb final rule for process controllers and pumps required to meet a zero-emission standard (*i.e.*, final rule allows up to one year from the publication date of the final rule). See section XI.D.4 (Compliance dates) of the final rule preamble for a discussion on the compliance dates finalized for process controllers (which also applies for pumps).

For the EG OOOOc, the EPA is finalizing a compliance timeline of 36 months from the deadline for state plan submittals, which provides owners and operators of designated facilities time to plan for compliance and supply chain issues. When the compliance timeline of 36 months is considered in conjunction with the state plan submittal deadline of 24 months, that means that sources could have up to 5 years between when the EG are final and when they are required to fully comply with the applicable standards of performance. The EPA believes that any concerns with possible equipment or staffing shortages, which commenters speculate could be an issue, would likely be addressed by industry and regulators in that timeframe. See section XIII.E.3 (Compliance timelines) of the final rule preamble for EPA's response to comments regarding the compliance timeline required under the EG.

### **3.5 NSPS Compliance Dates**

Comment: Commenter (2351-Jonah Energy LLC (Jonah)) notes that it is their understanding that the compliance date for the NSPS is 60 days following the final rule publication in the *Federal Register*, or 60 days after becoming an affected facility. For several emission source categories, including pneumatic controllers and pneumatic pumps for example, the commenter states

compliance implementation within 60 days may not be physically feasible. The commenter reports that they operate on federal lands, and the BLM has wildlife stipulations, such as greater sage grouse, burrowing owl, and ferruginous hawk, which restrict them from conducting various construction activities during these stipulation times.

Additionally, the commenter (2351-Jonah) explains that during the 6 winter months in Wyoming, there could be weeks with temperatures below freezing when it becomes unsafe to disconnect production facility equipment to retrofit with the necessary upgrades without wells and equipment freezing. The commenter states that with the existing supply chain and labor shortages, they can expect challenges with both contractor availability and equipment availability that necessitates a longer duration compliance timeline.

Similarly, commenter (2305-Williams Companies, Inc. (Williams)) recommends the EPA modify the rule applicability date and provide flexibility with the compliance deadlines set forth in the proposed regulations (both the NSPS and EG) to account for the existing delays experienced in the industry due to labor shortages and equipment availability/supply chain issues.

Commenters (2257-Michigan Oil and Gas Association (MOGA), 2305-Williams) state that equipment supply issues, which have already been experienced by the commenter, have not been factored into the timeline for compliance with the proposed standards. Commenter (2257-MOGA) states that they spent considerable time contacting equipment manufacturers regarding the development of new replacement equipment similar to the existing devices (Ex.: process control valves, level controllers) and found it often takes 3 to 4 years to design, fabricate, test and certify new equipment. The commenter provides that this process does not account for the future manufacturing, purchase, delivery, installation, operational cycles and assessment of whether the new equipment meets the new standards. If the equipment falls short of expectations, the field operators may require delivery of replacement parts, modification kits, component change-out or total abandonment until the manufacturer can isolate the problem, redesign the device, and manufacture the new replacement parts, which begins the evaluation process all over.

Another commenter (2305-Williams) states that the EPA did not factor in the realities of the current supply chain delays and cost increases for the equipment and devices necessitated by the NSPS OOOOb/EG OOOOc regulations. The commenter notes that they have experienced significant supply chain and manufacturing delays since 2020 and they are not alone in this dilemma and difficult circumstances. The commenter reports that these delays can add a few months or up to a couple of years to a project or repair schedule depending on the equipment needed. The upgrades and modifications that will take place nationwide and across the entire industry will only add more strain to an already strained supply chain. Through no fault of an operator, they explain that timely installation or compliance may not be possible due to an inability to obtain the necessary equipment and or have that equipment operational by the extended compliance date. The commenter recommends the EPA modify the rule applicability date and provide flexibility with the compliance deadlines set forth in the proposed regulations to account for the existing delays experienced in the industry.

Response II-3-14: The EPA has considered these and other comments on concerns related to supply chain issues when developing the final rule requirements under NSPS OOOOb and EG OOOOc. For example, the EPA has included repair and delay of repair provisions that consider supply chain issues, and as discussed under Response II-3-13 of this Chapter, revisions to the applicability and compliance timelines provide for sufficient time to plan for compliance and supply chain issues.

### **3.6 Applicability-Related Definitions/Clarifications**

Comment: Commenter (2210-LANXESS Corporation) states that the “Crude Oil and Natural Gas Production source category” is defined within 40 CFR 60.5430 and 40 CFR 60.5430a. The commenter requests that, to add regulatory certainty of the source category being regulated under NSPS OOOOb, EPA should also add a similar definition to 40 CFR 63.5430b.

Response II-3-15: The December 2022 Supplemental Proposal NSPS OOOOb defined the “Crude oil and natural gas source category” and the definition is finalized as proposed.

Comment: Commenter (2416-Alyeska Pipeline Service Company (APSC)) considers the proposed rule to be somewhat ambiguous in defining the demarcation between natural gas transmission and downstream users, including local distribution companies and industrial end users. First, the commenter contends there is a lack of consistency in the “Am I subject to this subpart?” between 40 CFR 60.5365 and 60.5365a (NSPS OOOO and OOOOa) with the similar provisions proposed in NSPS OOOOb and EG OOOOc. The provisions in NSPS OOOO and OOOOa include the phrase “that is located within the Crude Oil and Natural Gas Production source category, as defined in...” while NSPS OOOOb and EG OOOOc do not include a comparable phrase for this source category. The commenter states that a comparable phrase would be helpful to the regulated community because it indicates the scope and extent of the rule. The commenter suggests that the language in 40 CFR 60.5365b and comparable language in 40 CFR 60.5365c be added as follows:

You are subject to the applicable provisions of this subpart if you are the owner or operator of one or more of the onshore affected facilities listed in paragraphs (a) through (l) of this section, that is located in the crude oil and natural gas source category, for which you commence construction, modification, or reconstruction after November 15, 2021.

Additionally, the commenter (2416-APSC) provides that the definition of “Crude oil and natural gas source category” is vague for purposes of part (2) of the definition. The commenter notes that while there is some improvement in the understanding of the “crude oil and natural gas source category” through the reading of the definition for “natural gas transmission”, the definition is inadequate because it does not clearly demarcate the distinction between gas transmission/gas distribution and local distribution or industrial end user. The commenter recommends that EPA examine the definition of the “Natural Gas Transmission and Storage Segment” found at 40 CFR 60.5430 and 60.5430a. The commenter believes the text in that definition provides better clarity on the demarcation between gas transmission/distribution and the end user.

Regarding “Natural gas transmission and storage segment,” the commenter (2416-APSC) states that, for the purposes of the related subpart, natural gas enters the natural gas transmission and storage segment after the natural gas processing plant, when present. If no natural gas processing plant is present, natural gas enters the natural gas transmission and storage segment after the point of “custody transfer”. A compressor station that transports natural gas prior to the point of “custody transfer” or to a natural gas processing plant (if present) is not considered a part of the natural gas transmission and storage segment.” The commenter considers this definition to be important because it provides clarification to the natural gas transmission definition and the extent of the rule applicability for downstream facilities or sources. During the 2015 rulemaking of the NSPS OOOOa rule comments were made by the commenter and others to show that there are large commercial end users downstream of what is traditionally considered natural gas transmission, and EPA modified the definition of natural gas transmission and storage segment to exclude equipment that is used to deliver the natural gas to the end user and equipment used by the end user. Additionally, the commenter states that the natural gas transmission and storage segment definition is also consistent with the U.S. Department of Transportation definition of transmission line under 49 CFR 192.3, which reads:

*Transmission line* means a pipeline, other than a gathering line, that:(1) Transports gas from a gathering line or storage facility to a distribution center, storage facility, or large volume customer that is not down-stream from a distribution center...

The commenter (2416-APSC) suggests that if no changes are made, then a discussion in the final rule’s preamble would help the regulated community better understand the distinction between natural gas transmission and downstream facilities and end users.

Response II-3-16: The EPA agrees that, while the definitions section clearly defines the boundaries of the source category, additional clarification in the applicability section, in particular with respect to LDC custody transfer, would further help sources to identify if they might be subject to any of the requirements in NSPSs OOOOa and OOOOb and EG OOOOc. Therefore, these rules have been revised to include the following introductory language at 40 CFR 60.5365a and 60.5386c, as well as 40 CFR 60.5365a:

You are subject to the applicable provisions of this subpart if you are the owner or operator of one or more of the onshore affected facilities listed in paragraphs (a) through (j) of this section, that is located within the Crude Oil and Natural Gas source category, as defined in §60.5430b [or 40 CFR 60.5430a and 60.5430c, as relevant], for which you commence construction, modification, or reconstruction after September 18, 2015, and on or before December 6, 2022. Facilities located inside and including the Local Distribution Company (LDC) custody transfer station are not subject to this subpart.

Comment: Commenter (2428-API) recommends that EPA clarify its statements regarding the Crude Oil and Natural Gas source category and the extent of crude oil operations for purposes of this rulemaking. Within proposed NSPS OOOOb and EG OOOOc the Crude Oil and Natural Gas source category is defined consistent with historical definitions finalized in NSPS OOOO and OOOOa:

*Crude oil and natural gas source category* means:

- (1) Crude oil production, which includes the well and extends to the point of custody transfer to the crude oil transmission pipeline or any other forms of transportation; and
- (2) Natural gas production, processing, transmission, and storage, which include the well and extend to, but do not include, the local distribution company custody transfer station.

The commenter points out that in footnote “301” (87 FR 74833), EPA states:<sup>301</sup>

For purposes of the November 2021 proposal and this supplemental proposed rulemaking, for crude oil, the EPA’s focus is on operations from the well to the point of custody transfer at a petroleum refinery, while for natural gas, the focus is on all operations from the well to the local distribution company custody transfer station commonly referred to as the “city-gate”.

The commenter (2428-API) does not believe that EPA intends to regulate crude oil operations beyond the point of custody transfer from a well to a transmission pipeline and requests that EPA clarify and correct these statements in the final rule to align with the definition of the source category as proposed.

Response II-3-17: See Response II-3-16 of this Chapter.

### **3.7 Exemptions and Opt-in Provisions**

Comment: Commenter (2428-API) states that sites may periodically shut-in or depressurize all or partial equipment, where the entire site might be inactive or certain equipment might be inactive. The commenter believes this is an appropriate criterion for exemption for all affected or designated facilities under NSPS OOOOb and EG OOOOc. At a minimum, the commenter seeks clarification as the status of inactive facilities and depressurized equipment as they pertain specifically to fugitive emission monitoring and the retrofit of pneumatic controller and pneumatic pump provisions under EG OOOOc. The commenter does not believe it is EPA’s intent to require facilities that are not in active operations to retrofit the pneumatic controllers at the facility to non-emitting nor would it be appropriate for equipment that has been depressurized and inactive to be screened for fugitive emission monitoring.

Additionally, the commenter (2428-API) notes that some inactive sites or equipment might be put back into service, where the applicability under NSPS OOOOb versus EG OOOOc must be delineated. One example the commenter provides is under Pennsylvania’s § 127.11a. *Reactivation of sources*, which allows: “*a source which has been out of operation or production for at least 1 year but less than or equal to 5 years may be reactivated and will not be considered a new source if the following conditions are satisfied...*”. The commenter states that EPA already has included language addressing this concept as it pertains to storage vessels. The commenter believes EPA should extend this concept to all affected and designated facilities. The commenter suggests that if a site that was inactive were to become active, there should be adequate time for the site to comply with the provisions within EG OOOOc.

Response II-3-18: The EPA recognizes that when an entire site or some equipment is shut-in, depressurized, and not in operation, that there will likely be no routine emissions. In accordance, the emission source specific standards apply only during times when an affected facility is in operation and does not apply at sites that are shut in and depressurized such that no gas is routed to the affected sources. However, the requirements contained in 40 CFR 60.5370b(b) apply during these periods. Specifically, these requirements include “[a]t all times, including periods of startup, shutdown, and malfunction, owners and operators shall maintain and operate any affected facility including associated air pollution control equipment in a manner consistent with good air pollution control practice for minimizing emissions.”

If a site or equipment that has been out of service is placed back into service, this would not constitute a modification unless a physical change occurred during the shutdown that results in an increase in emissions from the period prior to the shutdown, or if the equipment was operated in a manner differently from prior to the shutdown (*i.e.*, an “operational change”) that results in increased emissions.

However, EPA disagrees that additional time should be allowed for compliance prior to the affected facility being put back into service. Owners and operators are fully aware of the requirements that apply and should plan accordingly for the equipment to be in full compliance upon re-start.

Comment: Commenter (2399-GPA) recommends that EPA include provisions in the final rule that would allow and facilitate those owner and operators that have existing affected facilities covered by NSPS OOOOa to opt-in to NSPS OOOOb requirements for some or all their facilities that are presently covered by NSPS OOOOa. The commenter states that this would be a voluntary measure for those owner/operators who wish to comply with what EPA determines in its final NSPS OOOOb regulation to be the current BSER for their facilities and that those owner/operators would opt-in because they are committed to achieving the reduced emissions and improved level of environmental performance that EPA would expect from implementing the expanded emission controls and other requirements in the latest BSER in NSPS OOOOb. The commenter provides that it would also facilitate the work of regulators overseeing and permitting those facilities, which could otherwise have different requirements at the same location with some equipment subject to NSPS OOOOa and some to NSPS OOOOb, if certain affected facilities are modified or reconstructed. In addition, the commenter expects it would also streamline owner/operator compliance programs, which should likewise improve compliance and overall performance.

Response II-3-19: See the discussion in Section IX.C (How will the final EG OOOOc impact sources already subject to NSPS KKK, NSPS OOOO, or NSPS OOOOa) in the preamble to the final rule.

## **Chapter 4. Fugitive Emissions from Well Sites, Centralized Production Facilities, and Compressor Stations**

### **4.1 NSPS OOOOb for Well Sites and Centralized Production Facilities**

#### **4.1.1 General Support**

Comment: Commenters (1611-East Liberty Presbyterian Church, 1620-Evangelical Environmental Network, 1627/1642-Peace, Justice, Sustainability NOW!, 1647-Private Citizen, 1655-American Academy of Pediatrics (AAP), 1658-Physicians for Social Responsibility, 2028-Westmoreland Marcellus Citizens' Group, 2038-Private Citizen, 2039-Citizens to Preserve Ligonier Valley, Inc., 2147-Private Citizen, 2163-EOS at Federated Hermes, 2164-Nordea Asset Management, 2177-Ute Indian Tribe, 2182-Ohio Conservative Energy Forum, 2190-Miller/Howard Investments, Inc., 2191-Boston Trust Walden Company, 2206-Legal & General Investment Management America, Inc (LGIM America), 2209-Public Land Solutions, 2212-Union of Concerned Scientists, 2217-Religious Action Center of Reform Judaism, 2226-Thermo Fisher Scientific, 2244-Private Citizen, 2245-Philip Mecham, 2249-National Association of Clean Air Agencies (NACAA), 2256-Mille Lacs Band of Ojibwe, 2271-Private Citizen, 2285-Bailard, 2313-Mimi Plevin-Foust, 2329-Lone Star Chapter of the Sierra Club, 2341-Harvard's Environmental and Energy Law Program, 2352-Environment Texas Research and Policy Center, 2356-Earthworks et al., 2364-CleanEarth4Kids.org, 2388-ExxonMobil, 2392-Earthjustice et al., 2394-Earthworks, 2396-Shell Oil Company, 2404-Dakota Resource Council (DRC), 2407-Methane Action, 2420-Wisconsin Health Professionals for Climate Action, Inc. (WHPCA), 2428-American Petroleum Institute (API), 2433-Environmental Defense Fund (EDF et al.), 2434-Private Citizen, 2436-Private Citizen, 2455-Private Citizen, 2456-Private Citizen, 2459-BMO Global Asset Management, 2461-Conservatives for Responsible Stewardship, 2466-Private Citizen, 2501-Orion Strategies, 2627-British Columbia Investment Management Corp.) 2628-Nancy Parks, 2796-Chicago Area Peace Action, 2883-US Senator Martin Heinrich et al., 3001-Great Old Broads for Wilderness, 3660-Center for Progressive Reform and Green Latinos, 3083-Transformative Wealth Management, 3335-Placer People of Faith Together--Environmental Interest Group, 3399-Mothers For Nuclear, 3418-Maine Solar Energy Association, 3486-Sharon Furlong, 3507-Save the Sound, 3585-Vote Solar, 3602-Private Citizen, 3621-Private Citizen, 3653-Private Citizen, 3705-Breathe Easy Susquehanna County, 3775-Mothers and Others For Clean Air, 3835-Private Citizen) generally support EPA's proposed fugitive emissions standards for well sites, centralized production facilities, and compressor stations. EPA should seek to reduce fugitive emissions to the greatest extent possible. Methane is a potent greenhouse gas for which its direct regulation is appropriate and necessary in order to bring about necessary methane emission reductions while further supporting the benefits of the increased use of natural gas for expeditiously reducing GHG emissions throughout the U.S. economy and in other countries. Some commenters note maintaining a strong fugitive emissions program will ensure that leaks from oil and gas facilities that disparately impact Black, Latino, tribal, and rural and low-income communities are addressed in a timely manner, resulting in much needed reductions of the dangerous and toxic pollutants emitted by these facilities.

Commenters (2163-EOS at Federated Hermes, 2164-Nordea Asset Management, 2190-Miller/Howard Investments, Inc., 2191-Boston Trust Walden Company, 2206-LGIM America,

2341-Harvard's Environmental and Energy Law Program, 2455-Private Citizen, 3705-Breathe Easy Susquehanna County) believe the rule should maintain strengthened provisions to require leak monitoring at all sites with leak-prone equipment, including high-polluting, smaller wells, while providing flexibility for compliance by allowing a wider selection of advanced technologies to be used if they deliver equal or better reductions. The commenter (2206-LGIM America) notes that research has shown that these wells can often be a significant source of methane emissions and the lack of ongoing monitoring may allow them to continue the outsized rate of pollution. The commenter (2206-LGIM America) adds that ownership data has also shown that such wells are often owned by large companies, who likely have the financial wherewithal to perform more robust maintenance.<sup>1</sup>

Commenter (2177-Ute Indian Tribe) supports the increased fugitive emissions monitoring at all sites and supports the inclusion of storage vessels such as tank batteries. However, given the sheer number of facilities that would be subject to the final rule, the EPA should consider working with the commenter to develop a comprehensive LDAR program which may include delegation of inspection and enforcement activities to the Tribe.

Commenter (2182-Ohio Conservative Energy Forum) indicates that the EPA's proposal improves methane regulation standards by requiring regular monitoring at well sites, including low-producing wells, which allows our methane mitigation industry to deploy technology to reduce emissions and generate revenue to boost our economy. The updated draft rule improves upon the original rule by eliminating the loophole in leak detection and repair standards and will require routine inspections at wells with equipment known to malfunction.

Commenter (2182-Ohio Conservative Energy Forum) finds according to research done by the University of Cincinnati in southeastern Ohio, many wells that produce less than a barrel of oil per day leak into the atmosphere more than 100 percent of their reported gas production. The gas wasted by these low-producing wells could meet the heating and cooking needs of nearly every home in the state of Ohio. The inclusion of routine monitoring at these low producing well sites is an important step forward in these proposed rules that will help us take advantage of capturing and eliminating methane waste. Solutions exist today for producers to eliminate roughly half of their methane emissions with existing technology at no net cost. Bringing this added gas to market increases tax revenues to communities from Ohio's severance tax, alongside corporate and payroll taxes and royalty revenues to leaseholders across the state.

Commenter (2215-West Virginia Rivers Coalition et al.) argues cutting methane emissions within the oil and gas sector is the quickest and most impactful way to limit global warming. In the United States, oil and gas systems are among the largest sources of methane emissions at 32 percent according to EPA's Greenhouse Gas Inventory. Yet research has repeatedly shown that the true extent of oil and gas methane emissions are likely much higher than this; for instance, a study funded by the Environmental Defense Fund found that oil-and-gas-sector methane emissions are 60 percent higher than EPA's estimates show. As the second most abundant greenhouse gas, methane is responsible for approximately 20 percent of global emissions and

---

<sup>1</sup> Environmental Defense Fund - By the numbers: Marginal oil and gas wells;  
[https://www.edf.org/sites/default/files/documents/MarginalWellFactsheet2021\\_0.pdf](https://www.edf.org/sites/default/files/documents/MarginalWellFactsheet2021_0.pdf).

estimated to cause between a quarter and a half of the warming our planet has experienced to date.

Commenter (2256-Mille Lacs Band of Ojibwe) applauds the EPA's efforts in creating a more comprehensive approach to reducing methane and VOC pollution. Methane is a powerful greenhouse gas with a 100-year global warming potential 28-34 times that of carbon dioxide, while other types of petroleum-based VOCs seriously pose both health and safety risks. We have natural gas transmissions piping paralleling major travel-ways, passing through our treaty-ceded territories, connecting communities along the way. They generally are low in emissions except for where the transmission piping is interrupted by a compressor station or to other types of gas-handling equipment. By reducing or eliminating the methane and other natural gas-associated VOCs at these connection points, this action will help the United States to meet its climate change mitigation goals.

Commenter (2455-Private Citizen) suggests the EPA leverage the additional reporting occurring in this program and create annually updated, gridded estimates of methane emissions across the US. These data products will be critical for improving methane emission science.

Commenters (2456-Hal Schmid, 3335-Placer People of Faith Together--Environmental Interest Group, 3486-Sharon Furlong, 3507-Save the Sound) agree, methane poses a grave danger to the planet. It exerts more than 80 times the impact of carbon dioxide, pound for pound, making it a major driver of global warming and climate change and the immediate low-hanging fruit in the effort to address health and climate change issues related to the gas and oil industry and our petroleum consumption. Commenter (2883-US Senator Martin Heinrich et al.) states methane is responsible for around 30% of the global warming we are experiencing today.<sup>2</sup>

Commenter (2364-CleanEarth4Kids.org) stresses the administration must take immediate action to cut methane pollution from oil and gas operations and development to 90% below 2005 levels by 2030.

Commenter (2392-Earthjustice et al.) notes that maintaining a strong LDAR program will ensure that leaks from oil and gas facilities that disparately impact Black, Latino, tribal, and rural and low-income communities are addressed in a timely manner, resulting in much needed reductions of the dangerous and toxic pollutants emitted by these facilities.

Commenter (2396-Shell Oil Company) has worked with EPA to help craft an efficient and effective regulatory framework for reducing methane emissions through leak detection and repair programs, enhanced pneumatic device standards, control requirements on regulated storage tanks, and reduced emissions completions on new and modified wells. Their support for methane regulation extends to EPA's Proposal to update, strengthen, and expand the current Subpart OOOOa NSPS standards for limiting methane and VOC emissions from new, modified, and reconstructed onshore facilities. These changes, as a general matter, will enhance and improve upon the existing regulations to limit emissions from the oil and gas sector.

---

<sup>2</sup> [https://urldefense.com/v3/\\_\\_https://www.iea.org/reports/global-methane-tracker-2022/methane-and-climate-change\\_\\_;!!Bg5easoyC-OII2vIEqY8mTBrtW-N4OJKAQ!YZMxPbtH7YrrnIJn0OQHgcZ8uus0caYMaK5JnAz-19qAX0u\\_DpXPTR06rEPwNPwoC2CM59-DPmk\\$](https://urldefense.com/v3/__https://www.iea.org/reports/global-methane-tracker-2022/methane-and-climate-change__;!!Bg5easoyC-OII2vIEqY8mTBrtW-N4OJKAQ!YZMxPbtH7YrrnIJn0OQHgcZ8uus0caYMaK5JnAz-19qAX0u_DpXPTR06rEPwNPwoC2CM59-DPmk$).

Commenter (2396-Shell Oil Company) adds their support for direct methane regulation extends to existing onshore oil and natural gas sources. The commenter has gone on record on many occasions supporting the adoption of effective and flexible federal regulations for limiting methane from existing onshore sources. The commenter believes that the EPA's strong commitment to develop such regulations in this area makes the Agency uniquely qualified for developing a workable regulatory framework for reducing methane emissions from existing onshore facilities within oil and natural gas sector in an efficient and effective manner.

Commenter (2433-EDF et al.) states fugitive emissions from leaks and equipment failures are the most significant source of methane emissions from the oil and gas sector, representing over two thirds of total emissions in the production segment.<sup>3</sup> Readily available and low-cost technologies exist to find and fix these leaks and malfunctions. Comprehensive LDAR standards are therefore an indispensable element of any program aiming to drive down methane emissions from oil and gas. EPA should seek to reduce fugitive emissions to the greatest extent possible, with the ultimate goal of fully eliminating these preventable and unnecessary emissions.

Commenter (2433-EDF et al.) argues final rules should ensure fugitive emissions reductions of at least 80%, or roughly equivalent to EPA estimates of what quarterly OGI would achieve. The commenter estimates that a comprehensive and frequent monitoring and repair regime could reduce methane emissions by over 1.5 million tons per year (tpy) and urge EPA to finalize standards at least as protective as what it has proposed.

Commenter (2466-Private Citizen) notes the oil and gas industry is one of the leading sources of methane pollution in the U.S., emitting roughly 16 million metric tons of methane every year. The commenter states low producing wells account for just 6% of production nationwide but are responsible for 50% of methane emissions at oil and gas well sites. According to data provided by Clean Air Council, in our region of the United States, these wells emit 1.2 million tons of methane annually. Methane is responsible for approximately one third of the warming from greenhouse gasses occurring today.

Response II-4-1: EPA acknowledges the commenters' support. The EPA is finalizing several requirements to strengthen requirements for fugitive emissions from well sites, centralized production facilities, and compressor stations.

#### ***4.1.2 Affected Facility/Definitions***

##### ***4.1.2.1 Modification to Centralized Production Facility***

Comment: Commenters (2177-Ute Indian Tribe, 2428-API, 2179-Kansas Independent Oil and Gas Association (KIOGA), 2304-Pennsylvania Independent Oil & Gas Association (PIOGA)) express concerns regarding the proposed definition of modification of fugitive emissions components at a centralized production facility.

Commenter (2177-Ute Indian Tribe) states the following requirement in §60.5365b(i)(2)(ii) is not feasible as wells sending production to a centralized facility may be owned by a different

---

<sup>3</sup> 2022 Joint Environmental Comments, *supra* note 1, at 65. [99] 87 Fed. Reg. at 63177.

entity and the owner/operator of the centralized facility is likely not aware of changes occurring at connected wells:

“A well sending production to an existing centralized production facility is modified, as defined in paragraphs (i)(1)(i) through (iii) of this section; or”

Commenter (2177-Ute Indian Tribe) recommends that: Changes in gas composition or volume received at a centralized production facility cause a significant increase in potential emissions. A significant increase in emissions is an increase that causes a change in applicability to existing regulations, or increases emissions of any regulated pollutant by more than 2 tpy or any single HAP by more than 0.5 tpy.

Commenter (2177-Ute Indian Tribe) recommends removing the requirement in §60.5365b(i)(2)(iii) that reads:

“A well site subject to the requirements of §60.5397b or §60.5398b removes all major production and processing equipment, such that it becomes a wellhead only well site and sends production to an existing centralized production facility.”

The commenter states the same rationale as provided above, that the centralized production facility may be owned by a different entity.

Commenter (2428-API) indicates that the operator of a centralized production facility may not know when an action occurs at an offsite well that would trigger modification at the centralized production facility since the upstream operator is typically only required to notify the centralized production facility operator when a new well is drilled and starts to send production to the gathering system. To address this concern, the commenter suggests that the modification criteria for centralized production facilities be limited to “An increase in design throughput capacity occurs with the addition of a storage vessel at an existing centralized production facility.” This criterion is simple, clear, and aligned with the purpose and definition of a centralized production facility, which is to gather hydrocarbon liquid production into storage vessels. The commenter offers the following revisions to §60.5365b(i)(2):

For purposes of §60.5397b and §60.5398b, a “modification” to centralized production facility occurs when: an increase in design throughput capacity occurs with the addition of a storage vessel at an existing centralized production facility.

~~(4) (Any of the actions in paragraphs (i)(1)(i) through (iii) of this section occurs at an existing centralized production facility;~~

~~(ii) A well sending production to an existing centralized production facility is modified, as defined in paragraphs (i)(1)(i) through (iii) of this section; or~~

~~(iii) A well site subject to the requirements of §60.5397b or §60.5398b removes all major production and processing equipment, such that it becomes a wellhead only well site and sends production to an existing centralized production facility.~~

Commenters (2179-KIOGA, 2304-PIOGA) note that EPA has abandoned the traditional definition of “modification” that typically requires an increase in emissions associated with a “modification” to trigger NSPS. A not-so-hypothetical hypothetical for owners/operators of low production wells/facilities is where there may be a few small oil wells that periodically vent as part of the normal production process. Those emissions could be controlled by tying the venting of those wells into a central production facility and ultimately reducing emissions, but the proposed rule would deem such changes a “modification” even though that control method results in emission reductions. EPA’s proposed definition of “modification”, without linking it to an increase in emissions, creates a huge disincentive for operators of low production wells to make changes that benefit the environment and their small business’s bottom lines. For example, older conventional, or “legacy”, oil and gas wells often produce far less gas than the capacity of the smallest available reciprocating compressor, which is about 3 horsepower (hp). Having one small compressor to draw from multiple wells is more practical, produces lower emissions, uses less energy, and is easier to maintain and more economical, but the proposed rule would discourage/punish such changes. A very small centralized compressor should be treated the same as a single well wellhead compressor because it has far less emissions, uses much less energy, and reduces pressure over the whole system, lowering the chance of leaks. A centralized compressor of 20 hp or less, or handling 100,000 cubic feet per day (or 100 mcf/d) should be treated as a single well compressor.

Commenter (2179-KIOGA) adds some operators in Kansas may drill 200 oil wells and perform work that would meet EPA’s definition of a “modification” for more than 250 existing wells in a five-year period. This is an average of 90 wells being drilled or modified each year, not including associated tanks or other fugitive emissions components. The commenter expects this level of activity to resume as oil price increase for some of the active owners/operators in Kansas. They believe that smaller owners/operators will reduce their drilling and maintenance programs until the oil price increases again. The reporting work will continue to grow each year as they continue to drill and modify wells because the current year work is added to all work from prior years. This growing work load will require the hiring of additional employees in the future.

Response II-4-2: Regarding the comments that a centralized production facility may be owned by a different company than the well sites, this is not EPA’s understanding of these sites. As discussed in the November 2021 Proposal, the centralized production facility definition was created, in part, to address the scope of fugitive emissions standards at well sites. The EPA described that these facilities are a type of well site; therefore, it is not the EPA’s understanding for them to have a different owner. If the liquids have undergone custody transfer, then the operations described are no longer in the producing operations and would be a natural gas processing plant or a compressor station, depending on the scope of operations present at the site. The commenter did not provide rationale why this understanding is not correct. See also the response in Chapter 13 Storage Vessels at II-13-40.

Regarding the comment that only “significant” changes in emissions should trigger modification, the EPA notes that modification is defined as “any increase” not a “significant” increase.

Regarding the comment that the definition of “modification” does not address the situation where a control method may result in an emissions reduction, such as when a owners/operators of low production wells/facilities may control small oil well venting by tying the venting of those wells into a central production facility, the EPA notes that both NSPS OOOOb and EG OOOOc

require a reduction in emissions, primarily through recovery of the gas. If the associated gas is sent to a centralized production facility for recovery and meets the requirements of 40 CFR §60.5377b(a), then the provisions of 40 CFR §60.14(e)(5) would apply, and this would not be a modification.

Regarding the commenter who notes the addition of employees, the EPA did not see that the commenter provided a specific comment request for the EPA to consider.

#### 4.1.2.2 Definition of Well Site

Comment: Commenter (2433-EDF et al.) cites to EPA’s proposed definition of a well site:

Well site means one or more surface sites that are constructed for the drilling and subsequent operation of any oil well, natural gas well, or injection well. For the purposes of the fugitive emissions standards at §60.5397b, a well site does not include:

- (1) UIC Class II oilfield disposal wells and disposal facilities;
- (2) UIC Class I oilfield disposal wells; and
- (3) The flange immediately upstream of the custody meter assembly and equipment, including fugitive emissions components, located downstream of this flange.”

Commenter (2433-EDF et al.) recommends that EPA make clear that a well site includes all the equipment at the site to ensure that all fugitive emissions components associated with equipment at the site are subject to the monitoring and repair standards.

Response II-4-3: The EPA has not revised the definition of a well site in response to this comment (see Response II-4-15 for an explanation of the definition revision). The EPA believes the final definition of “fugitive emissions component” clearly includes any component and that no additional clarification is needed per the commenter’s suggestion.

*Fugitive emissions component* means any component that has the potential to emit fugitive emissions of methane or VOC at a well site, centralized production facility, or compressor station, such as valves (including separator dump valves), connectors, pressure relief devices, open-ended lines, flanges, covers and closed vent systems not subject to §60.5411b, thief hatches or other openings on a storage vessel not subject to §60.5395b, compressors, instruments, meters, and yard piping.

In addition, §60.5397b(a) of the final rule clearly states all fugitive emissions components affected facilities must be monitored.

Part 3 of the definition of a well site cited by the commenter helps clarify the boundary of the well site at the point of custody transfer.

The EPA has also clarified in the final regulatory text which monitoring requirements apply to single wellhead only well sites, small well sites, multi-wellhead only well sites, and well sites and centralized production facilities with major production and processing equipment.

#### 4.1.2.3 Fugitive Emissions

Comment: Commenter (2000-Step2Compliance) suggests that the following definition of fugitive emissions:

“Fugitive emissions are defined as any indication of visible emissions from a fugitive emissions component that are not part of normal operations and intermittent in nature observed using optical gas imaging or an instrument reading of 500 parts per million (ppm) or greater using Method 21 of appendix A-7 to this part.”

Commenters (2363-Continuous Emission Monitoring Coalition (CEMC), 2433-EDF et al, 2448-Project Canary, PBC) believe the definition of fugitive emissions should be updated to account for emissions detected using alternative technologies to screen and/or monitor for fugitive emissions leaks. This definition appears to be identical to what is referenced in NSPS OOOOa, §60.5397a(a)(1). The definition is limited to OGI and Method 21. Commenter (2433-EDF et al) suggests amending the definition or otherwise clarifying in section 60.5398b that any emissions detected using the procedures described in section 60.5398b are considered fugitive emissions if the source is a fugitive emissions component.

Commenters (2363-CEMC, 2448-Project Canary, PBC) propose the following definition:

“Fugitive emissions are defined as any indication of visible emissions observed from a fugitive emissions component using optical gas imaging or an instrument reading of 500 parts per million (ppm) or greater using Method 21 of appendix A-7 to this part, or any emissions detected from a fugitive emissions component using an alternative screening technology as described in Tables 1 and 2 of this Subpart, or reaching a facility-appropriate action-level as defined in 60.5398bI(4)(i) using an approved continuous emissions monitoring system.”

Response II-4-4: In the December 2022 Supplemental Proposal, the EPA proposed to define fugitive emissions as:

*Fugitive emissions* are defined as any indication of visible emissions observed from a fugitive emissions component using optical gas imaging or an instrument reading of 500 parts per million (ppm) or greater using Method 21 of appendix A-7 to this part.

To reflect that the EPA has determined that inspections using AVO is also an appropriate method for identifying fugitive emissions, AVO has been added to the definition of fugitive emissions in the final rule in addition to OGI and Method 21.

The EPA is finalizing the following definition for fugitive emissions:

*Fugitive emissions* means, for the purposes of §60.5397b, any indication of emissions observed from a fugitive emissions component using AVO, an indication of visible emissions observed from an OGI instrument, or an instrument reading of 500 ppmv or greater using Method 21 of appendix A-7 to this part.

#### 4.1.2.4 Fugitive Emissions Component

Comment: Several Commenters (1583-Oklahoma Department of Environmental Quality (ODEQ), 2000-Step2Compliance, 2221-Texas Pipeline Association, 2326-American Exploration & Production Council (AXPC), 2337-Kansas Department of Health and Environment (KDHE), 2393-Oklahoma Office of the Secretary of Energy and Environment, 2428-API, 2433-EDF et al.) request various clarifications and revisions to the definition of fugitive emissions component.

Commenter (2000-Step2Compliance) states the definition of a fugitive emissions component<sup>4</sup> in OOOOa includes verbiage about devices that vent as part of normal operation. The definition of fugitive emissions component<sup>5</sup> in OOOOb and OOOOc was significantly reduced from the definition of fugitive emissions component in OOOOa, excluding the verbiage about venting due to normal operations, and there was a new definition added of fugitive emissions<sup>6</sup> which defines any visible emission detected with an OGI camera as a leak.

Commenter (2000-Step2Compliance) states with the original proposal that would have covered all facility types under the Appendix K protocol, there would have been the additional and clarifying definition Persistent Leak that is in the Appendix K definitions<sup>7</sup> to account for venting due to normal operations. The commenter states now that Appendix K only applies to natural gas processing plants, that leaves other facility types (well sites, centralized production facilities, and compressor stations) that are utilizing OGI for leak detection without the additional persistent leak definition that makes it appear that venting due to normal operations falls under the definition of fugitive emissions.

Commenters (2000-Step2Compliance, 2221-Texas Pipeline Association, 2283-Endeavor Energy Resources, 2399-GPA Midstream Association, 2433-EDF et al, 2363-Continuous Emission Monitoring Coalition (CEMC), 2448-Project Canary, PBC) state that the rule lacks a clear definition as to what is a fugitive emissions component and some offer alternatives for a definition and what it should include.

Commenters (2221-Texas Pipeline Association, 2283-Endeavor Energy Resources, 2399-GPA) ask that EPA not adopt a revised definition of “fugitive emissions component,” in proposed §60.5430b and §60.5430c, as the revisions could present substantial confusion and potentially unduly broaden the scope of fugitive emissions to include emissions from equipment designed as part of the process to vent emissions. The commenters urge EPA not to make this revision.

---

<sup>4</sup> Under OOOOa, Fugitive Emissions Component means any component that has the potential to emit fugitive emissions of VOC at a well site or compressor station, including valves, connectors, pressure relief devices, open-ended lines, flanges, covers and closed vent systems not subject to § 60.5411 or § 60.5411a, thief hatches or other openings on a controlled storage vessel not subject to §60.5395 or § 60.5395a, compressors, instruments, and meters. Devices that vent as part of normal operations, such as natural gas-driven pneumatic controllers or natural gas-driven pumps, are not fugitive emissions components, insofar as the natural gas discharged from the device's vent is not considered a fugitive emission. Emissions originating from other than the device's vent, such as the thief hatch on a controlled storage vessel, would be considered fugitive emissions.

<sup>5</sup> Fugitive emissions component means any component that has the potential to emit fugitive emissions of methane or VOC at a well site, centralized production facility, or compressor station, including valves, connectors, pressure relief devices, open-ended lines, flanges, covers and closed vent systems not subject to §60.5411b, thief hatches or other openings on a storage vessel not subject to §60.5395b, compressors, instruments, meters, and in yard piping.

<sup>6</sup> Fugitive emissions are defined as any indication of visible emissions observed from a fugitive emissions component using optical gas imaging or an instrument reading of 500 parts per million (ppm) or greater using Method 21 of appendix A-7 to this part.

<sup>7</sup> Persistent leak is any leak that is not intermittent in nature.

Commenter (2283-Endeavor Energy Resources) finds EPA's definition of fugitive emissions sources is unnecessarily broad and vague. The requirements should be clear and straightforward so that operators do not inadvertently miss inspections.

Commenters (2221-Texas Pipeline Association, 2326-AXPC) believe EPA should limit the list of fugitive emission components to equipment that is not designed to vent as part of its intended operations, so as to keep the rules' focus on equipment that creates emissions as the result of an abnormal, unintended condition that needs to be repaired. The definition should not include equipment such as thief hatches and crankcase vents, which are intended to release emissions as part of normal operations; as such, revising the definition to clearly exclude such equipment would bring the definition more in line with the traditional concept of what constitutes a fugitive emissions component, *i.e.*, a piece of equipment that is emitting fugitive emissions due to unintended malfunction, not intended operations. Commenter (2326-AXPC) adds uncontrolled storage vessels are designed and intended to emit to atmosphere and may do so through thief hatches or other openings. It is illogical for the observance of allowable and intended emissions from this equipment to trigger repair requirements.

Commenter (2221-Texas Pipeline Association) believes narrowing the list in this manner would also have the benefit of reducing the number of individual components that would be subject to the extensive survey, repair, replacement, and recordkeeping/reporting requirements that would apply to components covered by the fugitive emissions rules. The application of such onerous requirements should be as limited as possible, and in no event should such requirements be applied to equipment that is allowing emissions as an integral part of its design and operations. EPA has not seen fit to include an unrealistically expansive list of fugitive emissions components in other NSPS subparts; the leak detection and repair regulations in Subpart VVa, for example, list only the following covered equipment: "pump, compressor, pressure relief device, sampling connection system, open-ended valve or line, valve, and flange or other connector in VOC service and any devices or systems required by this subpart."<sup>8</sup>

Commenters (2326-AXPC, 2428-API) propose that EPA exclude buried in yard piping from the definition of fugitive emissions component. Buried in yard piping will remain difficult to monitor – in fact, impossible to monitor – so long as it remains buried. As proposed, difficult and unsafe-to-monitor equipment designations are available only where the operator monitors using Method 21, and for difficult-to-monitor equipment, an operator must monitor at least once per calendar year. These types of events represent potential loss of containment and are already repaired or corrected per industry practice and code.<sup>16</sup> Commenter (2326-AXPC) expects most operators to utilize OGI cameras, which have no difficult or unsafe-to-monitor equipment designation. Operators cannot ever monitor buried components and thus cannot comply with the requirement to monitor buried in yard piping, even on an annual basis if designated as difficult-to-monitor.

Commenter (2337-KDHE) believe AVO surveys on yard piping sound reasonable, but it is not reasonable to demand sensors be run up and down and around pipes as for Method 21 monitoring. Piping inspection should be limited to AVO, exempting Method 21 (when used in place of OGI) from inspection of plant piping.

---

<sup>8</sup> 40 CFR § 60.481a.

Commenter (2428-API) argues monitoring thief hatches and other openings on uncontrolled storage vessels adds no environmental benefit since the storage vessel emissions will be the same whether they are emitted from the tank vent or through thief hatches or other openings. Fugitive emissions component should include thief hatches or other openings on a controlled storage vessel that is not subject to NSPS OOOO, OOOOa, or OOOOb because of a construction/reconstruction/modification date on or before August 23, 2011, or a legally and practicably enforceable limit.

Commenter (2428-API) states definitions should also include the appropriate references to NSPS OOOO and OOOOa. As proposed, fugitive emission components include covers and closed vent systems and openings on storage vessels not subject to NSPS OOOOb requirements. Since EG OOOOc will be implemented over the coming years, the definition of fugitive emissions component should also include the appropriate reference to NSPS OOOO and OOOOa requirements. For that time period, a site could have storage vessels subject to NSPS OOOO or OOOOa and be subject to NSPS OOOOb fugitive monitoring.

Commenter (2428-API) recommends the following revisions, which retains much of the current NSPS OOOOa definition, to the proposed definition of fugitive emissions component in NSPS OOOOb and EG OOOOc:

Fugitive emissions component means any component that has the potential to emit fugitive emissions of methane or VOC at a well site, centralized production facility, or compressor station, including valves, connectors, pressure relief devices, open-ended lines, flanges, covers and closed vent systems not subject to §60.5411, §60.5411a, or §60.5411b, thief hatches or other openings on a controlled storage vessel not subject to §60.5395, §60.5395a, or §60.5395b, compressors, instruments, and meters, ~~and in yard piping~~. Devices that vent as part of normal operations, such as natural gas-driven pneumatic controllers or natural gas-driven pumps, are not fugitive emissions components, insofar as the natural gas discharged from the device's vent is not considered a fugitive emission. Emissions originating from other than the device's vent, such as the thief hatch on a controlled storage vessel, would be considered fugitive emissions.

Commenters (2393-Oklahoma Office of the Secretary of Energy and Environment, 2433-EDF et al.) and 1583-Oklahoma Department of Environmental Quality (ODEQ) commented that the definition for “fugitive emissions component” needs clarification regarding whether emissions from control devices should be included.<sup>9</sup> The December 2022 Supplemental Proposal preamble states, “EPA agrees that control devices should not be treated as fugitive emissions components and is therefore revising the definition in this proposal to not include those devices.” The commenters support this revision.

Commenter (2433-EDF et al.) recommends including tank batteries and other site types in the definition to avoid potential ambiguity about where fugitive monitoring is required. Including a specific reference or a cross-reference to the affected facility definition is important to avoid

---

<sup>9</sup> See “State of Oklahoma’s Comments on EPA’s Proposed Standards of Performance for New, Reconstructed, and Modified Sources and Emissions Guidelines for Existing Sources: Oil and Natural Gas Sector Climate Review” Document ID EPA-HQ-OAR-2021-0317-0727.

ambiguity and ensure fugitive monitoring occurs at tank batteries and centralized production facilities, which are known large sources of fugitive emissions. Finally, the commenter recommends that EPA include a non-exhaustive but more comprehensive list of fugitive emission components and equipment to help ensure they are not overlooked during fugitive monitoring and to reduce the potential for interpretations that might incorrectly narrow the scope of fugitive monitoring.<sup>10</sup>

Commenter (2433-EDF et al.) supports the inclusion of yard piping, and again urge EPA to clarify that the list of components is non-exhaustive. The commenter recommends that EPA revise the language to ensure fugitive emissions components include all components on all types of equipment located anywhere at a well site, centralized production facility, tank battery, or compressor station.

Commenter (2433-EDF et al) believes EPA is not defining control devices as fugitive emissions components and has proposed separate monitoring requirements to ensure control devices operate as intended, including monthly Method 22 inspections. The commenter agrees with this approach, but urge EPA to also require that flares and control devices be monitored for compliance assurance during all fugitive emissions surveys, both under the OGI and AVO program and under the alternative periodic screening options. Control devices and flares are among the most commonly-observed sources of methane emissions, including super-emitter events.<sup>11</sup> It is therefore critical that they are regularly inspected and monitored to ensure proper operation. Monitoring flares and control devices during fugitive emission surveys poses very little additional burden and can ensure emission events are avoided. Large methane slip, unlit flares, and other types of malfunctions are all violations of EPA's proposed and existing requirements for the operation of control devices.<sup>12</sup> We therefore support regular monitoring for compliance assurance purposes both through EPA's proposed requirements and during fugitive emissions surveys.

Commenter (2433-EDF et al.) urges EPA to make clear that fugitive monitoring would be required at any source receiving a variance under EG OOOOc or otherwise not subject to the standards applicable to pneumatics, control devices, covers and closed vent systems, and tanks. If given a variance, those sources would not be required to monitor for compliance assurance and any leaks would therefore properly be characterized as fugitive emissions and must be monitored during fugitive emissions surveys. The commenter urges the agency to ensure that entire sites are comprehensively monitored (whether as part of LDAR or for compliance assurance) during every survey and believe that emissions from equipment in violation of underlying standards are properly characterized as violations rather than fugitives.

Commenter (2433-EDF et al) analyzed the most commonly reported leaking components.<sup>13</sup> The commenter found that the dataset contained 56,836 reported component leaks from 174 unique component types and 20 types of equipment. Table 6 within the commenter's attachment displays the most commonly reported component leaks in upstream fugitive emissions surveys

<sup>10</sup> See *id.*

<sup>11</sup> See, e.g., Genevieve Plant et al., Inefficient and Unlit Natural Gas Flares Both Emit Large Quantities of Methane, 377 Sci. 6614 (2022), <https://www.science.org/doi/10.1126/science.abq0385>.

<sup>12</sup> See Proposed 40 C.F.R. § 60.5412b(a)-(c).

<sup>13</sup> For a full description of the methodology, see Env't Def. Fund, OOOOa Compliance Report Analysis Methodology, *supra* note 116.

using OGI. This information confirms the importance of monitoring at failure-prone equipment types that contain the most commonly leaking fugitive emissions component types.

Commenters (2393-Oklahoma Office of the Secretary of Energy and Environment, 2433-EDF et al) and 1583-ODEQ) state EPA is defining fugitive emissions components to include all thief hatches and other openings on storage vessels that are not also subject to control as storage vessel affected facilities. Commenters support this structure as long as all storage vessels and controls on storage vessels are regularly monitored. EPA's newly proposed compliance monitoring requirements ensure this, and the commenters believe this structure is appropriate given the underlying tank control standards.

Commenter (2399-GPA) argues EPA provided no rationale for altering the longstanding definition and did not either acknowledge the revision or the change in interpretation that appears to significantly expand the types of equipment considered to be "fugitive emissions components."<sup>14</sup> Any final rule should restore the previous definition of "fugitive emissions components."

Commenter (2399-GPA Midstream Association) request that EPA restore the word "Controlled" in the definition of "Fugitive Emissions Component," which the commenter states EPA deleted without any explanation. The definition in §60.5430a currently includes "thief hatches or other openings on a controlled storage vessel not subject to §60.5395 or §60.5395a." Fugitive emissions from thief hatches or openings on uncontrolled tanks are expected as the tank breathes in and out through these vents to prevent the tank from rupturing. EPA should acknowledge that the vents on uncontrolled tanks are expected to vent and should not be considered fugitive emissions.

The commenter (2399-GPA Midstream Association) recognizes that even uncontrolled, atmospheric tanks are operated under a slight amount of pressure, often at approximately one ounce. The commenter ran a generic process simulation in ProMax comparing uncontrolled tanks with one ounce of pressure and uncontrolled tanks with zero pressure. Assuming all other inputs are the same, the total tank emissions were nearly identical with only a two percent difference (2.53 tpy vs. 2.58 tpy).

Commenter (2399-GPA Midstream Association) continues, the TSD's discussion of model production facility plants further supports the commenter's position. That discussion states that "Model Plant 3 contains tanks, but as they are uncontrolled, the emissions from these tanks are allowed to vent to the atmosphere. Controlled tanks in Model Plant 4 must be vented through a closed system to a control device. Here, an open thief hatch or leak in the closed vent system could require action to repair the leak."<sup>15</sup> The TSD's Table 1 showed zero tanks for Model Plant 3 because there are zero controlled tanks.<sup>21</sup>

---

<sup>14</sup> Despite changing the definition of "fugitive emission components" to include thief hatches and other openings, EPA's Technical Support Document does not account for them. It expressly states that the "analyses for fugitive emissions from compressor stations included in the November 2021 proposed TSD has not changed." EPA, Supplemental Background Technical Support Document for the Proposed New Source Performance Standards (NSPS) and Emission Guidelines (EG), EPA-HQ-OAR-2021-0317-1578 (Oct. 2022) ("TSD") at 5-1.

<sup>15</sup> Coburn-Strott Memo at 14.

Commenter (2399-GPA Midstream Association) states this indicates that EPA failed to realize the importance of the definitional change, the proposal has made the change without providing any explanation. Conversely, if EPA intended to require leak detection monitoring for components that are no longer part of a closed vent system, then the agency must explain the rationale for this regulation and define the benefit EPA claims this could possibly yield. Otherwise, the commenter requests that EPA expressly state that it will apply the definition of “fugitive emission component” currently found in §60.5430a to NSPS OOOOb and EG OOOOc.

Response II-4-5: As summarized above, the EPA received a number of comments requested various revisions to the definition of fugitive emissions component. The final rule retains the definition of fugitive emissions components mostly as proposed and reads as follows:

*Fugitive emissions component* means any component that has the potential to emit fugitive emissions of methane or VOC at a well site, centralized production facility, or compressor station, such as valves (including separator dump valves), connectors, pressure relief devices, open-ended lines, flanges, covers and closed vent systems not subject to §60.5411b, thief hatches or other openings on a storage vessel not subject to §60.5395b, compressors, instruments, meters, and yard piping.

The EPA disagrees with comments asserting that the EPA did not explain the reason for the change in the definition of a fugitive emissions component. The December 2022 Supplemental Proposal explained why EPA found it appropriate to propose certain revisions to the definition that was proposed in November 2021.<sup>16</sup> This included EPA acknowledging that it was correcting an error made in the November 2021 proposal, which inadvertently included storage vessels that would already be subject to control as storage vessel affected facilities/designated facilities, including regular inspections of thief hatches and other sources of fugitive emissions that are separately required as part of the proposed standards for storage vessel affected facilities/designated facilities. As reflected in the final definition of fugitive emissions components shown above, the EPA is defining fugitive emissions components to include all thief hatches and other openings on storage vessels that are not subject to control as storage vessel affected facilities. The EPA does not believe it is appropriate to specify “controlled storage vessel” because thief hatches and other openings (except vents) on uncontrolled tanks are not expected to allow emissions during normal and proper operation and thus the openings should be monitored for fugitive emissions. As discussed in the December 2022 Supplemental Proposal, EPA maintains that control devices should not be treated as fugitive emissions components. The EPA anticipates that control devices will be used to meet at least one of the emissions standards in the final rules, and as such, they would be subject to the control device requirements in NSPS OOOOb or EG OOOOc. The EPA believes these revisions provide clarity and eliminate overlapping and redundant requirements.

In the final NSPS OOOOb and EG OOOOc rules, the EPA has retained yard piping<sup>17</sup> in the definition of fugitive emissions components. A definition of yard piping was added for clarity.

---

<sup>16</sup> 87 FR 74723-74724.

<sup>17</sup> The EPA recognizes that the terms “yard piping” and “in yard piping” were used interchangeably in the December 2022 Supplemental Proposal. The final rule uses the term “yard piping” consistently.

As discussed in the December 2022 Supplemental Proposal, pipes can experience cracks or holes, which can lead to fugitive emissions. The inclusion of yard piping in the definition of fugitive emissions components will help ensure that fugitive emissions from these sources do not go undetected during fugitive emissions monitoring and that issues found from the pipe itself leading to the fugitive emissions are addressed. If industry is already conducting checks for leaks as standard practice and code, this would further assist in ensuring that fugitive emissions are minimized. AVO and OGI can be used to detect fugitive emissions from cracks and other defects in yard piping by scanning along the length of the piping. However, the EPA acknowledges that EPA Method 21 does not include instructions for monitoring yard piping; therefore, the EPA is providing directions in this final rule on how to monitor yard piping while conducting an EPA Method 21 monitoring survey in NSPS OOOOb and EG OOOOc.

The EPA recognizes the difficulty of monitoring yard piping that is buried, as it may require disturbing the surface, which could inadvertently cause emissions; therefore, the final NSPS OOOOb and EG OOOOc rules only require monitoring of yard piping and associated fugitive components (*e.g.*, connectors) that are “at or above ground level.”

Regarding a commenter’s request that the definition of fugitive emissions components explicitly includes separators, the EPA agrees that, although the list of components in the definition is not exhaustive, it is worthwhile to eliminate any ambiguity that separator dump valves are fugitive emissions components. The EPA is finalizing a definition of fugitive emissions components in NSPS OOOOb and EG OOOOc that specifically includes separator dump valves, thus clarifying that the separator dump valve is subject to monitoring by OGI, AVO, or other detection methods. In addition, because malfunctioning separator dump valves are a known source of large emissions (as the commenter noted) and because sometimes there is visual evidence of the malfunction, the EPA is requiring in the final rule that, during the regular AVO monitoring surveys (either quarterly or bimonthly depending on the site), a visual inspection must be conducted of all separator dump valves to ensure that they are free of debris and not stuck in an open position, and any dump valve not operating as designed must be repaired.

The EPA believes that the fugitive emissions components definition and the fugitive emissions components affected facility definition both clearly include centralized production facilities, which include tank batteries in the production segment.

See the final rule preamble section XI.H.2 for the response to the request for monitoring of flares for compliance assurance.

Comment: Commenter (2286-Colorado Department of Public Health and Environment (CDPHE)) requests that EPA define “yard piping” as used in the supplemental proposal and proposed regulatory language.<sup>18</sup> Under Colorado’s LDAR program and Storage Tank Emission Management (STEM) requirements pursuant to Colorado’s Regulation Number 7, the Division has included various piping in control configurations and as components subject to the LDAR program or as a piece of a closed vent system subject to monitoring. The commenter requests

---

<sup>18</sup> See 87 FR 74702 at 74723, EPA is proposing to add yard piping as one of the specifically enumerated components in the definition of a fugitive emissions component ... to ensure that when fugitive emissions are found from the pipe itself the necessary repairs are completed accordingly.

that EPA define yard piping to ensure clarity in application of both the federal and Colorado's programs.

Response II-4-6: The EPA agrees with the commenter that a definition of yard piping should be included in the regulatory language. The final rule defines yard piping as follows:

*Yard piping* means hard-piping at a well site, centralized production facility, or compressor station that is not part of a closed vent system.

Comment: Commenter (2197-Roy Massengale) notes the current proposed definition of fugitive emissions component would include rod packing vents already regulated under §60.5385b (*i.e.*, duplicative regulation). The commenter recommends including a sentence in the definition of fugitive emissions component such as:

“Rod Packing vents regulated under §60.5385b would not be considered a Fugitive emissions component.”

Response II-4-7: The fugitive emissions requirements in §60.5397b of the final rule do not apply to rod packing for reciprocating compressors because this is a regulated source under the rule. The EPA believes the rule make this clear, and EPA does not find it necessary to revise the definition of fugitive emissions components for this purpose.

#### 4.1.2.5 Open-Ended Valve/Line

Comment: Commenter (2433-EDF et al.) cites the definition of open-ended valve or line or open-ended vent line:

*“Open-ended valve or line or open-ended vent line* means any valves, except safety relief valves, having one side of the valve seat in contact with process fluid and one side open to the atmosphere, either directly or through open piping.”

Commenter (2433-EDF et al.) states EPA should eliminate the exception for safety relief valves. Safety relief valves can malfunction and cause unintended and fugitive emissions, and should therefore be considered a fugitive emissions component.

Response II-4-8: The EPA disagrees with the suggestion to remove the exception for safety relief valves. The definition of open-ended valve or line or open-ended vent line is consistent with the definition of this term in 40 CFR part 60, subparts VV and VVa and has been retained in this final rule.

#### 4.1.2.6 Wellhead Only Well Site

Comment: Commenter (2179-KIOGA) states the EPA needs to include a definition for wellhead only well sites and low production wells in the yet to be proposed regulatory text.

Response II-4-9: The final rule includes the following definitions for wellhead only well sites:

*Single wellhead only well site* means a wellhead only well site that contains only one wellhead and no major production and processing equipment.

*Multi-wellhead only well site* means a well site that contains two or more wellheads and no major production and processing equipment.

Comment: Commenter (2428-API) notes that EPA is not providing a meaningful opportunity to comment on a key basis for removing the wellhead only exemption because the underlying data for the DOE study is unavailable.

Response II-4-10: EPA acknowledges the commenter's observation. Following the December 2022 Supplemental Proposal, the EPA received the underlying dataset for the DOE Study, which was previously not available. The EPA further evaluated the methane emissions data obtained during the field campaigns of the DOE Study, as discussed in section XI.A.1.d of the preamble to the final rule.

#### 4.1.2.7 Small/Marginal Well Sites

Comment: Several commenters (2177-Ute Indian Tribe, 2348-Energy Workforce and Technology Council, 2436-Louis Pochet, 2439-State of Michigan Department of Environment, Great Lakes and Energy, 2446-IPAA, 2462-Cynthia Walter) express concern over how EPA has defined and classified a small well site in the proposed rule.

Commenter (2177-Ute Indian Tribe) recommends that EPA revise the definition of "small well site" removing references to natural gas-driven pneumatic controllers, or specifying high-bleed natural gas-driven pneumatic controllers.

Commenter (2177-Ute Indian Tribe) recommends an exemption for wells producing less than 60 MCF/day or 10 BOE/day, as defined by the IOGCC (Interstate Oil & Gas Compact Commission). Wells of these size generally have fewer vented emissions and there is therefore a diminishing rate of return in requiring emission controls for these small sources.

Commenter (2436-Louis Pochet, 2462-Cynthia Walter) provide the following comments on the definition of small well site:

1. The criteria to require monitoring might have been made based on the "potential to emit," but that potential is very hard to predict. Small, new, or old wells that did not produce much gas or oil still have the potential to emit substantial, unintended pollution.
2. Many processes can alter geologic conditions around a well and allow releases of emissions.
3. The large number of abandoned wells, *e.g.*, 200,000 for Pennsylvania alone, and unknown location for most abandoned wells means that more than one well may intersect with a well that was intended to be "small."
4. Research on water contamination from intersecting wells indicates the changing nature of geology and emission potentials from wells. For example, "well" water became contaminated, and chemistry of the water differed substantially among neighbors only 300 feet apart and across days because nearby fracking altered underground geology and the movement of contaminants among aquifers.

Commenter (2348-Energy Workforce and Technology Council) suggests that a small well site be defined as “two or less wells on pad with no other production equipment.” Pad size is an incomplete or insufficient metric on which to base monitoring. Instead, the amount of production should also be factored in, as well as other considerations such as whether artificial lift or other operations with high emission potentiality operate onsite.

Commenter (2439-State of Michigan Department of Environment, Great Lakes and Energy) notes the EPA is defining small well sites as any site with a single wellhead and no more than one piece of certain major production and processing equipment, and associated meters and yard piping. The commenter notes it is unusual for there to be only a single wellhead and one piece of equipment on a wellsite. Typical well sites for small operators and marginal wells are a single wellhead, separator, or heater-treater, and two tanks. Changing the definition of a small well site to include a single wellhead and two to three pieces of equipment would be appropriate.

Commenter (2446-IPAA) indicates that the definition of a small well site appears to overly constrain the scope of sites that should fall into it. For example, EPA estimates that 95,000 sites will fall within its small well site definition. 83 percent of low production wells produce 6 boe/day or less. In total, there are over 600,000 wells in this category (over 330,000 are less than one boe/day and 200,000 are between 1 and 4 boe/day). While many will be single well or multiple well sites, it is highly likely that a sizable number of these wells will fall into EPA's large well definition. Because the large well matrix category captures everything above a threshold of not being a single well site, a multiple well site and a small well site, EPA needs to ensure that its threshold is appropriate. EPA notes in the preamble that the larger end of the DOE Study found wells that were emitting 3 to 4 tpy. In its FEAST model analysis EPA uses an emissions threshold of 8.51 tpy. This emissions rate translates into a well producing about 290 mcf/d and is within EPA's concept of a large facility. However, a facility emitting 3 to 4 tpy will essentially be at the top end of the low production well definition and its emissions will likely be consistent with EPA's small well site matrix category.

Response II-4-11: The EPA is finalizing the definition of a small well site as follows:

*Small well site* means, for purposes of the fugitive emissions standards in §§60.5397b and 60.5398b, a well site that contains a single wellhead, no more than one piece of certain major production and processing equipment, and associated meters and yard piping. Small well sites cannot include any controlled storage vessels (or controlled tank batteries), control devices, natural gas-driven process controllers, or natural gas-driven pumps.

#### 4.1.2.8 Major Production and Processing Equipment

Comment: Commenter (2433-EDF et al) states for the definition of major production and processing equipment, EPA should eliminate the last clause of the definition (“for the purpose of determining whether a well site is a wellhead only well site.”) because major production and processing equipment is also referenced in section 60.5397b(g)(1)(iii)(D) for purposes beyond determining whether a well site is a wellhead only site. The commenter therefore recommends that qualifier be eliminated. EPA should also add language to ensure that all types of storage vessels are included.

Response II-4-12: The EPA disagrees with the commenter that it should remove the wellhead only well site qualifier from the definition of major production and processing equipment. The EPA believes this is a necessary inclusion in order to ensure the requirements that apply for fugitive emissions monitoring are clear. The EPA agrees that it is appropriate to include all types of storage vessels in the definition. The EPA is finalizing the following definition of major production and processing equipment, which also includes the addition of control devices, natural gas-driven process controllers, natural gas-driven pumps, and tank batteries.

*Major production and processing equipment* means reciprocating or centrifugal compressors, glycol dehydrators, heater/treaters, separators, control devices, natural gas-driven process controllers, natural gas-driven pumps, and storage vessels or tank batteries collecting crude oil, condensate, intermediate hydrocarbon liquids, or produced water, for the purpose of determining whether a well site is a wellhead only well site.

Comment: Commenter (2288-Department of Environmental Quality (NDDEQ)) notes that North Dakota state law requires that any emission of organic compound gases and vapors, except from an emergency vapor blowdown system or emergency relief system be controlled by a flare or an equally effective control device as approved by the NDDEQ. As such, even well sites with minimal emissions are required to have an operating control device onsite to control those emissions as well as to act as a backup in case there is an upset that would temporarily generate more significant emissions. It appears that EPA's supplemental proposal would count any such control device located at a well site as major production and processing equipment" 40 CFR 60.5397c(g)(1)(iii)(B), making the well site subject to more stringent monitoring and reporting requirements. The commenter requests that control devices that are not being used to comply with the requirements in the supplemental proposal be excluded from the definition of control devices for the purposes of determining rule applicability. The commenter does not want operators to encounter a situation where they are only subject to the supplemental proposal due to compliance with a previously existing state requirement.

Response II-4-13: The EPA understands the commenter's concerns, however, EPA is finalizing a definition of major production and processing equipment that includes control devices. Control devices, and other major production and processing equipment specified in §60.5397b(g)(1)(iv) and §60.5397c(g)(1)(iv) are sources individually are known sources of large emissions and emissions can leak from this equipment in substantial quantities if not functioning properly. Fugitive emissions components affected facilities located at well sites or centralized production facilities that have a control device would be subject to the requirements in §60.5397b and §60.5397c regardless of any separate requirements that the control device may or may not be subject to.

#### 4.1.2.9 Tank Battery

Comment: Commenter (2433-EDF et al) states for the definition of tank battery, EPA should clarify that if a tank battery exists at or near a well site, it is considered part of the well site for purposes of the fugitive emissions standards in sections 60.5397b and 60.5398b. EPA must clarify that tank batteries are subject to fugitive monitoring requirements regardless of where they are located, including tank batteries that are not part of a centralized production facility.

Response II-4-14: The EPA disagrees with the commenter. The definition of tank battery for the purposes of storage vessel applicability is unrelated to the scope of fugitive emissions at well sites, centralized production facilities, or compressor station sites. The fugitive emissions components affected facilities requirements in §60.5397b and §60.5398b and the definition of fugitive emissions components already include how to determine which components on storage vessels are included in the fugitive emissions monitoring and repair program.

#### 4.1.2.10 Definition of Centralized Production Facility

Comment: Commenters (2326-AXPC, 2433-EDF et al.) provide recommendations for revisions to the definition of centralized production facility.

Commenter (2326-AXPC) states the definition is important because requirements may differ if an affected facility is located at a well site or a centralized production facility. For example, reciprocating compressors located at a well site are not affected facilities, while those located at centralized production facility are affected facilities. EPA's definition of a well site does not provide complete information for an operator to determine if a location is a well site or a centralized production facility. The commenter requests that EPA clarify that a centralized production facility is a facility serving wells in which all wells are located off-site (*i.e.*, not on the same location as the centralized production facility). EPA's discussion of centralized production facilities in the November 2021 proposal does not make clear why EPA chose to define a centralized production facility as one servicing any offsite well, rather than a centralized facility receiving liquids from exclusively offsite wells.

Commenter (2428-API) suggests EPA add clarification to the definition for centralized production facility that addresses custody transfer.

Commenter (2433-EDF et al) recommend eliminating words that could support overly narrow interpretations of what constitutes a centralized production facility. The commenter recommends encompassing any site used to gather any produced hydrocarbons, again to prevent overly narrow interpretations. If EPA does not eliminate the word "offsite" from this definition, it must clarify that tank batteries at or near well sites are part of the well site fugitive emissions component affected facility. The commenter recommends the following changes:

*"Centralized production facility means one or more storage vessels and all equipment at a single surface site used to gather, ~~for the purpose of sale or processing to sell,~~ crude oil, condensate, produced water, ~~or~~ intermediate hydrocarbon liquid, or any other produced hydrocarbons, from one or more ~~offsite~~ natural gas or oil ~~production~~ wells. This equipment includes, but is not limited to, equipment used for storage, separation, treating, dehydration, artificial lift, combustion, compression, pumping, metering, monitoring, and flowline. ~~Process vessels and process tanks are not considered storage vessels or storage tanks.~~ A centralized production facility is located upstream of the natural gas processing plant or the crude oil pipeline breakout station and is a part of producing operations."*

Response II-4-15: In the November 2021 Proposal, the EPA determined that it was appropriate to include a definition of a centralized production facility to clearly distinguish between well sites and centralized production facilities (where liquids are received from at least one well site located offsite). The EPA provided extensive rationale for how the proposed definition of a

centralized production facility was developed at that time.<sup>19</sup> The EPA did not modify the definition in the December 2022 Supplemental Proposal. Further, the EPA did not propose to amend the definition of “well site,” except to remove the criteria for tank battery surface sites, which was being replaced (and expanded) with the definition of centralized production facility.

In response to one commenter’s request that EPA clarify that a centralized production facility is a facility serving wells in which all wells are located offsite (*i.e.*, not on the same location as the centralized production facility), the EPA disagrees, for the following reasons. First, the EPA believes that the proposed definition of “centralized production facility” was not clear for a facility receiving liquids from both on-site and offsite wells, as the proposed definition of centralized production facility was silent on the presence of on-site wells. Further, the proposed definition of “well site” was “one or more surface sites that are constructed for the drilling and subsequent operation of any oil well, natural gas well, or injection well,” which could overlap with the definition of “centralized production facility” if the “centralized production facility” receives liquids from both on-site and offsite wells.

Next, the EPA notes that the proposed “modification” provisions at 40 CFR §60.5365b(i)(2) for “centralized production facility” clearly anticipated that an on-site well may be present at an existing centralized production facility, because the modification actions include the drilling of an on-site well, or the hydraulic fracturing or refracturing of an on-site well. To address the overlap that the proposed definitions of well site and centralized production facility created, the EPA is finalizing the following definitions for centralized production facility and well site.

*Centralized production facility* means one or more storage vessels and all equipment at a single surface site used to gather, for the purpose of sale or processing to sell, crude oil, condensate, produced water, or intermediate hydrocarbon liquid from one or more offsite natural gas or oil production wells. The centralized production facility also may include one or more on-site wells. This equipment includes, but is not limited to, equipment used for storage, separation, treating, dehydration, artificial lift, combustion, compression, pumping, metering, monitoring, and flowline. Process vessels and process tanks are not considered storage vessels or storage tanks. A centralized production facility is located upstream of the natural gas processing plant or the crude oil pipeline breakout station and is a part of producing operations.

*Well site* means one or more surface sites that are constructed for the drilling and subsequent operation of any oil well, natural gas well, or injection well. If the surface site also receives liquids from one or more off-site natural gas or oil production wells, the surface site is a centralized production facility, not a well site.

Regarding the comment that the proposed definition of centralized production facility could result in overly narrow interpretations, the EPA believes that the concepts of on-site vs offsite are necessary, as described above, to avoid confusion where two definitions may appear to apply. The changes should not result in a gap, where the fugitive emissions standards do not apply. A tank battery located near well sites which receives liquids from at least one offsite well is a centralized production facility. If all of the wells are on-site, the site is a well site. The definition of fugitive emissions component clearly states that components at a centralized production

---

<sup>19</sup> 86 FR 63183-63185 (November 15, 2021).

facility and well site are included in the definition. Regarding the elimination or addition of other terms in the definition of “centralized production facility” that the commenter suggested, the commenter did not provide rationale as to why these changes are necessary and the EPA is not making these changes.

Regarding one commenter’s recommendation to address custody transfer in the definition centralized production facility, EPA included language in §60.5365b of the final rule that facilities located inside and including the Local Distribution Company (LDC) custody transfer station are not subject to this subpart.

### **4.1.3 Proposed BSER**

#### **4.1.3.1 General Comments**

Comment: Commenters (2248-NDPC, 2433-EDF et al.) express general support of the proposed BSER based on OGI monitoring.

Commenter (2458-MiQ) notes that based on their experience with its methane certification process, it supports the supplemental proposal’s frequency for OGI and AVO surveys and monitoring. The commenter recommends that the frequency of and monitoring requirements for OGI and AVO technologies and practices be updated annually based on available research.

Commenter (2248-NDPC) states before NSPS OOOOa, the oil and natural gas industry has been conducting OGI camera surveys and has learned much about fugitive emission leaks, their causes, and potential mitigation. As such, the OGI camera is a sustainable methane detection technology in North Dakota, especially with the challenges not present in, or significantly different than, other basins throughout the United States, such as inclement and harsh winter conditions presenting challenges precluding the use of a variety of methane detection technologies.

Commenter (2433-EDF et al.) states building from extensive experience, past regulations, and the experience of leading states, EPA has appropriately proposed leak detection and repair using OGI cameras as the best system of emission reduction for addressing fugitive emissions. OGI is a proven technology that has now been deployed for detecting and mitigating fugitive emissions from oil and gas operations for well over a decade.<sup>20</sup> EPA and other regulators have long relied on OGI monitoring because of its proven ability to detect emissions from a wide range of equipment and its ability to precisely pinpoint emission sources that can then be prioritized for repair.<sup>21</sup> This technology has been extensively tested and evaluated in the field,<sup>22</sup> and it has also

been deployed and used successfully by operators for years.<sup>23</sup>

Commenter (2433-EDF et al) OGI cameras have a very low detection threshold, meaning they are sensitive and can detect small leaks that other technologies miss. As proposed, OGI cameras would be required to have a 100% detection limit of 60 grams per hour. This is far more sensitive than the technologies that may be permitted under the alternative options, which only require the ability to detect emissions ranging from 1 to 30 kg/hr. This means that when used with the same frequency and coverage, OGI will always be more effective at reducing emissions because it will detect all the same large emissions and the portion of smaller emissions that are below the detection threshold of less sensitive technologies. In addition, OGI can almost always immediately pinpoint the emissions source, while alternative options may require a follow up on site survey to locate the emission source before a repair can be attempted. Technologies with higher detection thresholds will always miss a certain fraction of smaller emissions and therefore cannot mitigate certain emissions that OGI can, regardless of frequency.

Commenter (2433-EDF et al) continues, LDAR programs using OGI cameras are a highly effective, low cost, and proven means for reducing fugitive emissions. Numerous studies have shown that over time and with repeated inspections, OGI programs reduce emissions and also help to prevent large emission events.<sup>24</sup> Studies have indicated that such LDAR programs are highly effective—some finding that more than 90% of leaks remained fixed a year later.<sup>25</sup> The same study found that “emissions reduced by 44% across all 8 facilities between the first and second LDAR survey,” similar to EPA and Environment and Climate Change Canada’s assumption that an annual OGI-based LDAR survey will reduce emissions by 40%.<sup>26</sup> However, it also found that each individual survey reduced a site’s overall fugitive emissions by only 22% on average because of new leaks that occurred afterwards, indicating that “frequent LDAR surveys might be necessary for long-term emissions management.”<sup>27</sup>

Commenter (2433-EDF et al) states EPA’s assumptions about the effectiveness of OGI are supported by recent data and FEAST modeling. In Colorado for example, instrument-based monitoring (typically with OGI cameras) inspections found 90% of leaks, despite constituting just 5% of total inspections in 2020<sup>28</sup> Based on 2019 annual data, 89% of leaks were found with instrument-based monitoring. Studies have produced similar results, for example finding that

“over 80% of emissions can be detected [with OGI] from an imaging distance of 10 m.”<sup>29</sup> EPA has long assumed an 80% mitigation effectiveness for quarterly OGI and has updated that number to 77% in the supplemental proposal based on FEAST modeling results.<sup>30</sup> This assumption is reasonable and aligns with the literature, EPA’s past practice, and our own assumptions derived from FEAST.<sup>31</sup>

Response II-4-16: The EPA acknowledges the support for the general BSER determination for fugitive emission components. The EPA is finalizing the BSER determination as proposed.

Comment: Commenter (2193-California Air Resources Board (CARB)) argues the present proposed structure creates different LDAR requirements for every different type of facility, which is likely to result in extreme difficulty with respect to enforcement and compliance due to the different rules for nearly every type of facility as well as a great deal of regulatory complexity in implementation. In contrast, California’s Greenhouse Gas Emissions Standards for Crude Oil and Natural Gas Facilities (California Code of Regulations, Title 17, Sections 95665-95677) has the same LDAR requirements regardless of the facility type. Specifically, components in place after January 1, 2018, require quarterly Method 21<sup>32</sup> inspections.<sup>33</sup> OGI is permissible for leak detection and/or monitoring but may not be used in place of quarterly Method 21 inspections and the time limitations for leak repair are also applied evenly across the facilities.<sup>34</sup> This method has worked very well in California and enforcement of the regulation has proceeded smoothly. Amending this portion of the proposed Supplemental Rule to require quarterly Method 21 inspections, or alternatively, bimonthly advanced technology inspections with annual OGI monitoring, regardless of the type of facility, would ensure a streamlined process for states to implement and enforce in their plans.

Commenter (2193-CARB) argues to amend this portion of the proposed Supplemental Rule to require quarterly Method 21 inspections, or alternatively, bimonthly advanced technology inspections with annual OGI monitoring, regardless of the type of facility, would ensure a streamlined process for states to implement and enforce in their plans.

Response II-4-17: We disagree that a one-size-fits-all approach is appropriate for BSER analysis. A reasonable portion of the costs to monitor a site stem from fixed charges for monitoring crew to travel to the site and charges related to monitoring equipment rental fees. For facilities with few fugitive emission components, it is common that no new leaks will be present at the site

<sup>34</sup> Id.

during quarterly or even semi-annual monitoring events. When considering the fixed costs of a monitoring event and the lower emission reductions achieved at sites with few equipment components (small sites), we determined that quarterly OGI (or Method 21) monitoring is not cost effective. The CAA at section 111(a)(1) specifically states that a “standard of performance” must reflect “...the degree of emission limitation achievable through the application of the best system of emission reduction which (taking into account the cost of achieving such reduction and any nonair quality health and environmental impact and energy requirements) the Administrator determines has been adequately demonstrated.” As such, the EPA must consider the costs of achieving the emission reductions. Because the costs of achieving the emission reductions varies significantly based on the size of the site (number and types of fugitive emission components), we determined BSEER and develop different standards of performance for production facilities of different sizes.

Comment: Commenter (2410-California Office of the Attorney General et al.) states EPA’s revised approach seems to be largely based on Colorado’s leak detection and repair (LDAR) program, which has been in place since 2014, and requires each well site to calculate its baseline methane emissions for all of the equipment at the well site, the number of fugitive emissions components associated with each piece of equipment, and the site-specific gas composition. Colorado’s regulatory approach to leak detection and approved instrument monitoring method (AIMM) inspection of well production facilities is multi-layered. First, as of a December 2021 program update, all new well production facilities must conduct monthly AIMM inspections unless they are constructed and operated with specified design features that reduce the potential for emissions, such as constructing the site without hydrocarbon liquid storage tanks (i.e., tankless design).<sup>35</sup> Existing well production facilities must conduct inspections at a frequency that depends on the actual, uncontrolled VOC emissions from a storage tank.<sup>36</sup> Inspection frequencies range from annual, for the smallest sites, to monthly for the largest sites.<sup>37</sup> Colorado also incorporates stricter standards for operations in disproportionately impacted communities and, in some cases, where the operations are located within 1,000 feet of an occupied area.<sup>38</sup>

Commenter (2410-California Office of the Attorney General et al.) adds alternatively, EPA may consider streamlining the proposed LDAR program by requiring the same LDAR requirements for all facilities. California’s regulation requires quarterly LDAR inspections at all new and existing well sites without exemptions, and operators in California—including large and small entities—have complied with the requirements for many years now.<sup>39</sup> Specifically, components in place after January 1, 2018 require quarterly EPA Method 21<sup>40</sup> inspections.<sup>41</sup> OGI is permissible for leak detection and/or monitoring but may not be used in place of quarterly EPA

<sup>37</sup> Id.

<sup>38</sup> Colo. Rev. Stat. § 24-4-109.

<sup>39</sup> See Cal. Code Regs., tit. 17, § 95669.

<sup>40</sup> 40 C.F.R. § 60, Appendix A7 (“Method 21: Determination of Volatile Organic Compound Leaks”). The summary of Method 21 provides that “a portable instrument is used to detect VOC leaks from individual sources. The instrument detector type is not specified, but it must meet the specifications and performance criteria contained in section 6.0. A leak definition concentration based on a reference compound is specified in each applicable regulation. This method is intended to locate and classify leaks only, and is not to be used as a direct measure of mass emission rate from individual sources.” Id.

<sup>41</sup> Cal. Code Regs., tit. 17, § 95669(g) (2018).

Method 21, and the time limitations for leak repair are also applied evenly across the facilities.<sup>42</sup> Similarly, New Mexico's recently promulgated regulations apply LDAR requirements to all wells with no exceptions, with every well to receive leak inspections at least once a year, and larger, potentially higher emitting wells receiving semiannual or quarterly inspections.<sup>43</sup> And New York's recently adopted regulations require semiannual LDAR at all well sites with no exceptions.<sup>44</sup> Uniformity may facilitate and ensure that states are able to implement and enforce these requirements in their plans.

Response II-4-18: The EPA appreciates the summary of different state requirements. We note that our proposed provisions are very similar to those of New Mexico's. As noted in the immediately previous comment and response, we determined, based on the authority and requirements in section 111 of the CAA, that the fugitive emission component monitoring requirements should be different for differently-sized facilities.

Comment: Commenter (2180-Pennsylvania Department of Environmental Protection (DEP)) recommends the frequency of LDAR inspections should be as follows:

- Monthly AVO inspections at all affected facilities;
- Semiannual instrument-based LDAR inspections for well sites and remote pigging stations emitting less than 2.7 tpy of VOC;
- Quarterly instrument-based LDAR inspections for well sites and remote pigging stations emitting equal to or greater than 2.7 tpy of VOC, and for gathering and boosting stations, natural gas processing plants, and transmission stations.

Commenter (2180-DEP) notes Pennsylvania has required similar sources to perform monthly AVO inspections and quarterly or semiannual instrument-based LDAR inspections since 2013.

Response II-4-19: In EPA's November 2021 proposal, EPA proposed a monitoring approach using a potential emissions threshold for subcategorizing facilities for the fugitive emissions requirements. The EPA decided that there were several practical issues related to using such an emissions threshold (*e.g.*, should it be based on default emission factors versus actual emissions; what should happen if a facility has a large event – does this trigger into more frequent monitoring and, if so, how long?). The EPA determined that using the number of major equipment at the well site provided a more clear and appropriate method by which to subcategorize facilities relative to the fugitive emissions requirements. The EPA is finalizing the fugitive emission components monitoring and repair requirements as proposed.

Comment: Commenter (2394-Earthworks) provides detailed results from a number of case studies and field surveys in several states in order to track the progress of oil and gas regulations. The commenter provides information and results on case studies conducted in Colorado from which the commenter notes that despite the adoption of stricter oil and gas regulations in Colorado, pollution from the industry is still pervasive and persistent. The commenter provides a

---

<sup>42</sup> Id.

<sup>43</sup> See New Mexico Administrative Code 20.2.50, at 20.2.50.16, available at <https://www.env.nm.gov/air-quality/wp-content/uploads/sites/2/2022/07/Oil-and-Gas-SectorOzone-Precursor-Pollutants-Final-rule-20.2.50-NMAC-06Jul22.pdf>.

<sup>44</sup> 6 New York Codes, Rules and Regulations (NYCRR) 203-7.2(a) (effective Mar. 3, 2022).

similar summary based on a case study conducted in Pennsylvania, which the commenter believes demonstrates a clear need for frequent monitoring of emissions at every oil and gas well pad, including those previously overlooked due to production volume or size. Case studies performed in Texas where the commenter conducted thousands of individual site visits and submitted over 400 complaints with OGI video as evidence to various agencies, including the TCEQ. Based on those case studies, the commenter reports that there is an alarming failure to protect public health and safety and local environments. The commenter also notes that it has documented air pollution and emissions in New Mexico, reporting results of field surveys to the regulatory agency and highlights enforcement shortfalls, including the lack of appropriate capacity to enforce current rules and regulations. More information on the specific case study findings is provided in the commenter's letter.

Response II-4-20: The EPA acknowledges the information provided by the commenter and notes that it is aware of information available from multiple case studies in various areas reporting on results from different fugitive emissions monitoring and repair programs. The EPA is finalizing requirements that update, strengthen, and expand on the current requirements under CAA section 111(b) for methane and VOC emissions from sources that commenced construction, modification, or reconstruction after December 6, 2022

#### 4.1.3.2 AVO/OGI/Method 21

Comment: Commenters (2168-INOGA, 2177-Ute Indian Tribe, 2181-Ute Indian Tribe of the Uintah and Ouray Reservation, 2217-Religious Action Center of Reform Judaism, 2433-EDF et al., 2248-North Dakota Petroleum Council (NDPC), 2458-MiQ) appreciate EPA's consideration and implementation of AVO inspections to identify emissions sources. The commenters believe this is a cost-effective method to identify when there is a leak, so it can be identified and repaired.

Commenter (2433-EDF et al.) is supportive of AVO because regular site visits and upkeep are important at all sites and will help to prevent and mitigate fugitive emissions and equipment failures. Regular AVO inspections can also help secure additional emissions reductions from large and very obvious equipment failures. The proposed AVO requirements can help ensure operators actually address issues they find at sites indicating a potential leak rather than turning a blind eye. Especially at marginal and declining sites, lack of maintenance can lead to persistent and long-lasting leaks, and can sometimes result in major failures.<sup>45</sup> AVO can therefore serve an important additional purpose aimed at site hygiene and preventative maintenance that is not necessarily encompassed by OGI or periodic screening, which are both aimed at reacting after a problem has occurred.

---

<sup>45</sup> Jacob Deighton et al., Measurements show that marginal wells are a disproportionate source of methane relative to production, 70 J. Air Waste Mgmt. Assoc. 1030, 1030–42 (2020), <https://www.tandfonline.com/doi/epdf/10.1080/10962247.2020.1808115?needAccess=true&role=button> (finding that “the main driver of emissions from the wells visited is neglect. The state of maintenance at these wells was poor. Often, pumpjacks, tanks, and other infrastructure were rusty and sometimes appeared to have temporary fixes to just keep the well mechanically operational. . . . Some wells looked like they had not been serviced in years.”)

Commenter (2433-EDF et al) argues, to ensure the preventative value of AVO is realized, EPA should alter the regulatory language to require action when “evidence of a potential leak or likely future leak is found at any time.”

Commenter (2433-EDF et al) notes regulatory exemptions can result in irresponsible operations and business models that aim to keep declining wells in production beyond their useful lives in order to avoid plugging costs and exploit tax benefits.<sup>46</sup> This can lead to rusted, overgrown, and unmaintained sites that leak methane, create dangerous conditions, and are prone to orphanage.<sup>47</sup> Requiring the responsible operator to inspect these sites and fix visible problems will help combat these issues while disincentivizing business models centered on accumulating and neglecting declining sites.

The commenter’s (2433-EDF et al) compliance report analysis found much shorter OGI survey and travel times in reported data. This underscores that EPA is likely overestimating those same figures (and thus costs) in its assumptions about AVO as well.<sup>48</sup> Indeed, travel times for AVO surveys are likely to be the same as for OGI, and inspection times will be shorter for AVO than OGI.

Response II-4-21: The EPA is finalizing fugitive emissions monitoring requirements that requires different AVO inspection frequencies depending on the type of site; either by itself, or in combination with regular OGI surveys. Inspections using AVO is a cost-effective method to identify when there is a leak, but is, as discussed in the December 2022 Supplemental Proposal preamble<sup>49</sup> not sufficient for well sites with additional fugitive emissions components such as connection points and valves that also present a potential source of fugitive emissions. Emissions from these types of components are generally smaller, and not easily identifiable using AVO. See section X.A.1.a.ii for the final standards for all well sites and centralized production facilities, which includes quarterly AVO for single wellhead only well sites and small well sites, and a combination of AVO and OGI monitoring for multi-wellhead only well sites and well sites with major production and processing equipment.

Comment: Commenter (2433-EDF et al) argue EPA’s OGI and AVO cost-effectiveness assumptions are reasonable and conservative. Fugitive monitoring and repair with OGI cameras is low cost, with a commonly cited per-site inspection cost of \$600.<sup>50</sup> With new regulatory requirements, company-set emission reduction targets, and rapid growth in the methane

---

<sup>46</sup> See, e.g., Zachary R. Mider & Rachel Adams-Heard, *An Empire of Dying Wells*, Bloomberg (Oct. 2021), <https://www.bloomberg.com/features/diversified-energy-natural-gas-wells-methane-leaks-2021/>.

<sup>47</sup> Deighton et al., *supra* note 123, at 1030–42.

<sup>48</sup> Supplemental TSD, *supra* note 121, at 5–18 (“a travel time of 1.25 hours round trip was assumed at the same hourly rate for operators as is used for the development of a monitoring plan and other actions. Inspection times ranging from 15 minutes (single wellhead only well sites) to 1 hour (centralized production facilities) to account for the added complexity at larger sites, were assumed.”)

<sup>49</sup> 86 FR 74732 (December 6, 2022).

<sup>50</sup> U.S. Env’t Protection Agency, EPA’s Methane Detection Technology Virtual Workshop Transcript Day Two at 24 (Aug. 24, 2021) (Doc. ID No. EPA-HQ-OAR-2021-0317-0181).

mitigation sector,<sup>51</sup> it is likely that OGI monitoring will become even lower cost in the coming years and prior to the initial date for existing source compliance.

Commenter (2433-EDF et al) states in this supplemental proposal, EPA's cost assumptions remain largely unchanged from the November 2021 proposal. There, EPA examined three elements of OGI monitoring costs: (1) periodic monitoring for leaks; (2) repair of leaks identified; and (3) documentation of the detection and repair activities. EPA breaks these down into specific cost components that include: reading of the rule and instructions; development of a company-wide fugitives monitoring plan; recordkeeping database system set-up fee; cost for OGI monitoring (OGI camera survey); repair costs; costs to resurvey; annual recordkeeping database maintenance/license fee; additional recordkeeping/data management costs; and preparation of annual reports. EPA assumes a fugitive monitoring program will cover an average 22-site area and then distributes costs across sites. EPA uses these cost estimates and the reductions achieved by various inspection frequencies to estimate cost-effectiveness.

Commenter (2433-EDF et al) analyzed EPA's assumptions underlying the OGI cost estimates and cost-effectiveness analysis.<sup>52</sup> The commenter found that various cost components included double counting—meaning the same cost was accounted for in two or more cost components. EPA's 2021 analysis of OGI costs for well sites overestimated costs by double counting reporting, recordkeeping and data management, and other costs such as travel time. In addition, EPA relies on averages of API data that overestimate costs for recordkeeping and data management. The commenter reviewed compliance reports from EPA's WebFIRE database and found that most reported travel and survey times were far shorter than EPA's assumptions.

Commenter (2433-EDF et al) presents an updated and fully comprehensive cost analysis based on their review of data from over 16,000 upstream OGI surveys included in compliance reports submitted under NSPS OOOOa.<sup>53</sup> The commenter downloaded and reviewed all of the 26,724 annual compliance reports submitted to EPA from 2017 to early 2021 via the WebFIRE database. This timeframe captures the most recent reporting using an EPA template that includes survey time data; after March 31, 2021, annual compliance reports submitted to EPA do not include survey times.

Commenter (2433-EDF et al) states these annual compliance reports shows an average combined travel and survey time of 1.75 hours, much less than EPA's 2.5-hour assumption. The commenter also found a median survey time of 30 minutes and an average of 60 minutes.<sup>54</sup> This supports and aligns with EPA's use of a 30-minute survey time in its recent cost analysis. The average is affected by a small number of surveys that took over 90 minutes, as presented in the

<sup>52</sup> 2022 Joint Environmental Comments, *supra* note 1, at 72–84.

<sup>53</sup> For a complete description of the methodology, see Env't Def. Fund, OOOOa Compliance Report Analysis Methodology (included as Attachment B).

<sup>54</sup> See OGI Survey Time Analysis Final (included as Attachment C), for a full printout of the figures.

histograms included in with the full attached analysis. The results of this analysis are presented in the Figures 1 and 2 of the commenter's letter.<sup>55</sup>

Commenter (2433-EDF et al) notes their analysis also examined all the available information on travel time between surveys. For the upstream LDAR surveys with reported start- and end-time data in the dataset, the commenter looked at surveys conducted by the same surveyor at multiple locations on the same date (*i.e.*, at least two surveys conducted on the same date by the same surveyor). They then calculated the time elapsed between the end of one survey and the start of the next. The average time between surveys that occurred on the same date by the same surveyor was 43 minutes.<sup>56</sup> Figures 3 and 4 show the distribution of times between surveys (*e.g.*, there were 2,905 occurrences in the dataset when the elapsed time between the end of one survey and the beginning of the next was less than 15 minutes).

Commenter (2433-EDF et al) states given that their analysis encompassed every reported survey time and all of the available information on travel, EPA should use both the 30 minute median survey time and 43 minute average travel time in its analysis, for a total combined time of 73 minutes. Sites subject to OOOOa fugitive monitoring are likely more complex than the average site, and the commenter expects that survey times for OOOOb/c sites would typically be shorter.

Commenter (2433-EDF et al) states using their revised survey and travel time, as well as a revised labor rate and recordkeeping and reporting costs, which avoid double counting as described in their initial comments,<sup>57</sup> the commenter recreated EPA's cost-effectiveness tables from the TSD accompanying the supplemental proposal.<sup>58</sup> For each model plant, the commenter analyzed the single pollutant cost-effectiveness of OGI monitoring under six scenarios:

- Scenario 1m: includes revised median survey and average travel time, labor rate, and recordkeeping/reporting costs;
- Scenario 2m: includes revised median survey and average travel time, and labor rate; and
- Scenario 3m: includes revised median survey and average travel time.
- Scenario 1a: includes revised average survey and travel time, labor rate, and recordkeeping/reporting costs;
- Scenario 2a: includes revised average survey and travel time, and labor rate; and
- Scenario 3a: includes revised average survey and travel time.<sup>59</sup>

Commenter (2433-EDF et al) states for the single wellhead-only model plant, the commenter finds that semiannual OGI is within the range EPA considers cost-effective under scenarios 1m and 1a using both leak rate assumptions (0.5% and 1% leak rates). For both the multi-wellhead-only and the well site and centralized production facility model plants, the commenter finds that quarterly OGI is cost-effective and incrementally cost-effective under all scenarios. These

<sup>57</sup> 2022 Joint Environmental Comments, *supra* note 1, at 72–84.

<sup>58</sup> See U.S. Env't Protection Agency, Supplemental Background and Technical Support Document for the Proposed NSPS and EG, Tables 5–10 to 5–17b (Oct. 2022) (Doc. ID. No. EPA-HQ-OAR-2021-0317-1578) [hereinafter Supplemental TSD].

<sup>59</sup> These tables are included with our comments as PDF's located in the Revised OGI Cost Effectiveness Tables (included as Attachment F) and each is also accompanied by the associated revised cost evaluation spreadsheet with revisions and notes in green.

findings support the reasonable cost of EPA's proposed standards and also support the commenter's recommendations for more frequent monitoring at certain site types.

Response II-4-22: The EPA acknowledges the information and analysis the commenter has conducted. The EPA has undertaken a significant effort to estimate the costs of various fugitive emissions monitoring and repair program, which has included information from NSPS OOOOa compliance reports, industry-provided information, and other sources. The EPA discussed extensively the inputs to the costs of the program in the 2021 TSD, and described additional edits to the costs in the December 2022 Supplemental Proposal.<sup>60</sup>

The EPA determined that due to the nature of emissions sources located at single wellhead only well sites (including large emission sources identified in the DOE Study), identification of emissions would not require the use of OGI, but AVO inspections would easily identify these sources. Therefore, the EPA evaluated a periodic AVO inspection and repair program and found that quarterly AVO inspections for fugitive emissions from single wellhead only well sites was cost-effective.

Consistent with the commenter's conclusion, the EPA also found that quarterly OGI monitoring at multi-wellhead only well sites and well sites with major production and processing equipment and centralized production facilities are cost-effective. But, for multi-wellhead only well sites, as discussed in the December 2022 Supplemental Proposal, the EPA did not find the incremental cost-effectiveness of moving from semiannual OGI monitoring to quarterly OGI monitoring to be reasonable. However, the EPA analyzed the possibility of additional monitoring in the form of AVO inspections outside of semiannual OGI monitoring for multi-wellhead only well sites, and found that the addition of quarterly AVO inspections would be cost-effective as well. Note that under the scenario of evaluating quarterly AVO inspections, only two AVO inspections would be required outside of the OGI surveys, thus the inspection costs would be half what is estimated for quarterly AVO inspections. The EPA also evaluated the addition of AVO inspections in addition to quarterly OGI monitoring for well sites with major production and processing equipment and centralized production facilities. The EPA found that the addition of bimonthly AVO in combination with quarterly OGI monitoring would be cost-effective in that case. The EPA is finalizing the fugitive emissions monitoring requirements as proposed under the December 2022 Supplemental Proposal.

Comment: Commenters (2202-Texas Oil and Gas Association (TXOGA), 2403-The Petroleum Alliance of Oklahoma (PAO) supports the removal of the requirement to comply with Appendix K for well sites and centralized production facilities.

Commenter (2202-TXOGA) requests that EPA not incorporate Appendix K as the OGI monitoring protocol for NSPS OOOOb and EG OOOOc. The commenter provides that the EPA acknowledges that extensive comments were filed on this issue after the November 2021 proposal. The commenter acknowledges that EPA's December 2022 supplemental proposal appears to have been responsive to comments/concerns raised in its November 2021 proposal. Indeed, the commenter states that the December 2022 supplemental proposal states that EPA is "not including a requirement to conduct OGI monitoring according to the proposed appendix K . . . as" was stated in the November 2021 proposal.<sup>1</sup> Instead, the commenter states that EPA is now

---

<sup>60</sup> 87 FR 74727-74729 (December 6, 2022).

proposing “to require OGI surveys following the procedures specified in the proposed regulatory text for NSPS OOOOb (at 40 CFR 60.5397b) or according to EPA Method 21.” While the commenter appreciates that EPA has incorporated their comments in regard to OGI monitoring, they do not agree with the proposed alternative approach of using NSPS OOOOb to accomplish the same.

Commenter (2403-PAO) states that they provided significant concerns with Appendix K in their comments on the November 2021 proposal. In the December 2022 supplemental proposal, the commenter acknowledges that the EPA is proposing to require OGI monitoring for well sites and centralized production facilities following the monitoring plan required in proposed 40 CFR 60.5397b instead of requiring the procedures being proposed in Appendix K for these sites. The commenter supports this change.

Response II-4-23: The comments are supportive on an aspect of the December 2022 Supplemental Proposal that has remained unchanged in the final rule; as such, no response is required.

Comment: Commenters (2167-West Virginia Surface Owners' Rights Organization, 2200-NuEnergy Operating Inc., 2314-Miller Energy Company, 2462-Cynthia Walter) question why EPA is not allowing other devices such as gas sniffers/meters as an alternative to detecting fugitive emissions.

Commenter (2167-West Virginia Surface Owners' Rights Organization) is concerned about the inadequacy of AVO inspections to detect methane leaks when it is so incredibly cheap and effective to use a meter capable of detecting methane. A simple search for "methane detector meters" on Amazon results in a wide choice of meters capable of detecting methane appearing starting at a price of only \$32. Perhaps some are only sensitive to explosive levels of methane, but one by Forensic for \$100 advertises it has a detection range from “0-10,000ppm”.

Commenters (2167-West Virginia Surface Owners' Rights Organization, 2462-Private Citizen) continue, an inspection using an actual meter is obviously much more effective than an olfactory inspection since methane has no odor unless the gas being produced has impurities. Worse, a visual inspection is not all that useful since methane is clear -- though if there is water standing in the equipment you can often see methane bubbling out of a well. Audio listening can sometimes tell a person there is a big leak, but lots of leaks are not large enough to make a sound.

Commenter (2167-West Virginia Surface Owners' Rights Organization) asks to determine the volume of the leak, would a FLIR camera be better, or a dynamic flux chamber, or testing using the inverse dispersion model? Yes. But not requiring testing with a handheld methane meter costing \$100 because they are not as good at testing volumes would be the epitome of letting the perfect interfere with the good. Whatever the size of the leak, it needs fixed, and often at the wells to which we are exposed it could be fixed with only a wrench.

Commenter (2167-West Virginia Surface Owners' Rights Organization) states the extent of the problem in West Virginia is demonstrated scientifically by a study done by Princeton and McGill

Universities.<sup>61</sup> They did a variety of testing in 13 counties in northern West Virginia. They tested 338 conventional vertical wells in those counties in West Virginia and found that 53% of active wells, 28% of unplugged inactive wells, and even 20% of plugged wells were leaking significant methane into the atmosphere. In particular they tested 79 active, conventional (vertical) wells by first using a handheld detector capable of detecting 10 ppm or more. If methane was detected at or above that level they then used either a flux chamber or inverse dispersion. They found that 53% of those wells were leaking 9 cubic feet of gas -- per hour. So testing even with just handheld meters can detect methane and could make a big impact on stopping fugitive methane emissions.

Commenter (2167-West Virginia Surface Owners' Rights Organization) note there are many small single wells owned by individual surface landowners in West Virginia. The commenter's Department of Environmental Protection counts 75,000 total wells in West Virginia, the vast majority of those being single wells on individual surface property owners. Methane leaking from these wells is just plain wasteful, deprives our members who are royalty owners of some royalties, deprives the state of severance taxes, contributes to climate change, and often stinks.

Commenter (2462-Cynthia Walter) also argues AVO inspections are not reliable because fugitive emissions could easily be invisible, have no smell, and the sounds can be masked by other equipment or road noise. In-person inspections of sites are important, however, to make sure monitoring equipment is in the correct place and to document that equipment is working or idle, and conditions are normal.

Commenter (2462-Cynthia Walter) provides an example, a researcher was contracted to compare air pollutants upwind and downwind from a compressor station adjacent to a water treatment facility for 130,000 people, Beaver Run Reservoir in Westmoreland Co., PA. Values were similarly low for all sensors. Later, the researcher was told that the compressor was not in use that week.

Commenter (2200-NuEnergy Operating Inc.) indicates there are alternative cost-effective solutions that could be performed during normal operation visits from company staff like daily or weekly AVO site visits and annual OGI with monthly AVO surveys with an inexpensive handheld gas meter. The commenter indicates that it is already performing leak surveys during routine visits, and requests guidance whether this would meet the EPA's desired increase of fugitive emissions monitoring.

Commenter (2200-NuEnergy Operating Inc.) additionally questions if gas sniffers could be used during inspections instead of costly OGI equipment. The commenter asks if increased AVO monitoring with inexpensive hand-held gas meters used by field operators during normal work routines be a cost-effective alternative to expensive OGI equipment.

Commenter (2314-Miller Energy Company) notes that the investment required to install fixed monitoring equipment on 600+ marginal wells would not be financially feasible. The commenter has a hands-on, low-tech approach to ensuring their operations are environmentally sound. The commenter's field staff visit sites daily and complete AVO inspections at each well and facility.

---

<sup>61</sup> Available on the commenter's website: <https://wvsoro.org/a-study-by-scientists-conventional-vertical-wells-in-west-virginia/>.

If regular AVO inspections are not deemed adequate, the field staff may be able to utilize mobile devices on a reasonable schedule to confirm emissions are within regulation. The commenter encourages the EPA to consider low-cost solutions that would be sufficient for monitoring low-emission wells/facilities, specifically looking at mobile gas meters that can be used across the operation instead of fixed units per well.

Response II-4-24: The EPA acknowledges the commenter's remarks regarding gas sniffers and low-cost methane detectors. As specified in §60.5397b(g) of the final rule, techniques for determining fugitive emissions include AVO, Method 21 of appendix A-7 of 40 CFR part 60, or OGI. However, owners and operators can apply for an alternative means of emissions limitation for technologies that achieve an equivalent level of emissions reduction as the technologies in the final rule under §60.5399b of the final rule. In addition, the final rule at §60.5398b includes provisions for owners and operators to apply to use alternative technologies to meet the standards that apply to fugitive emissions components affected facilities. We do not expect low-cost methane detectors to be as sensitive as the required instrument monitoring alternatives (specifically Method 21) nor has EPA developed a method for use of these detectors. Operators may elect to use these as part of their AVO surveys to help find leaks; however, we are not requiring the use of low-cost methane detectors as part of the AVO program.

First, we disagree with commenters suggesting that AVO is completely ineffective. While we understand that pure methane is colorless and odorless, production facilities do not produce pure methane. The gas produced commonly includes trace compounds, like hydrogen sulfide or benzene and other aromatic hydrocarbons, that are readily identified by olfactory methods. Liquids are also commonly co-produced with natural gas and leaks of liquid containing fluids are readily identified by visual methods.

Second, for these low-cost methane detectors to identify appreciably more leaks than a typical AVO inspection, the operator would have to sniff each individual component at very close range, similar to Method 21, greatly increasing the time and costs associated with conducting AVO inspections. The cost of Method 21 monitoring is driven by the time needed to conduct the monitoring rather than the cost of the Method 21 instrument. Thus, we find that a requirement to effectively use low-cost methane detectors to identify fugitive emissions is not appreciably different than the instrument monitoring methods that we evaluated in our BSER analysis. We expect the instrument would be less accurate and sensitive, so it would find fewer leaks than the instrument methods we included in the rule, but it would be just as expensive to conduct as those methods. Therefore, we maintain our BSER determination that instrument monitoring be conducted at the frequency determined to be cost effective and that AVO monitoring be conducted at specified frequencies to enhance the instrument monitoring program.

Comment: Commenters (2168-INOGA, 2172-KOGA, 2205-Kriebel Well Services, Inc., 2304-PIOGA) believe that EPA should support and recommend soap bubble tests as a cost-effective method second step to isolate the location of a leak after it has been identified by an AVO inspection. Soap bubble verification should also be an acceptable method to verify that a leak has been repaired. Soap bubble tests have been effectively used for decades for leak checks in residential and commercial buildings. The commenters believe that this method is just as effective at identifying leaks for oil and gas production assets, especially those that are not complex or do not cover a large area. Using soap bubbles does not require expensive equipment

and an operator with specialized training to be paid to travel to a well site, tank battery, or gas processing location, as EPA is currently proposing.

Response II-4-25: Similar to the allowance in NSPS OOOOa, EPA proposed to allow the use of a soap bubble test to verify that emissions from fugitive emissions components have been repaired. Method 21 allows a user to spray a soap solution on components that are operating under certain conditions (e.g., no continuous moving parts or no surface temperatures above the boiling point or below the freezing point of the soap solution) to determine if any soap bubbles form. If no bubbles form, the components are deemed to be operating with no detected emissions. We note that spraying soap solution to confirm whether a component has been repaired may not work for all fugitive emissions components, such as a leak found under the hood of the thief hatch since it would be difficult to apply the soap solution or observe bubbles. However, we believe that this alternative will provide some owners and operators a simple, low-cost way to confirm that a fugitive emissions component has been repaired. This would also allow the resurveys to be performed by the same personnel that completed the repairs instead of other certified monitoring personnel or hired contractors that would have to come back to verify the repairs. Therefore, we are finalizing the use of the alternative screening procedures specified in Section 8.3.3 of Method 21 for resurveying repaired fugitive emissions components, where appropriate.

#### 4.1.3.3 Equipment-Based Approach

Comment: Commenters (2036-National Parks Conservation Association (NPCA), 2236-Physicians for Social Responsibility Pennsylvania (PSR), 2303-National Tribal Air Association (NTAA), 2408-Colorado Local Government Coalition, 2410-California Office of the Attorney General et al., 2433-EDF et al, 2462-Cynthia Walter) express support for an equipment-based fugitive emissions monitoring approach and provide specific comments below.

Commenters (2036-National Parks Conservation Association (NPCA), 2303NTAA), 2408-Colorado Local Government Coalition, 2410-California Office of the Attorney General et al.) appreciate EPA's revised approach for fugitive emissions monitoring at all well sites based on the specific types of leak-prone equipment or equipment that can be the source of large emission events—such as flares, storage vessels, and pneumatic devices—rather than just well production.

Commenters (2236-PSR, 2433-EDF et al, 2462-Cynthia Walter) state the PTE is very hard metric to predict. Existing non-measurement-based estimation methods, like the PTE calculation in the initial proposal, tend to misrepresent emissions and, in particular, miss super-emitters. The commenters urge EPA to move toward an equipment-based approach where monitoring requirements depend on the presence of equipment at a site and that equipment's potential to leak or fail.

In their previous comments, commenter (2433-EDF et al) submitted extensive evidence outlining the serious problems with an approach that based monitoring requirements on potential emissions calculated by operators using an equation that did not adequately predict actual emissions nor account for equipment failures.<sup>62</sup>

---

<sup>62</sup> 2022 Joint Environmental Comments, *supra* note 1, at 84–91.

Commenter (2433-EDF et al) states it is appropriate to base monitoring frequency on the presence of certain types of equipment at a site because such equipment has been commonly observed as the source of large emission events through numerous field studies. The presence of major equipment also indicates higher component counts, which correlate to a greater probability of fugitive emissions.

Commenter (2433-EDF et al) cites a study, Zavala-Araiza et al. (2017) explains that abnormal process conditions, both persistent or episodic, include “failures of tank control systems, malfunctions upstream of the point of emissions (for example, stuck separator dump valve resulting in produced gas venting from tanks), design failures (for example, vortexing or gas entrainment during separator liquid dumps) and equipment or process issues (for example, over-pressured separators, malfunctioning or improperly operated dehydrators or compressors).”<sup>63</sup> Another study by Lyon et al. found that emissions from tank vents and hatches accounted for roughly 90% of all detected hydrocarbon sources emitting more than 3–10 kg per hour.<sup>64</sup> Lyon et al. also observed emissions from separator pressure relief valves, dehydrators, and flares.

Commenter (2433-EDF et al) notes a more recent study, Rutherford et al., found that tanks are the largest emission source and biggest reason for disagreement between the study results and EPA Greenhouse Gas Inventory (GHGI) data.<sup>65</sup> Rutherford et al. also found that flare methane emissions are underestimated in the GHGI, and that pneumatics and separators are also large sources of emissions.<sup>66</sup> Tyner and Johnson (2021) also recently found that “[m]ore than half of emissions were attributed to three main sources: tanks (24%), reciprocating compressors (15%), and unlit flares (13%).”<sup>67</sup> Robertson et al. (2020) found that simple sites with less equipment had lower emissions than those with more equipment.<sup>68</sup> And Zavala-Araiza et al. (2015) found that stuck separator dump valves and tank flashing events were causes of super-emitters.<sup>69</sup>

Commenter (2433-EDF et al) states their PermianMAP project has observed many emission events from tanks and flares.<sup>70</sup> Helicopter surveys found 79% of methane plumes were from tanks; and among marginal wells, 17% of complex sites (with multiple pieces of equipment) had emissions, while none were detected at “pump-jack only” sites.<sup>71</sup> Ravikumar et al. (2020)

<sup>70</sup> Observed emissions by equipment type: Tank-Vent 42.96%, Tank Thief Hatch 33.43%, Flare Stack 14.54%. PermianMAP, Prevalence of Emissions by Equipment Type, (Observed emissions by equipment type: Tank-Vent 42.96%, Tank Thief Hatch 33.43%, Flare Stack 14.54%).

<sup>71</sup> *Id.*

similarly found the largest emissions from tanks, concluding that “[t]he outsized role of tanks in contributing to overall methane emissions at natural gas facilities has been a defining feature in many recent studies, and points to a critical need for tank-focused LDAR regulations.”<sup>72</sup>

Commenter’s (2433-EDF et al) review of OOOOa compliance reports further supports EPA’s equipment-based approach.<sup>73</sup> The commenter downloaded over 20,000 compliance reports and isolated 80,121 reported component leaks from instrument-based fugitive emissions surveys. They then categorized each reported leak by component type and by equipment type when possible. The commenter was able to assign an equipment category to 46% of reported component leaks. Table 2 of the commenter’s letter contains information on leaks that could be categorized by equipment type.

Commenter (2433-EDF et al) states EPA’s proposed equipment-based approach aligns with the substantial body of science and data characterizing emissions from certain types of failure-prone equipment, in particular flares, storage tanks, and gas-driven pneumatic controllers.

Commenter (2433-EDF et al) adds another benefit of the tiered equipment-based approach is that it incentivizes operators to eliminate polluting sources from their sites by designing sites with minimal emissions points and electrifying certain equipment types. For example, instead of creating five separate well sites with tanks and other major processing equipment that would all be subject to quarterly OGI, EPA’s proposed structure incentivizes the use of centralized production facilities and wellhead-only well sites. By utilizing this type of design, operators can focus monitoring resources on the centralized production facility.

Commenter (2462-Cynthia Walter) states well-head failure is common even for new wells, resulting in substantial fugitive emissions. For example, Ingraffea et al. reported wells after 2005 had well-head failure rate of about 10% within the first year and rising to 40% likelihood of failure within the first 10 years, based on real world inspections of thousands of wells in Pennsylvania.<sup>74</sup>

Response II-4-26: The EPA agrees that an equipment-based fugitive emissions component monitoring and repair approach is appropriate. This approach has been retained in the final rule. The specific requirements being finalized are described in section X.A.1 of the preamble to the final rule.

Comment: Commenter (2353-CrownQuest Operating, LLC.) states EPA used the referenced study<sup>75</sup> to show that emissions strongly correlate to the amount of equipment on site and no other significant factors. The EPA uses this study to mark all well sites as affected facilities by component counts and potential for fugitive emissions while ignoring the specifics of types of wells, equipment used for unique well types, geological particularities, and geographic location

<sup>75</sup> Quantification of Methane Emissions from Marginal (Low Production Rate) Oil and Natural Gas Wells[<https://www.osti.gov/servlets/purl/1865859>].

cannot be considered as the correct application of this study. This study does support the idea that leak frequency is strongly correlated to major component counts present. It is logical to deduct that more equipment on-site results in a higher frequency of leaks. However, this point fails to justify regulation when the purpose is to decrease emissions and not instances of leaks.

Commenter (2353-CrownQuest Operating, LLC.) argues the justification that the EPA should use to support the implementation of NSPS OOOOb/EG OOOOc is a strong correlation between major component count and the emission rates and inspection frequency and a decrease in emissions. This study does not demonstrate either of those two categories but instead says more leaks will occur when more equipment is present. This study states that equipment count has a weak correlation to emission rates while also admitting that emission monitoring frequency does not correlate with the frequency of detected emissions.

Commenter (2353-CrownQuest Operating, LLC.) notes the EPA reference data shows that increasing LDAR surveys might find more leaks but will not decrease the overall emission rates. The study finds that the second strongest correlation in their dataset is the Basin lending significant credence to the point that sweeping federal regulation across all basins would be unnecessary and ineffective. Overall, this study does not address the magnitude of emissions, emissions root cause, or the reduction of emissions. To use this study as the basis for implementing a BSER of more frequent surveying is an incorrect application of the actual conclusions of this study.

Response II-4-27: The EPA does not agree with most of the arguments presented by the commenter. The EPA did not solely use the results of the DOE Study to justify BSER. The BSER analysis presented in the December 2022 Supplemental Proposal was based on data and information from several sources including results from FEAST modeling and a cost analysis of different fugitive emissions monitoring and repair programs. The EPA found that the DOE Study supported the development of various model plants based on equipment and component counts, where the DOE Study indicated a strong correlation between the major equipment count and the frequency of fugitive emissions. As discussed in the December 2022 Supplemental Proposal preamble, EPA noted that it requested comment on other thresholds that could be used to set monitoring requirements for well sites. One option was to include an equipment-based approach, in which well sites with specific leak-prone equipment would have one set of requirements, while well sites with other equipment (or that lack leak-prone equipment) would have a different set of requirements. This was the fugitive emissions monitoring approach the EPA proposed in the December 2022 Supplemental Proposal, which is also the approach for the final rule.

The EPA notes that the information collected in the DOE Study regarding the frequency of routine leak inspections did not include data on the type of inspection conducted. Facilities indicating weekly or monthly inspections were likely using AVO methods, whereas facilities reporting annual or semiannual inspections are more likely to have been referring to OGI inspections. The EPA's FEAST modeling suggests that less frequent OGI inspections achieve similar emission reduction performance as frequent AVO inspections, which could be the reason emission performance was not strongly tied to leak inspection frequency in the DOE Study. The EPA recognizes that leak generation rates and leak size are highly variable. Therefore, the EPA relied on Monte Carlo simulations of the model plants (plants with different number and types of equipment) using FEAST to assess the average performance of different LDAR programs for reducing emissions. The EPA maintains that this is the appropriate method for evaluating the

average performance of different LDAR programs for the BSER determination considering the variability in fugitive emissions.

Comment: Commenter (2353-CrownQuest Operating, LLC.) states the EPA references the report by Omara, *et al.*<sup>76</sup> to support the claim that marginal wells are responsible for approximately half of the well site emissions. However, this study fails to support the EPA's claims for several reasons. First, the study references six other studies that used data collection methods that are not admissible by the EPA's inspection standards. The referenced studies use "Top-Down" data collection methods that fail the OGI and LDAR standards required by EPA Method 21.

Commenter (2353-CrownQuest Operating, LLC.) states the data collected in these studies and their results are not acceptable. Beyond being unacceptable, much of the data is too old to be accurate. Several studies happened before the implementation of NSPS OOOOa regulation and did not account for the industry's decrease in emissions over the past decade. Finally, the study collects data from only a few basins and does not represent the entire US's oil and gas production. Overall, the data drawn for this study is not comprehensive and is inadequate to support regulation. The production data referenced (from Enverus) is generic and not site-specific. Each emissions study referenced does not meet the EPA's requirements for LDAR inspections. Many of these referenced studies are older than the EPA OOOOa regulation. If the EPA wants to justify action, it is perplexing that the EPA refuses to reference or use its data from OOOOa, which contains over 10 years' worth of legally submitted OGI surveying results.

Commenter (2353-CrownQuest Operating, LLC.) argues this data is the best available data and science on emission reductions. The EPA should use the supplemental data voluntarily submitted to and aggregated by The Environment Partnership, which with the willing participation of more than 70% of onshore oil and gas production and midstream companies, has performed more than 345 million legal and EPA-acceptable LDAR inspections on sites in almost all basins across the US. The EPA should not cherry-pick studies that use cherry-picked data with inadequate methods by their standards to justify nationwide new regulations.

Commenter (2353-CrownQuest Operating, LLC.) adds the EPA claims they do not have any accurate analysis of component-specific emissions and that natural gas-actuated controllers, controlled storage vessels, and controllers are "known to be sources of large emissions events." This conclusion is contradictory and has no significant data to be the basis for classifying specific components as "known sources of large-scale emissions." Ultimately, the study's conclusions take a step towards categorizing wells based on age and production. However, their conclusions contradict this study (<https://www.osti.gov/servlets/purl/1865859>) referenced elsewhere in the preamble. It concludes the frequency of detected emissions and magnitude of emission rates are "weakly correlated" to total production.

Response II-4-28: As part of response to comments on the November 2021 proposal requesting that production volumes be a factor in establishing different fugitive emissions monitoring requirements for different well sites, the EPA referenced the report by Omara, *et al.*<sup>77</sup> in the December 2022 Supplemental Proposal in conjunction with other reports (including the DOE Study) to support why EPA could not draw a conclusion that production levels should provide

---

<sup>76</sup> <https://www.nature.com/articles/s41467-022-29709-3>.

<sup>77</sup> <https://www.nature.com/articles/s41467-022-29709-3>.

the basis for consideration of different fugitive emissions requirements for well sites, but that there are significant emissions from well sites producing less than 15 boe/day and that distinguishing among well sites based on equipment and component counts would be appropriate. The EPA did not directly use the data collected in the six studies mentioned in the Omara, *et al.*<sup>78</sup> report. Furthermore, EPA acknowledged in the preamble to the December 2022 Supplemental Proposal that the study was not limited to fugitive emissions, but included, conclusions from this study cannot be directly applied to the specific fugitive sources covered by this action.

Comment: Commenters (2392-Earthjustice et al., 2433-EDF et al.) ask EPA to specifically consider regulating sites that have separators, which are known to be a source of large emissions.

Commenter (2392-Earthjustice et al.) argues EPA should strengthen the LDAR requirements by adding separators to the list of failure-prone equipment such that any site with a separator is subject to quarterly OGI.

Commenter (2433-EDF et al.) believes that EPA should add any sites with a separator to the definition of fugitive emissions component, thereby excluding a single separator from the list of permissible equipment at small well sites. Separators are a known source of large fugitive emission events.

Commenter (2433-EDF et al.) notes EPA clearly explains why fugitive emissions from wellheads and tanks can be detected and remedied without an OGI survey. However, this justification is not provided for separators, even though numerous studies find that separator malfunctions are a source of large emissions events.<sup>79</sup> In the DOE marginal well study, three of the ten largest measured emissions events stemmed from separator dump valves.<sup>80</sup> This study identified separators with ages as high as 72 years in their survey of field sites and found that 26% of separators at light oil sites and 67% of separators at gas sites had detectable emissions using OGI.<sup>81</sup> Separators are well-documented as a source of frequent and often large emissions events, and they are also a source of smaller emissions that may not be detectable through AVO.<sup>82</sup>

Commenter (2433-EDF et al.) states separators are a very prevalent piece of failure-prone equipment at smaller well sites. The commenter used 2016 Information Collection Request (ICR) data to analyze single well sites with a single piece of major processing or production equipment. Our analysis found that 11% of the well sites reported to the ICR would meet EPA's proposed definition of a small well site. Of those sites, 77% had a single separator present. EPA's proposed definition of small well sites therefore likely exempts many single well sites

---

<sup>78</sup> <https://www.nature.com/articles/s41467-022-29709-3>.

<sup>79</sup> Rutherford et al., *supra* note 133 (Figure 3 shows separators as large source of emissions within the equipment leak category.); Zavala-Araiza, Super-emitters, *supra* note 131 (In the second paragraph of their discussion, they cite stuck separator dump valves, design failures like vortexing or gas entrainment during separator liquid dumps, and equipment or process issues such as over-pressured separators as some of the many abnormal process conditions observed in field campaigns.).

<sup>80</sup> Richard L. Bowers, Quantification of Methane Emissions from Marginal (Low Production Rate) Oil and Natural Gas Wells Report at 19 (2022), <https://www.osti.gov/biblio/1865859>. [hereinafter "Bowers Report"].

<sup>81</sup> Richard L. Bowers, Quantification of Methane Emissions from Marginal (Small Producing) Oil and Gas Wells. at Slide 21 (Aug. 2021), [https://netl.doe.gov/sites/default/files/netl-file/21CMOG\\_OG\\_Bowers.pdf](https://netl.doe.gov/sites/default/files/netl-file/21CMOG_OG_Bowers.pdf).

<sup>82</sup> Zavala-Araiza, Super-emitters, *supra* note 131; Lyon et al., Aerial Surveys, *supra* note 132.

with separators from regular OGI inspections. This is concerning given the prevalence of large emissions events originating from separators.

Commenter (2433-EDF et al) states EPA notes in modeling the rule's impacts that small well sites were not treated differently than single wellhead-only sites on the assumption that these sources would have comparable emissions. However, because separators will be present at the majority of sites falling into EPA's proposed small well site category, the commenter does not believe that assumption is correct. Based on their review of EPA's model plants, they believe that the emissions profile of a single wellhead site with a separator is much closer to the well site model plant and the multiple wellhead only model plant than the single wellhead only model plant.

Using Rutherford 2021 emission factors, commenter (2433-EDF et al) estimates the emissions from small sites with separators to be 3.94 tpy per gas site and 1.13 tpy per oil site. Applying the direct ICR equipment proportions (77% of small sites have a separator, 2% have a reciprocating compressor, 1% have a dehydrator, 19% have a tank) yields average Rutherford emissions of 3.71 tpy and 1.04 tpy for gas and oil wells, respectively. Even when averaged with the lower DOE study emission factors, the average baseline emissions from small sites is much closer to the 0.5% leak generation rate baseline emissions of multi-wellhead only sites. The commenter believes that when equipment types at small sites are accurately represented, these sites more closely represent the multiple wellhead only or well site model plants.

Commenter (2433-EDF et al) argues OGI surveys are effective at detecting emissions from separators. Their analysis of upstream OGI surveys in OOOOa compliance reports finds that reported leaks from separators are common and only eclipsed in frequency by tanks, pneumatic devices, and flares.<sup>83</sup> However, the commenter does not have data to indicate that AVO surveys can effectively detect emissions from this component. Continuing to include sites with separators in the small well site category will likely lead to significant fugitive emissions and super-emitters that could otherwise be detected and repaired with OGI. EPA should therefore remove a single separator from the list of major production and processing equipment that can be present at a small well site and ensure any site with a separator is subject to quarterly OGI. The commenter estimates that doing so will increase the emissions coverage of OGI to over 80% of total emissions, thereby ensuring greater overall reductions.

Response II-4-29: The EPA acknowledges the commenters' concerns regarding regulating sources to be known to be sources of large emissions, including separators. As discussed in the December 2022 Supplemental Proposal preamble, EPA noted that it requested comment on other thresholds that could be used to set monitoring requirements for well sites, one option which was to include an equipment-based approach, in which well sites with specific leak-prone equipment would have one set of requirements, while well sites with other equipment (or that lack leak-prone equipment) would have a different set of requirements. This was the fugitive emissions monitoring approach the EPA proposed under the December 2022 Supplemental Proposal and this approach is being finalized.

To ensure that large emissions from well sites and centralized production facilities with separators do not go undetected, the EPA is specifying that owners and operators of well sites

---

<sup>83</sup> See Table 6, *infra*, (finding 699 separator leaks).

and centralized production facilities that have separators conduct a visual inspection of all separator dump valves to ensure the dump valve is free of debris and not stuck in an open position must be conducted in conjunction with the monitoring survey. The owner or operator must repair any dump valve not operating as designed. This requirement would specifically apply fugitive emissions components affected facilities at small well sites, and well sites or centralized production facilities with major production and processing equipment.

In addition to including the specific requirement to inspect the separator dump valve in conjunction with the monitoring survey, the EPA is also clarifying in the fugitive emissions component definition that “valves” include separator dump valves in order to eliminate any ambiguity as to whether separator dump valves are considered fugitive emissions components. The EPA is finalizing a definition of fugitive emissions components that specifically includes separator dump valves, thus clarifying that the separator dump valve is subject to monitoring by OGI, AVO, or other detection methods. In addition, because emissions from malfunctioning separator dump valves are a known source of large emissions (as the commenter noted) and because sometimes there is visual evidence of the malfunction, the EPA is requiring in the final rule that during the regular AVO monitoring surveys (either quarterly or bimonthly depending on the site), a visual inspection must be conducted of all separator dump valves to ensure that they are free of debris and not stuck in an open position, and any dump valve not operating as designed must be repaired.

#### 4.1.3.4 Single Wellhead Only/Small Well Sites

Comment: Commenters (2039-Citizens to Preserve Ligonier Valley, Inc., 2179-KIOGA, 2200-NuEnergy Operating Inc., 2205-Kriebel Well Services, Inc., 2223-Texas Alliance of Energy Producers, 2238-SOOGA, 2294-Ohio Oil and Gas Association, 2428-API, 2433-EDF et al, 2439-State of Michigan Department of Environment, Great Lakes and Energy) support the ability to use AVO at single wellhead only well sites.

Commenter (2428-API) states an AVO inspection is the most appropriate tool to rapidly identify large emissions at wellhead only sites. As EPA has already concluded, AVO inspections are a useful tool at sites that lack extensive background noise and have field gas containing mixtures of methane and VOCs and condensate or produced liquids (87 FR 74727).<sup>84</sup> Not only do wellhead only sites match these criteria, but their emission points are closer to ground level compared to other sites. For these reasons, out of all well site configurations, AVO is expected to perform the best at wellhead only sites, and it generally can be applied more frequently than other leak detection methods.

Commenter (2428-API) argues given wellhead only sites number in the tens of thousands, the prudent and most efficient use of resources is to focus on detecting the rare occurrence of large fugitive emissions from wellheads, which can be accomplished with AVO inspections. Coupled

---

<sup>84</sup> On the other hand, AVO inspections are a useful tool for identifying when there are indications of a potential leak without the need for expensive equipment or specialized training of operators. For example, at sites that lack extensive background noise, a person would be able to hear if a high-pressure leak is present, which could present as a hissing sound. Field gas produced at well sites contains a mixture of methane and various VOCs, which have the potential to be detected by smell. Where the field gas contains a lot of condensate or other produced liquids, any resulting leaks would present as indications of liquids dripping or potentially puddles forming on the ground.

with proposed requirements<sup>85</sup> for conversion to nonemitting pneumatic controllers at existing sites, the increased cost of additional OGI screening at these sites raises further concerns regarding premature shut-in of production and states' ability to preserve the remaining useful life of facilities.

Commenter (2433-EDF et al) notes EPA estimates that approximately 95,000 well sites nationwide, or approximately 12 percent of the total nationwide well site count, would meet the definition of "small well site."<sup>86</sup> EPA's analysis also estimates that roughly 50% of total well sites nationwide would be classified as either single wellhead-only well sites or small well sites. Based on the commenter's analysis, 408,700 well sites are responsible for 24% of fugitive emissions. Therefore, small well sites should be subject only to quarterly AVO inspections.<sup>87</sup>

Commenter (2433-EDF et al) urges EPA to consider instrument-based inspections or a single initial OGI inspection at smaller and marginal sites to further drive down emissions. At minimum, EPA should provide an alternative semiannual OGI compliance option for any site subject to the proposed quarterly AVO only requirements. While the commenter supports the proposed AVO requirements, AVO cannot detect emissions as effectively as OGI, especially emissions from certain equipment types. The commenter recommends the site be required to reclassify and conduct quarterly OGI (or the equivalent alternative).

Commenter (2433-EDF et al) notes that while stakeholders have raised concerns about compliance burdens associated with monitoring at smaller wells, 92% of marginal wells are owned by large companies with average revenues of over \$100 million per year.<sup>88</sup>

Response II-4-30: The EPA agrees AVO inspections for fugitive emissions monitoring for single wellhead only well sites and small well sites are appropriate. This approach has been retained in the final rule. The specific requirements being finalized for single wellhead only well sites and small well sites are described in section X.A.1.a.ii of the preamble to the final rule for new sources under NSPS OOOOb and in section X.A.1.b.ii of the preamble to the final rule for existing sources under EG OOOOc.

Comment: Commenters (2185-New York State Common Retirement Fund (CRF), 2333-LongPath Technologies, Inc. (LongPath), 2408-Colorado Local Government Coalition, 2436-Louis Pochet, 2462-Cynthia Walter) have concerns with the proposed AVO-only requirements

---

<sup>85</sup> See Comment 7.0.

<sup>86</sup> Data from the 2016 ICR.

<sup>87</sup> Env't Def. Fund., Methodology for Estimating Emissions Covered by AVO-Only Standards (Attachment G).

<sup>88</sup> Env't Def. Fund, Updated Marginal Well Operatorship Analysis (included as Attachment H). Our updated analysis uses improved Enverus from 2022. This impacted EDF analysis of well operatorship based on Enverus 2019 production data; however, the overarching conclusion remains the same. With respect to coverage, the number of well sites with non-zero oil and gas production in 2019 increased from ~704k to ~745k and the corresponding number of operators increased from ~12k to ~13k. The percentage of marginal wells owned by large operators remains the same at 92%. Total 2019 gross revenue generated by large operators decreased slightly but remains above \$300B (\$303B down from \$329B). The average 2019 gross revenue per operator decreases slightly but remains above \$100M (\$111M down from \$128M).

for small well sites and single wellhead only sites. Small well sites can have leaks<sup>89</sup> and AVO is not an effective method for identifying leaks.

Commenter (2185-CRF) urges EPA to consider concerns with the sole use of AVO techniques raised by the Interstate Technology and Regulatory Council (ITCR) in its 2018, Evaluation of Innovative Methane Technologies, Methane-1.<sup>90</sup> As noted by ITCR, the use of this technique relies on the use of an individual person's senses, which are subject to individual variation. It is important to note that these senses may be impaired in individuals either by age or by regular exposure to the loud noises and strong odors that may be found on oil and gas production sites. The commenter states the EPA should consider requiring the use of additional technologies, such as handheld natural gas detectors, to back up the use of AVO monitoring to ensure that leaks are accurately detected at this class of sites.

Commenters (2333-LongPath, 2348-Energy Workforce and Technology Council) state AVO inspection may detect leaks after the event, but AVO inspection does not identify potential failures caused, *e.g.*, by seal failures or loosening of threaded/flange connections. This is an inherent flaw in the AVO inspection methodology, *i.e.*, it is not predictive, and it only catches emissions happening at the moment of inspection. Continuous monitoring, on the other hand, allows an inspector to monitor over time.

Commenter (2408-Colorado Local Government Coalition) recommends that EPA require annual OGI for single wellhead only and small well sites, based on rules adopted by Colorado and New Mexico. While the commenter does appreciate the proposed AVO inspections, OGI methods can detect leaks that a human may not be able to detect. AVO inspections, in contrast to OGI inspections, rely on a person's senses of smell, hearing and sight to achieve maximum emissions reductions. Such senses may not be as reliable as instruments. Moreover, EPA may require operators retain video footage demonstrating that OGI inspections in fact occurred and documenting the results of those inspections. The same is not true for AVO inspections. Absent a way to document reliably that an operator, or more likely a contractor, conducted a thorough AVO inspection, the commenter fears this requirement will be abused and will not lead to the emissions reductions EPA expects.

Commenter (2408-Colorado Local Government Coalition) goes further, Colorado and New Mexico require instrument-based inspections for small wells, and New Mexico requires instrument-based inspections for wellhead only facilities. Colorado requires all well production facilities that commence operation on or after May 1, 2022, to conduct monthly instrument-based inspections, regardless of size or emissions potential.<sup>91</sup> The only exceptions to this is for facilities which are not home to leak-prone equipment (*i.e.*, facilities without storage tanks, natural gas-fired reciprocating internal combustion engines and gas-powered pneumatic devices)<sup>92</sup> or those that contain robust monitoring for leak prone equipment (*i.e.*, those that install an automatic pressure management and pilot light system on controlled storage tanks).<sup>93</sup> Such facilities must

<sup>91</sup> 5 Colo. Code Regs. § 1001-9-D-II.E.4.e.(ii).

<sup>92</sup> 5 Colo. Code Regs. § 1001-9-D-II.E.4.f.(i).

<sup>93</sup> 5 Colo. Code Regs. § 1001-9-D-II.E.4.f.(ii).

conduct instrument-inspections semi-annually or annually, depending on emissions potential.<sup>94</sup> Well production facilities that commenced operation before May 1, 2022 must conduct at least annual instrument-based inspections.<sup>95</sup> New Mexico requires at least annual OGI inspections of **all** well sites, including wellhead only well sites.<sup>96</sup> New Mexico's proposal has the support of the local community and national environmental groups.<sup>97</sup>

Commenter (2436-Louis Pochet) adds AVO inspections are – by themselves - helpful but not fully reliable. Fugitive emissions could easily be invisible, have no smell, and the sounds can be masked by other equipment or local noise. In-person inspections of sites are extremely important, however, to make sure monitoring equipment is in the correct place and to document that equipment is working or idle, and conditions are normal. Researchers could be contracted to compare air pollutants upwind and downwind from the compressor stations, wells and mercaptan addition locations.

Response II-4-31: While we agree that the performance of AVO is more variable and dependent on the sensitivity and thoroughness of the inspector; however, we found that it is not cost-effective to require instrument monitoring for the well-head only sites, even at an annual frequency. While our assessment of instrument monitoring specifically considered OGI, we expect that it is indicative of the costs of any monitoring inspection that can achieve comparable emission reductions to OGI. We specifically considered instrument monitoring first because we expect less variability in the performance of instrument monitoring. However, after determining the cost-effective OGI monitoring frequency, we evaluated the ability of using AVO inspections to achieve additional emission reductions. For the wellhead only sites, this assessment determined that annual instrument monitoring was not cost effective, but that AVO inspections would produce cost-effective emission reductions and determined to be BSER. We are finalizing the requirements for small well sites as proposed.

Comment: Commenters (2304-PIOGA), 2713-Northeast Natural Energy LLC) state a "well site" consists of a well head, tank, meter, and perhaps a separator, all confined within perhaps a 25 foot diameter. EPA's characterization of this as "major production and processing equipment" is just nonsensical. It would almost be laughable, except that the adverse economic consequences to the family-run, "small business" as defined by the Regulatory Flexibility Act is anything but funny. These businesses are their livelihoods. EPA has abandoned terminology accepted by the industry – and regulators – that often characterized these truly small well sites as "marginal wells." That terminology aptly describes the economic reality of these wells - their existence is marginal. Unnecessary costly quarterly OGI requirements will make many of these wells uneconomical to operate. Commenter (2304-PIOGA) and the families and local economies that depend on the continued operation and existence of these low production wells ask that EPA sharpen its pencil and find a more fair and workable solution.

---

<sup>94</sup> 5 Colo. Code Regs. §1001-9-D-II.E.4.f.

<sup>95</sup> 5 Colo. Code Regs. §1001-9-D-II.E.4, Table 5.

<sup>96</sup> N.M. Code R. §20.2.50.116.

<sup>97</sup> Community and Environmental Parties Joint Proposed Statement of Reasons, New Mexico Environmental Improvement Board rulemaking in the Matter of Proposed New Regulation, 20.2.50 NMAC, Oil and Gas Sector, Ozone Precursor Pollutants (Jan. 20, 2022), available at <https://www.env.nm.gov/opf/wp-content/uploads/sites/13/2022/01/2022-01-20-EIB-No.-21-27-Comty.-and-Env.-Parties-Proposed-Statement-of-Reasons-pj.pdf>.

Commenter (2713-Northeast Natural Energy LLC) states the monitoring/screening requirements for small well sites seem reasonable until one examines the definition of a small wellsite. A small wellsite is defined as single wellhead well sites that do not contain any controlled storage vessels, control devices, pneumatic controller affected facilities, or pneumatic pump affected facilities, and include only one other piece of major production and processing equipment. Major production and processing equipment that would be allowed at a small well site would include a single separator, glycol dehydrator, centrifugal and reciprocating compressor, heater/treater, and storage vessel that is not controlled. The forgoing does not consider the production rate at the site, therefore a marginally producing gas or oil well located on a site with a single separator and a single water storage tank would no longer be considered a small well site and would be required to follow the same screening frequency and screening methods as a large multi-well unconventional site producing 100 mmcf per day and includes multiple gas processing units, possibly a glycol dehydrator unit and several storage tanks, as well as other "major production and processing equipment". EPA should consider using a production threshold regardless of the equipment count or type methodology.

Response II-4-32: The EPA disagrees with the commenter. Fugitive emissions are not a function of production or throughput, but the number of fugitive emission components in service at the site and the types of major equipment at the site. Therefore, if a marginal wellsite has several major production or processing equipment, the EPA determined that OGI monitoring is cost-effective and therefore BSER.

Comment: Commenters (2168-INOGA, 2172-KOGA, 2238-Ohio Oil and Gas Association, 2294-SOOGA, 2304-PIOGA, 2403-PAO) urge EPA to create a fifth (intermediate) source category via the expansion of the components in the "small well site" facility, to ensure that higher producing, albeit still "low production", wells are not regulated as a "large well site." This includes increasing the count of major production equipment from one to two, to further differentiate the requirements applicable to the lowest of the low production wells. Limiting a "small well site" to only one of those pieces of equipment inherently – albeit inaccurately – disqualifies true small well sites from the "small well site" classification. AVO inspections should apply to this "intermediate" source category.

Response II-4-33: The EPA disagrees with the commenter. Fugitive emissions are not a function of production or throughput, but the number of fugitive emission components in service at the site. The commenter appears to suggest that "large well sites" would have lower emissions if they have lower throughput, but that is not the case. The EPA maintains that sites with two or more major production or processing equipment must conduct quarterly OGI (or the equivalent advanced technology monitoring).

Also, the EPA developed well site model plants for the December 2022 Supplemental Proposal that were believed to be representative of common well site configurations. The well site model plants developed were not expected to represent every possible well site setup, but the distinct model plants that were developed were designed to account for various equipment types located at sites ranging from single wellhead only well sites and small well sites to complex sites with various major production and processing equipment known to be sources of large emissions.

Comment: Commenters (2168-INOGA, 2172-KOGA, 2279-U.S. Small Business Administration, 2304-PIOGA, 2205-Kriebel Well Services, Inc.) believe EPA underestimates how often well and

production sites are visited by the operator's personnel, dramatically reducing the potential for any leak that would develop and go unnoticed for any length of time. Production equipment present at these types of locations, whether compressors, separators, or dehydrators, are very important for continuous operation and require frequent visits. The two pieces of equipment used or occasionally used at well or production sites with the greatest potential to have fugitive emissions are heavily used valves that may develop small stem leaks and pressure relief valves that could very rarely malfunction and stick partially open after being actuated. In both cases, this type of equipment is located at sites that are regularly visited and would be quickly identified and corrected. EPA's eliminating the requirement of OGI for fugitive emission surveys at wells and small production sites to identify methane leaks is more than compensated by the frequency with which the small operator's personnel visit the sites potentially identifying any leaks that might develop.

Commenter (2172-KOGA) notes most single wellhead gas well sites still use orifice meters to measure gas flow utilizing paper charts, the wells are visited by a pumper on at least a monthly basis. Most oil wells are visited daily. The commenter believes that limiting fugitive methane emissions from legacy producing properties typical of small operators is best accomplished for the small operator by utilizing existing personnel who know what a leak is and how to repair it and educating them as to the urgency of repairing and reporting leaks found.

Response II-4-34: The EPA acknowledges the commenters' remarks. As proposed, the rule finalizes quarterly AVO inspections for single wellhead only well sites and small well sites.

Comment: Commenters (2168-INOGA, 2172-KOGA, 2198-University of Denver College, 2351-Jonah Energy LLC, 2433-EDF et al) agree small well sites should be subject only to quarterly AVO inspections.<sup>98</sup> Commenter (2198-University of Denver College) feel quarterly monitoring of these new or modified sites under NSPS, for the entire life of the site, is a needed addition to the proposal. This will provide information on fugitive emissions and emissions from covers and CVS.

Response II-4-35: The EPA acknowledges supportive comments. As proposed, the EPA is finalizing quarterly AVO inspections for single wellhead only well sites and small well sites.

Comment: Commenter (2304-PIOGA) believes EPA needs to create an "Intermediate Well Site" category based on a combination of throughput and component count, and the associated monitoring should be more heavily based on AVO surveys, with perhaps an initial OGI survey, which is phased out or not at all necessary if no leaks are detected. The reality is that EPA's proposed definition of a small well site fails to understand typical conventional/vertical wells sites in Pennsylvania and much of Appalachia.

Commenter (2304-PIOGA) states most conventional wells in this region involve one well (occasionally two), one or two brine tanks, a separator, and/or possibly one controller. Nonetheless, these sites typically will have two pieces of equipment that EPA has deemed "major production and processing equipment." Most of these single well, or even two well, sites provide 1-3 barrel of oil equivalent (BOE) per day – if that. Sites producing more than 8 BOE a day are the exception. For example, one family run company with approximately 50 employees

---

<sup>98</sup> Env't Def. Fund., Methodology for Estimating Emissions Covered by AVO-Only Standards (Attachment G).

owns/operates approximately 1,900 low (very low) production wells. Approximately 90% of their wells would fall into the "large category" because they have more than one piece of "major production and processing equipment."<sup>99</sup> This is also a problem for conventional "centralized production facilities" as well. One of the commenter's members reported they operated approximately 21 "centralized productions facilities" that typically have 20 or more wells "feeding" the production facility, and yet all of them are under EPA's previous exemption threshold of 15 BOE a day. The previous low production well exemption was a reasonable compromise and would have allowed most low production wells to operate – but perhaps that was why EPA shifted away from the production-based exemption.

Commenter (2304-PIOGA) adds the Department of Energy (DOE) study on emissions from low production/marginal wells demonstrated that lowering the throughput from 15 BOE to 8 or perhaps even slightly lower would have had minimal adverse impact on emission reductions but would have allowed hundreds of thousands of existing low production/marginal wells to continue to operate. Again – perhaps that is why EPA shifted away from basing requirements on throughput. Regardless, the commenter has proposed yet another compromise that is more realistic utilizing both "component count" and throughput.

Response II-4-36: The EPA disagrees with the commenter. Fugitive emissions are not a function of production or throughput, but the number of fugitive emission components in service at the site. The commenter appears to suggest that "large well sites" would have lower emissions if they have lower throughput, but that is not the case. The EPA maintains that sites with two or more major production or processing equipment must conduct quarterly OGI (or the equivalent advanced technology monitoring).

The EPA developed well site model plants for the December 2022 Supplemental Proposal that were believed to be representative of common well site configurations. The well site model plants developed were not expected to represent every possible well site setup, but the distinct model plants that were developed were designed to account for various equipment types located at sites ranging from single wellhead only well sites and small well sites to complex sites with various major production and processing equipment known to be sources of large emissions.

Comment: Commenters (2205-Kriebel Well Services, Inc., 2304-PIOGA, 2359-Kevin D. Dayaratna, Heritage Foundation) state EPA's pollution is the commenter's product – there can be no more pure economic incentive to capture and not waste every molecule of methane. EPA paints a picture with its discussion of "super-emitters" as if the owner/operators of low production wells are scofflaws that do not care if something breaks and there are uncontrolled emissions to the environment. Nothing could be further from the truth. The owners/operators of wells visit well sites frequently – and the more productive the well, the more frequently they visit. One small business in Pennsylvania reported over 70% of their wells are visited weekly, if not daily. Again, all of these wells are still below the low production well exemption threshold, but the more productive wells are visited multiple times a week. Even the least productive wells are typically visited at least monthly. Owners/operators are looking for signs of leaks – whether

---

<sup>99</sup> This is not an isolated example. An operator with a similar number of wells reported over 80% of their wells would trigger the quarterly OGI requirements despite an average gas production of 5 mcf/d and oil production of 0.6 BOE/d. Another family owned business reported that, of their approximate 550 wells, approximately 98% are low production wells with an average production of 4 mcf/d – anything less than 90 mcf/d or 15 BOE/d is considered a low production or marginal or stripper well.

smelling gas, hearing gas or seeing signs that a connection is leaking (discolored vegetation), and to the greatest extent possible, they fix leaks on-site and confirm they are fixed – often with simple soap and bubbles – an OGI camera is not needed. To the extent the issues cannot be addressed onsite when leaks or malfunctions are identified, owners/operators will normally close-in or make process changes to minimize or eliminate the leaks – they are protecting the environment and their product.

Response II-4-37: The EPA acknowledges the commenters’ remarks. As proposed, the rule finalizes quarterly AVO inspections for single wellhead only well sites and small well sites.

Comment: Commenter (2166-Ohio Department of Natural Resources (ODNR)) states additional factors need to be considered when requiring a surface casing valve to be closed. Since 2012, Ohio has required that the valve on the surface production casing annulus or surface-intermediate casing annuli be accessible and equipped with a pressure gauge to allow continual monitoring of mechanical integrity. The valve is also required to be equipped with a properly functioning pressure relief valve to be set in a manner that prevents annular over pressurization for safety. Simply closing a surface casing valve without proper monitoring and safety considerations can endanger public health and safety. Ohio is currently proposing strengthening annular monitoring for all wells and revising rules to require horizontal wells to route pressure relieve systems into their vapor recovery system.

Response II-4-38: The EPA acknowledges the commenter’s remarks regarding surface casing valves. As discussed in the December 2022 Supplemental Proposal, AVO can easily be used to identify whether the surface casing valve is open or closed during an inspection and would not require the use of OGI to detect the leak.

EPA acknowledges that on certain pieces of equipment pressure relief devices need to be used for safety reasons. However, safety relief devices should not be continuously left in the open position, and it is important to check that these devices are in the closed position when there is no safety concern, as pressure relief devices will release fugitive emissions when open. These devices are a large source of emissions when they are continuously left in the open position. In a properly designed system, there should be no need to have a continuously open pressure relieve device.

#### 4.1.3.5 Multi-Wellhead Only Well Sites

Comment: Commenter (2433-EDF et al) supports EPA’s proposal to require semiannual OGI monitoring at wellhead-only sites with more than one wellhead. Numerous studies have found emissions from wellheads and the risk of greater emissions and larger leaks increases with the number of wellheads.<sup>100</sup> As determined by EPA, semiannual OGI monitoring is cost-effective at multiple wellhead-only well sites.<sup>101</sup>

---

<sup>100</sup> Deighton et al., *supra* note 123 (measuring wellhead emissions and finding that “[s]ome wells were emitting all or more of the reported gas produced at each well, or venting gas from wells with no reported gas production”); Stuart Riddick et al., Measuring methane emissions from abandoned and active oil and gas wells in West Virginia, 651 *Sci. of the Total Env.* 1849 (2019), <https://doi.org/10.1016/j.scitotenv.2018.10.082> (measuring wellhead emissions and finding a “mean of 8.8% of production lost (leaked) at the wellhead.”).

<sup>101</sup> See Revised OGI Cost Effectiveness Tables Folder (included as Attachment F).

If EPA does not adopt the commenter's recommendation to require quarterly OGI at single wellhead sites with separators, the commenter (2433-EDF et al) urges EPA to require semiannual OGI at those sites. The commenter believes ongoing OGI is important for detecting emissions from separators. Their analysis of EPA's model plants also shows that single wellhead sites with separators have an emissions profile that is more similar to well sites and multiple wellhead only sites than to wellhead only sites. The commenter believes this justifies similar treatment and supports ongoing OGI inspection requirements.

Response II-4-39: The EPA acknowledges the supportive comments. As proposed, the EPA is finalizing semiannual OGI with quarterly AVO inspections for multi-wellhead only well sites.

Comment: Commenters (2202-TXOGA, 2326-AXPC, 2428-API, 2446-IPAA) argue that EPA should only require quarterly AVO inspections for multi-wellhead well sites.

Commenter (2202-TXOGA) supports only AVO for wellhead only well sites and not OGI, due to its cost and because the incremental benefit of using OGI on top of AVO would not meaningfully reduce emissions, even using the rationale in the proposal.

Commenters (2202-TXOGA, 2428-API) argue that wellhead only sites make up a very small proportion of methane emissions. Indeed, a study conducted over the Permian Basin determined that simple sites, such as wellhead only sites, experience emissions two orders of magnitude smaller than complex sites.<sup>102</sup> Another study that addressed over 5000 pieces of equipment at over 1400 facilities across 250 square miles showed that only 2 percent of detected emissions were from wells, and in terms of incidence, similarly, only 5 percent of total detections were from wells.<sup>103</sup>

Commenter (2202-TXOGA) states EPA suggests that it received comments that the emissions from these sources can be large, but clearly such emissions events are not common; otherwise, wellhead only sites would comprise a larger share of methane emissions from the Crude Oil and Natural Gas Source Category. EPA then concludes that OGI is reasonable at multi-wellhead only sites because of the increased number of pipes, connections, valves, and other potential leak sources when there is more than one wellhead.<sup>104</sup>

Commenters (2202-TXOGA, 2428-API) argue BSER factors do not support a conclusion that OGI is reasonably applied to multi-wellhead only sites. As we understand the rationale, EPA would conclude that more resource-intensive OGI surveys are warranted to chase small leaks from multi-wellhead only sites, which comprise a small subset of an already small share of sector methane emissions. In support of the decision to remove the exemption for wellhead only sites, EPA explains that AVO is appropriate for detecting large emissions for single wellhead only sites in the context where there is a lack of ambient noise.<sup>105</sup> Commenter (2202-TXOGA) agrees with this conclusion, and this logic applies equally to multi-wellhead only sites. The commenter

<sup>102</sup> See 87 Fed. Reg. at 74,729.

<sup>103</sup> Methane Collaboratory, Permian Basin Survey: An Array of Aerial Surveys in the Permian Basin to Acquire the Baseline Distribution of Methane Emission Rates and Sources, available at [https://methanecollaboratory.com/wpcontent/uploads/2021/08/Scientific-Insights-Aerial-Survey-in-Permian-August2021\\_vFinal.pdf](https://methanecollaboratory.com/wpcontent/uploads/2021/08/Scientific-Insights-Aerial-Survey-in-Permian-August2021_vFinal.pdf).

<sup>104</sup> 87 Fed. Reg. at 74,732.

<sup>105</sup> See id. at 74,727.

urges EPA to remain focused on detecting large emissions from multi-wellhead only sites as well and only require AVO at these sites. Multi-wellhead only sites share key features with single wellhead only sites that make AVO effective, in particular the lack of ambient noise.

Commenters (2202-TXOGA, 2428-API) continue, given that AVO is effective and does not require the specialized equipment and training of OGI, imposing OGI on top of AVO should not be determined to constitute BSER. This is particularly so given the tens of thousands of wellhead-only well sites across the United States, from which methane emissions comprise only a small fraction of overall methane emissions.<sup>106</sup>

Commenter (2326-AXPC) believes quarterly AVO inspection of wellhead only sites would be an effective and economic means to monitor for leaks at wellhead only sites.

Commenter (2326-AXPC) indicates that wellhead only sites generally have fewer fugitive emissions components, and wellheads are constructed with thicker, higher pressure-rated iron causing flanges to be larger such that AVO inspections are able to reliably detect any leaks that may occur. In addition, quarterly AVO requirements would allow operators to train field personnel who are already familiar with sites to conduct AVO inspections during their routine rounds.

Commenter (2428-API) states more frequent monitoring may also be challenging since many existing wellhead only sites can only be reached on foot due to remote location and lack of lease road access. While the commenter believes quarterly AVO is the appropriate frequency for all wellhead only sites, at a minimum, bimonthly AVO inspections only would also be acceptable as the monitoring requirement for multi-wellhead only sites.

Commenter (2428-API) notes EPA's basis for applying OGI to multi-wellhead only sites is centered around additional connection points and valves with generally smaller emissions.<sup>107</sup> While this basis is true, the focus appears to be misguided. If the principal concern with a single wellhead only site is to find the rare, but possible, large emissions leak, then it should follow that the principal concern for a multi-wellhead only sites should also be the rare occurrence of large emission leaks because it is relatively more likely with more than one well-head. That is, what warrants more attention to a multi-wellhead only site should not be the potential for more small emission leaks, but the greater potential for a large emission leak. Any significant difference in emissions leak potential from a single wellhead only site versus a multi-wellhead only site is not likely to be because of a small emission leak.

Commenter (2446-IPAA) notes that since the output from the FEAST analyses becomes the baseline for EPA's assessment of emissions reductions from various control strategies and the

---

<sup>106</sup> Methane Collaboratory, Permian Basin Survey: An Array of Aerial Surveys in the Permian Basin to Acquire the Baseline Distribution of Methane Emission Rates and Sources, available at [https://methanecollaboratory.com/wpcontent/uploads/2021/08/Scientific-Insights-Aerial-Survey-in-Permian-August2021\\_vFinal.pdf](https://methanecollaboratory.com/wpcontent/uploads/2021/08/Scientific-Insights-Aerial-Survey-in-Permian-August2021_vFinal.pdf).

<sup>107</sup> Multi-wellhead only well sites. For wellhead only well sites with two or more wellheads, the EPA anticipates that the same large emissions source (i.e., surface casing valves) would be present. In addition to these valves on the wellheads have additional piping, and thus connection points and valves that also present a potential source of fugitive emissions. Emissions from these types of components are generally smaller, and not easily identifiable using AVO.

basis for the calculations of cost effectiveness, these differences that are two to six times the DOE Study values can produce significant changes in some of the determinations. The commenter states models assuming an average DOE Study methane emissions value of 0.82 tpy and VOC emissions value of 0.23 tpy make different conclusions evident. Based on using more accurate assessments of the emissions from multiple well sites, EPA's proposed approach fails to pass the cost-effectiveness threshold test of \$2,165/ton of methane and the \$5,540/ton of VOC. Consequently, the commenter recommends that EPA use a quarterly AVO program only for its multi-wellhead well sites category like it proposes for the single well sites.

Commenter (2446-IPAA) believes that EPA should have developed its regulatory strategy by first applying an AVO control approach and determining its cost effectiveness. Next, EPA should assess the impact of adding an OGI component, like the semiannual proposal or perhaps an annual proposal. EPA should then evaluate the incremental costs per ton of these additions to determine whether such requirements were cost effective. In other words, the baseline for control would be a periodic AVO requirement and any OGI would be judged on its incremental costs and benefits. This does not appear to be the approach EPA used. EPA appears to have used an OGI baseline and then substituted AVO for quarterly OGI to generate its OGI-AVO combination of requirements.

Response II-4-40: The EPA disagrees that only quarterly AVO inspections should be required for fugitive emissions monitoring for multi-wellhead only well sites. The EPA specifically disagrees that BSER factors are not supportive of EPA's proposal for multi-wellhead only well sites. As discussed in detail in the December 2022 Supplemental Proposal, EPA evaluated the cost-effectiveness of various frequencies of OGI monitoring alone, as well as in combination with different AVO monitoring frequencies.<sup>108</sup> The EPA determined that semiannual OGI monitoring is cost-effective by itself, and in combination with quarterly AVO inspection.

As also discussed in the December 2022 Supplemental Proposal, multi-wellhead only well sites feature both large emission sources that can be identified with AVO as well as additional, generally smaller sources of emissions that are more challenging to identify using AVO. In order to capture both large and small emissions from multi-wellhead only well sites, the EPA proposed semiannual OGI monitoring and quarterly AVO surveys for NSPS OOOOb and EG OOOOc.

The commenters do not appear to be challenging EPA's cost analysis for multi-wellhead only well sites, and in response to comments that EPA should have assessed AVO first, the EPA disagrees (see discussion in section XI.A.1.c of the preamble to the final rule). The EPA is therefore finalizing semiannual OGI with quarterly AVO inspections for multi-wellhead only well sites, as proposed.

Comment: Commenter (2351-Jonah Energy) asks that EPA consider annual LDAR inspections of multi-wellhead only well sites rather than semiannual LDAR inspections in addition to quarterly AVO inspections of all wellheads. The commenter makes the following arguments:

- Semiannual LDAR inspections at multi-wellhead only well sites will divert the commenter's LDAR team from conducting more frequent LDAR inspections at larger centralized production facilities that have a higher potential to emit.

---

<sup>108</sup> 87 FR 74732-74733 (December 6, 2022).

- The commenter conducts wellhead LDAR inspections currently. The latest data set shows that less than 10% of inspections find an actionable leak and only 5% of the leaks exceed 6 scf/hr. The commenter agrees with wellhead inspections, and the commenter conducts a robust wellhead maintenance program as a business best practice. While the commenter has periodically found, measured, and repaired emissions at their wellheads, they are not nearly as material of an emission source as the production equipment. And the leaks have found from wellheads represent a small percentage of overall leaks, which itself is a relatively small percentage of the commenter's overall emission inventory as determined through measurement campaign.

Response II-4-41: The EPA disagrees. As discussed in the December 2022 Supplemental Proposal, EPA evaluated the cost-effectiveness of various OGI frequencies and found that semiannual OGI monitoring is cost-effective.<sup>109</sup> In fact, EPA additionally found that the cost of quarterly OGI monitoring was also reasonable compared to a baseline level of no monitoring. However, the incremental value of going from semiannual monitoring to quarterly monitoring was outside the range of costs the EPA has found to be reasonable for this source category. Instead, the EPA evaluated whether the addition of less expensive AVO inspections would be reasonable and EPA found that the addition of quarterly AVO to semiannual OGI monitoring was cost-effective and was determined to be BSER for this category of well sites.

#### 4.1.3.6 Well sites with Major Production/Processing Equipment and Centralized Production Facilities.

Comment: Commenters (2177-Ute Indian Tribe, 2433-EDF et al., 2351-Jonah Energy LLC) express support for the proposed monitoring requirements for well sites with major production and processing equipment.

Commenter (2177-Ute Indian Tribe) agrees that quarterly OGI surveys are reasonable for well sites and centralized production facilities with major production and processing equipment, but bimonthly AVO inspections are not necessary combined with the quarterly OGI survey. The quarterly OGI requirement should suffice, in the commenter's opinion. If the requirement is kept, the commenter recommends adding language to allow for monitoring survey to be conducted "when personnel is on site, or bimonthly, whichever is less frequent."

Commenter (2351-Jonah Energy LLC) agrees with, and currently conducts, OGI inspections at well sites with production and processing equipment.

Commenter (2433-EDF et al.) supports EPA's subcategorization of well sites, which ensures that more complex sites and those with failure-prone equipment are subject to quarterly OGI and bimonthly AVO.

Response II-4-42: As discussed in the December 2022 Supplemental Proposal, the cost of quarterly OGI with bimonthly AVO inspections was found to be reasonable and was determined to be BSER.<sup>110</sup> In the final rule, the EPA is finalizing the work practice standards for monitoring and repairing (including replacing) fugitive emissions components at fugitive emissions

---

<sup>109</sup> 87 FR 74732-74733 (December 6, 2022).

<sup>110</sup> 87 FR 74733-74736 (December 6, 2022).

components affected facilities located at well sites and centralized production facilities, as proposed in the December 2022 Supplemental Proposal. This includes requiring well sites with major production and processing equipment and centralized production facilities to conduct quarterly OGI (or EPA Method 21) monitoring combined with bimonthly AVO inspections.

Comment: Commenter (2279-U.S. Small Business Administration) asks EPA to consider whether there can be a further subcategorization of well sites with major equipment such that some sites might have bimonthly AVO and semiannual OGI. The commenter also suggests that EPA clarify that sites can change between subcategories, and thus change monitoring requirements, as equipment is installed and removed from the site.

Response II-4-43: The EPA developed well site model plants for the December 2022 Supplemental Proposal that were believed to be representative of common well site configurations. The well site model plants developed were not expected to represent every possible well site setup, but the distinct model plants that were developed were designed to account for various equipment types located at sites ranging from single wellhead only well sites and small well sites to complex sites with various major production and processing equipment known to be sources of large emissions.

The final rule at §60.5420b(c)(14)(iii) requires the owner or operator to track and record the removal of all major production and processing equipment such that the well site contains only one or more wellheads. Conversely, if major production and processing equipment is subsequently added back to the well site, record the date that the first piece of major production and processing equipment is added back to the well site.

#### 4.1.3.7 Small/Marginal Wells

Comment: Commenters (2157-Division of Air Pollution Control Tennessee Department of Environment & Conservation, 2168-Indiana Oil and Gas Association (INOGA), 2172-KOGA, 2179-KIOGA, 2237-Industrial Commission of North Dakota, 2186-Missouri Department of Natural Resources, 2204-LIP, LLC), 2205-Kriebel Well Services, Inc., 2211-Lambda Energy Resources, 2219-Wyoming Oil and Gas Conservation Commission (WOGCC), 2220-Wyoming Department of Environmental Quality, 2238-Southeastern Ohio Oil and Gas Association (SOOGA), 2248-North Dakota Petroleum Council (NDPC), 2249-NACAA, 2257-Michigan Oil and Gas Association (MOGA), 2279-U.S. Small Business Administration, 2288-North Dakota Department of Environmental Quality, 2294-Ohio Oil and Gas Association, 2295-Timothy Hauck, 2297-Petro-Vest, 2308-National Stripper Well Association, 2310-Montana Department of Environmental Quality (DEQ), 2314-Miller Energy Company, 2321-Apollo Exploration and Development, Inc., 2325-Aclima, 2330-Kentucky Division for Air Quality, 2353-CrownQuest Operating, LLC., 2401-State of Wyoming, 2403-PAO, 2437-Muskegon Energy Company (MEC), 2438-Muskegon Operating Company (MOPC), 2439-State of Michigan Department of Environment, Great Lakes and Energy, 2713-Northeast Natural Energy LLC, 3185-Lease Management, Inc) recommend that EPA maintain an exemption for low production wells. This exemption has been discussed between industry and EPA for several years. This is meaningful relief for small businesses with minimal potential impact from exempting the wells from compliance requirements.

Commenter (2157-Division of Air Pollution Control Tennessee Department of Environment & Conservation) believes EPA should reconsider its removal of the exemption for low-producing well sites. The commenter notes that there are 16,434 wellheads within the state, and removal of the exemption is likely to add substantially to the state's permitting and compliance workload.<sup>111</sup> The commenter notes that cost effectiveness alone may not consider the ability of a single wellhead-only site, or of a multiple well-head only site with a small number of low producing wells, to afford the cost of compliance, since a small facility's ability to comply depends not only upon the cost per ton but also the total cost of compliance and the revenue generated by the site. The commenter urges EPA to consider not only the cost effectiveness for the regulated entity, but also the cost to delegated air programs that have seen relatively flat federal funding support under Section 105 of the CAA for about two decades.

Commenter (2168-INOGA) adds Illinois Basin crudes are typically undersaturated with associated gas. The initial gas to oil ratios is typically in the 300-400 cubic feet/bbl range, while greater than 1,000 cubic feet/bbl in other basins. In older Illinois Basin waterfloods the gas to oil ratios is too low to reliably operate a separator. For example, an operator made a discovery in 1974 that produced 10 cubic feet per bbl upon initial production. This well is still producing with virtually no associated gas produced. Requiring additional regulations on this type of low production well is not cost effective or provides meaningful environmental benefits.

Commenters (2168-INOGA, 2172-KOGA) state small operators cannot afford to perform OGI surveys, and it is often not available. Each FLIR camera cost more than \$90,000 and requires training to properly operate the equipment. Utilizing EPA Method 21 requires each operator to pay an outside contractor to visit each location with monitoring equipment and produce a report of leaking components. Because of the size of a single wellhead well site, particularly those found in the Appalachian and Illinois Basins constructed of less than 120 total components (including fewer than 25 valves), a brief walk around the surface wellhead and associated equipment by the operations team allows for easy discovery of most gas leaks. The natural composition of the gas in these basins gives it a distinctive odor without any additives and the smallest leaks allow even an untrained person to sense if a leak is present through their olfactory senses.

Commenters (2168-INOGA, 2172-KOGA) states the next commonsense step would be to narrow the location by sound, or if too small to hear, soap bubbles can be applied. Plumbers have been using soap bubbles to identify leaks in domestic low pressure plumbing for decades and the plumbing of a low-pressure low volume gas well is essentially the same. The design gas pressure for residential appliances is approximately 7 inches of water column, which is 0.25 psig. If soap bubbles can detect a gas leak at 0.25 psig, the soap bubbles will also be able to detect a gas leak at this low pressure well sites.

Commenters (2168-INOGA, 2179-KIOGA, 2205-Kriebel Well Services, Inc., 2257-MOGA, 2279-U.S. Small Business Administration, 2283-Endeavor Energy Resources, 2308-National Stripper Well Association, 2325-Aclima, 2353-CrownQuest Operating, LLC) express concern

---

<sup>111</sup> TDEC's Division of Air Pollution Control has no information on the size of specific oil and gas wells within the state, but TDEC's Division of Mineral & Geologic Resources advises that Tennessee's wells tend to be small, lower-producing operations.

over the fugitive emissions monitoring requirements, especially as they relate to small businesses.

Commenters (2179-KIOGA, 2283-Endeavor Energy Resources) ask that EPA simplify and clarify the LDAR requirements. The commenters find EPA's proposed approach confusing and asks that the requirements in any final rule be simplified. Upstream operators are frequently small businesses and will have to track monitoring requirements across many sources and facilities.

Commenters (2168-INOGA, 2179-KIOGA, 2205-Kriebel Well Services, Inc., 2257-MOGA), 2279-U.S. Small Business Administration, 2308-National Stripper Well Association, 2325-Aclima, 2353-CrownQuest Operating, LLC.) state small entities remain concerned about the cost of OGI requirements and their ability to procure the services of OGI contractors, particularly within the timeframes that EPA's proposal would require. Although EPA's analysis is that OGI is cheaper than AVO inspection, the small businesses with whom the commenter (2279-U.S. Small Business Administration) has consulted insist that AVO inspections are generally preferred. They can be done more frequently and without specialized equipment, more people can be trained to perform them properly, and they are well-suited to detect the leaks most likely to occur at small sites.

Commenters (2172-KOGA, 2237-Industrial Commission of North Dakota, 2288-North Dakota Department of Environmental Quality) state EPA's premise seems to be that every wellhead will develop a leak every year and the more times a site is surveyed the more leaks are found. The commenter believes these are incorrect assumptions. A wellhead constructed properly has no reason to develop a leak without some significant "catastrophic" occurrence such as a tree falling on it.

Commenters (2237-Industrial Commission of North Dakota, 2288-North Dakota Department of Environmental Quality) provide an anecdotal example, a small shallow gas field in S.E. Kentucky drilled in 2005. The wellheads are constructed with between 30 and 45 components including between six and eight 1" and 2" valves. All 19 wells have been checked for leaks multiple times over the last ten years using AVO and soapy water, and there have never been any leaks found. These inspections are performed by the operator because the company is a good environmental steward and to prevent the loss of revenue from equipment leaks. Commenters (2237-Industrial Commission of North Dakota, 2288-North Dakota Department of Environmental Quality) have only observed a handful of wellhead-only well sites with fugitive emissions over the past few years. It appears that in those handful of cases that the emissions were more a result of specific operator error rather than being indicative of widespread fugitive emissions at well sites.

Commenter (2179-KIOGA) states EPA never took any significant data to identify the emissions profile of low production wells. It has relied on specious studies by environmentalists, used outdated studies from the mid-1990s that were never designed for regulations, and in its most recent NSPS OOOOa proposal relied on data from about 25 wells in one area, half of which do not appear to be low production wells. Only the DOE conducted a study of emissions from low production wells. That study was complete in May 2022. If any federal agency is creating regulations that have the capability of wiping out three-quarters of the facilities in an industry, it must have a full understanding of the industry and its regulatory actions. This has not been done.

Commenter (2186-Missouri Department of Natural Resources) encourages EPA to fully consider whether the inclusion of these sites will result in meaningful environmental protection or improvement when weighed with the costs that both industry and the regulating agencies will bear. Due to the low emissions expected from these sources, the Air Program does not expect measurable improvement to air quality by regulating these sources and requests EPA to consider removing requirements on these sites in the final action.

Commenter (2205-Kriebel Well Services, Inc.) states their main concern is that there appears to be a disconnect with understanding the differences between a large natural gas and oil producer (*i.e.*, Shell and BP) and a small marginal natural gas and oil producer (approximately 100 employees or less). This misunderstanding appears to have led to an excessive NSPS proposal that imposes a strong cost burden on the marginal well producer.

Commenters (2211-Lambda Energy Resources, 2257-MOGA) are concerned regarding the costs of maintaining a LDAR program, including the costs of surveys, data capture and collection, reporting and variable costs regarding repair as non-marginal well progress into the marginal and low production category. Low production and marginal wells cannot internalize the same regulatory costs as non-marginal wells.

Commenter (2211-Lambda Energy Resources) state regulations that might be appropriate in the Permian Basin are not necessarily feasible for lower pressure, less productive Michigan wells. Most hydrocarbon emissions come from newer, higher production (and higher pressure) wells, rather than from lower pressure, lower production sources. The proposed regulations are geared toward higher producing, higher pressure wells, and not to marginal wells.

Commenter (2219-WOGCC) notes in Wyoming there are over 6,000 of these low producing wells. In 2021 they produced over 7,000,000 bbls of oil and 20,000,000 mcf of gas. These are wells that are typically operated by small, local Wyoming businesses. These small business owners and their employees live and work in the local communities. The premature shut in or plugging of these wells caused by the proposed rule will cost the local communities jobs and revenue.

Commenter (2219-WOGCC) continues, orphaned wells will become the responsibility of the BLM in the case of federal or tribal wells and the commenter in the case of fee or state wells. Forfeited bonds may cover some of the costs to plug the orphaned wells and reclaim the sites, but it is likely other sources of funding will need to be utilized to plug these wells. The premature shut in and plugging of these wells will result in lost royalties and taxes, likely far more than what little may be gained by capturing the small amount of gas that is not already sold from these low producing wells. Operation of these wells also generates additional revenue in local communities in the form of sales taxes and spending by their employees in local communities.

Commenter (2220-Wyoming Department of Environmental Quality) is concerned how the compliance requirements in the proposed regulatory text for NSPS OOOOb and EG OOOOc would affect “low production” wells or smaller companies. While EPA revised some of its proposed monitoring and repair requirements for well sites in the supplemental proposal from what was required in the 2021 proposed rule, there are still potentially onerous requirements in the proposed NSPS OOOOb and EG OOOOc regulatory texts. These requirements could affect many stripper wells in Wyoming (defined by the Wyoming Oil and Gas Conservation

Commission (WOGCC) as wells that produce an average of 15 barrels of crude oil (BBLs) or less per day) and some very small-scale, independent well site operations that strictly operate on a single owner's private property. According to the commenter, Wyoming has approximately 6,524 stripper wells.

Commenter (2249-NACAA) states one area of the proposal that offers a measure of uncertainty is the extension of wellsite monitoring to apply to the smallest wells. On November 23, 2022<sup>112</sup>, the commenter requested an extension of the comment period for this proposal in order to analyze technical aspects such as the implications of this extension of applicability. EPA denied this request on February 3, 2023.<sup>113</sup> As such, the commenter cannot offer a detailed response about the implications of discontinuing waivers for these sources, or unqualified support for these provisions of the proposal if they are not given the resources to succeed. Anecdotally it appears as though this expansion could represent a dramatic increase in the responsibilities falling to state and local clean air agencies to permit, monitor, inspect, and assure compliance by, these wells. The commenter champions the goal of reducing wellsite emissions, but new programs will require new resources, and EPA cannot ignore the possibility that this provision could overburden them beyond state and local agencies' ability to successfully implement it. EPA should better understand these implications, and where they increase the responsibilities of our agencies, EPA should take steps to assure those responsibilities are met with appropriate federal support and resources for implementation.

Commenter (2257-MOGA) believes the EPA has not considered the broader economic and environmental impacts the early plugging of wells may have in Michigan. Further, the EPA has not provided a cost-benefit analysis showing a valuable correlation between any possible benefits of expanding the NSPS regulations to the economic and environmental costs associated with additional drilling to offset lost production from the early plugging of wells.

Commenter (2308-National Stripper Well Association) adds the vast majority of those small operators have actively producing stripper wells in the United States that produce 15 barrels of oil equivalent/90 MCF of gas or less per day. In fact, almost 80 percent of the oil and gas infrastructure in the U.S. are stripper wells.

Commenter (2314-Miller Energy Company) states the cost-benefit analysis did not consider operators like Miller Energy that are comprised of marginal-stripper wells producing ½ to 2 BOED on average. The commenter's wells are vastly different from super-emitters yet the bill recommends they be treated the same. With less production comes less emissions per well/facility. With smaller production outputs also comes less available profit margin to recapture the capital investments required to install the proposed monitoring and field equipment.

Commenter (2314-Miller Energy Company) would like the EPA to consider excluding marginal wells from this regulation. If existing marginal wells cannot be excluded, the commenter would like to propose a tiered system that uses production quantities and potential emissions to determine the level of compliance requirements. With reduced production and emissions,

---

<sup>112</sup> This letter is available online at <https://www.4cleanair.org/wp-content/uploads/NACAA-OilandGasSectorExtensionRequest-11292022.pdf>.

<sup>113</sup> This letter is available online at <https://www.4cleanair.org/wp-content/uploads/EPA-methane-extension-denial.pdf>.

marginal wells should require less monitoring and controls than the super emitters. The removal or reduction of regulation for marginal wells will not impact the EPA's goal to reduce methane emissions as they have a de-minimis impact. The removal will also reduce state and federal tax spending for the oversight required to manage this program.

Commenter (2321-Apollo Exploration and Development, Inc.) notes that the proposed rules are designed to be one size fits all which does not make sense when you compare emissions from a large production well to a marginal well. The economics of compliance and the emissions reductions will be drastically different, yet the proposed rules seem to ignore that fact. This will discriminate against small businesses and make fair competition in a free-market economy unattainable. Depleted reservoirs/marginal wells have less pressure, make less production and in effect have smaller potential for emissions. By making additional costs, some marginal wells may end up being plugged prematurely which wastes natural resources as well as ignores mineral owners correlative rights. Prematurely plugged wells are a detriment not only to the industry but also to the local, state and national economy.

Commenter (2321-Apollo Exploration and Development, Inc.) iterate a significant one-time financial and environmental cost is required to drill a single well. Over-regulation of marginal wells, as proposed in Subpart OOOOb and Subpart OOOOc, will lead to the early plugging of wells while the remaining assets are still economically viable to recover. This will prevent small business operators from recovering their initial capital investment. Also, the early plugging of marginal wells, while still economically viable, will likely exacerbate the need to drill additional wells to meet consumer demand. The unrecovered initial capital investment from drilling a well, combined with the demand to drill additional wells would yield a spiraling economic decline for small businesses by not allowing them to manage profit revenue from existing marginal wells for investment in new wells to meet future demand. This impact would have a rippling effect through our nation as oil, natural gas, gasoline and petroleum derivative prices would skyrocket based on declining supply and rising demand.

Commenter (2403-PAO) notes the DOE study provides data showing that marginal well sites overwhelming fall below the 3 tpy of methane emissions (as provided in the 2021 Proposal) based on actual sampling.<sup>114</sup> The commenter requests EPA incorporate thresholds at which the requirements for fugitives emission monitoring no longer applies. These thresholds should use terminology that is understandable, and useable by small oil and gas businesses so they can easily comply, avoiding the need to hire consultants which will increase the cost of compliance. As an alternative, EPA could develop a framework that provides smaller operators the option to use in lieu of conducting detailed calculations to determine if the methane emission at their site exceed the proposed thresholds. This would benefit state delegated agencies to better manage the large number of existing facilities in their state.

Commenters (2179-KIOGA, 2248-NDPC, 2310-DEQ, 2713-Northeast Natural Energy LLC) argue the proposed monitoring requirements and schedule are excessive for these sites, provide little environmental benefit, and are prohibitive for small owners and operators and will result in the end of their operations. Commenter (2179-KIOGA) states it is an issue when the regulated emission is methane which triggers a nationwide existing source requirement where the brunt of

---

<sup>114</sup> U.S. Department of Energy, National Energy Technology Laboratory, Quantification of Methane Emissions from Marginal (Low Production Rate) Oil and Natural Gas Wells, April 28, 2022.

the impact falls on the 750,000 low production wells that average about 2.5 barrels/day and 25 mcf/d.

Commenter (2179-KIOGA) urges the EPA to modify the rule to include a production rate threshold which would exempt wells making less than 6 BOEPD.

Commenters (2168-INOGA, 2172-KOGA) support EPA's position that operators should perform one leak inspection on low production wells to ensure that no emission sources exist and then do not need to perform additional inspections and maintain associated documentation. This will be a significant step in reducing the complexity of the regulations. The commenters state most of the low production wells are low pressure, requiring artificial lift, and have a low Gas to Oil Ratio (GOR). The PTE from the low production wells is low, yielding reduced benefits for the cost incurred and efforts employed. Dedicating resources to emission sources with a greater PTE will yield greater reduction in emissions. The commenters recommend that the threshold for low production wells match the tax definition of a stripper well for consistency, 15 BOED.

Commenter (2179-KIOGA) states results from the DOE third-party methane emission study of low production wells and facilities indicates that wells producing less than 6 BOED would emit less than 3 tpy of emissions. The emission calculation is based on Subpart W, but most low production existing well producers fall below the Subpart W reporting threshold and the cost and complexity of completing Subpart W reporting for these operators is not just burdensome, it is cost prohibitive for many small businesses. If EPA needs to design a low production well program, it should utilize the emissions profile information developed by the DOE and then focus on the most cost-effective options to address the key sources.

Several commenters support EPA exempting very small wells and establishing subcategories of sources for low production wells and small well sites that have less onerous monitoring, recordkeeping and reporting requirements. This will be a benefit to small business entities with limited staffing resources. In addition, EPA could unintentionally incentivize small businesses to abandon low production wells without these exemptions. This would be a lose-lose situation for small businesses and the environment.

Commenter (2205-Kriebel Well Services, Inc.) notes the DOE study report provides a perspective for an effective low production (marginal) well leak management program that is far less costly compared to the very expensive OGI program. This includes:

1. Routine AVO inspections of tanks and other equipment to assure proper operation,
2. Routine AVO inspection of wellheads to assure proper operation,
3. Periodic simple testing (*i.e.*, use of soap & water bubbles), to check for leaks as needed, and
4. Use of production rates and equipment counts to determine the applicability of the program, rather than costly emissions calculations that were not done for the low production well.

Commenter (2205-Kriebel Well Services, Inc.) asks the EPA to please consider AVO as the means to detect leaks for the marginal well producer. Anything above and beyond simple AVO proves to be unnecessary and extremely cost burdensome.

Commenters (2257-MOGA, 2437-MEC) suggest the EPA consider past small businesses' documented emission reductions as a factor in their required fugitive monitoring schedule. Once again, the EPA appears to be penalizing small businesses that have adhered to requirements outlined in the current Subpart OOOOa and previous Subpart OOOO rule. These small businesses feel "targeted" for their emission reduction efforts based on past regulations and the commenters wonder if it will end. The commenter attended several meetings with the EPA during which, the EPA admitted the bulk of emissions come from a small group of sites and companies. For these reasons, commenter (2257-MOGA) believes the EPA should avoid penalizing small businesses with documented emission reduction efforts with an "Exemption Classification" for fugitive emission monitoring.

Commenters (2297-Petro-Vest, 2321-Apollo Exploration and Development, Inc., 2437-MEC, 2438-MOPC) argue it is unfair and unwise to treat marginal wells in the same manner as larger producers. Marginally producing wells (15 BOEPD/90 MCFPD or less) must be exempt from EPA rules because the emissions are insignificant and the rules would make the wells uneconomic. There must be a regulatory "off ramp" for wells such as ours that are low producers.

Commenters (2295-Timothy Hauck, 2403-PAO) notes that essentially, EPA is placing the same requirements on facilities that produce thousands of barrels of oil per day in the same category as a marginal well that produces 1.4 barrels of oil per day (Bpd) while claiming the requirements are cost effective for these lower producing, marginal wells. A one-size-fits-all rule that applies to all wells is not appropriate or reasonable, is an inefficient use of manpower and funds, and fails to understand the unique aspects of the lifespan of an oil and gas well as production declines over time. The expansive regulations provided in the proposed rule will lead to service and equipment availability issues that will unnecessarily increase costs for the low producing, marginal well operator, and it may limit the ability of operators to comply with the proposed rule and/or continue to operate. Supply chain issues are still a significant issue for our members, and it is more difficult for smaller operators to secure services or equipment (as compared to larger companies).

Commenter (2204-LIP, LLC) states a well making 200 barrels of oil or 2,000 million cubic feet of gas a day does not have the same emissions and economics as a well making 5 barrels or 5 million cubic feet a day. The majority of wells in this county are more of the later, namely marginal wells. The commenter only does oil field consulting with marginal well producers. The proposed regulations would force the plugging of most of the wells they produce as it would not be economically justified to make these upgrades. This in effect would wipe out over half of Michigan's natural gas production, which is badly needed to heat homes in this climate and generate electricity.

Commenter (2437-Muskegon Energy Company (MEC)) states the economic viability of companies relies on efficient and low-cost operations. The commenter opposes the proposed regulations known as NSPS OOOOb and EG OOOOc. The proposed rules will have significant detrimental impacts on our economic viability, costs, overhead, reserve recovery, and plugging costs. The regulations will unnecessarily, unreasonably, and disproportionately raise company's costs and jeopardize our ability to produce marginal wells. The commenter's company will not be able to absorb the additional regulatory costs and the proposed regulations will put them out of business.

Commenters (2297-Petro-Vest, 2437-MEC) are not in agreement with the process or the proposed regulations. Many of the proposed regulations are not feasible and/or do not pass costs-benefits analysis. The EPA's proposed regulations are a "one size fits all" approach and do not adequately take into account smaller companies and marginally producing wells.

Commenter (2713-Northeast Natural Energy LLC) argues a single well or multiple well sites that do not exceed 15 bbls of oil per day or 90 mcf of natural gas per day should be considered as small well sites and be subject only to the quarterly AVO requirement. Sometimes it is not clear if a quarterly OGI survey requirement can always be satisfied using method 21 in lieu of a FLIR/OGI instrument.

Commenter (2439-State of Michigan Department of Environment, Great Lakes and Energy) states the following adjustments to the proposed rule would be equally protective and have less impact to production and small businesses:

- Additional consideration for economic solutions, such as allowing AVO and reasonable reporting frequency for compliance at Small Well Sites;
- Less frequent OGI verification;
- Modification of the small well site definition to include additional pieces of equipment;
- Acceptance of state oil and gas program approved plans and plugging records;
- Consideration of production levels.

Commenter (3185-Lease Management, Inc.) states the proposed rules are based on 1974 data from a large producer in Fort Worth Texas, which is not valid for current operations and totally irrelevant to current operations for small, marginal producers. Ignoring the differences between large 1974 operations and 2023 small operations is totally unacceptable and should never be used for proposing new rules. The DOE recognized these flaws and performed a current, technically sound study of actual emissions from small producers across the country. This data was made available to the EPA last year and should be utilized as a basis for new rules, not 49-year-old data. The proposed rule discriminate against small operations and will shut down small businesses like ours. As a marginal well operator in Michigan, the commenter notes that it can understand and can manage logical regulations, but these rules are simply logical for small producers. The EPA did not allow enough time for me to fully understand all the details, but on the surface these proposed rules fail the logic test. The EPA is ignoring the best available data, using 49-year-old data, and rushing forward with bad rules. The commenter questions the following:

1. The EPA using this 49-year-old irrelevant data as a basis.
2. The EPA ignoring the current data generated by the DOE.
3. Is this EPA intentionally trying to shut down small businesses?
4. Why is the EPA rushing these rules forward?
5. How does the EPA rationalize using 49-year-old data as a one size fits all approach to current small producers?

The comments submitted by the IPAA and MOGA have more detailed comments of the commenter's concerns.

Response II-4-44: As EPA has discussed,<sup>115</sup> emissions from lower producing wells can be a significant source of fugitive emissions and EPA did not find that production rates correlate to the amount of fugitive emissions. Therefore, the EPA is establishing a fugitive emissions monitoring and repair program in the final rule that is based on distinguishing among well sites with different equipment and component counts.

The EPA is maintaining AVO inspections for fugitive emissions monitoring for single wellhead only well sites and small well in the final rule. The specific requirements being finalized for single wellhead only well sites and small well sites are described in section X.A.1.a.ii of the preamble to the final rule for new sources under NSPS OOOOb and in section X.A.1.b.ii of the preamble to the final rule for existing sources under EG OOOOc.

As stated in the November 2021 Proposal, the EPA remains mindful about how the fugitive emissions monitoring requirements will affect small businesses. The EPA discusses the financial conditions of marginal wells in section 5.2 of the RIA. There are many factors that might affect the profitability of marginal wells and the decision to shut-in and plug a well, making it difficult to determine the full impact of regulation on the financial status of marginal well owners. The EPA has also taken steps to include regulatory flexibility and streamline recordkeeping requirements in the fugitive emissions standards of the final rules.

Comment: Commenters (1611-East Liberty Presbyterian Church, 1648-Presque Isle Audubon Society and PA Audubon Council, 1649-The Sisters of St. Francis of Philadelphia, 1655-AAP, 2028-Westmoreland Marcellus Citizens' Group, 2185-New York State Common Retirement Fund (CRF), 2203-Ceres, Inc., 2212-Union of Concerned Scientists, 2226-Thermo Fisher Scientific, 2236-Physicians for Social Responsibility Pennsylvania (PSR), 2285-Bailard, 2299-NEI Investments, 2302-Texas State Representatives, 2303-NTAA, 2364-CleanEarth4Kids.org, 2408-Colorado Local Government Coalition, 2410-California Office of the Attorney General et al., 2429-Wyoming Outdoor Council, 2433-EDF et al, 2461-Conservatives for Responsible Stewardship, 2766-1000 Grandmothers for Future Generations) support EPA's elimination of the exemption from fugitive monitoring and repair for low production or marginal wells—including well sites with a potential to emit (PTE) of less than 3 tpy—and are encouraged that EPA is requiring regular fugitive emissions monitoring and repair for all well sites regardless of their PTE or production level.

Response II-4-45: The EPA acknowledges the comments. The final rule maintains the requirements as proposed in the December 2022 Supplemental Proposal, specifically requiring regular fugitive emissions monitoring and repair for all fugitive emissions components affected facilities.

Comment: Commenters (1643-Ohio River Valley Institute (ORVI), 1648-Presque Isle Audubon Society and PA Audubon Council, 1655-AAP, 2199-Rocky Mountain Farmers Union, 2226-Thermo Fisher Scientific, 2429-Wyoming Outdoor Council, 2433-EDF et al, 2462-Cynthia Walter) note lower-producing wells contribute a significant amount of methane emissions. Nationally, low producing (marginal) wells account for only 6 percent of oil and gas production,

---

<sup>115</sup> 87 FR 74731 (December 6, 2022).

but are responsible for roughly 50 percent of all wellsite pollution.<sup>116</sup> Marginal wells represent an outsized source of leaked methane and GHGs relative to their production benefit. Given this context, the commenters think it's appropriate to have regular inspections on all sites with leak-prone equipment (with more frequent inspections required for sites with more significant potential for emissions).

Response II-4-46: The EPA agrees that emissions from lower producing wells can be a significant source of fugitive emissions. The EPA is maintaining AVO inspections for fugitive emissions monitoring for single wellhead only well sites and small well in the final rule. The specific requirements being finalized for single wellhead only well sites and small well sites are described in section X.A.1.a.ii of the preamble to the final rule for new sources under NSPS OOOOb and in section X.A.1.b.ii of the preamble to the final rule for existing sources under EG OOOOc.

Comment: Commenters (2038-Private Citizen, 2303-NTAA, 2433-EDF et al, 2460-Private Citizen) emphasize EPA has historically underestimated methane emissions from the oil and natural gas industry and that the sources' emissions are likely causing even more harm than previously believed. In addition, the commenters note that marginal wells can have high methane emissions and should be included within programs such as fugitive emissions leak detection and repair that require a root cause analysis to ensure that an owner or operator can identify equipment and operational issues that could trigger high emission events. They also noted that the distribution of emissions rates is skewed so the speed of detecting and stopping large emission sources is critical for reducing total emissions.

Commenter (2038-Private Citizen) gives an example on a facility grossly underreporting annual methane emissions, in response to the NJDEP request for comments on the Tennessee Gas Pipeline TGP) Title V Operating Permit in Wantage TWP, New Jersey. In this comment, the commenter detailed out based on TGP's own documentation and specifications provided to FERC that the operator has been publishing false impossibly low methane emissions in a range between .4 tons to 1.5 tpy from 2009 through to 2023 when the potential emissions as identified by TGP to FERC was expected to be greater than 650 tons of methane each year. NJDEP issued their response to comments on 1/19/2023<sup>117</sup>.

Th commenter (2038-Private Citizen) has discovered and uncovered through research and interaction with agencies:

1. Currently, only a subset of the natural gas fired compressor station facilities are being required to provide annual GHG and HAP emissions estimates each year.
2. The few stationary sources that are required to provide annual estimate emissions severely underreport annual emissions based only on combustion emissions and not venting or leaking fugitive emissions. In all of the facilities that the commenter has reviewed in many different states, it is clear that none of the facilities the commenter has reviewed report emissions anywhere close to estimate or even actual emissions each year.

---

<sup>116</sup> Omara, M., Zavala-Araiza, D., Lyon, D.R. et al. Methane emissions from US low production oil and natural gas well sites. Nat Commun 13, 2085 (2022). <https://doi.org/10.1038/s41467-022-29709-3>.

<sup>117</sup> <https://dep.nj.gov/wp-content/uploads/boss/public-notices/final-hearing-officer-report-1-19-23-signed.pdf>.

3. There are many facilities within the natural gas supply chain that are not required to provide any estimate emissions. Most notably for New Jersey are natural gas electric compressor station facilities. While these facilities can emit more than 100 tons of methane each year along with the associated HAP (such as benzene) due to leaking and venting fugitive emissions, there are no requirements for these facilities to report their annual emissions.

Yet, the commenter (2038-Private Citizen) has found operational electric facilities that the commenter has visited which routinely smell like major gas leak even 2,000 feet away from the facility during times when demand is high (indicating that emissions is not blowdown, but just fugitive leaks) such as on cold winter mornings. Commenter (2038-Private Citizen) has also uncovered new proposed electric facilities that specify the facility will emit more than 100 tons of methane each year (example is TGP CS-327, where TGP provided in its submissions to FERC indicating that CS-327 will emit 142 tons of methane each year). Yet these facilities remain undocumented, unmonitored and none existent in the EPA GHG stationary source inventory.

Of all the facilities that Commenter (2038-Private Citizen) has researched and or visited, the few that have to report, always underreport by at least a factor of 50; that the emissions do not include fugitive emissions and that the reporting is inconsistent across facilities owned by different companies and also varies by which state the facility resides in.

Commenter (2460-Private Citizen) adds to ensure under-reporting ends, the following provision should be regulated:

- Monitoring of emissions need to be continuous over sufficiently long periods of time to obtain information about emissions during abnormal, as well as normal, operating conditions.
- Alarm systems are needed to alert facility personnel when emissions unexpectedly rise.
- Occasional independent checks are needed to determine if on-site monitoring systems are in compliance.
- Emissions from small operation should be allowed to be significantly greater than those from large ones. The current situation is so dire as to require that all emissions be limited to the greatest degree possible.
- The EPA should consider using data obtained by citizens using techniques such as OGI to track leakage at downstream sites such as compressor stations. This could identify areas that need to be formally monitored, perhaps using services from organizations such as Climate TRACE.

Response II-4-47: The EPA acknowledges the commenters' concerns and notes reports cited to and the recommendations provided.

Comment: Commenter (2254-Permian Basin Petroleum Association (PBPA)) states EPA's proposed monitoring schedule is challenging for many basins, including the Permian Basin, due to the distance between sites. There are not enough LDAR technicians in the basin to comply with the new requirements and, even if there were, it would be prohibitively expensive for producers. EPA should instead allow periodic inspections to occur through areal fly-overs or

through the use of other remote technology and only require in-person monitoring on a much less frequent basis.

Commenter (2254-PBPA) states their environmental partnerships have demonstrated that emissions are much lower than EPA projects. The Environmental Partnership, which launched in 2017, has surveyed over 340,000 sites and over 750 million components. The average leak rate from companies participating in the partnership is 0.08%. The partnership is comprised of over 95 companies in industry, from operators to midstream. EPA used the FEAST model, but has not explained why the FEAST model is preferable to data collected by the Environmental Partnership, calling into question the basis for its BSER proposals.

Response II-4-48: The final rule at §60.5398b includes provisions for owners and operators to apply to use alternative technologies to meet the standards that apply to fugitive emissions components affected facilities.

With respect to FEAST modeling, the EPA noted in the December 2022 Supplemental Proposal preamble that although EPA used this model for the purposes of evaluating the various fugitive emissions monitoring and repair programs, similar results are expected using other available modeling tools.

#### 4.1.3.8 Initial and Subsequent Monitoring Surveys

Comment: Commenter (2453-Carbon Mapper and RMI) support the monitoring of small well sites within 90 days of startup or modification of well sites and compressor stations, as long standing and/or undiscovered leaks may generate considerable emissions over time. This is particularly true of remote sites not frequently visited by operators otherwise.

Response II-4-49: In the final rule, the EPA has retained the requirement to conduct the initial monitoring survey at single wellhead only sites and small sites, multi-wellhead only well sites, well sites or centralized production facilities that contain major production and processing equipment, and compressor stations within 90 days of the startup of production.

Comment: Commenter (2399-GPA Midstream Association) proposes that EPA provide 180 days to conduct the initial fugitive emissions monitoring. Conducting compliance monitoring is a lengthy process requiring the development, coordination, and scheduling of internal and contracted services. Often, these monitoring services must be planned and scheduled more than 90 days in advance. Here, affected facilities and service contractors must first develop and update required systems and plans under proposed §60.5397b(b)-(d) for newly affected facilities. Then they – along with the rest of the industry – must attempt to schedule contractors for the initial fugitive emissions monitoring. EPA should accept the initial fugitive monitoring results performed in accordance with NSPS OOOOa for sites constructed after the applicability date of NSPS OOOOb as those sites had to meet NSPS OOOOa requirements until NSPS OOOOb was finalized. Further, the fugitive monitoring requirements under both subparts are effectively the same.

Response II-4-50: The EPA disagrees and has retained in the final rule, the requirement to conduct the initial monitoring within 90 days of the startup of production. The EPA believes this

amount of time is sufficient for facilities to achieve normal operating conditions, but any additional beyond 90 days of startup would not allow for timely repair of any initial issues.

#### 4.1.3.9 Repair

Comment: Several commenters (2168-INOGA, 2172-KOGA, 2227-Western Energy Alliance, 2399-GPA Midstream Association, 2403-PAO, 2410-California Office of the Attorney General et al., 2428-API, 2433-EDF et al) suggest that EPA revise repair timelines under the final rule.

Commenter (2428-API) states the repair timelines should be the same whether the fugitive emissions at well sites, centralized production facilities, and compressor stations are identified using AVO, OGI, or Method 21 because the necessary repair actions are agnostic to the detection method. In other words, operators should have the same time to make repairs regardless of leak detection method because the repair actions depend more on the leaking component rather than detection method.

Commenter (2428-API) states EPA's reason for requiring shorter repair timelines is "*so that the monthly AVO inspections do not overlap the repair schedule*".<sup>118</sup> This justification is insufficient for two reasons:

- As proposed, monthly AVO inspections would apply only to compressor stations. This overlap would not occur for bimonthly or quarterly AVO inspections at well sites and centralized production facilities.
- EPA has allowed repair timelines to overlap with inspection in other regulations. Under existing LDAR regulations, a component may be on delay of repair for multiple monitoring periods in certain circumstances.

Commenter (2428-API) continues, while AVO is generally more effective at detecting larger emissions, the existing OGI repair timelines do not consider emission rate because OGI cannot quantify the leak rate. The same inability to quantify fugitive emissions also applies to AVO, and so EPA should have the same repair timelines for both detection methods. Finally, consistent timelines would also streamline compliance.

Commenter (2428-API) offers the following suggested redline of §60.5397b(h):

(h) Each identified source of fugitive emissions shall be repaired in accordance with paragraphs (h)(1) and (2) of this section.

(1) A first attempt at repair shall be made ~~in accordance with paragraphs (h)(1)(i) and (ii) of this~~

~~(i) A first attempt at repair shall be made no later than 15 calendar days after detection of fugitive emissions that were identified using visual, audible, or olfactory inspection.~~

---

<sup>118</sup> 87 FR 74737.

~~(ii) If you are complying with paragraph (g)(1)(i) through (iv) of this section, a first attempt at repair shall be made no later than 30 calendar days after detection of the fugitive emissions.~~

~~(2) Repair shall be completed as soon as practicable, but no later than 15 calendar days after the first attempt at repair as required in paragraph (h)(1)(i) of this section, and 30 calendar days after the first attempt at repair as required in paragraph (h)(1)(ii) of this section.~~

Commenter (2433-EDF et al) argues EPA’s definition of “first attempt at repair” is too broad and could allow actions without any probability of leading to a successful repair to be interpreted as an “attempt.” The commenter therefore recommends tying the attempted action to the outcome, which is a successful repair. EPA should include language that makes clear the “attempt” must be one that, if completed, would successfully mitigate the emissions. The commenter also encourages EPA to broaden the non-exhaustive list of examples. Many fugitive emissions will require repairs that are much more significant than the list EPA has included.

Commenters (2168-INOGA, 2172-KOGA, 2227-Western Energy Alliance, 2403-PAO) recommend that EPA standardize all leak repair times to be as soon as possible, not to exceed 30 calendar days. This will provide consistency with prior regulations and avoid confusion for operators as they are developing their compliance programs.

Commenter (2403-PAO) believes the proposed monitoring timeframes (e.g., quarterly, bimonthly and monthly AVO) and repair frequencies (e.g., within 15 days of inspection vs. first attempt at repair within 30 days and final repair within 30 days of first attempt) are confusing and may lead to non-compliance.

Commenters (2168-INOGA, 2172-KOGA) note the difference between the repair frequency for AVO (15 days) and OGI (30 days) in the rule. The commenters indicate that leaks discovered with AVO may be as difficult to repair as leaks discovered with OGI. The commenters recommend that the repair time for AVO should also remain consistent with OGI repairs, 30 days to attempt repair and 30 additional days to confirm the repair is complete.

Commenter (2433-EDF et al) notes EPA is proposing to require a first attempt at repair within 30 days of identifying fugitive emissions, with final repair required within 30 days of the first attempt, for a potential total of 60 days. The commenter believes this is unnecessarily long and could lead to large emissions going unmitigated for up to two months. Repair timelines can significantly affect overall mitigation,<sup>119</sup> and EPA’s projections of emissions reductions achieved by the rule assume only a 30-day delay between detection and repair.<sup>120</sup> EPA’s projected reductions will not be realized if repairs are allowed to extend beyond 30 days.

Commenter (2433-EDF et al) states a 30-day repair timeline is feasible and is already required by leading states, like Colorado and New Mexico.<sup>121</sup> The commenter therefore urges EPA to

---

<sup>119</sup> See Felipe J. Cardoso-Saldaña, Tiered Leak Detection and Repair Programs at Oil and Gas Production Facilities 325 (2022), <https://chemrxiv.org/engage/chemrxiv/article-details/636d4595afea7fcd1c9f5f67>.

<sup>120</sup> See Supplemental RIA, *supra* note 110, at 228.

<sup>121</sup> See Colo. Code Regs. § 1001-9-D-II.E.7; N.M. Code R. § 20.2.50.116(E) (2023).

require a first attempt at repair within 15 days of detection and a final repair within 15 days of the first attempt, for a maximum of 30 days between detection and final repair.

Commenter (2433-EDF et al) argues EPA should eliminate the “technically infeasible” exemption language from the repair requirements and only allow extended repair timelines in the specified instances. This language is too open-ended and is not necessary given that EPA has already specified the situations in which a repair would be technically infeasible. Additionally, EPA should include a requirement that inspection crews attempt to complete repairs at the time leaks are detected when safe and feasible. This practice is already the norm for leading operators and should be encouraged by EPA.

Commenter (2433-EDF et al.) continues, EPA should also ensure that documentation and reporting occurs when an OGI or AVO survey detects emissions, but the operator determines that the emissions are from a permissible event or part of normal operations that does not require repair. This will help to align requirements with the alternative screening option while allowing EPA to track and ensure that operators are taking appropriate follow-up action after detecting emissions. The commenter also recommends that EPA require the initial monitoring survey to occur earlier so that companies can address problems sooner and mitigate potentially large emissions that would otherwise go undetected for up to 90 days.

Importantly, EPA should align OGI and AVO follow-up and repair requirements for control device failures with those described in section 60.5398b(b)(4)(iv). Misalignment between the scope of monitoring and follow-up and repair requirements between the OGI program and the alternative could disincentivize use of the alternative. The commenter therefore urges EPA to ensure control devices are monitored during OGI surveys for compliance with the requirements of section 60.5413b and are subject to parallel root cause and corrective action requirements if problems are detected.

Response II-4-51: The EPA believes 30 days is a necessary amount of time to complete the first attempt at repair after detection of the fugitive emissions with OGI or EPA Method 21, plus an additional 30 days to complete the final repair. Based on information from annual compliance reports, most fugitive emissions components repairs could be completed within 30 days, however, not all repairs are expected to be able to be completed within the first attempt of repair and therefore additional time is needed to ensure repairs are completed and would also eliminate the need for further delay of repair. Therefore, contrary to one commenter’s remark that allowing for final repair within 60 days could lead to large emissions going unmitigated for up to two months, the EPA disagrees, because as stated, most fugitive emissions are expected to be repaired in the first attempt.

Also, the EPA clarifies that when fugitive emissions are identified through AVO inspections, the EPA is requiring that repairs be completed within 15 days after the first attempt in order to not overlap the repair schedule of repairs of emissions detected with OGI or EPA Method 21. For single wellhead only well sites and small well sites, the issue the commenter mentions of detected emissions going unmitigated for up to two months would not occur because the rule requires quarterly AVO inspections and because the first attempt of repair is 15 days following detection of emissions and final repair is 15 days after the first attempt of repair for a total of 30 days. For multi-wellhead only well sites and well sites with production and processing equipment and centralized production facilities, the issue the commenter mentions would not be

an issue either because of the combination of AVO inspections and OGI monitoring, and specifically the fact that quarterly AVO inspections (for multi-wellhead only well sites) and bimonthly AVO inspections (for well sites with production and processing equipment and centralized production facilities) would pick up any large emissions occurring in that time frame and not go unnoticed.

Comment: Commenter (2172-KOGA) states because there may be an unusual circumstance where there is some failure of a part, such as a valve stem in a valve that is not readily available, leaks identified by AVO should be on the same 30-day schedule to attempt a repair and an additional 30 days to finalize a repair that is allowed leaks found with OGI.

Commenter (2436-Louis Pochet) adds well-head failure is common even for new wells, resulting in substantial fugitive emissions. For example, it has been reported that wells studied after the year 2005 had well-head failure rate of about 10% within the first year and rising to 40% likelihood of failure within the first 10 years, based on real world inspections of thousands of wells in Pennsylvania.

Response II-4-52: The EPA acknowledges comments regarding wellhead failure probability and the availability of parts needed for repair. The final rule allows delay of repair of fugitive emissions components due to unavailability of replacement components (or parts thereof) in certain circumstances at well sites, centralized production facilities, and compressor stations. Specifically, delay of repair is allowed if replacement is required but cannot be acquired and installed within the repair timeline due to either of the following conditions: (1) replacement valve supplies have been sufficiently stocked but are depleted at the time of repair; or (2) a replacement fugitive emissions component or a part thereof requires custom fabrication.

Comment: Commenters (2298-Pioneer Natural Resources USA, Inc., 2326-AXPC) note EPA's proposal requires spacing consecutive quarterly OGI/Method 21 monitoring surveys at least 60 days apart. Due to safety issues and facility availability, 60 days is too restrictive. Further, requiring spacing inspections at least 30 days apart will allow for inspection across varying operating conditions. For these reasons, commenters (2298-Pioneer Natural Resources USA, Inc., 2326-AXPC) request that EPA reduce the §60.5397b(g)(1)(iii)(F) OGI/Method 21 inspection survey spacing from 60 days to 30 days.

Commenter (2298-Pioneer Natural Resources USA, Inc.) recommends that EPA add language stating that the initial AVO inspection should begin between 30 and 60 days after the OGI inspection and to clarify that AVO be required only during the month no OGI inspection occurs. This will still ensure regular monitoring of facilities for leaks between OGI surveys; and an AVO conducted during the same month as an OGI would not help reduce emissions, but instead only be a record keeping burden.

Response II-4-53: The EPA disagrees that owners and operators subject to quarterly monitoring surveys should have the option to space the surveys 30 days apart (as opposed to 60 days). The minimum spacing between quarterly monitoring surveys of 60 days is being finalized to allow sources flexibility for improved scheduling of surveys and anything less than 60 days is too narrow of a window to ensure the quarterly monitoring requirements detect changes in emissions that can occur over time. 30 days from the previous survey could miss emissions that could have developed since the last survey and specifying 60 days accommodates for that without getting to

close to the next scheduled quarterly survey. This is in line with the spacing requirements for consecutive semiannual surveys that must be conducted at least 4 months apart and no more than 7 months apart.

For single wellhead only sites and small sites, the final rule specifies that the initial monitoring survey using AVO (or any other detection methods) must be conducted within 90 days of the startup of production. For multi-wellhead only well sites, well sites or centralized production facilities that contain the major production and processing equipment, the final rule specifies that the initial monitoring survey must be conducted using OGI or Method 21 within 90 days of the startup of production. For multi-wellhead only well sites, the final rule specifies that AVO must be conducted quarterly after the initial survey and OGI semiannually after the initial survey. For well sites or centralized production facilities that contain the major production and processing equipment, the final rule specifies that AVO must be conducted bimonthly following the initial survey and OGI quarterly following the initial survey. The EPA believe the timing for the different monitoring requirements with AVO and OGI is clear and no additional clarification is needed to specify that AVO be required only during the month no OGI inspection occurs. The EPA believes the rule as written ensures regular monitoring of facilities for leaks between OGI surveys.

Comment: Commenters (2172-KOGA, 2221-Texas Pipeline Association, 2270-Private Citizen, 2399-GPA Midstream Association, 2428-API) made various recommendations related to the delay of repair provisions. The recommendations are described below.

Commenters (2221-Texas Pipeline Association, 2270-Private Citizen) add shutdowns can occur for many different reasons, and a shutdown that is not scheduled for maintenance purposes can be a highly inappropriate occasion for conducting or completing repairs. Some planned shutdowns do not occur for maintenance reasons, last for a very short time, and are made on short notice. It would be unreasonable, and unworkable in practice, to require that repair personnel be mustered and repairs be made during these events. In addition, requiring complicated repairs to be made in these circumstances would disrupt normal operations more than would otherwise be the case and thus would disrupt production and transmission activities by delaying the unit's return to normal service. Similarly, it would be unreasonable to require repairs to be made where a leak was detected shortly before a scheduled shutdown, as it might not always be possible or feasible to locate appropriate repair personnel and/or parts in a timely manner given the short notice that would be involved. Again, requiring repairs to be completed during such a shutdown could greatly lengthen the shutdown, causing unnecessary disruption to natural gas supply.

Commenter (2221-Texas Pipeline Association) states it is appropriate for EPA to clarify that completion of delayed repairs is required during a scheduled shutdown where maintenance activities have been scheduled, not the next shutdown of any kind. This represents a reasonable accommodation of the issues expressed above and would align the oil and natural gas NSPS more closely to the delay-of-repair provisions in other NSPS, *e.g.*, Subpart VVa.<sup>122</sup>

Commenters (2172-KOGA, 2399-GPA Midstream Association) state the time required to order parts and make the repair should be at least 30 days in today's economy (with continuing supply

---

<sup>122</sup> See, *e.g.*, 40 CFR § 60.482-9.

chain challenges) and with the expected increased demand associated with the new regulations. Should EPA finalize the rule, it should allow for 30 days to attempt a first repair of any leaking component detected through an AVO inspection. EPA should not be concerned about the repair being outstanding during the next scheduled AVO inspection. When moving to a frequency like monthly, it is unreasonable for EPA to assume there will not be overlap in surveys and repairs.

Commenter (2399-GPA Midstream Association) adds Colorado regulations require that a first attempt at the repair of a leaking component be made within five days if a site is located within 1,000 feet of an occupied area or within a disproportionately impacted community.<sup>123</sup>

Commenter (2428-API) requests that delay of repair requirements should be expanded. The commenter indicates that consistent with the requirements for natural gas processing plants, EPA should allow for delay of repair due to parts unavailability. The commenter notes NSPS OOOO and OOOOa allow for delay of repair beyond a unit shutdown if “valve assembly supplies have been depleted, and valve assembly supplies had been sufficiently stocked before the supplies were depleted.”<sup>124</sup> In the Preamble to the November 2021 Proposal,<sup>125</sup> EPA recognized that operators of older equipment may experience delays in obtaining replacement parts. Given current supply chain issues and the larger number of well sites, centralized production facilities, and compressor stations, EPA should expand the current delay of repair requirements to include delays because of parts unavailability.

In addition, the commenter (2428-API) believes EPA should add other potential circumstances beyond an operator’s control that would require a delay of repair. Repairs may be delayed due to circumstances not currently listed in the rule. Specifically, there are seasonal constraints related to farming and/or endangered species where operators cannot bring a rig in or have surface disturbance. Delay of repair should be allowed for these unique situations.

Commenter (2428-API) suggests the following revisions to §60.5397b(h)(3), which are based on existing regulatory language from NSPS VVa:

(3) Delay of repair will be allowed:

(i) If the repair is technically infeasible, would require a vent blowdown, a compressor station shutdown, a well shutdown or well shut-in, or would be unsafe to repair during operation of the unit, the repair must be completed during the next scheduled compressor station shutdown for maintenance, scheduled well shutdown, scheduled well shut-in, after a scheduled vent blowdown, or within 2 years, whichever is earliest. A vent blowdown is the opening of one or more blowdown valves to depressurize major production and processing equipment, other than a storage vessel;

(ii) If the necessary replacement part supplies have depleted and supplies had been sufficiently stocked before supplies were depleted, the repair must be completed as soon

---

<sup>123</sup> 5 Colo. Code Regs. §§ 1001-9:D.II.E.6.f-g, II.E.7.b (adopted Dec. 17, 2021).

<sup>124</sup> 40 CFR §60.482-9a(e).

<sup>125</sup> 86 FR 63174.

practicable, but no later than 30 days once the necessary replacement part supplies are available; or

(iii) If the necessary repair equipment cannot be brought to the site for reasons, such as lease restrictions for farming or seasons for endangered species, the repair must be completed as soon practicable, but no later than 30 days once repair equipment may be brought to the site.

Response II-4-54: Based on the comments received on delay of repairs provisions for well sites, centralized production facilities and compressor stations, the EPA is allowing delay of repair of fugitive emissions components due to unavailability of replacement components (or parts thereof) in certain circumstances. Specifically, delay of repair is allowed if replacement is required but cannot be acquired and installed within the repair timeline due to either of the following conditions: (1) replacement valve supplies have been sufficiently stocked but are depleted at the time of repair; or (2) a replacement fugitive emissions component or a part thereof requires custom fabrication. In either situation, the required replacement must be ordered within 10 calendar days after the first attempt at repair. The repair must be completed within 30 calendar days after receipt of the replacement or during the next scheduled shutdown for maintenance after the replacement is received (if the repair requires a shutdown). See section XI.A.2.b of the preamble to the final rule for EPA's reasons for allowing delay of repair under these specified conditions, other responses to the major comments on this issue, and additional details on this provision.

#### 4.1.3.10 Recordkeeping and Reporting

Comment: Commenters (1649-The Sisters of St. Francis of Philadelphia, 2152-California State Teachers' Retirement System (CALSTRS), 2185-New York State Common Retirement Fund (CRF), 2242-Seventh Generation Interfaith, Inc., 2285-Bailard, 2287-Climate Change and Environmental Justice, Interfaith Center on Corporate Responsibility (ICCR), 2424-As You Sow, 2455-Private Citizen, 2459-BMO Global Asset Management) ask for a transparent, credible, and empirically based methane emissions reporting framework to improve the accuracy and credibility of reported methane emissions data, and enable them, as investors, to clearly differentiate between leaders and laggards. Commenter (1649-The Sisters of St. Francis of Philadelphia) adds plans must include deadlines and the local public should be informed as the EPA moves swiftly to finalize comprehensive standards.

Response II-4-55: The EPA generally agrees with the commenters. The final rule includes clear timelines affected facilities are required to comply with the emission standards, as well as the recordkeeping and reporting elements that are needed to ensure compliance with the rule.

Comment: Commenter (2393-Oklahoma Office of the Secretary of Energy and Environment) concurs with EPA's proposal to allow companies to develop a monitoring plan that covers multiple facilities rather than a separate plan for each site. This is not an endorsement of the entirety of the proposal, but a preference for this particular alternative.

Response II-4-56: The final rule specifies at §60.5397b(b) of the final rule that the fugitive emissions monitoring plan that covers all fugitive emissions components affected facilities must

be developed for each company-defined area. The EPA assumes that each company-defined area consists of 22 well sites.

Comment: Commenters (2168-INOGA, 2179-KIOGA, 2223-Texas Alliance of Energy Producers) believe reporting requirements for single wellhead well sites, small well sites, and small production sites should be minimized for the benefit of the small business operator. Single well sites which are visited monthly if not more often, and small well sites and small production sites that are visited daily and observed for leaks, should require no more than an annual report that might include estimated number of times visited and number of leaks identified. Training an operator's personnel is more important to identify, stop, report, and correct leaking components than to force operators to commit their resource's time and funding to burdensome compliance activities.

Response II-4-57The recordkeeping and reporting requirements in the rule that apply for each fugitive emissions affected facility, including single wellhead only well sites and small well sites, represent the minimum level of tracking and documentation necessary to ensure compliance with the rule. The final rule requires quarterly AVO inspections for single wellhead only well sites and small well sites, as proposed. Affected facilities are required to report annually the results of the quarterly AVO surveys, which would include key elements such as the dates the quarterly AVO surveys were performed, number and type of equipment for which leaks were identified, or, if no leaks were detected, a statement that there were no leaks on the day of inspection, information regarding the number and type of equipment for repairs occurred, and number and type of equipment with delayed repair. EPA emphasizes that recordkeeping and reporting are vital components of compliance assurance and believes the recordkeeping and reporting requirements established in the final rule are reasonable and appropriate.

Comment: Commenter (2325-Aclima) indicates that EPA's estimated annual per-well cost of complying with the rule is estimated to range from \$2,490 for biennial OGI monitoring to \$8,140 for monthly OGI monitoring at the average well site. Rolled up, that is between \$54,780 to \$179,080 per year for the average owner of 22 wells. Networked small sensor technologies can be implemented at a fraction of these costs, with the enhanced benefit of continuous, networked monitoring across all wells.

Commenter (2325-Aclima) notes that each well owner is also expected to develop their own monitoring plan, purchase a recordkeeping data management system specific to fugitive emissions monitoring and repair, and shoulder those upfront costs.

Commenter (2325-Aclima) states innovative cost-sharing data business models can meet the market needs, but this rule does not incentivize. Rather than unlock innovation across the industry, the rule as currently written may propagate siloization of data, non-standardized implementation, fragmented markets for solutions, and slow, bureaucratic reporting processes, further delaying the aggressive emissions reductions that are critically needed.

Commenter (2325-Aclima) provides the example, the rule speaks minimally to digital infrastructure, including cloud-based storage and database systems which enable novel analysis, visualization, and reporting of LDAR data. Such systems can facilitate rapid and automated operationalization of measurement data, as well as enable efficient reporting to regulators,

reduced friction of compliance, and sharing of best practices across the industry. The commenter urges the EPA to consider digital and standardized methods of reporting.

Response II-4-58: The EPA acknowledges the commenter's observations and suggestions for streamlining reporting. To increase the ease and efficiency of data submittal and data accessibility, the EPA is finalizing, as proposed, a requirement that owners and operators submit electronic copies of performance test reports, semiannual reports, annual reports, and other notifications through the EPA's Central Data Exchange (CDX) using the CEDRI. For additional discussion on electronic reporting, see section X.N of the preamble to the final rule. In addition, the rule finalizes as proposed, that allow for the use of alternative test methods using advanced methane detection technologies for periodic screening or continuous monitoring for fugitive emissions and emissions from covers and CVS used to route emissions to control devices. This provision will allow owners and operators to use multiple advanced technologies in combination, and facilitate the use of the most sensitive advanced technologies.

Comment: Commenter (2403-PAO) notes EPA states that owners and operators would be required to use the appropriate spreadsheet template to submit information to Compliance and Emissions Data Reporting Interface (CEDRI) for annual and semiannual reports. EPA states that a draft version of the proposed templates for these reports was included in the docket for this action. The EPA specifically requests comment on the content, layout, and overall design of the templates. The commenter indicates that it was not able to find this document. The commenter requests EPA make this document available for public review and comment.

Response II-4-59: The CEDRI reporting templates for the 60.5420(b) Annual Report and 60.5422(b) Semiannual Report for NSPS OOOOb and EG OOOOc were posted in the rulemaking docket for the December 2022 Supplemental Proposal prior to the start of the comment period. The document ID for the templates is EPA-HQ-OAR-2021-0317-1536.

#### 4.1.3.11 Other

Comment: Commenters (2308-National Stripper Well Association, 2403-PAO, 2446-IPAA) request that there be a pathway to less frequent monitoring for situations where emissions are declining or are when emissions are not detected.

Commenters (2308-National Stripper Well Association, 2446-IPAA) state if quarterly OGI is not identifying emissions issues that are not being found and addressed by the AVO component of the program, it needs to be revised to a semiannual requirement; if it adds no benefits as a semiannual program, it needs to be revised to an annual program or eliminated.

Commenter (2403-PAO) adds EPA should include a process whereby operators of existing facilities can reduce or cease monitoring if fugitive emissions monitoring results are not detecting emissions or there is little to no benefit.

Response II-4-60: The EPA disagrees that a reduced monitoring frequency is appropriate for situations where emissions potentially could be declining or not detected during a monitoring survey. The fugitive emissions monitoring requirements under NSPS OOOOb and EG OOOOc do not require the quantification of fugitive emissions; only the assurance that any fugitive emissions that are detected are properly repaired. Even if emissions quantification can be done

(or some other measure of performance such as recording the number of leaking components over time), the EPA believes the burden associated with tracking emissions and varying compliance requirements would be a burdensome and complex undertaking. Further, even if no emissions are detected during a fugitive emissions monitoring survey, it does not eliminate the possibility that emissions could be present in the future as emissions can occur at any time, and fugitive emissions are likely to increase as equipment ages. Requiring less frequent monitoring could lead to fugitive emissions being undetected longer. Therefore, the EPA is finalizing a fugitive emissions components fixed monitoring frequency program with no change due to leak rate performance. Comment: Commenter (2347-Clarke Valve) supports proposed regulations that are as stringent as practicable and technologically feasible, *e.g.*, using the BSER. One study provides examples of major available methane mitigation, or abatement, technologies and measures for the oil and gas sector “that are specified in at least one assessment” as follows:<sup>126</sup>

“[u]pstream leak detection and replacement\*, replacing pumps\*, replacing with instrument air systems\*, vapour recovery units\*, blowdown capture\*, replace with electric motor, early replacement of devices, replace compressor seal or rod, install flares, install plunger, downstream leak detection and replacement.”

(\* indicates sometimes can be implemented at no net cost).<sup>127</sup>

Commenter (2347-Clarke Valve) adds the same report indicates that rapid deployment of such available, cost-effective abatement technologies and measures alone could reduce methane emissions by nearly 25 percent below anticipated levels by 2030, with the oil and gas sector dominating this avoided warming potential.<sup>128</sup>

Commenter (2347-Clarke Valve) believes that EPA’s proposals to use 500 ppm as the defined leak detection limit is problematic. Legacy globe control valves are highly prone to leaks. In addition, EPA’s decision to not require replacement of leaking equipment with “low-emitting” (“low-e”), respectfully, is flawed. According to the commenter, while a legacy globe control valve may be rated at 500 ppm for fugitive emissions when “new” or “recently adjusted,” the actual leakage between adjustments can be as high as 200,000 ppm (or 20 percent of the flow volume in the pipe). This is a particular problem at remote sites and for marginal wells that are not constantly monitored. The main technical problem with wound graphite packing, which is currently used in all legacy globe control valves, whether a manufacturer markets them as “low-e” or not, is that, like a wind-up watch, a globe control valve’s graphite packing gradually begins to unwind itself, immediately after having been adjusted. If left to unwind for a long enough time, the leakage could be many times greater than manufacturers’ claims. It is unrealistic to expect that millions of globe control valves in the field with wound graphite packing will always be properly adjusted. Even “low-e” valves use graphite packing which will unwind and, hence, will regularly exceed their factory rating of 100 ppm between adjustments.

Commenter (2347-Clarke Valve) states several manufacturers of non-globe type control valves use non-graphite packing, which do not require adjustments. Legacy globe control valve

---

<sup>126</sup> Ilissa B. Ocko, et al.. Acting rapidly to deploy readily available methane mitigation measures by sector can immediately slow global warming. (2021) Environ. Res. Lett. 16 054042 (Ocko, et al., 2021).

<sup>127</sup> Ocko, et al. (2021).

<sup>128</sup> Ocko, et. al. (2021).

manufacturers should be required to utilize similar solutions. One way to achieve this is to impose a ban on graphite packing for any valves used in methane applications. While the commenter is aware that EPA considers 500 ppm a reasonable limit, this does not account for the leakage between adjustment intervals, particularly at remote sites or marginal wells, which may rarely or never be adjusted after installation.

Commenter (2347-Clarke Valve) argues significant scientific and material advances have been available for the last few decades that easily allow manufacturers to meet a more stringent standard. In fact, several valve manufacturers already are using widely-available, mature seal technology, such that their valves are achieving emissions below 50 ppm even after 100,000 cycles, which equates to 10 years of simulated use. High grade seals that enable valves to achieve emissions of 50 ppm or less typically cost less than \$5.00 each.

Commenter (2347-Clarke Valve) concludes thus, the leak detection limit should be adjusted, *i.e.*, lowered, or made more stringent, to 50 ppm. Some EPA Consent Decrees already rely on a 100 ppm corrective action leak detection limit. Increasing the stringency of the leak detection limit also would reflect an acknowledgement of the availability and cost effectiveness of technologies that can reduce or virtually eliminate fugitive emissions and the need for fewer (if any) repairs, which, in turn, would enable semiannual and quarterly monitoring to suffice.

Commenter (2347-Clarke Valve) encourages EPA to require oil and gas operators to measure emissions at a site or on a piece of equipment immediately prior to any adjustments or repairs being made. Having “before” and “after” emissions levels will facilitate a comparison of emissions levels, an assessment of whether intended emissions reductions actually have been obtained, and whether any additional modifications might be needed. Doing so still does not necessarily capture the duration of a leak or extent of excess methane emitted, but it is a step and will reflect a snapshot in time.

Commenter (2347-Clarke Valve) supports EPA’s plans to allow/require monitoring using LDAR for certain types of equipment/operations. However, it is worth considering that adjustments to certain types of equipment do not necessarily constitute “repairs,” because the modifications often are quite temporary.

Response II-4-61: The EPA agrees with the commenter that lower-emitting technologies can help to lower the frequency of leaks from fugitive emission components. However, they cannot necessarily prevent them from happening. Therefore, the EPA maintains that an effective fugitive emissions monitoring and repair program must include routine monitoring. As noted by the commenters, replacing equipment components with low-e components can be cost-effective solution in some applications, but that depends on the size, operational characteristics, and expected service life of the equipment. For many production sites, the expected service life of a well may not warrant additional cost of low-e equipment. The EPA also has limited data on the failure rates of different low-e technologies, so it is difficult to quantify the cost and emission reductions associated with a requirement to use low-e components. As such, the EPA could not determine use of low-e equipment for BSER. However, the EPA recognizes that selecting low-e equipment can help to reduce emissions, so we sought to promote its use to the extent practical. For natural gas plants, for example, EPA included reduced monitoring requirements when low-e equipment are used. The EPA will continue to collect information on the cost and performance of low-e equipment to further assess these technologies in future rulemakings.

Comment: Commenters (2251-National Association of Manufacturers (NAM)), 2429-Wyoming Outdoor Council) urge EPA to allow advanced technologies as alternatives to OGI.

Commenter (2251-NAM) specifically suggests if a methane leak is a process emission and the production operator is operating within its permitted levels that EPA not require OGI. The commenter recommends that companies be given the option to use alternative technology.

Commenter (2429-Wyoming Outdoor Council) asserts EPA should allow advanced technologies to be used for LDAR, if they are shown to deliver equal or better emissions reductions. Based on Wyoming's experience in the Upper Green River Basin, the commenter thinks operator flexibility (within reason) is critical for the EPA to codify into the final rules. This is key to encouraging private sector innovation, incentivizing operators to invest in new technologies that can benefit the broader oil and gas industry, and growing Wyoming's methane regulation economy. It is also important that EPA help facilitate experimentation with new technologies so their development will be accelerated. Industry experience in our region suggests that the cost of implementing these technologies drops significantly over time, with one prominent Wyoming-based company in particular reporting a 75 percent reduction in the cost of LDAR over five years of implementation.<sup>129</sup>

Response II-4-62: EPA has provided a pathway for use of advanced technologies in NSPS OOOOb and EG OOOOc. See Volume II, Chapter 5, and discussion in section X.B of the preamble to the final rule for information on advanced technologies.

#### **4.1.4 Modeling**

Comment: Commenter (2333-LongPath) agrees with the blind test verification of the functioning of alternative technologies. However, the commenter believes that the same criteria should apply to verify the efficacy of OGI surveys, EPA Method 21 surveys, and AVO surveys. The commenter notes that EPA's language suggests that an "adequate demonstration" is required of BSER and AVO forms a substantial portion of the BSER in the supplemental proposal; yet, while EPA conducted an extensive literature review on the range of performance and limitations of OGI, as well as commissioning multiple laboratory studies and OGI technology evaluations, the commenter is not aware of a body of literature or comprehensive testing and evaluation of AVO. Further, they add that AVO performance specifications are parameterized in the Fugitive Emissions Abatement Simulation Toolkit (FEAST) model; and AVO inspections are given a 0 percent chance of failure for any leak above a very small leak rate, despite this number never having been tested or proven at any scale. The commenter also provides as part of their comment, a case study demonstration of the inability for AVO to identify even very sizeable leaks.

The commenter (2333-LongPath) believes that if EPA is to define AVO as all or part of BSER, it will be necessary for blinded studies and field tests to be performed across a range of operator experience levels, complexity of equipment and sites, leak types (including aperture size, height

---

<sup>129</sup> EDF Factsheet: Finding, fixing leaks is a cost-effective way to cut oil and gas methane emissions. Available at: [https://www.edf.org/sites/default/files/content/ldar\\_fact\\_sheet\\_updated\\_with\\_citations.pdf](https://www.edf.org/sites/default/files/content/ldar_fact_sheet_updated_with_citations.pdf).

above ground level and flow rate), and ambient conditions (wind, rain, snow, and against the substantial noise volumes on large production sites in, for example, the Permian basin). According to the commenter, until such time as demonstrable support for AVO as BSER, the FEAST models should not include any emissions reduction from AVO, as there is no supportable evidence of its efficacy.

The commenter (2333-LongPath) also notes that the gold standard for testing and quality assurance that will be applied to alternative technologies is objective third-party blind testing. The commenter suggests that the requirement for boot-strapping experience levels, by having senior OGI operators audit junior OGI operators, runs the risk of cross-organizational problems with OGI accuracy and does not meet this same standard.

Response II-4-63: First, the EPA provides specific requirements for testing and verifying the OGI instrument can detect a defined hydrocarbon release within NSPS OOOOb. Similarly, EPA Method 21 includes very specific instrument specifications and quality control requirements to ensure that these instruments are operating as intended. As such, the EPA finds no need to require further third-party verification of these methods. For the alternative technologies, the EPA does not have specific procedural and quality assurance methods as the purpose of the alternative technology provisions are to allow the use of additional technologies without having to define test methods and QA procedures within the rule for each of these technologies. Thus, for the alternative technologies, a blind test verification is needed to determine the detection level of the method (key parameter used to assess the alternative technology).

The EPA acknowledges that the AVO inspections have much less well-defined quality assurance specifications compared with the OGI and EPA Method 21 leak inspections or “instrument monitoring methods.” For these reasons, the EPA considered the instrument monitoring methods first when determining BSER. The EPA notes that the FEAST modeling conducted for AVO, we used higher detection limits and used a 90 percent maximum probability of detecting leaks at the high-end of the leak spectrum, so we anticipated that AVO inspections would not be as effective as the instrument monitoring methods. Nonetheless, EPA found that additional AVO inspections could result in cost effective additional emission reductions. However, EPA did not include any emission reductions from AVO when developing the alternative technology equivalency matrix. As such, the final equivalency matrix is based on the emission reductions projected considering the instrument monitoring methods that have specified quality assurance approaches. In this manner, we consider we have similar quality of data between the instrument monitoring methods and alternative technologies that must establish detection limits based on blind test verifications.

Comment: Commenters (2286-CDPHE, 2333-LongPath) question the effectiveness of AVO used in FEAST modeling for the December 2022 Supplemental Proposal.

Commenter (2286-CDPHE) notes that in evaluating the annual costs of an LDAR program, EPA incorporated the results of FEAST modeling to include the modeled number of components identified as leaking, assuming an average of 0.62, 1.25, and 3.7 leaks requiring repair found annually at single wellhead only and small well sites, multi-wellhead only well sites, and well sites and centralized production facilities, respectively. EPA explained that the dataset included all leaks measured across numerous studies. The commenter highlights the many years of LDAR

data collected in Colorado since Colorado's adoption of a regulatory LDAR program in 2014.<sup>130</sup> Colorado's data shows both different annual rates for leaks requiring repair<sup>131</sup> as well as the few leaks requiring repair as detected by AVO.<sup>132</sup> The difference in the data collected under Colorado's well established LDAR program as compared to EPA's estimated model plant values and the differences between Colorado's applicability provisions (*e.g.*, well production facilities with estimated uncontrolled actual VOC emissions from the highest emitting storage tank >12 and <50) and EPA's defined facilities (*e.g.*, single wellhead only well site) further highlights the need to provide flexibility for states in comparing existing and effective state programs to EPA's model EG. The commenter also reiterates that EPA should permit states to use VOC emissions as a proxy for comparing the stringency of a state program with EPA's proposed thresholds.

Commenter (2286-CDPHE) invites EPA to review the annual LDAR reporting analyses of operator reported data for all LDAR completed as required under Colorado's Regulation Number 7. These analyses represent real world data submitted by operators on an annual basis. The LDAR reporting and analyses emphasizes the efficacy of OGI detection, and the disparity in detection between AVO and the advanced monitoring technology.

Commenter (2333-LongPath) points to the academic literature's lack of studies on the efficacy of AVO inspections for: emissions with variable rates, intermittent emissions, emissions elevated above ground level, emission point aperture sizes, and emissions occurring in varying ambient conditions (*e.g.*, wind, rain, and other ambient equipment/process/compressor noise that may obstruct detection). The commenter therefore recommends that EPA perform or seek out studies of AVO effectiveness across this range of conditions before incorporating it into the FEAST model for calculation of emissions reductions for purposes of equivalency demonstration for alternative monitoring solutions. For example, continuous monitoring is known to have higher effectiveness for emissions detection and mitigation than AVO (see joint comment from Dan Zimmerle, Stefan Bokaemper and Caroline Alden, as well as Appendix B of the commenter's attachment).

Commenter (2333-LongPath) adds for larger sites, the commenter has mitigated emissions from process malfunctions on production equipment that were not identified with AVO. For example, some types of malfunctions can result in emissions from tank equipment with wide-aperture release points. This combination of factors: methane emissions spread across multiple, wide-aperture emission points means that audial, visual, and olfactory senses may be unlikely to identify a problem.

Response II-4-64: With respect to AVO effectiveness, the EPA did use an upper level of detection of 90 percent for AVO monitoring. The EPA acknowledges that the level of detection for AVO will be more variable than OGI because leaks detected by olfactory methods (smell) will largely rely on other constituents present in the natural gas. However, the modeling runs

---

<sup>130</sup> See Colorado's Leak Detection and Repair (LDAR) Annual Reports at <https://cdphe.colorado.gov/oil-and-gas-and-your-health/oil-gas-compliance-and-recordkeeping>.

<sup>131</sup> See Colorado's 2021 LDAR Annual Report, *e.g.*, in 2021, (a) 1,384 leaks requiring repair were detected during 2,790 semi-annual OGI inspections, resulting in an annual rate of 1 leak requiring repair per facility, and (b) 3,668 leaks requiring repair were detected during 9,187 monthly OGI inspections, resulting in an annual rate of 4.8 leaks requiring repair per facility.

<sup>132</sup> See Colorado's 2021 LDAR Annual Report, *e.g.*, in 2021, only 1,546 leaks were detected during 564,427 AVO inspections.

when using AVO alone provided reasonable agreement to the emissions from oil and gas production sites that rely primarily on AVO inspections as reported in the DOE study data.<sup>133</sup> Therefore, the EPA concluded that the modeling assumptions regarding the effectiveness of AVO monitoring were reasonable.

Comment: Commenters (2393-Oklahoma Office of the Secretary of Energy and Environment (OSEE), 2446-IPAA) are not in a position, at this point, to opine on EPA's use of FEAST modeling to demonstrate equivalency with the statutory requirement of BSER. The commenter encourages EPA to continue to consider/accept other models. Consistent with the Oil and Gas Industry's position that EPA should not regulatory lock in a particular technology, like OGI, EPA should retain flexibility to encourage innovation. Commenter (2446-IPAA) recommends EPA also consider whether additional combinations of detection limits and sample frequency detections can enable a broader range of technologies if they can demonstrate equivalency to EPA's determined BSER. For example, EPA could include additional frequencies and combinations of technologies to encourage the deployment of technologies that can demonstrate equivalency with BSER.

Response II-4-65: The EPA is finalizing a fugitive emissions monitoring approach for well sites and centralized production facilities that establishes the monitoring frequency and detection method (AVO and/or OGI) based on results obtained from using FEAST, as discussed in the December 2022 Supplemental Proposal. As previously acknowledged, although the EPA relied on FEAST to model the various programs, EPA expects other available modeling simulation tools to produce similar results.

The final rule includes technology flexibility and does not stipulate a specific technology under the advanced methane detection technology program. Owners and operators have the ability to use a combination of technologies that align with the minimum screening frequencies and minimum detection threshold of screening technology detection thresholds specified in the matrix in the final rule.

Additionally, see Volume II, Chapter 5 for more responses related to alternative technologies and sections X.B.1 and XI.B.1 of the preamble to the final rule for discussion on the final standards related to periodic screening using advanced methane detection technologies and development of the screening matrices.

Comment: Commenter (2446-IPAA) notes that EPA creates three model facilities with detailed component count elements and uses emissions assumptions and emissions simulations using FEAST to create various control technology options. Essentially, EPA produces FEAST based on emissions levels related to throughput – 1% or 0.5% of throughput. For its single wellhead only well site, its multiple wellhead only well site, and its small well site facilities, the production level would be below the threshold of EPA's earlier definition of a low production well. For its large facility, the production level would be three times the level of a low production well. It is because of these assumptions that the model is really more pertinent to the EG since no producer would be planning to drill new wells with these levels of production.

---

<sup>133</sup> Memorandum from Jeff Coburn, RTI International. *Summary of Additional FEAST Modeling Runs*. April 24, 2023.

Commenter (2446-IPAA) states EPA used two resources to justify the validity of its FEAST results – the DOE Study and the Rutherford Study. If EPA had relied on the DOE Study’s actual data for low production wells for the single well site, multiple well site, and small well site analyses, it would need to shift its FEAST inputs. As EPA describes in its materials, the DOE study would have produced the following differences: [Table shows EPA FEAST Emissions – 0.5% Leak Generation and the DOE Study – As Reported by EPA for a single, multiple, or small wells site. The EPA FEAST Emissions had higher estimations for all well sites.]

Commenter (2446-IPAA) disagrees with commenter (2433-EDF et al), stating there is no reason why EPA should use the Rutherford Study as a data source. The genesis of the Rutherford Study relates to the ongoing disputes of differences in studies and inventories, such as the Inventory of U.S. Greenhouse Gas Emissions and Sinks ("GHGI"), which is bottom-up calculations and atmospheric studies. The Rutherford Study seeks to close the gaps by addressing the emissions factors used in the GHGI. It turns to the array of other studies and effectively cherry picks emissions factors from those studies to replace ones in the GHGI. Inherent in this effort is reliance on the same studies that have been used for prior analyses. The commenter has addressed the shortcomings of these studies in past comments – limited sampling times, little or no information on the facility operation, and no certainty on quality control of the data. And, as in past situations, these reports only incidentally take data on the low production wells that are the focus of EPA's analysis. Finally, the Rutherford Study brings no new data to the analysis; it merely regurgitates old, inadequate material.

Commenter (2446-IPAA) states the DOE provides new information with emissions data taken and with facility information at the time of the sampling. The issues with the DOE Study relate to EPA's interpretation. The DOE Study provides substantial new information on the emissions profile of low production wells, but EPA has chosen to limit the use of this material.

Commenter (2446-IPAA) provides an example, with its inordinate focus on component counts as the sole basis to regulate fugitive emissions, EPA immediately discounts how the DOE Study can be used to create a much simpler regulatory path. At this point, it is pertinent to bring into the discussion the use of AVO monitoring for fugitive emissions at oil and natural gas production sites. The commenter has supported the use of AVO monitoring as an alternative to the costly OGI and Method 21 LDAR that have been the primary basis for previous fugitive emissions programs. The commenter supports EPA's decision to embrace AVO in its regulatory framework. It is particularly significant for low production wells. Consequently, in assessing the material in the DOE Study, evaluating the emissions information in a post-AVO application context is imperative. That is, while there may be higher emitting components at a facility, in looking at how to assess regulatory options, those that would be eliminated by an AVO program should be excluded. (Similarly, if the higher emitting component is regulated under a part of EG OOOOc that is separate from the fugitive emissions program, it should be excluded.) The DOE Study demonstrated that low production well sites significant emissions resulted from predictable sources – tank vents or thief hatches, pneumatic controllers at separator vessels, open valves, or damaged piping. All of these can be identified with AVO. This reality is particularly clear for well sites producing 6 BOED or less. Compared to the complicated matrix of well site options in the EPA proposal, this approach would be easily identifiable. Moreover, it would mean that 83 percent of the regulatory burden on low production wells would be managed in a straightforward program.

Commenter (2446-IPAA) notes while EPA continues to believe that component count approaches should define its various regulatory matrices, its regulatory analysis is based on use of FEAST. The commenter lacks the resources to duplicate the EPA FEAST analyses or conduct an independent analysis of the model, but at this point the commenter supports the use of the model and encourages EPA to utilize other models and accept additional modeling results produced after the close of the comment period.

Response II-4-66: As discussed in the December 2022 Supplemental Proposal preamble and noted by the commenter, EPA estimated the fugitive emissions under different monitoring scenarios at well sites uses a FEAST modeling approach. The modeling uses built-in emissions data from various emissions measurement campaigns which were supplemented with additional study data to provide an empirical emissions dataset for the model simulations. The EPA acknowledges the commenter's input regarding the Rutherford, *et al.*, study.

The emissions data used in the FEAST model included data from direct measurement campaigns. Despite some shortcomings of the data in studies analyzed in the Rutherford, *et al.*, study, the study is useful because it analyzes and reconciles multiple sources of data and multiple methods of estimating emissions to arrive at a more robust and validated model of component-level emissions from well sites. The EPA chose to use the Rutherford, *et al.*, study and the U.S. DOE marginal well study to help inform assumptions necessary to establish a baseline emissions scenario in the FEAST model because they represent credible compilations of relevant emissions data at the well site level. The set-up of the FEAST model was further validated by finding that the results generated by FEAST regarding the effectiveness of different OGI monitoring frequencies align well with other values reported in literature. The EPA found that the FEAST results align with the EPA's historical assumptions of 40, 60, and 80 percent, for annual, semiannual, and quarterly OGI monitoring, respectively,<sup>134</sup> and these percent efficiencies compare well to those discussed in the TSD for the 2020 Technical Rule.<sup>135</sup>

EPA disagrees with the commenter's characterization that that EPA placed an inordinate focus on component counts as the sole basis to regulate fugitive emissions. This is not true and EPA and although EPA has noted that the U.S. DOE marginal well study concludes that the frequency and magnitude of emissions from well sites are more strongly correlated with equipment counts than with production rates, this is not the solely basis for the fugitive emissions monitoring structure, which is also based on the equipment located at the well site, importantly, leak-prone equipment known to emit large emissions.

Comment: Several commenters (2286-CDPHE, 2387-Energy Institute, Colorado State University) provide feedback on EPA's FEAST modeling.

---

<sup>134</sup> Specifically, for large well sites at a 0.5 percent leak generation rate, FEAST estimates reductions of 47, 67, and 78 percent, for annual, semiannual, and quarterly monitoring, respectively. For multi-wellhead only well sites at a 0.5 percent leak generation rate, FEAST estimates reductions of 44, 67, and 78 percent, for annual, semiannual, and quarterly monitoring, respectively. For single wellhead only well sites, FEAST estimates reductions of 48, 68, and 77 percent, for annual, semiannual, and quarterly monitoring, respectively.

<sup>135</sup> See section 2.4.1 of "Oil and Natural Gas Sector: Emission Standards for New, Reconstructed, and Modified Sources Background Technical Support Document for the Final Reconsideration of the New Source Performance Standards 40 CFR Part 60, subpart OOOOa." August 2020. EPA-HQ-OAR-2017-0483-2290.

Commenter (2286-CDPHE) concurs with EPA's statement that while EPA used FEAST, EPA expects that other modeling simulation tools would produce similar results. Through the commenter's alternative Approved Instrument Monitoring Method (AIMM) application process, commenter has evaluated applicants' use of both FEAST and the Leak Detection and Repair Simulator (LDAR-Sim). Colorado is also involved in discussions around the development of the Methane Emissions Estimation Tool (MEET). The commenter agrees that determining the appropriate inputs and assumptions in the models is very important, but notes the importance of providing flexibility to technology developers and owners and operators to evaluate the use of alternative monitoring technologies and systems, such as through a variety of tested modeling tools, controlled testing, and/or field testing.

Commenter (2387-Energy Institute, Colorado State University) states EPA should implement representative intermittency in modeling, including the current FEAST model.

Response II-4-67: The EPA acknowledges the commenters input regarding available modeling tools, recommendations for proper inputs to the FEAST model EPA used, and other modeling related comments.

Under the advanced methane detection work practices of the final rule, flexibility in selecting the appropriate advanced methane detection technology is included while ensuring that the alternative standard achieves equivalent or greater efficacy in detecting and reducing methane emissions compared to the use of ground-based OGI surveys, EPA Method 21, and AVO inspections.

With respect to the recommendation to include intermittency in the model, the EPA first notes that intermittency is largely reported with respect to super-emitters. Traditional equipment leaks, like those modeled for fugitive emission components in the BSER analysis are much less prone to intermittency. While some intermittency may occur, the EPA expects that very few of the fugitive emission components will have intermittent emissions, so the inclusion of intermittency is not expected to appreciably impact the BSER determination. Second, the EPA has limited data by which to model intermittency, especially for the more traditional fugitive emission components. To model intermittent emissions, assumptions would have to be made regarding the fraction of leaks that exhibit intermittent behavior and the typical duration of emissions when they are leaking. This information is not available for the fugitive emission components modeled in the BSER analysis. The EPA attributes the limited availability of data regarding intermittency of smaller but more common leaks to the scarcity of intermittent behavior for this class of fugitive emission components and the limited impact of intermittency on the emissions from these traditional fugitive emission components.

Comment: Commenter (2353-CrownQuest Operating, LLC.) notes EPA's FEAST models mistakenly use notably high numbers (1.0% and 0.5%) for leak prevalence (the percentage of components found emitting fugitive emissions during inspections). At first, these figures appear conservative compared to the numbers produced from the Closing the methane gap study referenced by the EPA. Closing the methane gap found a leak frequency of 1.3% using a dataset of 3700 measurements, many of which are from before OOOOa regulation in 2015.

Commenter (2353-CrownQuest Operating, LLC.) states the data the EPA uses as the foundation for its models is from a small and old sample set. The referenced study is not the newest data or a

representative sample group, which skews the sensitive numbers used by EPA to feed their models. The EPA has access to better data. The EPA has millions of component surveys recorded from over seven years of OOOOa regulatory inspections. This data would represent a much larger dataset and newer data than used here, but the EPA chooses not to use it.

Commenter (2353-CrownQuest Operating, LLC.) argues an even better option for quality data is The Environmental Partnership. The Environment Partnership has conducted millions of measurements in the last several years following EPA LDAR inspection regulations. This dataset shows a leak frequency of only 0.08% across millions of OGI surveys conducted within the last several years, which is less than one-sixth of the lowest number used by the EPA to feed a very input-sensitive model. The EPA should use one of these better data sources if it plans to use FEAST models to justify regulation.

Response II-4-68 In the December 2022 Supplemental Proposal, the EPA discussed how it evaluated different leak generation rates for each well site model plant.<sup>136</sup> The EPA modeled AVO and OGI programs at two leak generation rates (1.0 percent and 0.5 percent) to compare the resulting baseline methane emissions against empirical emissions data and identify which model results more closely reflect real-world emissions measurement campaign results. As discussed, EPA's analysis indicated that 0.5 percent leak generation rate was more likely to be representative of the actual average emissions from single wellhead only well sites, small well sites, and multi-wellhead only well sites, based on comparing FEAST modeling results to the average of the U.S. DOE marginal well study and the Rutherford, *et al.*, study. The same conclusion was reached for well sites with major production and processing equipment and centralized production facilities, i.e., a leak generation rate of 0.5 percent appeared to be most representative of real-world emissions from these sources. The sources used to evaluate FEAST modeling results at different leak detection rates are documented credible empirical studies. The final rule establishes a fugitive emissions monitoring program based on the evaluation of a 0.5 percent leak detection generation rate, proven to be appropriate for consideration of the costs of control and appropriate monitoring frequency at all well sites.

#### **4.1.5 Costs/Resources Needed**

Comment: Commenters (2168-INOGA, 2179-KIOGA, 2205-Kriebel Well Services, Inc., 2257-MOGA, 2279-U.S. Small Business Administration, 2308-National Stripper Well Association, 2325-Aclima, 2353-CrownQuest Operating, LLC.) state small entities remain concerned about the cost of OGI requirements and their ability to procure the services of OGI contractors, particularly within the timeframes that EPA's proposal would require.

Commenter (2168-INOGA) states because of the size of a single wellhead well site, particularly those found in the Illinois Basins constructed of less than 120 total components (including fewer than 25 valves), an AVO survey in proximity of the wellhead and associated equipment by the operations team allows for discovery of most gas leaks. The natural composition of the gas in this basin is distinctive, without any additives. Small leaks allow can be identified by an untrained person through their olfactory sense.

---

<sup>136</sup> 87 FR 74729-74739.

Commenters (2168-INOGA, 2172-KOGA) add the small production sites, typical of the legacy gas producing properties of the Illinois Basins often include small compressors and dehydrators and possibly an un-controlled tank but are plumbed together with a minimal number of components and valves. OGI survey requirements for these small sites are unnecessary and a financial and reporting burden on their operator.

Commenter (2439-State of Michigan Department of Environment, Great Lakes and Energy) states the EPA attempts to rationalize the cost of conducting OGI inspections by providing their estimate on what an OGI inspection will cost, however, it seems the EPA's estimates of cost may vary significantly between states. The cost of conducting AVO inspections and reasonable reporting frequency may be as protective, and more economic at existing marginal wells since inspections can be completed during normal business operations and would not require any specialized equipment or travel expenses. Further, production levels could be reconsidered as a basis for consideration of different fugitive emission requirements if one is mindful of the impact these proposed rules will have on small businesses.

Commenters (2205-Kriebel Well Services, Inc., 2308-National Stripper Well Association) state an OGI camera alone costs approximately \$100,000. Some low production well operators may need to purchase more than one to cover the proposed LOAR requirement. Another option for producers would be to hire a consultant, but this becomes costly as well. Consultants charge anywhere from \$500 to \$1,000 to perform OGI to meet the proposed LOAR requirement. Low production well operators with 500 plus wells would conceivably have to budget \$1,000,000+ annually. Commenter (2308-National Stripper Well Association) adds building new reporting systems is expensive and would come with additional increases in payroll costs as new employees would be needed to process all of the required documentation. This will drive these small businesses out of business!

Commenter (2179-KIOGA) cites the independent oil and gas industry should not be burdened with purchasing and learning how to operate an OGI device costing approximately \$90,000 to comply with the fugitive emissions requirements at wellhead only sites. The EPA did not evaluate the cost for these small entities to comply with the proposed EGs; therefore, they should be excluded from applicability.

Commenter (2446-IPAA) states when EPA undertakes its cost-effectiveness analysis for its OGI based proposal, it again assesses the use of AVO as an addition to an OGI program. While this may be appropriate for truly large well sites, a more appropriate analysis for those sites on the borderline between small well sites and large wells would be the initial application of the small well site AVO program followed by the addition of an OGI requirement. This is particularly important because the shift between the requirements is from an all AVO quarterly program to a bimonthly AVO and quarterly OGI program – a fourfold cost increase. A more logical approach would be to move from an AVO small well program to an AVO/OGI mixed program for an intermediate well site to its AVO/OGI program for large sites.

Response II-4-69: The EPA agrees AVO inspections for fugitive emissions monitoring for single wellhead only well sites and small well sites are appropriate. This approach has been retained in the final rule. The specific requirements being finalized for single wellhead only well sites and small well sites are described in section X.A.1.a.ii of the preamble to the final rule for new

sources under NSPS OOOOb and in section X.A.1.b.ii of the preamble to the final rule for existing sources under EG OOOOc.

The EPA did consider the impact of the fugitive emissions monitoring requirements on small businesses in general (*i.e.*, requirements that affect small operators at new and existing sites). This was a factor in determining that for single wellhead only well sites and small well sites, quarterly AVO surveys were appropriate. Inspections using AVO do not require specialized equipment or operator training but does allow the identification of large leaks. In addition, AVO monitoring can easily be built into regular maintenance activities that are designed to keep the equipment at the site in good working order. The EPA is also including final requirements which allow AVO and soap bubble tests as an option for finding fugitive emissions, particularly because they are low cost and easy to implement alternatives for detecting leaks. The EPA believes this will particularly benefit small entities because AVO surveys at these types of well sites are effective at identifying the types of large emissions from sources located at these well sites at a much lower cost than OGI surveys. As shown in Table 10 of the December 2022 Supplemental Proposal, the cost of quarterly AVO inspections at single wellhead only well sites and small well sites were estimated at \$660 per year per site with a cost-effectiveness of less than \$1,200 per ton of methane reduced, which EPA found to be reasonable.

#### **4.1.6 Well Closure Requirements**

##### **4.1.6.1 General Support/Opposition**

Comment: Commenters (1633-Natural Resources Defense Council (NRDC), 1643-Ohio River Valley Institute (ORVI), 1649-The Sisters of St. Francis of Philadelphia, 2156-Catholic Charities of Gallup Diocese, 2163-EOS at Federated Hermes, Ute Indian Tribe-2177, 2181-Ute Indian Tribe of the Uintah and Ouray Reservation, 2201-West Virginia Highlands Conservancy, 2209-Public Land Solutions, 2212-On behalf of the Union of Concerned Scientists, 2215-West Virginia Rivers Coalition et al., 2217-Religious Action Center of Reform Judaism, 2315-New York State Department of Environmental Conservation (NY DEC), 2236-Physicians for Social Responsibility Pennsylvania (PSR), 2271-Private Citizen, 2303-NTAA, 2310-Montana Department of Environmental Quality (DEQ), 2352-Environment Texas Research and Policy Center, 2392-Earthjustice et al., 2394-Earthworks, 2408-Colorado Local Government Coalition, 2410-California Office of the Attorney General et al., 2429-Wyoming Outdoor Council, 2433-EDF et al, 2448-Project Canary, PBC, 2456-Hal Schmid, 2883-US Senator Martin Heinrich et al., 3705-Breathe Easy Susquehanna County) support the proposed rule requirement to monitor abandoned and unplugged wells until all wells have been plugged and equipment removed and require owners to be responsible for all necessary closure plans, financial assurance, and post closure surveying as well as repairs if emissions are detected post closure.

Commenter (1643-ORVI) notes a recent report by the PA DEP found that more than half the conventional oil and gas well operators in the state never report production data and that they have issues over 3,000 violations to “Failure to plug a well upon abandoning it” over the last five years. The report also found that 59% of conventional well operators failed to report mechanical integrity of their wells which means they are not making sure their oil and gas wells are not leaking fluids into groundwater or surface water or natural gas into the air or operating their wells safely.

Commenter (1643-ORVI) states despite producing just 7% of oil and gas in in the four-state Ohio River Valley region, which includes Kentucky, Ohio, Pennsylvania, and West Virginia, low producing stripper wells make up 90% of active wells. The state of WV – because it has so few inspectors, just 9, or one inspector for every 13,000 wells – hardly issues any violations. In 2018, they only inspected 13 abandoned wells and issued 80 notices of violation. Meanwhile, PA DEP issued over 6,000 in 2018 or 75 times the amount in WV despite having just twice as many wells.

Commenters (2201-West Virginia Highlands Conservancy, 2392-Earthjustice et al., 2408-Colorado Local Government Coalition, 2410-California Office of the Attorney General et al.) appreciate EPA’s acknowledgement that emissions from idle wells are, in some cases, “very large,”<sup>137</sup> and EPA’s proposal for monitoring until no emissions are detected by OGI.

Commenter (2408-Colorado Local Government Coalition) adds in Colorado operators must continue to conduct LDAR inspections at shut-in wells provided such wells remain under pressure.<sup>138</sup> In addition, Colorado requires operators conduct Bradenhead monitoring and testing on a monthly basis for wells an operator intends to plug and abandon, as indicated by inclusion on an operator’s out-of-service list, until the operator plugs and abandons the well.<sup>139</sup> Operators must also conduct an AVO or other inspection of each out of service well annually to confirm integrity of the wellhead.<sup>140</sup> New Mexico requires annual Method 21 or OGI inspections at idle wells, beginning 30 days after a well is placed into idle status.<sup>141</sup>

Commenter (2201-West Virginia Highlands Conservancy) agrees with the EPA that idled and unplugged wells can be large sources of emissions. In West Virginia this is certainly true. In West Virginia the number of idled and unplugged wells dwarfs the number of active and producing wells. The commenter strongly supports the requirements to conduct a final monitoring survey using OGI. There are legions of well sites in West Virginia that have never been properly closed. In order to make this rule effective, all of those sites must be included. The commenter would also welcome monitoring at all well sites for the life of the site, until the wells are properly plugged. Well site owners/operators should also have to submit a well closure plan that includes the necessary steps to close the wells, including plugging all wells, documenting financial assurance to complete the well closure, and scheduling for completing closure activities.

Commenters (2177-Ute Indian Tribe, 2181-Ute Indian Tribe of the Uintah and Ouray Reservation) support the proposed AVO and OGI monitoring frequencies until all wells are plugged, equipment removed, and no fugitive emissions are present.

Commenter (2236-PSR) adds leaking equipment, such as valves, pumps, and connectors, are a large source of emissions of VOC and volatile HAP and the EPA and its state counterparts such as the Department of Environmental Protection in Pennsylvania must improve and increase the

---

<sup>137</sup> 87 Fed. Reg. at 74,736.

<sup>138</sup> Colorado APCD PS Memo 14-04, p.10, (May 16, 2022), available at <https://cdphe.colorado.gov/air-permitting-guidance-memos>.

<sup>139</sup> 2 Colo. Code Regs. § 404-1-434.d.(11).A.

<sup>140</sup> 2 Colo. Code Regs. § 404-1-434.d.(11).D.

<sup>141</sup> N.M. Code R. § 20.2.50.116.C.(3)(g).

work of leak detection and repair. The commenters have a massive amount of orphaned and abandoned wells in the state of Pennsylvania.

Commenter (2315-DEC) agrees that proper well closure is important to minimize risk to nearby communities. The commenter's well plugging program focuses on protection of both air and water quality. Their well plugging requirements are designed to prevent brine and hydrocarbons from moving through the well bore and contaminating freshwater aquifers or from escaping at the surface. However, states should have the flexibility to allow gas venting where the risks to groundwater are judged too high.

Commenter (2408-Colorado Local Government Coalition) recommends EPA require operators review, and revise if appropriate, well closure plans for all wells they acquire in an asset transfer transaction. Purchasers should be required to update well closure plans if any circumstances covered by the well closure plan have changed. Specifically, purchasers must provide EPA with an updated well closure plan if any of the following has changed since the original submission of the well closure plan: the steps necessary to close all wells at the well site, including plugging of all wells; the financial requirements and disclosure of financial assurance to complete closure; and the schedule for completing all activities in the closure plan. This will ensure well closure plans remain relevant and up to date.

Commenters (1643-Ohio River Valley Institute (ORVI), 2201-West Virginia Highlands Conservancy, 2212-On behalf of the Union of Concerned Scientists, 2392-Earthjustice et al., 2410-California Office of the Attorney General et al., 2447-Clean Air for the Long Haul) agree with the EPA that idled and unplugged wells can be large sources of emissions.

Commenter (2429-Wyoming Outdoor Council) states, according to estimates from the Wyoming Oil and Gas Conservation Commission, Wyoming has more than 1,300 documented abandoned oil and gas wells on state and private lands alone.<sup>142</sup> These wells are a source of unregulated emissions as well as a liability for citizens and taxpayers. It is critical that EPA's final rule addresses reducing emissions from these wells and establishes clear guidelines for future well closures, such as requiring a closure plan and post-closure OGI surveys to avoid this problem in the future.

Commenter (2433-EDF et al) strongly support EPA's proposal to ensure that all sites are affected facilities subject to some form of ongoing monitoring. Significant emissions, including super-emitter events, have been observed at marginal wells,<sup>143</sup> shut-in wells,<sup>144</sup> abandoned wells<sup>145</sup> and wellheads,<sup>146</sup> underscoring the importance of regular monitoring at these sites until they are properly plugged. These sites are typically older and declining in production, meaning they are

<sup>146</sup> Riddick et al., *supra* note 151; Bowers Report, *supra* note 147, at 19.

less likely to be regularly visited or prioritized for equipment upgrades and repairs. Aging and poorly maintained equipment at these sites can easily fail and leak. EPA's proposed AVO monitoring requirements therefore address an important problem and can both help to prevent emissions and mitigate existing or recurring problems.

Commenter (2433-EDF et al) highlight that exempting declining sites from regulatory requirements could exacerbate end-of-life well issues.<sup>147</sup> This could happen in at least two ways. First, exempting declining sites from inspection requirements means they can exist in a regulatory gray area, subject neither to standards for active wells nor standards for well closure. This may be desirable to operators who seek to avoid facing the costs of plugging and closure.<sup>148</sup> Second, regulatory exemptions for declining sites may increase their attractiveness to potential buyers, some of whom are likely to become insolvent or lack the funds for proper closure.<sup>149</sup> As leading operators seek to reduce emissions, they may offload underperforming and high-emitting assets to private companies lacking environmental commitments or those with business models aimed at prolonging the life of declining assets. This "transferred emissions problem" is a growing concern that can negatively impact emission reduction efforts.<sup>150</sup>

Response II-4-70: The EPA acknowledges supportive comments. As proposed, the EPA is finalizing the requirement to continue fugitive monitoring for all well sites until the site has been closed, including plugging the wells at the site and submitting a well closure report.

Comment: Commenters expressed disagreement with EPA's proposed well closure requirements. Comments on the specific well closure requirements are provided below.

Commenter (2337-KDHE) disagrees with the proposed requirement, particularly for EG OOOOc, that monitoring at all well sites continue for the life of the site, until the wells are properly plugged, and a final monitoring survey using OGI shows there are no emissions. Operators with wells that are not producing oil and/or gas should not have to bear the burden of continual periodic monitoring. The commenter would agree with an initial survey of non-producing wells (exempting Class I and Class II disposal wells as included in the proposed Emissions Guidelines document) and require repair of any leaks found at that time. Beyond that, however, non productive wells, the great majority of which are already pending plugging operations, would be considered exempt from monitoring by the commenter on the basis of remaining useful life (RULOF).

Commenter (2353-CrownQuest Operating, LLC.) states the EPA uses the referenced study<sup>151</sup> to support more monitoring and reporting on temporarily abandoned, plugged, and abandoned wells. Firstly, the authors mentioned nothing about their sampling method. The EPA only selected 37 wells to study in Pecos County. Such a sampling method is not random, which would

<sup>149</sup> See *id.*

<sup>150</sup> Env't Def. Fund, *Transferred Emissions: How Risks in Oil and Gas M&A Could Hamper the Energy Transition* (2022), <https://business.edf.org/insights/transferred-emissions-risks-in-oil-gas-ma-could-hamper-the-energy-transition/>.

<sup>151</sup> Direct measurements from shut-in and other abandoned wells in the Permian Basin of Texas indicate some wells are a major source of methane emissions and produced water <https://iopscience.iop.org/article/10.1088/1748-9326/abf06f/pdf>.

make the data unusable due to human bias in the selection process. The commenter adds Pecos County is known for having very corrosive water and old equipment; it is hardly representative of the Permian basin or the US. In this study, the researchers acknowledge that they tested wells in a region (The Permian) with a uniquely high methane exhaust. Understanding these characteristics is of utmost importance when looking at the data of this study.

Commenter (2353-CrownQuest Operating, LLC.) states the EPA uses the referenced study<sup>152</sup> to justify adding reporting requirements to plugging wells. Not only is this duplicative with other regulations, but it is outside of the EPA's jurisdiction. Well-closure requirements are within the jurisdiction of State Oil and Gas Commissions and other agencies, not the EPA. State law requires a well to be plugged and abandoned when it has reached the end of its useful life.

Commenter (2353-CrownQuest Operating, LLC.) states the EPA identified leaks at 19 of the 37 sites. Of these 19 sites, 11 detections fell below the threshold of EPA-approved OGI cameras used in the LDAR surveys conducted under OOOOa regulations. Knowing that only 22% of wells were emitting at a concentration detectable through approved EPA inspection methods in an area with uniquely high methane emissions is not substantial enough evidence to base such broad inspection regulation on TA and P&A wells. It is unreasonable to apply the findings of such a microscopic study in one specific region to the whole industry. The EPA appears to have confirmation bias considering the study's scope and application in the preamble.

Commenter (2353-CrownQuest Operating, LLC.) adds all states require operators to provide written notice of plugging and comply with regulatory requirements to P&A the well, including removing equipment, setting downhole plugs, cementing in the casing, capping the well to prevent fluid migration, and restoring the surface site. The EPA should gather these records by request through the States rather than burdening operators with unnecessary and redundant reporting.

Commenter (2353-CrownQuest Operating, LLC.) states the EPA uses the referenced study<sup>153</sup> to support more monitoring and reporting on temporarily abandoned wells and plugged and abandoned wells. This study investigates emissions from plugged, unplugged, and idle wells in California, which is not a credible scientific data-gathering method to apply broadly across a large geographic area. The authors admit, "due to limited access, we could not measure wells in most major active oil and gas fields in California."

Commenter (2353-CrownQuest Operating, LLC.) argues a few poorly maintained old wells in California (not even in main production areas) do not represent oil and gas production across the US. Additionally, the two methods of inspection that the authors used do not meet the EPA's LDAR inspection requirements according to Method 21. This study fails to support further monitoring and regulation because it does not show adequate evidence that nationwide wells of this category have significant emissions issues or that more regulation would fix the problem.

Response II-4-71: The EPA acknowledges the comments provided regarding the reports cited in EPA's December 2022 Supplemental Proposal in the context of the proposed well closure

---

<sup>152</sup> Methane Emissions from Abandoned Oil and Gas Wells in California.  
<https://pubs.acs.org/doi/full/10.1021/acs.est.0c05279>.

requirements, however, the EPA disagrees with the commenter and maintains that it is crucial to ensure continued fugitive emissions monitoring on a routine basis to ensure that fugitive emissions continue to be addressed throughout the life of the well site and to prevent the well site from falling into disrepair or becoming orphaned. Therefore, as proposed, the EPA is finalizing the requirement to continue fugitive monitoring for all well sites until the site has been closed, including plugging the wells at the site and submitting a well closure report. See section X.A.1.a.ii of the preamble to the final rule for details.

Comment: Commenter (2177-Ute Indian Tribe) argues well closure regulation is not appropriate in these regulations and should be removed from NSPS OOOOb and EG OOOOc. The commenter requests that the entire well closure section be removed (i.e., §60.5397b(l) and §60.5397c(l)).

Response II-4-72: The commenter provides no information to support the argument to remove the well closure requirements in the rule. The well closure requirements in the final rule remain as proposed.

Comment: Commenters (2392-Earthjustice et al., 2410-California Office of the Attorney General et al, 2447-Clean Air for the Long Haul, 2460-Private Citizen) express that throughout the history of gas and oil production, abandoned or orphaned wells have been a major problem.

Commenter (2447-Clean Air for the Long Haul) states there are in excess of 4,000,000 unplugged, non-producing, and orphaned wells within the United States.<sup>154</sup> In fact the number of documented abandoned wells shot up over 12 percent since 2008 coinciding with the start of the hydraulic fracturing boom.<sup>155</sup>

Commenters (2392-Earthjustice et al., 2410-California Office of the Attorney General et al.) note EPA estimates that, as of 2022, there existed approximately 3.7 million orphaned and abandoned oil and gas wells in the United States, of which over two million remain unplugged and continue to contribute to adverse air and water quality impacts.<sup>156</sup> Further, in 2020, abandoned oil wells emitted 219,000 metric tons of methane and abandoned gas wells emitted 57,000 metric tons of methane.<sup>157</sup>

Commenter (2460-Private Citizen) states the EPA's suggestion of making sure that plugging cost are paid upfront is certainly good. However, there are serious questions as to what the price of plugging should be. The commenter can calculate the money required to plug a well once based

<sup>156</sup> EPA 2022 Greenhouse Gas Inventory, supra n.39, at 3-108 (explaining that only 41% of abandoned wells are properly plugged).

<sup>157</sup> U.S. EPA, Inventory of U.S. Greenhouse Gas Emissions and Sinks, 1990-2020, at p. 3-108 [2021 GHGI], available at <https://www.epa.gov/ghgemissions/inventory-us-greenhouse-gasemissions-and-sinks-1990-2020>. These numbers are likely an underestimate. See Att. 29, Williams et al., Methane Emissions from Abandoned Oil and Gas Wells in Canada and the United States, 55 Env. Sci. Tech. 563 (2020) (finding that annual methane emissions from abandoned wells are underestimated by 20% in the U.S.).

on the size of the well head. The problem is that, with current cement technology, these plugs may have rather short lifetimes, with most of the plugs failing before 50-100 years have passed. The wells will most likely resume leaking methane and other contaminants once the plugs have failed. Should a company be charged for one plug? Or 10? Or 100? Commenter (2460-Private Citizen) argues we need to stop almost all new drilling for gas before the end of this decade. Most wells will need to be decommissioned before 2050. The end of the fossil fuel industry as we know it is coming into sight. Unfortunately, leakage from old wells may last forever.

Commenter (2460-Private Citizen) notes there is promising new technology that suggests that we may be able to produce much stronger and longer lasting cement plugs in the future. A report from MIT highlights research that suggests why Roman cement has survived for millennia.<sup>158</sup> A 2020 paper discusses how nanoengineering approaches can be applied to improving repairs in leaking underground cement casings.<sup>159</sup> Some parts of this research might be applicable to cement plugs. New techniques for improved cement plugs may provide longer lifetimes at an increased cost. It isn't yet clear what the cost of long-lasting plugs will be, but it seems to me that the money required from companies should be greater than needed for just one plug per well using current technologies.

Response II-4-73: The EPA acknowledges comments. As proposed, the EPA is finalizing the well closure requirements to continue fugitive monitoring for all well sites until the site has been closed, including plugging the wells at the site and submitting a well closure report.

#### 4.1.6.2 Outside EPA Jurisdiction

Comment: Commenters (2166-ODNR, 2202-TXOGA, 2219-WOGCC, 2223-Texas Alliance of Energy Producers, 2248-North Dakota Petroleum Council (NDPC), 2254-PBPA, 2258-Marcellus Shale Coalition (MSC), 2294-Ohio Oil and Gas Association, 2298-Pioneer Natural Resources USA, Inc., 2308-National Stripper Well Association, 2326-AXPC, 2337-KDHE, 2353-CrownQuest Operating, LLC., 2401-State of Wyoming, 2403-PAO, 2428-API, 2446-IPAA) do not believe that EPA has the statutory authority to require financial assurance plans and well closure reports from the regulated community. Matters regarding orphaned wells are typically outside of EPA's jurisdiction, resting instead with other federal government departments and with state-level oil and gas commissions.<sup>160</sup>

Commenters (2166-ODNR, 2168-INOGA, 2172-KOGA, 2211-Lambda Energy Resources, 2213-Occidental (Oxy), 2315-NY DEC, 2214-BCAO, 2219-WOGCC, 2223-Texas Alliance of Energy Producers, 2227-Western Energy Alliance, 2252-PAW, 2254-PBPA, 2258-Marcellus Shale Coalition (MSC), 2288-North Dakota Department of Environmental Quality, 2294-Ohio Oil and Gas Association, 2298-Pioneer Natural Resources USA, Inc., 2308-National Stripper

<sup>160</sup> See e.g., Press Release, U.S. Dep't of the Interior, Through President Biden's Bipartisan Infrastructure Law, 24 States Set to Begin Plugging Over 10,000 Orphaned Wells (Aug. 25, 2022) (on file with author) ("The Department of the Interior today announced it has awarded an initial \$560 million from President Biden's Bipartisan Infrastructure Law to 24 states to begin work to plug, cap and reclaim orphaned oil and gas wells."); Colorado Oil & Gas Conservation Commission, Orphaned Well Program FAQ (Mar. 26, 2021) (on file with author) ("COGCC is launching the Financial Assurance Rulemaking, as required by SB 19-181, to address financial assurance requirements in Spring 2021.).

Well Association, 2326-AXPC, 2337-KDHE, 2388-ExxonMobil, 2403-PAO, 2428-API, 2439-State of Michigan Department of Environment, Great Lakes and Energy, 2446-IPAA) believe that EPA should rely upon the existing plugging and abandonment procedures in each state in determining when such plugging and abandoning has occurred. First, each oil and gas state has different and specific rules regarding plugging and abandonment. Each state has a relevant oil and gas commission or department with existing procedures relating to plugging and abandonment. Importantly, those regulations typically define when plugging and abandonment must occur, the notification requirements for plugging and abandonment and the requirements that must be followed in plugging and abandoning a well. Further, states also typically have existing provisions and requirements regarding financial assurance (typically put in place well before abandonment of the well is contemplated). EPA's proposed well closure plan does not consider these existing frameworks and may contradict these existing frameworks – among other problems.

Commenters (2166-ODNR, 2238-SOOGA, 2294-Ohio Oil and Gas Association) state the ODNR already administers a comprehensive regulatory program governing well plugging and abandonment. Ohio's current plugging rules not only address the isolation of natural gas and oil to the formation from which it originated but also consider the protection of ground water and natural resources. Ohio rules also address standards for materials to be used in the process of plugging a well. Commenter (2166-ODNR) requires inspectors to witness well plugging and has trained staff able and ready to do so. The commenters are unaware of evidence demonstrating that already required plugging plans are inadequate.

Commenter (2166-ODNR) finds many state oil and gas regulatory programs require blanket bonds as a means of providing financial assurance for the proper operation of the wells and plugging and abandonment of the wells. The amount of the financial assurance varies from state to state, but in Ohio the amount of a blanket bond is \$15,000. If an oil and gas operator has two oil and gas wells or 2,000 oil and gas wells, the amount of bond required is \$15,000. Should the proposed air emissions rule be adopted and if the cost of the emissions control requirements under the rule become too great, there is a high probability that an operator may abandon all of their wells and forfeit their bond. While Ohio has legal recourse to work to obtain funding from an operator in this example, it is a lengthy process that would result in wells sitting idle without a responsible owner. Worst case scenario, if the operator declares bankruptcy and has no money, Ohio will have the additional wells added to its orphan well inventory. Ohio's orphan well program could grow exponentially if enforcement against the operator fails or if the operator declares bankruptcy.

Commenter (2166-ODNR) continues, under the above-described scenario, the state would then have the responsibility to plug those wells. In Ohio, five companies own more than 16,000 wells. The current average cost to plug a well in Ohio is approximately \$125,000 and is likely to increase with inflation. Should those top five operators abandon all their wells, the plugging liability for the state at today's cost would be more than two billion dollars. In such a case, the burden to the state would be great, and it would defeat purposes established under the Infrastructure, Investment, and Jobs Act, which provided money to states to plug orphan wells to eliminate methane emissions. Even if a portion of the wells would be abandoned by operators, the impact would overwhelm Ohio's orphan well program.

Commenter (2166-ODNR) requests that the EPA remove the applicability of the rules to oil and gas wells that were constructed prior to November 15, 2021. The commenter requests the EPA look at a top-down BACT approach to OOOOb and a RACT approach to OOOOc since there is a potential for significant construction at an existing facility to implement the proposed BSERs.

Commenter (2294-Ohio Oil and Gas Association) argues ODNR's regulatory program governing the plugging and abandonment of wells in Ohio is robust and adequately addresses the concerns that EPA raised regarding the need for a well closure program in the Supplemental Proposal. The commenter provided several notable provisions of Ohio law and ODNR's regulations in their comment letter citing language from various provisions in Section 1509 Division of Oil And Gas Resources Management - Oil And Gas, including 1509.062 Temporary Inactive Well Status, 1509.07 Liability Insurance Coverage, 1509.11 Statement of Production of oil, gas and brine, 1509.12 Defective Wells and Well Plugging.

Commenter (2294-Ohio Oil and Gas Association) notes that ODNR's existing statutory authority and regulatory framework governing abandoned wells is robust, and adequately addresses EPA's concerns regarding such wells. The commenter, whose members operate in several other states, notes that other states have programs regulating abandoned wells similar to ODNR. Accordingly, EPA need not and should not insert itself into this state-led regulatory arena. The commenter states that should EPA proceed with the redundant well closure requirements, the plugging and abandonment of one well at a multi-well site should not require the plugging and abandonment of all wells at the well site.

1. EPA should allow for scheduling flexibilities in completing the well closure activities and eliminate the requirement to conduct an OGI to confirm no emissions from the well post-closure.

Commenter (2304-PIOGA) adds Pennsylvania requires well owners to post a bond or bonds for their wells. PADEP requires plugging with Class A Cement Column. PADEP also has detailed reporting requirements associated with plugging wells, including having PADEP personnel onsite during the plugging operation and requiring the equivalent of a closure report. The reality is each plugging operation is different because the well bore conditions are different, and unknown with certainty. The commenter's members work with PADEP personnel onsite to determine the best way to plug the wells. Respectfully, EPA dictating additional requirements and paperwork provides no additional environmental benefit and creates inefficiencies for owners/operators. The Supplemental Proposal's requirement of an OGI survey for every closed well is excessive and not cost-justified.

Commenters (2168-INOGA, 2172-KOGA, 2247-Ohio EPA) note the administrator will likely receive hundreds or maybe thousands of well closure plans. The commenters ask if EPA evaluated the workforce that will be needed to review these plans and whether this should take place at the federal level or should state resource agencies be in charge of well closure plans. If state agencies are in charge, commenters ask if there will be additional federal funding to assist the state in fulfilling this extra regulatory function.

Commenters (2166-ODNR, 2168-INOGA, 2172-KOGA, 2214-BCAO, 2219-WOGCC, 2227-Western Energy Alliance, 2237-Industrial Commission of North Dakota, 2238-SOOGA, 2288-North Dakota Department of Environmental Quality, 2252-PAW, 2258-Marcellus Shale

Coalition (MSC), 2294-Ohio Oil and Gas Association, 2298-Pioneer Natural Resources USA, Inc., 2304-PIOGA, 2310-Montana Department of Environmental Quality (DEQ), 2315-NY DEC, 2326-AXPC, 2439-State of Michigan Department of Environment, Great Lakes and Energy) provide state-specific comments on their state submission plans. Commenters argue this provision of the rule is unnecessary because the items it intends to require are already handled through other regulatory bodies. The CAA should not be used to add additional layers of redundant requirements. At a minimum, the rules should provide overlap provisions for equivalent state and federal requirements.

Commenter (2227-Western Energy Alliance) states the proposed rules should not require well closure plans. NSPS OOOOb and EG OOOOc should not require continued fugitive emissions monitoring surveys following the plugging and abandonment of a well or site.

Commenter (2227-Western Energy Alliance) provides an example, the 500 Series Rules of Practices and Procedure administered by the Colorado Oil and Gas Conservation Commission (COGCC) require operators to file an application to require plugging and abandonment of a well or closure of an oil and natural gas location. An operator of a well site that is a fugitive emissions component affected facility should be able to cease fugitive emissions monitoring surveys upon closure of the well or site, as provided by the state or federal authority regulating the oil and natural gas industry.

Commenters (2237-Industrial Commission of North Dakota, 2288-North Dakota Department of Environmental Quality) state North Dakota already has a long established well plugging procedure managed through the North Dakota Oil and Gas Division where plugging procedures are reviewed by the Division, aimed at protecting not only the oil and gas production zones from contamination but more importantly the freshwater aquifers that may exist around the well. The well closure plans appear to be redundant considering this review.

Commenter (2248-NDPC) requests that well closure requirements be removed. The EPA's involvement with the plugging and abandonment of oil and gas wells is unwarranted and is under the authority of the North Dakota Industrial Commission (NDIC). The commenter states North Dakota Legislature is currently considering a bill that would allow low producing wells to be idled in preparation for the use of enhanced oil recovery (EOR) methods in the future. EOR has proven to be a success in older wells in North Dakota that would normally be plugged and abandoned. In lieu of that, the ability to idle until the new technology is available prevents large volumes of oil from being stranded. The proposed rule would require operators to unnecessarily monitor those idled wells with OGI when emissions from those wells are minimal.

Commenter (2252-PAW) argues the Wyoming Oil & Gas Commission has a program in place to ensure plugging and abandonment activities occur in line with appropriate practices.

Commenter (2252-PAW) asks does the EPA assume to require different standards of companies through these plans than the companies are already subject to through other regulatory bodies. Does the EPA intend to require wells be closed based on its own judgment, or require additional financial assurance if it deems the BLM's amount insufficient? The EPA should remove all provisions and remove itself from any oversight with regard to well closure.

Commenter (2310-DEQ) notes Montana’s Board of Oil and Gas Conservation follows regional guidelines to plug orphaned wells. In addition, each abandonment plan is evaluated individually to ensure that adequate protections are incorporated. Again, Montana already has an established program to plug orphaned wells and reclaim the area around them.

Commenter (2337-KDHE) disagrees with the requirement for well closure plans, including steps to close the wells, including plugging all wells, documenting financial assurance to complete the well closure, and scheduling for completing closure activities (including any final OGI monitoring), which would effectively duplicate state requirements already in place by the Kansas Corporation Commission (KCC) and may constitute EPA overreach.

Commenters (2168-INOGA, 2172-KOGA) do not deny that wells were inappropriately plugged decades ago. Industry and state agencies have learned about how to appropriately plug wells and have adequately updated their regulations to reflect the current best practices to complete well plugging work. Commenter (2172-KOGA) adds specifically in Kentucky, the EPA’s involvement will require additional agreements to be developed between the Division of Oil and Gas (oversees oil and gas well permitting, operation, and plugging activities) and the Division for Air Quality (oversee compliance with EPA’s emissions regulations). This requirement will be an additional burden on the two state agencies that are at capacity with maintaining their current workload. EPA will be imposing undue burdens on the Division for Air Quality to monitor work that is satisfactorily performed by the Division of Oil and Gas. There is no added value with this requirement.

Commenters (2177-Ute Indian Tribe) state well closure activities are regulated by other agencies. It is not appropriate for EPA to require notification 60 days prior to beginning well closure activities. An annual report that includes all well closures or ownership transfers would be sufficient. The commenter asks the EPA to not require a description of the schedule for completing all activities in the well closure plan.

Commenter (2219-WOGCC) notes EPA is proposing to require operators submit notice of owner or operator changes on the well. This is already required by the state and or BLM, who has regulatory authority over this process. EPA states this will prevent wells from becoming orphan. In actuality, it will do nothing to prevent orphan wells. The unnecessary and tremendous burdens this rule places on operators will create significant numbers of orphan wells as described. EPA being notified who the current operator is will do nothing to remove the burdens or prevent orphan wells.

Commenter (2214-BCAO) states Alaska already has the AOGCC which regulates well closures.

Commenter (2254-PBPA) states the Railroad Commission of Texas regulates well closure requirements within Texas, while the Energy, Minerals, and Natural Resource Department regulates such activities in New Mexico. These requirements will increase the end-of-life costs for wells, and may have a particularly big impact on small businesses operating older wells that already produce less and, therefore, have lower margins. The entire Proposed Rule, but this provision in particular, will disproportionately impact these small operators.

Commenter (2254-PBPA) reiterates a “site” may cover several leases, and there could be situations where an operator no longer has the legal right to inspect a well on a lease that has

expired. To the extent any monitoring of plugged or abandoned wells is required, operators should have flexibility to utilize remote sensing methods or aerial flyovers to reduce burdens and avoid access constraints.

Commenter (2298-Pioneer Natural Resources USA, Inc.) believes EPA should simply require tire submission of written materials required by the relevant jurisdiction reflecting the plugging and abandonment of the well. Once these materials have been submitted, then an operator may cease fugitive emissions monitoring. Relying upon the required reporting to state oil and gas commissions is appropriate and has been relied upon for many years for reporting of well completion operations under OOOO/a.

Commenter (2298-Pioneer Natural Resources USA, Inc.) believes EPA must clarify the language as "steps necessary to permanently plug all wells at a well site" and remove the phrase "including permanent plugging of all wells." For the state of Texas, the proposed requirement to provide "steps necessary to close all wells" is already completed via the required process of Texas Railroad Commission through their W-3A (Intent to Plug) procedure process. This report is required for all permanently plugging of wells. For this reason, operators shouldn't have to duplicate work and submittals when a state has an existing program and process which meets the requirements of 60.5397b(l)(i).

Commenter (2315-NY DEC) notes in states like New York, where undocumented orphaned wells could provide conduits for methane to enter a freshwater aquifer and move into a homeowner's water well and ultimately into their residence due to overpressuring in a nearby plugged well. It is especially important to consider location of wells in the context of environmental justice communities. The commenter recommends that if a state has a plan in place for these communities, that state should be allowed to select the order wells are plugged. If additional incentives are developed, it is important to work with states in determining how incentives are established and distributed.

Commenter (2388-ExxonMobil) participated in a DOE Study that found low producing wells account for about 40% of oil system methane emissions and 60% of natural gas system methane emissions.<sup>161</sup> The commenter supports EPA's proposal for some assessment of a source's emissions level to be conducted before exemptions are applied. The Agency should depend on cooperating state agency determinations for completion of plug and abandonment activities to satisfy the requirement to discontinue monitoring.

Commenter (2428-API) proposes operators maintain records of a well closure plan approved by the local authority with jurisdiction. This recordkeeping only requirement would avoid unnecessary and duplicative requirements with State Oil and Gas Commissions. The records could be submitted to EPA upon request.

Commenter (2428-API) notes EPA provides little new evidence or arguments in the Supplemental Proposal as to why well closure standards are warranted. EPA explains in passing that states and other federal government agencies regulate well closures and have programs to address abandoned and orphan wells. Yet EPA does not conduct an in-depth assessment of these

---

<sup>161</sup> Department of Energy, National Energy Technology Laboratory, Quantification of Methane Emissions from Marginal (Small Producing) Oil and Gas Wells, Project Number DE-FE0031702 (Last Reviewed 09/13/2022).

programs or make any attempt to distinguish how much of the perceived problem with abandoned or orphan wells relates to wells that pre-date the current federal and state programs versus wells that are regulated by such programs. In other words, EPA asserts that well closure standards are needed to address the problem of emissions from abandoned or orphan wells but does not determine that current state and federal programs are somehow deficient and, therefore, need to be supplemented by EPA standards going forward.

Commenter (2428-API) states if EPA had delved more deeply into the current state of affairs, it would have seen that industry, states, and other federal government agencies are making great progress in addressing abandoned and orphaned wells. For example, the federal Bureau of Land Management highlights on its website its extensive regulatory and non-regulatory efforts to address orphan wells, including the hundreds of millions of dollars allocated by Congress in API Comments on NSPS OOOOb and EG OOOOc Supplemental Proposal February 13, 2023 106 the recent “Bipartisan Infrastructure Law” to support tribal, state, and federal efforts in this area. EPA does not even mention the Bipartisan Infrastructure Law in the original or Supplemental Proposals.

Commenter (2446-IPAA) agrees since idle and/or abandoned wells may have emissions, some monitoring might be authorized under the CAA, but EPA has provided no BSER analysis to justify OGI over AVO when a well has been idled or plugged/abandoned. The notice, recordkeeping, bonding, and closure plans are excessive and not sufficiently linked to reducing emissions to be warranted. Additionally, in most instances, they are duplicative and/or potentially inconsistent with what states already require. States and the Bureau of Land Management currently occupy this regulatory space and EPA's proposal is unnecessary.

Commenter (2439-State of Michigan Department of Environment, Great Lakes and Energy) adds Michigan’s plugging requirements are very specific to Michigan’s geology to prevent migration of fluids (including methane) and ensure successful, permanent plugging and abandonment. One example is the proposed rule, as written, would require an operator to wait 60 days before beginning plugging operations. Waiting a prescribed number of days presents a significant threat to human health and the environment. In northern states, weather and frost laws may also be factors and could close the window for timely plugging due to waiting 60 days. If this proposal is finalized as written, the EPA or delegated state program administrator would begin regulating plugging operations on all oil and gas wells in the United States, including those wells which the EPA does not currently permit, potentially diverting resources from oversight of high-priority emitters.

Commenter (3844-Senator Kevin Cramer et al.) states the individual states and the Department of Interior have regulatory oversight authority and programs governing the tracking and remediation of wells and well sites. Congress recently passed bipartisan legislation to fund these programs and the legislation specifically relies on those authorities and programs already in place. By doing this, Congress demonstrated the existing programs and authorities were sufficient to the task, and chose not to create an additional federal bureaucracy for this purpose. Neither should the EPA.<sup>162</sup>

---

<sup>162</sup> Public Law 117 - 58, Section 40601 - Infrastructure Investment and Jobs Act.

Commenter (3844-Senator Kevin Cramer et al.) argues the EPA's duplicative well-plugging language appears to require a well to be plugged if it does not produce for a period of 30 days.<sup>163</sup> This provision ignores the fact wells can be temporarily shut-in for mechanical upgrades, repairs, or in response to market forces.<sup>164</sup> For example, when the beginning of the pandemic shook oil and gas markets in early 2020 and the West Texas Intermediate spot price went negative, more than 770,000 barrels per day were taken off the market by May 2020. This was due to operators temporarily shutting in lower-margin wells and reducing flows in others. When market conditions improved, much later than 30 days, operators brought these temporarily shut-in wells back online and production returned - restoring essential energy supplies that supported the economic recovery from the pandemic.<sup>165</sup> This provision also disregards normal actions an operator may take that can leave a well idle for 30 or more days and all but prohibits transitioning mature wells for use in enhanced oil recovery, which Congress endorsed and incentivized through the 45Q tax credit. The EPA will be forcing states to regulate an oil and gas well constructed decades ago in the same manner as a new, modern well. While 20,000 new wells may be drilled annually, there are about one million existing wells - of which more than 700,000 are low- production, marginal wells. Many of these older marginal wells are owned by small, independent businesses operating on thin profit margins and cannot afford to be regulated the same as large multibillion-dollar corporations.<sup>166</sup> This one-size-fits-all best system of emissions reduction presumptive standard violates the Clean Air Act and its foundational cooperative federalism model. Under the law, the states are to implement and enforce standards of performance for existing sources with source-specific considerations and factors applied.<sup>167</sup> Further, oil and gas producing states are questioning how to fulfill the requirements of the proposal to newly regulate hundreds of thousands of low-producing wells in a relatively short period of time, particularly as no additional funding has been allotted to them to facilitate implementing what is likely an unfunded mandate.<sup>168</sup>

Response II-4-74: See EPA's rationale supporting the proposed well closure requirements provided in the December 2022 Supplemental Proposal<sup>169</sup> and in the November 2021 Proposal, including EPA's request for comment on various provisions that were considered for this program.<sup>170</sup> As described above in comments on the proposed well closure requirements as it relates to EPA's jurisdiction, EPA acknowledges that regulatory requirements exist in various states and other regulatory agency oversight occurs. However, in response to comments on the

<sup>169</sup> 87 FR 74736 (December 6, 2022).

<sup>170</sup> 86 FR 63240-63240 (November 15, 2022).

November 2021 Proposal, and as discussed in the December 2022 Supplemental Proposal, EPA is ensuring that requirements across states meet a minimum level of control, to address concerns by many stakeholders regarding continuing emissions from orphaned wells and unplugged idled wells. Studies have shown that idled wells can have fugitive emissions, and in some cases these emissions can be very large.<sup>171,172</sup> As discussed, the EPA finds that these data demonstrate the importance of continued fugitive emissions monitoring on a routine basis to ensure that fugitive emissions continue to be addressed throughout the life of the well site. Even if various states have their own requirements to address fugitive emissions from idling wells, requirements vary from state to state, and state agencies also have varying definitions for idle, inactive, dormant, or shut-in, but not plugged. State governments also have varied definitions of temporarily idled, orphaned, or non-producing wells. Also, as indicated by the EPA in the November 2021 Proposal, “The EPA recognizes that many oil and natural gas producing States require the plugging of non-producing oil and natural gas wells, and subsequent restoration of the well site. However, the large number of abandoned, unplugged wells nationwide suggests that Federal standards may be warranted.” 86 FR 63241.

The requirement for a well closure plan represents a key element in maintaining transparency for the responsible owner or operator and will also prevent well sites from becoming orphaned in the future. The EPA is finalizing this reporting requirement in the absence of identifying other mechanisms for obtaining this information in a better way.

#### 4.1.6.3 “Cessation” Of Production

Comment: Commenters (2177-Ute Indian Tribe, 2223-Texas Alliance of Energy Producers, 2248-North Dakota Petroleum Council (NDPC), 2257-MOGA, 2294-Ohio Oil and Gas Association, 2298-Pioneer Natural Resources USA, Inc., 2308-National Stripper Well Association, 2326-AXPC), 2428-API, 2446-IPAA) note EPA’s requirement of submitting a well closure plan within 30 days of “cessation” of production. The term “cessation” is ambiguous and does not take into account the wide range of production methods, unique geology, and production profiles that exist in each oil field in the US.

Commenters (2326-AXPC, 2428-API) state EPA’s proposed language regarding well closure could be interpreted to require submission of a well closure plan any time a well has been shut in for more than thirty (30) days. Specifically, EPA’s regulations state “[y]ou must submit a well closure plan to the Administrator within 30 days of the cessation of production from all wells located at the well site.” EPA does not define cessation of production. However, there are a number of instances or reasons that a well could cease production for 30 days without that well being a candidate for closure.

Commenter (2294-Ohio Oil and Gas Association) indicates that the applicability of the well closure requirements being triggered by the “cessation” of production operations is ambiguous. A cessation in production does not necessarily mean that a well is destined for or otherwise

---

<sup>171</sup> Amy Townsend-Small and Jacob Hoschouer. “Direct measurements from shut-in and other abandoned wells in the Permian Basin of Texas indicate some wells are a major source of methane emissions and produced water.” 2021 Environ. Res. Lett. 16 054081. <https://iopscience.iop.org/article/10.1088/1748-9326/abf06f>.

<sup>172</sup> Eric D. Lebel, Harmony S. Lu, Lisa Vielstädte, Mary Kang, Peter Banner, Marc L. Fischer, and Robert B. Jackson. “Methane Emissions from Abandoned Oil and Gas Wells in California.” Environmental Science & Technology 2020 54 (22), 14617–14626. DOI: 10.1021/acs.est.0c05279.

needs to be plugged and abandoned. A temporary cessation in production is quite common in the oil and gas industry and occurs for a variety of reasons including mechanical evaluations, reworking or repair of surface facilities, and to comply with government orders. The commenter requests that the word “cessation” be struck from the rule, and that EPA clarify that the development and implementation of a well closure plan be required only for wells planned for plugging and abandonment.

Commenter (2223-Texas Alliance of Energy Producers) adds wells are often temporarily shut in for mechanical considerations, wellbore issues, reworking or repair of surface facilities or government orders/enforcement.

Commenter (2298-Pioneer Natural Resources USA, Inc.) asks EPA to update the language to read “permanent cessation of production”.<sup>173</sup>

Commenter (2326-AXPC, 3818-AXPC) believes, for the requirement to submit a well closure plan within 30 days of cessation of production, EPA should clarify submittal of the plan is triggered by the operator’s intent to permanently cease production at all wells at a well site. Operators may temporarily cease production at a well site over the life of the site. Given EPA’s intent is to ensure periodic fugitive emissions monitoring occurs until a well is plugged and abandoned, it would be consistent with EPA’s intent to require submittal of a well closure plan only when the operator plugs and abandons all wells at a well site. Until such time as the operator completes the final monitoring survey to confirm no emissions following plugging and abandonment, the operator must continue to conduct leak monitoring surveys at the appropriate frequency. The commenter’s proposal would not change this requirement.

Commenters (2214-BlueCrest Alaska Operating BCO), 2219-WOGCC, 2221-Texas Pipeline Association, 2248-NDPC, 2270-Private Citizen, 2294-Ohio Oil and Gas Association, 2308-National Stripper Well Association, 2428-API, 2446-IPAA) state there are many reasons a well may be shut in for a period of time lasting longer than 30 days. This does not mean the well is at the end of its life and needs to be plugged.

Response II-4-75: The EPA is finalizing the well closure plan requirements as proposed in the December 2022 Supplemental Proposal. The EPA clarifies that that intention of the language in the regulatory text at §60.5397b(l)(1) and in §60.5420b(a)(4)(i) that refers to “cessation of production” means the permanent or final ending of production. The EPA does not find it necessary to make the suggested revision in the final regulatory text.

#### 4.1.6.5 Financial Assurance Requirement

Comment: Various recommendations were received from commenters on the financial assurance requirements in the proposal. These comments are described below.

Commenter (2039-Citizens to Preserve Ligonier Valley, Inc.) notes that bonds are not sufficient to ensure compliance with well closure.

---

<sup>173</sup> Note that Colorado has “well closure” process and it is only required for permanent closing of wells.

Commenter (2184-Social Responsibility Climate Ambassador) states that fracking and oil well sites are routinely monitored for leaks while in operation, and then when closed that they are closed using all available protective measures to ensure they do not leak. This must be done by requiring that drilling companies provide a nonrefundable bond before drilling or to continue drilling -- to prevent drillers from declaring bankruptcy without paying for these preventive measures to close drill sites properly.

Commenter (2298-Pioneer Natural Resources USA, Inc.) argues EPA needs to clarify “financial requirements” and “financial assurance.” These requirements to collect and submit need to be defined or explained with more context. For the state of Texas, the proposal requirement to provide "financial requirements" and “financial assurance” is already completed via the required process of Texas Railroad Commission through their annual P5. This report is required for all organizations and lists all inactive wells the company owns.

Commenter (2298-Pioneer Natural Resources USA, Inc.) believes exemptions should be added for operators who meet/are already meeting the 60.5397b(1)(ii) requirements through their state's program. The commenter's P5 (Organizational Report as well as renewals) with the Texas Railroad Commission are required annually. All inactive wells must be in compliance with the regulations and show they have not failed H-15 (fluid level). The commenter must also submit the following in order for the P5 to be approved/reapproved every year:

- Executed form P5 Organization Report
- Executed form P5O Organization Report Officer Listing
- Check in the amount of \$2,812.50 for P5 filing fee
- Form W3-X Application for Extension of Deadline
- Executed Continuation Certificate for Blanket Performance Bond
- Certificate of Good Standing from the Texas Comptroller of Public Accounts
- W-3C Certifications w/back up data.

Commenter (2252-Petroleum Association of Wyoming (PAW)) argues it is unnecessary for EPA to require companies to disclose their financial assurances to cover the cost of closing a well. State regulators, or other federal agencies such as the BLM, already have requirements for this. Again, this is a redundant and unnecessary function for the EPA to insert itself.

Commenter (2335-Private Citizen) argues oil and gas development companies must be required to provide a bond of a sufficient amount to pay for the monitoring and to ensure that any future problems can be remedied without the spending of significant government funds. This has not been the case in the past.

Commenter (2392-Earthjustice et al.) recommends suggests the inclusion of an estimate of actual closure costs.

Commenter (2425-TCS) states EPA should require financial assurance disclosures to include the bond coverage as well as plugging cost estimates per well, to help evaluate and identify any potential shortfall in cleanup liabilities. For example, the Bureau of Land Management (BLM), which oversees the federal onshore oil and gas program, accepts three types of bond coverage: individual lease bond, statewide bond, and nationwide bond. Due to the prevalent use of blanket

bonds, the average value of bonds held by the BLM in 2018 was \$2,122 per well, while full reclamation costs can range from \$20,000 per well to \$145,000 per well. Due to insufficient bonding, taxpayers will be paying \$46.2 million to plug orphaned wells and inactive wells at risk of becoming orphans. Many states also accept blanket bonds and are facing the same cleanup liability issue. Therefore, identifying the shortfall between actual reclamation cost and bond coverage is paramount before wells become orphaned. Commenter (2425-TCS) also urges the EPA to make financial assurance disclosures and reclamation costs, as well as all information required in well closure plans, publicly available, barring any confidentiality requirements, to increase transparency and accountability of the well plugging process.

Commenter (2433-EDF et al) notes that operators may claim that a statewide bond is sufficient to cover their plugging costs. If a statewide bond is relied on, EPA should require operators to say how much of that bond is allocated to each of their wells. In many cases, the minimum required statewide bond is not actually sufficient to cover the costs of plugging all of an operator's wells in the state. Available financial assurance for well closure should therefore be calculated and demonstrated on a per-well basis. For example, if the operator has posted a \$100,000 blanket bond to cover 500 wells in the state, the operator should report that \$200 are available for well plugging activities. Recent literature estimates typical well plugging costs of \$20,000 for plugging only and \$75,000 for plugging and surface reclamation, with horizontal wells sometimes reaching hundreds of thousands of dollars.<sup>174</sup> Table 5 within the commenter's attachment shows how much money would be available per well for closure assuming a \$20,000 cost, underscoring the inadequacy of most statewide bonds.<sup>175</sup>

Commenter (2433-EDF et al) states the financial demonstration required by EPA should contain an estimate of actual closure costs per well so that EPA and stakeholders can evaluate whether the operator's finances are actually sufficient to close the well in question. Financial requirements to close the well should be based on actual plugging costs from operators' previous plugging operations or the best available data for the well type and region, and should account for the relevant state or federal agency plugging requirements. Subject to confidentiality, these financial requirements and assurance disclosures should be made publicly available and easy to download. EPA should also require operators to submit a financial demonstration immediately in the first annual report and to reaffirm it each year. The commenter recommends that in addition to the schedule for completing the well closure, operators report the physical activities needed to close the well and the requirements of the relevant state and federal agencies. The submitted schedule should enumerate all steps necessary to close each well and the estimated timing of each.

Commenters (2219-WOGCC, 2202-TXOGA, 2428-API) explain emissions from abandoned wells are not as great as EPA suggests and that issues related to well closure are more appropriately addressed by the states and BLM. If EPA decided to move ahead with such standards, the possibility of requiring a demonstration of financial capacity should not be a part of that proposed rule given EPA has no authority under the CAA to impose a financial assurance requirement. EPA cites no legal authority and provides no legal analysis for any aspect of the proposed well closure standards. Such an explanation is needed for such a key and novel aspect of this proposed rule so that interested parties have the opportunity to formulate and submit

---

<sup>174</sup> Daniel Raimi et al., Decommissioning Orphaned and Abandoned Oil and Gas Wells: New Estimates and Cost Drivers, 55 *Env't. Sci. Tech.* 10224 (2021), <https://pubs.acs.org/doi/10.1021/acs.est.1c02234>.

<sup>175</sup> The full analysis is presented in *Env't Def. Fund., Well Bonding Tables* (included as Attachment I).

comments on EPA's legal rationale. CAA § 307(d)(3). The final rule will be procedurally deficient if EPA does not cure this problem.

Commenters (2219-WOGCC, 2202-TXOGA, 2428-API) state the December 2022 Supplemental Notice did not identify any provision of the CAA §111 that provides it with the authority to issue these financial assurance requirements.<sup>176</sup>

Commenter (2202-TXOGA) is also unaware of any such provision. While Congress may have delegated to EPA the power to collect financial assurance reports in the Resource Conservation and Recovery Act, Congress was silent on this matter in the CAA.<sup>177</sup> EPA cannot claim an implicit grant of statutory authority to require this information from owners and operators.<sup>178</sup> In sum, well closure should be monitored until plugged and financial assurance plans should be handled by other agencies, in whose jurisdiction such matters have historically fallen.

Commenter (2219-WOGCC) state EPA's proposed requirement to request financial assurance information is ill timed at best. It appears this requirement is only an attempt to address the rule's creation of additional orphan wells as detailed in previous comments in this letter. Unfortunately, it will do nothing but create even more orphan wells and again illustrates EPA's lack of understanding of the oil and gas industry.

Commenter (2219-WOGCC) notes there are many reasons a well may be shut in for a period of time lasting longer than 30 days. This does not mean the well is at the end of its life and needs to be plugged. In Wyoming, there are wells that are inaccessible in the winter months and must be shut in until warmer weather when roads can be kept open and the site accessible. Shutting in these wells is prudent operatorship and does not mean the well should be plugged and should not require an operator to submit a well closure plan. In other cases, wells may need maintenance and an operator is waiting for parts, supplies, or the availability of a rig or service crew. These can all take much longer than 30 days to schedule or receive and should not trigger a well closure requirement. Other times, the operator is waiting on regulatory approvals to conduct work necessary on the well. Although the commenter attempts to review the plans and grant approvals in less than 30 days, the same cannot be said for various federal agencies that may be involved in the process for wells located on federal or tribal lands.

Commenter (2219-WOGCC) adds that in those cases where a well does need to be plugged, either because is at the end of its economic life or because of issues with the well that requires its plugging, requiring a 60-day notice to EPA prior to conducting plugging operations is problematic. This is especially true if the well has integrity issues and should be plugged as soon as possible to eliminate any risks to public health or the environment. The commenter's regulations require approval of well plugging operations through a Notice of Intent to Abandon form and also a verbal or email notice to the agency a minimum of 24 hours prior to plugging.

---

<sup>176</sup> Comment 10.1.1 on page 40 in EPA-HQ-OAR-2021-0317-0808.

<sup>177</sup> Compare 42 U.S.C. § 6924(a)(6) (Allowing for, among other things, "additional qualifications as to ownership, continuity of operation, training for personnel, and financial responsibility (including financial responsibility for corrective action) as may be necessary or desirable."), with 42 U.S.C. § 7414(a)(1)(A)-(G) (Silent as to "financial responsibility" or "financial assurance plans.").

<sup>178</sup> *W. Virginia v. Env't Prot. Agency*, 142 S. Ct. 2587, 2595 (2022) ("[T]he agency must point to 'clear congressional authorization' for the authority it claims.") (citing *Util. Air Regul. Grp. v. Env't Prot. Agency*, 573 U.S. 302, 324 (2014)).

Within these requirements are plans for plugging the well. These are written for the specific well and take into consideration the well construction details, current condition of the well, zones requiring protection (groundwater, mineral bearing formations, etc), and nearby features. WOGCC rules require plugging the well in such a manner that the well will not allow migration of oil, gas, or water between formations or to the surface. EPA does not have the trained petroleum engineering staff or the understanding of localized site conditions to effectively determine appropriateness of plugging operations.

Commenter (2219-WOGCC) requires operators to post financial assurance for all state and fee wells and are in place to ensure operator compliance with WOGCC rules and regulations including the plugging and reclamation of the well at the end of its life. The commenter conducts an annual review of each operator's financial assurance to ensure the amount each operator has posted is appropriate. EPA requesting financial assurance at the time of plugging requires an operator to shift available capital from plugging the well to purchasing or providing financial assurance. Many operators will have no further funds available to plug the well, which will then become orphan. When this occurs, will EPA forfeit the financial assurance and plug the well? Not likely since EPA does not have the appropriate staff to properly plug a well. Instead, it will fall to the state agency or BLM to complete.

Response II-4-76: In the December 2022 Supplemental Proposal, EPA proposed under the well closure plan requirements in §60.5397b(l)(1) that the plan include a description of the financial requirements and disclosure of financial assurance to complete closure. The final rule retains this requirement at §60.5397b(l)(ii) as a necessary element to prove final closure. As stated in the November 2021 Proposal,<sup>179</sup> “The primary purpose of detailing financial capacity as part of a compliance plan, and to potentially require some financial assurance bonding, is to ensure that State governments have adequate resources to plug oil and gas wells when the owner or operator is unwilling or unable to do so.” The EPA maintains the belief that compliance assurance for well closure requirements will necessitate financial assurance on the part of well owners and operators.

#### 4.1.6.4 AVO/OGI To Prove Final Closure

Comment: Commenter (2433-EDF et al) supports EPA’s proposal to require closure plans and post-closure OGI surveys to demonstrate that plugging has been effective. These requirements will help facilitate plugging in accordance with applicable standards while defining a clear point in time after which a well is no longer an affected facility. Commenter (2428-API) indicates that it is supportive of a final OGI survey to confirm no detected fugitive emissions after well closure.

Commenter (2433-EDF et al) recommends that EPA develop sampling methods for post-closure OGI surveys to ensure plugging has been effective. EPA should ensure all types of abandoned wells are clearly covered by the requirements and clarify who would be subject to these requirements. For example, there are “zombie wells” that are abandoned and not in operation but have a known solvent owner. The commenter believes that these wells should be subject to EPA

---

<sup>179</sup> 86 FR 63241 (November 15, 2021).

fugitive monitoring standards unless and until they are properly plugged, or otherwise declared orphans and then addressed through orphan well plugging programs.

Response II-4-77: The EPA acknowledges the supportive comment. As proposed, the EPA is finalizing the requirement to conduct a final OGI survey of the well site to ensure there are no emissions following plugging all of the wells at the site and completing closure activities. Steps must be repeated until emissions are eliminated as confirmed by no emissions imaged by the OGI instrument.

Comment: Commenters (2168-INOGA, 2172-KOGA, 2177-Ute Indian Tribe, 2223-Texas Alliance of Energy Producers, 2294-Ohio Oil and Gas Association, 2298-Pioneer Natural Resources USA, Inc., 2337-KDHE, 2446-IPAA, 2713-Northeast Natural Energy LLC) state the use of OGI to prove final closure is expensive and unnecessary. If a well is insufficiently plugged, the operator will know after the cement is pumped to protect the freshwater zones. State oil and gas agency verification of proper plugging, absence of gas cut cement, and proper plating of the well should be sufficient to ensure the plugged well is not leaking. Commenter (2439-State of Michigan Department of Environment, Great Lakes and Energy) currently utilizes OGI camera to verify inadequate plugging where other evidence exists and has made operators drill out and re-plug wells where gas cut cement has occurred. These instances should not occur if wells are plugged properly under static conditions.

Commenters (2168-INOGA, 2172-KOGA) indicate that the use of OGI to prove final closure is expensive and unnecessary for the typical Illinois Basin wells. The wells have been producing from low pressure reservoirs. Liquid and gas flow can be eliminated from most of these wells by filling the wellbore with a column of water. The static head of water (i.e., pressure) created by filling the wellbore with water is greater than the pressure of the reservoir. Filling the wellbore with cement and fresh water is sufficient to overcome reservoir pressure.

Commenters (2168-INOGA, 2172-KOGA) state a final AVO survey with soap water or possibly a survey with a “flame pack” gas leak detector should be sufficient proof of plugging without the use of expensive OGI. Commenters (2223-Texas Alliance of Energy Producers, 2713-Northeast Natural Energy LLC) state AVO or a hand-held methane detector is certainly sufficient.

Commenter (2294-Ohio Oil and Gas Association) believes EPA should allow for scheduling flexibilities in completing the well closure activities and eliminate the requirement to conduct an OGI to confirm no emissions from the well post-closure.

Commenter (2308-National Stripper Well Association) proposes regulatory requirements for inactive wells be addressed through an AVO only program, perhaps semiannually.

Commenters (2223-Texas Alliance of Energy Producers, 2308-National Stripper Well Association) argue EPA has provided insufficient technical and factual analysis to justify use of OGI when a well has been idled or plugged/abandoned. Further, EPA provided no explanation of why AVO would not suffice. The economics dictate that a well that is being plugged is more likely than not to be a low production well, and that low production well is operated by a small business. Requiring OGI when a well is plugged would place a disproportionate cost on small businesses that is not justified.

Commenter (2446-IPAA) agrees since idle and/or abandoned wells may have emissions, some monitoring might be authorized under the CAA, but EPA has provided no BSER analysis to justify OGI when a well has been idled or plugged/abandoned. EPA provided no explanation of why AVO would not suffice. The economics dictate that a well that is being plugged/abandoned is more likely than not to be a low production well and that low production well is operated by a small business. Requiring OGI when a well is plugged would place a disproportionate cost on small businesses that is not justified. The notice, recordkeeping, bonding, and closure plans are excessive and not sufficiently linked to reducing emissions to be warranted. Additionally, in most instances, they are duplicative and/or potentially inconsistent with what states already require. States and the Bureau of Land Management currently occupy this regulatory space and EPA's proposal is unnecessary.

Response II-4-78: The EPA acknowledges comments asserting that OGI to prove final closure is expensive and unnecessary and request for alternatives. However, the EPA disagrees, and as proposed, the EPA is finalizing the requirement to conduct a final OGI survey of the well site to ensure there are no emissions following plugging all of the wells at the site and completing closure activities. If any emissions are identified, the owner or operator would be required to take steps to eliminate those emissions and resurvey. The OGI survey would ensure there are no emissions present, and the well site would be considered closed and no further fugitive emissions monitoring would be required. In response to request for alternative methods to prove there are no fugitive emissions, such as the use of AVO, EPA disagrees. Detection of the smallest emissions are not easily identifiable using AVO. The use of OGI to provide final closure of the well has therefore been retained in the final rule at §60.5397b(l)(3). This requirement provides a clear indication when fugitive emissions are no longer a concern at the site, plus this requirement would prevent well sites from becoming orphaned or left in an idled and unplugged state with no form of emissions monitoring and repair.

#### 4.1.6.5 Other Well Closure Requirements

Comment: Commenters (2394-Earthworks, 2403-PAO, 2410-California Office of the Attorney General et al., 2433-EDF et al, 2439-State of Michigan Department of Environment, Great Lakes and Energy) note EPA proposes to require owners and operators to develop and submit a well closure plan within 30 days of the cessation of production from all wells at the well site or centralized production facility. The plan would include: (1) The steps necessary to close all wells at the well site, including plugging of all wells; (2) the financial requirements and disclosure of financial assurance to complete closure; and (3) the schedule for completing all activities in the closure plan. The EPA is also proposing to require that owners and operators submit a notification to the Agency 60-days before beginning well closure activities. Additionally, EPA is proposing to require owners and operators to report, through the annual report, any changes in ownership at individual well sites so that it is clear who the responsible owners and operators are until the site is plugged and closed and fugitive emissions monitoring is no longer required.

Commenters (2392-Earthjustice et al., 2408-Colorado Local Government Coalition) support the requirement that an operator submit a well closure plan. However, the commenter recommends EPA require operators submit this plan at the beginning of a well's life (specifically within 30 days of receipt of approval to drill a well) rather than at the end of a well's life. This is necessary to ensure that operators have an adequate plan in place to ensure the proper plugging and abandonment of all wells. The time when an operator is best positioned to put aside resources to

cover the costs of properly plugging, abandoning, and reclaiming any environmental contamination, is during the initial phase of well development. It is then that a well is most productive and the operator has access to a steady revenue stream from hydrocarbon production. Waiting to require a well closure plan until a well is at the end of its life, and thus at the tail end of its productive, revenue-generating life, could lead to the submission of inadequate plans.

Commenter (2326-AXPC) states nothing in EPA's preamble suggests that EPA is intending to use (or even legally could use) these well closure plan requirements to mandate the plugging and abandonment of wells. EPA's preamble makes clear that EPA simply intends to have written confirmation of plugging and abandonment of the well before an operator may cease fugitive emissions monitoring. Fortunately, EPA does not need to create a new well closure plan to obtain this information. Rather, EPA should simply require the submission of written materials required by the relevant jurisdiction reflecting the plugging and abandonment of the well. Once these materials have been submitted, then an operator may cease fugitive emissions monitoring. Relying upon the required reporting to state oil and gas commissions is appropriate and has been relied upon for many years for reporting of well completion operations under OOOO/a.

Commenter (2326-AXPC) believes, for the requirement to submit a well closure plan within 30 days of cessation of production, EPA should clarify submittal of the plan is triggered by the operator's intent to permanently cease production at all wells at a well site. Operators may temporarily cease production at a well site over the life of the site. Given EPA's intent is to ensure periodic fugitive emissions monitoring occurs until a well is plugged and abandoned, it would be consistent with EPA's intent to require submittal of a well closure plan only when the operator plugs and abandons all wells at a well site. Until such time as the operator completes the final monitoring survey to confirm no emissions following plugging and abandonment, the operator must continue to conduct leak monitoring surveys at the appropriate frequency. The commenter's proposal would not change this requirement.

Commenter (2392-Earthjustice et al.) recommends that operators submit a schedule enumerating all steps necessary to close the well along with estimating timing for each activity.

Commenters (2223-Texas Alliance of Energy Producers, 2308-National Stripper Well Association) argue the notice, recordkeeping, bonding, and closure plans included in the proposed rule are excessive and not sufficiently linked to reducing emissions. Commenters (2308-National Stripper Well Association, 2446-IPAA) note EPA provides no justification or rationalization for requiring a description of the steps to close all wells at the well site when it is not uncommon for simply one well to be identified as uneconomical and thus slated for plugging while remaining wells remain in service.

One commenter (2453-CMRMI) supports the EPA proposal to require owners and operators to communicate all changes of ownership of individual well sites through annual reports to increase visibility and reinforce each new owner's responsibilities. Given orphaned wells often have no defined legal and responsible owners, improperly closed and orphaned wells are at risk of indefinitely producing emissions. The commenter notes that the inclusion of this disclosure in annual reports, as clear documentation, consolidated within the EPA's repository, should decrease confusion regarding ownership and associated obligations. Annual reports should include information about owners, operators if different, and certification of notification to relevant state authorities (departments of environmental quality, counties, oil and gas authorities,

etc.) for record keeping and consistency between state and federal agencies. Many state authorities already require such notifications and checking that such steps are processed in federal annual reports would greatly increase participation and improve the accuracy of state-wide databases. Similarly, other relevant information such as state customer numbers, authorized signatories, site contact information, and corporate/administrative contact information could be included to further synchronize state and federal databases. If state-wide databases are up-to-date and in sync with federal databases, state authorities may be able to better assist the EPA in preventing orphaned wells and ensuring proper well closure.

Furthermore, commenter (2453-CMRMI) notes that change in ownership may affect sites included within the super-emitter program. As the EPA is seeking comment on all aspects of this proposed program, we recommend also sharing information regarding changes in ownership with the super-emitter public database, in order to highlight if ownership has changed since notice of the event.

Response II-4-79: EPA is finalizing the well closure requirements as proposed, which requires the inclusion of the steps necessary to close all wells at the well site, including permanent plugging of all wells as well as submitting a description of the schedule for completing all activities in the well closure plan. The EPA is maintaining the requirement that owners and operators submit a notification to the Administrator 60 days before beginning well closure activities, but EPA does not believe it is necessary for operators to submit their schedule in advance of the planned well closure activities.

The final well closure plan is intended to demonstrate that a well site has reached that point where it is appropriate to cease fugitive monitoring, and the steps necessary to close all wells at the well site, including plugging of all wells; the financial requirements and disclosure of financial assurance to complete closure; and the schedule for completing all activities in the closure plan. The well closure plan makes sure owners or operators detail the necessary information in order to ensure compliance.

Comment: Commenter (2418-South Dakota Department of Agriculture and Natural Resources (DANR)) notes on page 74736 of the preamble, EPA requests comment on additional provisions that could be added, including, for example, automatic consequences for missed monitoring reports, as a means of assuring that companies remain engaged with the site, including conducting monitoring, until all the wells at the site are properly closed.

Commenter (2418-DANR) responds, South Dakota is a rural state, which means companies and the state may need to drive hundreds of miles to reach a regulated site. In addition, South Dakota's significant weather changes (e.g., winter blizzards) can impact travel and mail delivery. As such, the commenter recommends EPA not add automatic consequences for any type of late or missing reports but instead give states flexibility in their decision making on enforcement responses.

Commenter (2410-California Office of the Attorney General et al.) suggest an automatic consequence for an owner's or operator's repeated failure to submit monitoring reports should include a requirement to permanently cease production, submit a well closure report, and permanently plug all wells at the site. When owners and operators are no longer monitoring and staying engaged with well sites there is a greater potential for them to deteriorate and leak or

become orphan wells. By requiring owners and operators to close well sites as an automatic consequence of failure to comply with monitoring requirements, the NSPS and EG will incentivize owners and operators both to comply with monitoring requirements and to either produce or plug wells, rather than leaving them idled and unplugged or abandoning them to become orphan wells.

Response II-4-80: In the December 2022 Supplemental Proposal, the EPA solicited comments on potential additional provisions that could be added to the well closure provisions, including, for example, automatic consequences for missed monitoring reports, as a means of assuring that companies remain engaged with the site, including conducting monitoring, until all the wells at the site are properly closed. The EPA acknowledges comments provided in response to this solicitation, but EPA is not incorporating any automatic consequences in the final rule as this could be overly restrictive and not account for circumstances beyond the operator's control.

Comment: Commenter (2410-California Office of the Attorney General et al.) disagrees with comments stating EPA should consider adding restrictions on the amount of time that operators are allowed to idle wells and limit the number of idle wells that an individual owner or operator can hold.<sup>180</sup> For instance, under New Mexico's regulations, an operator is allowed to idle no more than a certain percentage of its wells: two wells or 50 percent of the wells the operator operates, whichever is less, if the operator operates 100 wells or less; five wells if the operator operates between 101 and 500 wells; seven wells if the operator operates between 501 and 1,000 wells; and 10 wells if the operator operates more than 1,000 wells.<sup>181</sup> New Mexico also requires operators to either properly plug and abandon a well or place the well in approved temporary abandonment after drilling operations have been suspended for 60 days, the well has been determined to be no longer usable for beneficial purposes, or the well has been inactive for one year; and limits the time allowed for approved temporary abandonment to five years.<sup>182</sup> The longer wells are allowed to remain idle, the greater potential that they will become orphan wells. Also, a high percentage of idle wells may indicate an increased vulnerability of the owner becoming insolvent and leaving orphan wells.

Response II-4-81: EPA acknowledges the comments. The final rule does not restrict the amount of time that operators are allowed to idle wells.

Comment: Commenter (2298-Pioneer Natural Resources USA, Inc.) notes in 60.5397b(l)(3) the proposal states that operators must update the well closure plan specified in paragraph (1)(1) of this section to include the video of the OGI survey demonstrating closure of all wells at the site, and in §60.5410b(k)(5) that operators should keep records as stated in §60.5420b(c)(14). The commenter does not understand the need for a video of the OGI survey for the well closure requirements, especially since videos are not required for routine OGI inspections for LDAR. Keeping this "video footage" for the required 5 years of NSPS requirements is not only difficult but almost impossible when it comes to data restraints for technology, downloads, data storage, etc. Therefore this requirement is infeasible and overly burdensome.

---

<sup>180</sup> See Att. 21, IOGCC, Idle and Orphan Oil and Gas Wells: State and Provincial Regulatory Strategies 2021 (detailing state regulatory strategies for addressing orphaned wells).

<sup>181</sup> 19.15.5 NMAC.

<sup>182</sup> 19.15.25 NMAC.

Commenter (2298-Pioneer Natural Resources USA, Inc.) strongly urges EPA to remove this OGI video requirement altogether and/or require it only for facilities required to comply with Appendix K where EPA has justified more extensive monitoring, recordkeeping, and reporting requirements.

Response II-4-82: The EPA disagrees with the commenter and is maintaining the requirement in the final rule to include the video of the OGI survey in the well closure plan demonstrating closure of all wells at the site. This requirement will allow EPA and state agencies the ability to review the OGI survey video and confirm compliance with the rule.

The EPA does not believe that the standard requirement of maintaining records for 5 years is an onerous requirement and the rule includes alternatives to maintain records, and any records required to be maintained by this subpart that are submitted electronically via the EPA's CDX may be maintained in electronic format.

Comment: Commenters (2177-Ute Indian Tribe, 2271-Private Citizen, 2410-California Office of the Attorney General et al.) support EPA's proposal to require reporting, through the annual report, of any changes in ownership at individual well sites. The commenter agrees that such a requirement will help prevent well sites from becoming orphaned by providing clarity as to who the responsible owners and operators are until the site is plugged and closed and LDAR is no longer required.

Response II-4-83: The EPA acknowledges supportive comments.

Comment: Commenter (2433-EDF et al) recommends that EPA require the final well closure plan to be submitted 30 days prior to the cessation of production of any well located at the site. Public reporting should also occur when the well has been properly plugged so regulators can verify closure and so EPA can de-list the site.

Response II-4-84: EPA is finalizing the well closure requirements, including the requirements for the well closure plan in §60.5397b(l)(1) as proposed, which specifies submitting the well closure plan to the Administrator within 30 days of the cessation of production from all wells located at the well site. The EPA disagrees the well closure plan should be submitted prior to the end of production and believes maintaining flexibility in the submittal timing is appropriate.

#### **4.1.7 Other**

Comment: Various commenters provided input regarding the treatment of plugged and abandoned wells. These comments are summarized below.

Commenters (2039-Citizens to Preserve Ligonier Valley, Inc., 2199-Rocky Mountain Farmers Union, 2209-Public Land Solutions, 2212-On behalf of the Union of Concerned Scientists, 2217-Religious Action Center of Reform Judaism, 2335-Loren Karro, 2352-Environment Texas Research and Policy Center, 2408-Colorado Local Government Coalition, 2414, 2453-Carbon Mapper and RMI, 2425-Taxpayers for Common Sense (TCS), 2447-Clean Air for the Long Haul, 2448-Project Canary, PBC) suggest that plugged and abandoned wells be intermittently monitored to be sure that the plugging actions taken are sufficient to eliminate oil and gas leakage in perpetuity.

Commenters (2219-WOGCC, 2401-State of Wyoming) add the well closure section of EPA's proposed rule states that requiring well closure plans would address concerns regarding continuing emissions from orphaned wells and idled wells. Mentioning orphan wells here seems to imply that EPA would implement these well closure requirements on orphan wells. EPA has no authority over how the commenter manages its orphan well program and no authority to require commenters (2219-WOGCC, 2401-State of Wyoming) to implement these well closure requirements. While commenter (2219-WOGCC) requests EPA strike the entire section on well closure since it is outside of EPA's authority, EPA should also recognize it cannot require the states to implement any of this program on orphan wells and should remove any reference to orphan wells in this section.

Commenter (2223-Texas Alliance of Energy Producers) notes that abandoned and plugged wells are no longer accessible by operators in Texas. This is because the operator retains zero access rights once a well has been properly plugged and reported as abandoned to the state regulator. An operator, if EPA's proposal was adopted, would be forced to maintain existing rights to the well and under existing law would be forced to delay proper and necessary plugging operations. Here, EPA risks contaminating groundwater or surface soils in the name of air monitoring which is completely contrary to the overall goals of improving the air and water subject to EPA's jurisdiction.

Commenter (2226-Thermo Fisher Scientific) agrees with the EPA's proposed requirement to monitor abandoned and unplugged oil wells using OGI. However, the commenter encourages the EPA to conduct additional monitoring with technology beyond OGI. In certain circumstances, OGI can miss emissions due to operator error, or emissions may change after the survey. The commenter recommends using more acute handheld measurement devices (like Thermo Fisher's Toxic Vapor Analyzer 2020) in conjunction with the OGI to ensure emissions are appropriately accounted for. Additionally, the EPA should consider continuous emissions monitoring technology for abandoned and unplugged wells of high risk for gas leaks.

Commenters (2363-CEMC, 2448-Project Canary, PBC) believe operators should monitor pre-plugging and document any flow rate and concentration to determine a calculated emissions rate (grams per hour) using best available technology, such as a high-fidelity (1 gram/hour or lower), ground-based technique and instrumentation and conducted by a person trained in that measurement methodology. For this level of fidelity, OGI is not sensitive enough to conduct a detect/non-detect for these wells. After a well is plugged, the operator should monitor the well to confirm that the plug was successful and there are no longer emissions present, whether through the wellbore itself or nearby soil. Data measurement and quality assurance criteria should meet the federal program information needs for methane measurement and allow for aggregation. Documentation should include weather/environmental conditions under which the measurement occurred, location of the detection, and the maximum emissions concentration recorded in ppm. It is recommended that multiple measurements be recorded before and after plugging the well to verify the effectiveness of the measurement.

Commenter (2392-Earthjustice et al.) states the median cost for decommissioning an orphaned well is roughly \$20,000 for plugging, and \$76,000 when surface reclamation is also required.<sup>183</sup>

---

<sup>183</sup> Daniel Raimi et al., Decommissioning Orphaned and Abandoned Oil and Gas Wells: New Cost Estimates and Cost Drivers, 55 *Env't Sci. & Tech.* 10224, 10224 (2021), <https://pubs.acs.org/doi/pdf/10.1021/acs.est.1c02234>.

Because these wells have no solvent owner on record, the burden of remediation falls on local, state, and federal governments and diverts resources that could otherwise be used for the public good.

Commenter (2392-Earthjustice et al.) continues, the adverse economic impact imposed by remediation of orphaned and abandoned wells is disparately distributed. States with the largest Latine populations also have significant concentrations of orphaned and abandoned wells. For instance, the populations of California and Texas are both approximately 39% Latine<sup>184</sup> and these two states had 5,063 and 7,151 known orphaned wells in 2022, respectively.<sup>185</sup> And of the nearly 9 million people in the United States living within one mile of one of these wells, approximately 2.5 million are Latine.<sup>186</sup> In Pennsylvania, the state with the largest number of orphaned and abandoned wells, wells are concentrated in rural and low-income areas.<sup>187</sup>

Commenter (2392-Earthjustice et al.) adds research has repeatedly identified a link between proximity to abandoned wells and declining values of nearby property. A recent study in southwest Pennsylvania found that, over fifty years, the two acres around orphaned wells had approximately half as much development as the area around plugged wells.<sup>188</sup> The study further found that “the typical unplugged well leads nearby properties to have a market value 12% less than properties near plugged wells,” resulting in wide-ranging impacts on local economic development and revenue raising for schools and basic municipal maintenance.<sup>189</sup> A similar study conducted in Colorado found that “shale development negatively impacts house prices,” and that merely having a well in sight of a house reduces its value by approximately \$3,000.<sup>190</sup> Because oil and gas wells are disproportionately located in and near low-income communities and communities of color, as discussed above, these communities are left to bear the economic burden of this infrastructure.

Response II-4-85: In response to comments on the November 2021 Proposal, the EPA did not propose any requirements for these sources in the December 2022 Supplemental Proposal. The

EPA is finalizing well closure requirements, but no requirements are being finalized for abandoned wells, unplugged wells, or wells that are plugged insufficiently.

Comment: Commenter (2196-Roy Massengale) notes a probable citation error/typo. The cited section should say (g)(1)(iii)(A) through (C).

§60.5397b(g)(1)(iii)(D): Two or more pieces of major production and processing equipment not specified in paragraphs (g)(1)(ii)(A) through (C).

Response II-4-86: The commenter is correct. The EPA has corrected the citation in the final regulatory text.

Comment: Commenter (2298-Pioneer Natural Resources USA, Inc) designs multi-well pads that direct the flow into large, centralized tank batteries. Wells are not drilled on multi-well pads all at once but rather wells are added to existing pads over time. Therefore, the commenter has assessed that it will have both NSPS OOOOa and NSPS OOOOb affected wells on the same pads. Due to difficulty this could present with the different monitoring requirements on the same pads, the commenter recommends that EPA align the monitoring requirements/or wells on the same pad. Similar to the approach EPA took for pneumatic controllers in §60.5365b(d)(1),<sup>191</sup> it would streamline monitoring if one well on the pad is subject to NSPS OOOOb, that all of the wells on the pad become subject to NSPS OOOOb - the result will be less miles driven and emissions generated.

Response II-4-87: The rule specifies at §60.5365b(i)(1)(i) that if a new well is drilled at an existing well site this would be considered a modification. The well site would therefore be subject to NSPS OOOOb if the modification occurred after December 6, 2022. Similarly, if a new well is drilled at an existing centralized production facility, this would also be considered a modification, and the centralized production facility would be subject to NSPS OOOOb if the modification occurred after December 6, 2022.

Comment: Commenter (2248-NDPC) is requesting clarification on acceptable methodology for determining a site's fugitive emissions. EPA should allow for any state-approved and/or industry best practices to quantify fugitive emissions.

Response II-4-88: The EPA is uncertain what the commenter is requesting. The fugitive emissions monitoring requirements in the December 2022 Supplemental Proposal were based on the equipment located at the well site. The final rule maintains this equipment-based approach, which does not require the quantification of fugitive emissions.

Comment: Commenter (2248-NDPC) wants to remind the EPA that LDAR programs do generate emissions, because the OGI inspectors must drive from site to site. The commenter believes the requirement to inspect wellhead only sites, and sites where wells have been abandoned, vehicle emissions will outweigh any benefit the program may identify.

---

<sup>191</sup> " ... in addition to the definition in §60.14, a modification occurs when the number of pneumatic controllers at a site is increased by one or more."

Response II-4-89: The EPA acknowledges the commenter’s concerns regarding secondary impacts. As mentioned in the November 2021 proposal preamble and the 2021 Proposal TSD, there are no secondary gaseous pollutant emissions or wastewater generated during the monitoring and repair of fugitive emissions components. Emissions would be generated during travel to or from sites during inspections and surveys. The emissions generated by that activity was presented in section 5.5.3 of the 2021 Proposal TSD.<sup>192</sup>

Comment: Commenter (2428-API) notes state rules, including New Mexico<sup>193</sup> and Colorado<sup>194</sup>, exempt depressurized equipment<sup>195</sup> from fugitive emissions monitoring because leak surveys are not anticipated to result in emissions reductions at these facilities. Monitoring would resume once the site or equipment is back in service. EPA should provide a clear exclusion for these types of facilities or equipment under both NSPS OOOOb and EG OOOOc. One suggestion would be to model the regulatory language on the existing storage vessel out of service and return service requirements.

Response II-4-90: The EPA agrees that the periodic fugitive emission monitoring should be conducted while the facility is operating such that there is a potential for emissions from fugitive emission components. Thus, if a site is down for maintenance when periodic monitoring was originally planned to occur, the periodic monitoring should be rescheduled for a time when the facility is operating. However, it appears the commenter is suggesting revisions to exclude “depressurized” equipment at an otherwise operating facility. The EPA believes this will increase burden rather than decrease burden. Monitoring must be conducted according to the monitoring plan, which identifies all fugitive emission components to be monitored. To effectively exclude one piece of equipment, the facility would need to continually revise its monitoring plan to track the fugitive emission components required to be monitored during changes in operation. For example, a compressor station may have four compressors, three operating compressors and one depressurized compressor. The compressors are commonly cycled so maintenance or other activities can be performed on the additional “fourth” compressor. Once an OGI camera operator is on site, it takes little time to monitor all four compressors additional piece of equipment; however, we expect it will take significant additional time to revise the monitoring plan based on constantly changing operations and the compressors are cycled in and out of service. The EPA notes that nothing in the rule prevents the owner or operator of a site to revise its monitoring plan. If a well is shut-in for a prolonged period, the monitoring plan can be revised to identify the fugitive emission components that must be monitored (those with a potential for VOC or methane emissions) during the shut-in. Thus, there are already provisions in the rule to allow facilities to exclude equipment that is no longer in service because they no longer meet the definition of fugitive emission component from their monitoring plan. However, we are not requiring facilities to update their monitoring plans each and every time a piece of equipment is depressurized.

Comment: Commenter (2211-Lambda Energy Resources) states many wells in the Michigan basin operate on vacuum from the wellhead to the sales point. Lambda’s wells operating on vacuum have continuous monitoring for oxygen at the sales point which would indicate a leak

---

<sup>192</sup> See November 2021 TSD at Document ID No. EPA–HQ–OAR–2021–0317–0166.

<sup>193</sup> 20.2.50.116.C(9) NMAC.

<sup>194</sup> <https://drive.google.com/file/d/1a3IJ74txUxJ241wgh-ZMRx0Rn7LV3z2V/view>.

<sup>195</sup> The CO regulations reference depressurized equipment, while the NM regulation references temporarily abandoned wells.

into the system, and in order to meet regulatory and third-party pipeline quality specifications. Commenter believes EPA should exempt from fugitive emissions monitoring those wells operating on a vacuum, since a well on vacuum by definition cannot leak to the atmosphere.

Response II-4-91: Fugitive emissions component is defined beginning with “... any component that has the potential to emit fugitive emissions of methane or VOC...” Monitoring must be conducted on all “fugitive emission components,” but components on equipment continuously operated under sufficient vacuum such that any “leaks” that occur would leak gas into the equipment rather than to the atmosphere would not meet this definition. We believe the requirements of the fugitive emission program are clear and the facility is free to develop a monitoring plan that includes all fugitive emission components, but excludes components that do not have the potential to emit VOC or methane.

## 4.2 NSPS OOOOb for Compressor Stations

### 4.2.1 Proposed BSER

Comment: Commenters (2392-Earthjustice et al., 2433-EDF et al.) urge EPA to require bimonthly OGI at all compressor stations.

Commenter (2433-EDF et al) indicate that compressor stations contain large numbers of fugitive emissions components and are a major known source of emissions.<sup>196</sup> For the reasons articulated in their initial comments and based on their revised cost-effectiveness analysis, the commenter urges EPA to require bimonthly OGI at all compressor stations.<sup>197</sup> Bimonthly monitoring at compressor stations is well within EPA’s cost-effectiveness range and should be required to ensure greater emission reductions from these large sources.<sup>198</sup>

Response II-4-92: EPA disagrees that bimonthly OGI should be required at all compressor stations. With regard to the frequency of OGI surveys, EPA conducted an in-depth analysis for the November 2021 Proposal that evaluated the emissions reductions and costs associated with more frequent OGI monitoring options for all types of compressor stations. That analysis was presented in the 2021 TSD. As discussed in Section XII.A.b of the November 2021 Proposal preamble, EPA determined that more frequent OGI monitoring than quarterly was not cost-effective, and for that reason maintained quarterly OGI monitoring. Consistent with that conclusion, EPA proposed to retain a quarterly OGI monitoring frequency in the proposed December 2022 regulation while adding requirements to conduct monthly AVO monitoring at compressor stations and that any fugitive emissions detected via AVO would be subject to repair in response to comments.<sup>199</sup>

While emissions reductions associated with bimonthly OGI were not directly analyzed for compressor stations, EPA did calculate emissions reductions for bimonthly OGI and the

---

<sup>196</sup> See, e.g., Evan Sherwin et al., Quantifying oil and natural gas system emissions using one million aerial site measurements, Preprint (2023) <https://www.researchsquare.com/article/rs-2406848/v1> (finding that emissions from midstream facilities can make up 50 percent of the total in certain basins).

<sup>197</sup> See EPA Docket No. EPA-HQ-OAR-2021-0317-0844, at 112–15.

<sup>198</sup> Daniel Zimmerle et al., Methane Emissions from Gathering Compressor Stations in the U.S., 54 Env’t. Sci. Tech. 7552 (2020), <https://pubs.acs.org/doi/10.1021/acs.est.0c00516>.

<sup>199</sup> See 87 FR 74739 (December 6, 2022), section IV.A.2.

combination of quarterly OGI and monthly AVO for large well sites; that analysis is presented in the Final TSD. In the large well sites analysis, the combination of quarterly OGI and monthly AVO achieved greater emissions reductions than bimonthly OGI. EPA believes that qualitatively, the same trend observed for large well sites is likely to be true for compressor stations, supporting that the finalized provision is the BSER.

With regard to cost-effectiveness determinations, CAA section 111 requires that NSPS “reflect[] the degree of emission limitation achievable through the application of the best system of emission reduction which (taking into account the cost of achieving such reduction and any nonair quality health and environmental impact and energy requirement) the Administrator determines has been adequately demonstrated.” The EPA considered these statutory factors in promulgating the final standards, including the fugitive emissions standards for compressor stations. One tool that the EPA has consistently used in evaluating control costs is the cost-effectiveness of available control options (i.e., the cost of reducing a ton of a specific pollutant per year). This this final rule is no exception. EPA considered total and incremental cost-effectiveness when determining the BSER and, in this case, determined that the BSER was quarterly OGI rather than monthly OGI due to total and incremental costs being considered cost effective and the small fraction of additional reductions realized at monthly monitoring; while the total cost of monthly OGI was considered cost-effective, the incremental cost of monthly OGI was not considered cost-effective. Because monthly OGI was only projected to achieve minor emissions reductions over quarterly OGI at over double the projected annual cost and the incremental cost was projected to be greater than the social cost of methane, quarterly OGI was determined to be the BSER over monthly OGI. The combination of quarterly OGI and monthly AVO is also expected to result in additional emissions reductions at no additional cost; EPA notes that no commenter disputed or otherwise questioned the low cost of AVO monitoring which EPA relied upon in the December 2022 Supplemental Proposal.

Regarding the cost-effectiveness numbers determined by other entities, the fact that states such as Colorado and New Mexico may determine different costs for similar standards in their states does not mean that the costs are the same on a national scale, or that standards that may be appropriate for facilities in any given state are appropriate on a national scale because each state only represents a fraction of the sector and costs may vary by state. Additionally, neither the cost estimates done for state regulations nor requirements of state regulations about compressor station fugitives are uniform nationally, highlighting differences in cost calculation methods and what is considered cost effective by different entities.

Comment: Commenter (2211-Lambda Energy Resources) believes it is overly burdensome and unnecessary to require monthly AVO and quarterly OGI or Method 21 monitoring and record keeping for compressor stations. Existing equipment and monitoring methods have proven effective and have minimized emissions, and Lambda believes a baseline threshold for low volume compressor stations and periodic AVO inspections and documentation would effectively achieve the goals of the proposed requirements.

Response II-4-93: The EPA disagrees that it is overly burdensome and unnecessary to require monthly AVO and quarterly OGI or Method 21 record keeping for compressor stations. As explained in the December 2022 Supplemental Proposal (87 FR 74739), regular AVO inspections at compressor stations can be conducted by any staff at the site without the need for any special expertise. In fact, AVO inspection was added in the December 2022 Supplemental

Proposal in response to recommendations by some commenters<sup>200 201</sup> on the November 2021 Proposal recommending AVO as a low-cost method that is effective at identifying emissions, even for small-company compressor stations. The commenters specifically noted that even though small-company compressor stations are not manned 24 hours per day, they are visited weekly, if not daily. The EPA found the comments persuasive and did not see a need to confirm the commenters' assertions by conducting its own cost analysis for conducting monthly AVO inspections for compressor stations. The EPA notes that no commenter disputed or otherwise questioned the comments described above regarding the low cost of AVO monitoring, which the EPA relied upon in its December 2022 Supplemental Proposal. With regard to the comment suggesting that OGI monitoring is unnecessary because AVO surveys during these frequent visits would effectively achieve the EPA's emission reduction goals, the EPA disagrees that AVO surveys alone (i.e., without quarterly OGI monitoring) qualify as the BSER because OGI is needed to detect fugitive emissions that are not detectable by AVO. In addition, the EPA received no information that caused it to change its assessment that quarterly OGI at compressor stations is not cost-effective. Accordingly, the EPA is finalizing its determination that monthly AVO monitoring and quarterly OGI monitoring, in combination with repair requirements, represents the BSER for fugitive emissions components at both new and existing compressor stations. The commenter did not provide any additional data demonstrating that quarterly monitoring for compressor stations is overly burdensome.

#### **4.2.2 Delay of Repair for Lack of Availability of Parts**

Comment: Commenter (2483-INGAA) states the proposed delay of repair relief for lack of availability of parts for valves provided to onshore natural gas processing plants should also be given to compressor stations. In addition, that delay of repair relief should be expanded to include equipment beyond valves, particularly at existing sources. The equipment used for gas transmission is highly specialized and is not always readily available or in stock. In some cases, the parts need to be fabricated, which can take, for example, four to five months for smaller station valves (e.g., 8-12 inch lines) and 10 months or longer for large valves; larger, unique parts that require fabrication may take more than a year.

Commenter (2483-Interstate Natural Gas Association of America (INGAA)) has long advocated for EPA to allow for delay of repair due to the lack of availability of parts. The commenter has repeatedly expressed concern that any emission guideline for existing compressor stations needs to contain a delay of repair provision for parts availability to avoid reliability impacts to customers and system disruptions.<sup>202</sup> The commenter felt encouraged when EPA sought comment on several specific issues related to a replacement part delay of repair provision in the 2021 proposal for *compressor stations*.<sup>203</sup> Specifically, EPA asked for:

[D]ata to better understand the breadth of this issue with replacement parts for existing compressor stations. Additionally, we are soliciting comment on whether 30 days following receipt of the replacement part is appropriate for completing delayed repairs at existing *compressor stations*, whether there should be any limit on delays in repairs under

---

<sup>200</sup> EPA Docket No. EPA-HQ-OAR-2021-0317-0585.

<sup>201</sup> EPA Docket No. EPA-HQ-OAR-2021-0317-0814.

<sup>202</sup> EPA Docket No. EPA-HQ-OAR-2021-1391, INGAA Comments on the 2021 Partial Proposal at 9.

<sup>203</sup> 86 Fed. Reg. at 63,174 (noting "for compressor stations, we are soliciting comment on delayed repairs by existing sources when parts are not readily available and must be special ordered").

these circumstances, and whether this compliance flexibility should be limited or disallowed based on the severity of the leak to be repaired.<sup>204</sup>

Commenter (2483-INGAA) provided such data, giving EPA further information on the importance of delay of repair, discussing the types of equipment for which a delay in availability can occur, and providing in-depth information on valves and the dozens of components that make up a valve.<sup>205</sup> Despite providing this information and meeting with EPA numerous times to discuss the importance of this issue, it does not appear that EPA is providing delay of repair related to parts availability to compressor stations. The Agency is providing such relief, however, to valves at onshore natural gas processing plants.<sup>206</sup> The commenter hopes that omitting this relief from the section of the proposed regulatory text regarding existing compressor stations may be an oversight or error on the part of EPA given that it had specifically solicited comment in the 2021 Partial Proposal on providing delay of repair to compressor stations.

If this is not an error, then commenter (2483-INGAA) respectfully asks EPA to reconsider providing the relief that it proposes to give to onshore natural gas processing plants to compressor stations as well. There is no discussion at all in the preamble about delay of repair due to lack of availability of parts, and thus it is impossible to understand whether this is indeed a mistake or whether EPA actually intends to provide this important relief to natural gas processing plants but not compressor stations.

Commenter (2483-INGAA) stresses delay of repair due to lack of availability of parts is needed to ensure reliability of the natural gas system, which is of paramount importance. Operators routinely need to manage various challenges to meet demand. Adopting a rule that would require or prolong equipment or station shutdowns while awaiting parts would inhibit operators' ability to keep the system operating reliably and to meet their contractual commitments. Potential reliability disruptions are not limited to certain seasons such as winter or summer when natural gas demand may be higher. Many natural gas transmission pipelines operate at high capacity year-round, and there is little redundancy in the transportation chain. Some compressor stations are located logistically where their operations are important for reliability, operate year-round, and are difficult to take out of service without impacting an operator's ability to serve its customers. As more power plants are fueled by natural gas, and they need to run during the summer and other periods of time when pipelines historically performed scheduled maintenance on equipment, it may become more challenging to have compressor stations out of service and continue to meet electric demand. Regulations should not be written in a manner that creates a tension between complying with an environmental regulatory requirement and meeting contractual commitments governed by Federal Energy Regulatory Commission tariffs. While it is imperative to comply with environmental regulations intended to minimize the impact of operations to the environment, failing to meet contractual delivery obligations could also create health and safety risks (e.g., loss of home heating during the wintertime, loss of natural gas

---

<sup>204</sup> [Id.] (emphasis added).

<sup>205</sup> EPA Docket No. EPA-HQ-OAR-0317-1391, INGAA Comments on the 2021 Partial Proposal at 9-15.

<sup>206</sup> Proposed 40 C.F.R. §§ 60.5400b(h)(6)(iv), 60.5400c(h)(6)(iv). INGAA notes that the text of §§ 60.5400b(h)(6)(iv) and 60.5400c(h)(6)(iv) is identical to delay of repair relief provided for the synthetic organic chemicals manufacturing industry in Subpart VVa (other than Subpart VVa specifying that delay of repair "will be" allowed if certain conditions are met and § 60.5400c(h)(6)(iv) specifying that delay of repair "is" allowed if those same conditions are met). [Compare] 40 C.F.R. § 60.482-9a(e) [with] Proposed 40 C.F.R. §§ 60.5400b(h)(6)(iv), 60.5400c(h)(6)(iv).

supplied to power plants during hot summer months when there is an increased demand for electricity to run air conditioning, etc.) unless EPA provides for reasonable delay of repair provisions as it did with onshore natural gas processing plants.

Commenter (2483-INGAA) continues, if the omission of delay of repair provisions for compressor stations is not a mistake, it is impossible to understand EPA's rationale in providing this relief to one subcategory of sources (onshore natural gas processing plants) and not another (particularly one that has been asking for this relief for a long time). Treating these subcategories differently without explanation is arbitrary and capricious. There is no legitimate reason for EPA to conclude that onshore natural gas processing plants are somehow more unique and warrant different treatment than other sectors. Both compressor stations and natural gas processing plants include an array of various size (some very large), high-pressure gas valves where parts and/or replacement may require special machining, valve build, and other special circumstances. In fact, things may be more variable for compressor stations than for gas processing plants in some cases.

Commenter (2483-INGAA) provides the example, larger and older compressor stations, which will be subject to OOOOc, are probably more likely to have an array of unique valves due to how many existing stations were expanded over time, which led to there being large valves associated with different compressor sizes and types (and different vintages). For example, a larger station that was initially built 50 to 70 years ago may have started with a couple of units and expanded to include 10 or more compressors (or even more than 20 compressors in some cases) with add-ons occurring incrementally over multiple decades. As a result, a compressor station can have compressor houses with different size and vintage compressors, reciprocal, and centrifugal units. All of this equipment will have multiple valves, and each expansion project will very likely have unique equipment (compressors, drivers, valving, etc.). The array of large valves that require special service for parts or replacement (dozens of different sizes and types in some cases) for compressor stations may thus be more complicated than at some gas processing plants. The commenter submitted comprehensive comments on this, including photographs, in their Appendix B on Pre-Rulemaking Request for Information.<sup>207</sup>

Commenter (2483-INGAA) asks that the following regulatory text (which is identical to the delay of repair due to parts availability given to onshore natural gas processing plants) should also be provided for valves at compressor stations:

Proposed Regulatory Text for Valves at Compressor Stations – §§ 60.5397b(h)(4), 60.5397c(h)(4)<sup>208</sup> (additions are underlined; deletions are in strike-through):

(4) Delay of repair beyond a compressor station shutdown for maintenance is allowed for a valve, if valve assembly replacement is necessary during the compressor station shutdown for maintenance, valve assembly supplies have been depleted, and valve assembly supplies had been sufficiently stocked before the supplies were depleted. Delay

---

<sup>207</sup> EPA Docket No. EPA-HQ-OAR-0317-2483, INGAA Comments on Pre-Rulemaking Request for Information at 12-21 (App. B) (attached as Attachment 4 to Attachment A of these Comments).

<sup>208</sup> The currently proposed 40 C.F.R. §§ 60.5397b(h)(4) and 60.5397c(h)(4) would each need to be renumbered as (h)(5). Please note that broader proposed regulatory text is also provided for EPA to consider in Section V.B that would cover more parts than just valves. If that proposed regulatory text is adopted, then this proposed regulatory text should be ignored.

of repair beyond the next compressor station shutdown for maintenance will not be allowed unless the next compressor station shutdown for maintenance occurs sooner than 6 months after the first compressor station shutdown for maintenance.

Response II-4-94: With regard to delay of repair provision related to parts unavailability, EPA considered the information submitted by the commenters and is including provisions to allow the delay of repair due to the lack of availability of parts in some circumstances. Section X.A.2 of the preamble to the final rule details the fugitive emission standards concerning delay of repair due to parts unavailability, and section XI.A.2.b of the preamble to the final rule details EPA's rationale and reasoning regarding delay of repair due to parts unavailability. In response to comments, EPA is allowing delay of repair that requires replacement but the replacement cannot be acquired and installed within the repair timeline due to replacement valve supplies that have been sufficiently stocked but are depleted at the time of repair, similar to the provisions for valves at onshore natural gas processing plants. EPA concludes that well sites and compressor stations face some of the same valve assembly supply constraints as onshore natural gas processing plants and that operators can ensure timely ordering of replacement fugitive components or parts thereof but cannot control replacement delivery timelines. Thus, EPA is including similar delay of repair provisions for valve assembly supplies that had been sufficiently stocked but are depleted at the time of the required repair for wellsite and compressor station fugitives as for onshore natural gas processing plants in this rule. The final fugitive emissions standards for well sites and compressor stations under NSPS OOOOb (and presumptive standards under EG OOOOc) allow delay of repair due to depletion of supplies for valves only. This is consistent with the standards for onshore natural gas processing plants, which have provided such allowance for *valves only* since the standards were first promulgated in 1985, and the EPA has not received information showing difficulty of repair due to well stocked supplies of other fugitive emissions components or parts thereof that were depleted before repair could be completed.

Comment: Commenter (2483-INGAA) argues EPA should provide delay of repair for other equipment beyond valves. Equipment utilized for gas transmission is highly specialized and is made to stringent engineering specifications. The parts necessary to repair a leak are not always readily available or in stock. Not only do parts come in various sizes, but parts are not interchangeable between different manufacturers, models, or even different vintages of the same equipment. Some existing source compressors may be more than 50 years old, and compressors have changed over time. If a part breaks on an older piece of equipment, the comparable part that is used for new compressors may not be the right size or configuration for that older equipment. For example, the specifications of an older compressor valve might not be standard, the system associated with an older unit might have additional connections for recirculation piping, or there might be additional changes that the operator needs to make to that system to address other regulatory requirements, such as PHMSA regulations. In such cases, the appropriate parts for that equipment will need to be custom ordered and/or manufactured, and it may take several months to fabricate such parts.

Commenter (2483-INGAA) continues, the delivery time on receiving such equipment can also be prolonged because some parts are manufactured overseas. As has been seen in recent months, supply chain delays have lengthened the times for overseas products to be delivered, and even if a part is manufactured in the United States, it could be affected by supply chain delays because the materials needed to manufacture the part are delayed. While operators can control the

ordering of needed parts and can ensure this is done in a timely fashion, they cannot control how quickly that part will arrive. System reliability should not suffer because of supply chain delays.

Commenter (2483-INGAA) states the occurrence of such situations where the need for replacement parts that are not readily available and for which a delay of repair allowance will be appropriate is nevertheless likely to be a relatively rare occurrence, and thus the emissions associated with these occurrences are therefore likely to be small. The commenter's members currently report that the typical lead-times for smaller valves (i.e., those that are between 8 and 12 inches) are in the neighborhood of 16 to 20 weeks. The lead times for larger valves are generally 20 to 40 weeks, with large bore valves taking approximately 40 weeks and new valve actuators taking approximately 20 to 24 weeks. The need for parts with unique design requirements is rare, but because these parts must be special ordered, it can typically take up to 12 months to obtain them. All lead times are subject to change based on market conditions.

Commenter (2483-INGAA) adds an analysis of the commenter's members' affected sources reveals that there are over 20 different engine manufacturers and over 100 different models, each with their own model-specific parts. Further, these various engines span a wide range of vintages, such that even parts from a single supplier can vary significantly from model year to model year. Likewise, there are several different turbine manufacturers and dozens of different turbine models. The complications arising from different model year equipment requiring different parts applies with equal force to turbines. All of this equipment, moreover, is itself composed of many unique sub-assemblies, potentially comprising thousands of sub-components for each facility. Any one of these thousands of components and subcomponents could be required to repair a leak and need to be replaced.

Commenter (2483-INGAA) notes Appendix B to INGAA's Pre-Rulemaking Comments helps to further explain the enormity of the challenge posed by part availability for existing compressor stations by providing examples of the types of equipment and potential leak sources that are most likely at compressor stations. As Appendix B explains, a typical compressor house will have multiple compressors within the building and a compressor station may have several compressor houses.<sup>209</sup> The appendix provides photographs and diagrams of just some of the key equipment located in these compressor houses to illustrate the scale and breadth of the issue for the industry. The examples reviewed in Appendix B begin with integral reciprocating compressors, which are common in gas transmission.<sup>210</sup> These units include flanges, cover plates, and bolted surfaces encasing natural gas, and each of these components is a potential leak source and piece of equipment that may need to be replaced.<sup>211</sup> Looking at a cross-section of the integral reciprocating compressor itself, Appendix B further identifies the engine fuel system and compressors, and the flanges and cover plates associated with the compressor variable valve pockets and distance piece as additional potential leak sources.<sup>212</sup>

Commenter (2483-INGAA) continues, looking more in-depth into just one category of these potential leak sources – valves – the appendix explains that each type of valve is itself made up of dozens of components, “including: the valve stem packing, grease nipples, bleed ports, valve

---

<sup>209</sup> EPA Docket No. EPA-HQ-OAR-0317-2483, INGAA Pre-Rulemaking Comments, App. B at 13 (attached as Attachment 4 to Attachment A of these Comments).

<sup>210</sup> [Id.]

<sup>211</sup> [Id.] at 15.

<sup>212</sup> [Id.] at 16.

body seals (e.g., where the bonnet bolts to the valve body, retainer connections), packing guide, and any monitoring ports on the stem packing system.”<sup>213</sup> As explained above, and as further described in Appendix B, the number of these potential leak sources must be multiplied by the different sizes, manufacturers, and model years for the equipment in use at the source to fully appreciate the number of pieces of equipment that could require replacement and the enormity of the stockpile of spare parts that would be needed for each facility.

Commenter (2483-INGAA) states an argument often given against delay of repair for parts availability is that operators should keep an inventory of parts on hand. This argument simply does not understand the scope and scale of the issue. Given the number of engines and turbines and the considerable variation in design among manufacturers and across model years, it is not feasible for individual companies or facilities to stockpile every type and size valve or part that might be needed to repair a leak. An operator has no reasonable way to predict which parts will need to be replaced and when, particularly considering that the operator’s initial attempts to stop the leak using other repair methods may be successful. Moreover, these parts are very expensive, with larger valves costing in the range of \$50,000 to \$200,000.

Commenter (2483-INGAA) argues for the same reason and because of generally low demand for what are often relatively unique or uncommon parts, manufacturers cannot be expected to maintain an inventory of parts ready for rapid shipment when a facility discovers a part must be replaced. Maintaining such an inventory would have considerable tax and cash flow implications because the parts may never sell due to low demand. In addition, many parts have a shelf-life that limits the time they can remain in inventory, and an operator may question whether a part may have been sitting on the shelf for too long and is still good for use. In the commenter’s experience, manufacturers limit their inventory to items that move quickly or are more commonly required, which means there is not a ready inventory of expensive, unique, or parts for older equipment. Because it is not feasible to keep a complete stockpile of all possible equipment that may need to be replaced to address a leak, allowing a delay of repair to provide time for acquisition of replacement parts is necessary.

Commenter (2483-INGAA) concludes the number of parts that may potentially require replacement at any given facility is enormous, and the time needed to obtain some of these parts can be lengthy. The equipment used for gas transmission is highly specialized and is not always readily available or in stock. When parts need to be fabricated, it can take four to five months to obtain smaller station valves (e.g., 8-12 inch lines) and 10 months or longer for large valves; larger, unique parts that require fabrication may take more than a year. Given this, the only reasonable solution that preserves reliability of the gas supply is to include a delay of repair provision related to availability of all parts (not just valves) in OOOOb and OOOOc for compressor stations:

Proposed Regulatory Text for All Parts at Compressor Stations – §§ 60.5397b(h)(4), 60.5397c(h)(4)<sup>214</sup> (additions are underlined):

---

<sup>213</sup> [Id.] at 18.

<sup>214</sup> The currently proposed 40 C.F.R. §§ 60.5397b(h)(4) and 60.5397c(h)(4) would each need to be renumbered as (h)(5).

(4) Delay of repair beyond a compressor station shutdown for maintenance is allowed for parts replacement, if the parts replacement is necessary during the compressor station shutdown for maintenance, parts supplies have been depleted, and parts supplies had been sufficiently stocked before the supplies were depleted. Delay of repair beyond the next compressor station shutdown for maintenance will not be allowed unless the next compressor station shutdown for maintenance occurs sooner than 6 months after the first compressor station shutdown for maintenance.

Response II-4-95: With regard to delay of repair provision related to parts unavailability, EPA considered the information submitted by the commenters and is including provisions to allow the delay of repair due to the lack of availability of parts in some circumstances. Section X.A.2 of the preamble to the final rule details the fugitive emission standards concerning delay of repair due to parts unavailability, and section XI.A.2.b of the preamble to the final rule details EPA's rationale and reasoning regarding delay of repair due to parts unavailability. The comments on the November 2021 Proposal and December 2022 Supplemental Proposal also include supporting information on exceptional, infrequent circumstances where a replacement part requires custom fabrication. Specifically, the information includes insight into the quantity and variety of vintage equipment at compressor stations, the unlikelihood of manufacturers stocking replacement parts for vintage equipment and thus the need for custom fabrication of replacement supplies, and the timeline for fabrication and delivery of custom supplies. Recent examples of extensive supply chain delays have highlighted that a delay of repair may be needed for circumstances beyond an owner or operator's control.<sup>215</sup> In light of the information on the challenges and the time needed to acquire parts that require custom fabrication and the current supply chain issue, we are including in the final NSPS OOOOb and the model rule in EG OOOOc provisions for delay of repair where replacement is required and the replacement fugitive emissions component or a part thereof requires custom fabrication. This provision allows for delay of repair for parts beyond valves that require custom fabrication.

Comment: Commenter (2366-BHE) reiterates their January 2022 comments<sup>216</sup> and strongly recommends that EPA allow delay of repair (DoR) when parts are not available for all natural gas segments, and states that the allowance should not be limited to valves because other parts also may not be readily available. The commenter refers to detailed comments and example scenarios they provided in their January 2022 comments as well as comments provided by the Interstate Natural Gas Association of America (INGAA) in January 2022, on the same topic.<sup>217</sup> The commenter is concerned because EPA support documentation does not explain why processing is treated different than other natural gas industry segments. The commenter believes there is no legitimate reason for EPA to conclude that processing valves are somehow more unique and warrant different treatment than other natural gas industry segments. By way of example, the commenter states that both transmission compressor stations and processing plants include an array of various size, high pressure gas valves, including very large valves where parts and/or replacement may require special machining, valve build, etc. In fact, according to the commenter, due to the wide array of compressor drivers and compressors in transmission and

---

<sup>215</sup> EPA Docket No. EPA-HQ-OAR-2021-0317-2483.

<sup>216</sup> Berkshire Hathaway Energy Company (BHE). Public Comments Re: Standards of Performance for New, Reconstructed and Modified Sources and Emissions Guidelines for Existing Sources: Oil and Natural Gas Sector Climate Review, 86 Fed. Reg. 63,110 (Nov. 15, 2021). January 21, 2022. EPA Docket ID EPA-HQ-OAR-2021-0782.

<sup>217</sup> EPA Docket No. EPA-HQ-OAR-2021-0317-1391.

due to different manufacturers, models, and vintage, there may be more unique, large legacy part types in transmission compressor stations than for processing plants. By way of example, the commenter states that larger and older compressor stations subject to EG OOOOc are probably *more* likely to have an array of large, unique valves because larger, existing stations were likely expanded over time. Thus, they note that there are large valves and compressor components associated with different compressor manufacturers, models, sizes, and vintages because incremental horsepower may have been added in several projects over multiple decades for a station originally constructed in the 1950s, and each would likely have unique equipment (compressors and drivers, valving etc.). The commenter contends that DoR due to parts availability is not unique to natural gas processing plants and should apply to all affected sectors [segments].

Similarly, the commenter (2366-BHE) suggests that these DoR provisions should apply to parts other than valves. By way of example, the commenter explains that compression includes an array of parts associated with the compressor driver (e.g., reciprocating engine or combustion turbine), the compressor, and associated valving, piping, and other processing equipment. They explain that a valve is one example of a part type that may not be available for repair or replacement, but other unique parts are also associated with other process equipment, such as the array of components associated with a large natural gas compressor. According to the commenter, the issues associated with the broad range of large valves for legacy equipment are just as relevant for legacy compressors and associated sub-components and large, unique legacy parts may need to be machined or more major components may need to be constructed. Thus, the commenter explains, DoR provisions due to unavailable parts should apply to any substantive part where the situation can be documented rather than only applying to valves. While the commenter believes that DoR due to these scenarios is not expected to be a common occurrence, they assert that it must be addressed in the regulations to ensure that equipment/facility shutdown is not mandated, and natural gas system reliability is not compromised, due to the unavailability of parts.

The commenter (2366-BHE) requests that the related regulatory text be revised to delete (or define) ambiguous terms such as “sufficiently stocked,” as it is unclear what amount of supplies EPA considers sufficient to meet this requirement. There is no discussion of this provision in the preamble, and clarification is required, according to the commenter. The commenter explains that many large and relatively unique parts cannot be stocked and may require special construction and/or machining. The term “sufficiently stocked” fails to recognize the scenarios explained in detail by this commenter and others, and neither the proposed rule text or preamble provide discussion of this term or acknowledge or explain scenarios where a parts inventory is infeasible, the commenter states.

Response II-4-96: As discussed in response to the previous response in this section, the EPA is including a delay of repair provision related to parts unavailability in the final rule for up to two years in specific circumstances. Provisions are included for valve assemblies and parts thereof and parts beyond valves that require custom fabrication. This provision is included in §60.5397b(h)(3)(ii) of the final rule.

With regard to removing the term “sufficiently stocked”, EPA disagrees that the term should be removed or specifically defined in the final rule because what may be considered “sufficient” may reasonably vary among parts, equipment counts, and facilities.

### **4.2.3 BSER Analysis/Emissions/Costs**

Comment: Commenter (2440-Nevada Nanotech Systems, Inc.) notes compared to state-of-the-art continuous monitoring systems, the proposed BSER of monthly AVO inspections and quarterly OGI inspections provides neither the greatest emissions reduction, nor does it provide the most economical solution. CP-CMS technology provides immediate detection of leaks and the greatest reduction in emissions for as little as \$4998 per year (Total Cost of Ownership). This price includes hardware installation, automated, continuous monitoring software and support, all required maintenance, automated leak notifications, visualization of the leak location via computer, tablet or phone and automated reporting of emission statistics. The commenter encourages the EPA to also allow continuous monitoring technology solutions as a BSER for compressor stations.

Response II-4-97: The EPA disagrees that continuous monitoring technology is the BSER for compressor stations because we do not have sufficient information to include this new but rapidly advancing technology in the BSER analysis; however, the EPA supports the use of continuous monitoring systems to detect fugitive emissions at compressor stations. The EPA is providing a pathway for owners and operators to utilize continuous monitoring technologies at compressor stations as part of the advanced methane detection technology provisions of the rule. Please see section X.B.2 of the preamble to the final rule which details EPA's final standards related to advanced methane detection technology.

Comment: Commenter (2283-Endeavor Energy Resources) states EPA should recognize that the proposed compressor station requirements will also have a direct economic impact on upstream producers. Under the Methane Proposal, compressor stations would be required to conduct monthly fugitive emissions inspections through AVO monitoring, coupled with quarterly monitoring using OGI or Method 21. While the commenter leases all compression from a third party, it is confident that the increased expense attributable to these new requirements will be passed on to Endeavor and other upstream producers, which risks further chilling domestic production. As a result, the commenter requests that EPA take these considerations into account in its economic analysis and work to also limit or simplify the monitoring burdens on compressor stations.

Response II-4-98: The EPA disagrees that it is appropriate to attribute costs for compressor station fugitives to upstream producers because the EPA does not consider it appropriate to attribute the costs of the same provision in multiple places in the same rulemaking and the costs have already been attributed to compressor station fugitives. With regard to limiting or simplifying the fugitive emission standards, EPA concludes that the BSER for compressor station fugitives is quarterly OGI and monthly AVO. Please see section 4.2.1 of this chapter for responses to similar comments related to the BSER.

## **4.3 EG OOOOc Fugitive Emissions from Well Sites and Centralized Production Facilities**

### **4.3.1 General**

Comment: Several commenters (1583-ODEQ, 2200-NuEnergy Operating Inc., 2211-Lambda Energy Resources, 2244-Private Citizen, 2248-NDPC, 2393-OSEE) express specific concerns

regarding the proposed requirements for existing sources under EG OOOOc and argue that the same fugitive emissions monitoring should not apply to existing sources as those for new sources under NSPS OOOOb.

Commenters (1583-ODEQ, 2393-OSEE) state that EPA should collect additional empirical data before implementing new regulatory requirements, especially where those requirements will be imposed on existing oil and gas facilities. For example, in the preamble, EPA acknowledges that “certain well sites are smaller than our model facilities, and that as a result the model may overstate emissions reductions, and thus cost-effectiveness, for fugitive emissions programs at such small sites.” This further warrants the justification for an exemption threshold for well sites with low potential emissions. There are too many existing well sites for EPA to properly characterize the fraction that experience unacceptably high fugitive emission rates and to properly assess the cost of control absent additional study. EPA should gather data from a large sample of existing wells with different configurations and fund multiple pilot studies to gather better cost data before embarking on such an ambitious regulatory project.

Commenter (2200-NuEnergy Operating Inc.) states the EPA is proposing the same fugitive emissions monitoring schedule for both new and existing wells. It does not make sense that potential emissions based on throughput, production pressure and product constituents vary between a 20 year old well and a 2 year old well with the exact same equipment. This is unworkable.

Commenter (2211-Lambda Energy Resources) operates about 789 gas and oil wells, 70 central processing facilities, two Natural Gas Processing Plants, and crude oil and natural gas gathering systems. A typical Lambda well produces 6 barrels of oil equivalent per day (BOEPD) and is between 20-50 years old. The IRS classifies as marginal a well producing less than 15 BOEPD. The commenter finds it necessary to voice their concerns over the proposed modifications and additions NSPS OOOOa (new sources), NSPS OOOOb and especially EG OOOOc (existing sources), and the drastic costs and effect these proposed regulations will have on marginal well producers and its employees, vendors, royalty owners, and throughout Michigan and the United States.

Commenter (2244-Private Citizen) supports states’ requirement to provide a written report annually to verify compliance using mandated reporting from all fossil fuel companies.

Commenter (2248-North Dakota Petroleum Council (NDPC)) states the EPA should not make the EG OOOOc the same for existing sources as it does for the new sources covered under NSPS OOOOb. In EPA’s NSR (New Source Review) rule they recognize the challenges of how control technology requirements are applied to major sources (new and existing, and in attainment vs non-attainment). For major source EPA’s regulations on NSR, there are three levels of controls: Reasonably Available Control Technology (RACT) for existing sources, BACT for new sources, and Lowest Achievable Emission Rate (LAER) for new sources in non-attainment. It appears that the EPA is applying LAER type requirements as the BSER for every affected facility and for both NSPS OOOOb and EG OOOOc.

Response II-4-99: As discussed in the December 2022 Supplemental Proposal, the EPA determined that the methods for identifying fugitive emissions (*i.e.*, AVO, OGI, and EPA Method 21), methane emissions reductions, costs, and cost effectiveness for methane emissions

discussed for the fugitive emissions components affected facility at new well sites are also applicable for the fugitive emissions components affected facility at existing well sites. For the final rule, the EPA maintains that the analysis developed for the NSPS OOOOb to determine the BSER is also appropriate for the proposed presumptive standards for the EG OOOOc. The EPA is finalizing this approach for fugitive emissions monitoring, which for existing single wellhead only well sites requires quarterly AVO inspections and for existing small well sites quarterly AVO inspections and closed and sealed requirement for thief hatches. As shown in Table 15 of the December 2022 Supplemental Proposal, the cost of quarterly AVO inspections at existing single wellhead only well sites and small well sites were estimated at \$660 per year per site with a cost-effectiveness of less than \$1,200 per ton of methane reduced, which EPA found to be reasonable.

Comment: Commenter (2410-California Office of the Attorney General et al.) states the undersigned support EPA's adoption of a presumptive standard for existing well sites that follows the same fugitive monitoring and repair program as for new sources. Detecting and repairing leaks does not require installation of controls on existing equipment or retrofits. Rather, as noted by EPA,<sup>218</sup> the technology to address methane leaks is the same at new and existing sites, as are the emission reductions, costs and cost-effectiveness. It is therefore reasonable for EPA to promulgate a presumptive standard for fugitive emissions at well sites that mirrors the new source performance standard.

Response II-4-100: The EPA agrees. The EPA is finalizing presumptive methane standards for existing sources under EG OOOOc that are the same as the methane standards for new sources under NSPS OOOOb.

Comment: Commenter (2179-KIOGA) states the EPA did not provide any regulatory text on EG OOOO, therefore, the ability to provide comments is limited.

Response II-4-101: The commenter is mistaken. The proposed regulatory text for Subpart OOOOc—Emissions Guidelines for Greenhouse Gas Emissions from Existing Crude Oil and Natural Gas Facilities was posted along with the December 2022 Supplemental Proposal on EPA's regulatory website at <https://www.epa.gov/controlling-air-pollution-oil-and-natural-gas-industry/epa-issues-supplemental-proposal-reduce>.<sup>219</sup>

Comment: Commenter (2198-University of Denver College) argue the quarterly monitoring of these new or modified sites under NSPS does not affect sites built before November 15, 2021. As older sites would surely have more issues with leaks. These grandfathered in sites "might try to make use of regular maintenance and repair as an opportunity to gradually rebuild the plant, classifying these as minor improvements rather than major modifications."<sup>220</sup> The addition of covering older sites under the new proposal would have a greater effect on reducing GHGs. Though the cost to do this would be massive, new technology in monitoring GHGs could be used as a cheap and creative solution.

<sup>220</sup> Salzman 2019, 126.

Response II-4-102: In the December 2022 Supplemental Proposal, the EPA proposed fugitive emissions standards for affected facilities for which construction, modification or reconstruction commenced after November 15, 2021 under NSPS OOOOb, as well as Emissions Guidelines for existing facilities under EG OOOOc.<sup>221</sup> The EPA is finalizing standards under NSPS OOOOb for facilities for which construction, modification or reconstruction commenced after December 6, 2022. Designated facilities in the crude oil and natural gas source category that commenced construction, modification or reconstruction on or before December 6, 2022, are subject to the EG OOOOc.

Comment: Commenter (2283-Endeavor Energy Resources) believes EPA should take additional time to craft EGs that reflect the realities of older, existing sources in the oil and gas industry as required by the CAA.

Commenter (2283-Endeavor Energy Resources) states existing source standards should not be simultaneously proposed with new source standards, as EPA has done here, but should instead be informed by experience from implementing finalized NSPS. As EPA has noted in the past, "proposing (or publishing) an emission guideline after promulgation of the corresponding standard of performance" allows EPA to "benefit from the comments on the standard of performance in developing the emission guideline."<sup>222</sup> That is equally true here: When EPA proposed Subpart OOOOa, it did not simultaneously propose EGs for methane at that time. This was appropriate, as it would allow for EPA to first benefit from the experience and information gained from observing ways in which Subpart OOOOa was, and was not, effective before applying any standards to the much larger universe of existing sources. Subpart OOOOa has not been in place for very long, due to the legal changes and changes in EPA's proposed requirements over the last few years. As a result, EPA does not yet have sufficient information about the effects or effectiveness of the various requirements it has imposed to limit methane emissions and therefore lacks sufficient information to determine what requirements would be appropriate and effective for existing sources.

Commenter (2283-Endeavor Energy Resources) adds, EPA has not yet received and reviewed comments on its new proposed NSPS, Subpart OOOOb, which introduces a number of additional requirements beyond Subpart OOOOa that have not yet been tested in the field and which are likely to present meaningful implementation challenges. In consideration of these meaningful information gaps, EPA should therefore withdraw the proposed Subpart OOOOc EGs and wait to propose a more appropriate set of regulatory requirements for existing sources with the benefit of additional information and experience. Otherwise, EPA risks finalizing EGs that are arbitrary, capricious, overly burdensome, and unworkable in practice, which would undermine EPA's goal of creating durable methane regulations.

Commenter (2283-Endeavor Energy Resources) notes that when EPA does propose EGs, they should be less stringent than the NSPS requirements in recognition of the very different set of burdens and considerations at play when regulating existing sources. Specifically, the proposed EGs should appropriately accommodate other factors, such as the remaining useful life of existing sources, as required by the CAA.<sup>223</sup> EPA's proposal should reflect the CAA's recognition that there are a fundamentally different set of considerations when regulating

---

<sup>221</sup> 87 FR 74702 (December 6, 2022).

<sup>222</sup> See, e.g., 40 Fed. Reg. 53,340, 53,345 (Nov. 17, 1975).

<sup>223</sup> 42 U.S.C. §741 l(d)(l).

existing sources for the first time. Like many operators, the commenter has already planned and budgeted for equipment upgrades at new or modified well sites, but upgrades at the older, existing sites will be more costly to make and will need to be made at far more sites than for new or modified sites. Depending on the specific well site, these capital upgrade costs could fundamentally alter economics associated with operating an existing well, or be entirely infeasible to implement. For example, many existing well sites contain a limited number of controllers, most do not have flares located on site, and the complete retrofit of these sites is likely cost-prohibitive based on well economics. EPA's proposal will require installing and retrofitting a broad range of equipment, including installing electric compressors for air controls, retrofitting all controllers to air systems, installing vapor recovery units on all tanks, installing new low- and high-pressure flares, and installing meters to monitor the volumes sent to flares. In addition, as explained further below, many older well sites do not have access to on-site electricity or a sale line for natural gas because the sites were not built with these considerations in mind. And due to the remote locations of many of these existing sites in the Midland Basin, these kinds of infrastructure upgrades will be extremely costly or entirely outside of an operator's control.

Commenter (2283-Endeavor Energy Resources) does not believe there are a sufficient number of contractors who can meet the needs of all operators in the Midland Basin, and "scaling up" too quickly would pose risks if contractors are forced to rely on new personnel who do not have qualifications, training, and experience to perform the necessary upgrades. This is just one example of why EPA cannot and should not assume that just because requirements have proven to be feasible for the much smaller pool of new or modified sources that operators are also able to implement these requirements more broadly for their existing sources. The commenter believes EPA should instead take the time to fundamentally revisit its proposed EGs after coordinating with the states, who have decades of experience regulating these sites, and operators, who likewise understand the practical realities of implementing these proposals. The commenter encourages EPA staff to visit a variety of well sites in our basin and others to better understand the nature of these facilities and the geography where the commenter is operating. By spending the necessary time up front to understand the industry, EPA can craft durable and workable requirements that will better serve the environment and the public in the long run and avoid issuing a rule that cannot survive legal challenges.

Response II-4-103: EPA disagrees that it is inappropriate to issue New Source Performance Standards and Emissions Guidelines simultaneously for a sector. Draft regulatory text and analyses supporting the proposed text were presented in the December 2022 Supplemental Proposal after taking into account comments on the November 2021 Proposal, and comments on both have been considered in developing the final rule. Differences in costs analyses between new and existing sources are detailed in the 2021 and 2022 TSDs. With regard to a lack of contractors, the commenter does not provide any data supporting their statement.

#### ***4.3.2 Component Counts***

Comment: Commenters (2205-Kriebel Well Services, Inc., 2238-SOOGA, 2294-Ohio Oil and Gas Association, 2446-IPAA) encourage the EPA to not use component counts to define its emissions guidelines. The commenters ask the EPA to align the proposal with states' mindset and use production rates or emissions estimates to define their programs. The use of elaborate component counts is absent in state regulatory programs. This is a major reason why the

commenters have repeatedly recommended using production rates – with the framework of the federal tax code as the calculation method – to define regulatory requirements. EPA's own efforts to try to develop a component count regulatory basis shows that the calculation process is imprecise.

Commenter (2446-IPAA) adds, despite EPA's dismissal of production rates as not being a precise link to emissions, no other approach has shown itself to be appreciably better. In reality, when dealing with a million existing sources that span a wide range of emissions profiles and where the emissions data on those operations are based on a small fraction of the operations, there will never be a structure that provide certainty. In the next phase of this regulatory process – the development of state plans – EPA is setting the stage for unnecessary confrontations with states over the drafting of regulations and the determinations of equivalency. EPA tries to minimize state flexibility by announcing that its analysis is so persistent that states will not be able to demonstrate alternative choices. But, each state has its own regulatory framework and EPA's threatening approach will not easily bend their will. The end result could be regulatory chaos; EPA could end up generating federal plans that it has neither the staff nor the skills to implement. Producers will be faced with two simultaneous regulatory programs which is a patently unfair situation and for small businesses likely crippling. EPA needs to address these predictable consequences now.

Response II-4-104: As discussed in the December 2022 Supplemental Proposal, the EPA did not find that production rates correlate to the amount of fugitive emissions and therefore would not be appropriate to use as a basis for establishing different fugitive emissions monitoring requirements among well sites, including existing well sites. However, the EPA did find that data supports distinguishing among well sites based on equipment and component counts. This approach is applicable to both existing and new well sites.

As discussed in the December 2022 Supplemental Proposal, the EPA found no reason to develop separate requirements for existing well sites, as the monitoring techniques, costs, reductions, and cost-effectiveness were found to be the same for new and existing sites. The EPA is finalizing this approach in the final rule, which includes a less onerous fugitive emissions monitoring structure for single wellhead only well sites and small well sites using AVO inspections only. This final requirements for single wellhead only well sites and small well sites take into consideration the impact of the fugitive emissions monitoring requirements on small businesses, including requirements that affect small operators at existing sites). Inspections using AVO do not require specialized equipment or operator training and is a less costly and burdensome requirement. More stringent is being finalized for multi-wellhead only well sites and large well sites with major production and processing equipment that using OGI and AVO to detect fugitive emissions.

#### ***4.3.3 Definitions and Text Changes***

Comment: Commenter (2177-Ute Indian Tribe) suggests the following change to OOOOc:

"~~Discussion of s~~System calibration requirements, including but not limited to, the calibration procedures and calibration schedule for the detection systems and meteorology systems."

Response II-4-105: The EPA disagrees that this change is necessary. The final rule maintains the language as proposed.

Comment: Commenter (2214-BCAO) requests clarification of 40 CFR 60.5420c(b)(8)(i)(A) as to whether there is a hierarchy on which type of site should be reported if there is more than one type of site at a facility, or if the facility is to report them all.

Response II-4-106: There is no hierarchy as to which site is to be reported. Each fugitive emissions components designated facility at a well site, centralized production facility, or a compressor station should be reported. Each fugitive emissions components designated facility can occur at only one type of site; the same designated facility would not be located at both a well site and a compressor station, for example. While both sites may have fugitive emissions components, and the fugitive emissions components at both sites may be designated facilities, they would be separate designated facilities. Both designated facilities could be included in the same annual report, but they would be reported as separate designated facilities within the report, with the type of site indicated for each of the designated facilities.

#### **4.3.4 Small Business/Cost Concerns**

Comment: Commenters (2211-Lambda Energy Resources, 2218-TCEQ, 2238-SOOGA, 2247-Ohio EPA, 2353-CrownQuest Operating, LLC.) express concerns over the costs that could be incurred by sources subject to EG OOOOc, particularly for smaller operators.

Commenter (2211-Lambda Energy Resources) states most significantly, the proposal to base emissions estimates for well equipment and monitoring on the types and counts of equipment at a site rather than throughput, will require the same expensive retrofitting and monitoring for a typical Lambda well producing 6 BOEPD as is required for a well producing 100 barrels BOED and 20 times the revenue and emissions. Lambda estimates that required retrofitting and increased monitoring and recordkeeping for existing marginal wells required by the proposed regulations would impose new, additional costs of between \$5 and \$10 thousand dollars per well per year, and between \$4 and \$8 million total annually, for Lambda as a company.

Commenter (2218-TCEQ) states the proposed rule also presents increased regulatory overlaps and inconsistencies between currently available construction authorization mechanisms and previous NSPS for this source category as related to monitoring requirements. Texas minor source air authorizations (including Permits by Rule (PBR), Standard Permits, and Case-by-case Permits) have established fugitive monitoring programs that differ based on the facility types and quantity of emissions at a site.

The commenter (2218-TCEQ) notes Texas has many smaller oil and gas sites that may not be subject to registration requirements as part of an authorization under the PBR specified above. Also, many of these sites are already subject to additional monitoring under the previous NSPS (Subparts OOOO or OOOOa). These overlapping requirements make it difficult for the commenters and regulated entities to keep track of the applicable regulations and evaluate compliance. The commenter recommends the proposed rule include an alternative monitoring schedule for sites that demonstrate low leakage rates.

Commenter (2218-TCEQ) states as of December 2022, there are over 287,000 active wells (including oil, gas, and service wells) monitored by the Texas RRC. Many of these are unmanned or minimally staffed well sites in remote locations, presenting potential logistical and compliance issues. Owners or operators of affected sites in remote locations may have difficulty recruiting and retaining sufficient staff to support a regular monitoring program. It will also be burdensome for the commenter (2218-TCEQ) to conduct additional on-site compliance and enforcement activities.

Commenter (2218-TCEQ) states the sheer number and distribution of wells in Texas makes quarterly AVO monitoring a burden for operators and results in only a slight reduction in emissions. Additionally, this may place a significant burden on smaller operators. There are numerous small operators for which the costs of complying with the proposed requirements will be high compared to the income from their operations. In Texas alone, over 4,100 operators own and operate 10 or less oil leases and gas wells. Therefore, AVO monitoring of wellhead only sites would likely provide minimal additional reductions compared to cost.

Commenters (2200-NuEnergy Operating Inc., 2211-Lambda Energy Resources, 2238-SOOGA, 2294-Ohio Oil and Gas Association, 2403-PAO, 2446-IPAA) state EPA's BSER for fugitive emissions fails to properly account for the impact of declining production reducing the potential magnitude of emissions from production facilities. This results in inflexible and, thus, unreasonable monitoring requirements under the Supplemental Proposal. The commenter requests that EPA provide for flexibility in the fugitive monitoring requirements such that as production declines and a well site moves from the large well facility category to the small well facility category, the requirements applicable to the facility should change accordingly to the appropriate facility status, *i.e.*, single well site, multiple well site, small well site or intermediate well site.

Commenter (2200-NuEnergy Operating Inc.) states the EPA is not addressing production decline, stripper well operation, marginal well production, or the IRS's definition of marginal wells when considering the cost benefit analysis.

Commenter (2211-Lambda Energy Resources) adds that the exemption in previous proposals for existing marginal wells has been removed from the December 6 proposed regulations, and there is no "off ramp" for wells once they reach marginal production status.

Commenter (2403-PAO) requests EPA incorporate into the rule a regulatory framework that reflects the nature of oil and natural gas production *i.e.*, well production/emissions decline over time.

Commenter (2446-IPAA) states whatever has been done to develop NSPS fugitive emissions regulations has always been a precursor to its impact on existing source facilities that were never directly addressed in the NSPS regulations. Even the CTG only adopted the basic fugitive emissions regulatory framework for its model regulation. On the other hand, all of the information that EPA has used in its regulatory development – both emissions estimates and technology evaluations – comes from existing sources.

Commenter (2238-SOOGA) expresses that one of the critical flaws of the subpart OOOO regulations, including subpart OOOOb and OOOOc, is the failure to properly account for the

declining production of oil and natural gas from a well over time. The corresponding decline in emissions in connection with various operational changes at the well site is also associated with the decline in production. While initial production at a well may be significant, it will deplete as the well ages and eventually become a low production well. The failure to properly account for this change skews the fundamental basis of the entire subpart OOOO program, *i.e.*, the cost-effectiveness analysis for establishing the BSER for each source that is subject to the program. The magnitude of this fundamental flaw is most significant in the resulting EG OOOOc for existing sources, which have a disproportionate and detrimental impact on low production wells and small businesses.

Commenter (2238-SOOGA) adds the corresponding decline in emissions in connection with various operational changes at the well site is also associated with the decline in production. While initial production at a well may be significant, it will deplete as the well ages and eventually become a low production well. The failure to properly account for this change skews the fundamental basis of the entire Subpart OOOO program – *i.e.* the cost-effectiveness analysis for establishing the BSER for each source that is subject to the program. The magnitude of this fundamental flaw is most significant in the resulting EG OOOOc for existing sources, which have a disproportionate and detrimental impact on low production wells and small businesses.

Commenter (2238-SOOGA) believes the fundamental flaw in EPA's Subpart OOOO regulations has resulted in a misguided BSER determination for existing sources that effectively regulates existing sources the same as new and modified sources. The Supplemental Proposal is based on the assumption that existing facilities can be retrofitted at a reasonable cost to meet the same emissions standards applicable to new and modified sources. The EPA made a gross miscalculation in this regard. Many of the commenter's members lack the financial capital to retrofit existing sources with the equipment necessary to comply with the emissions standards under the Supplemental Proposal. The burden becomes heavier to have technical staff and legal advisors to assist with understanding and complying with the myriad of requirements that they will be subject to, including AVO inspections, conducting root cause analyses, recordkeeping, and reporting, all with significant costs associated with conducting those activities. Even assuming operators *could* pay for costs to retrofit, as a well approaches the end of its useful life, there is a point at which it is no longer economic to make the necessary retrofits. The EPA assumes compliance to be feasible and cost-effective, however, the reality is that the stringent emissions standards under the Supplemental Proposal are impossible, impractical, and inconsequential to methane reduction in most cases, and especially for low volume production wells.

Commenter (2247-Ohio EPA) states in many of those cases, wells have transitioned from a production well that sells the gas/oil produced to a well that simply provides gas/oil to a single-family home. In other cases, small businesses own multiple wells in an area.

Commenter (2247-Ohio EPA) continues, these single families or small businesses will struggle to do the AVO program inspections and reporting. The commenter's experience is that these small operators will not be able to fully understand what they need to do under these rules. Rather than asking these small operators to figure out what they need to do under the EGs, there needs to be either (1) some de minimis cut-off for small wells so they do not have this burden, or (2) a different approach where the small business assistance program or a consultant (with federal funding) does this work for them. The goal of making sure these small wells are not

leaking significant quantities of gas may be a good one, but the traditional approach of writing a rule and then expecting small operators to figure out what needs to be done to comply, in their experience, does not work well. Rules for these small

Commenter (2326-AXPC) asks the EPA to appropriately quantify and assess the feasibility, costs, and benefits of implementing new requirements for existing facilities.

Commenter (2353-CrownQuest Operating, LLC.) states EPA should have considered the OOOOc costs and impacts of the RIA on small businesses. The EPA has already stated that it will not accept traditional state plans, such as Texas' permit-by-rule methods. They will require all states to meet at least their minimum requirements. The EPA's proposed BSERs are restrictive, limit state implementation, and significantly affect a much larger universe of small businesses because OOOOc is basically identical to OOOOb. For example, Texas' (using the Railroad Commission's 2021 production data) top 22 operating entities account for 55% of Texas' production, while the smallest 2,477 entities account for less than 1%. These proposed rules will primarily impact those operators. The total production from those entities was 31,055 BOPD and 99,710 MCFPD (36 BCF/year) from 29,520 leases equaling 3 MCFPD per lease. The proposed regulations are uneconomic based on capital, operating increases, and regulatory burden. The proposed BSER's recordkeeping and reporting will make operating these leases uneconomic.

Response II-4-107: As discussed in the December 2022 Supplemental Proposal, the EPA did not find that production rates correlate to the amount of fugitive emissions and therefore would not be appropriate to use as a basis for establishing different fugitive emissions monitoring requirements among well sites. However, the EPA did find that data supports distinguishing among well sites based on equipment and component counts. The EPA is finalizing this approach in the final rule, which includes less burdensome requirements for smaller sites, and a more stringent monitoring regime for well sites with leak-prone equipment.

Contrary to a commenter's assertion that requiring monitoring based on the type and counts of equipment at a site rather than throughput will require the same expensive retrofitting and monitoring for a lower-producing well and a higher-producing well, the EPA disagrees. First, the methods for identifying well site fugitive emissions (*i.e.*, AVO, OGI, and EPA Method 21), methane emissions reductions, costs, and cost-effectiveness for methane emissions, are the same for fugitive emissions components affected facilities at new well sites and at existing well sites. Second, the fugitive emissions monitoring requirements do not require the installation of controls on existing equipment or the retrofit of equipment.

During the development of the rule, the EPA assessed all aspects associated with the feasibility, costs, and benefits of requiring fugitive emissions monitoring for existing facilities. The annual costs and cost-effectiveness for the fugitive emissions monitoring type and frequency chosen for existing well sites and centralized production facilities were provided in Tables 15-19 of the December 2022 Supplemental Proposal preamble.<sup>224</sup> In the December 2022 Supplemental Proposal, the EPA also presented the costs and cost-effectiveness of the other monitoring frequencies that were evaluated, but that were determined to have costs that were not reasonable.

---

<sup>224</sup> 87 FR 74738-74739 (December 6, 2022).

The EPA also considered the impact of the fugitive emissions monitoring requirements on all small businesses (*i.e.*, requirements that affect small operators at new and existing sites). This was a factor in determining that for single wellhead only well sites and small well sites, quarterly AVO surveys were appropriate. Inspections using AVO do not require specialized equipment or operator training but does allow the identification of large leaks. In addition, AVO monitoring can easily be built into regular maintenance activities that are designed to keep the equipment at the site in good working order. The EPA is also including final requirements which allow AVO and soap bubble tests as an option for finding fugitive emissions, particularly because they are low cost and easy to implement alternatives for detecting leaks. The EPA believes this will particularly benefit small entities because AVO surveys at these types of well sites are effective at identifying the types of large emissions from sources located at these well sites at a much lower cost than OGI surveys.

#### **4.4 EG OOOOc Fugitive Emissions from Compressor Stations**

Comment: Commenter (2410-California Office of the Attorney General et al.) supports EPA's revised approach of monthly AVO monitoring and quarterly OGI monitoring of fugitive emissions at new and existing compressor stations. California requires quarterly Method 21 inspection of compressor stations with the option of OGI monitoring, as long as a Method 21 inspection is performed in the event OGI monitoring detects a leak.<sup>225</sup> New York regulations require bimonthly monitoring at compressor stations using EPA Method 21, OGI, or an approved alternative that is at least as effective.<sup>226</sup> Colorado's regulations require quarterly inspections of fugitive VOC emissions greater than or equal to 50 tpy, bi-monthly if greater than or equal to 50 tpy and located within a disproportionately impacted community or within 1,000 feet of an occupied area, or monthly if greater than or equal to 50 tpy.<sup>227</sup> The States and Cities further support EPA's adoption of a presumptive standard for compressor stations in the OOOOc emission guidelines that follows the same fugitive monitoring and repair program as for new sources.<sup>228</sup> As EPA recognizes,<sup>229</sup> the BSER analysis is the same for both new and existing sources.

Response II-4-108: The comment is a supportive comment on an aspect of the December 2022 Supplemental Proposal that has remained unchanged in the final rule; as such, no response is required.

#### **4.5 Well Sites and Compressor Stations on Alaska North Slope**

Comment: Commenter (2317-Alaska Oil and Gas Association (AOGA)) believes EPA should revise the proposed fugitive emissions LDAR requirements to address the unique conditions that face Alaska producers.

Commenter (2317-AOGA) states in the November 2021 proposal, EPA proposed several amendments to LDAR monitoring frequency requirements for Alaska North Slope (ANS) well

---

<sup>225</sup> Cal. Code Regs., tit.17, §§ 95668-95669.

<sup>226</sup> 6 NYCRR 203-7.2(c).

<sup>227</sup> 5. Colo. Code Regs. 1001-9:D.II.E.3.a & Tbl. 3.

<sup>228</sup> 86 Fed. Reg. at 63,174.

<sup>229</sup> *Id.* at 63,196.

sites and compressor stations in recognition of the cold temperatures that prevail for longer periods on the ANS than in other parts of the country, and the infeasibility of conducting OGI during half the year.<sup>230</sup> The commenter states in support of these provisions, and requested several additional adjustments to account for the logistic challenges of conducting LDAR monitoring on a large number of facilities during a very short season.<sup>231</sup>

Commenter (2317-AOGA) request that EPA allow up to 14 months between annual surveys, and provided a detailed technical justification for the additional month.<sup>232</sup> The commenter notes that the current proposal retains the 13 month interval maximum interval between surveys,<sup>233</sup> and the preamble does not mention or address the commenter's request.<sup>234</sup>

Response II-4-109: The EPA acknowledges the comments provided regarding the special challenges facilities located on the Alaska North Slope face. The EPA is already including different provisions for fugitive emissions components affected facility located on the Alaska North Slope. These provisions take into consideration the unique challenges of well sites and compressor stations on the Alaska North Slope by providing an annual fugitive emissions monitoring schedule, which the EPA believes accommodates for the extreme cold temperature. In the final rule, the EPA is retaining the annual monitoring requirement for well sites and compressor stations located on the Alaska North Slope. Consecutive annual monitoring surveys would be required at least 9 months apart and no more than 13 months apart.

Comment: Commenter (2317-AOGA) requests a limited extension of the two year deadline for repairs that are technically infeasible or unsafe for facilities located on the Alaska North Slope.<sup>235</sup> The commenter points out that the emissions impacts of shutting down a well site to fix a leaky flange can vastly exceed the emissions from the leak itself, especially when a line needs to be evacuated (vented) to allow for safe work. The commenter urges EPA to apply the schedule imposed in other LDAR rules by omitting the two year hard deadline, but retaining the requirement that delayed repairs must be completed during the next scheduled shutdown.<sup>236</sup> The commenter recognizes that EPA may not want to have indefinite periods of time where a leak is detected but not repaired. If EPA believes that the rule must include a hard deadline, the commenter suggests that the EPA specify the deadline for completion of repairs as the earlier of three years from detection or during the next scheduled shutdown. The longest turnaround interval reported by the commenter's members is three years. The additional scheduling flexibility will avoid the scenario in which the emissions from a forced shutdown to repair the leak dwarfs the emissions impact from the leak itself.

Response II-4-110: The EPA is finalizing provisions to allow for delay of repair for parts unavailability, in no case allowing for delay beyond 2 years. The EPA believes this time frame is sufficient.

<sup>235</sup> 2022 AOGA Comments at 5-6.

<sup>236</sup> Id. at 6.

Comment: Commenter (2440-Nevada Nanotech Systems, Inc.) states difficult environmental conditions such as the North Slope are an ideal application for advanced continuous monitoring systems. The most advanced of such systems contain Built In Self Test features that ensure reliable operation even in harsh environments for up to 15 years. They operate accurately at temperatures down to -40C and have been tested night and day in all environmental conditions (rain, snow, dust etc). The commenter encourages the EPA to also allow continuous monitoring technology solutions as a BSER for the North Slope to provide year-round continuous monitoring and maximum reduction of methane emissions.

Response II-4-111: The EPA disagrees that continuous monitoring technology is the BSER because we do not have sufficient information to include this new but rapidly advancing technology in the BSER analysis; however, the EPA supports the use of continuous monitoring systems to detect fugitive emissions. The EPA is providing a pathway for owners and operators to utilize continuous monitoring technologies at well sites and compressor stations as part of the advanced methane detection technology provisions of the rule. Please see section X.B.2 of the preamble to the final rule which details EPA's final standards related to advanced methane detection technology. These alternative GHG and VOC standards through the use of continuous monitoring system apply to all fugitive emissions components affected facilities, including fugitive emissions components affected facility located on the Alaska North Slope.

Comment: Commenter (2248-North Dakota Petroleum Council (NDPC)) adds, like Alaska, North Dakota's weather poses many safety and logistical challenges that can limit inspector access to oil and natural gas locations for days or weeks. Ice, snow, rain, fog, frigid temperatures, high winds, and flooding are common occurrences in North Dakota. North Dakota is the coldest state in the Continental U.S. during the winter and fall,<sup>237</sup> and in 2022 saw temperatures below -27 °F with the wind chill as low as -60 °F. The commenter requests that similar variances be given to wells in areas that lack the adequate infrastructure or experience the same limitations on access.

Commenter (2248-NDPC) adds unlike some oil and natural gas basins where the facilities are densely spaced, facilities in the Willison Basin are spread out. LDAR inspectors have a lot of windshield time between facilities, and this can be significantly impacted by bad driving conditions. Increasing the frequency of LDAR inspections reduces the window of opportunity a company must reschedule inspections delayed by bad weather conditions. Also, some activities at well sites may increase the safety risk to the LDAR Inspector. These activities include but are not limited to well completion, maintenance, construction activities, or times when a well site is shut-in from production. The commenter does not wish to expose the inspector to unnecessary safety risks during these times.

Commenter (2248-NDPC) notes there may be periods of time when a facility LDAR inspection must be delayed for the reasons stated above. The commenter would like to see some additional acceptable reasons for delaying inspections added, including adverse weather conditions, unsafe site conditions, and facility production shut-in.

Commenter (3604-Riverside Operating Company (ROC)) adds ROC owns and operates over 5,000 natural gas wells in northern Michigan and there are concerns with respect to the proposed

---

<sup>237</sup> [www.worldatlas.com](http://www.worldatlas.com).

regulations, namely, economic impact on marginal wells and the overall cost burden, as well as increased operational challenges in northern Michigan; to include lack of sunlight in the winter months preventing solar power from being a viable option along with hundreds of well sites located in remote rural areas.

Response II-4-112: The EPA has included in the final rule, as proposed, a provision in §60.5397b(g)(4) that accommodates for special weather conditions below 0°Fahrenheit where quarterly OGI monitoring is required. Specifically, the quarterly OGI monitoring requirements in §60.5397b(g)(1)(iv) and (v) are waived for any fugitive emissions components affected facility located within an area that has an average calendar month temperature below 0°Fahrenheit for two of three consecutive calendar months of a quarterly monitoring period. The EPA believes this satisfies the commenter's concern.

## Chapter 5. Advanced Methane Detection Technologies

### 5.1 General Comments and Support

Comment: Several commenters (2181-Ute Indian Tribe of the Uintah and Ouray Reservation, 2198-Private Citizen, 2212-Union of Concerned Scientists (UCS), 2235-SLB, 2237-State of North Dakota Industrial Commission and North Dakota Department of Environmental Quality, 2256-Mille Lacs Band of Ojibwe, 2296-New Mexico Environment Department (NMED), 2310-Montana Department of Environmental Quality (MTDEQ), 2333-LongPath Technologies, Inc. (LongPath), 2432-Action Group for Incentivizing Methane Emissions Detection by Advanced Technologies (AGIMEDAT), 2433-Environmental Defense Fund (EDF) *et al.*) express support for EPA's consideration of alternative methane detection technologies under the proposed requirements for fugitive emissions.

Commenter (2181-Ute Indian Tribe of the Uintah and Ouray Reservation) states staff of the Ute Tribe's Air Quality Program have had the opportunity to accompany EPA inspectors during EPA inspections, accompany oil and gas operators conducting LDAR inspections, and have also conducted our own inspections using an OGI camera. In all instances, it has been observed that a majority of the facilities have some form of fugitive emissions.

However, given the sheer number of facilities that would be subject to the final rule, the EPA should consider working with the Ute Indian Tribe to develop a comprehensive LDAR program which may include delegation of inspection and enforcement activities to the Tribe. Additionally, the EPA should consider allowing technologies that provide quantifiable, verifiable, consistent monitoring, and compliance data at a scale that can accommodate large remote regional areas consisting of hundreds or even thousands of facilities. As the EPA heard in the public hearings on this Proposed Rule, there is a great benefit to all operators and regulators to allow the use of new and widely accepted technologies to prevent leaks and fugitive emissions.

Commenter (2198-Private Citizen) notes EPA assumes emissions impacts of these new proposals will begin in 2026. From now until the impacts of these new processes have merit, it would be unfortunate to use antiquated methane measuring techniques. The potential for EPA to work with new satellite technology could be a huge leap forward in monitoring all greenhouse gases.

Commenter (2212-UCS) notes that technologies enabling methane leak detection and monitoring have been rapidly advancing, greatly expanding awareness and understanding of the scale and scope of the methane pollution problem<sup>1</sup> as well as beginning to facilitate rapid and targeted repairs. These technological advances have made clear the limitations of earlier monitoring approaches and the importance of EPA developing pathways for regularly incorporating new methodologies and technologies as they become available.

---

<sup>1</sup> Results from one recent three-year aerial survey focused on the Permian Basin identified nearly 1,100 super emitters over the course of the study, including 30 sites that emitted methane for multiple years (see, *e.g.*, Carbon Mapper and Environmental Defense Fund reporting here: <https://www.edf.org/media/dozens-super-emitting-oil-and-gas-facilities-leaked-methane-pollution-permian-basin-years-end>).

Commenters (2235-SLB, 2432-AGIMEDAT, 2433-EDF *et al.*) commend the EPA for including provisions in the Proposed Rule for the use of advanced technologies as alternatives to optical gas imaging (OGI) surveys.

Commenter (2256-Mille Lacs Band of Ojibwe) believes that by encouraging the deployment of innovative and advanced monitoring technologies all along the natural gas and crude oil pipelines and their systems would ensure accountability and reliability in identifying methane and volatile organic compound (VOC) leaks early, so that they may be rectified as quickly as possible.

Commenter (2296-NMED) strongly urges the EPA to authorize the use of next generation monitoring tools to determine compliance with the requirements of the proposed rule. This is an equally important concept for industry to utilize to monitor emissions as it is for states to use to assure compliance with applicable rules. There are several innovative compliance approaches that can be used to effectively and efficiently monitor sources for compliance, while balancing the already strained resources of state agencies. Given the magnitude of affected sources that will be brought under the rule, EPA should consider allowing technologies that provide quantifiable, verifiable, and consistent monitoring and compliance data at a scale that can accommodate large remote regional areas consisting of hundreds or even thousands of facilities. The commenter supports these innovative approaches and has provided a mechanism for their use in our state rule. Alternative monitoring strategies must be effective, enforceable, and equivalent and are a critical option for ensuring that emission leaks are identified and repaired as required.

Commenter (2310-MTDEQ) supports the utilization of new technologies and techniques and encourages further development of the proposed rule in this area if it is to be implemented.

Commenter (2333-LongPath) states that to ensure that the rule is technology neutral, and that maximum emissions reductions are achieved, it urges EPA not to include greater response requirements or more stringent emissions thresholds for some technologies than others. The commenter is very supportive of the progress made between the November 2021 draft proposal and the supplemental proposal for continuous monitoring. The commenter strongly supports the use of methane emission rates (rather than concentrations) and the use of these technologies for emissions monitoring of covers and closed vent systems (CVS). The commenter also believes EPA is correct in identifying “valid” (that is, 3rd party blind validated for accuracy) emission rate measurements as a prerequisite for use of technologies under these provisions.

Commenter (2432-AGIMEDAT) supports EPA’s aim to create a technology-agnostic, performance-based alternative test method framework that provides pathways for utilizing existing and future advanced technologies and performance improvements. These provisions have the potential to improve the efficacy and efficiency of emissions monitoring because advances technology can provide more comprehensive spatial and/or temporal coverage than that required for standard OGI surveys, which can lead to a greater volume of detected emissions.

Based on cost information that is available, commenter (2433-EDF *et al.*) also understands that these technologies are typically much cheaper to deploy than OGI (half the cost or less).<sup>2</sup>

---

<sup>2</sup> 2022 Joint Environmental Comments, *supra* note 1, at 116–19.

Allowing advanced technologies as an alternative to OGI through a matrix is a reasonable decision that fits well with EPA's section 111 authority and the Clean Air Act (CAA) more broadly. The CAA is a technology-forcing statute,<sup>3</sup> and section 111 "looks toward what may fairly be projected for the regulatory future, rather than the state of the art at present."<sup>4</sup> EPA can therefore design frameworks that accommodate reasonably anticipated improvements in detection capabilities, rather than the limitations of currently in-use technologies, particularly where (as here) the anticipated advancements are optional rather than mandatory. Most importantly, in providing any alternative compliance option, EPA must ensure that emission reductions equal to or greater than the best system of emission reduction (BSER) will occur.<sup>5</sup>

Commenter (2433-EDF *et al.*) points out that the D.C. Circuit has indicated that "EPA may provide sources with multiple work practice compliance options if EPA demonstrates that at least one of these options is cost effective and 'expressly provides for the alternative in the standard.'"<sup>6</sup> The commenter indicates that the OGI based BSER is cost-effective and EPA has proposed an alternative work practice of "periodic or continuous screening with advanced measurement technology instead of OGI and audio, visual, and olfactory (AVO) monitoring according to minimum detection sensitivity of technology."<sup>7</sup> This voluntary (but once chosen, enforceable) alternative is supported by precedent,<sup>8</sup> and EPA has appropriately followed the statutory requirements by ensuring equivalent emission reductions will occur.

Response II-5-1: EPA acknowledges the commenters' support for alternative methane detection technologies for fugitive emissions.

Comment: Commenter (1649-The Sisters of St. Francis of Philadelphia (SSFP)) asks EPA to require innovative technology. The commenter states it is not enough to "encourage" innovative technology; EPA must "require" it. EPA must also recognize that States are lagging in using updated technology and it is time to implement technical and procedural fixes to record methane leakage. The commenter suggests that quality and expert education in these innovative technologies be required of oil and gas sector.

Response II-5-2: EPA acknowledges the commenters support for the use of alternative technologies. EPA disagrees that advanced methane detection technology is the BSER because we do not have sufficient information to include this new but rapidly advancing technology in the BSER analysis. Additionally, these technologies and associated methods for their applications have not been adequately demonstrated to achieve the same emission reduction as OGI, which is the required BSER in this rulemaking. However, EPA supports the use of these

systems to detect fugitive emissions. The EPA is providing a pathway for owners and operators to utilize advanced methane detection technologies at well sites, centralized production facilities, and compressor stations as part of the final rule. See discussion in section X.B of the preamble to the final rule which details EPA's final standards related to advanced methane detection technology.

Comment: Commenter (2226-Thermo Fisher Scientific (Thermo Fisher)) encourages EPA to move forward with finalizing the rule to initiate the program as soon as possible so that the capable measurement and monitoring technologies that are ready today can be deployed. This would also enable technology providers to begin to understand and prepare for equipment needs and behaviors under the program, as well as under the WEC, or 'methane fee' program, that the oil and gas industry must adhere to if they do comply with the NSPS for new and existing sources. At this time, the commenter requires further insights as to how the oil and gas industry will interact with measurement and monitoring technologies so that we can supply the equipment necessary for compliance in a timely manner. The development of future technologies relies largely on the needs and opportunities as outlined in the final version of this EPA program. Due to supply chain challenges and ramp-up timescales, the commenters states that their industry requires ample lead time to develop and manufacture the equipment necessary for these programs. Thus, advance notice and insights to inform proper scaling up is key. With this information, the commenter is certain that it can provide the equipment necessary to achieve the goals of the program.

Response II-5-3: EPA acknowledges the commenter's support for advanced methane detection technologies. EPA is providing a pathway for owners and operators to utilize advanced methane detection technologies at well sites, centralized production facilities, and compressor stations as part of the final rule. See discussion in section X.B of the preamble to the final rule which details EPA's final standards related to advanced methane detection technology.

### ***5.1.1 Technology-Neutral/Matrix Approach/Flexibility***

Comment: Commenters (1609-Qnergy, Inc., 1649-SSFP, 2039-Citizens to Preserve Ligonier Valley, Inc., 2152-California State Teachers' Retirement System, 2163-EOS at Federated Hermes, 2164-Nordea Asset Management, 2177-Southern Ute Indian Tribe (Southern Ute), 2184-Physicians for Social Responsibility (PSR), 2185-New York State Comptroller (NYSC), 2190-Miller/Howard Investments, Inc., 2191-Boston Trust Walden Company, 2203-Ceres, Inc. (Ceres), 2206-Legal & General Investment Management America, Inc., 2212-UCS, 2226-Thermo Fisher, 2242-Seventh Generation Interfaith, Inc., 2247-Ohio Environmental Protection Agency (OHEPA), 2251-National Association of Manufacturers (NAM), 2254-Permian Basin Petroleum Association (PBPA), 2256-Mille Lacs Band of Ojibwe, 2287-Interfaith Center on Corporate Responsibility, 2298-Pioneer Natural Resources USA, Inc. (Pioneer), 2299-NEI Investments (NEI), 2309-Planet Labs PBC (Planet), 2310-MTDEQ, 2316-ABB, Inc. (ABB), 2326-American Exploration and Production Council (AXPC), 2350-Cheniere Energy, Inc. (Cheniere), 2355-Constellation Energy Corporation (CEC), 2363-Continuous Emission Monitoring Coalition (CEMC), 2365-Climate Action California, 2388-ExxonMobil, 2424-As You Sow, 2429-Wyoming Outdoor Council, 2433-EDF *et al.*, 2446-Independent Petroleum Association of America (IPAA), 2458-MiQ, 2459-BMO Global Asset Management, 2627-

British Columbia Investment Management Corporation (BCI), 2696-Congressman Scott H. Peters *et al.*) express support for EPA's proposal to include the flexibility to use advanced methane detection technologies to assess leaks in lieu of OGI or EPA Method 21.

Response II-5-4: EPA acknowledges the commenters' support for EPA's allowance of advanced methane detection technologies to assess leaks in lieu of OGI or EPA Method 21.

Comment: Commenters (2203-Ceres, 2298-Pioneer, 2446-IPAA, 2458-MiQ) believe that there is sufficient evidence to show that aerial screening and monitoring technologies on the market today are capable of detecting fugitive emissions from affected sources as well as periodic surveys using OGI or Method 21. Further, aerial technologies have been shown to detect certain types of emissions that OGI has missed, particularly in field deployment comparisons and across larger areas.

Commenter (2251-NAM) suggests that EPA give oil and gas operators the option to choose between multiple alternative detection technologies in their leak detection and repair (LDAR) plan. Operators should be able to tailor their own LDAR plan for their location and unique operational circumstances. Leak detection technologies that work great in the Permian Basin might not be equally great for the Williston or Marcellus Basins. The commenter encourages EPA to fully embrace and use flexibility in detection/abatement techniques since the technologies get better each year.

Commenter (2308-National Stripper Well Association) believes that technology requirements must be applied fairly. In addition, while EPA is making efforts to allow emerging technologies to be used in fugitive emissions programs, these new technologies are evolving constantly. Whether they currently compare to EPA's assessment of its OGI program, the potential for future technologies cost effectively exceeding the current OGI technology capabilities is likely. As a result, EPA's current mix of technologies and frequencies should change to reflect better methodologies. Producers should not be constrained to the use of outdated methods when better ones arise.

Response II-5-5: EPA has provided flexibility in the final rule for owner and operators to choose the appropriate detection platform for their methane detection surveys by finalizing matrices that tie the frequency of inspection to the method's minimum detection threshold. Owners and operators complying with the alternative fugitive emissions standards using advanced methane detection technologies may choose any approved (or multiple approved) methods to conduct periodic screening events or continuous monitoring. EPA recognizes that technology will continue to improve and has structured the rule to allow for continued improvement instead of relying on legacy measurement approaches by not specifying particular advanced methane detection technologies that owners and operators must meet. Instead, the rule relies on the detection capabilities of the technology.

Comment: Commenter (2299-NEI) believes this flexibility will help offset the cost of enhanced monitoring while also incentivizing the development of increasingly sophisticated direct measurement technologies. The measurement techniques and methodologies that have been relied on traditionally are not providing an accurate capture of methane emissions data and this

lack of accurate data creates a real risk of misallocation of capital. Direct measurement technologies have the potential to provide much more decision useful information.

Response II-5-6: EPA disagrees that existing monitoring techniques for fugitive emissions are inaccurate or ineffective. However, EPA recognizes the benefits of advanced methane detection technologies and encourages the use of these technologies. EPA is providing a pathway for owners and operators to utilize advanced methane detection technologies at well sites, centralized production facilities, and compressor stations as part of the final rule. See discussion in section X.B of the preamble to the final rule which details EPA's final standards related to advanced methane detection technology.

Comment: Commenter (2433-EDF *et al.*) strongly supports EPA's proposed alternative periodic screening option for LDAR at well sites, centralized production facilities, and compressor stations that would allow for the use of advanced methane detection technologies. Innovation in methane detection technologies and deployment methods is advancing rapidly and EPA has taken a careful, technology-neutral approach that will enable the use of these technologies for regulatory compliance.

Commenter (2627-BCI) states the EPA should provide flexibility for compliance by allowing advanced technologies to be used should they deliver equal or better methane mitigation. As these wells drive a significant proportion of all wellsite emissions, the commenter views this as a strong approach to ensure that oil and gas companies can deliver more robust carbon reduction commitments.

Response II-5-7: EPA acknowledges the commenter's support for advanced methane detection technologies. EPA is providing a pathway for owners and operators to utilize advanced methane detection technologies at well sites, centralized production facilities, and compressor stations as part of the final rule. See discussion in section X.B of the preamble to the final rule which details EPA's final standards related to advanced methane detection technology.

Comment: Commenters (2203-Ceres, 2298-Pioneer, 2446-IPAA, 2458-MiQ) commend EPA's efforts to incorporate advanced technologies as a regulatory option, as well as the inclusion of a matrix in this proposal.

Commenter (2446-IPAA) supports the use of a matrix that takes into consideration inspection frequency and minimum detection sensitivity. The commenter appreciates EPA's willingness to adopt a matrix approach, but as proposed will likely be of limited benefit – the concept is solid, but the implementation falters. The commenter notes that emerging technologies to be used in fugitive emissions program are evolving constantly and whether they currently compare to EPA's assessment of its OGI program, the potential for future technologies cost effectively improving upon the current OGI technology capabilities is high. As a result, EPA's current mix of technologies and frequencies should change to reflect better methodologies. Producers should not be constrained to the use of outdated methods when better ones arise.

Commenter (2298-Pioneer) supports EPA's approach of enabling owners and operators to use advanced technologies through a performance matrix based on inspection frequency and

minimum detection sensitivity. The proposed matrix, combined with alternative test methods, can provide operators and technology developers well-defined requirements for use of an alternative technology for compliance. This clarity is essential for technology developers to continue investing in the design of, and for operators to choose to use, advanced technologies for compliance with this rule. The commenter also supports EPA's use of the Fugitive Emissions Abatement Simulation Tool (FEAST) modeling to demonstrate equivalency with the statutory requirement of BSER.

Commenter (2320-American Public Gas Association) states all aspects of the natural gas supply chain value innovation. In issuing a final rule, the commenter recommends EPA not implement mandatory, prescriptive detection requirements, as this action will disincentivize new technologies. The natural gas industry is committed to research and development efforts. Specifically, there is a track record of developing technologies that aid in the mitigation of methane emissions, which align with the goals of this Proposal. Accordingly, EPA should allow flexibility when it comes to the technologies and the techniques used by the industry for leak detection.

Commenter (2226-Thermo Fisher) supports EPA's decision to enable end-users to select from a range of technologies to adequately measure emissions based on unique site specifications.

Response II-5-8: EPA acknowledges the commenter's support for advanced methane detection technologies. EPA is providing a pathway for owners and operators to utilize advanced methane detection technologies at well sites, centralized production facilities, and compressor stations as part of the final rule. See discussion in section X.B of the preamble to the final rule which details EPA's final standards related to advanced methane detection technology.

EPA has provided flexibility in the final rule for owner and operators to choose the appropriate detection platform for their methane detection surveys by finalizing matrices that tie the frequency of inspection to the method's minimum detection threshold. Owners and operators complying with the alternative fugitive emissions standards using advanced methane detection technologies may choose any approved (or multiple approved) methods to conduct periodic screening events or continuous monitoring. EPA recognizes that technology will continue to improve and has structured the rule to allow for continued improvement instead of relying on legacy measurement approaches by not specifying particular advanced methane detection technologies that owners and operators must meet. Instead, the rule relies on the detection capabilities of the technology.

Comment: Commenter (2405-Bridger Photonics, Inc. (Bridger)) states since the November 2021 proposal, significant research has been made public that bears critical implications for modeling the performance of different emissions monitoring approaches. To ensure that the final rules are based on an accurate representation of existing emissions distributions as observed by recent measurement campaigns, and modeling is based on the emissions reductions that can be achieved by advanced technologies, the EPA must take this research into consideration. For example, Bridger recently submitted a paper for publication that describes an emission rate distribution measured in the Permian Basin with continuous coverage from large emission rates down to rates

below 2 kg/hr (2 kg/hr emission rates were detected with 90% PoD).<sup>9</sup> It is possible to compare the distribution of emissions simulated in FEAST<sup>10</sup> with this extensive empirical emission rate distribution because it overlaps with the large-emitter, tank, and component emissions rate distributions that were bootstrapped during the EPA's FEAST modeling. Preliminary investigations suggest that emissions with rates between 600 and 1 kg/hr were significantly underrepresented in FEAST simulations, meaning that critical reevaluation may be necessary to avoid promulgating final rules that incorrectly represent the efficacy of different detection sensitivity tiers in the alternative emissions monitoring framework. The commenter urges the EPA to compare FEAST simulated leak fields to Bridger's empirical emission rate distribution to correct and validate modeling inputs. This should be done in a publicly transparent process so that stakeholders can help identify pitfalls and have confidence in equivalency determinations.

Response II-5-9: See discussion in section X.B.1 and XI.B.1 of the preamble to the final rule related to the data EPA used for the FEAST modeling.

Comment: Commenter (2696-Congressman Scott H. Peters *et al.*) expresses that this is an opportunity to allow industry to utilize all the technological tools at their disposal to reduce methane emissions as opposed to the Agency choosing a specific slate of technologies or being overly prescriptive. The commenter urges EPA to work together with states to promulgate regulations that comply with the CAA and allow for the broadest variety of methane emissions detection technologies, or combinations of technologies, while driving towards the use of best available technologies to measure actual site-level emissions. Operators are already using innovative, proven technologies such as on-site continuous monitoring, as well as aerial and satellite monitoring. A technology-neutral approach will enable operators to choose the technology and system design best suited and cost-effective for their facility and geographic region. This is particularly important for rural areas that may have an extra burden to access certain facilities in person, particularly during a time when many companies are having a difficult time recruiting a robust workforce.

Response II-5-10: EPA acknowledges the commenter's support. Through the advanced methane detection technology work practices EPA has finalized, we are applying a technology-neutral approach to this application. Owners and operators are free to the technology that best fits their needs from the approved technologies.

Comment: Commenter (2696-Congressman Scott H. Peters *et al.*) states the result could be a matrix of technologies that could be deployed to achieve the specified level of detection and control. Such a matrix will allow operators to choose the most effective system design for their location without the need for a cumbersome site-specific equivalence demonstration or alternative application process. The matrix should recognize that some technologies have a more sensitive detection threshold, thereby making it possible to require less frequent monitoring. Conversely, for technologies that have a less sensitive threshold, the matrix could require

---

<sup>9</sup> Kunkel, W. M. et al. Extension of Methane Emission Rate Distribution for Permian Basin Oil and Gas Production Infrastructure by Aerial LiDAR. EarthArXiv (2023).

<sup>10</sup> US EPA. Supplemental Background Technical Support Document for the Proposed New Source Performance Standards (NSPS) and Emissions Guidelines (EG) 40 CFR Part 60, subpart OOOOb (NSPS) 40 CFR Part 60, subpart OOOOc (EG). (2022).

relatively more frequent monitoring. In addition, the matrix should make it possible for operators to evaluate and use a combination of technologies. The commenter believes this will promote ongoing best available technology development towards actual direct emissions measurement and achieve the most emission reductions at least cost.

Response II-5-11: EPA acknowledges the commenter's support. EPA is finalizing an advanced methane detection technology work practice that employs a matrix approach to link inspection frequency to minimum detection threshold.

Comment: Commenter (2284-Kairos Aerospace (Kairos)) strongly supports EPA's decisions to both use fugitive emissions program modeling and to incorporate into its modeling the latest peer reviewed science on emission distributions based on remote sensing technology. The area of emission measurement and computer simulation of leak detection programs is a rapidly evolving one. The commenter encourages EPA to consider periodically updating its modeling protocols based on our evolving scientific understanding to ensure EPA continues reflecting the best available information.

Commenter (2299-NEI) urges EPA to work with States and industry to continue to encourage innovation in monitoring, and specifically to develop means for operators to share monitoring resources and data (where relevant) in order to scale efforts and bring down costs for everyone. Commenter (2458-MiQ) recommends that the matrix be updated on an annual basis using applicable new research.

Response II-5-12: EPA acknowledges the commenters' support of EPA's modeling in development for work practices for advanced methane detection technologies. EPA cannot continuously update the standards in NSPS OOOOb and EG OOOOc after finalizing the standards, as this creates regulatory uncertainty for owners and operators; the standards are based on the best available data and assumptions at the time of this rulemaking.

EPA is aware that our underlying assumptions may change as more emissions data are collected after the implementation of this rule. EPA may use this data to evaluate existing assumptions in the equivalency model and whether any changes are warranted to the periodic screening matrix, as part of the required NSPS review cycle.<sup>11</sup>

Comment: Commenter (2316-ABB) asserts that in all cases, EPA should allow owners and operators a choice in selecting commercially available methane detection technologies that are best suited and most effective for their applications. EPA should emphasize to all stakeholders that the most effective technology, for the greatest public benefit, is rarely the least expensive to purchase. Rather, successful reduction of methane emissions will require the purchase and deployment of proven, effective technology and methods that enable rapid, reliable detection and quantification of large, small, and even hidden leaks. EPA should educate all stakeholders about the availability of new methods that save valuable time (and thus operating costs) by minimizing false positives as well as false negatives. As addressed in a subsequent point, legacy technologies, such as OGI, are simply unable to address current methane leak reduction

---

<sup>11</sup> Clean Air Act Section 111 requires that at least every 8 years, the EPA review and, if appropriate, revise standards of performance for regulated NSPS sources.

requirements. Choice in commercially available methane leak detection should also be applied to the proposed “Super-Emitter” program.

Response II-5-13: EPA acknowledges the commenter’s concern. The final rule is designed to provide owner or operators with additional options for methane monitoring. EPA is technology agnostic in the final rule. EPA will post all technologies that are approved for use under §60.5398b(d) on EPA’s Emissions Measurement Center webpage. Owners and operators may investigate and choose the technology that best meets their needs from those listed or request and alternative test method for methane detection technology.

Comment: Commenters (2248-North Dakota Petroleum Council (NDPC), 2294-Ohio Oil & Gas Association (OOGA)) disagree with the above commenters and argue the proposed approach for utilizing alternative leak detection technologies is unworkable and lacks support. Commenter (2248-NDPC) does support the use of advanced methane detection technologies and urges EPA to reconsider including prescriptive requirements within the NSPS rules that could preclude the use of technologies. The commenter is urging the EPA to provide flexibility in the NSPS to use technologies that are presently proven to be successful in each basin. A layered or tiered application of multiple technologies will be the most cost-effective with the greatest emissions detection capability.

Commenter (2294-OOGA) appreciates EPA authorizing alternative leak detection technologies under the Supplemental Proposal. However, the approach for implementing such alternative technologies is based on a matrix of requirements that incentivizes operators to not use any alternative technologies. That is, the Supplemental Proposal allows the use of alternative technologies in place of OGI but with increased monitoring frequencies. EPA’s approach lacks justification and may not be cost effective. The commenter also notes that the technology certification process is unworkable (another disincentive) and that the basis for the continuing monitoring thresholds lacks justification.

Response II-5-14: The matrix frequency is based on a determination of equivalency with the existing BSER for the fugitive program and cover and closed vent system requirements. EPA did not evaluate cost of the alternatives, because they are considered alternatives to the BSER.

EPA has provided flexibility in the final rule for owner and operators to choose the appropriate detection platform for their methane detection surveys by finalizing matrices that tie the frequency of inspection to the method’s minimum detection threshold. Owners and operators complying with the alternative fugitive emissions standards using advanced methane detection technologies may choose any approved (or multiple approved) methods to conduct periodic screening events or continuous monitoring. EPA recognizes that technology will continue to improve and has structured the rule to allow for continued improvement instead of relying on legacy measurement approaches by not specifying particular advanced methane detection technologies that owners and operators must meet. Instead, the rule relies on the detection capabilities of the technology.

### ***5.1.2 Incentivize Advanced Technology***

Comment: Commenters (2333-LongPath, 2363-CEMC, 2448-Project Canary) believe EPA should align requirements between OGI and advanced technologies inspections for instances where an advanced technology finds “deviations” from non-fugitive emission components. Thus, to ensure operators are not assuming additional risk for using an advanced technology that can better detect emissions, the final rule should clarify that if operators discover a process failure using an advanced technology—such as a malfunctioning flare or other failed control device—the operator should repair the failure within a specified period of time and not risk a violation. Operators should also be required to report the failure. If the detected process malfunction is corrected within that specified period and was not caused by operator error or negligence, the owners and operator should not be liable for any violation for a failure of the control device. This approach is consistent with EPA’s 2015 petroleum refinery NESHAP, which would find a deviation only if emissions are caused by operator error, operator negligence, or repeat violations. The commenters urge EPA to design the final rule to create an incentive to look for and repair emission sources through a compliance pathway for process malfunctions for advanced technologies.

Response II-5-15: EPA disagrees with commenters that a change in emission standards is necessary to incentivize the adoption of advanced technologies. EPA recognizes that emissions detected by advanced methane detection technologies could result in finding deviations from emission standards.<sup>12</sup> But owners and operators have a legal duty to operate any affected facility in compliance with applicable standards, including emission limits, and affected facilities must be in compliance with the requirements of the rule at all times. Frequent detection of excess emissions by advanced monitoring technologies should not occur if control devices and other emission sources are adequately engineered to continuously meet applicable emission standards. Allowing “grace periods” for repair during which compliance with emission limits is not required would be inconsistent with and weaken the emission limits determined to be the best system of emission reductions because it would no longer require continuous compliance. “Grace periods” would further disincentivize efforts to address the underlying causes of deviations and take corrective measures to ensure continuous compliance with applicable standards. If monitoring with advanced methane detection technology results in the identification of a deviation from an emission standard, corrective actions should be taken as soon as possible to address the failures. Further actions may also be necessary to address the underlying causes of the deviation and avoid future emission detections by the advanced monitoring technologies. For example, where advanced technologies indicate emissions from covers and closed vent system on an affected facility, which are required to achieve a no identifiable emission standard, an engineering evaluation may be warranted to confirm the system is adequately designed to meet the no identifiable emission standard.

Comment: Commenters (2248-(NDPC), 2360-Devon Energy (Devon)), 2363-CEMC, 2448-Project Canary, 2432-AGIMEDAT, 2458-MiQ) ask that EPA establish a compliance pathway that will incentivize deploying advanced technologies.

---

<sup>12</sup> See 87 FR 74743-74744 (December 6, 2022).

Commenter (2248-NDPC) feels the advancement of new technologies are critical for any industry; however, the commenter feels EPA's current proposal on advanced methane detection technologies does not incentivize its use, but conversely disadvantages its use.

Commenter (2360-Devon) supports the proposal of a matrix framework that allows for the use of advanced detection technologies as part of a flexible and effective fugitive emissions monitoring and repair program and offers suggestions to avoid potential disincentives. The commenter states methane emission detection technologies are evolving rapidly and are a key component of the commenter's strategy for broader emission reductions. The commenter believes these technologies have the potential to be more effective at finding leaks on a broader scale, allowing for faster detection and mitigation, leading to a greater reduction in methane emissions. The commenter is concerned that there may be inadvertent disincentives that are contrary to the intent of EPA, which is to encourage innovation resulting in meaningful emissions reductions. If these disincentives persist in the final rule, it may encourage operators to simply continue their existing OGI survey programs as the default option and hinder broad development and adoption of advanced detection technologies.

Commenter (2458-MiQ) recommends that EPA provides a clear 'pathway' for methane detection reporting that would include a defined period or periods to address fugitive methane emissions. According to this recommended approach, the operator would not be out of compliance if the detection is addressed before the end of the regulatorily determined period and a report of the methane emissions, including a quantification of the extent of the emissions, was reported to EPA and relevant state authorities. This compliance pathway could be tiered based on the reason and source of the leak and emission type, as well as the monitoring technology in effect. If the emission source is not mitigated by the end of the determined period, the operator would be in violation. Similarly, if an operator repaired the leak within the allowed period, but did not report the emission, the operator would also be in violation.

Commenter (2458-MiQ) provides the example, the type of tiered structure recommended in this comment could consist of the following:

- Tier 1: Leaks from sources that are not required to be monitored and where performance is not regulated by other regulatory requirements.
  - Repair timeline: x days
- Tier 2: Leaks that include both traditional LDAR leaks and that are already subject to regulatory monitoring; and sources that are not required to be monitored but where performance is subject to other regulatory requirements.
  - Repair timeline: < x days
- Tier 3: Emission detected using OGI technology. If advanced methane technology is available and appropriate for the facility in question and has a lower methane detection limit than the OGI technology that was used to detect the leak.
  - Repair timeline: < x-y days (where x and y are whole numbers)

Response II-5-16: EPA developed the matrix framework to provide a pathway for alternative methane detection technology to be applied to the rule without the requirement to go through the alternative means of emission limitation (AMEL) process, which is like the rulemaking process

in that it requires public notice and an opportunity for public comment. The periodic screening matrix framework EPA is finalizing pairs monitoring frequency with the detection sensitivity of the alternative technology and is a “plug and play” approach. Because the matrix was developed using modeling that demonstrated equivalency to the BSER, there is no need for owners and operators to demonstrate equivalency for individual sites, as long as the owner or operator uses the periodic screening matrix and a technology approved by the Administrator. By approving the technology through an Administrator approval process, EPA can approve technologies in a more streamlined fashion. We disagree this approach disincentivizes the use advanced technology, as any approved technology could be used within the periodic screening matrix framework to achieve equivalent emission reductions to the BSER.

The alternative work practice standards using advanced methane detection technologies clearly lay out the actions (and the timeframes for those actions) that owners and operators must take in response to a detection during a periodic screening event or exceedance of an action level.

EPA notes that owners and operators still have the capability to request an AMEL for an alternative work practice standard to the work practice standards that are included in the final rulemaking. Entities requesting an AMEL would be required to provide a demonstration of equivalency as part of the AMEL application.

Comment: Commenter (2360-Devon) argues, as proposed, the matrix framework seems to require an “all or nothing” approach to advanced detection methods. While these detection technologies have been adopted widely within voluntary programs,<sup>13</sup> there may be times where deployment of these technologies is hindered due to certain weather conditions in the field. For instance, the commenter’s northern assets may have seasonal snow cover that would otherwise prevent the deployment of certain technologies. The commenter encourages EPA to incorporate within the final rule a pathway that allows for programs that use a combination of technologies, both traditional and advanced, to achieve equivalent emission reductions. For example, the commenter could craft a monitoring plan that incorporates traditional OGI surveys during the months when advanced detection technologies cannot be deployed.

For the suite of methane detection technologies that can be classified as continuous or near continuous, the commenter (2360-Devon) is concerned that the rule as proposed will present a barrier to their use as an alternative within a compliance program. The commenter encourages EPA to ensure the rule is technology neutral by not holding some technologies to greater response requirements than others. There is an obvious benefit to encourage the use of technologies that can facilitate rapid detection and mitigation of significant emission events, so they should not be inadvertently discouraged by overburdening them with more stringent response requirements simply because they can detect emissions more frequently. The commenter believes continuous and near-continuous technologies could fit within the periodic screening matrix frequency and detection thresholds, with an appropriate work practice.

Response II-5-17: EPA agrees with the commenter. We did not intend for the periodic screening matrix framework to be an all or nothing system. As explained in Section X.B.1 and XI.B.1 of

---

<sup>13</sup> <https://www.prnewswire.com/news-releases/devon-energy-to-use-aerial-gas-mapping-lidar-to-track-down-methane-emissions-across-full-portfolio-301477706.html>.

the preamble of the final rule, EPA has revised the final rule to allow multiple technologies to be used so long as the frequency of the monitoring is reflective of the technology with highest detection threshold.

Comment: Commenter (2360-Devon) also encourages EPA to consider how operators should follow up on methane emissions events detected by advanced continuous, near-continuous, and non-continuous detection technologies. In many cases, the cause and mitigation of an identified emission event can be determined remotely using operational information, including Supervisory Control and Data Acquisition (SCADA) data, negating the need for a follow-up OGI inspection in each and every case. In many cases, it can also provide verification that the event is no longer occurring. This has an additive safety and environmental benefit of reducing the number of miles driven and the resulting emissions from travel to and from the site in question. The commenter also encourages EPA to consider whether the proposed follow-up and repair timeframes are appropriate in every circumstance, particularly given the large amount of data obtained during a flyover screening survey. Operators should be given flexibility to prioritize those events with the highest estimated emission rate when using technologies that have the capability of providing a quantification estimate. Lower priority emission events (*i.e.*, those events with a lower estimated emission rate) should be allowed additional time for follow-up so that available operator resources can be utilized to address higher estimated emission rate events first.

Response II-5-18: EPA agrees that SCADA data is a valuable tool in identifying probable causes of emissions. However, EPA considers it important to follow-up a periodic screening event with a confirmed detection with a ground level measurement to determine if emissions are still occurring, even if at low levels, and whether there are other sources contributing to the detection, other than the source determined through SCADA data. EPA also agrees that SCADA or other data can provide owners and operators with information that allows them to prioritize emission events and address events with larger leaks quicker. The final rules provide sufficient time for follow-up inspection of all detections identified with advanced screening technology.

For continuous monitoring technologies, the final rulemaking requires the owner or operator to conduct an investigative analysis following an exceedance of an action level. The final rulemaking does not dictate what actions the owner or operator must take in response to the action level exceedance, allowing the owner or operator to determine what actions are necessary to reduce the mass emission rate below the action level.

Comment: Commenter (2432-AGIMEDAT) believes the rule inadvertently disincentivizes the adoption of advanced technologies by penalizing more effective detection of emissions with a burden of unnecessary full-site OGI follow-up surveys and/or compliance violations. The final rule should encourage, rather than penalize, the efficient and effective detection of emissions. The commenter advocates for critical revisions to the rule that will incentivize the detection, characterization, and mitigation of emissions by ensuring that (a) the follow-up response to emissions detected with advanced technologies is appropriate to the emission and (b) a compliance pathway is provided for operators to correct detected emissions that would otherwise result in an immediate compliance violation. The commenter urges the EPA to implement the following three technology-agnostic, performance-based solutions as revisions to the final rule.

1. Exclude from the follow-up OGI survey requirement those emissions which are conclusively attributable to sources by investigative analysis.
2. Change the follow-up OGI survey requirement to pertain only within the localization uncertainty region of the advanced technology.
3. Incentivize the detection and mitigation of compliance issues detected by advanced technologies.

Commenter (2458-MiQ) states to incentivize the continued adoption and use of advanced screening technologies, the commenter recommends that a) EPA dedicates resources to the testing and approval process for advanced monitoring technologies, per the process outlined in the supplemental proposal; and b) the matrix be updated on an annual basis using applicable new research. OGI efficacy and inspection frequency should also be updated on an annual basis using applicable new research. This research could, for example, include studies of the comparative effectiveness of different monitoring technologies (both new and existing). Similarly, updated guidance concerning AVO methodology and surveys should be conducted on an annual basis.

Response II-5-19: EPA agrees with the commenter that when a technology has sufficient spatial resolution, it may be unnecessary to conduct a full site wide screening. As explained in Section X.B and XI.B, EPA has revised the final rule to include three different classes for spatial resolution; site-level meaning technology that can identify excess emissions from an area containing a well site, centralized tank battery, and/or compressor station; area-level meaning technology that can detect emissions within 2m<sup>2</sup>, and component-level meaning technology that can detect emissions within 0.5m<sup>2</sup>. Each class of technology has a different OGI follow-up requirement to account for the locality of the detected emissions.

Additionally, see response II-5-12, which responds to the issue of updating the advanced methane detection technology work practices periodically.

### ***5.1.3 Industry Advancing Technologies***

Comment: Commenter (2410-California Office of the Attorney General (CA AG) *et al.*) encourages EPA's support for the use of advanced methane detection technologies for identifying fugitive emissions. The State of California has partnered with private companies, federal agencies, and several academic and philanthropic entities to advance the use of remote sensing plume-mapping technology for detecting emissions. The State of California has committed \$100 million towards the purchase of this type of data from satellites, which will be awarded by a competitive request for proposal process. This technology can pinpoint and quantify leaks and other emissions of methane and carbon dioxide. These efforts build upon a successful partnership between the California Air Resources Board, the California Energy Commission, and the NASA Jet Propulsion Laboratory on a statewide study to identify large methane sources across California. That study, called the California Methane Survey, used similar technology envisioned for the satellites but mounted on airplanes to "see" methane emissions. Many commercial satellite companies are in the early stages of developing and deploying satellites equipped with similar methane plume mapping instruments, along with capabilities to observe up to 25 other environmental indicators. California will continue to

explore how best to use this new information to mitigate emissions even further, both in California and globally.

Commenter (2410-CA AG *et al.*) notes however, given that this technology is still emerging and developing, the States and Cities recommend that alternative screening methods (*e.g.*, aerial surveys) should complement, and not yet completely replace, traditional OGI/AIMM inspections. The commenter further suggests that EPA let states have the flexibility to employ alternative screening after individualized review of the appropriateness of the technology, frequencies, follow-up and repair timelines, as is most effective in the region and for the sites for which the alternative screening is deployed.

Response II-5-20: EPA acknowledges the commenter's support for the alternative technology program. EPA notes that due to the lack of approved technologies and associated methods for their applications, OGI remains the BSER in this rulemaking. However, EPA is providing a pathway for owners and operators to utilize advanced methane detection technologies at well sites, centralized production facilities, and compressor stations as part of the final rule. See discussion in section X.B of the preamble to the final rule which details EPA's final standards related to advanced methane detection technology. Owners and operators would not be able to employ advanced methane detection technologies for compliance with NSPS OOOOb or EG OOOOc until EPA has reviewed and approved the technology.

EPA notes that in implementing regulations for which they have been delegated administrative authority, air agencies may have more stringent requirements than the requirements in federal rules. Additionally, states have flexibility through submittal of the state plans developed for EG OOOOc to identify solutions for the oil and gas basins in their jurisdiction.

Comment: Commenter (2350-Cheniere) supports the EPA's inclusion of advanced methane detection technologies in the supplemental proposal. The commenter notes that in 2021, it embarked on a multi-year, multisector quantification, monitoring, reporting, and verification ("QMRV") program with a number of our key suppliers and a host of leading technology vendors. The commenter initiated the program to assess the capabilities of novel emissions measurement technologies and improve understanding of measurement-informed greenhouse gas emissions specific to the commenter's supply chain. The QMRV program is designed, conducted, and analyzed by scientists at the Payne Institute for Public Policy at the Colorado School of Mines, and University of Texas at Austin, and Colorado State University. In 2022, the

commenter initiated the QMRV program with midstream infrastructure partners and at our pipeline and liquefaction facilities. Results from this work have been published<sup>14</sup> or submitted to peer-reviewed journals.<sup>15, 16</sup>

Commenter (2350-Cheniere) finds the application and efficacy of these emissions measurement technologies vary depending on multiple factors and the sector of the natural gas supply chain. For facilities in the production sector of the supply chain, the commenter concluded that multi-scale measurements are important and necessary to detect and develop measurement-informed inventories, which then can support emission reductions. For the midstream sector, Brown *et al.* (2023) concludes that there are challenges to the use of alternative technologies and additional scientific investment is required to better characterize methane emissions to support reduction activities.

Response II-5-21: EPA acknowledges the support of the alternative technology program.

Comment: Commenter (2316-ABB) indicates that with today's commercially available technology, monitoring and collection of comprehensive data characterizing methane leaks can be done quickly and efficiently. For example, ABB's methane leak detection equipment includes an automated documentation process that can record rigorous data efficiently and cost effectively without, as older methods require, expensive calibration to validate measurements. Data collection is no longer a prohibitive, time-intensive, laborious exercise. More importantly, owners and operators can feel comfortable that their interests are properly and accurately represented to federal, state, local, and tribal authorities.

Response II-5-22: EPA acknowledges the support of the alternative technology program and agrees that advanced technology should include sufficient documentation so that the systems can be appropriately audited. As explained in Section X.B.3 and XI.B.3 of the preamble of the rule, EPA has revised and expanded the information that entities must submit to the EPA when requesting an advanced methane detection technology test method.

Comment: Commenter (2213-Occidental (Oxy)) supports EPA's efforts to streamline the process for obtaining approval to demonstrate compliance using advanced measurement technologies. The commenter explains that they are actively engaged and have participated in numerous technology pilots in the pursuit of supplementing our LDAR capabilities, including fixed monitors, drone-mounted cameras, fixed-wing aircraft surveys, and satellite surveys.

Multiscale Methane Measurements at Oil and Gas Facilities Reveal Necessary Frameworks for Improved Emissions Accounting. *Environmental Science & Technology* 2022, 56, 14743–14752.

<sup>15</sup> Daniels, W. S.; Wang, J. L.; Ravikumar, A.P.; Harrison, M.; Roman-White, S.A.; George, F.C.; Hammerling, D.M. Towards Multi-Scale Measurement-Informed Methane Inventories: Reconciling Bottom-Up Inventories with Top-Down Measurements using Continuous Monitoring Systems. DOI: 10.26434/chemrxiv-2023-jp5nt. Pre-print can be found at: <https://chemrxiv.org/engage/chemrxiv/article-details/63e526b9cfb27a31f7c0a6c>.

<sup>16</sup> Brown, J.A.; Harrison, M.; Rufael, T.; Roman-White, S.R.; Ross, G.B.; George, F.C.; Zimmerle, D. Informing Methane Emissions Inventories Using Facility Aerial Measurements at Midstream Natural Gas Facilities. Pre-print. DOI: 10.26434/chemrxiv-20230dq01m. Pre-print can be found at: <https://chemrxiv.org/engage/chemrxiv/article-details/63e6b8aafcfb27a31f8ec5b9>

The commenter deploys drones at several of their oil and gas production facilities. At their DJ basin facilities, the commenter uses drones to survey thousands of wellheads as part of a voluntary initiative to reduce emissions. In addition, the commenter surveys wellheads, facilities, and pipeline segments across U.S. operations with fixed-wing aircraft, deploying both broad-coverage campaigns and individual asset surveys. The commenter participates in The Environmental Partnership and its collaborative efforts to better understand and utilize the capabilities of remote sensing technologies that are being developed. A summary of The Environmental Partnership's efforts and learnings can be accessed at <https://theenvironmentalpartnership.org/collaboration-on-remote-sensing-technologies/>.

These innovative LDAR technologies show great promise as tools to supplement traditional LDAR methods. For instance, aerial surveys – both fixed-wing and satellite – allow operators to rapidly inspect large geographic areas, including remote sites, pipelines and gathering lines, that cannot readily be traversed at ground level and elevated equipment such as columns or towers at facilities. Fixed monitoring stations allow for operators to continuously gather monitoring data, creating additional opportunities to identify and address leaks that may otherwise not be identified until a periodic survey is conducted using currently approved LDAR inspection methods. These benefits can assist operators and inspection and maintenance personnel in efficiently and timely directing resources and response efforts to high-priority sites, with less time spent traveling to remote locations that could be covered by fixed monitors or remote sensing.

Response II-5-23: EPA acknowledges the support of the alternative technology program.

Comment: Commenter (2348-Energy Workforce & Technology Council (EWTC)) explains that since 2018, a team has been utilizing drones equipped with methane detection cameras and sensors in the Permian Basin. It has conducted over 1,000 inspections using drones and drone mounted sensors, combined with an artificial intelligence (AI) enabled software platform. This effort is contributing to meeting an operator's goals of maintaining methane emissions intensity below 0.2% by 2025 and meeting the requirements of the Oil and Gas Methane Partnership (OGMP) 2.0 framework.

Commenter (2348-EWTC) notes that since 2018, there has been commercially available continuous monitoring using a sensor network strategically placed at an oil or natural gas production site to monitor for emissions. Industry-wide, there are at least 5 million sensor operation hours for continuous monitoring, providing years of reliable and actionable emissions data for operators. The real-time and historical trend data available from continuous monitoring has provided many advantages in data science and process automation for operators including new levels of emissions visibility and how emissions correlate to the operational schedules and processes. Ultimately this not only provides a better source of information to help prioritize repair efforts, but also significantly shortens the time between initial detection and repair.

Commenter (2348-EWTC) adds that there is also gas cloud imaging (GCI) system in Europe to provide automated and continuous monitoring for leaks of dangerous and polluting gases such as methane at oil and gas, chemical and power generation facilities across the continent. The Mini GCI systems can be placed throughout an industrial facility to continuously monitor for gas leaks

and provide alerts as soon as they occur. The system provides facility operators with an easy-to-interpret, colored visualization of the gas plume type, location, direction, size and concentration. This allows for an earlier and more effective response before leaks have the chance to grow into bigger emissions or safety issues.

Response II-5-24: EPA acknowledges the support of the alternative technology program.

Comment: Commenter (2251-NAM) believes EPA should educate all stakeholders interested in methane (including those parties during the Title V permitting renewal process) about the availability of new methods that save valuable time by minimizing false positives as well as false negatives. EPA needs to assure the public that the wider choices in technology options by producers is the most cost effective and accurate method to find the methane and fix the leaks.

Response II-5-25: EPA is technology agnostic in the final rule. As explained in Section X.B.3 and XI.B.3 of the preamble of the final rule. EPA will post all technologies that are approved for use under §60.5398b(d) on EPA's Emissions Measurement Center webpage.

Owners and operators may investigate and choose the technology that best meets their needs from those listed or request an alternative test method for advanced methane detection technology.

Comment: Commenter (2309-Planet) states that current approaches to measure methane emissions at the scale of individual facilities – focused on detection of intermittent activity – present challenges especially in terms of transparency, accuracy, scalability, and cost. The commenter is working to overcome technological barriers to enable accelerated action to reduce methane emissions with plans for a new, groundbreaking hyperspectral satellite constellation called Tanager, expected to begin launching in 2023. The commenter's hyperspectral mission is designed to measure energy in the visible through shortwave infrared wavelengths (400-2500 nm) in over 400 spectrally contiguous bands with 30-meter ground sample distance (GSD). This capability can support the identification of methane emissions at the facility scale, along with a myriad of other applications to improve life on earth spanning across areas such as biodiversity, water quality, land use, national security, agriculture, and more.

Commenter's (2309-Planet) hyperspectral mission brings the promise of ushering in a new era of increased transparency and accountability by providing rapid methane leak detection for super emitters, while our partner Carbon Mapper is developing a global portal to enable wide adoption and transparency, providing a trusted certification chain underpinned by our public-private partnership.

The commenter's (2309-Planet) methane-specific hyperspectral offering could enable users to identify and quickly address methane plumes emanating from specific facilities. These capabilities can be tasked to assist in infrastructure surveys or as a monitoring capability engaged at regular user-driven cadences. The satellite-based technology is intended to balance coverage and sensitivity, covering enough area with a frequency to meet end user needs while providing the sensitivity needed to find facility-level leaks. This would provide federal, state, and local

governments with the tools to measure point-source methane emissions and also support industry in monitoring and measuring their own emissions to enable remediation and prevention.

Commenter (2309-Planet) states EPA should support the leveraging of satellite technologies to fill data gaps which have prevented more widespread identification, mitigation, and prevention of methane emissions. The commenter's satellites orbit the Earth every day collecting consistent data which can be used to gain insights into emissions happening around the world. This global coverage includes remote locations in all 50 states and every municipality across the country. Tanager data products could provide more timely data to identify the source of and support quantification of methane emissions, track mitigation progress, and verify project completion. This facility-level data is needed to enable actionable decisions by industry and government alike.

Response II-5-26: EPA agrees that emissions data from satellites provide value in identifying very large emissions events.

See discussion in section X.B of the preamble to the final rule which details EPA's final standards related to advanced methane detection technology. Additionally, see responses in Volume II, Chapter 14 for responses related to technology use in identifying super-emitter events.

Comment: Commenter (2419-Exploration Robotics Technologies, Inc. (Xplorobot)) describes that it has developed a component-level solution for detection and quantification of methane emissions in oil and gas facilities. The commenter's solution provides a three-dimensional (3D) map of methane concentration, makes visible emissions that may otherwise be invisible to the naked eye on a 3D model of the equipment, identifies the emission's source to the component level, calculates the methane concentration as a function of the distance from the emission's source and quantifies the emission rate based on an industry-standard dispersion model. The commenter's clients use the Xplorobot solution to detect and quantify emissions and to verify the effectiveness of the mitigation steps.

Commenter (2419-Xplorobot) indicates that in response to operators' concerns, the commenter designed a solution such that it does not require a certified inspector to detect, visualize and quantify methane emissions. The solution can be deployed by operators as part of their routine duties, providing savings not only on the hourly rate of the personnel that deploys the solution, but also saving incremental driving or helicopter flying time, given that the solution is deployed as part of field/pad visits to address issues of daily operations by the personnel who operate the fields/sites. Implementation of the commenter's solution is viewed by their clients as the means to comply with the new EPA requirements for cadence and accuracy of methane inspection in a labor and cost-effective manner. It is also considered as an enabler for certification of "clean gas" production for low production wells that cannot afford quarterly OGI inspections or installation of continuous monitoring devices.

The commenter's technology has been validated in laboratory experiments at the Lawrence Berkeley National Laboratory in November of 2022 and January of 2023. Accuracies of methane emissions rate quantifications down to 0.1 kg/hr were achieved. In January of 2023, field

experiments at Methane Emissions Technology Evaluation Center (METEC) achieved a 100% rate of emissions detection on Pads 1, 4 and 5 and are now in the process of validating the quantification accuracy against the known rates of the emissions.

Response II-5-27: EPA acknowledges the commenter's support for advanced methane detection technologies. EPA is providing a pathway for owners and operators to utilize advanced methane detection technologies at well sites, centralized production facilities, and compressor stations as part of the final rule. See discussion in section X.B of the preamble to the final rule which details EPA's final standards related to advanced methane detection technology.

## **5.2 Multi-Layer/Combination of Technologies**

Comment: Commenters (2235-SLB, 2284-Kairos, 2326-AXPC, 2388-ExxonMobil, 2391-Chesapeake Energy Corporation (CEC), 2428- American Petroleum Institute (API)) make the argument that EPA should explore the option of deploying a combination of alternative technologies. Commenter (2388-ExxonMobil) urges EPA to ensure the regulations provide as much flexibility to optimize emerging technologies as possible, including the layering of technologies.<sup>17</sup>

Commenters (2235-SLB, 2284-Kairos, SLB, 2326-AXPC, 2428-API) request that EPA consider a multi-layered approach to leak detection that would allow operators to combine multiple detection technologies.

Commenter (2235-SLB) indicates that the proposed matrices do not provide guidance on deployment of combinations of alternative technologies. Deploying alternative technologies in combination can allow the complementary strengths of the different technologies to be combined in practice. More effective monitoring can occur in many situations if different technologies are combined. Examples exist of how periodic screening technologies and continuous monitoring technologies can be deployed in combination to achieve particularly effective monitoring.<sup>18</sup> Additionally, the matrices do not provide guidance on customized emissions distributions or edge situations between the five frequency versus threshold scenarios presented in each table.

Response II-5-28: EPA agrees with the commenters that owners and operators should be able to use one or more alternative test methods for advanced methane detection technology to conduct

---

<sup>17</sup> See Cardoso-Saldaña FJ, Tiered Leak detection and Repair Programs at Oil and Gas Production Facilities, ChemRxiv. Cambridge: Cambridge Open Engage (2022). "Methane emission rates originating from oil and gas production facilities are highly skewed and span 6-8 orders of magnitude. Traditional leak detection and repair programs have relied on surveys with handheld detectors at intervals of 2 to 4 times a year to find and fix emissions, however this approach may lead to leaks being active for the same interval independently of their magnitude. In addition, manual surveys are labor intensive. Novel methane detection technologies offer opportunities to further reduce emissions by quickly detecting the high emitters, which account for a disproportionate fraction of total emissions."

<sup>18</sup> <https://chemrxiv.org/engage/api-gateway/chemrxiv/assets/orp/resource/item/636d4595afea7fcd1c9f5f67/original/tiered-leak-detection-and-repair-programs-at-oil-and-gas-production-facilities.pdf>.

periodic screening. Sections X.B.1 and XI.B.1 of the preamble to the final rule include a discussion on the use of multiple technologies with the periodic screening matrices.

Owners and operators could use periodic screening technologies to enhance continuous monitoring systems by using these periodic screening technologies to keep emission rates from exceeding the action levels for the site. For work practice standards other than those included in the final rulemaking, including the use of different inspection frequencies, owners and operators still have the capability to request an AMEL. Entities requesting an AMEL would be required to provide a demonstration of equivalency as part of the AMEL application.

Comment: Commenter (2226-Thermo Fisher) understands that lower-producing wells may find the economics of procuring the measurement and monitoring equipment and resources challenging. As developers and suppliers of measurement and monitoring equipment, further information on who will be deciding the type(s) of technology used to measure gas leaks at well sites will help inform the commenter and other companies in our industry of any potential need for additional technical assistance or technical information. The commenter recognizes there are many measurement and monitoring technology options available to in-house oil and gas personnel and third-party contractors and selecting the correct equipment for specific needs and environmental conditions is key.

Response II-5-29: EPA has provided flexibility in the final rule for owner and operators to choose the appropriate detection platform for their methane detection surveys by finalizing matrices that tie the frequency of inspection to the method's minimum detection threshold. Owners and operators complying with the alternative fugitive emissions standards using advanced methane detection technologies may choose any approved (or multiple approved) methods to conduct periodic screening events or continuous monitoring.

Comment: Commenter (2448-Project Canary) recommends EPA consider whether additional combinations of detection limits and sample frequency detections can enable a broader range of technologies if they can demonstrate equivalency to EPA's determined BSER. For example, EPA could include additional frequencies and combinations of technologies to encourage the deployment of technologies that can demonstrate equivalency with BSER.

Response II-5-30: EPA acknowledges the commenter's recommendation. As explained in sections X.B.1 and XI.B.1 of the preamble to the final rule, we have included more flexibility to use multiple technologies in the matrix framework in the final rule; however, we are not expanding the framework as part of this final rule.

Comment: Commenter (2316-ABB) notes that given today's commercially available technology, it supports the regular monitoring of ALL well sites (and continuous monitoring, when appropriate). However, to reach the leak detection and reduction goals stated in the proposed and supplemental rules, the EPA should focus on the methane leak rate rather than the use of specific leak detection technology. For example, legacy technologies such as OGI, are unable to provide the necessary performance, reliability, and sensitivity needed to adequately meet current challenges. When sufficiently advanced leak detection technology is employed, the owner/operator will be able to effectively inventory all fugitive methane emissions and

subsequently prioritize their remediation based on the volumetric rate (flux) estimations. This will allow the largest emitting sources to be addressed most quickly and most efficiently.

Response II-5-31: EPA acknowledges the commenter's recommendation and agrees that new technology may have the ability for owner or operators to meet their emission reductions. As such, we have included a pathway for advanced technology in the final rule. EPA does not agree with the commenter that OGI does not provide sufficient sensitivity, performance, and reliability in identifying leaks from this sector. OGI continues to be the BSER for monitoring fugitive emissions affected and designated facilities.

Comment: Commenter (2284-Kairos) notes a key missing provision from EPA's proposed leak detection matrix is a pathway for combinations of technologies to be used. While it may be difficult to proactively imagine every possible technology combination and include it in the Proposed Rule, there are some clear examples that EPA should evaluate and develop pathways for approval.

Commenter (2284-Kairos) states the first case is related to seasonal conditions which may inhibit certain survey approaches. For example, aerial screening surveys may be limited in certain regions during certain times of the year due to weather constraints. Winter in places like North Dakota or Wyoming can be long and harsh, and aircraft may not be able to safely operate, particularly under the more frequent survey programs (*e.g.*, monthly surveys at 30 kg/hr). To remedy this and allow for regions with harsher conditions to benefit from advanced technology screenings, the commenter suggests EPA consider ways to allow OGI surveys or other combinations of technologies, like continuous monitoring systems, to be used in combination with aerial techniques. To illustrate, one possible program might involve using monthly aerial screenings March through November, with an OGI survey for the December-February timeframe. As EPA's modeling has made clear, a 1:1 trade out of inspection methods won't necessarily be equivalent, so three monthly OGI surveys during that three-month timeframe would create additional expense and complexity that isn't necessary to achieve equivalence with the BSER.

Commenter (2284-Kairos) continues, the second case would be situations where individual screening surveys are delayed or perhaps canceled due to extreme weather. For instance, a major hurricane could impact Gulf Coast operations and potentially close airfields for several weeks or longer, depending on the severity of damage. The probability of a situation such as this impacting a survey schedule might be higher for higher frequency programs.

Commenter (2284-Kairos) recommends the EPA allow for combinations of advanced screening surveys and other technologies, such as periodic OGI surveys, to be used to increase flexibility for how and where advanced technologies can be deployed. Once a methodology has been established, this could be expanded to other leak survey methods. EPA should establish a process for how to proceed with leak detection programs in situations where a single survey may be impacted by extreme weather or other force majeure.

Commenter (2284-Kairos) states EPA's current work practice for remote screening technologies dictates that when an operator receives a reported aerial detection, they must visit the site and

conduct a comprehensive OGI screening survey of that site. The commenter believes the general work practice of using ground observation in conjunction with remote screening is appropriate, as it's the most consistent and measurable way to identify and eliminate emissions. The commenter believes this proposed work practice can be strengthened through minor modifications.

Commenter (2284-Kairos) is also aware of arguments that in some instances a reported aerial detection is enough to determine a corrective course of repair, or that survey results can be dismissed as being tied to a process event through SCADA without a ground visit. This may be true in some instances, but in the commenter's extensive experience of conducting hundreds of thousands of facility measurements, they have found that there can be multiple disparate sources on a pad or single process unit (*e.g.*, multiple components on a vapor recovery system) that combine into a single "plume" from an aerial measurement system. This is true even for the highest resolution aerial imagery. The commenter is also aware of instances where incorrect assumptions regarding the nature of an airborne detection led to delayed follow up inspection and mitigation, and instances where SCADA data was unable to fully characterize deviations that led to significant emissions. Without ground truth verification, it's possible for emissions to be improperly diagnosed or only partially repaired.

Commenter (2428-API) believes a combination of technologies approach recognizes that each leak detection technology has strengths and weaknesses in terms of detection threshold, proximity to the source, localization performance, deployment frequency, and costs. For example, ground based OGI has a low detection threshold and localizes the leak to a particular component but requires proximity to the source and is infeasible to deploy at higher frequencies. Whereas satellites, aerial and continuous technologies can be deployed more frequently than ground based OGI, the increased distance from the source may not detect leaks on the component level. With these remote detection technologies, resources can be deployed more efficiently to repair leaks – operators would only need to visit sites with detected emissions to make repairs whereas using only OGI surveys require operators to visit each site but could result in no detected emissions. A continuous monitoring system can quickly detect a leak and depending on sensor location, provide an approximate location, but may not fully visualize its location like a plume map from a satellite or aerial survey. In other words, no individual leak detection technology offers a perfect solution.

Commenter (2428-API) states that by allowing the option for a combination of these various technologies into a single monitoring plan or framework, the weaknesses of one technology can be offset by the strengths of another, and the selected technologies work together to improve leak detection and reduce emissions in a flexible and cost-effective manner. Technologies can be combined such that larger emissions are quickly detected, and technologies that detect smaller emissions are deployed less frequently. Finding and fixing the biggest leaks quickly can greatly impact the overall emission reductions.

Commenter (2428-API) indicates that a multi-layered approach for leak detection combines various technologies to achieve greater emission reductions. Some fugitive emissions may be detected with traditional OGI or AVO during regular LDAR inspections. Intermittent emissions are not always detected during OGI or AVO inspections; however, they may be detected by a

continuous monitoring system. Deploying continuous monitors is not an option for all sites, such as those without access to reliable grid power. Alternatively, an aerial survey may detect emissions from such sites over a large area. Although satellites cannot always detect emissions at the component level, they can be useful for basin-wide detection of large emissions that may occur outside of scheduled inspections. This concept of layering various leak detection technologies is illustrated in the graphic below where lines and layers represent strengths of a given technology while the dashed circles represent weaknesses allowing undetected emissions. An example of this multi-layered approach using data from the Permian Basin can be found in an industry prepublication paper.<sup>19</sup> The commenter provides in their comment letter Figure 1. Multi-layered approach for leak detection showing satellite, aerial survey, and continuous monitoring.

Commenter (2428-API) adds that EPA has already included the idea of layering technologies with the screening survey plus annual OGI survey options in the periodic screening matrices. The commenter has two specific suggestions regarding an alternative multi-layered approach for leak detection:

- Add continuous monitoring and satellite technology as options directly in the matrices in combination with the periodic survey with and without annual OGI.
- Include an additional optional and flexible framework independent from the periodic screening matrices and case-by-case alternative means of emission limitation (AMEL) process where an operator can develop a monitoring plan for each basin/site with their chosen suite of EPA-approved technologies via EPA approved modeling.

Commenter (2428-API) believes that this flexible framework gives operators a clear pathway for a custom, fit-for-purpose option and would be an alternative to both the AVO/OGI requirements and alternative technology requirements. To benefit smaller operators, EPA should consider both a conservative, and realistic, default plan that allows for flexibility in monitoring technology as well as an option where an approved monitoring plan can be used by other operators with similar assets.

Response II-5-32: EPA has included the suggested layered approach in the final rule as described in Response II-5-28. While not discussed in the previous response, the layered approach allows the owner or operator to choose the most appropriate technology for the time of year. Additionally, the final rule allows the owner or operator at any time to conduct an OGI survey in lieu of conducting a required periodic screening event.

Comment: Commenter (2391-Chesapeake Energy Corporation (CEC)) supports EPA's continued encouragement of emerging technologies that enhance detection of potential emissions from the natural gas sector. Deploying a broader suite of advanced technologies is an important part of achieving additional cost-effective emission reductions. Still, the commenter urges EPA to expand its approach to provide greater flexibility and to ensure compatibility with and encourage the development of future technologies.

---

<sup>19</sup> Cardoso-Saldaña FJ. Tiered Leak Detection and Repair Programs at Oil and Gas Production Facilities. ChemRxiv. Cambridge: Cambridge Open Engage; 2022; This content is a preprint and has not been peer-reviewed. DOI: 10.26434/chemrxiv-2022-f7dfv.

Commenter (2391-CEC) supports alternatives for periodic screening and continuous monitoring, however, neither option accounts for companies using multiple technologies as part of a robust methane monitoring and detection program. The commenter is singularly committed to enhanced methane monitoring and achieving methane reductions from its dry gas assets. The company now has more than 2,000 continuous methane monitoring devices operating today. Over this, it layers satellite imagery with periodic aerial Gas Mapping LiDAR scans to quickly identify potential emission events. EPA's proposed periodic screening alternatives recognize that activities of a certain frequency that meet the minimum detection thresholds are equivalent to the OGI surveys and AVO inspections otherwise required by the proposed regulations. But neither the matrix nor the proposed continuous monitoring framework says anything about the equivalency of a combination of alternative technologies. This omission fails to serve EPA's goal of incentivizing new technologies and makes it difficult for the matrix to keep pace with future alternatives as they become available or as current options become more cost effective.

Commenter (2391-CEC) believes that in order to correct this, EPA should identify and implement a methodology that operators can use to determine the equivalency of a particular combination of technologies. Currently, the only other available avenue is CAA section 111(h)(3), but AMELs are simply not a workable approach for new technologies. The AMEL process has historically been extremely complicated due to onerous regulatory requirements, with no alternative certifications being granted thus far. Identifying a way to determine the equivalency of various technologies and make use of a combination of alternatives outside of the statutory AMEL process will further enhance advancement and innovation in this space and allow operators to capitalize on these technologies to reduce emissions cost effectively.

Response II-5-33: In the final rule, EPA has confirmed that multiple technologies could be used within the existing matrix framework and because the frequency of the monitoring is tied to the least sensitive technology, we recognize that approach could result in greater emission reduction if owners or operators use technology with better sensitivity in their monitoring.

### **5.3 Screening Frequency/Minimum Detection Threshold**

Comment: Commenter (2346-Encino Environmental Services, LLC (Encino)) believes EPA should establish both technology-specific and site-specific minimum detection thresholds<sup>20</sup> for all sensors, cameras, and advanced methane sensing technologies. Representative baseline detection limits established from clear baseline procedures that reflect actual emissions scenarios will allow operator flexibility for various processes, sources, or sites. Currently, all sensors, cameras, and meters are tested the same, but each has a unique detection ability that the testing does not account for with current commonly used procedures.

First, commenter (2346-Encino) indicates that all technologies are not created equal, each type of methane monitoring tool can have its own unique skill set (and utility) that if tested and evaluated in the same manner would discourage technological advancement. For example, 500

---

<sup>20</sup> Minimum Detection Level: Super Emitter 100 kg/hr; InfraRed Only may include camera 500 ppm; Short term action level 7-day average calculated each day; Long term action level 90-day average calculated each day; Wellhead only 15 kg/hr; Well sites with other equipment and compressor stations 21 kg/hr; Fugitive emission monitoring wellhead 1.2 kg/hr; Fugitive emission monitoring for well sites 1.6 kg/hr.

ppm (methane) (with EPA Method 21) allows for granular leak detection. However, there are several limitations: (a) it is an intermittent inspection program, (b) time lag regarding repairs and verification of the sustainability of each repair (resurvey), and (c) produces only a concentration value (not a mass or volumetric rate) while advanced methane technologies can establish mass emission and flow rates that can achieve the proposed 1.2 kg/hr MDL. Thus, as technology advances, improved detection results will decrease MDLs and improve the identification of methane emissions over time.

Second, commenter (2346-Encino) indicates each detection technology can have unique advantages and disadvantages. With each type of source releasing varied emissions at distinct levels, there are specific tools and procedures for monitoring these complex scenarios. Technology is available that can establish normal operating baselines for each source and monitor for irregularities that exceed these (pre-established) baselines. These action levels are sufficient for NSPS compliance demonstration; therefore, these action levels should be accepted for emission factor development (*e.g.*, permitting activities, and emission inventories).

Third, commenter (2346-Encino) indicates that sites are a combination of sources and technologies that are varied across specific monitoring situations. As technology improves the combinations of emission sources at a site will be quantifiable in a manner that will allow for real-time monitoring and detection of conditions that exceed EPA regulations on a monthly, daily, and potentially even hourly basis.

Commenter (2346-Encino) notes that methane intensity is not an accurate measurement of a site's action level. Methane intensity is commonly established by using emission factors, and vetted production data, neither of which includes analysis of the actual emissions profile of those sites. Accordingly, the correct measurement should be measured averages over time. For example, when construction projects increase emissions estimates of methane intensity the impact will not change, however, measured average projects will naturally fall within true action levels.

Response II-5-34: EPA acknowledges the commenter's support of continuous methane monitoring approach in the rule. We agree that as the measurement systems mature, sensitivity and time resolution of the measurements will improve.

Comment: Commenter (2406-Energy Emissions Modeling and Data Lab (EEMDL)) states recent work on multi-scale methane measurements indicates the importance of survey frequency in detecting intermittent large emitters. While the modeling referenced in this comment limited large emitter duration to 5 days, field observations indicate significantly shorter durations (in the order of minutes to hours) are possible. Furthermore, technologies used in this study (aerial- and drone-based screening) were able to attribute emissions to particular equipment. Identifying the emitting component for future repair only required follow-up OGI screening on the equipment group identified by the aerial system. Thus, the spatial resolution of the site-wide screening method may enable direct, equipment-specific emissions and will not require follow-up OGI survey on the entire site.

Response II-5-35: See discussion in section XI.B.1.c of the preamble to the final rule which details EPA's final standards related to spatial resolution of advanced methane detection technology.

The final rule also outlines different follow-up procedures based on the spatial resolution, or localization capabilities, of the technology. EPA has expanded on these details in Response II-5-19.

## **5.4 Compliance Issues/Deviations Detected by Advanced Technologies**

Comment: Commenters (2284-Kairos, 2298-Pioneer, 2333-LongPath, 2336-Kuva Systems (Kuva), 2348-EWTC, 2402-Differentiated Gas Coordinating Council (DGCC), 2405-Bridger, 2428-API, 2440-Nevada Nanotech Systems, Inc. (NNS)) express concerns that emissions detected using advanced technologies could be deemed compliance violations.

Commenters (2284-Kairos, 2298-Pioneer, 2333-LongPath, 2348-EWTC, 2402-DGCC, 2405-Bridger, 2440-NNS) ask if operators discover a process failure, such as a malfunctioning flare or other failed control device using an advanced technology, and the detection is fixed within that specified period, are the owners/operator liable for any violation for a failure of the control device?<sup>21</sup> EPA should ensure the Final Rule creates an incentive to locate and repair emission sources by creating a compliance pathway for process malfunctions detected by innovative technologies.

Response II-5-36: EPA disagrees with commenters that a change in emission standards is necessary to incentivize the adoption of advanced technologies. EPA recognizes that emissions detected by advanced technologies could result in deviations of emission limits applicable to an emission source. [See Section X.B and XI.B of the preamble of the rule]. But owners and operators have a legal duty to operate any affected facility in compliance with applicable standards, including emission limits, and affected facilities must be in compliance with the requirements of the rule during all times. Frequent detection of excess emissions by advanced monitoring technologies should not occur if control devices and other emission sources are adequately engineered to continuously meet applicable emission standards. Allowing "grace

---

<sup>21</sup> For example, in the Supplemental Proposal preamble regarding Control Vent System (CVS) requirements, EPA notes that "based on comments received on the November 2021 proposal, there appears to be confusion whether the proposed no detectable emissions (NDE) standard would be an emissions limit or a work practice standard. For example, one commenter stated that as written, the NDE standard would be a work practice standard because ' [a]s with all other fugitive emissions components, detection of a leak (in this case, defined as detectable emissions) through routine LDAR monitoring triggers the obligation to repair the leak. If that repair is accomplished according to the specific requirements in the rule, then there is no violation because the work practice has been fully implemented.' This interpretation of the standard is not correct. In fact, CVS must be designed and operated to route all gases, vapors, and fumes to a control device or to a process, which is defined as an emission limit of NDE. The corrective actions (in the form of the repair provisions) are provided to ensure that owners and operators bring the CVS back into compliance with the NOE emission limit as quickly as possible." EPA should clarify whether repairing the leak qualifies identified with advanced technology qualifies as complying with a work practice or whether it is a deviation under the rules.

periods” for repair during which compliance with emission limits is not required would be inconsistent with and weaken the emission limits determined to be the best system of emission reductions because it would no longer require continuous compliance. “Grace periods” would further disincentivize efforts to address the underlying causes of violations and take corrective measures to ensure continuous compliance with applicable standards. If advanced technologies monitoring results in the identification of violations of emission limits at non-fugitive components, corrective actions should be taken as soon as possible to address the failures. Further actions may also be necessary to address the underlying causes of the violations and avoid future emission detections by the advanced monitoring technologies. For example, where advanced technologies indicate emissions from covers and closed vent system that are not fugitive components and are required to achieve a no identifiable emission standard, an engineering evaluation could be warranted to confirm the system is adequately designed to meet the no identifiable emission standard.

Comment: Commenter (2333-LongPath) indicates that continuous monitoring is an effective means of detecting emissions from these types of systems, which can be intermittent in time or otherwise difficult to detect with AVO or OGI. Operators should be incentivized to use continuous monitoring in either the periodic screening matrix or under the continuous monitoring provisions, for example by not characterizing caught leaks as violations, but instead incentivizing operators to more rapidly find and repair the underlying problems. Because site-wide continuous monitors can measure all emissions but may not always be deployed so as to localize emissions, the thresholds for exceeding total site-wide total baseline emissions by the action levels determined in the matrix (periodic screening or continuous) should trigger an investigative analysis from desktop and, if needed, field, to identify the cause of the emission. That is, there should not be changes to the proposed action thresholds, so that all technology types can participate equally.

Commenter (2336-Kuva) states that due to spatial and temporal coverage of advanced technologies, different emission sources may be revealed that could represent compliance issues as compared to standard OGI surveys. Examples of such sources include compressor engine incomplete natural gas combustion and control devices issues. According to the commenter, the proposed rule inadvertently disincentivizes the adoption of advanced technologies by penalizing more effective detection of emissions with a burden of an often unnecessary full-site OGI follow-up survey. The commenter believes the final rule should encourage, rather than penalize, the efficient and effective detection of emissions. The commenter therefore advocates for critical revisions to the Proposed Rule that will incentivize the detection, characterization, and mitigation of emissions by ensuring that (a) the follow-up response to emissions detected with advanced technologies is appropriate to the emission and (b) a compliance pathway is provided for operators to correct detected emissions that would otherwise result in a compliance violation. The commenter urges the final rule to provide an efficient and explicit compliance pathway for addressing such compliance issues detected by advanced technologies that enables operators to avoid a violation if the source is appropriately mitigated.

Response II-5-37: EPA disagrees with commenters that a change in emission standards is necessary to incentivize the adoption of advanced technologies. EPA recognizes that emissions

detected by advanced technologies could result in deviations of emission limits applicable to an emission source. [See Section X.B and XI.B of the preamble of the rule].

Comment: Commenter (2428-API) states that emissions detected from covers and closed vents systems using alternative technology or while doing required follow-up surveys do not constitute a violation of the “no identifiable emissions” standard provided work practice standards are fully implemented.

According to commenter (2428-API), emissions detected from covers and closed vent systems are not necessarily violations of the “no identifiable emissions” standard since it is a work practice standard rather than a numerical zero emission standard. As with all other fugitive emissions components, detection of a leak (in this case, defined as identifiable emissions) through alternative technology or a required follow-up survey triggers the obligation to repair the leak. If that repair is accomplished according to the specific requirements in the rule, then there is no violation because the work practice has been fully implemented. Treating emissions detected from covers and closed vent systems as violations not only fails to acknowledge technical reality contrary to BSER, but it also disincentivizes the use of alternative technology.

Response II-5-38: EPA disagrees with the comment. While some CVS components are fugitive emission component, a no identifiable emission standard applies as an emission limit to covers and non-fugitive component CVS. The no identifiable emission standard, where applicable, is an emission limit and not a work practice standard, and owners and operators have an obligation to comply with that emission standard where it applies. Because covers and CVS are required to be designed and operated with no identifiable emissions, indications of emissions from these sources could result in violations of the emission limit applicable to CVS where the CVS is not a fugitive emissions component. While the final rule provides different options for demonstrating compliance with the operation of the cover and CVS no identifiable emissions standard, any detection of emissions, including during the use of alternative monitoring technology, is an indication of detected emissions that may be a violation of the no identifiable emission standard. While applicable repair, delay of repair or exceptions for unsafe and difficult to inspect equipment may appear to condone a “grace period” during which compliance with an emissions limit is not required, because the no identifiable standard in the final rule is established as an emission limit, operation in exceedance of that limit may be a violation even if the repair provisions are followed.

EPA further disagrees with commenters that a change in emission standards is necessary to incentivize the adoption of advanced technologies. EPA recognizes that emissions detected by advanced technologies could result in violations of emission limits applicable to an emission source. But owners and operators have a legal duty to operate any affected facility in compliance with applicable standards, including emission limits, and affected facilities must be in compliance with the requirements of the rule during all times. Frequent detection of excess emissions by advanced monitoring technologies should not occur if control devices and other emission sources are adequately engineered to continuously meet applicable emission standards. Allowing “grace periods” for repair during which compliance with emission limits is not required would be inconsistent with and weaken the emission limits determined to be the best system of emission reductions because it would no longer require continuous compliance.

“Grace periods” would further disincentivize efforts to address the underlying causes of violations and take corrective measures to ensure continuous compliance with applicable standards. If advanced technologies monitoring results in the identification of violations of emission limits at non-fugitive components, corrective actions should be taken as soon as possible to address the failures. Further actions may also be necessary to address the underlying causes of the violations and avoid future emission detections by the advanced monitoring technologies. For example, where advanced technologies indicate emissions from covers and closed vent system that are not fugitive components and are required to achieve a no identifiable emission standard, an engineering evaluation may be warranted to confirm the system is adequately designed to meet the no identifiable emission standard.

## 5.5 Follow-up OGI

Comment: Commenter (2305-Williams Companies, Inc. (Williams)) is generally supportive of EPA’s required alternative monitoring frequencies and screening levels. The commenter suggests, however, that monitoring survey and inspection activities in § 60.5398b(b)(4)(ii) (A) through (C) not be triggered when screening levels are exceeded as a result of the following permitted activities:

- Equipment maintenance blowdowns;
- Pig trap blowdowns;
- Emergency blowdowns; and
- Vented equipment emissions.

Response II-5-39: EPA recognizes the input from the commenter. It can be difficult to directly attribute all emissions identified by an aerial survey. While these short-term events can trigger a “hit” from an aerial survey, these events may also mask other leaks at the facility that could have also triggered a “hit” by the aerial survey. As such, we are retaining the requirements to conduct a ground survey when there is a “hit” during an aerial survey as detailed in Section X.B.1 and XI.B.1 of the preamble of the final rule.

Comment: Commenter (2405-Bridger) states the “blanket” follow-up OGI survey for emissions detected by advanced technology in the periodic screening matrix is an ineffective approach to mitigating emissions. Advanced technologies may detect, record, and characterize many emission sources for which OGI follow-up is unnecessary, unhelpful, and/or impractical. A mandatory OGI sweep will create a disincentive for operators to deploy advanced technologies for compliance with the Proposed Rule by causing an undue burden when it is not an appropriate or useful response. Moreover, sending an OGI crew for each detected emission (instead of more effective responses) will also decrease safety. NIOSH / CDC found that in 2017 (and qualitatively similar results in 2015-2016), vehicle accidents for oil and gas extraction related field operations were the leading cause of fatalities (42%). Of these, the majority were on roadways to/from/between sites.<sup>22</sup>

---

<sup>22</sup> <https://www.cdc.gov/niosh/topics/fog/data2017.html>.

Commenter (2405-Bridger) argues the mandatory OGI follow-up is particularly burdensome for the more sensitive detection tiers because more sites with emissions will be identified by the advanced technology leading to a greater OGI follow-up burden. For the 1 kg/hr (90% POD) tier, the commenter will detect emissions on more than 50% of sites in the Permian Basin and OGI crews would be required to be deployed to each of these sites. Therefore, as written, the Proposed Rule disincentivizes better detection sensitivities.

Commenter (2405-Bridger) adds, compared to a universal OGI follow-up requirement, a better approach to responding to emissions will often involve investigative analysis using a combination of advanced technology data (Figure 1), compressor runtime data, process control / SCADA data, maintenance activity logs, AVO inspection, and prior screening results. The spatiotemporal data from advanced technologies (including replicate infrastructure scans) can be especially useful in this process if the advanced technology can precisely localize the emission, identify the emission as normal or abnormal, identify the emission as intermittent, and/or directly identify its cause.

Commenter (2405-Bridger) states intermittent emissions are one scenario where OGI follow-up may be an ill-suited response. For example, process upsets may cause over pressurization of cover/closed vent systems resulting in emissions that are detected during an infrastructure scan but are no longer present according to a successive scan to evaluate persistence. Because of intermittent behavior, follow-up OGI has a reduced likelihood of confirming the emission and would not provide additional helpful information in either case. Commenter (2405-Bridger) adds meanwhile, suitable advanced technologies will already have clearly identified the emission point. An investigation into the process upset conditions that caused the emission could help elucidate necessary updates to system parameters that would mitigate future emissions. In this example, an OGI follow-up does not increase emissions reductions and causes undue burden on the operator. For intermittent emissions, investigative analysis is the appropriate requirement instead of a blanket OGI follow-up requirement.

Commenter (2405-Bridger) states for normal process emissions that are detected by alternative emissions monitoring, OGI follow-ups may be ineffective. In the case of permitted emissions from natural gas fired internal combustion engines and control devices, OGI may have difficulty differentiating between normal and abnormal operation, which, for control devices, was recognized in the Proposed Rule.<sup>23</sup> However, these emission sources are regularly detected by advanced technologies even when normally operating. To provide fair and consistent rules, the EPA should not require onsite follow up in response to emissions detected during periodic screening that correspond to normal process emissions operating within permitted emission bounds. Separate performance standards in the Proposed Rule already apply to these types of emission sources. If permitted process emission are detected and conclusively identified, then no response other than recordkeeping and reporting should be necessary.

---

<sup>23</sup> “One commenter stated that emissions resulting from noncompliance with control device requirements should not...be defined as fugitive emissions...since control devices are inherently designed to have emissions, even when well operated, it should be expected that some amount of methane and VOC would be detected during an OGI survey for fugitive emissions. The EPA agrees that control devices should not be treated as fugitive emissions components...”

Response II-5-40: As noted previously, it is often difficult to tell if a “permitted” emission event may mask other fugitive emission releases. It is very difficult to identify all of the different scenarios in the regulation to specify the criteria of a survey technique (with respect to the detection value and geographical specificity), the type of investigative analysis that must be conducted, the specific results that would be needed to not send an OGI crew. We have sought to develop an enforceable rule that directly allows the use of alternative technologies.

However, in an effort to incentivize technology with tighter spatial resolutions, which includes those technologies that are typically more sensitive, emissions coming from process regulated through other programs (*e.g.*, methane slip from a RIE emission combustion exhaust) would not trigger a follow-up, so long as the emissions are documented, and the technology used is spatially resolved enough to distinguish those emissions from a fugitive component and/or covers and closed events systems.

Comment: Commenter (2305-Williams) recommends §60.5398b (b)(4)(ii)(D) be added to provide direct repair of a fugitive emissions component that is conclusively identified using an alternative screening method, without prompting a full fugitive emissions survey of the effected facility.

Response II-5-41: The equivalency of the alternative technology matrix is predicated on a ground OGI survey being conducted on every “hit” from an aerial survey, which would cause repairs of small leaks as well as the larger leaks identified during the aerial survey.

However, in an effort to incentivize the use of advanced methane detection technology in the final rule and to acknowledge that for those technologies with proven spatial resolution, the final includes the ability to conduct a more targeted follow-up when using certain approved methane detection technology.

Comment: Commenter (2458-MiQ) is very concerned that the current construction of the supplemental proposed rule would create disincentives to the adoption and/or use of advanced monitoring technologies. The monitoring framework included in the supplemental proposal for the use of advanced monitoring technologies would entail a follow-up monitoring survey of the entire facility through the use of OGI technology if an advanced monitoring technology identifies a leak. Under this regulatory construction, the OGI survey serves as the monitoring ‘floor’ for a compliance monitoring scheme. That is, even where an approved advanced monitoring technology system may have identified a leak, OGI monitoring technology must be used as a follow-up. Not only must it be used, OGI technologies must – according to the current proposed regulatory language - be used to survey the entire facility. This is the case, even if the advanced monitoring technology detection had identified a localized source. The proposed regulations state:

“You must conduct a monitoring survey of the entire fugitive emissions components affected facility following the procedures in your fugitive emissions monitoring plan. During the survey, you must observe each fugitive emissions component for fugitive emissions.”

Commenter (2458-MiQ) argues this proposed framework would result in a number of disincentives for the use of advanced monitoring technologies – even at the same time that some of these technologies may be more effective than some OGI technologies at identifying sources of fugitive methane emissions. The use of advanced monitoring technologies may be viewed as superfluous and unnecessary because an operator will realize that an OGI survey must be completed in any case if a detection is identified. Additionally, an inefficient use of operator resources and unreasonable incurred costs for being required to do a full facility OGI survey even if the advanced monitoring technology has localized the emission source with a high degree of probability.

Commenter (2458-MiQ) continues, based on these elements, an operator may choose to dispense with the use of advanced monitoring technologies, and simply implement a basic quarterly OGI monitoring program. The result of these disincentives is that an operator may likely make a decision to not adopt advanced monitoring technologies, or to discontinue the use of these technologies. This is especially the case if the methane detection limit (MDL) is lower for the advanced monitoring technology than it is for OGI. The results of this undesirable outcome would include:

- Methane emissions that continue to take place at levels not detectable by the OGI technology in place.
- Methane emissions that occur between quarterly OGI inspections that would have been detected through advanced monitoring technology inspections taking place on a more frequent basis.
- The development of advanced monitoring technology would be hindered. The structural disincentive put in place, were this rule to be promulgated, would significantly limit market interest in developing more effective and sensitive monitoring technologies. As a result, not only would the sector be locked into using [over time] fewer effective technologies, but the nation would also be inhibited in minimizing methane emissions.

In order to address the very problematic construction of the proposed regulations, commenter (2458-MiQ) recommends the following:

1. Eliminate the requirement for a facility-wide follow-up OGI survey and replace it with an OGI survey that is pertinent to the localization uncertainty region of the advanced monitoring technology. If an advanced monitoring technology identifies a leak and has an emission performance of x-meters, with a robust confidence factor, the follow-on OGI survey should be limited to that radius. This will reduce operator costs and could allow resources that would have been spent on a full facility OGI survey to be spent on additional advanced monitoring technology surveys or other methane mitigation activities.
2. If an advanced monitoring technology survey detects an emissions leak and the operator, then identifies the specific emission source through a root cause analysis (or causal examination) the follow-on OGI survey should not be required by the EPA as necessary. The root cause analysis could include SCADA data, maintenance activity logs, advanced monitoring technology data, compressor data, and process control information. In addition to being an unnecessary cost in those situations, the OGI survey may or may not

be able to differentiate between operation types (and therefore the emission source) – whereby a root cause analysis may be able to. If a root cause analysis, as described above, cannot determine the source or reason for the emissions event, the use of a localized OGI survey would be appropriate.

Response II-5-42: The equivalency of the alternative technology matrix is predicated on a ground OGI survey being conducted on every “hit” from an aerial survey, which would cause repairs of small leaks as well as the larger leaks identified during the aerial survey. We did not identify equivalencies by only repairing the “big” leaks. Based on our modeling, repairing only the big leaks would not be equivalent to routine ground OGI surveys. We disagree with the commenter that relying on the routine ground OGI surveys would result in poorer environmental outcomes compared to using application of advanced technologies.

Comment: Commenters (2284-Kairos, 2326-AXPC, 2428-API) recommend EPA align alternative screening technology, OGI, and AVO response timeframes.

Commenter (2284-Kairos) believes that the timelines for the Super-Emitter Response Program, various response timelines for alternative screening technologies, OGI, and AVO throughout the rule could benefit from alignment. EPA proposes response time frames ranging from 24 hours (completion of root cause analysis for fugitive emissions caused by failure of a control device) to 30 days (completion of final repairs for most sources of emissions). These varying timelines will create confusion and cause undue burden on owners and operators for what is likely negligible emissions abatement. The commenter recommends a standard 30-day response timeframe for completion of repairs for non-Super Emitter fugitive emissions. As stated previously, FEAST modeling is capable of measuring the impacts of repairs over a range of timeframes and should be used to weigh the costs and benefits of aligning these response timeframes.

Commenter (2428-API) similarly recommends that repair timelines be consistent between traditional (AVO, OGI, or Method 21) and alternative (periodic screening or continuous) leak detection programs. Repair actions depend more on the leaking component rather than detection method. The proposed repair or corrective action timelines in §60.5398b(b)(4) for periodic screening and §60.5398b(c)(6) for continuous monitoring are shorter than those in §60.5397b(h) for fugitive emissions components and §60.5416b(b)(4) for covers and closed vent systems. The shorter repair timelines for alternative leak detection technologies may disincentivize their use. Consistent repair or corrective action timelines would streamline compliance and facilitate the use of multiple technologies. If EPA chooses to finalize shorter repair timelines for alternative technology, the commenter recommends that repairs be prioritized based on higher detected emissions.

Commenter (2326-AXPC) agrees with API’s comment that follow-up surveys and inspections, including OGI camera inspections should not be required in instances where the source of detected emissions can be identified based on the localization performance of the alternative technology, AVO inspection, and/or other operation data known to the company.<sup>24</sup> And where source-specific attribution can be determined by the alternate technology, no ground-based inspection follow-up should be required – only the potential for corrective action if the emissions

---

<sup>24</sup> See API Supplemental Proposal Comments § 3.3.2.

are not authorized. Lastly, EPA refers to ground-based surveys. However, where follow-up is required, EPA's regulations should ensure that operators can utilize drone-mounted, or helicopter mounted OGI for further investigatory analysis.

Response II-5-43: The equivalency of the alternative technology matrix is predicated on a ground OGI survey being conducted on every "hit" from an aerial survey, which would cause repairs of small leaks as well as the larger leaks identified during the aerial survey. We did not identify equivalencies by only repairing the "big" leaks. Based on our modeling, repairing only the big leaks would not be equivalent to routine ground OGI surveys.

Comment: Commenter (2391-CEC) believes that to require the operator to conduct a ground-based OGI survey of all fugitive emissions components at the site to identify the source of the emissions can be burdensome and not necessary depending on the technology used.

Commenter (2391-CEC) believes EPA should permit operators to first review their records to see if the source of emissions can be identified without a further survey. The cause may often be apparent in operator logs, SCADA data, and similar records. Where the cause cannot be identified based on other records, an AVO inspection should be allowed as the first response. Only when AVO cannot identify the cause of emissions, should an OGI survey be required.

Commenter (2391-CEC) adds that if—once the record review and AVO inspection have occurred—an OGI survey is still required, EPA should not assume the survey must cover the entire facility. Doing so fails to recognize that some alternative technologies can detect source level emissions. When those technologies are used, surveying the entire facility is simply not necessary to identify the source of the emissions.

Commenter (2391-CEC) suggests that when an OGI survey is necessary, EPA should allow operators the flexibility to conduct the survey using OGI cameras mounted to drones or aircraft as appropriate. Either can be a more effective approach than ground-based OGI but proposed §60.5398b(b)(4)(iv) and §60.5398c(b)(4)(iv) each eliminates these by referring to the OGI survey in an earlier paragraph as "ground-based." EPA should remove this term from both regulations. It is not necessary to refer to the OGI survey as "ground-based" to ensure OGI surveys are conducted at the appropriate distance; the requirements in proposed §60.5397b(c)(7) and §60.5397c(c)(7) are sufficient for this purpose.

Response II-5-44: The equivalency of the alternative technology matrix is predicated on a ground OGI survey being conducted on every "hit" from an aerial survey, which would cause repairs of small leaks as well as the larger leaks identified during the aerial survey. We did not identify equivalencies by only repairing the "big" leaks. Based on our modeling, repairing only the big leaks would not be equivalent to routine ground OGI surveys.

Comment: Commenter (2369-ChampionX) notes the current language in the proposal is written to address fixed sensors, which identify that there is a leak in a geographic area. However, when using a manned or unmanned aircraft, a leak can be pinpointed to the exact source of the fugitive emission. This would allow maintenance personnel to repair the leaking component identified during the advanced measurement screening.

Commenter (2369-ChampionX) has demonstrated that an aerial OGI screening from at least 150' can pinpoint small to large fugitive emission leaks. The ability to positively identify a leak for repair negates the need to have an entire site inspected to find the potential leak. The commenter's aerial technology has demonstrated a minimum detection limit that is below the threshold of 30 kg/hr and capable of meeting the Quarterly + Annual OGI minimum screening frequency.

Commenter (2369-ChampionX) notes that the proposed language would trigger a ground monitoring event of all fugitive emission components at the site where the advanced screening survey occurred. The proposed language discourages the use of periodic surveys through advanced screening methods for the following reasons:

1. Many locations are remote and mobilizing an inspection crew in 14 days is challenging.
2. Inspecting hundreds of sources due to one leak is not cost effective.

Using advanced technology such as manned and unmanned aerial systems allow for more sites to be inspected per day, and thus larger leaks can be found quicker.

Commenter (2369-ChampionX) recommends separating the proposed requirements for fixed detectors and aerial OGI advanced measurement technologies. Commenter (2369-ChampionX) recommends removing the requirement for ground monitoring for leaks identified through aerial OGI advanced measurement technologies. The fugitive component repair of the leak identified would be in accordance with the same repair deadlines as those for regular fugitive surveys (*i.e.*, a first attempt at repair within 30 days of the OGI survey and final repair completed within 30 days of the first attempt)

Response II-5-45: The equivalency of the alternative technology matrix is predicated on a ground OGI survey being conducted on every "hit" from an aerial survey, which would cause repairs of small leaks as well as the larger leaks identified during the aerial survey. We did not identify equivalencies by only repairing the "big" leaks. Based on our modeling, repairing only the big leaks would not be equivalent to routine ground OGI surveys.

Comment: Commenter (2446-IPAA) recommends three revisions to the use of OGI for "follow-up" survey requirements:

1. Change the full-site follow-up OGI survey requirement to a follow-up OGI survey only over the spatial extent corresponding to the verified localization performance of the detection technology.
2. Exclude from the follow-up OGI survey requirement those emission sources corresponding to normal permitted (*i.e.*, allowable) operating process emissions or emission events that are otherwise confirmed to no longer exist.
3. If any degree of OGI follow-up remains a requirement, a leak detected with aerial technology must be confirmed by a second fly over pass before it is deemed an actionable event that triggers the follow up.

Response II-5-46: The equivalency of the alternative technology matrix is predicated on a ground OGI survey being conducted on every “hit” from an aerial survey, which would cause repairs of small leaks as well as the larger leaks identified during the aerial survey. We did not identify equivalencies by only repairing the “big” leaks. Based on our modeling, repairing only the big leaks would not be equivalent to routine ground OGI surveys.

EPA has allowed for some allowance for when technology is spatially resolved enough to distinguish process emissions from fugitives’ emissions, and in some instances, we have also allowed for more targeted follow-up, but only those technologies with proven spatial resolution and as defined by the EPA. These follow-ups must be conducted using OGI and Method 21 which are sufficiently sensitive enough to pick up the smallest of leaks.

## **5.6 Allow NSPS OOOOa Sources to Comply with NSPS OOOOb**

Comment: Commenters (2360-Devon, 2428-API) ask that EPA allow NSPS OOOOa sources to comply with NSPS OOOOb to use alternative technology for compliance.

Commenter (2360-Devon) encourages EPA to consider mechanisms to enable sources subject to subpart OOOOa, prior to the effective date of 111(d) state or tribal plans under subpart OOOOc, to demonstrate compliance with applicable fugitive emission requirements with any advanced technologies approved under the alternative test method approval process (Proposed OOOOb §60.5398b(d)).

Commenter (2428-API) encourages EPA to consider mechanisms to enable sources subject to subpart OOOOa, prior to the effective date of 111(d) state or tribal plans under subpart OOOOc, to demonstrate compliance with applicable fugitive emission requirements with any advanced technologies approved under the alternative test method approval process (Proposed OOOOb §60.5398b(d)). Both the AMEL process and EG OOOOc state plan implementation could take years. EPA can make the NSPS OOOOb alternative technology a compliance alternative for NSPS OOOOa since EPA is planning to update certain aspects of NSPS OOOOa in conjunction with this rulemaking. This addition should not require further notice since the requirements are at least as stringent as the existing NSPS OOOOa requirements. Some alternative technology (*e.g.*, aerial surveys) is deployed over a particular basin or portion thereof and could include both NSPS OOOOa and OOOOb sites. Therefore, allowing the use of alternative technologies for NSPS OOOOa compliance without an AMEL would further incentivize the adoption of these emerging technologies.

Response II-5-47: See discussion in sections IX.C and XI.B.1.a of the preamble to the final rule which details EPA’s final standards related to use of alternative methane detection technologies.

## **5.7 Recommended Changes/Clarifications**

Comment: Commenter (2448-Project Canary) states while continuing to improve, our current understanding of emissions throughout the US is imperfect. EPA’s use of peer reviewed studies to develop the matrix is reasonable and appropriate recognizing the available data when EPA developed the Supplemental Proposal. However, the commenter encourages EPA to consider any

additional recent studies and refine the Final Rule accordingly, to ensure it reflects our up to date understanding of emissions and technology opportunities and constraints. Additionally, given that emissions data will continue to rapidly improve as operators use advanced technology and as EPA implements Inflation Reduction Act funding for methane detection, it will be important to have a regulatory process and expectation that EPA will refine the matrix over time.

First, in addition to evaluating EPA's assumptions and inputs for FEAST with any additional peer-reviewed studies submitted as part of comments or released before the Final Rule, Commenter (2448-Project Canary) recommends that EPA make clear in the Final Rule that it will periodically update the matrix by updating the FEAST modeling and inputs as additional data becomes available. This update can be completed, for example every three to five years, to help maintain regulatory certainty for operators and technology developers. By providing this expectation, stakeholders will have notice of this opportunity and can participate in the regulatory process. Additionally, specifying the timing for updates will also provide clarity on when EPA will need to receive proposed updates to studies and versions of modeling software to enable the Agency to rely on such new information in the periodic update.

Second, EPA should make clear that as part of alternative test method approval process, site-specific emission monitoring plans, or state 111(d) plans, entities can use the most recent publicly available versions of FEAST and other models, as well as recent peer reviewed studies specific to basins within that state as modeling inputs. This way, EPA can ensure the requirements for advanced technologies reflects the best information available. For example, a state, or a group of states in a single basin, may want to submit a 111(d) plan that relies on basin specific emissions data to enable the deployment of advanced technologies best suited to reduce emissions in that area provided the emission reductions are consistent with BSER. EPA should clarify that states have the flexibility to incorporate such tailored modeling, subject to EPA approving such a plan as "satisfactory" in meeting the requirements of section 111(d) and all other applicable equivalency requirements.<sup>25</sup>

Response II-5-48: It is possible that the distribution and magnitude of methane emissions from affected well sites, centralized production facilities, or compressor stations will change as these facilities come in compliance with the new and existing source rules. We also understand that many of the oil and gas basins are unique, and the distribution and leak generation rates will be variable depending on the basin. Therefore, we agree that states have flexibility in the development of their state plans to develop the most appropriate system for emission reductions so long as they are consistent with the BSER in OOOOb. Including the development of state-specific alternative technology approaches (e.g., matrix).

Finally, the Clean Air Act requires that the EPA shall, at least every 8 years, review and, if appropriate, revise such standards. As new information emission data comes available, EPA will use this information as to inform these reviews and as necessary, propose revisions to the standard.

---

<sup>25</sup> Methane Roundtable, "Letter 1: Comments and Recommendations for the Alternative Survey Matrix" (hereinafter "Methane Roundtable Letter 1") (text under the heading: "Support the Comparison of Direct Benefits of Advanced Technologies") (citations omitted.)

Comment: Commenter (2399-GPA Midstream Association (GPA)) notes §60.5398b(d) contains a link to EPA’s Emission Measurement Center webpage (<https://www.epa.gov/emc/oil-and-gas-approved-alternative-test-methods>). This link does not work.

Response II-5-49: EPA has updated the website in the final rule to <https://www.epa.gov/emc/oil-and-gas-alternative-test-methods>. We intend to make this link active by the time the final rule is published.

Comment: Commenter (2399-GPA) notes the proposed § 60.5398b(c)(1)(i) states that the “sensitivity of the system must be such that it can at least measure an order of magnitude less than the action-level defined in paragraph (c)(4)(iii) of this section.” The proposed regulatory text does not contain a §60.5398b(c)(4)(iii).

Response II-5-50: EPA has corrected this reference in the final rule.

Comment: Commenter (2399-GPA) notes several sections of the proposed rule require differing accuracy, with some requiring four decimals of a degree, see, *e.g.*, proposed § 60.5398b(c)(2)(i) and others to five decimals of a degree.<sup>26</sup> Whether EPA intended to require four decimals or five decimals, it should correct those that are inconsistent.

Response II-5-51: EPA notes that in different places in the rulemaking, we may require a different degree of accuracy for coordinates, depending on what the data is used for. For the purposes of the advanced methane detection technology work practices, we have made revisions in the final rule to require at least four decimals of a degree for latitude and longitude identification.

Comment: Commenter (2247-OHEPA) observes that there are entities proposing alternate control measures to the EPA that will provide nearly equivalent level of control. The commenter believes EPA should evaluate these alternative proposals and accept these options to provide effective control measures in a cost-effective manner.

Response II-5-52: EPA acknowledges the comment and points the commenter to the alternative means of emission limitation in §60.5399b, which addresses alternative control measures (*e.g.*, fugitive emission controls). The alternative work practice standards using advanced methane detection technology in this final rulemaking is only designed to evaluate the measurement technology and detection capabilities, with the work practice requirements standardized and outlined in the final rulemaking.

Comment: Commenter (2405-Bridger) states that further clarity is needed to indicate that alternative test methods can be used in the place of both OGI and AVO inspection requirements. The commenter understands that it is the EPA’s intent to enable both the periodic screening and continuous monitoring alternative approaches to replace both OGI and AVO inspection requirements for any affected well site, compressor station, or centralized production facility. However, this provision was difficult to understand in the proposal. The commenter urges the EPA to make it clear throughout the preamble and in the regulatory text that periodic

---

<sup>26</sup> 60.5398b(b)(1)(i).

screening and/or continuous monitoring alternatives may replace both OGI and AVO inspection requirements in fugitive programs.

Similarly, commenter (2405-Bridger) urges the EPA to make it clear throughout the preamble and in the regulatory text that both periodic screening and continuous monitoring alternatives can also be used instead of OGI for compliance verification of any zero emission requirements for affected facilities at well sites, centralized production facilities, and compressor stations.

Response II-5-53: EPA agrees that use of the alternative methane detection technologies replaces both OGI and AVO inspection requirements. The introductory text in §60.5398b and §60.5398c indicate that the alternative standards in those sections are an alternative to the fugitive emissions components affected facilities in §60.5397b and §60.5397c, respectively. Therefore, the work practices outlined in §60.5398b and §60.5398c replace the entire work practice required in §60.5397b and §60.5397c, which includes both AVO and OGI (or EPA Method 21) inspections. This applies for both the periodic screening matrix alternative work practice and the continuous monitoring work practice.

## **5.8 Alternative Periodic Screening**

### ***5.8.1 Matrix Approach***

Comment: Commenters (2249-National Association of Clean Air Agencies (NACAA)), 2258-Marcellus Shale Coalition (MSC), 2326-AXPC, 2403-The Petroleum Alliance of Oklahoma (PAO), 2458-MiQ) are generally supportive of EPA's matrix approach. Certain commenters have additionally suggested revisions that they believe are needed before operators can implement, as described further below.

Commenter (2249-NACAA) generally supports EPA's proposed matrix approach for approving methane detection technologies, although advocate that EPA's engagement with affected agencies to explore nuance and specifics that vary by location, rather than depending entirely on detection limits and a basis for selection.

Commenter (2458-MiQ) supports EPA's developed matrix for monitoring frequency of advanced technologies, based on their respective minimum detection threshold included in this matrix framework.

Commenter (2403-PAO) supports the use of alternative monitoring technologies that allows operators flexibility in using technologies tailored for their site-specific conditions. However, EPA's proposed matrix is too prescriptive focusing on frequency and sensitivity - the less sensitivity a technology, the more frequently it should be used and visa vise while requiring the use of overlapping technologies. However, this matrix is more stringent than the use of OGI. The commenter is concerned that the Proposed Rule will stifle new technology development and limit flexibility. There are multiple ways to achieve monitoring and EPA should not limit or prescribe a technology when a variety of technologies would suffice to find and fix leaks. The commenter requests EPA reconsider and revise its matrix that encourages the development of

new technologies that can be used interchangeably by operators (based on site specific conditions) to find and fix leaks quickly and economically.

Response II-5-54: EPA acknowledges the commenters points and argues the matrix approach is technology agnostic and is designed to accommodate the continued advancement of this technology. The matrix is not more stringent than the use of OGI as the tiers are based on the equivalent emission reduction you would expect of the BSER program as detailed in our supplemental TSD FEAST memos in the docket of this rule.

EPA does agree with the commenters that the matrix approach could be applied to multiple technologies and the final rule now makes that allowance explicit.

Comment: Commenter (2258-MSC) indicates that the alternative monitoring matrix is not adoptable by operators in its current form. The following suggestions would assist with developing requirements that would allow operators to utilize alternative technologies now and provide the ability to adjust frequencies and use of technology as the technology improves and costs reduce.

- Develop a technology agnostic matrix that allows a combination of techniques (*e.g.*, AVO, OGI, flyovers, continuous monitoring) at varying frequency. For example, an operator could deploy both flyovers, continuous monitoring, and OGI, but at reduced individual frequencies as proposed in the rule.
- It is important to not under-represent the effectiveness of OGI or under-represent the effectiveness of alternative technology with the modeling inputs. The commenter requests EPA to work closely with stakeholders such as API or others who have spent considerable time determining the appropriate inputs to the model that establishes a baseline performance for OGI and equivalency for alternative monitoring methods.

Response II-5-55: EPA acknowledges the commenter's feedback and disagrees with the assertion the alternative periodic monitoring through the matrix framework is not adoptable. As EPA is finalizing the matrix framework with some revisions explained in Section X.B and XI.B of the preamble of the final rule.

Comment: Commenter (2387-Energy Institute, Colorado State University (CSU)) believes AVO performance is likely overestimated in EPA modeling. While it was unknown if operators had implemented some type of enhanced AVO protocols<sup>27</sup>, essentially none of these emitters was discovered by AVO methods. These data suggest a near-zero probability of AVO detection for a minimum of 4.8 [0.91 to 12] days for LongPath data and 86 [2.5 to  $0.22 \times 103$ ] days for Kuva data. These data suggest that the AVO efficacy used in EPA's models may overstate the performance of AVO methods. The commenter encourages EPA to review, study, or reduce reliance on AVO methods in calculating the proposed matrix parameters.

---

<sup>27</sup> The authors know of no defined protocol which would separate normal operational practice from an enhanced AVO survey.

Response II-5-56: EPA did not include the hybrid OGI/AVO approach when modeling the matrix equivalency. For the periodic screening matrix, we assumed essentially no AVO triggered repairs.

Comment: Commenter (2419-Xplorobot) requests that the matrices for alternative screening be amended to include “Annual OGI or equivalent hand-held component-level inspection” in place of “Annual OGI” to provide for the opportunity to deploy novel hand-held component-level solutions in combination with aerial surveys or continuous sensors for cost-effective methane monitoring of oil and gas operations.

Response II-5-57: EPA acknowledges the commenters request; however, EPA has chosen to maintain OGI requirements in the final rule as proposed. This rule also is forward leaning on potential alternatives methane monitoring solutions including multiple alternative pathways for their use and encourage the commenter to explore the most appropriate pathway for their methane solution.

Comment: Commenter (1686/2345-GHGSat, Inc. (GHGSat)) believes the minimum detection levels and monitoring frequencies currently specified in the proposed matrix are insufficiently differentiated between the five tiers with respect to detection levels. The commenter is concerned that the matrix definition will unintentionally hamper the utilization of remote sensing approaches that have the capability of more frequent surveys with higher minimum detection limits. Since the proposed minimum detection thresholds of the lower tiers are within the same order of magnitude, it will be extremely difficult for existing technologies to meet these requirements because there are other factors such as wind speed, light conditions, and atmospheric considerations that will produce errors resulting in an effective overlap between the tiers.

Commenter (1686/2345-GHGSat) recommends a revision to each matrix such that the first three tiers with the lowest detection limits become a single tier of 5 kg/hr that requires quarterly monitoring plus an annual OGI survey. The 10 kg/hr and 30 kg/hr can remain as proposed. The commenter would then recommend the addition of two new tiers, one with a minimum detection threshold of 60 kg/hr in which biweekly surveys plus an annual OGI survey need to be performed, and a final tier with a detection threshold of  $\leq 100$  kg/hr that requires performing weekly surveys plus an annual OGI survey. The commenter believes that adding these two tiers establishes a bridge between the current proposed detection thresholds and the proposed super emitter program. The commenter believes that with this modification to the survey matrix, the EPA will minimize controversy regarding the qualification and approval of technologies in the 1 to 4 kg/hr. The commenter believes that controversy could exist with companies trying to select an alternative monitoring technology due to the narrowness of the tiers and the differences in frequencies amongst them. Also, technology providers understand that during the assessment and creation of detection curves, multiple environmental conditions could have an impact in detecting emissions. For that reason, a typical measure of MDL is associated with a 50% POD, as it provides additional flexibility to account for varying environmental conditions.

Commenter (1686/2345-GHGSat) notes that EPA relied on FEAST modeling to derive the different tiers listed in the matrices. One of the conclusions was that technologies with minimum

detection threshold above 30 kg/hr could not be deemed equivalent to the proposed fugitive emissions monitoring and repair program at any screening frequency, even when coupled with an annual OGI ground-based survey. The commenter disagrees with that conclusion, and believes that, even though modeling scenarios help in the understanding of an outcome based on certain variables and input parameters, the empirical knowledge reflects a different outcome. The commenter's satellites and aircraft continue to detect emissions from different oil and gas infrastructure across the United States and around the world. The same empirical knowledge applies to the breakdown of the smallest tiers in the matrices. The emissions distributions used in the model represent the conditions at the time of the study. Drawing conclusions of different tiers within the same order of magnitude skew the actual conditions on the field.

Commenter (1686/2345-GHGSat) also believes the EPA should provide a mechanism that accounts for the combination of technologies that, when working in tandem, can achieve the methane reduction equivalent to a single solution. The commenter understands that the EPA would expect other available modeling simulations to be included in the different analyses. The commenter has recently performed a novel study following a tiered topdown approach using satellite and aircraft to monitor oil and gas facilities in the Permian basin.<sup>28</sup> An abstract, highlights, and link to this paper can be found in Appendix C.

Commenter (1686/2345-GHGSat) indicates that there are different technologies capable of detecting and quantifying emissions operating with different techniques and at a different level. These technologies, and the combination of them working in tandem in a tiered approach, can provide greater reductions at a lower cost, when compared to OGI alone.<sup>29</sup>

Response II-5-58: EPA acknowledges the comment's input. However, we are finalizing the matrix approach as proposed, with the exception of the removal of the highest tier (30 kg/hr) due to the concern over equivalency with the BSER being overly reliant on the annual OGI backstop.

Comment: Commenters (2340-Honeywell International Inc. (Honeywell), 2363-CEMC, 2402-DGCC, 2448-Project Canary) believe that continuous monitoring technologies should qualify for use as periodic screening systems, and the rule should allow for greater flexibility within the periodic screening matrices. The regulations should provide maximum flexibility to allow for the use of any type of technology—including a networked system of various monitoring technologies capable of providing effective emissions monitoring under either the periodic screening or continuous monitoring alternative LDAR programs. In particular, the final rule should specify that (a) continuous monitoring systems may also qualify as periodic screening systems provided, they meet the prescribed criteria, and (b) FEAST modeling can be used to determine a greater variety of detection thresholds and screening frequencies than those presented in the periodic screening matrices.

Commenter (2340-Honeywell) believes continuous monitoring systems should also qualify as periodic screening systems if they meet the detection thresholds and probability of detection specified in the survey matrices. In addition to measuring emissions on a continuous basis, such systems, including Honeywell's Rebellion and Signal Scout technologies, can detect emissions

---

<sup>28</sup> Esparza, et al., 2023 (under peer-review).

<sup>29</sup> (Esparza, et al., 2021); (Esparza, et al., 2021); (Esparza, et al., 2022); (Esparza, et al., 2023 (under peer-review)).

on a periodic screening basis at the thresholds provided in the survey matrices. The commenter provides substantial information in their comment letter describing their Rebellion technology (Rebellion Gas Cloud Imaging (GCI) system) and their Signal Scout technology (Honeywell Emission Management Solution, comprising of Honeywell Versatilis™ Signal Scout™ detectors, Gateway and Anemometer). The commenter believes that both these continuous monitoring solutions are capable of meeting the detection thresholds set out in the periodic screening matrices while providing much more frequent monitoring.

Commenters (2298-Pioneer, 2363-CEMC, 2402-DGCC, 2448-Project Canary) note that EPA recognizes that continuous monitoring technologies “could be valuable tools in quickly detecting large emissions events, as well as identifying when emissions at the site begin to rise”. However, EPA proposes to regulate non-visual continuous monitors separately by requiring operators to screen more frequently and at lower detection levels than required in the periodic screening matrix, and it is unclear how camera based continuous monitors can be deployed under the proposal.

Commenters (2298-Pioneer, 2363-CEMC, 2402-DGCC, 2448-Project Canary) assert that EPA’s proposed approach would discourage the use of continuous emission monitors for compliance with the rule. EPA proposes greater response requirements for operators using the continuous monitor approach by requiring operators to initiate an investigative analysis each time there is an exceedance of relatively small site-wide emission rates compared with the survey matrix’s relatively large point-source emission rates. The approach also does not recognize that continuous emission monitors with valid quantification and full-site coverage can directly measure both baseline and fugitive emissions. Temporal information can easily identify when deviations from baseline emissions occur.

To ensure that the rule is technology neutral, commenters (2298-Pioneer, 2363-CEMC, 2402-DGCC, 2448-Project Canary) urge EPA not to include greater response requirements or more stringent emissions thresholds for some technologies. If a technology can detect more frequently than required in the periodic screening matrix, that should not create additional (more frequent response requirements) than would apply to an owner or operator deploying OGI or other periodic screening technologies. While a company may use a technology that collects emissions information more frequently than monthly, the obligation should be to demonstrate compliance with fugitive emission requirements no more frequently than the frequency required by the matrix based on the application detection threshold for the technology.

Commenters (2298-Pioneer, 2363-CEMC, 2402-DGCC, 2448-Project Canary) therefore, urge EPA to allow owners and operators to use both image-based and nonvisual continuous monitoring technologies under the periodic screening matrix provided the technologies can meet the screening matrix’s frequency and detection thresholds or equivalent thresholds based on concentration levels.

Response II-5-59: EPA never intended to limit continuous monitoring technologies (visual or non-visual) from the periodic screening approach in the December 2022 supplemental proposal. In the final rule we have clarified the record that continuous monitoring technology may be applied to the periodic screening framework.

Comment: Commenter (2333-LongPath) recommends that EPA:

- Consider an organizational structure of technology classes for ease of characterizing the different response requirements in the periodic screening matrix that is consistent with the following:

|                              | <b>Visual (plume-level)</b>                                                                                                                                                                                                                                                                                                                                                | <b>Non-Visual (site-wide or source-level)</b>                                                                                                                                                                                                                                                                                                                                               |
|------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Periodic Screening</b>    | <ul style="list-style-type: none"> <li>Detection and/or quantification of discrete emission sources; cannot directly quantify site-wide emissions.</li> <li>Discrete in time; cannot characterize intermittency.</li> <li>Examples include aircraft, drone and satellite platforms.</li> <li>A subset of these solutions may produce valid mass emission rates.</li> </ul> | <ul style="list-style-type: none"> <li>Detection and/or quantification of total sitewide emissions; may also localize emission sources.</li> <li>Discrete in time; cannot characterize intermittency.</li> <li>Examples include mass balance from drone, aircraft and mobile platforms, and OTM-33a.</li> <li>A subset of these solutions may produce valid mass emission rates.</li> </ul> |
| <b>Continuous Monitoring</b> | <ul style="list-style-type: none"> <li>Detection and/or quantification of discrete emission sources; cannot directly quantify site-wide emissions</li> <li>Continuous in time; can be used to characterize intermittency</li> <li>Examples include fixed camera-based platforms</li> <li>A subset of these solutions may produce valid mass emission rates</li> </ul>      | <ul style="list-style-type: none"> <li>Detection and/or quantification of total sitewide emissions; may also localize emission sources</li> <li>Continuous in time; can be used to characterize intermittency</li> <li>Examples include arrays of point sensors, and line sensors</li> <li>A subset of these solutions may produce valid mass emission rates</li> </ul>                     |

- Create a clear option for the use of the above technologies in the periodic screening matrix. Commenter (2333-LongPath) provides the following suggestions for how to avoid inadvertently disincentivizing any technology classes:
  - Perform equivalency modeling for all solutions directly in the FEAST model, rather than developing a separate set of standards based on FEAST model outputs from other methods.
  - If a technology can detect more frequently than required in the periodic screening matrix, there should not be additional (more frequent) response requirements than would apply to an owner or operator deploying OGI or other periodic screening technologies. That is, detections made outside the defined periodic screening frequency intervals should not require immediate follow-up, just as additional aircraft surveys in between periodic screening frequency intervals do not.
  - Specifically for non-visual site-wide monitors that produce a valid mass emissions rate:
- Fugitive emissions and action levels should be defined as “above baseline emissions”, because these monitors measure permitted (“allowable”) emissions in addition to point source (fugitive) emissions.
- Response requirements should be based on Action Levels (plus baseline) rather than Detection Levels.

- Adjust the follow-up OGI requirements to recognize that temporal and spatial information from advanced technologies may be able to identify the root cause of the emission without OGI (in the case of quantitative, temporal information) or more effectively direct follow up OGI to a smaller area (in the case of spatial information that shows the location of the leak). If a technology is capable of determining a leak's level of intermittency (most continuous monitors), then follow-up OGI can be omitted for intermittent emissions (since spot-check and survey methods rarely identify intermittent leaks.<sup>30</sup>

Response II-5-60: EPA acknowledges the commenters input, when a more continuous system is used in a periodic screening application, when a leak is detected (*e.g.*, emission event above 10kg/hr) during a screening period, however defined in your Alternative Test Method for Methane Detection Technology, you are required to follow-up regardless of intermittency unless the technology used has component level resolution and is sufficiently sensitive to confirm a leak isn't present.

Additionally, leak definitions in the periodic screening program are independent of background concentration of a facility. If background is a consideration, this must be integrated into the methane detection alternative test method with supporting evidence as to why this is required.

Comment: Commenter (2333-LongPath) urges EPA to clarify the spatial coverage requirements for all monitors in the periodic screening matrix. Some continuous monitoring solutions may permanently miss certain equipment (*e.g.*, visual solutions may have "blind spots" due to line-of-sight blockage) or systematically under-sample certain equipment for long periods of time (*e.g.*, ground-based sensors may not consistently detect plumes from tall equipment). Some aerial screening solutions may miss covered equipment. It is important for EPA to set a standard for which equipment must be screened and when. The commenter presumes that the same equipment that is required to be scanned by OGI should also be required to be scanned by alternative technologies, but requests that EPA more clearly define this requirement.

Commenter (2333-LongPath) argues a technology must demonstrate how often all required equipment is scanned. Therefore, assuming that the EPA's definition would be, for example, 100% of fugitive equipment sources, then this parameter would be set to 100% coverage of all equipment over some period of monitoring. The methods (*e.g.*, averaging time and scanning time) required for achieving 100% site coverage will be highly technology-specific, and should therefore be included in each solution's alternative test method application.

Response II-5-61: EPA appreciates the commenter's input. EPA's assumption is that technology used for methane detection would include 100% coverage of a site which and the ability to measure all components at a site would be evaluated as part of a technology providers applications for Alternative Test Method for Methane Detection Technology.

Comment: Commenter (2333-LongPath) states for continuous monitors used in the periodic screening matrix, the time-to-detect should be the same as all other technologies in the same

---

<sup>30</sup> See joint comment submitted by Dan Zimmerle, Stefan Bokaemper and Caroline Alden (EPA-HQ-OAR-2021-0317-2387).

matrix frequency bin. To ensure that the rule is technology neutral, the commenter urges EPA not to include greater response requirements or more stringent emissions thresholds for some technologies. If a technology can detect more frequently than required in the periodic screening matrix, that should not create additional (more frequent response requirements) than would apply to an owner or operator deploying OGI or other periodic screening technologies. While a company may use a technology that collects emissions information more frequently than monthly, the obligation should be to demonstrate compliance with fugitive emission requirements no more frequently than the frequency required by the matrix based on the application detection threshold for the technology.

Response II-5-62: For those technologies that are continuous in nature, when used in periodic screening, a screening survey should be at least 2X the time-to-detect for any given technology. The number of screening events is dependent on the tier of the matrix framework most appropriate for the technology. There is not a reason that a technology couldn't continue to operate outside of a survey period.

Comment: Commenter (2446-IPAA) notes there are many approaches to developing matrices to frame a series of fugitive emissions requirements that reflect the emissions profiles of oil and natural gas production facilities. The commenter believes that the most straightforward approach would be to use production rates with some adjustments for specific onsite equipment. This approach would utilize information from DOE Study. However, EPA has an inordinately intense fascination with the use of component counts at facilities. This reliance on a system that uses component counts portends a potential complicated conflict implementing the EG because states have not used component counts in their current regulatory programs and could resist EPA's actions to force the approach on them.

Response II-5-63: EPA acknowledges the commenter's input.

Comment: Commenter (2192-Blue Sky Measurements, Inc. (BSM)) agrees with the proposed matrix. The commenter notes that NIRview can be considered a high frequency periodic screening technology capable of measuring multiple times per day with a detection threshold <4 kg/hr. NIRview is a passive device dependent on sunlight. NIRview units will operate on cloudy days with filtered sunlight but performance is diminished on heavy overcast days where the condition persists the entire day. Also, like all other sensing technologies currently in operation, NIRview performance is a function of environmental conditions such as wind speed and rain but as a fixed position monitor, multiple measurements per week will be the norm.

Response II-5-64: EPA acknowledges the commenter's input, and we agree environmental conditions are important factors to consider when measuring methane at an oil and gas facility.

### **5.8.2 Action Levels**

Comment: Commenter (2333-LongPath) argues for site-wide, quantitative continuous monitors, Action Levels should be defined as "above baseline emissions." Non-visual continuous monitors (the lower right-hand box in the table above) with valid mass emission rates measure total, site-wide emissions. This means these monitors measure the sum of permitted process emissions and

fugitive emissions. By definition, the emissions mitigated by OGI in the FEAST model (those used to calculate the continuous monitoring action levels) are exclusively fugitive emissions; the FEAST model does not mitigate permitted emissions.

Commenter (2333-LongPath) states examples of permitted emissions that contribute to a persistent but variable, non-zero baseline emission rate are compressor exhaust (“slip”), incomplete combustion (*e.g.*, 5% loss from flares), and pneumatic devices. The CEMC comment provides an example in which a site with 8 pneumatic valves (standard on many sites) would easily exceed the lowest frequency periodic survey rate (and the continuous monitoring LongTerm Action Level). Another example would be a single 2-stroke lean-burn engine for a permitted compressor, which would exceed the lowest frequency periodic survey rate (and the Long-Term Action Level) by 3 times. Therefore, solutions that measure site-wide emissions should not be required to act on permitted emissions.

To address this, commenter (2333-LongPath) suggests that emissions from allowable activities not be included in the total rate of emissions that require action for site-wide emissions monitors. The commenter recognizes that EPA may have sought to achieve parity with VOC reductions, however there is no such requirement for non-continuous monitors. Therefore, it would not be technology-neutral to create this added burden for continuous monitors. In short, technologies capable of providing more comprehensive measurement of total emissions should not be inadvertently disincentivized for use in the periodic screening matrix or in the continuous monitoring provisions by requiring action on permitted emissions.

Commenter (2333-LongPath) states to ensure owners and operators respond to leaks and process failures, and to ensure that site-wide continuous monitors are not unfairly burdened in the rule, EPA will need to define Action Levels as above the measured baseline allowable emissions. Because continuous emission monitors with valid quantification and full-site coverage can directly measure both baseline and fugitive emissions, it should be allowable for site-wide continuous monitors to quantify baseline emissions through time and identify emissions that exceed the sum of the baseline emissions plus the action levels defined in the matrix.

Response II-5-65: Leak definitions in the periodic screening program are independent of background concentration of a facility. If background is a consideration, this must be integrated into the methane detection alternative test method with supporting evidence as to why this is required.

Comment: Commenter (2405-Bridger) states quantification is crucial for the periodic screening approach because mass emission rates are needed to generate emission rate distributions. These distributions are a powerful tool for auditing the detection sensitivity of alternative test methods during field deployment. In the Technical Support Document for the Proposed rule, an emission rate distribution is used to model super emitter events. By inspecting the distribution, researchers concluded that there were false negative detections between 5 and 50 kg hr<sup>-1</sup> based on the low number of detections in this emission rate region.<sup>31</sup> Recently, the commenter released a preprint

---

<sup>31</sup> US EPA. Supplemental Background Technical Support Document for the Proposed New Source Performance Standards (NSPS) and Emissions Guidelines (EG) 40 CFR Part 60, subpart OOOOb (NSPS) 40 CFR Part 60, subpart OOOOc (EG). (2022).

describing a rigorous statistical analysis of this emission rate distribution which revealed the detection sensitivity that was actually realized.<sup>32</sup> In other comments, the commenter urges the EPA to audit emission rate distributions to assure stakeholders that alternative test methods achieve stated detection sensitivity. Requiring periodic screening technologies to demonstrate quantification capabilities also provides consistency with requirements for continuous monitoring technologies.

Commenter (2405-Bridger) states that Advancing Development of Emissions Detection (ADED) protocols referenced by the commenter provide standard protocols for evaluating the quantification performance of periodic screening methane sensing technologies and continuous monitoring systems. The EPA should require alternative test method applicants to demonstrate quantification through third party testing using these protocols to provide consistency and transparency.

Response II-5-66: EPA recognizes the commenter's input; For discussions on EPA's modeling and the methane detection alternative test methods, please see sections X.B.1, X.B.3, XI.B.1, and XI.B.3 of the preamble to the final rule.

### ***5.8.3 Screening Frequency/Minimum Detection Threshold***

Comment: Commenter (2428-API) expresses that the proposed periodic screening matrices do not incentivize the use of the alternative technology.

The commenter states while API acknowledges EPA's proposed matrices of minimum detection thresholds and frequencies, they do not incentivize the use of alternative technology as proposed. To have the same monitoring frequency as OGI, alternative technology must have a minimum detection threshold of  $\leq 1$  kg/hr for both quarterly OGI and semiannual OGI requirements. This proposed performance level effectively limits the alternative technology options as operators are more likely to use technology with the same or less frequent monitoring than OGI. The proposed performance standards in the matrices are more stringent than needed in part because EPA's FEAST model overestimates the effectiveness of AVO and OGI inspections as mentioned previously in Comment 3.1.4. To incentivize the use of alternative technologies, the commenter believes that quarterly screening surveys with an annual OGI survey should equate to a minimum detection threshold of  $\leq 10$  kg/hr for sites subject to quarterly OGI; the rest of the matrices would be adjusted accordingly.

Commenter (2428-API) states these matrices also do not appear to be based primarily on the minimum leak detection threshold. In proposed Table 1 to Subpart OOOOb of Part 60, the minimum detection threshold is proportional to screening frequency between monthly and bimonthly frequencies without annual OGI (*i.e.*, minimum detection threshold is halved for twice as frequent monitoring). However, if an annual OGI survey is included with monthly and bimonthly screening surveys, the minimum detection threshold is decreased by a factor of 3 instead of the expected 2 (*i.e.*, monthly + annual OGI requires 30 kg/hr detection while bimonthly + annual OGI requires 10 kg/hr instead of the expected 20 kg/hr). While frequency

---

<sup>32</sup> Kunkel, M. W. et al. Extension of Methane Emission Rate Distribution for Permian Basin Production Infrastructure by Aerial LiDAR. (2022).

and detection threshold are not the only parts of a leak detection program, one would expect frequency and detection thresholds to be roughly proportional assuming that other aspects of the leak detection program (e.g., repair timelines) are constant.

Commenter (2326-AXPC) notes that it also supports the API's more extensive comments on this issue. The commenter believes EPA's proposed matrix is a step in the right direction. However, EPA's alternative leak detection program requires critical revisions before operators could utilize it as a viable alternative to traditional inspection methods.

Response II-5-67: EPA recognizes the commenter's input; For discussions on EPA's matrix framework, please see sections X.B.1 and XI.B.1 of the preamble to the final rule.

Comment: Commenter (2406-EEMDL) states annual OGI survey as part of site-wide screening strategy is more critical when the detection threshold of the screening technology is 10 kg/hr or higher. Thus, all site-wide screening surveys using technologies with detection thresholds >10 kg/hr require annual OGI surveys to mitigate below detection threshold emissions and achieve equivalence.

Response II-5-68: EPA acknowledges the commenter's input; this statement is consistent with EPA's modeling.

Comment: Commenter (2406-EEMDL) states the annual OGI survey associated with equivalence conditions for site-wide screening is a significant contributor to emissions reductions when paired with screening technologies with high detection thresholds. Figure 1 shows the site-level emissions in metric tons per year associated with monthly site-wide screening, with and without annual OGI survey for a large emitter duration scenario of 45 days. The difference between site-level emissions with and without annual OGI increases as the detection threshold of the site-level technology increase. With a technology with detection threshold 4 kg/h, site-level emissions with and without annual OGI are similar (given model uncertainties). However, using a technology with detection threshold 30 kg/h, the site-level emissions with annual OGI is significantly lower compared to that without annual OGI. This is because the site-level screening technologies does not detect below detection threshold emissions, and with increasing detection threshold, more of the normal fugitive emissions are not detected by the screening technology. Furthermore, as the duration of large emitter events decrease, the contribution of normal fugitive emissions to total emissions increases, thereby increasing the importance of annual OGI surveys.

Figure 1. Site-level emissions (metric tonnes per year) with (blue) and without (orange) annual OGI using three site-wide screening technologies for a large emitter duration of 45 days.

Commenter (2406-EEMDL) states Table 2 compares site-level emissions in metric tonnes per year with and without annual OGI for two site-wide technologies with detection thresholds 4 kg/h, 10 kg/h, and 30 kg/h, with that of quarterly OGI for large emitter duration of 90 days. For the site-wide screening with detection threshold 4 kg/h, the site-level emissions from monthly site-wide screening with and without annual OGI (7.5 mtpy vs. 5 mtpy) are not statistically significant, implying that the annual OGI does not significantly increase emissions reductions.

Thus, in this model, monthly site-wide screening with a 4 kg/h detection threshold technology will be equivalent to quarterly OGI (although the EPA methane rule specifies bi-monthly site-wide screening with annual OGI as the equivalence condition for quarterly OGI surveys, the underlying EPA modeling identifies two equivalence points: bi-monthly site-wide screening with annual OGI or monthly site-wide screening without annual OGI). By contrast, the site-level emissions when using a screening technology with a detection threshold of 30 kg/h demonstrate the impact of annual OGI survey, along with monthly site-side survey. The site-level emissions under monthly survey with and without annual OGI is 7.4 tpy and 38.4 tpy, respectively. The equivalence condition with quarterly OGI is achieved only when monthly site-wide screening is paired with an annual OGI survey, similar to the matrix provided in the supplemental rule. This is observed across different assumptions about duration of large emitters modeled in this study.

Table 2: Site-level emissions (metric tonnes per year) for three site-wide screening technologies with and without annual OGI with a 90-day large emitter duration.

Commenter (2406-EEMDL) states this result can be explained by observing emissions across different categories of emitters and demonstrates two competing effects. As the duration of large emitters decrease, monthly site-wide surveys are more effective in detecting large emitters compared to quarterly OGI surveys. However, at the same time, the contribution of large emitters to total emissions decreases as the duration of the large emitters decrease. This increases the importance of reducing normal emitters. These two features counterbalance each other, thus keeping the equivalence condition similar to those for persistent large emitters as shown in the supplemental proposal.

Response II-5-69: EPA acknowledges the commenter's input.

Comment: Commenter (2196-Private Citizen) states that the EPA is proposing a matrix of new periodic BSER options to facilitate the acceptance of what is considered advanced measurement techniques (AMT): Below is BESR option for quarterly frequency and number 1 below is included for reference:

- Human operated or Handheld OGI (Non-AMT BSER).
  - Can depict as low as 1 g/hr methane in calm conditions.
  - Can depict 10 g/hr in windy conditions where a technician would be out surveying
- Periodic Screening (Flyovers & Satellites)
  - Allowed  $\leq 1000$  g/hr or  $\leq 1$  kg/hr & Annual Human OGI required annually

Commenter (2196-Private Citizen) states these two BSER options are not equivalent even when you require the "annual OGI". The proposed non-AMT BSER (Human OGI) is 2 to 3 orders of magnitude lower when detecting leaks. LDAR is a mature process, though more recently applied to upstream and midstream oil & gas. Two factors impact reduction in emissions from equipment leaks. These are inspection frequency and leak threshold. The suggested periodic quarterly AMT leak frequency is the same as the non-ATM BSER option (except you require an annual Human OGI inspection). Again, the leak threshold allowed by periodic BSER (AMT) in Table 1 (Row 1) is 2 to 3 orders of magnitude higher than the Non-ATM BSER (Human OGI) that it would be

replacing. [Table 1 shows the commenter's recommended changes to the (1) Minimum Screening Frequency and (2) Minimum Detection Threshold of Screening Technology matrix approach.]

Commenter (2196-Private Citizen) continues, inspecting at the same frequency at conceptual leak definition that is 2 to 3 orders of magnitude higher than the other option it is conceptually equivalent to. The scenario is counter to EPA's LDAR reduction's philosophy since the beginning in the late 1980's. That is, if you want equipment leak reductions you either 1) inspect more frequently, or 2) the frequency remains the same and you drop your leak threshold. EPA has historically established this with a Monte Carlo analysis. In the alternative proposed for periodic AMT, the frequency remains the same even though the leak threshold increases by 2 or 3 orders of magnitude.

Commenter (2196-Private Citizen) recommends that the EPA has attempted too many stratifications as it tries to facilitate the emergence of new technologies. It is recommended that you only have 2 stratifications for the periodic AMT. The highest being one order of magnitude lower than the proposed super emitter program which is 100 kg/hr (*i.e.*, 10 kg/hr) and the lowest one being 1 order of magnitude lower than the higher one (1kg/hr or 2 kg/hr, I would say 2 kg/hr would be acceptable. 2 kg/hr is essentially close to an order of magnitude and ultimately would be more achievable by a larger number of pending AMT's. This approach simplifies and applies an overall system approach to leveraging the use of Alternative Monitoring Technologies to reduce emissions.

- 100 kg/hr – detection level proposed for Super-emitter program
- 10 kg/hr – Detection level for highest AMT allowed. (1 order of magnitude lower than Super-emitter) ... (More than Likely Satellite Technology)
- 2 kg/hr – Detection level for lowest AMT allowed (1 order of magnitude lower than highest AMT) .... (Most likely, flyover type technology)
- 0.01 kg/hr – Conservative detection level for Human-based OGI

Response II-5-70: EPA acknowledges the commenter's input; for clarification purposes the matrix framework is not BSER and instead is a determination of equivalent methane emission reduction based on equivalency modeling as described in Section X.B.1 and XI.B.1 in the preamble of the rule.

Comment: In the periodic screening matrix, commenter (2333-LongPath) strongly recommends that EPA require monitoring and reporting on the same cadence for each technology class. Additionally, voluntary OGI screening between the required frequency intervals can enable operators to mitigate additional emissions, but EPA does not require operators to take regulatory action based on those efforts. So should operators be allowed to collect and use continuous monitoring data between the required frequency intervals for voluntary, additional emissions mitigation, without an EPA requirement for response. The commenter therefore suggests that EPA allow for the use of non-visual continuous monitors to provide coverage of all regulated equipment with the same frequency as is prescribed by the periodic screening matrix, but to exclude information from outside that time interval from fugitive regulatory action (closed vent monitoring may be considered separately). It is far better to allow operators to leave continuous monitor data "on" in between periodic screenings, and to use that data for additional voluntary

mitigation, than it would be to inadvertently incentivize operators to turn continuous monitor data “off” between periodic screenings so as to avoid response requirements.

Commenter (2333-LongPath) states if a technology can detect more frequently than required in the periodic screening matrix, that should not create additional (more frequent) response requirements than would apply to an owner or operator deploying OGI or other periodic screening technologies. While a company may use a technology that collects emissions information more frequently than monthly, the obligation should be to demonstrate compliance with fugitive emission requirements no more frequently than once a month—or the frequency required by the matrix based on the application detection threshold for the technology. Just as an operator should be allowed to perform more frequent OGI or aircraft surveys than required by the matrix without being subject specific response requirements in case of a detection, operators should also be able to use continuous monitoring information in the periods between the required survey frequency without added response burdens. In short, operators should be allowed to perform additional, more comprehensive emissions reductions voluntarily without incurring additional regulatory compliance burdens. Just as operators will be given leeway in deciding when to perform the required periodic screening with OGI or a survey technology, so long as the frequency requirements are met, operators should be given the same leeway in determining when to perform required periodic screening with continuous technologies, so long as those same frequency requirements are met.

Commenter (2333-LongPath) notes that the term “frequency” is typically poorly defined because of a hidden but important contributing dimension: spatial coverage. While a continuous monitor may deliver a mass emission rate every minute, the key question is how much of the site was “covered”, “seen”, or “represented” with that measurement. Put another way, what is the upwind fetch of each measurement, and how much time would it take to “see” all regulated equipment on the site is critical. Models show that it can take hours to days or even weeks, depending on sensor geometry and location, to achieve full coverage of all emission sources on a site. Similarly, while a periodic screening aircraft survey might cover the entirety of the site, there may be equipment hidden from line-of-sight. To avoid confusion, frequency specifications must always therefore be accompanied by clear definition of “how much of the site” and “how often for all equipment”.

Response II-5-71: EPA has revised the final rule to allow for technology that operates continuously to be used for either periodic screening or continuous applications dependent on the choice of an owner or operators and whether a technology can meet the applicable requirements. When used for periodic screening, the screening period will be determined according to what is defined in a technology’s alternative test method for methane detection technology. An owner or operator is not required to operate the systems outside their screening frequency, however continued used could be valuable these systems provide valuable information.

Comment: Commenter (2405-Bridger) states requirements for continuous monitoring and periodic screening require greater consistency. Because continuous monitoring is higher frequency emissions monitoring than monthly screening, the proposed 30 kg/hr periodic screening tier provides a less stringent work practice for emissions reduction. Because different options for emissions monitoring work practices should achieve equivalent levels of emissions

reduction, the commenter urges the EPA to remove the 30 kg/hr detection tier. To the commenter's understanding, all commercial airborne remote sensing methane detection technologies are capable of achieving 10 kg/hr (90% probability of detection) including sensing technologies deployed from a high-altitude aerial platform.<sup>33</sup> Removing the poorest sensitivity (30 kg/hr, monthly scans) option would therefore not exclude any current commercial airborne technology class.

Commenter (2405-Bridger) adds it must also be noted that the efficacy of the 30 kg/hr detection tier will be reduced in less heavy-tailed basins than the Permian. The EPA evaluated detection sensitivity tier equivalence using a large emitter emission rate distribution measured in the Permian Basin where large emissions represent an outsized share of cumulative emissions. However, when comparing a basin with a less heavy-tailed emission rate distribution to a basin with a more heavy-tailed distribution like the Permian (Figure 2), it is clear that emissions above 30 kg/hr represent a much smaller percentage of emissions and significantly fewer emissions reductions will be achieved using this detection sensitivity tier. This phenomenon is accentuated at higher detection tiers such as 30 kg hr<sup>-1</sup> compared to lower detection tiers.

[Figure 2. Cumulative emission rate distributions measured by GML in two different North American production basins. The percent of total measured emissions that had rates above 30 kg hr<sup>-1</sup> is significantly greater in the basin with a more heavy-tailed emission rate distribution compared to the basin with a less heavy-tailed distribution. The difference in percent measured emissions above a given emission rate is smaller for lower emission rates.]

Response II-5-72: EPA acknowledges the commenter's input. For discussions on EPA's matrix framework, please see sections X.B.1 and XI.B.1 of the preamble to the final rule.

Comment: Commenter (1686/2345-GHGSat) notes that its operational and growing satellite constellation and fleet of aircraft are available now to satisfy the proposed requirements under section 111 of the CAA. To achieve the greatest possible reductions in methane while remaining achievable and cost effective, the EPA must embrace a broader range of technological innovations for regulatory screening.

Commenter (1686/2345-GHGSat) believes that an aspect of the supplemental proposal that needs reconsideration is the minimum detection levels and monitoring frequencies currently specified in the proposed matrix. The commenter is concerned that the matrix as currently defined will unintentionally hamper the utilization of technological innovations that have the capability to enable the greatest possible reductions in methane by having more frequent surveys with higher minimum detection limits. The commenter recommends the EPA consider revising its proposed matrix approach with respect to detection levels with a reorganization of the detection thresholds and monitoring frequencies that would be more operationally effective and also establish a bridge between detection threshold and the proposed super-emitter program while providing a mechanism that accounts for the combination of innovative technologies that,

<sup>33</sup> Digital Roughnecks. How to Pick the Right Technology to Future-Proof Your EPA OOOO b/c LDAR Program. YouTube <https://youtu.be/m4y1Rtil2bE> (2022).

when working in tandem, can achieve the methane reductions mandated under Section 111 of the CAA.

Commenter (1686/2345-GHGSat) recommends a revision to the matrix such that the first three tiers with the lowest detection limits become a single tier of 5 kg/hr that requires quarterly monitoring plus an annual OGI survey. The 10 kg/hr and 30 kg/hr can remain as proposed. The commenter would then recommend the addition of two new tiers, one with a minimum detection threshold of 60 kg/hr in which biweekly surveys plus an annual OGI survey need to be performed, and a final tier with a detection threshold of  $\leq 100$  kg/hr that requires performing weekly surveys plus an annual OGI survey.

Response II-5-73: EPA acknowledges the commenter's input. For discussions on EPA's matrix framework, please see sections X.B.1 and XI.B.1 of the preamble to the final rule.

Comment: Commenter (2316-ABB) believes that the EPA should comprehensively study commercially available methane leak detection technologies and products to understand the available features in the state-of-the-art offerings (which provide improved performance and reliability). This will enable the EPA to consider which minimum detection thresholds are feasible, not cost prohibitive and ultimately help enable the effective reduction of methane leaks.

Response II-5-74: EPA acknowledges the commenter's input. EPA is aware how quickly these methane detection measurement systems are being developed and improved. To complete a comprehensive study of all measurement solutions could take years and by the end of the study, our findings could be dated. The approach in this rule is technology agnostic and provides performance targets for these technologies.

Comment: Commenter (2325-Aclima) believes the detection thresholds in the matrix Table 20 and Table 21 are fair detection thresholds that are achievable with today's technology. However, even lower detection thresholds are imminently achievable using sensor-based technology that can be installed permanently on each well and monitor continuously for less cost than periodic surveys.

Commenter (2315-New York State Department of Environmental Conservation (NYSDEC) appreciates EPA's proposal to allow for alternative technology through a matrix approach, but there are considerations beyond the detection limit that should be considered to ensure appropriate alternative detection technology is selected. The commenter recommends that EPA convene a multi-faceted workgroup to sort and evaluate detection technology most appropriate for recommendation. A similar effort took place through the Environmental Council of States Interstate Technology & Regulatory Council (ECOS's ITRC) program in 2017, where a document was generated to evaluate detection technology.<sup>34</sup> The commenter recommends EPA convene a similar group here.

Response II-5-75: EPA acknowledges the commenter's input.

---

<sup>34</sup> <https://methane-1.itrcweb.org>.

#### 5.8.4 Proposed Requirements

Comment: Commenter (2235-SLB) indicates that for alternative period screening using advanced methane detection technologies, the proposed regulations contain many additional elements that can complicate an operator's use of alternative screening. These additional elements and requirements can inadvertently discourage use of advanced technologies over the straightforwardness of the prescribed approach using older technology. These additional elements do not relate directly to the performance or effectiveness of the proposed alternative technology but rather amount to additional work not tied to technology selection. Examples of such additional elements required for alternative period screening beyond what is required for AVO and/or OGI fugitive emissions monitoring include:

- §60.5398(b)(1) (vi and vii) – requiring procedures and timeframe for identifying and repairing fugitive emissions in the fugitive emissions monitoring plan. This would require the upfront monitoring plan to anticipate all possible points of emissions and describe how to repair them prior to determining the source and nature of an emission.
- §60.5398(b)(4)(i) – requiring receipt of periodic screening in no less than 5 calendar days.
- §60.5398(b)(4)(ii) – in the event of a confirmed detection from periodic screening, a full site OGI survey or Method 21 must be conducted, with no option for AVO, notwithstanding that AVO is the default at single well facilities under the prescribed approach.
- §60.5398(b)(4)(iii) – a root cause analysis must be initiated to determine cause of failure and determine corrective action within 24 hours of the monitoring survey and inspection. “Root cause analysis should include a determination as to whether the system was operated outside of the engineering design analyses and whether updates are necessary for the system.” In some instances, regardless of whether the detection technology is OGI, AVO, or an advanced alternative, the cause of an emission may be readily available (*e.g.*, an ajar thief hatch) rendering a root causes analysis of the engineering design of the system unnecessary. Requiring root cause analysis for any detection made by an advanced alternative technology creates an additional burden for use of that alternative technology on an operator or technology provider and acts as an impediment to its use.

Each one of these additional elements, any combinations, or all collectively may discourage implementation or hamper implementation of an advanced screening technology by virtue of the additional work or constraints applied to alternative periodic screening.

Response II-5-76: EPA acknowledges the commenter's input. EPA has made some revisions consistent with these comments, for discussions on the periodic screening using alternative technology, please see sections X.B.1 and XI.B.1 of the preamble to the final rule.

Comment: Commenter (2433-EDF *et al.*) believes that AVO inspection requirements should apply to sites opting for alternative periodic screening. Aerial screening does not serve the same site upkeep and preventative maintenance purposes as AVO inspections. Allowing sites opting for the alternative to forgo AVO inspections means they may not be visited for years (depending on where in the matrix they fall) and could therefore fall into states of neglect and disrepair,

making them more prone to leaks and equipment failures that might be under the detection limit of the screening technology. Including these sites in AVO requirements is also important for ensuring the equivalency of emissions reductions.<sup>35</sup>

Response II-5-77: EPA acknowledges the commenter's input.

Comment: Commenter (2405-Bridger) states OGI inspections and M21 are methane emissions screening approaches that would fit into the periodic screening framework in the Proposed Rule. Implementing their use for regulatory LDAR using the same provisions that apply to other methane sensing technologies is consistent with the EPA's goal to approve emissions monitoring options based on their performance. To implement these monitoring approaches in the same systematic manner as other technologies, the EPA would establish a sensitivity/scan frequency tier in the periodic screening matrix that corresponds to the performance of these technologies.

Commenter (2405-Bridger) argues to determine the sensitivity corresponding to OGI and M21, further research may be necessary. Performance needs to be demonstrated through analysis studies representative of field conditions commensurate with the requirements for other monitoring approaches. Although OGI cameras and the detectors used for M21 are highly sensitive, their field performance is subject to environmental conditions, user error, and survey procedures. One research study indicated that surveys completed with a flame ionization detector according to M21 and surveys completed at the same sites with OGI detected a similar volume of emissions,<sup>36</sup> meanwhile another study indicated that existing advanced methane sensing technology detected a greater volume of emissions than OGI indicating the need for more research into the capacity of M21 and OGI to comprehensively identify emissions during field deployment.<sup>37</sup> As previously discussed in Comment 2.2, under simulated field conditions, experienced OGI surveyors reached 90% PoD at ~135 g hr<sup>-1</sup> (less experienced surveyors had reduced performance; they never achieved 90% POD for any emission rate).

Response II-5-78: EPA acknowledges the commenter's input.

Comment: Commenter (2283-Endeavor Energy Resources, L.P. (Endeavor)) believes EPA should revise the fugitive emissions testing requirements to reflect the realities of upstream oil and gas operations and provide additional flexibility for operators to use new, evolving, and more cost-effective methods of leak detection.

Response II-5-79: EPA acknowledges the commenter's support for the alternative technology approach in the rule.

Comment: Commenter (2283-Endeavor) states the proposed LDAR requirements ignore operational realities and as a result would impose unjustified burdens on the oil and gas industry. As noted above, well sites in the areas where the commenter operates, such as the Midland

---

<sup>35</sup> See Supplemental RIA, *supra* note 110, at 235.

<sup>36</sup> Pacsi, A. P. et al. Equipment leaks detection and quantification at 67 oil and gas sites in the Western United States. *Elementa* 7, (2019).

<sup>37</sup> Tyner, D. R. & Johnson, M. R. Where the Methane Is - Insights from Novel Airborne LiDAR Measurements Combined with Ground Survey Data. *Environ Sci Technol* 55, 9773–9783 (2021).

Basin, are often in remote locations, geographically spread out, and do not have permanent on-site staff. As a result, any provisions in the Methane Proposal that would require on-site personnel to perform a task presents a meaningful cost and operating challenge for producers. This is all the truer when these requirements are tacked on to existing sources under proposed Subpart OOOOc. Unless EPA allows for remote monitoring, the requirements will be unworkable and arbitrary and capricious in violation of the Administrative Procedures Act. The best approach is one that balances regulatory certainty with flexibility; to that end, The commenter recommends that EPA include a non-exhaustive list of methods of inspection that can be used, including aerial and remote-sensing options, as well as a clear and efficient process for additional methods not included on the list to be recognized and approved by the agency.

Response II-5-80: The use of alternative technology in the periodic screening or continuous monitoring approach in the final rule are alternatives to the BSER. EPA has provided a pathway for these to be approved for use, but it is inappropriate for the EPA to approve technology without thorough review.

Comment: Commenter (2283-Endeavor) adds there are simply not enough technicians in the Midland Basin to comply with the new requirements. EPA's current proposal would require periodic in-person monitoring. Based on the commenter's past experience, they estimate that one LDAR technician is needed to comply with current Subpart OOOOa LDAR requirements for every 40 sites. The commenter estimates that it would need to at least triple the number of LDAR technicians it employs to comply with the Methane Proposal, and this proposed requirement would represent millions in additional costs when multiplied across all operators in the Midland Basin. EPA's proposal will significantly strain the capacity of existing LDAR technicians and there are real concerns about the ability to scale up additional support. In addition, operators like the commenter would need additional resources to perform the monitoring (*i.e.*, purchase additional OGI camera at a cost of approximately \$100,000 per camera) and respond to any leaks. This would simply be cost-prohibitive for most producers, particularly as applied to low producing wells, and the Methane Proposal therefore risks driving producers to plug and abandon wells sooner than they would otherwise because this proposal is simply not economically viable, especially for the many low-producing wells that will be subject to EPA's proposal.

Commenter (2283-Endeavor) argues EPA should instead allow periodic inspections to occur through aerial flyovers or through the use of other remote technology and only require in-person monitoring on a much less frequent basis. Due to the remote locations of many of the sites that would be covered by the Methane Proposal, one technician might be able to visit three sites in a day through on-the-ground inspection. By contrast, an aerial inspection could inspect 200 sites at the same time. Aerial flyovers therefore allow operators to respond to leaks in real time in a more cost-effective way. Based on its own operations and experience, The commenter estimates that producers in the Midland Basin would save millions in compliance costs if EPA allowed for the use of aerial inspections in lieu of in-person inspections. This approach comes with air emissions benefits as well: it would drastically decrease the truck traffic needed to make these site visits and would allow operators to respond much quicker to any fugitive emission leaks found during the inspections. It would also avoid diverting operators' compliance resources from spending all of their time simply driving from site to site and allow them to instead focus on sites with known

leaks. EPA can therefore better address its true concerns through this flexible approach. And notably, EPA has included aerial flyovers as an accepted method of gathering information about fugitive emissions under its proposed Super-Emitter Response Program. While the commenter has concerns with the Super-Emitter Response Program and EPA's inclusion of aerial flyovers in the proposed program indicates that EPA has found this to be a reliable method of detecting emissions. It would be arbitrary (in violation of the APA) for EPA to allow for the use of aerial flyover monitoring in one part of the rule without allowing for its use in LDAR monitoring. EPA should therefore allow operators the flexibility to use this same approach for monitoring. At the very least, EPA's cost estimates should accurately reflect both the monetary costs of in-person surveys as well as the additional emissions that would result from such surveys.

Response II-5-81: EPA acknowledges the commenter's support for the alternative technology approach in the rule. The purpose of this rule is to provide a pathway to use these technologies within the rule to incentivize potentially cost-effective measurement solutions in identify excess methane emissions.

EPA has not pre-approved any technology for use in the alternative periodic screening or continuous monitoring approaches.

#### ***5.8.5 Follow-up OGI/Emissions Localization***

Comment: Commenter (2405-Bridger) states when an emission is detected by periodic screening, the Proposed Rule requires a full-site OGI survey to determine the source of the detected emission and any other fugitives present. However, many advanced methane sensing technologies have equipment scale resolution, and it is redundant and burdensome to require an OGI survey of all equipment pieces at a site to locate the emission source, which has already been identified to belong to a single equipment unit. It is a standard practice to use OGI to determine the specific emitting component by screening infrastructure within the localization uncertainty of the methane sensing technology. When OGI is an appropriate element of investigative analysis for an emission detected by advanced technologies, the commenter urges the EPA to allow operators to direct the OGI survey within the localization uncertainty region of the advanced technology. This practice maintains the efficiency gained by technologies that can rapidly screen oil and gas sites for emissions and precisely localize emission sources.

Commenter (2405-Bridger) notes FEAST modeling was used to support the periodic screening framework development. Modeling efforts simulated periodic screening as aerial surveys with site-level resolution. In the simulation protocol, emission detection at a site triggered a full-site OGI survey. Although this approach was based on prior literature,<sup>38</sup> it is not suitable for modeling a technology agnostic framework. Various methane sensing technologies that could be used in this framework have localization capabilities spanning site-level, equipment group-level, equipment unit-level, and component-level precision. For technologies with site level localization, a large set of infrastructure may need to be investigated to conclusively identify emissions sources. For technologies that can localize emissions to specific components

---

<sup>38</sup> Kemp, C. E. & Ravikumar, A. P. New Technologies Can Cost Effectively Reduce Oil and Gas Methane Emissions, But Policies Will Require Careful Design to Establish Mitigation Equivalence. *Environ Sci Technol* 55, 9140–9149 (2021).

additional emissions screening is redundant. It is foreseeable that advanced handheld instruments, unmanned aerial vehicle-mounted sensors and/or aerial technologies will provide component-level resolution and be used for periodic screening. The commenter urges the EPA to develop regulations that recognize the localization capabilities of advanced methane sensing technologies and encourage technological improvement in this area. Follow-up requirements for emissions detected by alternative test methods should be guided by the known capabilities of advanced methane sensing technologies. Extensive studies have been performed to characterize emission source localization such as those completed at the METEC which was developed with support from the Department of Energy's Advanced Research Program Agency-Energy (ARPA-E).<sup>39,40,41</sup> These studies categorize localization precision as site-level, equipment group-level, and equipment unit-level precision. The commenter recommends the EPA to refine alternative emissions monitoring follow up requirements to correspond to these localization precision levels. For a test method to be classified at a given level of localization precision, 95% of its detections should be correctly localized.

Response II-5-82: EPA acknowledges the commenter's input. As explained in Section X.B.1, X.B.3, XI.B.1, and XI.B.3, EPA has revised the final rule include allowances for technologies which have proven spatial resolution.

Comment: Commenter (2333-LongPath) states several groups and coalitions have recommended that OGI follow-up for certain types of emissions may be unnecessary and inadvertently disadvantage alternative technologies compared with BSER. For example, if permitted process emissions are detected and conclusively identified as permitted, then OGI follow-up should not be required. Similarly, if emissions are identified as intermittent, then follow-up OGI may be unlikely to find or provide any additional information about the source and therefore be unnecessary. Continuous monitoring provides temporal information about emissions that can typically lead to the identification and resolution of the cause without requiring a site visit or OGI survey. Indeed, EPA's continuous monitoring provisions do not require OGI follow-ups in any scenario. The commenter therefore recommends that for technologies that can provide information contributing to understanding of the cause of the emission, including information about the temporal nature of the emission (*e.g.*, intermittency) or links to maintenance or permitted processes, that OGI follow-ups not be required as part of the "root cause analysis" (like other stakeholders, the commenter prefers the term "investigative analysis").

Commenter (2192-BSM) responds to the requirement for a monitoring plan to include "(5) procedures for conducting ground-based monitoring surveys in response to confirmed emission detection events from periodic screening surveys." The commenter requests that the process for reporting a "confirmed emission detection" allow for the possibility of measurement verification. One of the major benefits of a fixed position system like NIRview is the ability to quickly validate with either automatic scan repeats or even by remote control via user-directed "point and

<sup>41</sup> Bell, C., Ilonze, C., Duggan, A. & Zimmerle, D. Performance of continuous emission monitoring solutions under single-blind controlled testing protocol. *Chem xiv* (2022). doi:10.26434/chemrxiv-2022-4hc7q-v2.

measure” operation. The commenter would like to make sure that if an advanced measurement technology has a means of measurement validation that it be allowed to be incorporated into the process of providing a confirmed emission detection event.

Response II-5-83: EPA acknowledges the commenter’s input. As explained in sections X.B.1 and XI.B.1 of the preamble to the final rule, EPA has revised the final rule to include allowances for technologies which have proven spatial resolution to conduct reduced follow-up. See response II-5-19 for further discussion.

Comment: Commenter (2298-Pioneer) recommends that EPA change the full-site follow-up requirement to a follow-up OGI survey only over the spatial extent corresponding to the verified localization performance of the detection technology.

Commenter (2298-Pioneer) says that third parties (*e.g.*, METEC) are currently in place to characterize and document the emission source localization performance of methane detection technologies just as they do for detection sensitivity performance. Rather than requiring a full-site follow-up OGI survey, the commenter urges the EPA to require an OGI follow-up survey only over the spatial extent corresponding to the detection technology localization performance. By way of example, if a detection technology has proven emission source localization performance of 2-meter radius with 95% confidence bound (*e.g.*, verified by METEC under the ADED protocol), then the follow-up OGI survey must only be performed over a radius of that spatial extent and a follow-up OGI survey of the remainder of the site would not be required. However, if a sitewide OGI inspection sweep is performed to identify the emission component source, the commenter agrees with EPA that such an OGI sweep would satisfy any required annual OGI screen if that is required for that specific technology or under the matrix.

Response II-5-84: EPA acknowledges the commenter’s input. As explained in Section X.B.1, X.B.3, XI.B.1, and XI.B.3, EPA has revised the final rule include allowances for technologies which have proven spatial resolution to conduct reduced follow-up.

Comment: Commenter (2336-Kuva) argues a “blanket” follow-up OGI survey for emissions detected by advanced technology in the periodic screening matrix conflicts with emissions reduction goals and disincentivizes advanced technology. Advanced technologies may detect, record, and characterize many emission sources for which OGI follow-up is unnecessary or impractical.

Commenter (2336-Kuva) states operators may be able to conclusively identify the emission source through investigative analysis other than OGI using a combination of advanced technology data, compressor runtime data, process control / SCADA data, maintenance activity logs, and prior screening results. In these cases, an OGI survey is unnecessary and burdensome. Moreover, OGI is impractical for following up on emission sources such as compressor engines and control devices because OGI cannot inherently differentiate between normal and abnormal operation. These emission sources are regularly detected by advanced technologies even when normally operating. If permitted process emissions are detected and conclusively identified, then no response other than recordkeeping should be necessary. For emissions identified as intermittent or nonpersistent (*e.g.*, those coming from over-pressurization of a closed vent system

or a maintenance event) additional OGI screening is unlikely to be helpful and investigative analysis (especially with camera based continuous monitoring systems) is the appropriate response.

Response II-5-85: EPA acknowledges the comments and agrees that when a technology identifies emission event from a maintenance event should trigger an OGI inspection, however we disagree that an OGI inspection of an emission event of a closed vent system is not an appropriate response. It is critical to identify the cause of the emission event and to ensure that a release has not moved to another portion of the CVS system.

Commenter (2336-Kuva) states the Proposed Rule for periodic screening burdens each detected emission by an advanced technology with a full-site follow-up OGI survey despite the fact that the advanced technology may localize the emission source with better than site-level uncertainty. Therefore, when an OGI follow-up is appropriate, the commenter urges the EPA to require follow-up OGI surveys only within the localization uncertainty region of the advanced technology. By way of example, if an advanced technology has emission source localization performance of 2-meter radius with 95% confidence bound, then the follow-up OGI survey must only be performed over that spatial extent and a follow-up OGI survey of the remainder of the site is not required. Advanced technology localization performance is readily characterized by third parties using consensus testing protocols (*e.g.*, the ADED protocol).

Response II-5-86: EPA acknowledges the commenter's input, as explained in Section X.B.1, and XI.B.1, EPA has revised the final rule include allowances for technologies which have proven spatial resolution to conduct reduced follow-up.

Commenter (2345-GHGSat Inc.) agrees with requiring operators to conduct a root cause analysis to determine the corresponding corrective action within 24 hours and completion of repairs must occur within 30 days of notification from the screening survey. The commenter believes that this corrective action should be coupled with a first attempt to repair the leak, which may involve a temporary solution to minimize emissions (*e.g.*, emission source isolation, temporary replacement, etc.). These efforts should grant additional time to make a permanent repair in the event that the emission source is not fully resolved within 30 days of notification. Therefore, this should grant a delay-of-repair status, requiring an operator to fully document and amend, if necessary, the corrective action plan.

Commenter (1686/2345-GHGSat) understands that the EPA is proposing to perform a root cause analysis within 5 days of completing a ground-based inspection when a leak or defect in a cover or CVS is identified. Also, the EPA requires repairing the leak or defect within 30 days of the screening survey. The commenter believes that an initial root cause analysis should be performed within 24 hours, as it would be the standard practice in the event of a different type of emission source (*e.g.*, leaky valve). Adding a different timeline for covers and CVS just adds to the complexity of the rule and does not necessarily alleviate any burden. Most likely that companies will opt to make a 24-hour deadline across the board. Also, the commenter would like to stress to change the language to reflect that repairs must occur within 30 days upon notification, and not at the time when the emission source was identified.

Commenter (1686/2345-GHGSat) argues when emissions originate from sources like cover, CVS, or a control device, a root cause analysis must be conducted. In addition, this root cause analysis should provide an avenue for the operator to claim affirmative defense, when applicable.

Response II-5-87: In the final rule, EPA no longer uses the term root cause and instead has chosen the term investigative analysis when a confirmed detection was caused by a failure of a control device used to demonstrate continuous compliance in the applicable regulation. The criteria for the cover and closed vent systems are detailed in Section X.K and XI.K of the preamble of the final rule.

Comment: Commenter (2405-Bridger) argues the 30-day timeline for repairing emissions detected during periodic screening does not allow operators enough time to follow up on detected emissions. Certain advanced methane sensing technologies that will be used for periodic screening can cover 100+ sites in a single day. This level of efficiency is a major reason that operators benefit from access to these technologies. Compared to the ~5 sites per day that can be screened by OGI,<sup>42</sup> efficient aerial screening would generate a much larger workload of follow-up repairs in a short period of time. To overcome this challenge, the EPA should allow a longer repair timeline for emissions detected during periodic screening. It is also necessary to consider time needed for data to be fully processed before it is delivered to operators. Operators typically wait for fully processed datasets, which contain mass emission rates that they use to prioritize repair activities. More time is warranted to allow emissions data to be processed and delivered to operators. The commenter urges the EPA to allow operators 45 days for a first repair attempt on emission sources detected during the periodic screening alternative approach.

Response II-5-88: EPA acknowledges the commenter's input, and EPA has chosen to maintain the timeline criteria for repairing emissions for the periodic screening, as the 30-day repair timeline is consistent with the requirements for the BSER program for which the equivalent emission reduction in the matrix framework was based.

Comment: Commenter (2428-API) expresses that the proposed follow-up actions for periodic screening surveys should be revised. The proposed repair or corrective action requirements for alternative technology should not disincentivize their use. The commenter offers the following suggestions:

- The requirements on receiving results of periodic screening and conducting follow-up surveys should be separated from other repair requirements to avoid confusion. **The language in §60.5398b(b)(4) implies that receiving periodic screening results and conducting follow-up surveys are repair requirements when they are both monitoring requirements to detect or confirm leaks.**
- The timeline for receiving results of periodic screening should be extended from 5 calendar days to 5 business days. **Periodic screening surveys can cover hundreds of sites, and so vendors and operators need additional time to process the data for further action.**

---

<sup>42</sup> Zimmerle, D. et al. Detection Limits of Optical Gas Imaging for Natural Gas Leak Detection in Realistic Controlled Conditions. Environ Sci Technol 54, 11506–11514 (2020).

- Follow-up surveys and inspections should be limited to sites where the source of emissions cannot be identified based on the localization performance of periodic screening results and other operational information. **Follow-up OGI** surveys and cover and closed vent system inspections should not be required if the source of detected emissions can be identified based on the localization performance of the alternative technology and/or other data. Alternative technology has varying degrees of localization performance in terms of being able to identify emissions on the site-level, equipment group-level, equipment-level, or component-level. Our proposed follow-up action process gives operators the necessary flexibility in responding to detected emissions and is presented in Figure 2 and described in detail below.

[Figure 2. Flowchart of proposed follow-up for Periodic Screening Surveys]

Commenter (2428-API) states when emissions are detected in a periodic screening survey, the operator first tries to identify the source of emissions from the survey results and other available information. For safety and cost reasons, follow-up surveys in the field should be limited to situations where additional information is needed to identify or confirm the source of detected emissions. If the source of detected emissions can be identified, next steps would be based on the type of source.

- If the source of emissions is permitted or otherwise authorized, including maintenance activities, no further action would be required other than to keep documentation. Examples include, but are not limited to, engine or turbine exhaust, uncontrolled storage vessel, planned compressor blowdown, planned engine or turbine startup or shutdown, or properly operating control device. This situation is especially important to compressor stations where periodic surveys are likely to detect emissions from sources operating in compliance with applicable requirements.
- If the source of emissions is a process upset, leak, or other unauthorized release, the operator should be able to directly take necessary corrective actions rather than spending time and effort on a follow-up survey to confirm the source. Taking direct action with the appropriate timelines reduces emissions faster than conducting a follow-up survey first. If the operator determines that a follow-up survey is appropriate to confirm the source of detected emissions, they should be able to conduct one based on the localization performance of the technology or an optional full site survey.

Commenter (2428-API) notes if the source of detected emissions cannot be identified, operators would conduct a follow-up survey limited to the localization performance of the alternative technology or conduct a full site survey to satisfy the annual OGI survey requirement (if applicable). If two or more full site surveys are conducted within a 12-month period, the most recent full site survey would determine the deadline for the next required annual OGI survey (if applicable). As an example, an alternative technology that can only detect leaks on the site level would require a full site survey while one that can detect leaks down to the equipment would require follow-up surveys only on equipment with detected leaks. Requiring a full site survey anytime that emissions are detected from periodic screening surveys is practically the same monitoring requirement as the primary AVO/OGI requirements but with the additional cost of conducting periodic screening surveys. Due to the large volume of data that can be generated

from periodic screening surveys, limited follow-up surveys allow OGI resources to be used in a focused and cost-effective manner. Limited follow-up surveys could also have environmental benefits with reduced vehicle and road dust emissions due to less site visits compared to a full follow-up survey required for every time emissions are detected during a periodic screening survey. The commenter provides additional recommendations below (more specific details on these recommendations can be found in the commenter's letter):

- Repair timelines should be consistent with AVO/OGI requirements.
- The proposed investigative analysis for control devices in §60.5398b(b)(4)(iv) and covers and closed vent systems in §60.5398b(b)(5) should be initiated within 5 business days.
- The proposed investigative analysis for covers and closed vent systems in §60.5398b(b)(5) is more stringent than the repair requirements under §60.5416b(b)(4) and should be removed.
- "Root cause analysis" should be replaced with "investigative analysis".

Response II-5-89: EPA acknowledges the commenter's input. EPA has made changes to the periodic screening approach in the final rule as detailed in Section X.B.1 and XI.B.2. EPA has not made changes to the follow-up or repair timelines in the proposed rules.

Comment: Commenter (2406-EEMDL) states screening technologies are more likely to detect emissions at the equipment-level, thus making a targeted follow-up OGI survey more cost-effective than a site-wide OGI survey.

Response II-5-90: EPA acknowledges the commenter's input, as explained in Section X.B.1, and XI.B.1, EPA has revised the final rule include allowances for technologies which have proven spatial resolution to conduct reduced follow-up.

Comment: Commenter (2298-Pioneer) recommends that EPA exclude from the follow-up OGI survey requirement those emission sources corresponding to normal permitted operating process emissions or emission events that are otherwise confirmed to no longer exist.

Commenter (2298-Pioneer) indicates that emissions corresponding to normal operating process emissions that are within permitted bounds are not considered fugitive emissions affected facilities. Moreover, emissions corresponding to temporary process disruptions are often clearly identified and documented in operations and SCADA logs. If an emission event can be attributed with certainty as a normal operating process release, then a follow-up OGI survey should not be required. By way of example, if an emission was identified during one application of an alternative test method and verified to correspond to a normal operating process release with a follow-up OGI survey, then a subsequent identification of that emission source should not require a subsequent follow-up OGI survey. Similarly, a well-documented process upset detected during application of an alternative test method should be addressed by root cause analysis (or rather "investigative analysis" per comments below) and should not require follow-up OGI surveys. In both examples, the follow-up OGI survey does not reduce emissions, but could unnecessarily increase safety risk and economic burden associated with the follow-up OGI survey.

Response II-5-91: EPA acknowledges the commenter’s input, as explained in Section X.B.1, and XI.B.1, EPA has revised the final rule include allowances for technologies which have proven spatial resolution. When an operator uses a technology that can differentiate permitted releases (e.g., methane slip from an IC engine) from equipment covered in the periodic screening, you are not required to conduct a follow-up inspection. You must maintain a record of the survey and maintain a record why follow-up was not conducted.

Comment: Commenter (2435-Will Price) urges EPA to make the following two “make or break” revisions to rule based on the fundamental principle of removing inadvertent “penalties” or “disincentives” for detecting emissions under the alternative framework:

1. Provide an opportunity for operators to mitigate detected compliance issues instead of immediately classifying them as violations. With more comprehensive spatial and temporal coverage, advanced technologies will detect many more emission sources than OGI that represent compliance issues (e.g., malfunctioning control devices, cover and closed vent system failure). Penalizing operators with an immediate violation/fine create a strong disincentive inhibiting adoption of advanced technologies that will reveal these problems. Allow the operators a compliance pathway to fix the problem first.
2. Capitalize on the enhanced capabilities of advanced tech instead of requiring a “blanket” full-site follow-up OGI survey. Every detection by advanced tech triggers a “full-site” follow-up OGI survey, even if the tech identifies the emission source, even if the emission source is not required to be monitored by standard OGI (compressor exhaust), and even if the advanced tech shows the emission source no longer exists (intermittent). This penalizes the detection of emission sources and favors standard OGI. To remove this disincentive, the commenter suggest that EPA do not require OGI follow up if the emission source can be conclusively identified by the advanced technology or is intermittent. If it cannot be identified, the commenter suggests only requiring OGI follow up within the localization uncertainty of the advanced technology investigative analysis.

The commenter notes that requiring blanket OGI surveys unfairly saddles advanced technologies with OGI inefficiencies.

Response II-5-92: EPA acknowledges the commenter’s input, as explained in Section X.B.1, and XI.B.1, EPA has revised the final rule include allowances for technologies which have proven spatial resolution. EPA has explained its position on covers and closed vent systems in Section X.K and XI.K.

### ***5.8.6 OGI Requirements are Duplicative***

Comment: Commenters (2284-Kairos, 2298-Pioneer, 2345 GHGSat Inc., 2363-CEMC, 2428-API) agree with the EPA’s proposal to require a ground-based survey using OGI to identify the source of the emissions when periodic screening survey technologies are used. The commenters argue in turn, the full site follow-up OGI survey fulfills the annual OGI survey requirement, when applicable, as indicated in §60.5398b(b)(3)(iii).

Response II-5-93: EPA acknowledges the commenter's input and EPA agrees that a full-site follow-up would fulfill the annual OGI survey requirements in the matrix framework.

Comment: Commenters (2258-MS, 2284-Kairos, 2399-GPA) are not supportive of the requirement to conduct a full survey following a periodic screening.

Commenter (2399-GPA) states the proposed regulatory text offers the option of periodic screening, but if a leak is detected, the owner/operator would be required to conduct a full survey of every fugitive emission component. This would practically be the same monitoring requirement found in proposed §60.5397b. Thus, the periodic screening option not only provides no real benefit over quarterly monitoring with an annual OGI inspection, but it adds the cost of periodic screening – which would be a significant additional cost, where an owner or operator must also conduct bi-monthly or monthly screening. To make the periodic screening option meaningful, the commenter proposes that, for owners or operators that choose the periodic screening option, follow-up inspections be focused on the identified source of the leak instead of the entire facility.

Commenter (2258-MS) states the proposed requirement of a ground-based monitoring survey of the entire facility when emissions are identified by alternative technology are burdensome and not necessary in all cases. The requirement to assess the full facility with OGI following detection of emissions should be dependent on the capability of the alternative technology used. Many technologies can detect source level emissions. In this case, only the source should be evaluated. Cause(s) of emissions identified by alternative technology are often documented by other records. A facility/source level inspection should only be required if the cause cannot be identified by separate records such as operator logs, SCADA data, etc.

Response II-5-94: EPA acknowledges the commenter's input, EPA in maintaining OGI follow-up when periodic screening when emissions have been detected with periodic screening, but the final rule includes an allowance for a reduced screening when using technology with better spatial resolution. EPA considered the use of supplemental records such as SCADA data to be valuable, however they are not replacement for component-level inspection.

Comment: Commenter (2258-MS) states when OGI is necessary, the requirements in §60.5398b(b)(4)(iv) using the term “ground-based monitoring survey” should be removed. The term “ground-based monitoring survey” can be interpreted to exclude the ability to use OGI cameras mounted to drones or aircraft. The commenter believes the daily verification requirements that exist in the proposed rule §60.5397b(c)(7) and 40 CFR 60.5397a(c)(7) are sufficient to determine the distance at which the OGI camera can view the release, and the OGI inspection must be performed within that distance.

Response II-5-95: EPA disagrees that the terminology in §60.5398b needs to be revised. The terminology is not meant to limit how an owner or operator uses an OGI camera; it is meant to differentiate the OGI survey from surveys that will be conducted with alternative methane detection technologies. EPA considers a drone-based OGI inspection to still be ground-based, because the drone operator is located on the ground. EPA has previously acknowledged that the use of OGI cameras mounted to drones are acceptable for fugitive emission surveys in NSPS

OOOOa, so long as the criteria outlined in §60.5397a are met.<sup>43</sup> EPA has received numerous questions on this issue since that time, and we think it is important to clarify that when using an OGI camera mounted to a drone, the person who is trained and knowledgeable on the operation of the OGI camera should either be the person operating the drone or be viewing the results alongside the person operating the drone in order to make appropriate adjustments for interferences and background during the survey as needed – the results cannot be sent to the person trained and knowledgeable on the operation of the OGI camera after the inspection. Additionally, EPA does not believe that OGI cameras mounted on aircraft will meet the requirements in NSPS OOOOa or §60.5397b. The aircraft is likely to create wind effects that will disperse emissions, making them harder to detect. Additionally, it will be much harder for an OGI camera operator to have a proper thermal background for monitoring all components from an aircraft.

Comment: Commenter (2284-Kairos) suggests EPA broaden its ground follow-up for more rapid repairs and consequently, emission reductions. If a remote sensing technology flags a site for follow-up, the first visit of the year should conduct a comprehensive site survey, either via OGI screening or an alternative approved method. This should continue to satisfy the annual OGI requirement, as proposed by EPA. It also will align the alternative leak detection program with EPA's modeled emission reductions under the proposed matrix. The commenter states if a site is flagged by remote sensing technology for follow-up on subsequent surveys that year, operators should be able to survey the suspected source using OGI or an alternative approved method but should NOT be required to do a comprehensive site screening for small, unrelated emissions from process units clearly not associated with the flagged emission. For example, if an aerial survey identifies a site with emissions near the separator, and ground follow-up confirms a malfunctioning dump valve, that should be sufficient investigation for follow-up and repair. The operator in this instance would not need to conduct an OGI survey of an onsite compressor located on the far side of the facility that clearly was not the source of the emissions in the remote sensing survey. The commenter adds follow-up ground truth verification is extremely valuable—even the most precise aerial systems generally cannot definitively establish a root cause by themselves. OGI is a useful tool for ground truth verification, but the commenter recommends EPA allow other appropriate technologies (*e.g.*, a continuous monitoring system) to aid in that ground follow-up action. OGI should not be the only tool available, when other measurement systems can perform this same task.

Response II-5-96: The final rule now includes considerations for spatial resolution when conducting follow-up as described in Section X.B.1 and XI.B.1 in the preamble of the rule.

Commenter (2284-Kairos) argues by focusing on the large emission sources identified by screening technologies and prioritizing work practices around rapid repair, EPA will ensure these emission sources are addressed as quickly as possible. Similarly, by leaving the annual OGI screening (or another approved alternative method) as a part of the work practice, EPA can

---

<sup>43</sup> EPA's Responses to Public Comments on the EPA's Oil and Natural Gas Sector: Emission Standards for New, Reconstructed, and Modified Sources. May 2016. Page 4-184. Available at: <https://www.regulations.gov/document/EPA-HQ-OAR-2010-0505-7632>.

address Environmental Justice concerns that stem from the impact of unaddressed small leaks on local communities.

Commenter (2284-Kairos) summarizes their findings with the following recommendations:

- In addition to OGI, include other appropriate ground-based technologies as acceptable means of ground follow-up (*e.g.*, continuous monitoring systems).
- Leave requirements for comprehensive ground survey resulting from an advanced leak screening survey in place for the first site visit of the year resulting from a remote survey detection.
- Require subsequent visits resulting from remote survey detections to the same site to survey the impacted area/suspected emission source using an appropriate ground-based measurement technique (OGI survey or approved alternative method). Interpretation of SCADA data or AVO surveys may not always be sufficient based on our experience.

Response II-5-97: EPA acknowledges the commenter's input. EPA has detailed the requirement for follow-up to periodic screening in Section X.B.1 and XI.B.1 in the preamble of the rule.

Comment: Commenter (2363-CEMC) states that the proposal does not require operators to conduct this additional OGI sweep when monitoring fugitive emissions with OGI because OGI can sufficiently identify the location of the leaking component. Some advanced technologies can similarly identify the leaking fugitive emission component or process malfunction, thereby rendering follow up OGI duplicative for the purposes of identifying the source or cause. To identify the emission source, an operator might use the advanced technology's spatial and temporal information in conjunction with data analysis of process or runtime data. Alternatively, an operator may be able to use combinations of advanced technologies (*e.g.*, an aerial survey to comply with the fugitive emission requirement coupled with a continuous emission data) to identify the emission. A mandatory OGI sweep will create a disincentive for operators to deploy advanced technologies for compliance with the rule if that advanced technology can localize the emission to a component, identify the emission as normal or abnormal, or identify its root cause.

Response II-5-98: EPA acknowledges the commenter's input.

Commenters (2363-CEMC, 2405-Bridger) alternatively recommend that EPA design the final rule to allow operators to choose the most effective follow up response based on the advanced technology's capability to identify the emission cause.<sup>44</sup> EPA should consider providing more choices on how to respond when emissions are detected, similar to the approach used in the fenceline monitoring work practice promulgated by EPA in 2015 as part of the NESHAP for the petroleum refinery sector.<sup>45</sup> Under that rule, if an operator determines an action level exceedance, the operator must initiate an investigative analysis which may include: leak detection using Method 21, leak detection using OGI, or employing progressively more frequent sampling using

---

<sup>44</sup> This recommendation is in response to EPA's request for comments: "The EPA is soliciting comment on the proposed requirements for the root cause analysis and corrective action, the timeframes for conducting these activities, and the requirement for corrective action plan submittals." 87 Fed. Reg. 74745.

<sup>45</sup> See 80 Fed. Reg. 75178 (Dec. 1, 2015).

Method 325A and 325B.<sup>46</sup> In the preamble of that rule, EPA stated that “the premise of the fenceline monitoring is to provide the refinery owners or operators with the flexibility to identify the most efficient approaches to reduce the emissions that are impacting the fenceline level.”<sup>47</sup> The commenter recommends providing similar options for operators to use advanced technologies to efficiently fix leaks in the Final Rule.

Response II-5-99: EPA acknowledges the commenter’s input. EPA could consider an alternative to an OGI follow-up so long as the technology and methodology associated with the technology would yield the same level of detection probability as OGI.

Commenter (2405-Bridger) adds in addition to source identification, the OGI follow-up requirement was also developed to identify the presence of emissions that were not identified by advanced technology screening. However, this approach conflicts with the EPA’s mission to develop a framework for emissions monitoring that is performance based and technology agnostic. For the framework to fit these criteria, the desired emission reductions must be achieved by the alternative test method itself and not hinge on supplemental screening with OGI cameras to detect additional emissions at sites where emissions are detected by an alternative approach. Moreover, for sensitive technologies, the impact of searching for additional emissions will be minimal even though the Proposed Rule burdens increased sensitivity with a greater number of sites requiring OGI follow-up (as previously discussed).

Commenter (2405-Bridger) states although a full-site OGI scan should not be required every time an emission is detected at a site, if annual OGI is required at the periodic screening sensitivity tier being used, then operators should have the option to complete a full-site OGI survey during detection follow-up to satisfy the yearly OGI requirement at that site. This could improve operations efficiency and reduce a backlog of sites that need to be visited for yearly OGI. This recommendation is consistent with the November 2021 Proposed Rule.

Response II-5-100: EPA acknowledges the commenter’s input and EPA agrees that a full-site follow-up would fulfill the annual OGI survey requirements in the matrix framework.

Comment: Commenter (2363-CEMC) recommends that the final rule require that if an advanced technology confirms an emission detection, the operator should identify the emission source or cause.<sup>48</sup> The Final Rule need not specify only one option to identify the component releasing the emissions. Instead of automatically requiring a sitewide OGI sweep, the Final Rule should require operators to use:

- an advanced technology that EPA approves to identify the emission source or cause.
- an advanced technology combined with any relevant process data analysis to identify the emission source or cause.

---

<sup>46</sup> 40 CFR 63.658(g).

<sup>47</sup> 80 Fed. Reg. 75198.

<sup>48</sup> To the extent the Final Rule reflects this change, it would be important to update any modeling assumptions used in the FEAST modeling.

- advanced technology coupled with a continuous emission monitor<sup>49</sup> to identify the emission source; or
- OGI or Method 21 to identify the emission source.

Commenter (2363-CEMC) suggests that once the operator identifies the emissions source, the operator's obligation should be to repair all sources of fugitive emissions and initiate an investigative analysis for all process malfunctions. EPA can establish the requirements for an advanced technology's capability to localize a confirmed emission detection through work practice standards in the alternative test method approval process.<sup>50</sup>

Response II-5-101: EPA acknowledges the commenter's input; we have revised the final rule to include many of these suggestions which are explained in Section X.B and XI.B of the preamble of the rule.

Comment: Commenter (2298-Pioneer) recommends that if any degree of OGI follow-up remains a requirement, a leak detected with aerial technology must be confirmed by a second fly over pass to determine it is a nonintermittent event that triggers the follow-up.

Commenter (2298-Pioneer) recommends that EPA include language stating that before any degree of OGI follow-up is required, the emissions must be detected by the aerial technology twice: 1) an initial flight pass that identifies the leak; and also 2) a second flight pass to confirm the leak. In regard to the commenter's voluntary program with Bridger Photonics, Bridger routinely takes this approach and factors this confirmation pass over an initially detected leak into their services and cost structure. If they detect a leak, they fly over it a second time to confirm the leak and make sure it was not a random intermittent release that the OGI thermographers likely would not find if they went to the site. The timeframe between the two flight passes is typically within 2-3 days in order to let any one-time event like truck loading or a pneumatic actuation cease.

From the commenter's (2298-Pioneer) experience, the inclusion of this requirement will not impose an added disincentive for an operator to utilize an alternative aerial technology but rather will incentivize this technology by confirming leaks, thus avoiding futile ground truth efforts that will waste manpower hours.

Response II-5-102: EPA acknowledges the commenter's input, however EPA is unable to respond to this specific scenario without additional information. EPA has revised the periodic screening approach and alternative test method approval process in the final rule as detailed in Section X.B and XI.B of the preamble of the final rule.

---

<sup>49</sup> EPA could approve the use of a continuous emission monitor to identify the emissions source through an operator's site-specific monitoring plan.

<sup>50</sup> For example, the Methane Emissions Technology Evaluation Center (METEC) has developed such protocols with support from the Department of Energy.

### **5.8.7 FEAST Modeling/Equivalency**

Comment: Commenters (2284-Kairos, 2340-Honeywell) believe the periodic screening framework should provide further flexibility based on the use of FEAST modeling.

Commenter (2284-Kairos) indicates that to fully characterize the benefits of advanced leak detection technology, FEAST modeling should incorporate the additional indirect emission reductions generated by using advanced technology in lieu of AVO inspections. EPA could incentivize these more rigorous advanced solutions by allowing operators to eliminate AVO visits with advanced screenings. For example, a monthly aerial screening program at 30 kg/hr could replace the BSER requirements and the respective AVO visit requirements. Doing so would increase the incentives to utilize new technology while simultaneously providing clearer and more quantifiable emission benefits than the AVO program offers.

Commenter (2284-Kairos) adds that, similarly, advanced screening techniques are effective at identifying things like unlit flares that are classified as malfunctions instead of being classified as fugitive emissions. That classification, however, is arbitrary and any advanced leak screening technology that can identify these types of malfunctions should be incentivized and those emission reductions should be incorporated in FEAST modeling.

Commenter (2340-Honeywell) noted that EPA explains in the preamble to the proposed supplemental rule that it used FEAST modeling to determine the screening frequencies and methane detection thresholds that would provide equivalent fugitive emissions reductions to the BSER methods. This resulted in the periodic screening matrices, which prescribe a survey frequency (and in some cases an annual OGI backstop) depending on the minimum detection threshold of the survey technology, with a maximum detection threshold of 30 kg/hr.

Commenter (2340-Honeywell) supports EPA's efforts to provide flexibility through the screening matrices to accommodate a variety of methane survey technologies that can meet varying detection sensitivity thresholds. Doing so will facilitate further development and deployment of advanced technologies for methane emissions monitoring. Honeywell recommends, however, that EPA provide even further flexibility based on modeling, where screening frequency and detection thresholds are inversely related at least within specified bounds (as the benefit of increasing frequency may be limited when detection thresholds are above the vast majority of emissions rates). Rather than prescribing a limited set of screening frequencies and detection thresholds, the final rule should allow the use of FEAST modeling to determine the screening frequency based on the minimum detection levels that the technology can provide.

Commenter (2340-Honeywell) notes that EPA has established, through FEAST modeling, that periodic screenings with a detection sensitivity of greater than 30 kg/hr cannot be considered equivalent to BSER at any screening frequency. As such, the final rule can maintain 30 kg/hr as the upper bound of the detection thresholds. Greater flexibility within that range, however, will further encourage and facilitate the adoption of advanced screening technologies.

Response II-5-103: EPA acknowledges the commenters' input. As discussed in Section XI.B.1 of the preamble of the rule, EPA conducted FEAST modeling of our model plants based on the most updated information available to ensure the matrix framework was equivalent to the BSER program.

Comment: Commenter (2448-Project Canary) states EPA's FEAST modeling assumes that all super-emitter events are persistent and not intermittent under the "duration" parameter in FEAST. However, the matrices have the potential to enable technologies that can be deployed to better detect large emission events that are persistent as well as intermittent. To represent super-emitter events more accurately and better reflect the potential of advanced technologies to detect them, the commenter urges EPA to ensure the assumptions for the final FEAST modeling reflect the best available data including any information regarding the intermittent nature of some super-emitters. EPA can rely on additional peer-reviewed studies submitted in comments that corroborate EPA's already cited studies as well as any studies published and peer-reviewed in the future.

Response II-5-104: We assumed all the large events were part of the sources covered by the group of fugitive emission sources. We recognize that some "super-emitter" events may be short-term events related to sources like blowdowns. However, we assumed that fugitive emission components would likely have more sustained emissions. Therefore, we modeled the fugitive emission component releases as persistent.

Comment : Commenter (2284-Kairos) notes EPA's FEAST modeling compares alternative technology performance to OGI strictly on the basis of fugitive emission reductions. While the thought process here is understandable, it makes for an inaccurate comparison. Advanced screening programs, particularly when conducted on a more frequent basis than quarterly inspections, have the ability to replace AVO surveys of dubious efficacy with more rigorous, quantitative measurement. There is undoubtedly an emissions benefit to using state-of-the-art leak detection equipment over AVO techniques with little quantifiable benefit.

Commenter (2284-Kairos) recommends EPA should further incentivize advanced screening technology by allowing those techniques to replace periodic AVO visits and capture the emission reductions of using technology-based measurement in lieu of AVO in modeling. EPA modeling should also account for screening technology's ability to create indirect benefits, like rapidly identifying malfunctions that may not be classified as fugitive emissions. Advanced screening programs should satisfy AVO requirements and flare monitoring requirements as well as fugitive emissions monitoring, to further incentivize the use of more rigorous advanced technologies.

Response II-5-105: EPA acknowledges the input from the commenter, As discussed in Section XI.B.1 of the preamble of the rule, EPA conducted FEAST modeling of our model plants based on the most updated information available to ensure the matrix framework was equivalent to the BSER program.

In regard to flare monitoring, when a periodic screening identifies an emission and owner or operator is required to conduct a follow-up inspection to confirm the location of those emissions,

unless the technology used has sufficient spatial resolution to confirm the precise location of the emissions. See discussion in section XI.B.1 of the preamble of the final rule.

Comment: Commenters (2333-LongPath, 2428-API) believe EPA's current model overestimates the effectiveness of AVO and OGI. Commenter (2428-API) notes in EPA's model, the probability of detection curves for AVO and OGI have 100% probability of detection for leaks above approximately 200 g/hr and 60 g/hr, respectively. While these are useful detection methods in various applications, these characterizations overestimate their effectiveness in certain field conditions and leads to impractical performance standards for the alternative technologies for periodic screening and for continuous monitoring.

Commenter (2333-LongPath) understands that, in the EPA's FEAST model simulations, AVO is parameterized as having 100% probability of detection for emission rates of roughly 245 g/hr (0.245 kg/hr). The EPA states that "while there is a lack of information on the emissions reductions achieved through an AVO inspection, the EPA is confident that specific indications of potential leaks (*e.g.*, open valves or thief hatches) would be obvious to any operator...". The commenter respectfully suggests that field studies or data be used to justify the parameterization of a 100% probability, particularly for such small emission sizes.

Commenter (2428-API) says that for example, AVO inspections are less likely to find large leaks if they are located above the person performing the inspection, they occur in areas that the person cannot enter due to safety concerns (*e.g.*, potential for H<sub>2</sub>S exposure), or they are located in areas with high noise among other reasons. While 60 g/hr is the current NSPS OOOOa and proposed NSPS OOOOb and EG OOOOc standard for OGI cameras, probability of detection for OGI also depends on the camera operator and field conditions.<sup>51</sup> A more realistic characterization of AVO and OGI detection methods would create a more realistic equivalency model for alternative technologies.

Commenter (2333-LongPath) has many documented case studies in which AVO inspections failed to detect very large emissions, despite, in some cases, being deployed to find the root cause. For example, emissions in exceedance of 100 kg/hr that were caught by the commenter and diagnosed with SCADA data or OGI imagery, but which AVO inspections failed to detect or identify [Images of leak in commenter's attachment]. AVO inspections may suited for liquids leaks, or very specific instances in which a physical issue with the site is visually evident (*e.g.*, open thief hatch), but AVO inspections may not be reliable for the broader array of fugitive emissions causes.

Response II-5-106: In the proposed rule, we have a combination of OVA, OGI, and super-emitter response program, so we conclude that the rule as proposed (and finalized) would address the case indicated by the commenter.

Comment: Commenter (2421-Teledyne FLIR, LLC (Teledyne)) provides input on EPA's solicitation of comment on the use of LDAR effectiveness models in the development of the

---

<sup>51</sup> Daniel Zimmerle, Timothy Vaughn, Clay Bell, Kristine Bennett, Parik Deshmukh, and Eben Thoma. Detection Limits of Optical Gas Imaging for Natural Gas Leak Detection in Realistic Controlled Conditions. Environmental Science & Technology 2020 54 (18), 11506-11514 DOI: 10.1021/acs.est.0c01285.

requirements for the alternative screening approach, specifically on the appropriateness of the inputs and assumptions used in the EPA's FEAST modeling simulations. It is challenging to accept that a technology that has a minimum detection threshold of  $\leq 1$  kg/hr used on a quarterly basis plus an annual OGI inspection would be equivalent to using a technology that has a minimum detection threshold of 17 g/hr, as defined in Appendix K of this docket, used at a quarterly interval without the additional annual inspection. OGI used quarterly with a minimum detection threshold that is 58 times better would be much superior to a periodic screening technology of the same defined timeframe as described in Table 20. This comparison leads to uncertainty and the appropriate use of the defined modeling simulations that may be developed specifically to encourage alternative technologies that are less sensitive than existing BSER requirements.

Response II-5-107: We only proposed use of Appendix K for natural gas processing plants. The OGI methods specified for use at production facilities has a much higher allowable minimum detection threshold and does not require two separate views of each component. We consider the modeled detection curve used in the equivalency matrix is reasonable portrayal of the effectiveness of OGI as required by the fugitive emissions program.

Comment: Commenter (2202-Texas Oil and Gas Association (TXOGA)) believes the modeling assumptions should be adjusted to ensure the comparison baseline for advanced technologies is realistic.

Commenter (2202-TXOGA) states technology advances are happening on more than an incremental scale and the environment will benefit from rules that allow deployment without regulatory changes being required. EPA's regulations should facilitate such changes to the maximum extent practicable. And a key element of that is being realistic about what the baseline technology is actually achieving when making the equivalence determination. EPA's overall approach of marrying frequency with detection thresholds seeks to match the frequency of monitoring to the level of accuracy of a technology. While this concept makes sense, it is important that EPA not be so conservative in its assumptions that it results in dampening the effectiveness of the alternative technology program.

The commenter is concerned that the level of stringency in the model will make it such that the new technologies will have to be better than BSER in order to be deployed. The commenter encourages EPA to make more reasonable assumptions in its model inputs, *e.g.*, with respect to windspeed, so that experience can be gained through deployment. The market penetration and deployment of these technologies will allow them to improve and actually end up raising the bar in terms of emissions performance. And that ultimately is the goal of this program. Indeed, the NSPS program has always had an underlying technology-forcing aim. In practice, however, when NSPS regulations have been written prescriptively, the regulations have gotten in the way of technology advancement. This is why the commenter (2202-TXOGA) is gratified that EPA is considering these issues and incorporating them in the regulations at this time.

Commenter (2202-TXOGA) supports the matrix approach for its simplicity, but it requests that EPA reevaluate the modeling assumptions that OGI/AVO are 100 percent effective. The commenter believes that this assumption does not align with real-world experience and, when

modeling equivalence with OGI, places unrealistic leak detection performance expectations on the alternative technologies.

Commenter (2202-TXOGA) continues, other steps EPA could take to ensure that alternative technologies and periodic monitoring result in net benefits equivalent to traditional OGI include revising Table 20 to explain the science behind why a bimonthly frequency of <2 kg/hr and <10 kg/hr (if an annual OGI survey is completed) are equivalent. EPA could also demonstrate why, under the minimum detection threshold of <4 kg/hr, monthly monitoring can be bimonthly if the owner/operator completes an annual OGI survey per the <10 kg/hr requirements.<sup>52</sup> At bottom, a final rule should refine the survey matrices in a manner that would better reflect minimum screening frequencies and detection thresholds to incentivize adoption of alternative technologies and foster technology innovation.

Commenter (2202-TXOGA) adds due to the large discrepancies that can occur with mass conversion; EPA should not rely solely on the ability to determine a mass emission rate (kg/hr) when assessing alternative leak detection technologies. EPA should also allow alternative leak detection technologies to use a background concentration and increase from that background level as a means to provide an action level for leak detection. The conversion of a detected concentration of methane to a mass emission rate (*e.g.*, kg/hr) is an added step in estimation that requires site-specific operational data or information that only the operator can provide. There can be a large discrepancy in the mass conversion. Alternative leak detection technologies can also identify a background concentration of molecules and base action levels on an increase from that background level. This can be a reliable method of detecting and responding to leaks in real time and does not present some of the challenges encountered with mass conversion based on operator data and calculations.

Response II-5-108: While we agree that the assumptions were required when modeling the effectiveness of different programs using FEAST, we maintain that the assumptions used are reasonable and provide a reasonable approach for assessing the equivalency of different monitoring programs.

Comment: Commenter (2284-Kairos) states that EPA should also consider how OGI follow-up surveys are separately parameterized for FEAST modeling relative to quarterly or annual OGI that is conducted independently of an airborne survey detection. In our experience, follow-up surveys using OGI at sites with known aerial detections are generally more effective at identifying emissions due to the suspected presence of a likely large source of emissions and location information provided by the aerial survey data. For this reason, follow-up OGI surveys should retain a spatial coverage parameter of 100%.

Commenter (2284-Kairos) states EPA would also need to consider how to define spatial resolution and source accuracy as metrics for alternative technologies—which is extremely difficult. For example, a minimum pixel size requirement might not have any bearing on spatial resolution. To meet a pixel size standard, a technology developer could simply take a big pixel and divide it into four pixels and all four would still have the same value. Alternatively, a measurement system may generate data which is not saved into a gridded space, such as an

---

<sup>52</sup> Id.

airborne sniffer system, and therefore be fundamentally incompatible with a “pixel size” specification. EPA should avoid trying to get too prescriptive in spatial resolution guidance because it has the potential to forestall development of effective technology that does not meet some narrow, dated technology standard.

Commenter (2284-Kairos) argues if EPA moves away from requiring ground follow-up for some remote screening technologies but not others, it will need to carefully consider what impacts that has on the equivalency determinations it reached through FEAST modeling. Removing some ground inspection requirements but not others would likely require redoing FEAST modeling to properly understand the impacts on equivalency between programs.

Response II-5-109: We modeled all aerial surveys as site-wide survey and used the cumulative emissions from the site to trigger the OGI ground survey. Including spatial resolution into the model would require a well-pad site to be broken into numerous sub-sites, requiring assumptions on the number of fugitive components per sub-site, requiring a myriad of additional assumptions. While we understand that some technologies may have higher spatial resolution, that may not necessarily mean that they will find more leaks. For example, if a high spatial resolution detection method has a detection level of 1 kg/hr and there are two different leaks of 0.5 kg/hr at the site but spatially separate, the aerial survey as modeled would have deployed a ground crew (site total at or above 1 kg/hr) whereas the spatially resolute detection method would not have detected emissions. For the purposes of the generalized matrix approach, we maintain that the assumptions used are reasonable and provide a reasonable approach for assessing the equivalency of different monitoring programs.

Comment: Commenter (2414-Carbon Mapper/RMI) provides recommendations to the proposed matrix as well as assumptions used in FEAST modeling. The commenter believes the current proposal contains critical holes rooted in flawed assumptions in the FEAST modeling that underpins it. To address these concerns, the commenter provides evidence-based recommendations supported by empirical studies and a report conducted by Highwood Emissions Management commissioned by the authors (Appendix A). The commenter urges an expansion of the screening alternatives to leverage all technologies available to reduce emissions, specifically to:

- Recommendation 1: Expand matrix to include a Minimum Screening Frequency of “Weekly + Annual OGI” with a Minimum Detection Threshold of 100 kg/hr.
- Recommendation 2: Review and consider revising assumptions used in FEAST modeling for the Supplemental Proposal, including the assumed detection limits for OGI and AVO surveys, parameterization of spatial and temporal coverage, and leak generation rates, all of which can impact simulation results - particularly regarding intermittent high emission events.

Commenter (2414-Carbon Mapper/RMI) notes the EPA proposal states, “technologies with a minimum detection threshold above 30 kg/hr could not be deemed equivalent to the proposed fugitive emissions monitoring and repair program in NSPS OOOOb and EG OOOOc at any screening survey frequency.” The implications for this proposal, as written, are such that satellite technologies and some aircraft remote-sensing technologies will not be available as approved

alternative screening methods. To the commenter's knowledge, no satellites currently operational nor those expected for launch in the next few years and only a few currently operating airborne systems are capable of meeting a 30 kg/hr minimum detection threshold of screening at 90 percent probability of detection.

Commenter (2414-Carbon Mapper/RMI) states despite not meeting the currently proposed maximum detection threshold, many satellite and high-altitude aircraft remote-sensing technologies are uniquely capable of spotting intermittent super-emitters thanks to a combination of broader spatial coverage and higher frequency sampling. This means that, in practice, these technologies can provide operators across many U.S. oil and gas production regions maximum flexibility and affordability as part of LDAR regimes. In some instances, these technologies are already being deployed voluntarily by operators seeking to go "above and beyond" required practices.

Commenter (2414-Carbon Mapper/RMI) generally supports the use of equivalency modeling such as FEAST and other rigorous models to determine the matrices. However, as acknowledged by EPA, the inputs and assumptions used in any model are critical in determining equivalency between alternative screening and the standard fugitive emissions detection and repair program. In this case, the exclusion of an entire class of monitoring instruments capable of higher frequency monitoring is of primary concern and is a direct result of suboptimal assumptions in EPA's FEAST modeling. Specifically, there are concerns with the EPA's intermittency assumptions for super-emitters, inability to properly parameterize temporal and spatial coverage of conventional methods in FEAST, and unrealistic assumptions about AVO screening performance.

To address these concerns, Commenter (2414-Carbon Mapper/RMI) partnered with Highwood Emissions Management to conduct modeling with LDAR-Sim to test the sensitivity of EPA's FEAST modeling to key input assumptions and explore screening scenarios not explored by EPA. The Highwood analysis used LDAR-Sim to evaluate the relative mitigation performance of different screening scenarios for monitoring 2,000 sites in a virtual world over the course of one year. These simulations used the same emissions distribution EPA derived from the Cusworth *et al.* 2021 Permian study and other common assumptions in an attempt to replicate EPA's FEAST modeling while also evaluating different assumptions.<sup>53</sup> The Highwood analysis is most sensitive to the following parameters: leak production rate, leak rate distribution, minimum detection limit, spatial coverage, and sample frequency (temporal coverage). The full report, including inputs and results of the Highwood analysis, is provided in Appendix A of the commenter's letter.

Commenter (2414-Carbon Mapper/RMI) states industry, technology providers, and experts in LDAR simulation repeatedly bring into question key assumptions about AVO and OGI performance used in EPA's FEAST modeling. Overly optimistic parameterization of these two technologies has important ramifications for equivalency – when these parameters are adjusted,

---

<sup>53</sup> Cusworth, D., et al., "Intermittency of Large Methane Emitters in the Permian Basin," Environ. Sci. Technol. Lett. 2021, 8, 7, 567–573, <https://doi.org/10.1021/acs.estlett.1c00173>

conventional screening programs display more modest mitigation potential. The commenter also has concerns with other assumptions used in EPA's FEAST modeling.

Commenter (2414-Carbon Mapper/RMI) highlights the following five significant issues in EPA's FEAST modeling assumptions (more details can be found in the commenter's letter):

1. Spatial coverage is not parameterized in EPA FEAST modeling.
2. Temporal Coverage is not parameterized in EPA's FEAST modeling.
3. AVO MDL assumed in EPA's FEAST modeling is likely unrealistically low.
4. OGI MDL assumed in EPA's FEAST modeling is likely unrealistically low.
5. Leak generation rate assumptions in EPA FEAST modeling may be too low.

Commenter (2414-Carbon Mapper/RMI) states the methane mitigation performance of all evaluated satellite programs, most importantly with detection threshold 100 kg/hr and weekly screening, is equivalent to or exceeds the performance of options currently allowed in EPA proposal.

Commenter (2414-Carbon Mapper/RMI) notes the Highwood simulations evaluated the performance of an annual OGI inspection plus three hypothetical LDAR screening programs compatible with MDL and sample frequencies of representative satellite and airborne remote-sensing systems: 30 kg/hr, monthly; 50 kg/hr, biweekly (14 day); and 100 kg/hr, weekly. All three programs achieve greater emissions mitigation than quarterly OGI parameterized using Highwood assumptions (Figure 2, P\_OGI4x\_Highwood) under the Cusworth distribution. This is due primarily to the impact of the improved spatial and temporal coverage capabilities of remote sensing satellites and aircraft.

Commenter (2414-Carbon Mapper/RMI) notes that while some existing and planned satellites and aircraft are capable of achieving methane MDLs at or below 30 kg/hr, that typically only occurs under a narrow range of environmental conditions and hence the commenter recommends a 100 kg/hr threshold, which is likely more achievable for more technology providers.

The Highwood simulation results lead the commenter to strongly encourage Recommendation #1 and Recommendation #2 as described above and envisioned in Table 1B. Unless EPA expands the matrices to include the 100 kg/hr threshold, most satellites and many airborne systems will be excluded as alternative methods and dramatically limit the potential for emissions mitigation. For example, a recent review paper by Jacob et al 2022 noted most current and planned methane-capable satellites have detection limits well above 30 kg/hr but only a few report the ability to achieve detection limits as low as 100 kg/hr.<sup>54</sup> Commenter (2414-Carbon Mapper/RMI) notes that while EPA's and Highwood's modeling both use the same Cusworth et al. emissions distribution from surveys of the high emission Permian Basin, recent studies combining field measurements and simulation such as that from Sherwin et al. 2023 indicate that other major oil and gas basins exhibit similar emissions distribution characteristics.<sup>55</sup> Specifically, the Sherwin *et*

---

<sup>54</sup> See Table 3 in Jacob et al., *Atmos. Chem. Phys.*, 22, 9617–9646, 2022 <https://doi.org/10.5194/acp-22-9617-2022>.

<sup>55</sup> Sherwin, E., et al., 2023, "Quantifying oil and natural gas system emissions using one million aerial sites measurements," Figure 3, in review *Nature*, preprint: <https://doi.org/10.21203/rs.3.rs-2406848/v1>.

*al.* study indicates 40%-80% of total point-source emissions from the oil and gas sector exceed 100 kg/hr in the Permian, Barnett, Marcellus and San Joaquin basins. Additionally, cumulative distribution functions for point source emissions in those basins as well as the lower-emission Uinta and Denver-Julesburg basins do not display a large drop between 100 kg/hr and 30 kg/hr. Therefore, the commenter's recommended additions to the screening program would be equally effective in achieving similar methane reduction across most U.S. oil and gas producing basins.

Additionally, commenter (2414-Carbon Mapper/RMI) urges EPA to consider the influence that the design of its rulemaking will exert on a rapidly changing landscape: specifications in the final matrix will affect technology development for years to come. Moreover, the US approach to and inclusion of advanced technologies, namely satellites with global, high-frequency monitoring capabilities, have the chance to spur positive domestic impact beyond the sectoral scope of this rule (focused on onshore oil and gas production) and beyond our national borders. At this pivotal moment in time for climate mitigation, expanding the matrix per our recommendations would ensure that all technologies available for methane reduction remain eligible while not requiring operators to opt into these high-frequency screening programs. Finally, given that emissions data will continue to rapidly improve, the commenter encourages EPA to recognize the importance of having a regulatory process and expectation to update the screening protocols periodically over time.

Response II-5-110: Based on the modeling conducted, there is no frequency at which a 100 kg/hr detection limit would be equivalent to the required periodic OGI monitoring surveys. There are few sites that have emissions above 100 kg/hr, so at that detection limit, 99+ percent of sites would be projected to have significantly higher fugitive emission than the levels determined to be BSER.

Comment: Commenter (2353-CrownQuest Operating, LLC (CrownQuest)) asserts that EPA mistakenly assumes more is better and that if one survey is good, then two surveys are better, rather than acknowledging that all things have a diminishing return. The EPA should carefully evaluate when LDAR surveys can most economically reduce emissions rather than building an unrealistic model. The EPA requires more work to be done and assumes proportional benefits without getting a reduction in emissions. According to the commenter, The Environmental Partnership launched in 2017 and has acted to reduce emissions. The partnership collected operators' data and is not an estimated calculation based on a model. Since 2018, the partnership has surveyed over 340,000 sites, 1.23 million surveys, and over 750 million components. The average leak rate from companies participating in the partnership is 0.08%. Over 95 industry companies comprise the partnership, from operators to the midstream.

Commenter (2353-CrownQuest) notes that EPA's leak rate of 0.5-2% from the FEAST model is more than six times the observed leak rate from the industry's OGI survey. The Environmental Partnership's data collection and collaboration with operators and midstream companies should be the program the EPA relies on for emission reductions. The EPA should develop a BSER based on the universal successes of those widespread programs. EPA calculated emission reductions in the preamble seem to be consistent with the higher leak rates used in the FEAST model and not the industry leak rate or the EPA's OOOOa.

Commenter (2353-CrownQuest) says the EPA has accepted OGI imaging for OOOOa testing for years with a two-point demonstration standard for LDAR. The EPA is now setting a 16-point demonstration standard for new detection technologies, which is significantly more stringent than the OOOOa standard for OGI cameras. To date, there is no readily available data that the currently approved OGI camera technology meets the proposed OOOOb/c standards. The EPA should not create a new detection standard while exempting existing technology from meeting this standard.

Commenter (2353-CrownQuest) believes the EPA should be consistent with its standards for detection and not hold new technologies or methods to a higher standard than methods and technologies previously approved. Industry companies made inquiries to reputable LDAR camera suppliers regarding the testing of camera performance. The suppliers commented that they did not test the camera performance under the proposed conditions because the proposed rules are not yet approved. The suppliers reached out to a reliable third-party testing laboratory to take the test, but the testing lab said they could not prepare until the EPA finalizes the rule.

Response II-5-111: The commenter did not provide adequate data to assess the results of their monitoring surveys. If these monitoring events were conducted quarterly, then the annual leak rate would be 0.32% ( $0.08 \times 4$ ), which is close to the level used when determining BSER. We used leak rates from sites that were required to conduct quarterly monitoring to help inform our assumptions on the annual leak rates and we maintain that the assumptions we used to model the effectiveness of fugitive emission programs are reasonable.

Commenter (2298-Pioneer) supports EPA's proposed approach for utilizing FEAST model to estimate the emission reductions advanced technologies achieve. The inputs and assumptions used in the model are critical to "determine a matrix of survey frequencies and detection thresholds that would provide a demonstration of equivalency between the alternative screening and the standard fugitive emissions monitoring and repair program."<sup>56</sup> EPA cites recent aerial and satellite studies to conclude that "a primary advantage of more frequent screening with advanced technologies is to quickly identify large emission events (commonly referred to as 'super-emitters')" which may result from fugitive emissions or "other sources, such as unlit flares or process malfunctions."<sup>57</sup> Accordingly, EPA included process malfunctions in the equivalency assessment.

Commenter (2298-Pioneer) states EPA's use of peer reviewed studies to develop the matrix is reasonable recognizing the data that is available today.<sup>58</sup> However, the commenter encourages EPA to consider any additional updates and refinements for the Final Rule to ensure it reflects our up to date understanding of emissions and technology opportunities and constraints.

Commenter (2298-Pioneer) states in addition to supplementing EPA's assumptions and inputs for FEAST with any changes (i.e. changing the requirement for mandatory 001 follow-up for alternative technology as discussed above and thus revising this input in FEAST) or additional

---

<sup>56</sup> 87 Fed. Reg. 74 742.

<sup>57</sup> 87 Fed. Reg. 74742.

<sup>58</sup> d. For example, EPA developed its super-emitter distribution based on an aerial study by Cusworth, Daniel, et al. 2 June 2021, <https://pubs.acs.org/cloi/10.1021/acs.estlett.1c00173>.

studies submitted as part of comments or released before the Final Rule, the commenter recommends that EPA make clear in the Final Rule that it will periodically update the matrix by updating the FEAST modeling and inputs as additional data becomes available<sup>59</sup> (e.g., every two years). Given that emissions data will continue to rapidly improve as operators use advanced technology and as EPA implements the Inflation Reduction Act funding for methane detection, it will be important to have a regulatory process and expectation that EPA will refine the matrix over time. By providing this expectation, stakeholders will have notice of this opportunity and can participate in the regulatory process. Additionally, specifying the timing for updates will also provide clarity on when EPA will need to receive proposed updates to studies and versions of modeling software to enable the agency to rely on such new information in the periodic update.

Response II-5-112: We understand that the FEAST modeling assumptions can significantly alter the equivalency determinations. We used assumptions that were reasonable considering the myriad of differences in the advanced technologies. Allowing facilities or service technology providers to make significant changes in those modeling assumptions would often result in significantly altered modeling assumptions to “demonstrate” equivalency even in cases where there may not be reasonable equivalency. We maintain that the assumptions we used to model the effectiveness of fugitive emission programs are reasonable and we are maintaining the matrix approach are proposed.

### ***5.8.8 Handheld Alternatives to OGI***

Comment: Commenter (2419-Xplorobot) believes that it is essential that the language of the new NSPS OOOOb and EG OOOOc call for periodic screening using not only OGI cameras but also equivalent hand-held technologies that can provide component-level localization of the emissions and their quantification using physics-based measurements. The current language of the EPA regulations results in operators viewing Teledyne-FLIR OGI cameras or similar hardware provided by other vendors as the only technology that can meet the requirement to “make visible emissions that may otherwise be invisible to the naked eye”. There are novel technologies other than OGI cameras that can achieve the desired goal, including, but not limited, to the technology developed by the commenter. The commenter’s technology uses Tunable Diode Laser Absorption Spectroscopy (TDLAS) paired with advanced Computer Vision for precise localization of each TDLAS measurement relative to the equipment inspected in order to create a 3-dimensional map of methane concentration and a quantitative estimation of the emissions rate. The commenter suggests that the language of the revised 40 CFR Part 60 be revised to state “OGI camera or equivalent hand-held component-level detection and quantification technologies” in place of simply “OGI camera” to remove the bias to one specific technology and to encourage innovation and new technology development for hand-held sensors.

Commenter (2419-Xplorobot) respectfully requests that EPA issues a clarification for subparts OOOO and OOOOa to include not only OGI cameras but also equivalent hand-held component-level technologies that can “make visible emissions that may otherwise be invisible to the naked eye” and also quantify the methane concentration and the emissions rate.

---

<sup>59</sup> This is consistent with the Draft Science Advisory Board's January 4, 2023, recommendations. [add link]

Commenter (2419-Xplorobot) respectfully suggests that the Agency encourage the use of quantitative physics-based measurements for component-level hand-held devices such that the subjectivity of the inspection or impact of training or dwelling time is eliminated. Such quantification methods include but are not limited to the use of TDLAS sensors paired with advanced Computer Vision that provide precise localization of each TDLAS measurement relative to the equipment inspected to create a 3-dimensional map of methane concentration and a quantitative estimation of the emissions rate.

Response II-5-113: EPA acknowledges the comment, EPA could consider alternatives for OGI follow-up using other technologies through the alternative test method delegation in §60.8(b), so long as there is a defined method/procedure for use and that method/procedure yields the same sensitivity as OGI.

Comment: Commenter (2226-Thermo Fisher) recommends using more acute handheld measurement devices (like Thermo Fisher's Toxic Vapor Analyzer 2020) in conjunction with the OGI to ensure emissions are appropriately accounted for. Additionally, the EPA should consider continuous emissions monitoring technology for abandoned and unplugged wells of high risk for gas leaks.

Response II-5-114: EPA Method 21 is an allowed alternative to OGI in the rule, while we do not specify instruments to use with Method 21, EPA acknowledges that the instrument included in comment would meet the requirements for Method 21, in this rule.

Comment: Commenter (2185-NYSC) states the EPA should consider requiring the use of additional technologies, such as handheld natural gas detectors, to back up the use of AVO monitoring to ensure that leaks are accurately detected at this class of sites.

Response II-5-115: EPA acknowledges the commenters input; EPA is finalizing the options allowed in the proposed rule.

### ***5.8.9 Weather/Seasonal Considerations***

Comment: Commenters (2405-Bridger, 2428-API) believe the periodic screening alternative approach should be flexible to address seasonal environmental challenges.

Commenter (2405-Bridger) notes that seasonal environmental conditions need to be considered for emissions monitoring because they can adversely affect methane detection performance. A challenge for many remote sensing technologies is ground snow cover, which reduces light reflectivity at wavelengths used for methane detection. This means that a weaker signal is available for methane sensing. In regions that have snow cover for part of the year, operators using remote sensing technologies for emissions monitoring may need to anticipate periods of time when there is a reduced probability of detecting emissions. Other seasonal environmental challenges may also need to be considered. High winds disperse methane plumes, meaning that lower concentrations of methane are available for detection. Meanwhile, the performance of remote sensing technologies using solar radiation may be degraded during overcast periods. The EPA already provided provisions in the Proposed Rule for seasonal environmental challenges for

OGI surveys, *i.e.*, “quarterly monitoring may be waived when temperatures are below 0°F for two of three consecutive calendar months of a quarterly monitoring period”.

Commenter (2405-Bridger) observes that the EPA does not specify whether different periodic screening detection tiers can be applied within a single LDAR monitoring plan during different time periods. Doing so would help operators in regions with seasonal environmental challenges to achieve regulatory compliance within their LDAR monitoring programs. In this scenario, for intervals when environmental challenges reduce emission detection probability, operators could switch to higher frequency monitoring (*i.e.*, a different monitoring tier). The commenter recommends that the EPA provides clear language in the preamble and regulatory text describing the option to switch between detection sensitivity and frequency tiers of the periodic screening matrix on a quarterly basis. By way of example, for screening complex facilities, during three quarters of the year, a certain technology may be capable of achieving sufficient detection sensitivity to meet the most stringent tier (1 kg hr<sup>-1</sup>, 90% PoD). But during the fourth quarter, snow cover may only allow 2 kg hr<sup>-1</sup>. During that quarter, bimonthly (*i.e.*, more frequent) scans could be used to achieve compliance.

Commenter (2405-Bridger) states that the proposed rule includes an exemption for OGI surveys during extreme cold weather. To develop rigorously performance-based methane monitoring requirements, where exemptions exist for one monitoring approach, these same exemptions should extend to the other monitoring approaches. This results in the cold weather exemption also applying to the periodic screening and continuous monitoring alternative approaches. To remove ambiguity, the commenter asks the EPA to clarify whether “below 0 degrees Fahrenheit (°F)” refers to average temperature or some other metric, and how this is to be determined. In addition, because emissions screening during fugitive emissions monitoring can also be used for compliance verification of zero-emission standards, then compliance verification of these numerical standards should also not be required during the impacted quarter.

Commenter (2405-Bridger) says that to account for seasonal methane detection sensitivity limitations, they urge the EPA to make it clear that detection tiers may be selected on a quarterly basis, and to make emissions screening exemptions consistent across monitoring approaches. Commenter (2428-API) provides some examples:

- Snow cover can adversely affect the ability of some alternative technologies to detect methane during part of the year.
- High winds can also prevent aerial-based technologies from being deployed on certain days.
- Weather events such as hurricanes may limit the ability to deploy OGI camera operators to sites for surveys.

Commenter (2428-API) believes the alternative technology framework should allow different technologies to be deployed at appropriate frequencies throughout the year. The deadline for the next survey would be based on the type of site and the last survey conducted. As an example, at single wellhead only site, an operator could conduct AVO inspections for the first two quarters of the year followed by a screening survey at ≤ 2 kg/hr and then another AVO inspection no later than four months after the screening survey, based on EPA’s proposed requirements. Flexibility

in applying alternate screening technologies should include provisions that use of a different technology than originally planned (due to weather or other external factors) constitutes an allowance, not a deviation from an operator's monitoring plan.

Response II-5-116: EPA recognizes that environmental factors do affect the performance of alternative methane detection technology. EPA has provided flexibility in the final rule to replace a periodic screening survey using alternative methane detection technology with OGI at any time. EPA has also revised the final rule to allow flexibility in selecting your periodic screening technology as explained in Section X.B.1 and XI.B.1 of the preamble of the rule.

Comment: Commenter (2284-Kairos) explains that wind speed impacts the sensitivity of a remote sensing detection of methane, and therefore a measure of wind speed at a site to ensure good performance is needed. The commenter made the following points:

- In situ wind measurements at all sites are not feasible. Therefore, the commenter must use models or interpret the available wind data from a sparse network of meteorological stations.
- Given the known limitations and expected error associated with modeled or off-site wind estimates (*e.g.*, closest weather station), operating envelope thresholds for alternative technology cannot be implemented based on a single, rigidly defined wind speed value.
- Rather, an estimate of prevailing conditions, characterized by a group of measurements, should be the basis for defining an alternative technology operating envelope.
- EPA should develop guidance on how to define operating envelopes and use the available data sources to verify survey conditions adhere to the defined operating envelope.

Commenter (2284-Kairos) continues, so what wind data is available to EPA? It is technically infeasible for EPA to require alternative technologies to use site-level (in situ) wind readings or wind readings at the exact moment of survey for several critical reasons:

- Investing in wind sensors for the approximately 1 million wells in the US is both technically challenging (to install, maintain, calibrate, and replace, as well as hindered by data transmission limitations common to remote operating regions) as well as a significant economic burden.
- Consistency cannot be guaranteed between operators, wind measurement technologies, and installation locations.
- Integrating data from in situ weather monitoring systems operated and maintained by oil and gas operators with systems operated by alternative technology providers likely presents a logistical burden for both parties.
- Most critically, it's simply not necessary to build and maintain a network of 1 million new wind sensors nationwide to set operating envelopes.

Therefore, a wind estimate for a site must be interpolated, modeled, or extrapolated based on data collected off-site. Across an oil and gas basin, there are no other feasible options for field-wide wind measurements other than this type of estimation. However, using off-site data sources requires caution. Extending measurements across spatial and temporal dimensions will always generate an expected range of error relative to a ground truth, and therefore fixating on a rigid

threshold (as defined by a single value) for wind speed measurements would be highly problematic.

Any public standard that relies on interpolated, modeled, or extrapolated data should not rely on a single wind speed value, which provides rigid precision without any guarantee of accuracy. Instead, the public standard should define operating envelopes based on a group of measurements, or “prevailing conditions,” across an appropriate temporal window.

Commenter (2284-Kairos) presents an analysis of two public weather station networks to illustrate why a prevailing conditions approach is the most robust way to work with extrapolated data. The commenter selected one network with more stations (thus greater spatial coverage in several basins of interest) and another with high-frequency data (thus greater temporal coverage).

*Wider spatial network:* Collects meteorological data used by NOAA’s High Resolution Rapid Refresh (HRRR) weather forecasting model.

*High frequency network:* Collects hourly or sub-hourly data for US Meteorological Terminal Aviation Routine weather reports (METAR), generally located at airports.

Commenter (2284-Kairos) compared wellsite location data, sourced from DrillingInfo, to station locations in order to understand their proximity, and also examined the frequency of data measurements. The commenter’s results are presented in Table 2 of their comment [Available weather station data for two networks (HRRR and METAR) across multiple US oil and gas basins] for several basins across the country. The commenter finds that the vast majority of production sites in several high-producing basins, including the Permian, Anadarko, San Juan, Haynesville, and Eagle Ford, are greater than 10 miles away from the nearest weather station. Furthermore, the availability of high frequency measurements (hourly or sub-hourly) is extremely low in these basins.

Commenter (2284-Kairos) states using the Permian and the HRRR network as a further example, the commenter finds that there are only 133 HRRR weather stations across the entire 60,000 square mile basin. A full 60% of wells (greater than 100 thousand wells in total) are more than 10 miles away from a weather station. Moreover, only 28 stations provide at least hourly measurements. That means that for the 61,761 square mile Permian, just 28 stations provide even hourly wind data, or one station for every 2,026 square miles, which is an area larger than the entire state of Delaware.

Commenter (2284-Kairos) adds, HRRR stations are published with an 8-hour lag, so even datasets that are collected at hourly intervals are not available for assessing operating envelopes until well after a survey is concluded. This creates a significant logistical burden for alternative technology providers, as conditions may not be confirmed until the next day. The commenter’s results demonstrate that estimating a local wind speed value for most sites will require both spatial and temporal interpolation across significant distances and time steps. Because a single estimate will be inherently imprecise, a prevailing conditions approach that incorporates several measurements, e.g., by calculating a mean, will provide a more representative view.

Commenter (2284-Kairos) states commercial data models are generated with proprietary algorithms and sometimes at non-specified spatial and/or temporal timesteps. There is minimal assessment of error available for public review, which is problematic. So, what does this mean for establishing alternative technology operating envelopes?

- Wind speed impacts the sensitivity of methane detection systems, and therefore a measure of wind speed to ensure acceptable performance is needed.
- In situ wind measurements at all sites are not feasible for remote sensing programs; therefore, an interpolated, modeled, or extended measurement based on off-site data must be an acceptable source for wind data.
- Given the known limitations and expected error associated with an interpolated or off-site wind estimate, operating envelope thresholds for alternative technology cannot be implemented based on a single, rigidly defined wind speed value.
- Rather, an estimate of prevailing conditions, characterized by a group of measurements and/or model outputs, should be the basis for defining an alternative technology operating envelope.

Commenter (2284-Kairos) continues, if EPA were to take a position that under no circumstances could an aerial technology be used to survey a site when a single wind speed value, extracted from a distant wind station or interpolated wind product, showed a small exceedance of the operating envelope, it would severely disadvantage alternative technologies while providing de minimis environmental benefit.

In practice, such guidance would require commenter (2284-Kairos) to invalidate a site measurement based on one measurement from a meteorological sensor located 10 or more miles away and measured 45 minutes prior to the survey. Clearly, the wind measurement described in this example does not necessarily reflect conditions at the location and time of the survey, and so it should be treated with appropriate caution. The chilling effect on all alternative technologies stemming from this approach would be substantial, as well as unnecessary for ensuring good performance.

Commenter (2284-Kairos) states instead, EPA should require advanced screening technologies to determine adherence to operating envelopes using prevailing conditions. Prevailing conditions could be defined using a collection of measurements, *e.g.*, by calculating their average. This approach facilitates validation of appropriate operating conditions for alternative technologies while minimizing noise and the risks associated with rigidly precise, yet inaccurate, data collected offsite.

Commenter (2284-Kairos) notes given EPA's generous approach to factoring wind speed into OGI sensitivity in its FEAST modeling and operating envelope, it is appropriate for EPA to accommodate advanced screening technology by allowing the operating envelope to be defined by prevailing winds, as it provides the required data for ensuring sensitivity to a reasonable standard given the limits on wind data that are outside the control of alternative technology providers.

Commenter (2284-Kairos) states EPA should calculate prevailing conditions as an average of data across multiple stations and an appropriate time window. This is a preliminary recommendation and should be viewed as “directionally correct” but not robustly tested yet. Advanced screening programs could validate conditions for a given survey on a given day by thresholding the maximum wind speed as the mean calculated across some prescribed number of stations (*e.g.*, 3) and a window of time adequate for sparse temporal reporting (*e.g.*, 8, 12, or 24 hours). This would provide a reasonable estimate of wind speed to guarantee performance.

Commenter (2284-Kairos) provide an example, using 3 wind stations and a single, 8-hour averaging window:

- Wind station one (readings every 1 hour): [6,5,3,4,6,5,7,4] (winds in miles per hour)
- Wind station two (readings every 4 hours): [4,5,3]
- Wind station three (readings every 2 hours): [4,2,6,3]
- Average wind speed: 4.5
- Max wind speed for calculating conditions: 4.5 mph

Commenter (2284-Kairos) states using the example shown above, the technology provider would need to demonstrate that its system meets the prescribed sensitivity requirement at up to 4.5 mph. EPA may ultimately find that some alternative calculation, such as a median value, is more representative. By relying on multiple sources of wind data to quantify the prevailing operating conditions, EPA will provide guidance on suitable operating envelopes that satisfy the larger program goals. Ultimately, EPA’s aim is to reduce as much methane as cost-effectively as possible, not resolve wind speed conditions beyond a shadow of a doubt.

Commenter (2284-Kairos) concludes with two recommendations for the EPA:

1. EPA should allow alternative technologies to establish operating envelopes based on a prevailing conditions approach quantified by daily (8, 12, or 24 hour) wind speed averages (or similar method) and develop guidance on how to define operating envelopes using available wind data sources.
2. For advanced screening methods, in situ wind data is unavailable or infeasible to collect. The commenter recommends that EPA consider publicly available sources (such as HRRR model stations, METAR stations) and third-party modeling tools as possible options to determine wind conditions. EPA should consider the significant logistical challenges alternative technology providers face when estimating wind speed at a surveyed site, including spatial and temporal sparsity, data lag, imprecision, and lack of ground validation.

Since wind speed data is an area of emerging importance, commenter (2284-Kairos) suggests EPA consider developing stand-alone guidance on how alternative technologies address wind speed impacts on operating envelopes through separate guidance that can be updated periodically outside of the formal rulemaking process.

Response II-5-117: EPA recognizes the commenters input; EPA has expanded on the required information an alternative methane detection technology provider must submit to the EPA when requesting approval. These are detailed in Section X.B.3 of the preamble of the final rule.

EPA considers meteorology to be a critical component to any assumed rate base emission detection, however we leave it to the providers to determine what works best for their solution.

## 5.9 Continuous Monitoring

### 5.9.1 General Comments

Comment: Commenters (2226-Thermo Fisher, 2235-SLB, 2325-Aclima, 2333-LongPath, 2363-CEMC, 2409-BP America Inc. (BP), 2428-API, 2433-EDF *et al.*, 2462-Private Citizen) strongly support the proposed broadening of the requirement for monitoring to include continuous monitoring and specific rules for recording data and maintaining equipment. Continuous monitoring technology has the potential to shift the paradigm in methane detection and achieve significant methane emission reductions.

Commenter (2363-CEMC) strongly supports the EPA’s inclusion of provisions allowing operators to use advanced methane detection technologies for compliance purposes. However, the EPA has proposed to find that—at least at this time—periodic surveying with OGI and Method 21 is BSER that has been “adequately demonstrated.” The commenter indicates that there is substantial evidence that these systems fail to detect significant volumes of intermittent leaks that occur in between surveys, including leaks that qualify as “super-emitter” events. Additionally, as a recent study focusing on detection limits for OGI cameras indicates, “[o]verall detection rates from the camera-surveyor system are substantially lower than the detection rates estimated from studies focused solely on the camera performance...”<sup>60</sup> Further, the OGI surveyor experience level can also have a large impact on OGI use efficacy; “Study results indicate that OGI survey experience significantly impacts leak detection rate: Surveyors from operators/contractors who had surveyed more than 551 sites prior to testing detected 1.7 (1.5–1.8) times more leaks than surveyors who had completed fewer surveys.”<sup>61</sup>

Commenter (2363-CEMC) emphasizes that incentivizing operators to use alternative test methods is critical to the agency’s ultimate goals for this rulemaking and for the impending rules for the Methane Emission Reduction Program (MERP) and Subpart W established in §60113 of the Inflation Reduction Act (IRA). The MERP relies on methane intensity, which is why Congress also mandated in §60113 that the EPA update Subpart W to require “accurate” and “empirical” data. Advanced technologies, such as continuous monitoring solutions, provide the greatest temporal resolution, resulting in the most representative emissions profile and methane

<sup>61</sup> Detection Limits of Optical Gas Imaging for Natural Gas Leak Detection in Realistic Controlled Conditions Daniel Zimmerle, Timothy Vaughn, Clay Bell, Kristine Bennett, Parik Deshmukh, and Eben Thoma. *Environmental Science & Technology* 2020, 54, 18, 11506–11514. <https://pubs.acs.org/doi/full/10.1021/acs.est.0c01285>.

intensity of an oil and gas facility. These new requirements are simply not achievable without advanced technologies and continuous monitoring.

Commenter (2363-CEMC) adds that the proposal will:

Generate additional reductions of methane emissions and additional reductions of emissions of ozone-causing VOCs.

1. Increasing deployment of continuous monitoring systems will help the EPA develop a more accurate methane emissions inventory for the entire oil and gas sector.
2. Increased deployment of advanced monitoring technologies across a variety of well sites will help develop valuable information for the EPA about the performance of different configurations of these technologies in different settings, which will provide EPA with information to develop specific guidance on the proper operation of these systems.
3. EPA investment in continuous monitoring system infrastructure will ensure short-, medium- and especially long-term effective emission measurement and reductions. As super-emitter events are reduced in the future with improved satellite and aerial technologies, unintentional basin emissions will be increasingly dominated by smaller sources, which are more effectively discovered through continuous monitoring systems.

Commenter (2409-BP) urges EPA to consider the environmental and operational benefits of continuous monitoring in the broadest possible terms, so as not to limit innovation or diminish the impact of these technologies.

Commenter (2433-EDF *et al.*) supports EPA's proposal to allow continuous monitoring technologies as an alternative to periodic screening based on long- and short-term emissions rate thresholds that would trigger corrective action paired with monitoring plan requirements.

Commenter (2428-API) supports EPA's inclusion of continuous monitoring in §60.5398b(c) and believes there is great potential in the use of continuous/near-continuous methane monitoring technologies.

Commenter (2325-Aclima) proposes that Internet-connected sensor-based solutions exist at a high level of technical readiness today, allowing for continuous monitoring that is widely distributed, cost effective, and remote. This screening approach should be considered for fugitive emissions monitoring. The commenter urges the EPA to require continuous monitoring at each well site, both large and small. Costs would be in the hundreds of dollars per year, per well — a fraction of the cost of OGI surveys.

Commenter (2325-Aclima) says that as it is now feasible, EPA should expand monitoring requirements to require continuous monitoring and repair of leaks from wells with low production rates. In aggregate, these smaller wells can be a significant source of methane emissions and continuous monitoring is needed to ensure that leaks at these sources are detected and stopped. Distributed sensor technology makes this both possible and cost effective.

Commenter (2325-Aclima) adds that these sensors can be networked and connected to cloud analytic systems, providing real-time monitoring of leaks across large portfolios. This gives well owners a comprehensive and timely picture of assets in the field. Further, advances in big data processing and algorithmic analysis filter out false positives and provide early detection of super-emitting events. It is also possible to aggregate data into powerful cloud-based geospatial tools that can cover wide geographies and can serve entire consortiums of O&G customers, achieving economies of scale, network effects, and reduced costs.

Commenter (2462-Private Citizen) argues advances in technology make this equipment available and affordable. For example, the commenter's college students had access to a wide range of monitoring units and software to interpret trends; certainly, industry has even more.

Commenter (2333-LongPath) states that EPA has identified a clean solution that would result in very low overall emissions. The commenter respectfully suggests to the EPA, however, that the continuous monitoring provisions, as written, would be non-competitive with the periodic screening matrix or OGI screening program. The feedback the commenter has received from the dozens of operators who use them for continuous monitoring is that they would not use continuous monitoring under these provisions, because the response levels are not aligned with the requirements for OGI or periodic screening.

Commenter (2333-LongPath) states that given the profound potential for greater emissions reductions under more frequent screenings afforded by continuous monitoring, coupled with the myriad ways in which even the most careful regulations can easily inadvertently disincentivize continuous monitors, the commenter advocates for incentivization for operator use of continuous monitoring. One such incentive could be through extending corrective action deadlines and maintaining no requirement for OGI follow up.

Response II-5-118: EPA acknowledges the commenters' input. The role of continuous monitoring has been revised in the final rule as explained in Section X.B.2 and XI.B.2 of the preamble of the final rule. This approach relies on a performance base approach, as is the way in which any technology with the ability to meet the QA requirements of the rule could be included.

Comment: Commenter (2207-Private Citizen) provides detailed information on Project Astra, which is testing the effectiveness of a shared network of fixed methane emission monitors in the Permian Basin oil and gas production region in West Texas. The network is monitoring emissions from approximately 50 production sites. The Permian basin was chosen for this demonstration because it is the largest oil and gas production region (by volume of production) in the United States, because the region has simple topography and strong and persistent winds and because the close proximity oil and gas production sites in the Permian Basin enhances the advantages of a shared network of sensors.

Commenter (2207-Private Citizen) summarizes the main findings from Project Astra as follows (more detailed information can be found in the commenter's letter):

- Four sensor systems (Aeris, Canary, Quanta3 and Scientific Aviation) demonstrated sufficient precision to identify emissions of 5-10 kg/hr under the meteorological

conditions found in the Permian Basin, had one minute or better temporal resolution, and had data capture rates >80%, during 9 months of testing.

- For the conditions in the Permian Basin, simulations indicate that less than one continuous monitor per site is capable of consistently detecting emissions in the range of 5-10 kg/hr within one week of the onset of emissions, for both continuous and intermittent emission sources.
- Continuous monitoring networks can detect long duration (>1 day) emissions within an hour to a few days, even with just a single sensor deployed per site, under the meteorological conditions found in the Permian Basin.
- While continuous monitoring networks will not detect all short duration (<1 day) events, the number of undetected events can be estimated, based on dispersion modeling and the numbers of events of various durations that are detected.
- The emission reduction effectiveness of continuous monitoring systems coupled with OGI screening, can be included in the equivalency matrix defined in the Supplemental Proposal.
- Use of continuous emission monitors to identify and quickly respond to very large emission events can reduce the required frequency of OGI surveys, while maintaining a targeted level of emission reductions, for regions with large emission events.

Response II-5-119: EPA acknowledges the commenters' input.

Comment: While Commenter (2409-BP) appreciates EPA's effort in this Proposal to create a pathway for continuous monitoring, the commenter is concerned that the supplemental proposal may be too narrow and overly prescriptive, and that it does not sufficiently facilitate nor incentivize the adoption of continuous monitoring technology. EPA should establish a technology-neutral framework that allows for multiple types of continuous monitoring systems, rather than implicitly single out a handful of the technologies available today and provide a flexible pathway for demonstrating that a particular system meets the regulatory criteria for continuous monitoring as an alternative to the BSER.

Response II-5-120: EPA acknowledges the commenters' input. The framework in the final rule will indeed be technology neutral in that any technology capable of meeting specified QA requirements could be used as detailed in Section X.B.2 of the preamble of the rule.

Comment: Commenter (2333-LongPath) suggests that continuous monitoring with valid mass emission rate data be incentivized as an effective method for verification of repaired leaks. The commenter provides the following example, in which continuous monitoring data was uniquely able to accurately verify repair. A survey program, whether with ground based OGI, remote periodic screening, or AVO, would not have correctly verified or validated the repairs in this case study.

Commenter (2333-LongPath) identified higher-than-normal emission rates (using the Baseline + Action Level approach proposed in these comments). The operator conducted a visual inspection of the site and discovered a broken sight glass. Following that repair, emissions initially subsided, giving the impression of a verified repair. However, several days after the repair verification, emissions went up again. This time, a pressure relief valve (PRV) on a stock tank

was identified as malfunctioning and a repair was made. Again, following this action, emissions were temporarily reduced, such that a traditional repair verification would have again given the green light. However, intermittent emissions then persisted, driving the operator to visit the site one last time and make four additional repairs, including identifying and ameliorating the true root cause of the issue. This example demonstrates the unique capability of continuous monitoring for 1) effective and complete root cause identification of leaks and process malfunctions, and 2) high confidence validation and verification of successful repair.

Response II-5-121: EPA acknowledges the commenters' input. The work practice associated with continuous monitoring approach is designed with flexibility in mind and to avoid prescriptive find and fix provisions in the fugitive emission programs. This work practice better considers the intermittency of some leaks and puts the onus on owner or operator to determine the best way to keep their emissions below the action-level.

Comment: Commenter (2348-EWTC) states that continuous monitoring systems that do not quantify emissions provide value in aiding to understand where events are occurring and may be used with operational data to provide root cause of intermittent events.

Response II-5-122: EPA acknowledges the commenters' input.

Comment: Commenter (2283-Endeavor) supports EPA's proposal to allow operators to use a broader range of alternative technologies as such flexibility will spur continued innovation within the oil and gas sector. Because technology in this area is likely to outpace any future revisions to EPA's regulations, EPA should not codify a limited set of methods that operators can use to monitor fugitive emissions. Instead, EPA should develop standards and criteria and allow any technology or method that can meet that standard. EPA should also include a non-exclusive list of current technologies that would meet the standard so that operators know for certain that they can rely on those technologies. The commenter specifically requests that EPA include aerial flyovers as a monitoring option, as well as remote monitoring devices such as SOOFIE fixed continuous monitoring devices. In the commenter's experience, these methods of fugitive emissions monitoring have proven effective and cost-effective for remote sites. Endeavor also recognizes that the best method of detection can depend on the unique location and nature of each well site, and therefore encourages EPA to provide flexibility for operators to select the best method for their particular facilities.

Response II-5-123: EPA acknowledges the commenters' input. Technology QA and other qualifying requirements are detailed in the final rule and allow for increasingly improving and emerging technology to play a role in this area.

### ***5.9.2 Quantification***

Comment: Commenter (2428-API) indicates that currently available continuous/near-continuous monitoring technology detect methane emissions. The requirement for quantification should be amended, the commenter believes.

According to Commenter (2428-API), current continuous or near-continuous monitors are used to detect emissions and allow for a real-time response by operators; however, these monitors are not and should not be treated as a continuous emission monitoring system like a more traditional “CEMS”. These monitors are “high frequency” monitors and not necessarily “continuous” in a traditional sense. The main focus of the monitors should be in the detection of emissions similar to the current OGI framework where the technology is used to find a leak and an operator can then respond, and if appropriate, to fix the leak.

Commenter (2428-API) states the proposed framework should not be limited by a technology’s ability to quantify emissions as this severely limits the types of monitors that can be used and offers a disincentive for operators to deploy the high frequency monitors currently available for deployment. Many technologies on the market today purport to quantify, but industry experience is that the value and accuracy is driven by the system’s ability to act as a smoke alarm, where a certain threshold triggers a response system that notifies operators. There is no continuous monitoring technology today that actually “measures” a rate. The “quantification” capability is not derived from the underlying “smoke alarm” sensor but layering that sensor with wind, meteorological and other plume model / inversion model information / assumptions, which has untenable uncertainty.

Response II-5-124: For the purpose of this rule, EPA has defined continuous as a reading every 12-hours as it relates to the continuous monitoring provisions to the rule. As stated above in this chapter, an owner or operator can use technology that operates continuously for periodic screening approach but is not subject to the 12-hour requirement.

Comment: Therefore, commenter (2428-API) believes these types of monitors should be considered as effective as the BSER standard, which is quarterly OGI for many larger well sites, central production facilities, and compressor stations. This proposal would have the technologies follow an approach similar to the matrix for other alternate technologies provided in §60.5398b(b) and Tables 1 and 2 to Subpart OOOOb and not follow the action levels in §60.5398b(c).

Commenter (2428-API) argues continuous/near-continuous monitors should be evaluated against BSER, which is quarterly OGI. As mentioned, currently available monitors allow for an alarm and response framework that allows operators the ability to evaluate the alarm and mitigate potential leaks. Due to this, continuous monitoring should be compared against the effectiveness of the technology in allowing response and potential repair of leaks against the BSER requirement of quarterly OGI and not based on the type of “fenceline” type framework that has been proposed. Per §60.5398b(c)(1), EPA has defined continuous monitoring as “the ability of a measurement system to determine and record a valid methane mass emissions rate of affected facilities at least once for every twelve-hour block.” This equates to daily scans at the facility, which sets an unrealistically high bar for implementation when compared against BSER that sets the most stringent monitoring at quarterly OGI and monthly AVO. The use of high frequency monitors should be consistent with BSER based on the detection capabilities of the monitors.

Response II-5-125: The continuous monitoring provision is directly comparable to the potential methane emission reduction as quarterly OGI, however instead of the find and fix paradigm of a

traditional fugitive monitoring program, instead we have incorporated a separate work practice that will yield the same level of emission reduction by keeping maintaining the site-level emission (+ background) below an action-level.

Comment: Commenter (2333-LongPath) believes the EPA’s intention in specifying “valid quantification” was to distinguish accurate from inaccurate mass emission rate estimation (*e.g.*, kg/hr). Many solutions provide quantification data with unstated or unproven accuracy. It is important that accuracy be validated in extensive 3rd-party blind testing. It is important for EPA to distinguish between validated and non-validated emission rate quantification capabilities, given the differences between the accuracy stated by individual vendors and the accuracy defined in a recent continuous monitoring blind testing review.<sup>62</sup> The commenter has published blind validation of mass emission rate estimation results.<sup>63</sup> For example, the commenter’s blind test (at METEC) average quantification error of single-source emissions is 9.1%, for emission rates below 1 kg/hr. Blind field testing with operators shows no bias in reported emissions at rates up to and above 200 kg/hr. The commenter’s blind testing clearly shows the ability to average to the correct emission rate value over time.

Commenter (2333-LongPath) suggests the following definition of “Valid Quantification”: “The emission rate quantification accuracy of the solution has been validated in 3rd-party blind testing to meet a defined standard of performance.”

Response II-5-126: EPA acknowledges the commenters’ input. The required information for technology providers should submit for an alternative test method for methane detection technology are detailed in Section X.B.3 and XI.B.3 of the preamble of the final rule.

Comment: Commenter (2333-LongPath) suggests that EPA define a standard for accuracy in mass emission rate estimation that emphasizes the importance of correctly prioritizing the magnitudes of emission rates that will be required under the final rule. For example, a 200% error in quantification of a 0.1 kg/hr leak is a relatively minor error compared with a 200% error in quantification of a 10 kg/hr emission rate. The metric should thus be built around ensuring that the technology solution be capable of consistently distinguishing emission rates that are above or below the Action Level and Baseline.

Commenter (2333-LongPath) is aware that some groups may define “valid quantification” simply as a verified data point, that is, a data point that has passed quality assurance protocols and came from a technology solution that provides data in units of mass emission rate (*e.g.*, kg/hr). The commenter presumes that any data point used for compliance be required to be “valid” and therefore interpret EPA’s use of this word to mean something more.

Response II-5-127: EPA acknowledges the commenters' input. EPA has defined the requirements for continuous monitors in in Section X.B.2 and XI.B.2 of the preamble of the final rule.

Comment: Commenter (2333-LongPath) urges the EPA to define the word “valid” in the requirement for continuous monitors to mean: The emission rate quantification accuracy of the solution has been validated in 3rd-party blind testing to meet a defined standard of performance built to suit the continuous monitoring requirements.

Response II-5-128: EPA acknowledges the commenters' input. EPA has defined the requirements for continuous monitors in in Section X.B.2 and XI.B.2 of the preamble of the final rule.

### ***5.9.3 Downtime***

Comment: Commenter (2409-BP America Inc.) argue EPA should amend 40 CFR § 60.5398b(c)(1)(iii)(B) and § 60.5398b(c)(1)(iii)(C) to establish a more reasonable standard for operational downtime and inoperability that better accounts for the networked approach that many continuous monitoring systems utilize, whereby multiple sensors are deployed at each facility. For example, multiple sensors may be deployed for one fugitive emissions component; if one sensor stops working, that does not mean that the monitoring system for the component is down or “out-of-control,” and much less so for the broader network of sensors throughout the site.

Commenter (2409-BP America Inc.) states creating a reasonable standard for inoperability is critical because the supplemental proposal limits operational downtime to a rolling annual average of 10 percent. §60.5398b(c)(1)(iii)(A). Defining operational downtime as any time one sensor is inoperable in a network of multiple sensors will create an unreasonable standard for operators in the deployment of continuous monitoring technology and may disincentivize operators from deploying more sensors despite the fact that the use of more sensors provides greater coverage and accuracy. Instead, Commenter (2409-BP America Inc.) recommends that, for the purposes of this rule, EPA define operational downtime to mean that fewer than 75 percent of the sensors at the facility are functioning. Specifically, EPA should amend § 60.5398b(c)(1)(iii)(B) to define “operational downtime . . . as a period of time for which more than 25 percent of the monitors at the facility fail to collect or transmit data or are out-of-control.”

Commenter (2409-BP America Inc.) continues, EPA should similarly amend the definition of “out-of-control” to acknowledge that self-monitoring systems can provide data necessary to perform “ongoing quality assurance checks” without the need for constant human intervention. One of the advantages of advanced methane detection technology is to reduce the frequency of human intervention in the field for purposes of methane monitoring and detection, and thus to improve reliability, safety, and performance. As such, continuous monitoring systems can provide automated quality assurance mechanisms to ensure that the system is functioning properly and issue alerts when issues arise. Overreliance on human intervention for quality assurance is both inefficient and unduly burdensome on operators, and thereby discourages the

deployment of continuous monitoring systems. Commenter (2409-BP America Inc.) argues EPA should therefore amend § 60.5398b(c)(1)(iii)(C) to read: “A monitor is out-of-control if it fails ongoing quality assurance checks, as specified in the alternative test method approved under paragraph (d) of this section and which may include automated quality assurance checks performed by the monitoring system, or if the monitor output is outside of range.”

Commenter (2307-Qube Technologies Inc. (Qube)) believes that the proposed rules around mass quantification and downtime should be related. The EPA has proposed that the system must produce a mass quantification at a minimum of once every twelve hours. The commenter agrees that this approach is reasonable as most continuous monitoring technologies (the commenter’s included) are capable of producing mass quantifications rates at a much more granular level. The EPA has proposed that the continuous monitoring system must transmit quality assured data greater than 90 percent of the time on a 12-month rolling average. The commenter agrees that the 90% uptime target is reasonable however, the methodology used to calculate uptime isn’t described adequately. For downtime calculation methodology, the commenter proposes using the frequency of the mass quantification, currently defined as 12 hours, to determine the uptime. If the system produces a mass quantification rate in the 12-hour period, then the system is considered as being online.

Response II-5-129: EPA acknowledges the commenters’ input. EPA is maintaining the requirements downtime in the final rule as explained in Section X.B.2 and XI.B.2 of the preamble of the final rule.

EPA acknowledges the commenters’ concern about one of many sensors failing, however, sensors are one of several technology options and one which the commenter is not forced to use.

Comment: Commenter (2346-Encino) states that EPA’s proposed rules do account for intermittent and continuous monitoring. However, these rules do not reflect real-world applications where intermittent inspections take only a snapshot; a continuous-based optical monitoring device (like a handheld OGI in principle) can utilize a more advanced payload and technology package (*e.g.*, cooled detector array, advanced processing, system diagnostics, wireless communications), thereby adapting to environmental and operational flux. As such, remote operations will need to account for a grace period resulting from force majeure conditions. Within 24 hours after the condition has passed, and site is deemed safe (to return) would be appropriate. Otherwise, the survey will need to be restarted. Additionally, there should be an allowance (for the system) to provide time to achieve continuous monitoring system stability and operability once camera field of view (FOV) is tuned, network is stable, and data transfer is reliable.

Commenter (2346-Encino) adds, wireless connectivity uptime on camera systems may be limited for remote locations, and local imagery storage would be sufficient if captured for the minimal survey period. Connectivity is not required if the camera is functioning correctly and is capturing emission releases. A typical downtime may require up to four or more days a month and could result in exceeding the proposed downtime regulation. Accordingly, flexibility in downtime for remote locations is necessary. The commenter recommends including the hours required for CMS calibration, stability, and operability into uptime. Uptime includes all calibration tuning

until the FOV is tuned, network is stable, and data transfer is reliable. This practice will encourage proper camera operation and promote optimum detection capabilities with advanced methane technologies.

Commenter (2346-Encino) states a rule that allows testing to continue but has some values withdrawn from analysis due to meteorological data would allow for better detection of issues and reduce full recalibrations. One example of this is the general rule used by testing companies that if there is wind over 10 mph, then testing must be stopped and when restarted the testing device must be recalibrated.

Commenter (2346-Encino) notes similarly, if there was the ability to perform pre and post linearity testing to ensure system integrity of a monitoring system it would allow for fewer testing interruptions and calibrations. The fewer calibrations that must be performed, the less chance of human error occurring. Also, the definition of continuous monitoring should include any instrument that allows monitoring of a location for use over 24 hours and calibration at least every 14 days. Alternatively, alignment with EPA section 325(A/B) for VOC fence line monitoring could be appropriate.

Response II-5-130: EPA acknowledges the commenters' input. As explained elsewhere in the chapter, EPA is maintaining the definition of continuous monitors in the final rule and has clarified that continuous methane detection technology in the periodic screening approach. EPA has also provided these details in Section X.B and XI. B of the preamble of the final rule.

Comment: Commenter (2333-LongPath) sees no inherent problem with EPA's proposed downtime definitions, but strongly advocates for approaches that provide closer parity with BSER. The commenter believes that these types of details can be highly technology-specific and should therefore be considered in alternative method applications.

Commenter (2333-LongPath) argues if a monitor were down for a period of time equal to the BSER requirements for OGI frequency, it is more appropriate to specify that the operator begin to implement BSER OGI at the appropriate frequency until such time as the continuous monitoring can be reinstated. With that type of approach, EPA would not risk placing burdens on advanced technologies that far exceed the BSER OGI baseline of emissions reduction.

Commenter (2333-LongPath) further comments on the health checks defined in §60.5398b(c)(1), where it is required that continuous monitoring systems "must be confirmed for power and connectivity at least twice every six-hour block." The commenter finds this language to be overly prescriptive and redundant to the downtime specifications and suggest that it is better suited to be in an individual technology's alternative test method application.

Response II-5-131: EPA acknowledges the commenters' input.

Comment: Commenter (2177-Southern Ute) recommends, regarding operational downtime, to add a definition of 12-month rolling average. The commenter cites the following solicitation:

“The EPA is proposing that the operational downtime of the continuous monitoring system, or the time that any monitor fails to collect or transmit quality assured data, must be less than or equal to 10 percent on a 12-month rolling average, where the 12-month average is recalculated each month.”

The commenter believes the language used in §60.5398b(c)(1)(iii)(D) is not clear. The commenter also recommends that operational downtime should not exceed 10 percent during any 12-month rolling period. Downtime should be calculated monthly, in the commenter’s opinion.

Response II-5-132: EPA acknowledges the commenters’ input. EPA has also provided details on downtime in Section X.B.2 and XI.B.2 of the preamble of the final rule.

#### ***5.9.4 Fenceline/Within Fenceline***

Comment: Commenter (2428-API) generally supports EPA’s inclusion of continuous monitoring but believes the framework for continuous monitoring should be designed with both fenceline and within-the-fenceline technologies in mind. As written, EPA’s proposed requirements for continuous monitoring appear to be designed for fenceline technology. The commenter asks that EPA clarify that both fenceline and within-the-fenceline technologies can be used and provide details on how implementation would differ between them. The commenter fully expects continuous monitoring technology for methane detection to come within the fenceline and get closer and closer to the source, unlocking emissions reduction potential that is unlikely to be realized by sensors installed on the perimeter. These within-the fenceline technologies will not have many of the limitations of today’s fenceline solutions – including no need for wind or meteorological data because these sensors will be in closer proximity to equipment. Limiting the continuous monitoring requirements in this rulemaking to fenceline only would potentially reduce incentives to develop more advanced technology.

Response II-5-133: EPA acknowledges the commenters’ input. The goal of the continuous monitoring provisions in the rule is to quantify an emission flux from a facility, EPA recognizes that could be developed many ways and the design of these systems is not limited to fenceline monitors.

Comment: Commenter (2340-Honeywell) believes that the action levels and measurement averaging periods for continuous monitoring should be flexible, and the detection thresholds should be based on the probability of detection rather than a prescribed minimum. The framework for establishing minimum detection thresholds and action levels for continuous monitoring should be flexible enough to incentivize the development and deployment of best-in-class technologies, which can be deployed inside the fenceline and in the heart of the operations and should reflect their real-world value and advantages over periodic screening in providing overall emissions reductions and insights into a variety of emission types, sizes, and root causes.

In that regard, commenter (2340-Honeywell) recommends that the final rule adopt a framework that allows for a flexible approach to both the action levels and emissions measurement averaging periods and prescribes a probability of detection of the requisite leak rates rather than a particular minimum detection sensitivity. A more flexible framework should include the ability

to set higher action levels than those proposed based on shorter measurement averaging periods (e.g., a 30 kg/hr action level with a 1-day averaging period) to better reflect the use case found to be most valuable by some operators deploying continuous monitoring systems today. Setting a minimum probability of detection rather than a minimum detection sensitivity (as currently proposed) would enhance both reliability and provide a more technology-agnostic approach. The final rule can allow for this flexibility providing for the use of modeling (e.g., plume modeling and FEAST modeling) to determine the action levels, measurement averaging periods, and minimum detection sensitivities that would provide equivalence to BSER and ensure reliable emissions measurements.

Commenter (2340-Honeywell) believes that the proposed framework for continuous monitoring technologies is too prescriptive and stringent and does not create an outcome-oriented and technology-neutral approach that reflects the value and use cases for continuous monitoring to incentivize their deployment. In particular, by setting prescribed action levels and measurement averaging periods (i.e., the 7- and 90-day measurement periods), the proposed rule excludes systems that can also provide equivalent emissions reductions to BSER or periodic screening by implementing corrective action based on shorter measurement periods for larger leaks. Moreover, the commenter does not believe that the proposed requirement that continuous monitoring systems be capable of measuring emissions at an “order of magnitude” lower (i.e., 1/10) than the proposed action levels (e.g., 0.12 kg/hr for the 1.2 kg/hr long-term action level for wellhead-only well sites) is justified. This requirement is overly prescriptive and appears to be technology-specific rather than outcome-based and technology-agnostic. The proposed parameters for continuous monitoring technology are based on the presumption that all such systems will be deployed on the fenceline of a facility. In the context of the commenter’s technology (and many others in the industry), however, sensors are placed at the heart of the operation, and therefore the ability to detect emissions from a source does not require the same degree of sensitivity as a system deployed on the fenceline.

Commenter (2340-Honeywell) believes that the stringency and prescriptive nature of the proposed framework for continuous monitoring (a) is unnecessary for providing effective emissions monitoring and reductions, (b) lacks parity with the standards established for alternative periodic screening, (c) will disincentivize the development and deployment of continuous monitoring technologies, and (d) is not based on accurate modeling of emissions events or assumptions about the use of such technologies. The commenter recommends that EPA amend the framework to allow for the flexibility (similar to the periodic screening matrices) to set a variety of action levels and corresponding measurement timeframes, which could range from a 1-day averaging period to the currently proposed 7-day and 90-day averaging periods, so long as equivalent emissions reductions can be demonstrated. Further, instead of prescribing a minimum detection sensitivity, adopt a more technology-neutral approach which specifies a probability of detection (e.g., 90%) of the requisite leak rate.

Commenter (2340-Honeywell) states the value of continuous monitoring technology is that it detects fugitive emission events from the moment they begin through the moment that they end or are remedied. Periodic surveys, by contrast, provide only a snapshot of emissions at that one moment in time; fugitive emissions events that occur between periodic surveys therefore may go undetected. Screening frequency is a key component in effectively reducing emissions through

leak detection and repair, as well as in developing an accurate emissions inventory. However, the minimum detection thresholds required for continuous monitoring technologies are far more stringent than those required for periodic screening surveys and place a much greater emphasis on detection sensitivity in a way that may downplay the benefits achieved (as discussed further below) from the significantly increased frequency of monitoring. Doing so may therefore disincentivize the development and deployment of continuous monitoring systems.

Commenter (2340-Honeywell) continues the proposed framework for alternative periodic screening provides two matrices that, depending on the type of facility, allow operators to select a frequency of screening based on the minimum detection capability of the screening technology. For well sites with major production and processing equipment, for example, those minimum detection thresholds range from (less than or equal to) 1 kg/hr through (less than or equal to) 30 kg/hr, and several detection thresholds (*e.g.*, 2 kg/hr and 4 kg/hr) do not require an annual OGI survey as a backstop. The technology must be capable of detecting that a leak is occurring at the prescribed mass emissions rate (in kg/hr) or greater in that moment in time, which would then trigger a follow-up investigation and repair response.

Commenter (2340-Honeywell) states by contrast, EPA proposes that, for a well site with major production and processing equipment, a continuous monitoring system must be capable of detecting, at a minimum, a mass emissions rate of 0.16 kg/hr, and quantifying the size of the leak at or above that rate each time it takes a reading. EPA's proposal does not provide the basis for the requirement that continuous monitoring technologies be capable of a minimum detection threshold of an order of magnitude lower than the action levels. This requirement, apparently derived from the NESHAP fenceline monitoring work practice, is not necessary to derive the benefit of continuous monitoring technologies in providing equivalent or greater emissions reductions compared to the BSER and/or the periodic screening alternative.

Commenter (2340-Honeywell) provides the example, if a component at a centralized production facility is leaking at 1.6 kg/hr (the long-term action level for such sites), an operator electing to conduct a periodic screening survey using technology that detects leaks at 2 kg/hr or greater will not catch this leak, as there is no OGI backstop for those screenings. However, a continuous monitoring system capable of quantifying leaks at only 1 kg/hr or greater will catch this leak—likely on a much quicker timeframe—and it would not have been necessary to detect the leak at 0.16 kg/hr to do so. As this example demonstrates, continuous monitoring technologies are capable of providing significant leak detection benefits to operators and on a much quicker timeframe than periodic surveys, either with handheld OGI cameras or through alternative periodic screening, but the proposed supplemental rule requires far more stringent detection capability for continuous monitoring systems than it does for periodic screening. Doing so may disincentivize the development and deployment of continuous monitoring and bias the use of advanced methane monitoring technology toward periodic screening as an alternative to BSER.

Commenter (2340-Honeywell) adds, at least one study has shown that the “real-world marginal effectiveness of methane mitigation through periodic surveys approaches zero as leak detection

sensitivity improves.”<sup>64</sup> In other words, there is a point of diminishing emission abatement effectiveness with using more sensitive instruments in LDAR programs. The most important goal of any LDAR program is to maximize emissions reductions; by potentially excluding the use of continuous monitoring technologies through strict action levels and minimum detection levels, however, the proposed rule would undermine the adoption of a highly effective means of emissions reductions that can provide significant advantages over periodic screening.

Commenter (2340-Honeywell) states EPA notes in the preamble that the proposed continuous monitoring framework is akin to the NESHAP fenceline monitoring work practice, and that the “order of magnitude” requirement is “to ensure that the continuous monitoring systems used in the alternative continuous monitoring approach are sensitive enough to trigger at the proposed action levels...” The commenter understands that this requirement is consistent with the qualifications for alternative testing technologies under the NESHAP fenceline monitoring work practice. That rule similarly requires a minimum detection sensitivity of an “order of magnitude” lower than the action level.<sup>65</sup> However, EPA has not provided further explanation or context as to why the detection sensitivity must be 1/10th of the action level to ensure that the system triggers at the action levels. The record for the NESHAP fenceline monitoring rulemaking does not provide much more explanation, either, beyond noting that the requirement was included “[i]n order to quantify the emissions detected...”<sup>66</sup> Neither explanation justifies the need for detection sensitivities to be 1/10th of the action levels in order to properly quantify emissions or trigger a corrective response at the action level. Further, the commenter’s methane monitoring systems (both Rebellion and Signal Scout) are deployed inside the fenceline and at the heart of the operations, and therefore do not require the same detection sensitivities as fenceline monitoring systems.

Commenter (2340-Honeywell) states the stated rationale—EPA’s concern that the instrument be sufficiently sensitive to trigger at the action level—stands in contrast with the periodic screening framework, which sets detection thresholds and a probability of detection, but does not require a minimum sensitivity of an order of magnitude below those thresholds. To the extent that EPA’s proposal to require continuous monitoring technologies to meet such low detection sensitivities is meant to account for potential variability in emissions levels below the action level, Honeywell notes that an operator will need to make assumptions regarding the level of emissions below the minimum detection sensitivity regardless of that sensitivity level, and there is no provision in the supplemental proposal what that assumption should be. For example, if there are no emissions detected (*i.e.*, a reading of 0 kg/hr for a 12-hour period), it is unclear whether the operator should assume that there were zero emissions or assume some baseline amount above zero. In any event, the operator could apply that same assumption regardless of the minimum detection sensitivity of its continuous monitoring system. If this is, in part, the basis for the “order of magnitude” requirement, this issue further highlights the higher standard to which EPA appears to be holding continuous monitoring as compared to periodic screening; not only are the

Sci Technol.* 2018 52(4) 2368-2374, available at: <https://pubmed.ncbi.nlm.nih.gov/29351718>.

<sup>65</sup> See 40 CFR § 63.658(k)(3) (“The method detection limit must nominally be at least an order of magnitude below the action level, *i.e.*, 0.9 µg/m<sup>3</sup> benzene.”).

<sup>66</sup> EPA, “National Emission Standards for Hazardous Air Pollutants from Petroleum Refineries, Background Information for Final Amendments: Summary of Public Comments and Responses,” September 2015, p. 235.

minimum detection sensitivities for periodic screening higher, but the framework appears to assume that emission levels are zero if none are detected by the screening survey, as no corrective action would be triggered in that circumstance.

Commenter (2340-Honeywell) argues EPA's stated rationale therefore does not appear to support the need for detection sensitivities an "order of magnitude" below the action levels, and doing so lacks parity with the periodic screening alternative and is not necessary to ensure that continuous monitoring systems trigger corrective action at the requisite action levels.

Response II-5-134: EPA acknowledges the commenters' input. EPA has revised some details of the continuous monitoring approach as explained in Section X.B.2 and XI.B.2 in the preamble of the final rule.

Furthermore, the final rule maintains' EPA's technology agnostic and the performance of any methane detection technology approved for use must be supported through empirical measurements as explained in Section X.B.3 and XI.B.3 in the preamble of the final rule.

#### ***5.9.5 Action Levels and Baselines***

Comment: Commenter (2433-EDF *et al.*) notes EPA has proposed two action levels: a long-term action level (1.2-1.6 kg/hr based on rolling 90-day average) to limit emissions over time, and a short-term action level (15-21 kg/hr) to identify large leaks and malfunctions. Both would apply to all operators using continuous monitors and a root cause analysis and corrective action would be triggered when either action level is exceeded, requiring investigation and repairs within five days.

Response II-5-135: EPA acknowledges the commenters' support for the alternative continuous monitoring approach.

Comment: Commenters (2226-Thermo Fisher, 2235-SLB, 2428-API, 2433-EDF *et al.*) request that EPA lower the action levels proposed for continuous monitoring.

Commenter (2433-EDF *et al.*) states that given the broad variety of continuous monitoring systems and the multitude of factors that impact performance, EPA's approach is reasonably calculated to ensure equivalent emission reductions. The commenter urges EPA to consider lowering the short-term action level threshold or otherwise shortening the duration of the long-term action level. The commenter is concerned that the proposed framework could unnecessarily allow emissions to persist when they could be mitigated much sooner. EPA must also ensure sensor placement is adequate to detect emissions from all fugitive emissions components and any control devices, covers, or closed vent systems at the site. The commenter is aware of situations where continuous monitors have missed significant emissions events at sites due to sensors being placed too low. Because of these concerns, the commenter also urges EPA to require an OGI or AVO backstop at all sites opting for continuous monitoring consistent with our recommendations on the screening approaches.

Response II-5-136: EPA acknowledges the commenters' input; EPA has chosen to maintain the action levels for the continuous monitoring approach as they offer the equivalent emission reductions as the BSER.

Comment: Commenter (2433-EDF *et al.*) adds that certain continuous monitoring technologies may fit within the periodic screening framework, such as tower-based systems. The commenter therefore urges EPA to consider such technologies within that context during the alternative test method approval process. The commenter also recognizes that certain continuous monitoring systems may be highly effective but do not fit within the parameters set forth by EPA. The commenter urges EPA to evaluate those technologies through the technology approval process and through AMEL applications.

Commenter (2226-Thermo Fisher) provides feedback on whether there are different approaches that should be included for different types of continuous monitoring systems and how equivalency may be determined. It is the commenter's perspective that ground-based instrumentation networks are effective and that for any equivalency determination, the equipment should be tested in the field.

Response II-5-137: EPA acknowledges the commenters' input; EPA has revised the final rule to confirm that methane detection technology that operates more continuously could be used in the alternative periodic screening approach as detailed in Section X.B.1 and XI.B.1 of the preamble of the final rule.

Comment: Commenter (2226-Thermo Fisher) seeks clarification from EPA on the timescales, as the proposed rolling day averages may be long due to spikes and emission changes over time and may leave room for exposure risk. The commenter recommends the EPA consider shortening this requirement.

While commenter (2428-API) overall recommends that continuous monitoring be incorporated with periodic screening to create a single framework for alternative technology, the commenter has concerns with the proposed action levels if EPA choose to keep its proposed separate framework for continuous monitoring. The proposed action levels are based on EPA's FEAST modeling, which does not accurately characterize the effectiveness of AVO and OGI. The commenter sees merit in including a framework for future technologies that could detect and more accurately quantify emissions, but the currently proposed thresholds are not reflective of actual operations. Regarding the proposed action levels, the commenter offers the following suggestions (more details on the specific recommendations can be found in the commenter's letter):

- Action levels should be based on detected emissions above an established baseline.
- The rolling 90-day (long-term) action levels should be removed as they have no equivalent in the AVO/OGI/Method 21 or periodic screening requirements.
- The rolling 7-day (short-term) and rolling 90-day (if they remain) action levels should be revised.

The long-term 1.2 or 1.6 kg/hr action levels may also be below the baseline emissions for many sites, which would be especially problematic if they represent total site emissions. Some operators, therefore, would effectively be unable to adopt continuous monitoring for NSPS OOOOb or EG OOOOc compliance.

Response II-5-138: EPA acknowledges the commenters' input; EPA did not take into account background emissions in the December 2022 proposal, based on comment, EPA has revised the final rule to account for background emissions sources of these facilities as detailed in Section X.B.2 and XI.B.2 of the preamble of the final rule.

Comment: Commenter (2235-SLB) says that the requirements for continuous monitors to have a detection level an order of magnitude below the action level and to produce a measurement at a set frequency of every 12 hours are difficult for most continuous monitors available today to satisfy. Typically, the performance of continuous monitors typically depends on environmental conditions such as wind and sunshine. Under favorable weather conditions, many continuous monitors can achieve performance better than those requirements, however performance may suffer under unfavorable weather conditions. Continuous monitors cannot guarantee that the environmental conditions will be favorable at least once every 12 hours. The objective for a measurement every 12 hours may have been to ensure reliability of ongoing monitoring. But continuous monitors exist that can evaluate suitability of site conditions for taking a measurement, thereby ensuring reliability of measurements without requiring a fixed measurement frequency of at least once every 12 hours. Additionally, a fixed frequency of measurements is unnecessary for continuous monitors to produce an accurate rolling average to determine if an emission is actionable (*i.e.*, if the rolling average emission rate exceeds the action threshold). The commenter says that, for example, measuring the 90 days rolling average would involve averaging 180 data points (under one measurement every 12 hours schema), while an equally accurate 90 day rolling average could be computed with fewer data points.

Commenter (2235-SLB) suggests as an alternative approach where EPA could accept continuous monitors with higher detection levels and/or less frequent measurements, if the systems made conservative estimates during instances in which the emission rate was too small to be measured or the environmental conditions were unfavorable for measurement. For example, when the emission rate was too low for a continuous monitor to measure, that emissions could be reported at a rate equal to the limit of detection for purposes of computing the rolling average. That procedure would be protective of the environment, because the reported emission would be at least as large as the actual emission. Moreover, it would be more consistent with the actual performance of continuous monitors because it would allow for continuous monitors with different detection limits, provided the detection limit for a continuous monitor fell below the action limit. Finally, it would incentivize innovation and deployment of more sensitive continuous monitors because more sensitive measurement would result in lower reported emissions by reducing the default limit of detection amount.

Commenter (2235-SLB) adds similarly, EPA could accept continuous monitors with variable durations between measurements—including less than once per 12 hours—if emissions during the period where environmental conditions were unfavorable for measurement were reported as the greater of the emission rate measured before and after the period (*i.e.*, the greater of the data

“bookends”) when environmental conditions were unfavorable for measurement. That procedure would be protective of the environment, because the reported emission would likely be at least as large as the actual emission (there is no reason to expect that emission rates are more likely to increase than to decrease during periods where environmental conditions are unfavorable for measurement). Moreover, it would be more consistent with the actual performance of continuous monitors because it would allow for continuous monitoring during periods where environmental conditions prevent measurement for as long as the rolling average duration associated with the highest action level is used. Finally, it would incentivize innovation and deployment of faster and more environmentally robust continuous monitors, because faster and more environmentally robust continuous monitors would result in less time where reported emissions would likely be at least as large as the actual emission.

Response II-5-139: EPA acknowledges the commenters’ input; EPA wrote the continuous program as a performance-based approach. We recognize that many current continuous solutions may not be able to meet the criteria in the approach however we recognize the value of the more continuous systems and EPA has revised the final rule to confirm that methane detection technology that operates more continuously could be used in the alternative periodic screening approach as detailed in Section X.B.1 and XI.B.1 of the preamble of the final rule.

Comment: Commenter (2235-SLB) states the supplemental provides guidance about how continuous monitors should be used with action levels corresponding to 7 day and 90 day rolling average windows. Many continuous monitors are used with the objective of finding leaks quickly and measuring a leak for 90 days before acting is not consistent with the best use of many continuous monitors. More effective continuous monitoring would occur with different durations of rolling average windows. To address this concern, SLB recommends that in addition to the prescribed 7 day and 90 day rolling average windows, requestors be allowed the option to submit FEAST models with different rolling average windows, customized to maximize the effectiveness of the continuous monitoring technology. Some continuous monitors are most effective when deployed using two rolling average windows, but other continuous monitors are most effective when deployed using a different number rolling average windows. In all cases, FEAST modeling would ensure that the action levels are set corresponding to the number and duration of rolling average windows to ensure that the resulting emissions reductions are equivalent to BSER.

Response II-5-140: EPA acknowledges the commenters’ input.

Comment: Commenter (2333-LongPath) expresses that site-level monitoring is important for many reasons. It is critically important that site-wide monitor responses are not tied to detection limits, but instead use Action Levels, and that those Action Levels be in addition to baseline (permitted) emission rates. That is, emissions in exceedance of the baseline emission rate plus Action Level require a response. The EPA suggests that site-level methane emissions pose as a surrogate for VOC emissions. The commenter is concerned that adding more requirements and expectations onto site-wide continuous monitoring technologies than has been added on to any other technologies further risks inadvertent disincentivizing of their use.

Commenter (2333-LongPath) respects the EPA's intention in applying the equivalency standard twice (as a long-term and as a short-term threshold). However, the commenter respectfully requests only one Action Level, the Short-Term Action Level, remain in the final rule. The commenter requests that the Long-Term Action Level be removed. The commenter justifies this request as follows, which additional details provided in their comment letter:

- The long-term limits do not achieve rapid find-and-fix, the primary value add of continuous monitoring.
- The use of two thresholds that accomplish the same end is redundant and unequal to the other screening alternatives, which do not require double counting.
- Requiring both a long-term and short-term limit adds unnecessary complexity for operators, which disincentivizes the use of continuous monitoring.
- The 90-day long-term threshold is more than an order of magnitude below the action levels proposed for periodic screening using other advanced technologies, despite a 60x increase in required frequency.
- There is no equivalent standard to the long-term (90-day) action level in either the OGI BSER or the periodic screening matrix.

Response II-5-141: EPA acknowledges the commenters' input. EPA disagrees that there is unnecessary complexity with the existence of two limits and suggest operators are capable of tracking both. Two levels provide more flexibility and minimizes methane emissions more than a single limit. All technology developers, including the commenter, can develop approaches to meet one or both limits.

Comment: Commenter (2333-LongPath) states as with all other alternative technologies, the action level for continuous monitoring should be calculated directly using the FEAST model to determine equivalent emissions reductions to the BSER program.

Commenter (2333-LongPath) states it is necessary to provide all technologies with parity in determining action or detection thresholds. As stated in the Methane Roundtable comment, with the support of representatives from all major stakeholder groups, "EPA should evaluate equivalency for both periodic screening technologies and continuous emission monitoring using the same sets of tools and FEAST modeling assumptions to ensure that the final rule is technology neutral." Therefore, the commenter respectfully requests that the same sets of FEAST modeling tools and parameters be used equally, across the board, for equivalency estimation.

Commenter (2333-LongPath) argues with the removal of the Long-Term Action Level for continuous monitoring, it will be relatively straightforward for EPA to employ the FEAST or LDAR-Sim models for calculating emissions reductions from the continuous program. The commenter offers the following suggested guidelines:

- Frequency: EPA has made clear that the frequency of scanning a site with continuous monitoring is at least every 12 hours. Therefore, EPA can model the frequency as 12-hourly. However, if the EPA chooses a 7-day averaging window for emissions detection, then the appropriate frequency to use will be 3.5 days, as leaks will be caught on average, within 3.5 days. Finally, as is discussed in our above comments, the phrase "frequency"

is unclear without being accompanied by a requirement for spatial coverage. Therefore, if the EPA chooses to define frequency and spatial coverage together (for example, all equipment must be scanned within a 7-day timeframe, on average), then the average time-to-detect would, again, be 3.5 days. In all scenarios, the most appropriate time-to-detect frequency parameter would be 3.5 days.

- Spatial Coverage: As is described above in our comments, it is critical to co-define temporal and spatial coverage. To accomplish this, EPA could pursue two options:
  - EPA could model the percent of the site that is scanned in each 12-hourly reading (or the spatial coverage), assuming each scan gives an equal chance for every equipment area to be covered (no systematic biases or blind spots).
  - EPA could require that all equipment on site be scanned within a certain maximum timeframe (say, 7 days).
- Minimum Detection Limit: With the removal of the Long-Term Action Level, the EPA can define the necessary minimum detection limit relative to the Short-Term Action Level that is determined by the FEAST model to be equivalent to BSER. Given that no detections below the Action Level are required to be mitigated, the minimum detection limit can be modeled as equal to the Action Level.
- Action Level: a key difference between EPA's use of the FEAST model for the periodic screening matrix is that the continuous monitoring provisions make use of an "Action Level" rather than a Minimum Detection Threshold. Therefore, regardless of what the minimum detection threshold is, the only emissions that are mitigated in the FEAST modeling of continuous monitors are those emissions for which the rate is above the defined action threshold.

Response II-5-142: EPA acknowledges the commenters' input. We have explained the criteria for the alternative continuous monitoring provisions in Section X.B.2 and XI.B.2 of the preamble of the final rule.

EPA has not integrated a modeling approach to determine action-levels and the action-levels are based on expected emission reductions of the BSER for the model plants. Owners or operators that wish to design a different alternative work practice should petition the Administrator for an Alternative Means of Emission Limitation (AMEL).

Comment: Commenter (2333-LongPath) states spatial coverage of measurements is a critical and often over-looked factor in how comprehensive a survey or continuous monitoring alternative technology solution is. As long as all potential emission sources are "seen" in a reasonable timeframe, then it is reasonable to assume comprehensive and full coverage. The potential for systematic spatial coverage biases, or "blind spots" should be a focus of EPA's specifications for all survey types: AVO, OGI, periodic screening technologies, and continuous monitoring technologies.

Response II-5-143: EPA acknowledges the commenter's input; it is understood that any alternative measurement approach must measure the entirety of a facility.

Comment: For continuous monitors, Commenter (2333-LongPath) suggests that EPA define the timeframe over which 100% (full) site coverage is required. The commenter suggests a

maximum of 7 days, on average (30 day running mean), for a monitoring solution to “see” all regulated emission sources on the pad.

Commenter (2333-LongPath) respectfully suggests that EPA carefully examine the parameter choices in the FEAST and LDAR-Sim models to investigate whether these models are capable of modeling systematic blind spots, and not blind spots that would move around randomly from equipment group to equipment group. Because of the potential for skewed emissions potential from different emission sources (*e.g.*, an unlit flare may have higher emission potential or likelihood than a malfunctioning pneumatic valve), it is important to investigate whether these models currently have the capability to simulate systematic blind spots or whether further development effort is needed.

Commenter (2333-LongPath) states in the EPA’s supplemental proposal, continuous monitors are required to have a detection limit one order of magnitude below the required Action Level. This choice results in required detection limits of 0.12 kg/hr for small well sites and 0.16 kg/hr for larger well sites and compressor stations. By comparison, survey technologies are required to have a 90% probability of detection of the target detection level.

Commenter (2333-LongPath) requests more information for why different standards were applied and ask whether it would be achievable for the EPA use equal treatment between technologies for the required minimum detection limit to achieve the requisite action levels. The commenter believes that a simple solution could be to specify that the 90% or 99% probability of detection of the technology must be equal to or less than the required Action Level. The 90% or 99% probability of detection could be determined, for example, following the methods described in the Bell et al., preprint.<sup>67</sup> The difference between an Action Level (no emissions below that limit need response) and a Detection Limit (anything detected, even below that limit, requires response) could justify the use of the 99% probability of detection limit.

Response II-5-144: EPA acknowledges the commenters’ input. All alternative to the BSER for fugitives and covers and closed vent systems are equivalent to the expected emission reductions from the BSER.

Comment: Commenter (2333-LongPath) states that in order not to inadvertently disincentivize continuous emission monitoring, the commenter describes the necessity of defining Action Levels as above Baseline emission rates the commenter notes that this method has been vetted and approved by the Colorado Department of Health and Environment (CDPHE) and EPA as part of LongPath Alt. AIMM in the state of Colorado). If this change is not made, and Action Levels alone define the site-wide emissions permissible for well sites and compressor stations, then continuous monitoring will be unusable by most any operator.

Commenter (2333-LongPath) states site-wide monitors measure both fugitive and permitted and normal process emissions. Permitted and process emissions may include compressor methane slippage, un-combusted methane from flares, permitted tank venting, pneumatic devices and

---

<sup>67</sup> Figure 1 of Bell, C., Ilonze, C., Duggan, A., Zimmerle, D., Performance of continuous emission monitoring solutions under single-blind controlled testing protocol, preprint: <https://chemrxiv.org/engage/chemrxiv/article-details/638cd2ff14d92d3587a07c46>.

other sources. The commenter provides examples of permitted sources including engines, flares, and pneumatic valves, all which would have emissions higher than the proposed continuous monitoring sitewide emission rate limits. Even if the Long-Term Action Level is removed, the combination of two compressors and a flare would exceed even the proposed Short-Term Action Levels. Importantly, each of these sources can contribute to substantial temporal variability in the baseline emission rate. For example, methane slippage from compressors can vary depending on compressor operating setpoints and maintenance, and flaring intensity can vary significantly over time in correlation with production and oil-to-gas ratio fluctuations.<sup>68</sup>

Commenter (2333-LongPath) continues, bottom-up calculations are not sophisticated enough to accurately estimate the real-time magnitude and variability of baseline emissions. Baseline emission rates must therefore be measured; they cannot be calculated accurately in real-time from bottom-up principles. The consistently demonstrated mismatch between bottom-up and top-down calculations of emissions further supports this notion.

Commenter (2333-LongPath) notes the CDPHE, and the EPA evaluated and approved the use of non-visual quantitative continuous monitoring for 1) determination of baseline emission rates as well as 2) leak identification using baseline emission rates plus Action Levels. These details can be found in the commenter's recently approved Alt. AIMM application.<sup>69</sup> The commenter proved valid mass emission rate quantification of emissions and show that this capability allows the commenter to assess baseline emissions in a clean environment (with an OGI sweep at "startup" to ensure no fugitive emissions contribute to the baseline) and thereafter trigger alarms based on the baseline emission rate plus the defined Action Level for each monitored site type.

Response II-5-145: EPA acknowledges the commenters' input. As explained in Section X.B.2 and XI.B.2 in the preamble of the final rule, we have integrated a procedure for determining baseline emission and the action-levels are now considered to be above the baseline.

Comment: Commenter (2333-LongPath) states it is critical that continuous monitors capable of quantitative, full-site coverage be subject to Action Levels rather than Detection Limits. Therefore, FEAST can be parameterized so that 100% of leaks above the Action Level will be addressed by quantitative, full-site coverage continuous monitors.

Commenter (2333-LongPath) notes the EPA correctly identified in the Supplemental Rule's continuous monitoring provisions that Action Levels are the right response definition for continuous monitoring systems that are capable of quantification and full-site coverage. Specifically, if a site-wide continuous emissions monitor were subject to detection levels alone, then the EPA's requirement that any "detection" require action (regardless of whether it is above, at, or below the detection limit) would risk severely disincentivizing the use of continuous site-wide emissions monitors, given that their "on-the-ground" deployment typically leads to relatively low detection thresholds. For example, given the variable nature of permitted emissions, every permitted change in the operating conditions of the site (compressors on/off or flares on/off) could lead to an emission change that would require follow-up. This would make continuous monitors unusable for operators under this rule. Further, it could risk a "race-to-the-

---

<sup>68</sup> These calculations were performed by Kuva in the commenter's discussions of the EPA supplemental proposal.

<sup>69</sup> <https://cdphe.colorado.gov/public-information/alternative-aimm-public-notice>.

bottom” for technology vendors to degrade their detection and quantification capabilities for fear of disincentivizing operator use. The commenter therefore recommends that EPA specify that the “detection levels” in the periodic screening matrix act as “Action Levels above baseline” for site-wide quantitative continuous monitoring technologies that participate in the matrix.

Commenter (2333-LongPath) states the below table is an adaptation of the technology class table shown above, which defines which solution types should be subject to the requirement that all detections require a response, and which solution types should be subject to the requirement that only detections above the Action Level + Baseline require a response (they suggest Action and Detection levels be equal, to ensure technology neutrality).

|                              | <b>Visual (plume-level) non-Visual (site-wide or source-level)</b>                                                                | <b>Visual (plume-level) non-Visual (site-wide or source-level)</b>                                                                                                                                                                                           |

Commenter (2333-LongPath) provides examples based on the EPA’s proposed screening survey matrix (see below) of a non-visual quantitative continuous monitor with a minimum detection threshold  $\leq 1$  kg/hr. Under the suggested considerations above, this solution could monitor small well sites with semi-annual screenings, with required response to emissions the baseline emission rate plus 1 kg/hr. The same solution could alternatively use tri-annual screenings with required response to emissions the baseline emission rate plus 2 kg/hr. For larger well sites and compressor stations, this continuous monitor with a minimum detection level  $\leq 1$  kg/hr could screen bimonthly, with required response to emissions the baseline emission rate plus 2 kg/hr. That same solution could monitor on a monthly basis with required response to emissions the baselines plus 4 kg/hr, and so on. These suggestions would be equally valid for any monitor capable of accurate (valid) quantification of total, site-wide mass emission rates. These

suggestions provide direct parity to the visual technology solutions for which the proposed periodic screening matrix was created.

Response II-5-146: EPA acknowledges the commenters' input. EPA has made revisions to the Alternative Continuous Monitoring Provisions as detailed in Sections X.B.2 and XI.B.2 of the preamble of the rule.

Comment: Commenter (2307-Qube) states the EPA has proposed using a site rate (kg/hr) versus a gas concentration from continuous monitoring systems to define when an emissions event requires follow-up action. The commenter agrees that using a site rate calculation is more effective than using a gas concentration as gas concentration is affected by the wind speed and distance from the source while a site rate calculation normalizes for these factors.

Commenter (2307-Qube) strongly believes that the proposed long-term action level poses a threat to the adoption of continuous monitoring rather than an incentive. A large number of facilities have been designed and are permitted to emit greater than 1.6 kg/h thus continuous monitoring would not be suitable for use at these facilities for regulatory purposes under the proposed framework. Therefore, the commenter suggests that the concept of a baseline be used to establish an emissions profile and action levels be incremental to that baseline. The baseline is meant to capture normal emissions from the facility while responses to the long-term and short-term action levels are meant to reduce fugitive emissions.

Commenter (2307-Qube) requests that the EPA consider the following process for establishing a baseline:

- Once the monitors have been installed and are fully operational a 90-day baseline period begins;
- 7 days after the baseline period begins, the operator performs a LDAR inspection using an EPA approved methodology;
- At the end of the 90-day period, the operator performs another LDAR inspection using an EPA approved methodology, to confirm that there are no fugitive components contributing to the baseline; and
- Use the average emissions mass quantification of the 90-day period to establish the baseline for the facility.

Commenter (2307-Qube) also requests that the EPA consider updating on an annual basis to capture changes to the baseline such as improved maintenance programs, production increases / declines, and equipment changes. The commenter suggests a streamlined approach to establishing a new baseline requiring a single LDAR inspection while using the average mass quantification data from a facility of the previous year. As a concept, the commenter believes that baselines are more representative if they are developed over a longer duration.

Commenter (2307-Qube) also believes that the long-term action level averaging time creates a number of unintended consequences. In deployments of continuous monitoring equipment to date, the commenter has observed a number of instances where short-duration, large-volume emission events are identified by the continuous monitoring system early in the deployment. The

owner of the site will respond to data generated by the continuous monitoring system and make repairs and other changes to the site that result in substantial reductions in emissions. Figure 1 below is an illustrative example of how a large spike in emissions rate, which is subsequently repaired quickly, can lead to a rolling average which exceeds the action level for a period of months:

[Figure 1 – Example site showing how operational events today impact the 90-day average.]

Response II-5-147: EPA acknowledges the commenters' input. As explained in Section X.B.2 and XI.B.2 in the preamble of the final rule, we have integrated a procedure for determining baseline emission and the action-levels are now considered to be above the baseline.

Comment: Commenter (2307-Qube) states the EPA has proposed that site Owner/Operators initiate a "root-cause analysis" to investigate if the short-term or long-term threshold is exceeded. The time delay between site-rate decreases and 90-day rolling average decreases can be troublesome as this can penalize operators for a considerable period of time. Operationally speaking, the emission events are in the past and corrective action has already taken place. Additionally, any emissions event whether it be maintenance, or a fugitive leak will contribute to increasing the rolling average. It isn't clear how operators would deal with subsequent increases to the rolling average when corrective action has already been taken for the initial event. Thus, the commenter suggests shorter averaging time periods which are consistent with how most operators are using the technology today.

Response II-5-148: EPA has revised the nomenclature around follow-up investigation from "root-cause" to "investigative analysis". The continuous program is designed to allow an owner or operator to conduct any repairs necessary during normal operation on their time frame to avoid any exceedance of an action-level, in an effort to avoid prescriptive find and fix requirements in the fugitive program.

Commenter (2307-Qube) concludes in terms of the absolute values proposed for the short and long-term action levels, it may be worth revisiting the modelling assumptions for equivalency. The model plant (4), which is representative of a gas gathering facility, will emit significantly less than an oil tank battery which typically has higher counts of storage vessels and fired equipment.

Response II-5-149: EPA acknowledges the commenters' input.

Comment: Commenters (2363-CEMC, 2402-DGCC, 2448-Project Canary) believe action levels should be measured relative to a facility-specific baseline. Commenters support EPA's proposal in §60.5398b(c)(4)(i) to have both a short-term (7-day) and long-term (90-day) action level for continuous monitoring systems. This approach can address more significant, impactful fugitive releases, as well as smaller releases that can become significant if allowed to continue to vent unabated. However, as addressed in our comments above, the specific proposed action levels do not account for normal operations and associated "authorized" methane emissions rates. If EPA were to finalize the action levels as proposed, it would significantly discourage owners and

operators from adopting continuous monitoring systems, thereby eliminating significant opportunities for greater methane emissions reductions.

Commenters (2363-CEMC, 2402-DGCC, 2448-Project Canary) propose an additional methodology by which an operator that wants to use a continuous monitoring system at a facility can first establish the baseline emissions level at the facility. The approach, as generally outlined below, could be established specifically within the regulatory language in this section, or an approach could be provided and approved within the Alternative Test Methods provision and technology approval process.

Commenters (2363-CEMC, 2448-Project Canary) state it is important to understand that certain ground-based, fixed continuous monitoring systems will calculate site-level methane emissions flux, inclusive of all methane emitting sources at a given facility, with source allocation providing a general equipment level location from where methane is emitted. However, these algorithms could represent methane emissions from a source that doesn't meet the definition of a fugitive emissions component, or a cover and closed vent system, such as methane slip from a compressor engine. The result could trigger an action level exceedance, while the emissions flux may be what is expected and part of normal operation, thereby disincentivizing the use of a continuous monitoring system.

For illustration of this point, methane emissions from intermittent pneumatic bleed devices using 40 CFR Part 98, Subpart W, Equation W-36 can be modified to calculate hourly methane emissions. Below is both the calculation as listed in Subpart W and its modified version (in kg/hr):

[Image of equation W-36 from 40 CFR Part 98, Subpart W]

A modified version with results in units of kg/hr is shown below:

$$\text{Mass Rate CH}_4 = \text{EF} \times \text{CH}_4 \text{ frac} \times \rho$$

Where:

Mass Rate CH<sub>4</sub> = CH<sub>4</sub> mass flow rate in kg/hr

EF = Intermittent Bleed Pneumatic Device emissions factor (Subpart W, Table W-1A) in scf/hr

CH<sub>4</sub> frac = mole fraction of CH<sub>4</sub> in gas stream

ρ = density of CH<sub>4</sub> (0.0192 kg/scf)

$$\text{Mass Rate CH}_4 = 13.5 \text{ scf/hr} \times 0.80 \text{ frac CH}_4 \times 0.0192 \text{ kg/scf}$$

$$\text{Mass Rate CH}_4 \text{ per intermittent bleed pneumatic device} = 0.21 \text{ kg/hr}$$

Response II-5-150: EPA acknowledges the commenters' input. As explained in Section X.B.2 and XI.B.2 in the preamble of the final rule, we have integrated a procedure for determining baseline emission and the action-levels are now considered to be above the baseline.

Comment: Commenters (2363-CEMC, 2448-Project Canary) state therefore, a well site with eight intermittent bleed pneumatic devices (putting aside any other authorized methane sources) would exceed the proposed action level of 1.6 kg/hr methane mass emissions rate on an ongoing basis. The commenters understand that the majority of multi-well sites are likely to be equipped

with more than eight intermittent bleed pneumatic devices, as well as other normally operating sources of methane emissions.

Response II-5-151: As explained in Section X.D and XI.D of the preamble of the rule, the final rule will result in the phasing out of the use of intermittent bleed pneumatics and therefore it is not a long-term consideration. Also, as explained in Section X.B.2 and XI.B.2 in the preamble of the final rule, we have integrated a procedure for determining site-level baseline emission to account for allowed process emissions and the action-levels are now considered to be above the baseline.

Comment: Commenters (2363-CEMC, 2448-Project Canary) argue this situation is likely to be exacerbated at larger locations, where more natural gas fired engines and other methane emitting sources are present. In fact, at least one continuous emission monitoring service provider, Project Canary, has performed a preliminary analysis of one customer's facilities where site-level methane flux is calculated and determined that roughly 30% of those locations exceeded the 1.6 kg/hr, 90-day rolling average action level during normal operations. Consider also that, under the proposed action levels, a lower emitting oil and gas well site could potentially have a more persistent, slightly higher volume leak of methane than a higher emitting well site and still not exceed an action level which would otherwise be triggered at the larger site. The commenter believes this could both disincentivize the use of continuous monitoring systems and inadvertently allow for more fugitive leaks from smaller well sites.

Specifically, commenters (2363-CEMC, 2402-DGCC, 2448-Project Canary) suggest the following methodology for setting a baseline methane emissions rate for each wellhead-only and well site opting to use an approved continuous monitoring technology under §60.5398b(c)(1). Action levels would then be measured against this baseline. The methodology would work as follows:

- The owner or operator first installs and commences the operation of the EPA-approved continuous monitoring system.
- When the continuous monitoring system is fully operational, a 60-day baselining period begins. During this period, the owner or operator will perform periodic, full-site LDAR inspections using an EPA-approved method, such as OGI cameras or Method 21. These inspections shall occur within 7 days of the date the continuous monitoring system is fully operational, with an additional inspection at 30 days and 60 days. The additional OGI or Method 21 inspections will verify that the site is operating without unintentional methane emissions from fugitive components, thereby establishing the site's individual baseline emissions without leaks.
- The baseline will then be determined by averaging the valid methane mass emissions rates, determined once every twelve-hour block, during the baselining period.
- Short-term and long-term action levels will then be set as the values established in §60.5398b(c)(4)(i) of this section added to the average value obtained during the 60-day baseline period.
- The determined baseline methane mass emissions rate remains valid unless and until annual actual or potential emissions from the location change by more than 5%, at which time another baselining period should be initiated.

- The owner or operator may update the baseline voluntarily at any time.

Response II-5-152: EPA acknowledges the commenters' input. As explained in Section X.B.2 and XI.B.2 in the preamble of the final rule, we have integrated a procedure for determining baseline emission and the action-levels are now considered to be above the baseline.

Comment: Commenters (2363-CEMC, 2402-DGCC, 2448-Project Canary) provide comments on the potential use of methane intensity or production rates in the development and use as action levels for continuous monitoring systems.<sup>70</sup> The commenters' general understanding of production accounting within the oil and gas industry is that there can often be a significant lag in determining the actual production volumes that flow through a given location, sometimes up to 60 days or more. Changes to production levels reported through prior period adjustments over a month in arrears have the potential to sway intensity numbers on a given location in an unpredictable manner potentially resulting in missed action level exceedances. The commenters recommend the EPA not implement an action level determination utilizing either methane intensity or facility production.

Commenters (2363-CEMC, 2402-DGCC, 2448-Project Canary) recognize that methane intensity is the primary metric for the IRA MERP. However, the methane intensity metric in the MERP is calculated on an annual basis. It is reasonable to expect that an operator will be able to determine and report its annual production. And it is clear to us that Congress intended that there should be increasingly rigorous detection and quantification of methane emissions in the oil and gas sector. For example, the MERP requires EPA to levy the waste emissions charge on a *per-ton* methane intensity basis, which is not possible without highly accurate measurement of both emissions and throughput at affected facilities.

Response II-5-153: EPA acknowledges the commenters' input. EPA has chosen not to incorporate "methane intensity" into any of the standard if this final rule.

Comment: Commenter (2333-Longpath) appreciates EPA's interest in using percentage of intensity as a metric, given the vast differences in absolute rates of site-wide emissions across different asset types and basins in the US. Unfortunately, it is not yet clear how operators could use a single, simplified equation for methane intensity in real-time on their sites. Therefore, the commenter suggests more research and tools must be developed before this option can be written into the rules. However, perhaps EPA could craft a suitable alternative to the absolute Detection and Action thresholds proposed, without requiring its use.

Response II-5-154: EPA acknowledges the commenters' input.

Comment: Commenters (2363-CEMC, 2402-DGCC, 2448-Project Canary) support the proposal by the EPA to set action levels based on methane emissions rates rather than methane concentrations, in part, for the reasons provided in this solicitation. The commenters believe that

---

<sup>70</sup> Supplemental Proposal, at 74,744 ("EPA is also aware of industry led efforts to minimize methane emissions through the entirety of the value chain using the percentage of intensity or production as a metric. The EPA is soliciting comment on the potential use of intensity or production in the development of action levels, including appropriate thresholds for setting such action levels on both a short-term and long-term basis.")

the use of methane emissions rates will more closely harmonize with other rules currently in and planned for development, including the future revision to 40 CFR part 98, subpart W, as required by the IRA.

Response II-5-155: EPA acknowledges the commenters' support of the rule.

Comment: Commenter (2421-Teledyne) states another concern with both the periodic and continuous technologies is the determination of minimum detection threshold and how the EPA intends to set standards for these technologies to meet desired thresholds of detection. With the BSER technology, OGI, the EPA specifically designated minimum technology standards with respect to the capabilities of the technology. As an example, NSPS OOOOa regulation defined OGI as technology that must be capable of imaging a gas that is half methane, half propane at a concentration of 10,000 ppm at a flow rate of  $\leq 60$  g/hr from a quarter inch diameter orifice. In this supplemental proposal the EPA has set new parameters around this technology as determined in Appendix K including a new minimum detection threshold of 17 g/hr of methane. The EPA should be more descriptive as to how they will ensure that periodic and continuous technologies are developed and implemented appropriately to ensure the desired capabilities are met.

Response II-5-156: As explained in Section X.B.3 and XI.B.3, EPA has defined the criteria that alternative methane detection providers must provide to the EPA as part of their request to approved. This criterion includes a requirement to prove a provider can achieve the required detection limit under conditions as found in the field.

Comment: Commenters (2363-CEMC, 2402-DGCC, 2448-Project Canary) say that if the Final Rule allows operators to use continuous monitoring systems under the periodic screening matrix, EPA will need to approve action levels as part of the work practice standards to be submitted to EPA under Proposed OOOOb §60.5398b(d) for certain technologies rather than requiring a response with each detection. EPA correctly recognized that action levels are the right response definition for continuous monitoring systems that are capable of quantification and fullsite coverage. Some non-visual continuous monitoring technologies (e.g., point and open path sensors) and periodic screening technologies (e.g., plane or drone-based mass-balance technologies) detect both allowable emissions (e.g., compressor methane slippage) and fugitive emissions because they measure site-wide emissions. Thus, the work practice standards should allow site-wide continuous monitors to quantify baseline emissions through time and identify emissions that exceed the sum of the baseline emissions plus the action levels defined in the matrix. Of note, camera-based continuous monitoring solutions do not require baseline measurement as part of their work practice standards as they can distinguish permitted emission from process malfunctions. Thus, each work practice standard approved by EPA can include the specific criteria (e.g., a combination of emission rate and duration) that triggers a detection or action level, which requires an owner or operator to identify the cause of the emission or process malfunction through an investigative analysis.<sup>71</sup>

---

<sup>71</sup> Methane Roundtable Letter 1 (text under the heading "EPA should ensure that owners and operators can use continuous emission monitors under the periodic screening matrix and that response requirements are technology neutral.").

Commenter (2298-Pioneer) argues the work practice standard for continuous monitoring technologies should specify how many detections in a month should trigger a detection that requires an owner or operator to identify the source of the leak or process malfunction.

The commenter adds some continuous monitoring technologies and periodic screening technologies (*e.g.*, mass-balance technologies) will detect allowable emissions. To ensure owners and operators can respond to leaks and process failures, EPA will need to establish action levels that differ from detection levels to determine an owner or operators' response requirements. EPA can use its process for alternative test method approval for alternative technologies to identify the process by which to identify baseline emissions versus the action levels.

Response II-5-157: EPA acknowledges the commenters' input; EPA wrote the continuous program as a performance-based approach. We recognize that many current continuous solutions may not be able to meet the criteria in the approach however we recognize the value of the more continuous systems and EPA has revised the final rule to confirm that methane detection technology that operates more continuously could be used in the alternative periodic screening approach as detailed in Section X.B.1 and XI.B.1 of the preamble of the final rule.

#### ***5.9.6 Probability of Detection***

Comment: Commenter (2433-EDF *et al.*) states technology parameters are an important input for the FEAST model that affect the results and should also inform EPA's technology approval process, which applies to new technologies before they are deployed in the field for compliance purposes. Default FEAST inputs for technology parameters are based on probability of detection curves derived through controlled testing studies. Because technologies may perform differently under varying meteorological and geographic conditions, it is also possible to alter the technology parameters based on the intended uses. For example, an operator evaluating the effectiveness of aerial technologies that it intends to deploy in North Dakota might alter the technology inputs to reflect decreased performance in windy and snowy conditions. Conversely, an operator in the Texas Permian might assume better technology performance due to relatively more consistent weather and geographical conditions there.

Commenter (2433-EDF *et al.*) notes EPA appropriately excluded regionally variable factors like wind speed and snow cover, relying instead on broadly applicable and averaged assumptions derived from controlled testing. Because technologies permitted for compliance may be deployed anywhere across the country at any time, it would not be possible nor reasonable for EPA to attempt to evaluate performance or set standards based on varying meteorological and geographical conditions. Such considerations are instead better resolved during the new technology approval process or AMEL applications.

Response II-5-158: EPA acknowledges the commenters' input; EPA agrees with the commenter and recognizes that environmental conditions are extremely important component of POD. EPA has revised the required information an alternative technology provider must provide to the EPA as part of their alternative test method request as described in Section X.B.3 and XI.B.3 of the final rule.

EPA may provide caveats to any alternative test method approval to ensure a technology is being utilized properly.

Comment: Commenter (2340-Honeywell) requests that the final rule should provide a flexible framework for determining action levels and measurement averaging periods that require a minimum probability of detection.

Commenter (2340-Honeywell) states continuous monitoring sensors generally apply plume modeling to determine the mass emissions rate of a leak (in kg/hr) from concentration data measured by the point sensors, which is correlated in time with wind direction and speed. Because the continuous monitoring system is dependent on the variability of the wind direction to bring methane molecules from the emission point to the sensor, a certain amount of data collection is needed to build up enough statistics. This is dependent on dynamic weather conditions, but also on detector distances and detector sensitivity. Integrating those data to determine the mass emissions rate involves some inherent uncertainty based on the precision of each measurement. This is true as well for OGI cameras, which constitute BSER. As EPA notes in the preamble to the proposal, weather conditions and operator experience can significantly affect the detection capabilities of OGI cameras, which is why EPA has proposed standards for operator experience and require that such surveys only take place within a particular “operating envelope” of field conditions.

Commenter (2340-Honeywell) argues rather than limit the action levels, detection sensitivities, and measurement averaging periods (*i.e.*, the 7- and 90-day measurement periods) to one set of prescribed levels based on flawed FEAST modeling, the final rule should provide the flexibility to use modeling to determine the action levels and corresponding measurement periods for continuous monitoring systems, and require a minimum probability of detection instead of prescribing minimum detection thresholds. Doing so will better serve EPA’s goal of creating an outcome-based, technology-neutral standard that encourages the development and deployment of a wide variety of effective continuous monitoring systems. The commenter proposes that the final rule allow the use of both FEAST modeling and plume/inversion modeling to determine the detection thresholds at which a particular system can meet a minimum probability of detection and to set the appropriate action levels and measurement periods that provide equivalent emissions reductions.

Commenter (2340-Honeywell) states first, the final rule should allow for the use of plume or inversion modeling to determine, with independent verification, the threshold subject to a probability of detection requirement and placement of sensors in relation to a source at which a particular continuous monitoring technology can meet the requisite probability of detection. In order to determine the threshold for different continuous monitoring systems (*e.g.*, a fenceline system with highly sensitive detectors positioned far away from the emissions as compared to a hazloc system with lesser sensitive detectors positioned very close to the emissions) and the corresponding probability of detection, the commenter proposes the use of probability curves. For consistency with the alternative periodic screening framework, EPA may consider setting the baseline at a 90% probability of detection. Third-party research institutions, such as METEC, are already developing methodologies for testing advanced methane detection and determining probability curves for the detection sensitivity of such instruments; EPA should allow continuous

monitoring technology providers such as Honeywell to rely on the probability curves developed by third-party validators, such as METEC, to demonstrate the requisite detection level for their continuous monitoring systems.

Commenter (2340-Honeywell) continues second, based on the detection threshold at which the continuous monitoring system can measure a methane leak with the requisite probability of detection, the technology provider or operator should then be able to use FEAST modeling (or a similar method), to determine the combination of action levels and measurement periods that would provide equivalent emissions reductions to BSER. For example, an operator using a less sensitive instrument and a higher action level could measure a rolling average of emissions on a shorter timeframe (*e.g.*, a 1-day measurement averaging period with a 30 kg/hr action level). In the commenter's experience, some operators find that the best use case for continuous monitoring systems is to trigger corrective action sooner in response to larger emissions, while other operators focus on longer-term trending. Either approach can provide equivalent or greater emissions reductions to BSER and to periodic screening given the frequency of measurement. EPA used FEAST modeling to determine equivalency for the detection thresholds and monitoring frequencies provided in the periodic screening matrices and to set the action levels for continuous monitoring. It should therefore be possible to apply the same type of modeling to a variety of detection thresholds and action levels to determine the frequency of action that would provide equivalent or greater emissions reduction to BSER for continuous monitoring.

Commenter (2340-Honeywell) states third, EPA can establish certain boundaries and backstops, as it has done with the periodic screening matrices, that ensure equivalency with BSER. For example, similar to the upper limit of a 30 kg/hr detection threshold for periodic screening, the final rule could establish an upper limit of action levels that provides sufficiently equivalent emissions reductions to BSER. Honeywell proposes, for example, that the framework allow for an upper action level of 30 kg/hr for which an operator would use a 1-day rolling average for the measurement period. The final rule could similarly incorporate OGI backstops, as the periodic screening matrices do, for certain action levels used for continuous monitoring.

Commenter (2340-Honeywell) concludes the final rule should allow the use of modeling to (a) determine the detection level at which a given continuous monitoring system can provide a minimum-prescribed probability of detection (*e.g.*, 90%), and (b) determine the corresponding action levels and frequencies of action that would provide equivalent emissions reductions to BSER. With regard to the demonstration of the technology's probability of detection, the commenter recommends that EPA allow technology providers to rely on third-party validation, such as that provided by METEC, of a continuous monitoring system's probability curve with respect to its detection thresholds.

Response II-5-159: EPA acknowledges the commenter's input. EPA has explained the criteria for the alternative periodic screening, continuous applications, and the approval process for these alternative technologies in Sections X.B and XI.B of the final rule. EPA has not provided a pathway for technology specific work practices using FEAST modeling however, when appropriate, and individual could petition the Administrator for an AMEL.

Comment: Commenter (2405-Bridger) believes that meaningful detection sensitivity performance metrics should be required for continuous monitoring systems. The Proposed Rule indicates that the detection sensitivity of continuous monitoring systems should be an order of magnitude smaller than the action levels specified for the continuous monitoring approach. However, the performance metric for sensitivity is not defined. The commenter recommends that detection sensitivity is defined as the emission rate at which the technology has a 90% probability of detecting emissions, consistent with the requirements for periodic screening technologies. Using minimum detection levels is not suitable because it may have little bearing on field performance. Detection probabilities for continuous monitoring systems have already been evaluated by a third party, which illustrates that this is a practical requirement.

Commenter (2405-Bridger) states the demonstration of detection probabilities should be applicable to sites where the continuous monitoring technology will be deployed to ensure that systematic false negative detections do not occur due to exceedingly sparse spatial coverage (e.g., lofted emissions from tanks or flares could be missed and very specific sensor configurations and numbers may be required at individual facilities;<sup>72</sup> certain wind angles and speeds may be necessary for these systems to appropriately detect, quantify, and localize emissions).

For consistent and meaningful performance demonstration, commenter (2405-Bridger) urges the EPA to require continuous monitoring systems to report their detection sensitivity at 90% probability of detection

Response II-5-160: EPA acknowledges the commenters input. In the final rule, EPA has revised the requirement around detection threshold/probability of detection to require technology vendors provide us information on these thresholds as applied in the field. The 90% probability of detection is required for any technology operated under the periodic screening alternative; however, EPA is using detection threshold which is intended to be MDL for those systems as applied in the field.

Comment: Commenter (2402-DGCC) states the Supplemental Proposal provides guidance about how continuous monitors should be used with action levels corresponding to 7-day and 90-day rolling average windows. Many continuous monitors are used to find leaks quickly and measuring a leak for 90 days before acting is not consistent with the best use of many continuous monitors. More effective continuous monitoring would occur with different durations of rolling average windows.

Commenter (2402-DGCC) recommends that in addition to the prescribed 7-day and 90-day rolling average windows, EPA make clear that requestors can submit FEAST modeling as part of their applications (under proposed OOOOb §60.5398b(d)) with different rolling average windows, customized to maximize the effectiveness of the continuous monitoring technology. Some continuous monitors are most effective when deployed using two rolling average windows, but other continuous monitors are most effective when deployed using a different number of rolling average windows. In all cases, FEAST modeling would ensure that the action

---

<sup>72</sup> Chen, Q. et al. Assessing Detection Efficiencies for Continuous Methane Emission Monitoring Systems at Oil and Gas Production Sites. Environ Sci Technol (2023). doi: 10.1021/acs.est.2c06990.

levels are set corresponding to the number and duration of rolling average windows to ensure that the resulting emissions reductions are equivalent to the BSER.

Commenter (2402-DGCC) adds, EPA should make clear in the Final Rule that requestors can submit applications for a combination of periodic screening technologies and continuous monitoring technologies. Such applications should include FEAST modeling with the same input emissions distribution EPA uses in the Final Rule to enable EPA to evaluate those applications within the proposed 270 days alternative test method approval process.

Commenters (2336-Kuva, 2402-DGCC) note proposed Tables 1 and 2 to Subpart OOOOb of Part 60 (presented as Tables 20 and 21 in the Supplemental Proposal) provide survey matrices for alternative periodic screening approaches based on EPA's FEAST modeling and simulations. The matrices provide guidance on five minimum screening frequencies versus their corresponding minimum detection thresholds of screening technology, which are expressed as a 90% probability of detection threshold. In developing the detection limits for the matrix, EPA makes two critical assumptions in its FEAST modeling:

1. The statistical distribution of fugitive emissions, of super emitters and their intermittency
2. All emissions at a site at and above the detection limit listed in the matrix are detected with a 90% probability by the advanced technology for every screening and that no emissions are detected below the listed detection limit.

Response II-5-161: EPA acknowledges the commenter's input. EPA has explained the criteria for the alternative periodic screening, continuous applications, and the approval process for these alternative technologies in Sections X.B and XI.B of the final rule. EPA has not provided a pathway for technology specific work practices using FEAST modeling however, when appropriate, and individual could petition the Administrator for an AMEL.

Comment: Commenters (2336-Kuva, 2402-DGCC) state the second assumption in EPA's FEAST modeling is a disincentive for operators to utilize advanced technologies if the currently proposed language is interpreted by EPA as requiring alternative technologies to detect emissions from every fugitive component, cover, or CVS at a site at 90% probability of detection for every screening. Advanced technologies may not be able to guarantee this due to technology-specific circumstances related to site coverage and visual obstruction. At the same time, alternative technologies will detect significantly more emissions than assumed by EPA in its FEAST modeling due to the impact of the complete probability of the detection curve, which EPA's FEAST modeling does not currently consider. These incremental detections, due to the probability of the detection curve, can more than offset reduced detections due to visual obstruction or other coverage-related issues. Alternatively, an advanced technology solution provider may offset site coverage limitations with a lower limit of detection than required under the matrix.

Commenter (2336-Kuva) adds continuous camera solutions can detect significantly more emissions than assumed by EPA in its FEAST modeling due to the following three parameters:

- Impact of the complete probability of detection curve;

- Increase of screening frequency beyond monthly, for example once per week at a set point in time; and
- Impact of distance on probability of detection.

Commenters (2336-Kuva, 2402-DGCC) continue, a guarantee of detecting emissions from every fugitive component, cover, or CVS at a site at a 90% probability for every screening inspection may not be possible for many sites. Examples are:

- Venting from compressor rod packing at compressors that are covered by a roof may not be detectable by plane surveys due to lack of line of sight to the vent and the vent plume will be too dilute for detection once it is blown sideways out under the roof.
- An emissions plume from methane emissions slippage at compressors may frequently cover up underlying fugitive emissions from fugitive components in the vicinity of a compressor and make them undetectable by visual aerial detection. Any fugitive emissions will intermingle with the methane emissions slippage and will then be considered a permitted emission from the compressor instead of being detected.
- Emissions from high-up sources such as thief hatches on tall tanks may not drift down towards point sensors or reflector installations of open path detectors installed lower to the ground.
- Continuous installed OGI cameras may not have a direct line of sight to yard piping or other fugitive components due to visual obstruction behind storage vessels or other large structures
- Challenges with site coverage also exist for OGI inspections as EPA proposes exemptions for “Unsafe to inspect” or “Difficult to inspect” components in its OGI inspection requirements for covers and CVS.
- camera based continuous monitoring systems may not have direct line of sight to yard piping or other fugitive components due to visual obstruction behind storage vessels or other large structures.

Response II-5-162: EPA acknowledges the commenter’s input. It is requisite in this and any other fugitive/covers and CVS monitoring program to monitor each component individually and in this rule, we have introduced an alternative’s which allow the owner or operator to measure the aggregate so long as they have entire site coverage. EPA recognizes that each technology offers its own benefits and challenges, and therefore as explained in Section X.B.3 and XI.B.3 have allowed for the development of technology specific alternatives.

Comment: Commenter (2402-DGCC) states concurrently, advanced technologies do not have a fixed “cutoff value” for a detection limit as is assumed in EPA’s FEAST modeling, but instead a probability of detection curve that will detect emissions at lower emission rates at a probability below 90%. This will result in very significant additional emissions reductions as the frequency of emission events occurring is larger at lower emission rates. Alternatively, some advanced technologies will also have a 90% probability of detection limits that are below EPA’s matrix limit while still suffering from the site coverage constraints as described above.

Commenter (2402-DGCC) states the FEAST and Highwood Emissions Management's LDARSim models are capable today of modeling these limitations.<sup>73</sup> Specifically, they can model the incremental detection capabilities of advanced technologies due to their probability of detection curve or due to lower detection levels and they can model the reduced detection due to technology-specific limitations in site coverage. EPA could consider making assumptions in their FEAST modeling of on-site coverage and probability of detection curves. However, this may be challenging to implement in a technology-neutral way as the specifics of site coverage and of the shape of a probability of detection curve vary by advanced technology.

Commenter (2402-DGCC) recommends that EPA clarify that advanced technology solution providers can submit to EPA, under the alternative test method approval process, technology-specific FEAST modeling to demonstrate that their alternative test method and related work practice utilizing a combination of site-coverage parameter and probability of detection curve or improved detection limit results in equivalent or greater emission reductions compared to the matrix (combination of detection limit and screening frequency), which EPA has demonstrated is equivalent to BSER. The newly introduced site coverage parameter will become a part of the technology-specific work practice that has to be followed by operators for all sites. EPA should make clear that applicants can make this demonstration if they use EPA's assumptions in the Final Rule's FEAST modeling for the statistical distribution of fugitive emissions and for super emitters and their intermittency while being permitted to introduce an explicit parameter for less than 100% site coverage (and a corresponding coverage requirement in the technology-specific work practice) and for either using a lower detection limit than required by the matrix or for modeling a full probability of detection curve instead of a cutoff value.

Commenter (2402-DGCC) states there are currently no provisions pertaining to the simultaneous deployment of combinations of alternative technologies. Deploying alternative technologies in combination can allow the complementary strengths of the different technologies to be combined in practice. More effective monitoring can occur in many situations if different technologies are combined. Studies show examples of how periodic screening technologies and continuous monitoring technologies can be deployed in combination to achieve particularly effective monitoring.<sup>74</sup> Moreover, some operators may be willing to agree to a faster response time to detected emissions than required by EPA. The response time assumption is a significant variable in FEAST modeling—a faster response will increase the reduction of emissions. An example is a faster response to abnormal emissions from abnormal venting from fugitive components, covers, or CVSSs.

Commenter (2402-DGCC) states EPA's proposed rule includes only five combinations of detection limit and screening frequency for the screening matrix. This limits the flexibility of deployment of existing or future advanced technologies. For example, advanced technologies may be more cost-effective when deployed at a different combination of detection limit and screening frequency than anticipated by the EPA.

---

<sup>73</sup> LDARSim. (N.D.) Highwood Emissions Management. <https://highwoodemissions.com/ldarsim/>.

<sup>74</sup> Cardoso-Saldaña, F.J. (2022, Nov. 15). Tiered Leak Detection and Repair Programs at Oil and Gas Production Facilities. ExxonMobil Upstream Research Company. <https://chemrxiv.org/engage/chemrxiv/article-details/636d4595afea7fed1c9f5f67>.

Commenter (2402-DGCC) recommends that EPA clarify that advanced technology solution providers can submit to EPA, under the alternative test method approval process, technology-specific FEAST modeling to demonstrate that their alternative test method and related work practice utilizing : 1) a combination of screening technologies, 2) different requirement for operator response times to alarms, or 3) a different combination of detection limit and screening frequency. The EPA has demonstrated such practices are equivalent to BSER.

Commenters (2336-Kuva, 2402-DGCC) add the newly introduced parameters (*e.g.*, a combination of screening technologies, response times, detection limits, and screening frequencies) will then become a part of the technology-specific work practice that has to be followed by operators for all sites utilizing this technology. EPA should make clear that applicants can make this demonstration if they use EPA's assumptions in the Final Rule's FEAST modeling for the statistical distribution of fugitive emissions and for super emitters and their intermittency, while being permitted to introduce explicit parameters accounting for less than 100% site coverage (and a corresponding coverage requirement in the technology specific work practice), for modeling a full probability of detection curve instead of a cutoff value, for increasing screening frequency and for utilizing distance dependent detection curves (and related placement constraints for the camera).

Commenter (2336-Kuva) indicates that challenges with site coverage also exist for OGI inspections. EPA has accommodated these challenges by proposing exemptions for "Unsafe to inspect" or "Difficult to inspect" components in its OGI inspection requirements for covers and CVS in the current supplemental proposal.

Instead of creating exemptions for continuous cameras, commenter (2336-Kuva) is proposing for EPA top permit applicants for alternative test methods to consider other parameters in their application, namely Impact of the complete probability of detection curve, Increase of screening frequency beyond monthly, for example once per week at a set point in time and the impact of distance on probability of detection.

Commenter (2336-Kuva) notes EPA is currently not considering the complete probability of detection curve in its modeling and instead uses the 90% detection limit as a cut-off value. In a real-world deployment a continuous camera will also detect and can also alarm on emissions significantly below its 90% detection limit. Publications show that the 10% detection limit can often be a factor 10 or more below the 90% probability of detection limit. These detections contribute very significantly to the overall number of emissions detections as the frequency of smaller leaks is higher than for larger leaks. Unlike point sensors and scanning laser towers continuous cameras do not require a baseline measurement to be subtracted and they do not require an action level that is typically far higher than a detection limit. Instead, in principle cameras can alarm on all detections irrespective of size of the emissions.

Commenter (2336-Kuva) states an increase in screening frequency (for the same detection limit) will have a beneficial effect on emissions reductions as super emitters, and especially intermittent super emitters, are more likely to be detected and repaired quickly.

Commenter (2336-Kuva) states the probability of detection for cameras is dependent on the distance from emission. In a typical installation a continuous camera is installed such that distance to likely super emitters such as tanks is minimized, thereby increasing the likelihood that even small emissions are captured. This distance dependent probability of detection can be captured in FEAST modeling and in installation requirements as part of the work practice, for example an installation requirement that a certain percentage of components have to be within a certain distance from a camera.

Commenter (2336-Kuva) argues all three of these parameters are currently not considered in EPA's FEAST modeling. Incremental detections due to these three parameters can more than offset reduced detections due to visual obstruction or other coverage related issues. The FEAST and LDARSim models are capable today of modeling these limitations. Specifically, both FEAST and LDARSim can model the incremental detection capabilities of advanced technologies due to their probability of detection curve, due to increased detection frequency or due to probability of detection curves for multiple distances (by combining multiple simulations runs). LDARSim can model the reduced detection due to technology specific limitations in site coverage today and this feature is planned as an update for the near future for FEAST.

Commenter (2336-Kuva) states in establishing a Matrix EPA could consider making assumptions in their own FEAST or LDARSim modeling on site coverage, probability of detection curves, increased detection frequency or distance dependent detections. However, this would be very challenging to implement in a technology neutral way as the specific impact of each parameter varies very significantly with each type of advanced technology.

Response II-5-163: EPA acknowledges the commenters' input. An alternative to the alternative periodic screening or continuous monitoring approach using advanced methane detection technology, you may choose to petition the Administrator for an Alternative Mean of Emission Limitations (AMEL) for the fugitive monitoring program in §60.5397b. The criteria for this program are defined in §60.5399b.

### ***5.9.7 Matrix Approach***

Comment: Commenters (2213-Oxy, 2433-EDF *et al.*) appreciate EPA's inclusion of a matrix framework that allows alternative technologies to be used for varying survey frequencies based on the resolution of the technology. The commenters appreciate the inclusion of a framework for continuous monitoring systems based on certain action levels and supports the use of these technologies in lieu of the conventional AVO and OGI surveys.

Response II-5-164: EPA acknowledges the commenter's support for the matrix framework.

Comment: Commenter (2433-EDF *et al.*) states EPAs proposed quarterly OGI matrix aligns with their independent FEAST modeling results across a variety of scenarios and the commenter therefore supports the proposed frequencies. Commenter's (2433-EDF *et al.*) results for aerial technologies paired with annual OGI are similar to EPAs, and the commenter believes the proposed frequencies are appropriate. In coming years, detection capabilities are likely to improve, and the commenter supports EPA's inclusion of options that will drive this

improvement. Last, while EPA's FEAST results show that the addition of an annual OGI survey is necessary for equivalence for only some of the options, the commenter encourages EPA to nevertheless require a universal annual OGI backstop and ensure that any higher detection threshold options contain OGI pairings. Commenter (2433-EDF et al.) believes this is necessary to mitigate smaller (but cumulatively significant) persistent leaks that are detected under EPA's BSER determination for OGI but unlikely to be detected through advanced screening. The OGI pairing will also become increasingly important as super-emitters are reduced and begin to contribute less to total emissions.

Response II-5-165: EPA acknowledges the commenter's support for EPA's FEAST modeling.

Comment: Commenter (2433-EDF et al.) states for sites that would be subject to semiannual OGI or quarterly AVO (wellhead only and small well sites), EPA has proposed a different matrix that would achieve reductions equivalent to semiannual OGI. The commenter supports the frequencies and detection thresholds in this matrix also, and in particular believe the annual OGI pairings with the higher detection threshold technologies are appropriate. Sites subject to this matrix will often be producing very little and may not regularly experience large emission events. Consequently, many emissions at these sites are likely to be smaller leaks that may be missed by high detection threshold screening technologies. To mitigate these leaks thus requires the use of a more sensitive technology, like OGI.

Commenter (2433-EDF et al.) states most operators choosing the alternative advanced monitoring option will likely contract with a methane mitigation provider and will choose the alternative for a grouping of assets or all their assets. Operators typically also have mixed assets, meaning they have a variety of site types, some of which will fall into different monitoring subcategories. Screening all of an operator's sites based on the most stringent applicable requirement would therefore pose minimal additional burden in many cases. For example, if an operator owns twenty-two well sites in a basin, half of which would fall into the quarterly OGI matrix, and half of which would fall into the semiannual OGI matrix, the operator will likely screen all the sites pursuant to the more stringent requirement. In light of the potential efficiency advantages to applying the same approach to all sites in a geographic area, operators should be permitted to apply the most protective version of the matrix to groupings of sites.

Commenter (2433-EDF et al.) states EPA should also require some form of ongoing OGI or AVO inspections at all sites complying with this matrix as a backstop. For the reasons described in section IV.B.d.v, Commenter (2433-EDF et al.) thinks that AVO inspections are particularly valuable for declining end-of-life wells and reducing the risk of orphaning. Without some form of regular, ground-based inspection, operators may never visit these sites and preventative maintenance may never occur. Ground-based inspections better serve the purposes of regular upkeep and site hygiene that are important for end-of-life wells in particular and should therefore be required at all wellhead-only and small well sites.

Commenter (2433-EDF et al.) believes that EPA should revisit the assumptions underlying the matrices in the future. As large emission events are reduced through implementation of EPA's proposed standards, the commenter expects that emissions distributions across basins will become less heavy tailed. This means that higher detection threshold options will become less

effective over time as the fraction of total emissions below their detection threshold increases. Therefore, to achieve reductions equivalent to OGI, frequencies will need to increase, and detection thresholds will need to decrease. Further, the commenter expects that costs and improved detection capabilities will obviate the need for higher detection threshold options in the future.

Response II-5-166: EPA acknowledges the commenter's input and support. EPA agrees with the commenter that ongoing OGI is beneficial, however we found that it is not always necessary. EPA also agrees that we should revisit assumptions in the matrix as part of any future regulatory actions required by the Clean Air Act.

Comment: Commenters (2213-Oxy, 2428-API) have concerns with the proposed frequencies and action levels, respectively. The proposed frequencies and action levels may not promote the use of these technologies, and OGI/AVO may still be a more resource-efficient approach for many operators. Commenter (2213-Oxy) states for continuous monitoring systems, action levels should be reflective of the facility type, complexity, and design and should be in addition to authorized emissions to focus on identifying and resolving leaks and abnormal conditions. The commenter is supportive of the framework and believes that EPA can encourage the continued innovation and accelerated deployment of these technologies even more strongly in the final rule by incorporating the feedback mentioned above.

Response II-5-167: EPA acknowledges the commenter's input; EPA has set the action levels in the continuous monitoring approach and the matrix frequencies to be equivalent of the BSER.

Commenter (2428-API) states that the proposed rule language is unclear whether continuous monitoring technology could also be used under the periodic screening survey requirements in §60.5398b(b) and associated matrices. For continuous monitoring technology that simply detects rather than quantifies methane emissions, these technologies could be used for periodic screening surveys. In these situations, the continuous monitor acts like a smoke alarm to notify operators of potential issues. Since continuous monitors can be used more frequently than monthly, EPA should consider adding a more frequent tier or a separate continuous monitoring row to the matrices. The equivalent emission reductions from continuous monitoring could be demonstrated through appropriate modeling. The commenter recommends incorporating continuous monitoring into the alternative screening matrix for the reasons discussed and to streamline inclusion into the monitoring plan framework.

Response II-5-168: EPA never intended to exclude continuous type technologies from being applied in the periodic screening approach. EPA has made the necessary changes in the final rule as described in Sections X.B.2 and XI.B.2 of the preamble of the rule.

### **5.9.8 FEAST Modeling**

Comment: Commenter (2433-EDF *et al.*) states EPA's decision to use FEAST to model the effectiveness of different methods and advanced technologies is reasonable.<sup>75</sup> FEAST is a

---

<sup>75</sup> Fugitive Emissions Abatement Simulation Toolkit, SET Lab, <https://www.arvindravikumar.com/feast/> (last visited Feb. 13, 2023).

customizable, open-source modeling framework developed to evaluate the effectiveness of different LDAR programs at oil and gas facilities. Model inputs include the number and type of emissions sources, a leak generation rate by emission source type, a distribution of leak rates when a leak is generated, and the probability of the selected method detecting a leak of a given size. FEAST can therefore evaluate the effectiveness of different LDAR approaches, as well as voluntary programs undertaken by operators.

Response II-5-169: EPA acknowledges the commenter's input and support.

Comment: Commenter (2433-EDF *et al.*) believes that all of the inputs used by EPA are reasonable, appropriate, and ensure that advanced technologies deliver emission reductions commensurate with OGI across diverse basins. Innovation in methane detection technologies and deployment methods is advancing rapidly and EPA has taken a careful, technology-neutral approach that will enable the use of these technologies for regulatory compliance. EPA's proposed approach provides operators and technology providers with flexibility, while ensuring most critically that these technologies are used in a way that ensures emission reductions equivalent to OGI at all sites nationwide.

Commenter (2433-EDF *et al.*) notes EPA chose inputs and made assumptions based on nationally applicable factors and considerations. This is both appropriate and required by CAA section 111, which applies across the country to sources in different oil and gas producing regions and basins. While technologies and methods may perform differently in different regions and under varying conditions, EPA is required to ensure that equivalent performance will occur everywhere and under all conditions. EPA's modeling does this and the commenter therefore support the results, which also generally align with the results of independent modeling conducted with nationally applicable input assumptions.

The commenter's (2433-EDF *et al.*) primary recommendation is that EPA require ongoing ground-based inspections at all sites as a backstop. As an optional alternative to the OGI-based approach, EPA proposes to allow operators to use advanced methane detection technologies at varying frequencies (and with varied OGI pairings) depending on detection capabilities—a "matrix" approach. The requirements also vary by site type, tracking the subcategories described above. The proposed changes to the alternative screening option are intended to support the deployment and utilization of a broader spectrum of advanced measurement technologies than the initial proposal. EPA has therefore proposed two matrices of options that are expected to achieve emission reductions equal to or greater than OGI:

[Table 6 Number of Reported Leaks by Component Type]

[Table 7 Quarterly OGI Subject Sites: Frequency by Detection Capability]

[Table 8 Semiannual OGI & AVO Subject Sites: Frequency by Detection Capability]

Commenter (2433-EDF *et al.*) believes the frequencies and detection thresholds included in the matrices are largely appropriate and will ensure that equivalent emission reductions occur at all sites nationwide. The commenter's own FEAST modeling results using nationally representative

emissions distributions generated results similar to what is included in the matrices (described more below). The commenter also notes that EPA's results are intuitively correct given that OGI has a detection threshold below 1kg/hr, any technology that is less sensitive must be used at a higher frequency to achieve the same emissions reductions. As the detection threshold increases, so does the fraction of total emissions that cannot be detected by that technology. Therefore, to achieve the same level of emissions reduction as quarterly (or semiannual) OGI, technologies with higher detection thresholds must be used more frequently. And with very high detection thresholds, it is not possible to achieve the same level of reductions, regardless of frequency, because too large of a fraction of total emissions exists below the detection threshold.

Commenter (2433-EDF *et al.*) states prior to deploying a technology for regulatory compliance, EPA would have to approve the technology as meeting the parameters outlined in the proposal and matrices. EPA is proposing to streamline the pathway for technology developers and other entities to seek the agency's approval for the use of advanced measurement technologies under the alternative screening option. Approved technologies could then be deployed following the same operational parameters under which they were approved.

Commenter (2433-EDF *et al.*) states an operator choosing the screening approach must submit a monitoring plan identifying the sites, test methods, technology vendor, planned frequencies, follow-up survey plans, and repair plans. Upon detection of emissions, ground based OGI surveys are required, and repairs must be completed within 30 days of the screening survey. Root cause analysis and corrective action are required if the emissions are due to failure of a control device, a cover, or a closed vent system. The commenter supports EPA's proposed structure, matrices, deployment and repair requirements, and technology approval process.

Response II-5-170: EPA acknowledges the commenter's input and support.

Comment: Commenter (2340-Honeywell) states that the framework for continuous monitoring in the proposed supplemental rule appears to be based on modeling and assumptions that do not reflect the real-world deployment and capabilities of such systems or their efficacy in detecting methane emissions.

Response II-5-171: The continuous monitoring action levels are based off the expected emission reductions in the model plan for the BSER program (OGI). The action levels are independent of how any continuous monitoring solution has been applied.

Commenter (2340-Honeywell) states first, EPA explains in the supplemental proposal that the continuous monitoring framework is akin to the NESHAP fenceline monitoring work practice and assumes that continuous monitoring sensors would similarly be placed on the fenceline of the facility. However, Rebellion cameras and Signal Scout sensors are both placed within the fenceline and at the heart of the operations. In fact, Signal Scout sensors are placed directly adjacent to the emissions sources because they are hazardous area certified. Both systems are therefore much closer to potential leaks than technology deployed on the fenceline. Such systems do not need to be as sensitive as fenceline-based sensors to detect leaks of a particular size.

Response II-5-172: EPA acknowledges the commenters' input, EPA has made revision in the continuous monitoring provisions in the rule, as explained in Section X.B.2 and XI.B.2 to allow for additional monitoring solutions to use this approach. Likewise, these types of technologies could also be used in the periodic screening approach.

Comment: Commenter (2340-Honeywell) states data from the commenter's test deployment of Signal Scout indicate that a substantial number of large emissions events tend to be from process upsets, such as thief hatch releases and seal failures, that tend to be of limited duration (*e.g.*, less than 12-24 hours) and occur intermittently. Data from Signal Scout deployment in the field indicate that these intermittent events contribute significantly to overall site emissions. However, EPA's FEAST modeling—which is the basis for the equivalency analysis between periodic screening, continuous monitoring, and BSER—is based on data from periodic screenings (*e.g.*, aerial data). This data may not take into account these types of intermittent, shorter duration emissions of several hours, but which are nevertheless large emissions events. As shown below, for example, current FEAST modeling assumes that large emission events (referred to as super-emitters in the presentation cited below) are persistent or continuous over a longer duration of 5–45 days (rather than intermittent over a period of several hours) such that periodic surveys would be more likely to detect them.<sup>76</sup>

[Table of FEAST-EPA Model assumptions. Supplemental proposal FEAST assumption versus alternative modeling scenarios in FEAST]

Commenter (2340-Honeywell) states data shows that this assumption is flawed, and the failure to incorporate shorter-duration, actionable and large emission events of several hours into the modeling biases the equivalency determination in favor of alternative periodic screening, because it then fails to account for the advantages of continuous monitoring in detecting such events and thus contributing to overall emissions reductions. In addition to evading periodic surveys, these types of large emission events of several hours' duration do not require minimum detection thresholds as low as those proposed in the rule (*i.e.*, 0.12 kg/hr or 0.16 kg/hr) to be detected by continuous monitoring technologies. When these larger intermittent emissions events are taken into account, it becomes clear that continuous monitoring systems are likely to provide significant overall emissions reductions, and potentially much greater reductions as compared to periodic surveys. Taking this dynamic into account would allow EPA to relax the parameters necessary to determine equivalency between continuous monitoring and BSER.

Commenter (2340-Honeywell) argues prescribing inappropriately low action levels and detection thresholds undermines the purpose of LDAR programs to maximize emissions reductions, because doing so will push technology providers and operators toward the use of periodic screening over continuous monitoring. Instead, EPA should allow for a range of action levels and measurement averaging periods and set detection thresholds based on the probability of detection when using that particular technology to ensure sufficient sensitivity in a technology-neutral manner (whether it is on the fenceline or in the heart of the operations).

---

<sup>76</sup> See “EEMDL Launch Event: FEAST and the EPA Supplemental Rule,” p. 25, available at: <https://static1.squarespace.com/static/62e9555e53fbc63d4431547e/t/63c855f7411588605e3859a1/1674073622398/EEMDL+Launch+Webinar+Presentation.pdf>.

Comment: Commenter (2340-Honeywell) believes the current FEAST modeling on which EPA is utilizing for this rulemaking is limited because it relies heavily on data from periodic screening technology (e.g., aerial survey data) without benefit of commensurate data from continuous monitoring systems. One key area of weakness in the current FEAST dataset is with regard to the contribution of large emission events of limited duration that can dramatically impact annualized emission estimates and the ability of an operator to understand the root causes in order to respond quickly and reduce or prevent these emission events.

Response II-5-173: As previously discussed, the action level for the alternative continuous monitoring work practice is independent of what a technology can do and are based on the expected emissions of the BSER. The sensitivity requirements are based on the annualized emission rate of the BSER program and if a continuous technology cannot measure those levels, then we cannot assume that the alternative work practice is getting the equivalent emission reduction.

Comment: Commenter (2340-Honeywell) notes a study by Schissel, and Allen assessed the impact of emission intermittency on the ability of annual, semiannual, quarterly, monthly, and weekly measurements to accurately detect emissions, including large, short-duration events. They found significant uncertainty and bias can arise from insufficient sampling, which becomes more prominent for emission events with shorter durations. As an example, their simulations of monthly sampling of sites with 1-hour duration events led to an average absolute percent error of 23% in annual emission estimates. Further, the study's Monte Carlo analysis showed an annual emission estimate constructed from monthly sampling of 1-month events have a 15% probability of having an error of >100%.<sup>77</sup> Recent findings from repeated, frequent overflights by aircraft have found that many large emission sources are intermittent. In the Permian Basin, Stokes et al.<sup>78</sup> reported that half of the tank battery sites (oil and gas production sites with liquid storage and handling equipment) that had emission rates of >10 kg/h during an initial aircraft overflight had much lower emission rates (<10 kg/h) when resampled a few days later.

Data from the commenter's deployment of continuous monitoring technologies in the field suggest that emissions from such intermittent emissions events are also substantial and may even be a dominant contribution to overall site emissions. These types of releases can result from process inefficiencies, such as faulty thief hatch systems causing emissions releases from a bad seal. For example, data from one site using continuous monitoring, displayed in the picture below, showed significant emissions from a process-related event that lasted 21 hours (caused by multiple attempts of plant engineers to start up a burner while the pilot flame was off). The picture also shows the signature of a small ongoing fugitive leak happening at the same time in one of the valves. Noteworthy is that the process event was 10 times larger in size than the leaking valve: [Timeseries plot showing examples of a process event and fugitive leak.]

<sup>77</sup> Schissel, C.; Allen, D. T., Impact of the High-Emission Event Duration and Sampling Frequency on the Uncertainty in Emission Estimates, Environ. Sci Technol. 2022, 9(12), 1063-1067, available at: <https://pubs.acs.org/doi/10.1021/acs.estlett.2c00731>.

<sup>78</sup> Stokes, S.; Tullos, E.; Morris, L.; Cardoso-Saldaña, F. J.; Smith, M.; Conley, S.; Smith, B.; Allen, D. T., An Aerial Field Trial of Methane Detection Technologies at Oil and Gas Production Sites, 2022, ChemRxiv:10.26434/CHEMRXIV-2022-G2MJT-V2.

Commenter (2340-Honeywell) states the figure below shows the recorded emissions with approximately a dozen Signal Scout detectors mounted on the tanks of a well-head operation over a period of 1 month. This shows that the emissions are not continuous, but are intermittent, with a duration typically of 12 hours. All large emissions (>10 kg/h) were positively matched with an activity at the site, such as a thief hatch opening or repair. A periodic inspection at the middle of the month likely would have missed this event or, if caught during the inspection, the operator would have missed an opportunity to reduce the emissions earlier by replacing the faulty seal to prevent the excess emissions.

Commenter (2340-Honeywell) goes further, survey-based studies indicate that large emission events account for the majority of total emissions:<sup>79</sup> [Plot with x-axis: Emission rate (kg/h) and y-axis: % of total emissions. Plot for well sites, tanks, pipelines, etc.]

Response II-5-174: EPA acknowledges the commenters' input. EPA recognizes the power of continuous systems to identify intermittent large events from ongoing maintenance events.

Comment: Commenter (2340-Honeywell) states continuous monitoring detection and characterization of the duration and magnitude of such releases will enable operators to better understand process inefficiencies that lead to such emissions and facilitate reduction strategies while improving their operations performance. These data will not only enable further reductions in emissions, but more accurate emission profiles and annualized inventories that facilitate the eventual adoption of quantitative emissions reduction targets and the ability to focus on more programmatic controls and improvements to address these preventable emissions.

Commenter (2340-Honeywell) states in addition to providing useful data to operators and regulators on intermittent emissions that would not otherwise be caught by periodic screening surveys, the failure to fully account for such emissions in FEAST modeling disadvantages the treatment of continuous monitoring in the regulatory framework. EPA explained in the preamble to the supplemental proposal that it used FEAST modeling to determine whether and how alternative periodic screening and continuous monitoring could provide equivalent emissions reductions to the BSER approach. EPA used FEAST modeling to establish the matrices for periodic screening, and to determine the action levels (based on simulated annual emissions) for continuous monitoring. If such limited duration, large emission events are substantial and not adequately accounted for in FEAST modeling, then EPA's equivalence analysis will underweight the value of continuous monitoring. Doing so will discourage the adoption of continuous monitoring and thereby perpetuate a lack of understanding of shorter-duration emissions events.

Response II-5-175: EPA acknowledges the commenters' input.

Comment: Commenter (2340-Honeywell) argues EPA should ensure that FEAST modeling does not self-perpetuate an unwarranted or "built-in" disadvantage for continuous monitoring in the

---

<sup>79</sup> Daniel H. Cusworth, Riley M. Duren, Andrew K. Thorpe, Winston Olson-Duvall, Joseph Heckler, John W. Chapman, Michael L. Eastwood, Mark C. Helmlinger, Robert O. Green, Gregory P. Asner, Philip E. Dennison, and Charles E. Miller, *Environ. Sci Technol.* 2021 8 (7), 567-573, available at: <https://pubs.acs.org/doi/10.1021/acs.estlett.1c00173>.

equivalence determination, which will limit EPA's ongoing understanding and data gathering necessary for such emissions control. To do so, EPA should (a) facilitate and encourage the deployment of continuous monitoring technologies by establishing more flexible parameters for their use as an alternative to BSER (as discussed above), and (b) ensure that it updates its FEAST modeling to better incorporate data on intermittent emissions events captured by continuous monitoring systems.

Commenter (2340-Honeywell) believes that FEAST modeling should be refined through the incorporation of continuous monitoring data showing significant emissions from shorter-duration events unlikely to be detected by periodic screenings. EPA should utilize data from continuous monitoring systems to update its FEAST modeling inputs and assumptions. The commenter's data indicate that current FEAST modeling suffers from a significant gap with respect to large emissions events of several hours that are common but not identified with intermittent inspection technology used to construct the model. This results in modeling that is currently biased in favor of periodic screening (*e.g.*, aerial survey) data because it does not account for the important advantages of continuous monitoring to address shorter-term emissions events that are an important part of the inventory. Incorporating data regarding limited-duration, intermittent emissions into FEAST modeling will facilitate the use of continuous monitoring technology (by removing a bias in favor of periodic screening) as well as improvements in process inefficiencies (*e.g.*, thief hatch releases) by enabling operators to better understand those releases. Use of such continuous monitoring technology to enhance the understanding of these emissions events will also better enable EPA to develop regulatory solutions to address them.

Response II-5-176: EPA acknowledges the commenters' input.

Comment: Commenter (2433-EDF *et al.*) states the FEAST model outputs depend on the emissions distributions used to conduct the modeling. In general, using a heavy-tailed emissions distribution—meaning one where a small number of large emission events represent a significant portion of the total—will result in a relatively greater effectiveness of frequent screening with less-sensitive technologies. With a less-heavy tailed distribution—meaning one consisting of many smaller leaks—more sensitive technologies that can detect those smaller leaks will be more effective. In FEAST, this means that OGI monitoring results in a greater effectiveness with a more normalized emissions distribution, while a technology like aerial monitoring results in a relatively greater effectiveness with a heavy-tailed distribution.

Commenter (2433-EDF *et al.*) notes while heavy-tailed distributions have been found across basins (and in all basins, a subset of emission events disproportionately contribute to total emissions), in most basins, the bulk of the emissions are still generated smaller leaks. Thus, capturing the large emission events is necessary but not sufficient and the approach, across basins, should capture the entire distribution of leaks. Because emissions distributions vary significantly by basin, ensuring that technologies can achieve equivalent reductions across basins requires using an averaged distribution that reflects both individually smaller (but collectively significant) leaks as well as super-emitters.

Commenter (2433-EDF *et al.*) states the default FEAST emissions distribution is based on five field measurement studies and contains all the leaks found in those studies. EPA excluded leaks

that would not be addressed through the proposed monitoring requirements and supplemented the default distribution with two more recent studies. In addition, EPA accounted for large, super-emitting events with data from Cusworth *et al.*, 2021. The default FEAST distribution categorizes emissions into leaks, abnormal vents, and permissible vents. Because permissible vents are not mitigated by LDAR standards, EPA properly excluded this category of emissions.

Commenter (2433-EDF *et al.*) continues, the resulting averaged emissions distribution aligns with the regulatory structure and accounts for equipment component leaks, tank leaks, and large emission events based on data from seven studies across diverse basins. The distribution also accounts for the intermittency of emissions because it is based on studies that consist of actual field observations and rigorous statistical analyses. Emissions captured in these studies are those that were present at the time of observation. The resulting snapshot in time of emissions includes some events that were emitting and some that were intermittent, thereby incorporating intermittency. These studies further address intermittency through statistical analysis.

Commenter (2433-EDF *et al.*) states, as should be expected, FEAST modeling shows that a higher survey frequency improves performance when super-emitters are taken into account, regardless of the intermittency. While intermittent events can be missed if their average duration is lower than the survey frequency, FEAST modeling also shows that the emission reductions from advanced technologies compared to OGI are directionally higher as the duration of the super-emitter events increases. This is because longer super-emitter events result in a larger contribution to total cumulative emissions from super-emitters, which can be mitigated even with higher detection threshold technologies. While it is true that more empirical data is needed to further characterize average duration of intermittent super-emitter events across different basins,<sup>80</sup> current FEAST modeling captures the impact of super-emitter distributions in terms of the contribution to total emissions. This allows FEAST to produce robust frequencies for both OGI and advanced technologies to achieve significant emission reductions. Because many emissions from oil and gas sources are intermittent, frequent monitoring with OGI, advanced technologies, or both is necessary to ensure adequate mitigation.

Commenter (2433-EDF *et al.*) states to better understand the potential implications that altering the duration parameter in FEAST could have on EPA's proposed frequencies and mitigation effectiveness generally, the commenter recreated EPA's modeling but adjusted the persistence of super-emitters.<sup>81</sup> EPA's modeling does not alter the duration parameter, but instead holds super-emitters constant like all other types of emissions in the model. The commenter remodeled the same detection thresholds used by EPA with the same input assumptions but altered the duration of super-emitters to 5, 15, 45, and 90 days. The commenter found that this sensitivity analysis would not impact equivalency, or the frequencies proposed by EPA in the matrices. Given the

---

<sup>80</sup> Cardoso-Saldaña, *supra* note 169, at 20 (2022), ("There is also lack of data on the temporal characteristics of high-emitters, which is a very sensitive parameter. Future work should focus on obtaining information on duration of high-emitters and on root-cause analysis, which will be particularly relevant when doing LDAR modeling coupled with a process-based simulator that includes routine emissions and with a finer simulation temporal resolution.").

<sup>81</sup> See Arvind P. Ravikumar, Role of Intermittency in Methane Emissions Reduction (Feb. 2023) (included as Attachment J to the commenter's letter).

results of this sensitivity analysis, and for the reasons described, the commenter does not recommend that EPA alter the duration parameter for super-emitters in its equivalency modeling.

Commenter (2433-EDF *et al.*) states when the duration parameter is shortened for super-emitters, it results in fewer overall emissions and also in super-emitters making up a smaller fraction of total emissions. This means that more frequent screening (*i.e.*, monthly) detects and can therefore mitigate more super-emitters than less frequent methods (*i.e.*, quarterly). But because the overall contribution of super-emitters is significantly lower with shorter durations, the more frequent detections are less important to overall mitigation and do not impact equivalence. These results also underscore the need for an annual OGI pairing with the higher detection threshold technologies. With greater intermittency and lesser overall emissions from super-emitters, the annual OGI pairing becomes increasingly important for mitigating other types of emissions that then represent a larger portion of the total. Results of this modeling are displayed below, and the entire analysis is located in attachment J to the commenter's letter.<sup>82</sup> Figure 5 shows how the relative contribution of super-emitters to total emissions declines with greater intermittency.

[Figure 5 Total methane emissions by category bar chart]

Commenter (2433-EDF *et al.*) notes Table 9 below shows the effects on equivalency when the duration parameter is altered to account for intermittent super-emitters. It shows site-level emissions after quarterly OGI surveys and periodic screening surveys with three detection thresholds (with and without an annual OGI pairing) for three durations parameters (persistent, 90 days, and 15 days). As shown, the results do not support altering the frequencies proposed in EPA's matrices (equivalency condition shown in orange).

[Table 9 site level emissions with three detection thresholds for three duration parameters]

Commenter (2433-EDF *et al.*) states while it is important to understand the impacts of different intermittency assumptions on equivalence, the available data and modeling does not support revisiting the frequencies in EPA's proposed matrices. EPA's FEAST modeling is supported by seven different peer-reviewed studies based on field observations that incorporate intermittency and capture typical conditions. Absent explicit, peer-reviewed data characterizing intermittency that significantly affects the emissions distribution used in FEAST, additional modeling scenarios that alter the persistence parameter are not necessary and would have minimal impact on the outcomes. The commenter therefore recommends that EPA not alter the FEAST modeling underlying the proposed matrices. EPA should, however, assess the potential impact of intermittency based on data and information submitted during the comment period, such as that described above.

Commenter (2433-EDF *et al.*) adds numerous commenters have submitted modeling results, including Joint Environmental Commenters. In particular, some commenters have claimed, sometimes on the basis of their modeling results, that aerial screening technologies at lower

---

<sup>82</sup> Id.

frequencies, like quarterly, can be equally effective as quarterly OGI.<sup>83</sup> This claim, however, is specific to certain basins or operations with a disproportionately high share of super-emitters. Because that is not the case nationally, it would be arbitrary for EPA to rely on basin- or operator-specific assumptions about emissions distributions. Doing so would likely reduce screening frequencies in higher-emitting basins, resulting in approaches that would not be effective in other basins with normalized emissions distributions. And while less frequent monitoring in higher-emitting basins may lead to greater percentage reductions than it would elsewhere, it will not lower emissions to a level commensurate with the rest of the country. Capturing super-emitters is necessary but not sufficient and overall performance should not be sacrificed by only focusing on capturing individual high-emitting events. Further, with full implementation of EPA's proposal, including repeated LDAR surveys, the prevalence of large emission events should be greatly reduced. If EPA's modeling included a too heavy-tailed distribution, it would result in a matrix that would quickly become outdated and ineffective as super-emitters are reduced.<sup>84</sup>

Commenter (2433-EDF *et al.*) states to illustrate the differences in mitigation effectiveness across basins, the commenter also conducted FEAST modeling of OGI, Aerial 1 (lower detection threshold with and without annual OGI), and Aerial 2 (higher detection threshold with and without annual OGI) using two basin-specific emissions distributions.<sup>85</sup> For a heavy-tailed distribution, the commenter used data from the Permian, and for a less-heavy tailed distribution, the commenter used data from the Marcellus. Both emissions distributions include recent data on super-emitters from the respective basins. The results show how different technologies perform in different basins and demonstrate how higher detection threshold technologies are far less effective in basins with more normalized distributions. This underscores the importance of EPA using a nationally averaged distribution to ensure equivalent reductions and account for the decreasing prevalence of super-emitters anticipated in coming years and with implementation of EPA's proposal. The results also underscore the need to ensure permissible technologies are sensitive enough to detect the significant fraction of total emissions--often the majority--that are caused by smaller emissions. Takeaways from the basin-specific modeling are summarized below.

[Table 10 Modelling Results in Marcellus and Permian by Category]

Commenter (2433-EDF *et al.*) states the equivalency modeling results from the Marcellus demonstrate that aerial technologies cannot achieve the same level of reductions as OGI when used at the same frequency. The addition of an annual OGI survey is particularly important under this scenario, as it helps reduce the smaller leaks below the detection thresholds of the aerial

ID. No. EPA-HQ-OAR-2021-0317-0820) (Jan. 31, 2022), <https://www.regulations.gov/comment/EPA-HQ-OAR-2021-0317-0820>.

<sup>84</sup> EPA may consider addressing outlier situations through the AMEL process. However, for the reasons discussed in this section, any AMEL approaches should be time-limited, and EPA should continually revisit the underlying assumptions and update them for accuracy.

<sup>85</sup> Arvind P. Ravikumar, FEAST:US – Basin-level Modeling of LDAR Program for Methane Emissions Mitigation (included as Attachment K to the commenter's letter).

technologies. As shown below, quarterly OGI is more effective than aerial technologies in a basin with a more normalized emissions distribution.

[Figures 6 OGI Fugitive Emission Reduction % by survey frequency bar chart, Figure 7 Aerial 1 Fugitive Emission Reduction % by survey frequency bar chart, Figure 8 Aerial 2 Fugitive Emission Reduction % by survey frequency bar chart]

Commenter (2433-EDF *et al.*) notes the full results of this modeling are presented in attachment K and underscore the need for more frequent screening and, in some cases, an annual OGI pairing, in order to achieve equivalency across diverse basins. The results align with and support EPA's proposed matrices and annual OGI pairings.

Over the past two years, Commenter (2433-EDF *et al.*) has conducted FEAST modeling with different types of input assumptions, including using basin-specific emission distributions and the intermittency assumptions described above, as well as the nationally representative modeling submitted with our initial comments.<sup>86</sup> The key takeaways from this work include:

- Using rigorous and nationally representative emissions distributions is critically important—for EPA's section 111 standards, a nationally-averaged distribution is necessary to ensure advanced technologies deliver equivalent or better emission reductions across diverse basins.
- When super-emitters are less prevalent in the emissions distribution—as is the case in many basins already and should result more broadly from implementation of EPA's final regulations—higher-detection-threshold technologies are less effective.
- Altering intermittency assumptions through the duration parameter in FEAST has no significant impact on equivalence and reduces the overall contribution of super-emitters, thereby increasing the importance of OGI pairings with high-detection-threshold technologies.
- At higher detection thresholds, reductions eventually flatline even when frequency is increased—this is because a certain fraction of emissions cannot be detected or mitigated by these technologies.
- An annual OGI pairing can help address the fraction of emissions that fall below a technology's detection threshold but will not significantly increase total reductions in most cases; and
- Technologies with very high detection thresholds may not reliably achieve reductions equivalent to quarterly OGI, especially in the longer-term, and are therefore not suitable for regulatory deployment.

The results of the commenter's (2433-EDF *et al.*) modeling work, across a range of scenarios and with varied inputs, demonstrate that EPA's FEAST modeling and proposed matrices are robust and resilient to a range of sensitivities.

Response II-5-177: EPA acknowledges the commenters' support of EPA's FEAST Modeling.

Comment: Commenter (2387-CSU) provides results of field observations suggesting that EPA's assumptions used for modeling purposes, do not reflect the behavior of intermittent emitters, large or small, in the field environment. This means that the modeling overestimates the effectiveness of OGI and AVO relative to continuous monitoring.

The commenter (2387-CSU) provides results based upon preliminary analysis of data provided by two continuous monitor solutions (Kuva and LongPath) that have been deployed on multiple facilities for extended periods. Detailed information on the study's findings can be found in the commenter's letter.

The commenter (2387-CSU) explains that two sets of simulated results were developed:

- What is the probability that the emitter would be detected during one year of OGI surveys?
- If detected sometime in 10 years, how long before the first detection?

These two results are multiplicative, as the second occurs only when the first is true: when detected if successful. Even for 10 years simulations, many simulated OGI survey programs never detected the emitter.

The commenter (2387-CSU) shows results for Kuva, where annual success rates range from 3.7% [0.16% to 12%] for annual surveys to 31% [1.2% to 78%] for monthly surveys. In remainder of simulated years, the emitter was never detected. Using the full 10-year simulation, when an emitter was detected, the time to make that detection is 5.2 [3.6 to 6.2] years for annual surveys, dropping to 2.8 [0.69 to 5] years for monthly surveys.

Results for LongPath show that annual success rates range from 32% [12% to 67%] for annual surveys to 98% [80% to 101%] for monthly surveys. These values were higher than the Kuva data for two reasons. First, the LongPath records start after the emitter is detected, *i.e.*, after the alarm protocol identified an emitter with some level of persistence. This biases the LongPath data toward longer duration emitters, which is clearly seen in the results. Second, LongPath's longer observation time at any one location (21 [13 to 37] minutes) sets a minimum emitter duration that is several times longer than Kuva's data (5.9 [1.9 to 11] minutes).

According to the commenter (2387-CSU), results in the two datasets clearly illustrate how sensitive detection simulations are to seemingly small variations in assumed duration – detection changes of nearly 8:1 for annual surveys and 3:1 for monthly surveys.

Using the full 10-year LongPath data simulation and considering only MC iterations where the emitter was successfully detected, annual surveys detected the emitter in 3 [1.5 to 4.4] years, dropping to 0.3 [0.12 to 0.66] years for monthly surveys. Actual detection timing by the CM solution is not in these data sets, as they start after the detection occurred.

The commenter (2387-CSU) notes that the current data sets lack sufficient information to determine the fraction of facilities emitting at any one time, which would be required to compare detections with the Cusworth *et al.* data set used in the attachment. However, it is likely that the intermittency shown here is representative of many large emitters detectable by aircraft.

Commenters (2333-LongPath, 2387-CSU) state intermittency should be included in modeling. Prior studies on intermittency of super emitters include Stokes *et al.*<sup>87</sup> and Wang *et al.*<sup>88</sup> The data collected by Kuva and LongPath validate intermittency data published in literature that indicate more than 90% of super-emitters are intermittent with a duration of multiple hours to a day.

Commenter (2387-CSU) states CM solutions detect emitters not commonly found by OGI or AVO surveys. The vast majority of the detections represented in these data sets were discovered first by the CM solution. The intermittency of the emitters likely made follow-up more difficult; personnel arriving hours to days after the detection were highly unlikely to see the emitter. However, operators found it useful to review timing and location data from the CM solution to assist with follow-up diagnostic. These (qualitative) observations suggest that, without the repeat detections by the CM solution to identify the time-domain pattern of emissions, follow-up is often challenging. Therefore, the value of near-continuous monitoring goes beyond one-time-per-emitter detections from survey methods. The commenter encourages EPA to positively weight the ability of CM solutions to detect highly intermittent emitters when calculating parameters in the proposed matrix.

Commenter (2387-CSU) states the emitters reported in this data may be due to process problems or to fugitive emissions. Since well pads include many cyclic processes, all types of emitters may exhibit intermittent behavior. Examples: A well pad where wells use plunger lift behave in a highly cyclic fashion – long periods with no flow, interspersed with short periods with high flow. If wells flow continuously, snap-acting dump valves on separators may produce similar cycling behavior. Emitters may also depend on interaction between multiple factors. For example, a pressure relief valve on a tank may vent only if liquid level in the tank is above some threshold and multiple wells/separators are flowing at the same time. Most of the data used here, and most detections in the Cusworth *et al.* super-emitter distribution, are likely due to abnormal process conditions - either control failures or excess emissions where controls are not required. The commenter encourages EPA to consider a wide range of emitter types in setting parameters for the proposed matrix. The current approach considering only narrowly defined fugitive emissions is not aligned with field experience.

Response II-5-178: EPA acknowledges the commenters' input. EPA agrees that the continuous and near-continuous methane monitoring systems are much better in identifying intermittent emission points as opposed to the periodic screening. EPA does not have sufficient information regarding the intermittency of these large events to necessitate changes to the FEAST modeling.

<sup>88</sup> "Multiscale Methane Measurements at Oil and Gas Facilities Reveal Necessary Frameworks for Improved Emissions Accounting", <https://pubs.acs.org/doi/full/10.1021/acs.est.2c06211> (Oct. 6, 2022)

### ***5.9.9 Proposed Requirements Discourage Use***

Comment: Commenters (2235-SLB, 2333-LongPath) state the proposed regulations contain many additional elements for continuous monitoring that complicate an operator's use of alternative screening technology, thus discouraging use of continuous monitoring technologies over the certainty of a prescribed approach for use of older technology. These additional elements do not relate directly to the proposed continuous monitoring technology itself but rather amount to requiring additional work unrelated to technology choice.

Commenter (2235-SLB) adds examples of such additional elements required for continuous monitoring beyond what is required for AVO and/or OGI fugitive emissions monitoring include: §60.5398(c)(2)(iii), §60.5398(c)(2)(vi), §60.5398(c)(2) (ix and x), and §60.5398(c)(6).

Response II-5-179 : EPA acknowledges the comment and EPA has made revisions to the continuous monitoring approach as detailed in Section X.B.2 and XI.B.2 of the preamble of the rule, specifically in regards to the accounting of background methane emissions from a site. EPA considers to the continuous approach as less onerous than the prescriptive fugitive monitoring approaches reliant on find and fix approaches. The continuous approach is less burdensome on what an owner or operator must do, and instead allows for an owner or operator to take the actions they need to do to maintain their emissions below the action-level.

Comment: Commenter (2333-LongPath) recommends that, at a high level, EPA consider how a standard will act in the context of a voluntary program to go “above and beyond” BSER OGI requirements, rather than how a requirement and standard would best be crafted in a vacuum (e.g., a regulatory program that requires continuous monitoring).

Commenter (2333-LongPath) highlights as EPA points out, diverse stakeholders are interested in how EPA can “promote and accommodate [the] development and use” of “these new tools for methane identification and quantification”. Because EPA has defined BSER as periodic OGI, EPA will need to avoid any regulatory requirements that may inadvertently disincentivize continuous monitoring and other advanced monitoring systems that go beyond that basic standard. Conscious effort, in the form of incentives and careful avoidance of inadvertent disincentives, will be needed to effectively promote and accommodate continuous monitoring.

Commenter (2333-LongPath) offers the following examples of what would stifle the use of an alternative monitor:

- Increased emission data reporting requirements.
- Increased reporting requirements in general.
- Lower Action Thresholds requiring action on smaller emissions.
- Action Thresholds (Levels) that do not account for process emissions.
- Action Levels and programs that have not been modeled directly in FEAST to assess equivalency.
- Standards that go beyond methane to require or account for VOCs where other alternatives do not.
- Requirements to act on emissions with higher frequency or in a shorter timeframe.

- Use of simulation models with overly optimistic parameterizations of AVO and OGI efficacy.
- More prescriptive or intensive “up-time” requirements, particularly for continuous monitors.
- More complex data operationalization, for example the use of multiple action levels
- A general lack of “incentives” to participate in a more comprehensive program.
- Lack of accounting for the added cost of follow-up under the super-emitter program for emissions that have already been addressed by continuous monitoring.

Response II-5-180 : EPA acknowledges the comment, the continuous approach is an alternative to the BSER, EPA has made some revisions in this approach as described in Section X.B.2 and XI.B.2 of the preamble of the final rule.

Comment: Commenter (2333-LongPath) strongly recommends that record-keeping requirements be aligned across advanced technologies and with OGI. From §60.5242b, operators will be required to record mass emission rate information about each fugitive emission source identified. However, in our reading of the proposal, periodic screening is subject to no such requirement. Requiring this level of data sharing of some technology classes and not others risk severely disincentivizing operator use of technologies for which much more detailed reporting on emissions is required. The commenter respectfully requests more information on why operators would be required to report more data on emissions with one technology compared with others. The commenter further requests that technologies with greater data capabilities, for example the ability to produce a valid mass emission rate, not be disincentivized by having a greater burden for record keeping and data transparency. Relatedly, the commenter requests more information on why operators would be required to report each methane mass emission rate reading determined by the system, and each daily average, 7-day, and 90-day mass emissions rate which was determined in accordance with 60.5398b(c)(5). In the supplemental proposal, continuous monitoring is voluntary. The commenter therefore respectfully suggests that requiring more intensive operator data transparency, record-keeping and data sharing than any other alternative could strongly disincentivize operator use of continuous monitoring.

Response II-5-181: EPA recognizes the input from the commenter, The recordkeeping and reporting for alternative technology required in the rule are consistent with what a federal, state, local, or tribal authority need to evaluate compliance with the applicable regulations.

Comment: Commenter (2333-LongPath) noted that, if the continuous monitoring system is administered through a third-party provider, contact information where the provider can be reached 24-hours a day be provided. This is a highly burdensome requirement for small businesses, such as LongPath, that operate systems for customers. The commenter has detailed service agreements in place with all operators, with extensive details on safety, insurance and other risks and liabilities. The commenter requests further information on why EPA would require a third-party provider to be reachable at night or over weekends, given that this would be extending beyond the agreements already made between the third-party and the site managers or operators.

Response II-5-182: In order for the continuous monitoring work practice to be equivalent to the fugitive emissions BSER, the continuous monitoring system must be able to provide data on an ongoing basis. This is why EPA included a maximum system downtime in the rulemaking. It is critical that owners and operators be able to contact third-party providers any time that the system goes down, otherwise they face the risk of being out-of-compliance with the downtime requirement.

EA recognizes that not all third-party providers may not be readily available 24-hours a day, but we consider it important to maintain this requirement from the proposed rule.

#### ***5.9.10 Corrective Action/Timeline***

Comment: Commenter (2428-API) supports timely and flexible follow-up actions to address any leaks found and request similar repair timeframes consistent with §60.5397b and §60.5416. The commenter supports the flexible language proposed in §60.5398b(c)(6) that describes initiating an investigative analysis to determine the primary reason for the emissions detected. The commenter believes an operator can perform this investigation in numerous ways including using site-specific data. Due to the various ways that continuous monitors may be used for emissions detection, different follow-up actions may be appropriate for this technology when compared to AVO, OGI, or Method 21. The commenter offers the following recommendations (more details are provided in the commenter's letter):

- The timeline for initiating the investigative analysis should be extended from 5 calendar days to 5 business days.
- EPA should clarify that the investigative analysis and corrective actions can be conducted remotely where feasible.
- EPA should also clarify that limited or full site follow-up OGI surveys should be allowed in response to emissions detected by continuous monitoring depending on the localization performance of the continuous monitor(s).
- The timeline for completing the investigative analysis and initial corrective actions should be 30 days, not 5 days as proposed.

Response II-5-183: EPA recognizes the commenter's input. EPA has revised the final rule for continuous monitoring as described in Section X.B.2 and XI.B.2 of the preamble of the final rule. EPA has provided the owner or operator the flexibility to take the appropriate measures when conducting the investigative analysis.

Comment: Commenter (2348-EWTC) states an appropriate deadline for corrective actions should be uniform across all monitoring methodologies. If a deadline is lower than the super emitter threshold, it should be within 45-day window. Super emitters should be addressed as quickly as possible after determining the root cause of the event. It is important to determine the typical timeline in the industry to assess root cause, and to establish a standard.

While commenter (2348-EWTC) understands that corrective action should be taken to eliminate a leak once discovered, treating technologies equally in this manner may not be appropriate (except for super-emitters). A continuous monitoring device, for example, provides earlier notice

of emerging fugitive emissions that may/will deteriorate over time; continuous monitoring also detects periodic emission events that are less likely to be discovered by a quarterly or semi-annual inspection regime.

Response II-5-184: EPA acknowledges the commenter's input; EPA has provided more flexibility for continuous monitoring in part due to the lower action-levels and that these systems have the ability to measure the intermittency of an emission source. This program is designed to only trigger action when the emission rates exceed a rate greater than what is expected for the BSER program, however we expect owner or operators to continuously repair any excess emissions sources, so they maintain their rates below the action-levels.

Comment: Commenter (2333-Longpath) strongly urges the EPA to find ways to incentivize operators to use continuous monitoring, and not the reverse. Most periodic survey monitors commercially available today do not provide notification of an emission to an operator within 5 days. This means that these technologies are not capable of enabling an operator to make an initial corrective action within a 5-day timeframe. Therefore, the commenter respectfully suggests that these time frames be made more technology neutral.

Response II-5-185: EPA acknowledges the commenter's input; EPA considers the flexibility associated with the flexible work practices under the continuous monitoring to be an adequate incentive to use continuous monitoring.

#### ***5.9.11 Cost of Continuous Monitoring***

Comment: Commenter (2325-Aclima) states the annual per-well cost of complying with the proposed rule is estimated to range from \$2,490 for biennial OGI monitoring to \$8,140 for monthly OGI monitoring at the average well site. Rolled up, that's between \$54,780 to \$179,080 per year for the average owner of 22 wells. Networked small sensor technologies can be implemented at a fraction of these costs, with the enhanced benefit of continuous, networked monitoring across all wells.

Response II-5-186: EPA acknowledges the input from the commenter. The use of continuous monitoring in the rule is an alternative to the BSER and not a requirement, therefore EPA has not considered the cost of these systems in this rule.

Comment: Commenter (2440-NNS) notes compared to state-of-the-art continuous monitoring systems, the proposed BSER of bimonthly AVO inspections and quarterly OGI inspections provides neither the greatest emissions reduction, nor does it provide the most economical solution. Continuous monitoring technology provides immediate detection of leaks and the greatest reduction in emissions for as little as \$1600 per year for Major Production sites on a Total Cost of Ownership basis. This price includes hardware installation, automated, continuous monitoring software and support, all required maintenance, automated leak notifications, visualization of the leak location via computer, tablet or phone and automated reporting of emission statistics. The cost of CP-CMS is much less than Table 18 at \$4232 the annual cost for this monitoring.

Commenter (2440-NNS) states from an emissions reduction perspective, this will reduce average leak detection times from 45 days to less than one day for continuous monitoring systems. From a cost point of view, it compares well with the figures in Tables 10 and 15 at \$660 for quarterly AVO inspections.

Commenter (2440-NNS) encourages the EPA to also allow continuous monitoring technology solutions as a BSER for low production assets. The commenter recognizes that the performance of any specific continuous monitoring solution depends on verification of the performance and would agree that the regulations need to account for such validation.

Response II-5-187: EPA acknowledges the input from the commenter. The use of continuous monitoring in the rule is an alternative to the BSER and not a requirement, therefore EPA has not considered the cost of these systems in this rule.

### ***5.9.12 Root Cause Analysis***

Comment: Commenter (2226-Thermo Fisher) notes continuous monitoring technologies lead to greater, more timely emission detection. EPA proposes an alternative work practice standard, in which a root cause analysis is undertaken when the methane emissions rate exceeds certain levels at the boundary or fenceline of a facility to account for upwind or meteorological effects. This requires technologies that quantify site-level methane emissions rates at a detection level an order of magnitude less than the proposed action level and produce a valid mass emissions rate at least once every twelve hours. The commenter supports the inclusion of continuous monitoring approaches, as the commenter agrees this type of measurement provides better temporal resolution to catch a leak when it begins.

Commenter (2226-Thermo Fisher) expresses that in some cases, a combination of technologies for measuring and monitoring methane emissions is the best solution to ensure the detection of all emissions is possible. For example, a combination of a toxic vapor analyzer and OGI would provide ample coverage. It is worth noting adequate training needs to be readily available for OGI operators. OGI cameras have variations in their effectiveness at finding leaks based on the individual operating them. The accuracy of data collected using OGI cameras relies on good monitoring practices. The EPA should recognize that the data collected can be vastly different based on the individual's skill set and thus can make gas leaks difficult to quantify accurately. The commenter supports the EPA for advocating for continuous monitoring because it would ensure measurements are taken more often.

Response II-5-188: EPA acknowledges the support and input from the commenter.

Comment: Commenters (2298-Pioneer, 2363-CEMC, 2402-DGCC, 2428-API, 2448-Project Canary) have concerns that the investigation takes the form of a "root cause analysis" and ask EPA to clarify what is required for a "root cause analysis." EPA requires root cause analyses for any detections identified with advanced technology but not with OGI nor the compliance standards for non-fugitive emission equipment. Commenters (2177-Southern Ute, 2238-Southeastern Ohio Oil and Gas Association (SOOGA), 2298-Pioneer, 2363-CEMC, 2402-DGCC, 2428-API, 2448-Project Canary) argue the term "root cause analysis" is a term of art

under other non-EPA regulatory programs and is associated with a very specific and extensive set of analysis requirements, which the commenters believe would not be appropriate for the contexts addressed in the NSPS OOOOb and EG OOOOc regulations. Commenters (2177-Southern Ute, 2238-SOOGA) add a root cause analysis is overburdensome.

Commenters (2177-Southern Ute, 2363-CEMC, 2402-DGCC, 2428-API, 2448-Project Canary) request that the term “investigative analysis” should replace “root cause analysis.” If the EPA intends that such an analysis have particular elements, it should specify them.

Commenters (2298-Pioneer, 2428-API) continue, there is also a legal issue with how this term can be interpreted in any legal or enforcement proceedings, as well as how it could obligate operators to actions or additional requirements that are not necessarily included within this proposed rule. This could potentially involve a months-long endeavor and discourage operators from choosing to comply using advanced technology. Therefore, the commenters suggest that EPA should specify more precisely what is required to identify any process failures resulting in emissions and adopt a more accurate term such as “investigative analysis”, “causal examination”, or “proximate cause” and define the term in the Final Rule, specifying more precisely what is required to identify any process failures resulting in emissions.<sup>89</sup>

Response II-5-189: EPA acknowledges the commenters’ input, as explained in Section X.B.2 and XI.B.2 of the preamble of the rule, EPA has revised the rule to remove the “root cause analysis” language in favor for “investigative analysis”.

Comment: Commenters (2333-Longpath, 2399-GPA, 2428-API) suggest that references to “root cause analysis” be amended to “investigative analysis.”

Commenter (2399-GPA) adds that EPA does not define what is meant by a “root cause analysis” or what documentation it expects such an analysis to produce. As discussed in more detail below, a root cause analysis involves a formal systematic investigation, using multiple potential methodologies, into the potential causes of an incident that identifies corrective actions to reduce the probability of similar future incidents. See Section VII, *infra* (discussing root cause analysis requirement for the super-emitter program). Root cause analyses typically involve several specialized team members and take far longer than the five days specified in the proposed regulatory text. EPA has not considered the costs, or the time required to perform a formal root cause analysis. The commenter recommends that EPA use a more generic and appropriate term, such as “evaluation,” in describing the examination and determination described in the proposed regulatory text. Even as to an evaluation, EPA should allow a minimum of 30 days to make the necessary assessment. If a “root cause analysis” is retained, EPA should allow at least 90 days to complete that more formal and complex analysis.

---

<sup>89</sup> 87 Fed. Reg. 74741; this recommendation is in response to EPA 's request for comments: "The EPA is soliciting comment on the proposed requirements for the root cause analysis and corrective action, the timeframes for conducting these activities, and the requirement for corrective action plan submittals." 87 Fed. Reg. 74745.

Response II-5-190: EPA acknowledges the commenters' input, as explained in Section X.B.2 and XI.B.2 of the preamble of the rule, EPA has revised the rule to remove the "root cause analysis" language in favor for "investigative analysis".

Comment: Commenters (2363-CEMC, 2402-DGCC, 2448-Project Canary) add that when advanced technologies such as CEMS, are utilized, desktop evaluation will usually suffice to identify the cause of some types of exceedances, negating the need for onsite AVO or OGI follow-up inspections. Initiating an investigative analysis in response to the exceedance of an applicable action level may be conducted as follows:

- Desktop or Remote investigative analysis. A desktop or remote investigative analysis could include:
  - verbal or written communications with onsite personnel to verify the cause of an exceedance,
  - review of remote sensing or parametric data which could indicate the cause of the exceedance,
  - or other data acquisition methods which can adequately determine the source of the emissions and ensure the cause of emissions has been resolved.
- If the desktop or remote investigative analysis does not identify the cause of the exceedance, then the operator should conduct either:
  - Onsite AVO investigative analysis. If the source and cause of the emissions resulting in an exceedance of an action level cannot be determined through a desktop or remote investigative analysis, the owner or operator may perform an AVO investigative analysis to determine the cause; or an OGI camera or Method 21 investigative analysis. If the source and cause of the emissions resulting in an exceedance of an applicable action level cannot be determined through either of the previous methods, the owner or operator shall perform an OGI camera or Method 21 inspection. The inspection can be limited in scope, based on any source localization data from the continuous monitoring system, narrowing the area where the investigation should be performed to the area most likely to be the source of the leak.

Comment: Commenter (2307-Qube) suggests that the EPA consider a tiered approach to the root-cause analysis as many emissions events can be diagnosed using the data from the continuous monitoring system before sending someone to site, and suggest the following approach:

- Remote diagnosis of the emissions event using the continuous monitoring system
- Follow-up with an AVO or OGI inspection if the contributing emissions cannot be diagnosed remotely

In the commenter's (2307-Qube) opinion, continuous monitoring systems are one of the most effective tools for verification of repairs. This is because following a repair, the operator can immediately see a reduction in the quantified emissions at a site. In general, the commenter believes that seeing an emissions reduction following a repair at a facility has been one of the key reasons operators are adopting continuous monitoring technology.

Response II-5-191: EPA acknowledges the commenters' input. EPA has does not prescribe what investigations an owner or operator must conduct, and instead relies on the owner taking whatever action is necessary to get mass emission rate below the action level, as measured by the continuous emissions monitoring system.

### ***5.9.13 Follow-up and Continuous OGI***

Comment: Commenter (2405-Bridger) notes although the Proposed Rule requires follow-up OGI screening for emissions detected during periodic screening,<sup>90</sup> equivalent requirements are not delineated for the alternative continuous monitoring program, which damages the intended technology agnostic nature of the rule. Site-level emission action levels for the continuous monitoring alternative approach could be triggered by an aggregate set of emissions, and OGI screening would help locate individual emission sources and make sure the aggregate methane flux is accounted for. To reduce the OGI follow-up requirement to only what is necessary to reduce emissions, the scope of OGI surveys should correspond to the localization capabilities of the continuous monitoring method (as was recommended for the periodic screening approach in Comment 1.2). Continuous monitoring systems localize emissions with different degrees of precision, which has been characterized by independent researchers.<sup>91</sup> In order for the EPA to continue developing a consistent, practical, and technology agnostic framework to use advanced methane sensing technologies for emissions monitoring, the commenter urges the EPA to include the same OGI follow-up requirements for the continuous monitoring alternative approach as for the periodic screening alternative approach.

Response II-5-192: EPA recognizes the commenter's input; he has chosen not to require prescriptive requirements for follow-up actions when an action-level is exceeded. Because the standard is based on a whole site emission rate, any action which gets an emission rate below the action level is adequate.

Comment: Commenters (2363-CEMC, 2421-Teledyne, 2448-Project Canary) note that the EPA is aware of other continuous monitoring systems using technologies that are not designed to quantify a site-level methane emissions rate (e.g., camera-based continuous monitoring systems). While the EPA believes these systems could be useful in a methane mitigation program, they are not suitable for the proposed alternative continuous monitoring approach because they are not capable of quantifying site-level methane emissions, which is the basis for the equivalency demonstration of the proposed alternative continuous monitoring approach.

Commenters (2363-CEMC, 2448-Project Canary) are aware of camera-based continuous monitoring systems that are in use today or under development. As with other types of surveying and monitoring technologies, the commenter anticipates rapid innovation and improvement in their capabilities. Given the developments in this area, the commenter sees no rationale for the EPA to codify a categorical preclusion of any consideration of such technologies under the

---

<sup>90</sup> It is unclear if FEAST modeling used to investigate equivalence involved OGI follow-up. In the 'RS Run Script plane.txt' python script provided in the docket, the continuous monitoring LDAR program object, 'cont\_monitor' did include OGI in the 'dispatch\_object' field. Regardless, OGI follow up was not specified in the Proposed Rule.

<sup>91</sup> Bell, C., Ilonze, C., Duggan, A. & Zimmerle, D. Performance of continuous emission monitoring solutions under single-blind controlled testing protocol. ChemRxiv (2022) doi:10.26434/chemrxiv-2022-4hc7q-v2.

alternative test method provisions—whether as periodic surveying technologies or continuous monitoring systems. Such a preclusion is inconsistent with the policy objective of promoting technology innovation that is the foundation of the rest of the Supplemental Proposal.

For these reasons, commenters (2363-CEMC, 2448-Project Canary) respectfully recommend that the EPA withdraw this preclusion and instead evaluate proposed camera-based continuous monitoring systems on a case-by-case basis under the alternative test method provisions.

Response II-5-193: EPA agrees that camera-based solutions could be used as periodic screening technologies and has revised the final rule as detailed in Section X.B.1 and XI.B.1 to allow their use for those purposes.

Comment: Commenters (2235-SLB, 2340-Honeywell) request that EPA not generically disparage categories of technology<sup>92</sup> such as cameras in its proposed rule based on past information. Technology advances and adaptations continue to progress. While EPA's comment that camera technology is not capable of quantification may have been intended to refer to well-known OGI cameras used for decades, it could inadvertently discourage use of all camera technologies as advanced alternative technologies, now and in the future. The commenters request EPA not categorically exclude a promising and suitable type of technology from use based on the limitations of past examples of that technology genre.

Commenter: (2235-SLB) indicates that new camera and camera-combined technologies do exist that are capable of not only providing imaging but also quantifying emissions, thus satisfying the requirements for continuous monitoring technology.<sup>93</sup> Current state-of-the art camera systems, such as lidar-based gas imaging cameras, available from SLB and QLM, have been shown in multiple independent trials and evaluations (including at the METEC facility in 2022) to be capable of very accurate detection, localization and quantification of methane flow rates at great distances. When such a lidar system is deployed at an appropriate vantage point at an O&G site, the lidar camera, mounted on a 360-degree rotating stage, is capable of continuously detecting and quantifying emissions from all equipment or emissions points within radius of hundreds of feet and at detection levels satisfying the requirements for continuous monitoring technology. As such, the emissions of individually measured emission points can be summed to produce a continuous and highly accurate measurement of the total site emissions. Furthermore, these lidar cameras can also be mounted on such a site to image and quantify the entire down-wind plume that would be comprised of an aggregation of all the individual emission points on the site. For these reasons, currently available lidar-based imaging cameras are indeed suitable for the proposed alternative continuous monitoring approaches.

Response II-5-194: EPA recognizes the acknowledges the commenter's input.

---

<sup>92</sup> When the EPA states that camera-based continuous systems are not suitable for proposed alternative continuous monitoring approach (Fed Reg 87, 74745 Dec 6, 2022), the commenters argue it is overlooking recent developments in advanced camera technology that do provide means to quantify site emissions and thus are suitable for continuous monitoring applications.

<sup>93</sup> See for example [www.qlmtec.com](http://www.qlmtec.com).

Comment: Commenter (2340-Honeywell) cites the following text from the proposal preamble:

EPA is aware of other continuous monitoring systems using technologies that are not designed to quantify a site-level methane emissions rate (*e.g.*, camera based continuous systems). While the EPA believes these systems could be useful in a methane mitigation program, they are not suitable for the proposed alternative continuous monitoring approach because they are not capable of quantifying site-level methane emissions, which is the basis for the equivalency demonstration of the proposed alternative continuous monitoring approach.

Commenter (2340-Honeywell) indicates that this statement regarding camera-based monitoring systems is inaccurate. To be considered a continuous monitoring system, the proposed supplemental rule provides that “the system must produce a valid mass emissions rate (*i.e.*, kg/hr) from the site at least once every twelve hours.” Rebellion GCI cameras provide monitoring of fugitive emissions components at much greater frequencies than once every 12 hours. Moreover, Rebellion cameras are able to detect the gas type, location, plume direction, size, and concentration, thus providing a “valid mass emissions rate.”

Commenter (2340-Honeywell) believes that EPA should clarify in its final rule that, contrary to the preamble to its supplemental proposal, camera-based systems are capable of quantifying site-level methane emissions on a continuous basis. EPA should further note that it expects such systems to qualify as alternative continuous monitoring systems under the rule should they be capable of meeting the technology requirements.

Commenter (2421-Teledyne) responds to how camera based continuous systems, like continuous OGI solutions, could fit within the alternative continuous monitoring approach, what action levels should be applied to a non-emission rate based continuous monitoring system, and data to support those action levels in order to conduct an equivalency demonstration. Camera based solutions that provide the ability to quantify each emission event can easily be used in aggregate setting to provide site level emissions, which is the basis for equivalency demonstration. In addition, these solutions are unique in that they can also assist an operator in providing situational awareness of the emission event, which most other periodic or continuous solutions cannot. With camera-based solutions, specifically continuous OGI solutions, an operator can evaluate the event via a recorded event or live feed to understand if an event is a true emission or an operation emission, or vent situation, that may happen to ensure the safe operation of the facility.

Commenter (2421-Teledyne) adds, the EPA solicited comment on whether a different type of approach should be used for these camera-based continuous monitoring systems, and if so, what that approach would look like and how equivalency could be demonstrated between the approach and the proposed fugitive emissions monitoring and repair program and proposed covers and CVS requirements in NSPS OOOOb and EG OOOOc. It is recommended to separate continuous OGI technologies as they are unique and should be not coupled with fixed sensor for continuous monitoring or large-scale periodic monitoring technologies. This technology has similar minimum detection levels as periodic monitoring at the distances they are applied but provide a very unique result as the output is more aligned with the continuous technology solutions,

instead of larger times between inspections for periodic technologies like monthly, quarterly or semiannually.

Response II-5-195: EPA acknowledges the commenters' input, the criteria for the alternative continuous monitoring approach are performance-based and there isn't a limit on the technology used so long as a site-level emission rate can be determined. Any entity may petition for an alternative test method as described in Section X.B.3 and Section XI.B.3 of the preamble of the rule.

Comment: Commenter (2336-Kuva) believes EPA should regulate camera based continuous monitoring systems like camera-based solutions used for plane surveys as a screening solution.<sup>94</sup>

Commenter (2336-Kuva) supports EPA's approach of enabling owners and operators to use advanced technologies through a performance-based matrix based on inspection frequency and a probability of detection-based sensitivity. The proposed matrix, combined with alternative test methods, can provide operators and technology developers with well-defined requirements to use a technology for compliance. The commenter urges EPA to approach the classification of technologies into continuous or screening with a technology neutral approach and not assign any solution to any one of these two regulatory pathways.

Commenter (2336-Kuva) states the screening matrix approach lends itself equally well as the basis for an alternative test method for camera based continuous monitoring systems as it does for camera-based solutions used for plane-based surveys. Both plane-based and stationary cameras have the same advantage in that they can:

- Visually pinpoint emissions to their source.
- Distinguish permitted emissions (*i.e.*, compressor methane slippage, maintenance activity) from abnormal emissions.
- Enable root cause analysis of process malfunctions by analyzing time-stamped emissions data together with time-stamped process control data.

According to Commenter (2336- Kuva), camera based continuous monitoring systems have the added benefit that they are ideal in conducting root-cause analysis of intermittent super-emitters. Recent publications have shown that more than 90% of super-emitter events have a duration of

---

<sup>94</sup> This comment is in response to EPA's question: "The EPA is aware of other continuous monitoring systems using technologies that are not designed to quantify a site-level methane emissions rate (*e.g.*, camera based continuous systems). While the EPA believes these systems could be useful in a methane mitigation program, they are not suitable for the proposed alternative continuous monitoring approach because they are not capable of quantifying site-level methane emissions, which is the basis for the equivalency demonstration of the proposed alternative continuous monitoring approach. That said, the EPA solicits comments on how these types of systems could fit within the alternative continuous monitoring approach, what action levels should be applied to a non-emission rate based continuous monitoring system, and data to support those action levels in order to conduct an equivalency demonstration."

less than 24 hours.<sup>95</sup> The commenter has confirmed these findings in an analysis of its own camera installations in five basins.

Commenter (2336- Kuva) adds that camera-based continuous monitoring solutions are an established technology class and both the Kuva camera and other cameras have been well studied in 3rd party blind testing.<sup>96</sup> The commenter proposes to EPA to treat camera-based continuous monitoring systems based on the same detection limits under the matrix as proposed under the alternative screening matrix while allowing for flexibility in the alternative test method application (see discussion below). Camera based continuous monitoring systems may be used within the most frequent inspection frequency available (currently monthly).

Commenter (2336- Kuva) notes that for purposes of complying with the supplemental proposal and in order to prevent “cherry picking” of results stationary cameras may be required to conduct a monthly screening at the beginning of each month as soon as sufficiently favorable weather conditions are present, *i.e.*, as soon as all fugitive components, covers and CVS can be covered within the specified operating envelope of the given continuous camera system. This screening will be recorded as the official screening and stored as per EPA’s applicable record keeping requirements. As long as a once-a-month screening frequency is maintained the alarm criteria for a continuous camera can be the same as for a plane-based inspection, *i.e.*, a single image of detected gas constitutes an alarm. The alarm response for camera-based continuous monitoring solutions should be equivalent to plane-based screening with cameras and should be appropriate relative to the detected emissions.

To ensure that the rule is technology neutral, Commenter (2336- Kuva) urges EPA not to include greater uptime or response requirements for continuous cameras than for any other screening solution. If a technology can detect more frequently than required in the periodic screening matrix, that should not create additional (more frequent) response requirements than would apply to an owner or operator deploying OGI or other periodic screening technologies. While a company may use a technology that collects emissions information more frequently than monthly, the obligation should be to demonstrate compliance with fugitive emission requirements no more frequently than the frequency required by the matrix based on the application detection threshold for the technology.

While this once-a-month screening at the beginning of a month is used to comply with the requirements of the screening matrix, Commenter (2336- Kuva) expects that operators will want to operate any stationary camera continuously (outside of regulatory compliance obligations) for the following reasons:

- Fast detection of super-emitters as soon as they are created in order to prevent detection under EPA’s 3rd party super-emitter program;

---

<sup>95</sup> See table 5 in Wang et. al. “Multiscale Methane Measurements at Oil and Gas Facilities Reveal Necessary Frameworks for Improved Emissions Accounting”, <https://pubs.acs.org/doi/full/10.1021/acs.est.2c06211> (Oct. 6, 2022).

<sup>96</sup> See for example testing of 5 cameras in Bell, et al. “Performance of continuous emission monitoring solutions under single-blind controlled testing protocol”, <https://doi.org/10.26434/chemrxiv-2022-4hc7q-v2>

- As part of compliance with requirement for differentiated gas or oil certification;
- As part of compliance with future Methane Fee rules; and
- In order to conduct root-cause-analysis on detected emissions.

Commenter (2336-Kuva) argues stationary continuous cameras are to be installed in accordance with a vendor specific work-practice. Such work practice may include a requirement for an installation such that the camera provides line-of-sight to for example 80% or 90% of fugitive components, covers and CVS at a site. In order to provide for equivalent detection performance other parameters of the continuous camera such as increased screening frequency (beyond monthly), a full probability of detection curve and distance dependent detection limits may be considered as part of the alternative test method application via vendor specific FEAST modeling.

Response II-5-196: EPA agrees that camera-based solutions could be used as periodic screening technologies and has revised the final rule as detailed in Section X.B.1 and XI.B.1 to allow their use for those purposes.

#### ***5.9.14 Test Under Field Conditions***

Comment: Commenter (2340-Honeywell) indicates the approval process for alternative test methods should account for the various factors that may affect the accuracy and statistical certainty of the emissions measurement at particular detection thresholds. This is for two main reasons: to ensure that (a) applicants for approval of alternative monitoring systems are being evaluated on an even playing field, and (b) the approved monitoring systems are accurate as applied in the field.

Commenter (2340-Honeywell) recommends that EPA adopt a flexible standard for the use of continuous monitoring technologies that is based on the probability of detection of a leak of a given size. This would not only facilitate the adoption of continuous monitoring systems but would also hold each system's measurements to a common baseline confidence level to ensure accuracy. Various field conditions can affect the ability to detect/measure methane at a particular emissions rate and the statistical confidence of that measurement. This is particularly the case with regard to the assumptions and data points that factor into the algorithms to convert concentration readings (in ppm) to emissions rates (in kg/hr).

Commenter (2340-Honeywell) says that regardless of whether EPA adopts the commenter's proposal to base the continuous monitoring minimum detection requirement off of a probability of detection, the final rule should ensure that the alternative test method approval process requires applicants to establish and independently verify such metrics for their technologies under field conditions.

Commenter (2340-Honeywell) notes that the proposed supplemental rule already calls for applicants to submit supporting information verifying that their technology can meet the applicable detection thresholds in the field, as well as establish data quality objectives to ensure

detection thresholds are being met.<sup>97</sup> The commenter further notes that EPA has likened the proposed framework for continuous monitoring to the NESHAP fenceline monitoring work practice.<sup>98</sup> The NESHAP fenceline monitoring work practice similarly prescribes procedures for validating an alternative test method according to “Method 301.”<sup>99</sup> EPA has not clarified, however, whether it intends to use Method 301 or a similar procedure for the alternative test method approval process in the proposed supplemental methane rule. As explained above, several continuous monitoring technologies, including Honeywell’s, are deployed within the fenceline and in close proximity to the fugitive emissions source, in contrast to the NESHAP work practice. As such, Method 301, developed for fenceline monitoring test method approval, may not be appropriate in the context of inside-the-fenceline technology used for methane detection. Honeywell recommends that EPA instead consider the use of an independent third-party validator with experience in continuous methane detection technology, such as METEC, to validate the capability of a supplier’s continuous monitoring solution in terms of the detection sensitivity at a certain probability level.

Response II-5-197: EPA acknowledges the commenters’ input; EPA has revised the requirements for submitting an alternative test method for advanced methane measurement as described in Section X.B.3 and Section XI.B.3 of the preamble of the rule.

Comment: Commenter (2394-Earthworks) argues field implementation of CEMs provide unique challenges that are not addressed in current controlled studies and make them unreliable for detecting pollution events and/or identifying the source of pollution. Certainly, there is evidence that some CEM test methods could meet the EPA’s proposed detection limit (1.2 kg/hr for well only and 1.6 kg/hr for all others); however, this evidence comes from controlled experiments which do not and can never replicate field conditions.

Currently, Commenter (2394-Earthworks) is not aware of any examples of blind studies which provide evidence of any CEM detection capabilities in the field. Their own investigation of monitors in the field show that critical field decisions have the potential to render certain CEM technology virtually ineffective.

Commenter (2394-Earthworks) notes Colorado has recently introduced rules that require operators to submit and undertake an Air Quality Monitoring Plan using CEMs during pre-production and early production to detect VOC and/or methane pollution. Over the course of seven months in 2022, Earthworks OGI operators conducted a survey of sites in Colorado that were using CEMs under this new rule. In our 77 site visits during that period our OGI cameras detected 22 separate pollution events. These pollution events varied in size (small leaks to super emitter events), source (drilling equipment, tanks, ECDs, etc), and length of documentation (average each event lasted at least 15 minutes). However, according to operator records submitted to the Colorado Department of Public Health, the CEMs failed to detect any of the 22 events.

---

<sup>97</sup> See 87 FR 74,702, at 74,746.

<sup>98</sup> See 87 FR 74,702, at 74,744, n. 97.

<sup>99</sup> See 40 CFR § 63.7(f).

Commenter (2394-Earthworks) believes while this regulatory framework differs from the EPA's proposed process, it is still one of the few opportunities for the public to investigate how CEMs work in the field. Our study sample represented CEMs from four different manufacturers and countless implementation variations, yet the results were all the same: CEMs did not detect the pollution present at the time of our OGI survey.

Response II-5-198: EPA acknowledges the commenters' input; EPA's continuous monitoring approach is based on a site-level emission rate instead of an individual component leak definition. It is possible, an OGI survey or a site with a continuous system installed could identify emissions, but so long as the site-level emission rate was less than the action level, no additional action is required.

Comment: Commenter (2394-Earthworks) states given CEMs sensitivity to weather, reliance on internet connection, power supply, frequent maintenance, it is not surprising that on average they perform less reliably in the field compared to controlled environments. However, the commenter's survey also suggests that there are many other factors to consider. The commenter states nearly all of the sites visited had set up their CEMs in a way that likely reduced their capabilities. For example, Project Canary often cites studies from Colorado State University to show the capabilities of their Canary-S monitors. Those tests are conducted with a system of eight monitors placed 30-230 feet from pollution sources. In comparison, the sites visited with Canary-S monitors had three to four monitors, which were never closer than 150 feet to pollution sources and often much farther than that. The commenter argues these significant variations were not addressed by the operators, the CEM manufacturers, or the regulatory agency. These decisions were not justified by research either. The commenter also found that operators had intentionally placed monitors behind barriers such as sound walls and this placement was approved by the CDPHE. Placing sensors behind barriers can prevent them from detecting any pollution. Again, these decisions were not supported by any evidence.

Commenter (2394-Earthworks) has collected footage of methane for nearly a decade and this footage consistently shows methane rising as it moves from sources that are commonly tens of feet above the ground. Often CEMs are placed on poles that rise just six feet above the ground. This means there is a very low chance they would pick up even large events, and almost certainly would not pick up small but persistent releases.

Commenter (2394-Earthworks) argues even if placed properly in the path of methane pollution these monitors cannot be relied upon for accurate data without frequent calibration and still may suffer from malfunctions with the slightest changes in weather, small disruptions in power supply, loss of capacity to upload data, and other minor adjustments. Are companies going to pay for that frequent maintenance? With this level of maintenance, it would likely be more cost effective and accurate to perform LDAR with OGI cameras.

Response II-5-199: EPA recognizes the commenter's input. EPA has included requirements in the final rule to ensure that technology that has been approved by the EPA for use of continuous monitoring must be operated in the manner defined by the approved alternative test method discussed in Section X.B.3 and XI.B.3 of the preamble of the final rule. Likewise, EPA also

includes specific QA/QC that must be met for the continuous monitoring systems that are detailed in Section X.B.2 and XI.B.2 of the preamble of the final rule.

Comment: Commenter (2346-Encino) notes methane intensity over a year and action levels are more of a regulatory threshold. For example, fluid dynamic limitations and adiabatic expansion (thermodynamic variables) can cause inaccuracies when testing thermally dependent technology as there would be diminished or nonexistent plume detection when tubes are used for technology evaluation (thermal equilibrium diminishes signal quality – a phenomenon that is almost non-existent under authentic operating conditions/scenarios). Accordingly, there needs to be procedures set forth that allow for across-the-board qualification of different monitoring systems that properly mirror a scenario of the most common leaks. These procedures could be CMS-specific testing protocols that discourage tube release, which would eliminate detection limitations caused by non-representative flowrates and adiabatic expansion in tube-based gas sample testing programs which are not representative of operational environments.

Commenter (2346-Encino) states inclusion of the development of site-specific MDLs for any technology used to support this program, which includes meteorological, geographic, and environmental factors, is appropriate. Site specific action levels, where actual emissions are favored over emission factors due to factor uncertainty and improper duration of events (temporal attributes), are beneficial for tracking intermittency and duration of events, thereby, providing a more accurate temporal representation.

Response II-5-200: EPA acknowledges the commenter's input.

#### ***5.9.15 Consider Funding/Support of Continuous Monitoring***

Comment: Commenter (2428-API) recognizes and appreciates EPA's initial and important efforts in creating a framework for alternative leak detection technologies, including continuous monitoring, in NSPS OOOOb and EG OOOOc. However, the commenter urges EPA to make key adjustments in the final rules to enhance the use of these technologies and to not unintentionally disincentivize development and deployment of these technologies. Making alternative technologies more accessible in these rules can also have synergistic benefits with measurement-informed inventory goals in related rulemaking such as the IRA's MERP and EPA's GHGRP.

Commenter (2428-API) describes proposed adjustments in other section of this RTC, including initial comments on EPA's FEAST modeling. While the commenter is exploring additional modeling analyses, due to the short comment period, any additional modeling analysis may be provided in a subsequent submittal.

Response II-5-201: EPA acknowledges the commenter's input.

Comment: Commenter (2226-Thermo Fisher) applauds EPA's inclusion of a continuous emissions monitoring approach and the Agency's acknowledgment that technologies vary in how leaks are specifically detected. However, continuous emissions monitoring requires significant funding, and therefore raises uncertainty as to where such funding will come from, and in what

exact ways it will be allocated. It is possible that the oil and natural gas industry may not uptake continuous monitoring solutions in the near-term due to costs. The commenter encourages EPA to provide more insight into potential funding or support available to end-users to cover the cost delta between continuous monitoring and other solutions.

Response II-5-202: EPA recognizes the commenter's input.

Comment: Commenter (2315-NYSDEC) recommends that EPA reach out to researchers currently studying innovative detection technology. One study underway in New York State was presented at the American Geophysical Union (AGU) conference by Dr. Arvind Ravikumar, et al.<sup>100</sup> It should be noted that since this presentation, the scope of the study has already been expanded upon and more current work on continuous emissions monitoring is underway.

In addition to evaluating different technology and their associated challenges, Commenter (2315-NYSDEC) recommends that EPA also focus on the post-processing of the monitoring data because that may be a critical part of determining the reliability of the newest technology.

Response II-5-203: EPA acknowledges the commenter's input.

Comment: Commenter (2394-Earthworks) asserts that technology used together will increase emissions reductions and allow the EPA to gather information about new technologies with little impact on cost to operators.

Commenter (2394-Earthworks) notes as the EPA has said in the current proposed supplemental rule, while many new CEM systems exist, the "application of these systems appears to vary widely across the industry, with no consistent standard currently employed. This is especially true for how sources initiate identification of the cause of a leak." Therefore, there is a need to learn more about these systems and future systems before relying on them to reduce pollution.

Commenter (2394-Earthworks) states coupling new systems with a comprehensive LDAR program would allow the EPA to gather more information about the efficacy of new technologies. In the absence of sound evidence to show that any system or implementation methods can indeed identify and reduce pollution in the field, relying on these systems alone could just as likely miss pollution entirely and compromise the EPA's effort to improve air quality and limit impacts on public health.

Commenter (2394-Earthworks) notes an ongoing study from Colorado State University tested several CEMs in a blind study and found that at leak rates between .1 and 1 kg/hr "no solution reported mean estimates accurate to within  $\pm 40\%$ ." This is significant because this range "roughly corresponds to emission rates from component leaks that would be routinely identified in OGI surveys."<sup>101</sup> By using CEMs in a complementary role with the established industry

---

<sup>100</sup> <https://agu2022fallmeeting-agu.ipostersessions.com/default.aspx?s=79-C0-1F-F4-21-F7-4E-81-AC-AD-5F-CD-B2-82-24-92&guestview=true>.

<sup>101</sup> ChemRxiv, "Performance of continuous emission monitoring solutions under single-blind controlled testing protocol." December 2022, <https://chemrxiv.org/engage/chemrxiv/article-details/638cd2ff14d92d3587a07c46>.

standard OGI cameras, the EPA would guarantee that current efforts to reduce emissions are not compromised.

Response II-5-204: EPA will evaluate the effectiveness of a technology as applied in the field as part of the alternative test method process as described in Section X.B.3 and XI.B.3 of the preamble of the rule. EPA is providing flexibility to the owner or operator to choose the best system that fits their needs.

Comment: Commenter (2394-Earthworks) states one unexpected consequence of Colorado's rollout of CEMs at well sites is an increased dismissal of verified complaints from NGOs and communities living near drilling activities. Over the last year an increasing number of the commenter's complaints have been dismissed simply because the operator claims that their CEMs on site show no sign of the pollution that was documented via OGI.

Commenter (2394-Earthworks) argues without proper rules in place to guide regulatory staff on how to compare conflicting sources of evidence, air pollution that may have previously been inspected further is now going unaddressed. This is not happening because CDPHE staff were directed to favor one technology over another. It is happening simply because new CEM technology was included in one rule.

Commenter (2394-Earthworks) highlights this to show that there are significant negative impacts that can happen by implementing new technology without extensive review of how it affects protocols throughout a regulatory framework. The current draft of the EPA's rules similarly does not provide protocol on how new technology will be compared. In order to protect public health and eliminate barriers to public participation the commenter encourages the EPA to provide protocol for how all acceptable alternative technologies should be compared.

Earthworks' field observations suggest that it is critical the EPA gather as much information as possible about how to best implement CEM systems. It also supports our recommendation to remove the option for operators to replace OGI LDAR with CEM systems at this time.

Commenter (2394-Earthworks) states ambient air monitoring is important to understand impacts to community health; however, only monitors that can reliably provide quantitative measurements are useful for indicating issues with point source pollution. There are technologies that may provide more accurate and quantitative measurements which the commenter thinks also need further investigation. One example is continuous fixed OGI cameras with automatic detection technology, such as those used in many refineries. These cameras are manufactured by FLIR, a highly accredited company which the EPA is familiar with, and others. However, your current draft rule suggests that the EPA is not likely to consider these. The commenter encourages the EPA to reconsider this decision. The EPA should explore the use of these, as well as satellite imagery and aircraft equipped with OGI cameras, all of which provide reliable, quantitative data which the EPA requires to make informed decisions about pollution events.

Response II-5-205: EPA recognizes the commenter's input.

Comment: Commenter (2412-University of Calgary Centre for Smart Emissions Sensing Technologies (CSEST)) provides a 14-page draft report on a relevant study undertaken to model the economics and efficacy of low-cost fixed sensors. The comments pertain most specifically to the following continuous monitoring systems solicitations:

- Equivalency with Other Fugitive Emissions Monitoring/Cover-CVS Requirement;
- Operational Downtime; and
- Site-Level Methane Emissions/Data.

According to commenter (2412-CSEST), the draft study unpacks how fugitive emissions management programs designed with the base of low-cost fixed sensors can be subject to large operational costs, primarily as a result of OGI survey callouts from automated alerts. The prevalence and complexity of emissions on upstream sites poses a severe issue for triaging these automated alarms and could put operators in a situation of facing an infeasible number of alarm follow-up calls. Although giving operators some latitude in their response to alarms would improve the economics of these low-cost fixed sensor programs – it is possible that this latitude would negatively affect emissions reductions goals.

The commenter's (2412-CSEST) study explores this issue, with discussion of the regulatory nuances and economic headwinds that may affect low-cost fixed sensor guided programs.

Commenter (2412-CSEST) believes the EPA should deeply consider the practicalities of low-cost fixed sensor-based fugitive emissions management programs – and think particularly carefully about how to manage follow-up from all sensors. Additionally, the commenter believes the EPA must carefully mandate some standards of practice for low-cost fixed sensors to ensure they are maintained with a quality management program that ensures a defined level of uptime and performance.

Response II-5-206: The alternative technology provisions in the rule are technology agnostic. EPA identifies that low-cost sensors will be used in some of the measurement systems which will petition for approval. Like for any other alternative technology, the request must include system specific QA/QC needed to ensure accurate operation and the manufacturer must define and data processing procedures used to derive an output. These criteria are explained in Section X.B.3 and XI.B.3 of the preamble of the rule.

#### ***5.9.16 Recommendations and Text Changes***

Comment: Commenter (2409-BP) recommends the following:

1. Amend the definition and framework for continuous monitoring to allow for continuous monitoring systems that may require action based on the concentration of emissions as well as those that may require action based on the rate of emissions, thereby making a distinction between the underlying technology and continuous monitoring systems that use algorithms to produce an emission rate estimate.
2. Allow continuous monitoring systems to qualify as periodic screening systems.

3. Modify the conditions that determine operational downtime and “out-of-control” monitors used in continuous monitoring systems.
4. Define the “root cause analysis” required for continuous monitoring systems to clarify that it is describing an investigation into the source of detected emissions.
5. Amend the information required in the fugitive emissions plan to reflect the potential for deployment of continuous monitors within the fenceline.
6. Remove the requirement that an alternative test method, such as a continuous monitoring system, must be “commercially available” to be approved for use under the rule; and
7. Clarify that the “daily verification checks” required for continuous monitoring systems include remote verifications.
8. EPA should expand the framework for continuous monitoring to allow for concentration-based action levels and detection thresholds.
9. EPA should make additional amendments to the continuous monitoring framework to more accurately reflect how such systems operate.

Response II-5-207: EPA acknowledges the comments, any revisions to the alternative technology provisions of the final rule are detailed in Section X.B and XI.B of the preamble of the rule.

Comment: Commenter (2333-LongPath) provides the following recommended changes to the continuous monitoring provisions alternative to OGI:

- Do not include greater response requirements or more stringent emissions thresholds for continuous technologies.
- Remove the Long-Term Action Level entirely for the continuous monitoring provisions, and maintain only the more effective Short-Term Action Level, based on the following findings:
  - The Long-Term Action Level does not achieve rapid find-and-fix, the primary goal of continuous monitoring.
  - Two thresholds that achieve the same emissions reductions is redundant. ○ No other screening approach requires double counting of emissions with two methods, which disincentivizes continuous monitoring.
  - The requirement for both a Long-Term and Short-Term Action Level adds a layer of operational complexity for operators, which disincentivizes continuous monitoring.
  - The 90-day Long-Term Action Level is more than an order of magnitude below the action levels proposed for periodic screening using other advanced technologies, despite a 60x increase in required frequency.
  - There is no equivalent standard to a Long-Term Action Level in either the OGI (BSER) or the periodic screening matrix, which disincentivizes continuous monitoring.
- Model all emissions reductions directly in FEAST, in particular to determine the Short-Term Action Level that results in equivalent emissions reductions (do not use FEAST results indirectly).
- Define Action Levels as “above Baseline Emissions” for the continuous monitoring provisions. This method has been vetted and approved by CDPHE and EPA under the

Colorado Alt. AIMM program. Without this change, continuous monitoring will be unusable for the majority of well sites and compressor stations.

- Define requirements for spatial (full site) coverage and/or the maximum timeframe in which potential plumes from all regulated equipment must be detected (all equipment must be screened).
- Define the Minimum Detection Limit requirements in a manner that is more consistent with the use and definition of minimum detection limits elsewhere in the rule.

Response II-5-208: EPA acknowledges the comments, any revisions to the alternative technology provisions of the final rule are detailed in Section X.B and XI.B of the preamble of the rule.

Comment: Commenter (2433-EDF *et al.*) supports EPA's proposed alternative fugitive monitoring standards and provide the following recommendations for improvements:

- *Require initial monitoring within 30 days.* The early stages of production often involve abnormal process emissions and operational issues that may cause significant fugitive emissions. To address this, Colorado requires operators to inspect a well “no later than 30 days after the facility commences operation.”<sup>102</sup> The commenter recommends that EPA similarly require that the initial monitoring survey occur earlier so these problems can be addressed sooner and mitigate potentially large emissions that would otherwise go undetected for up to 90 days.
- *Require targeted follow up on all detections.* Certain advanced screening technologies (*i.e.*, those with lower detection thresholds) may be capable of pinpointing the emitting equipment or component, allowing for direct repair and potentially obviating the need for a site wide OGI survey. For technologies that EPA determines are capable of pinpointing the emitting component, the commenter urges EPA to require immediate repair without a site wide OGI survey when results of periodic screening identify a specific component. For technologies that EPA determines are capable of pinpointing an emitting piece of equipment, the commenter urges EPA to require an OGI survey of that piece of equipment to locate the leaking component. If during follow up, an operator determines detected emissions are the result of normal operations and permissible, thus not requiring repair, that should be documented and reported to EPA. For technologies that detect at the site-level, or in cases where a specific component or piece of equipment cannot be determined based on the screening results, EPA should require a site-wide OGI survey to pinpoint the source. This survey should also satisfy the operator's annual OGI requirement if it covers all fugitive emissions components at the site. Again, emissions resulting from normal operations that do not require repair should also be documented and reported.
- *Align repair requirements.* EPA should require that all final repairs be completed within 30 days of detection or of receiving the results of a periodic screening. As described above regarding OGI, the commenter believes that a 30-day total repair timeline (including any follow-up survey, first attempt, and final repair) is feasible and necessary

---

<sup>102</sup> 5 Colo. Code Regs. §1001-9-D-I.L.2. d. (2023).

to achieve the emissions reductions estimated by EPA. This timeline is feasible and already required by leading states.<sup>103</sup> In particular, results of aerial screenings are likely to indicate large emission events that should be quickly repaired. And to achieve the reductions anticipated by EPA through the equivalency modeling, regulatory repair timelines must align with modeling assumptions.

- *Align root cause analysis requirements.* The commenter supports EPA's proposed root cause analysis requirements for when emissions are detected from control devices, covers, and closed vent systems. These types of emission events may be large (particularly unlit or malfunctioning flares) and likely indicate a deviation from the applicable standards. A root cause analysis is an appropriate response and should be conducted as soon as possible to return the site back to normal and compliant operations. The commenter urges EPA to ensure these standards also apply when emissions from control devices, covers, and close vent systems are detected through OGI or AVO surveys under the primary standards.
- *Ensure monitoring plans are uniform.* The commenter supports providing flexibility to operators but urges EPA to ensure that applicable monitoring requirements are not so multifarious that it complicates compliance and enforcement efforts. The commenter therefore urges EPA to require that similar sites (based on either site characteristics or locations) be grouped together and subject to the same monitoring plan and screening option. The fugitive monitoring plan should also include the number and type of all pieces of major production and processing equipment at each site (including those relevant to the site's subcategorization), as well as the number of covers, closed vent systems, and control devices that are present at each site.
- *Align deployment and approval.* EPA should clearly specify in the regulatory text that periodic screening must occur 1) using a technology approved under the process described in section 60.5398b(d), 2) at the frequencies listed in Tables 1 and 2, and 3) in accordance with the standard and approved operating protocols. In other words, EPA should clarify in section 60.5398b(b) that the technology has to be deployed using the same operating protocols and under similar conditions as EPA approved under section 60.5398b(d). Technologies may be capable of achieving different requirements in Tables 1 and 2 under differing conditions or when following certain operational protocols. EPA must ensure deployment in the field conforms to the parameters approved by EPA.

Response II-5-209: EPA acknowledges the commenter's input and support for the rule. EPA has detailed the requirements with the advanced methane detection technology provisions in the rule as detailed in Section X.B of the preamble of the final rule and any revisions to these provisions are detailed in Section XI.B of the preamble of the final rule.

Comment: Commenters (2363-CEMC, 2402-DGCC) encourage the EPA to take into consideration continuous monitoring systems that have been approved for similar purposes under state regulatory programs, at a minimum to provide expedited approval of a technology. For example, CDPHE's Alt-AIMM program includes an extensive equivalency, and technology

---

<sup>103</sup> See, e.g., Colo. Code Regs. § 1001-9-D-II.E.7; N.M. Code R. § 20.2.50.116(E) (2023).

feasibility review, to ensure approved continuous monitoring systems will meet the LDAR objectives, meeting or exceeding an already robust OGI camera LDAR inspection program.

Commenters (2363-CEMC, 2402-DGCC) encourage the EPA to not discount the significant efforts of technology providers and state regulators that demonstrate efficacy of continuous monitoring technologies, not only expediting approval, but also adoption of approved systems resulting in greater emissions reduction more quickly.

Commenter (2402-DGCC) states the EPA's approach could be particularly important and valuable because by the time states are developing and submitting their EG OOOOc plans, the agency will hopefully have approved several methods. This will make it possible for state plans to authorize or require the use of technologies that provide improved detection and more precise quantification.

Response II-5-210: EPA has retained the authority to approve alternative technology for use in NSPS OOOOb and EG OOOOc. We recognize that some states have existing programs as part of a SIP, while information gathered as part of those programs could be useful for evaluating technology, however EPA will not offer expedited approval and they will be evaluated as detailed in Section X.B.3 and XI.B.3.

Comment: Commenters (2363-CEMC, 2448-Project Canary) requests additional clarity regarding the third-party provider requirement in §60.5398b(c)(2)(iii) which states:

“If the continuous monitoring system is administered through a third-party provider, contact information where the provider can be reached 24-hours a day.”

In many cases, an operator has a lease agreement with a technology provider to install and maintain a continuous monitoring system. However, these agreements also make clear that the operator has the day-to-day responsibility to take any corrective actions. Accordingly, the commenter suggests the EPA provide additional clarity to the phrase “administered by a third-party” to make clear that any entity providing only installation and maintenance services is not liable for any requirements under the NSPS OOOOb or EG OOOOc regulations.

Response II-5-211: The provision above is from the requirements for an owner or operator to develop a monitoring plan, it is the owner or operator's choice to third-party provider to support compliance activities, however only the owner or operator is responsible for compliance with applicable emission standards.

Comment: Commenters (2363-CEMC, 2448-Project Canary) are also asking for EPA to clarify the intent of providing contact information for an individual to be reached 24-hours a day. As the continuous emissions monitoring program is proposed with rolling 7-day and 90-day averages, the commenters are requesting that the EPA provide additional information regarding the intent or need for a 24-hour-a-day contact. The fugitive monitoring plan submitted to the EPA will make clear how the operator is notified (email, text, or other) when an action level is exceeded, and corrective action is required.

Response II-5-212: For the continuous monitoring work practice to be equivalent to the fugitive emissions BSER, the continuous monitoring system must be able to provide data on an ongoing basis. Therefore, EPA included a maximum system downtime in the rulemaking. It is critical that owners and operators be able to contact third-party providers any time that the system goes down, otherwise they face the risk of being out-of-compliance with the downtime requirement.

Comment: Commenters (2363-CEMC, 2448-Project Canary) seek clarity about the replacement of OGI/Method 21 and AVO if an operator adopts an approved continuous monitoring system in §60.5398b(c).

The Preamble to the Supplemental Proposal states:

Lastly, we are proposing to establish a clear and streamlined pathway for technology developers and other entities to seek the EPA's approval for the use of advanced measurement technologies under this alternative screening option. Under this pathway, entities would seek approval for alternative test methods to demonstrate the performance of alternative technologies, which would replace the use of OGI and AVO for fugitive emissions monitoring and the use of OGI for no identifiable emissions monitoring of covers and CVS (see section IV.K of this preamble) in both the proposed NSPS OOOOb and EG OOOOc.

Commenters (2363-CEMC, 2448-Project Canary) respectfully request that the agency explicitly incorporate this approach into the NSPS OOOOb, EG OOOOc regulatory language. Below is suggested regulatory text for §60.5398b (underlined text represents recommended addition):

**What alternative GHG and VOC standards apply to fugitive emissions components affected facilities and covers and closed vent systems?**

This section provides alternative GHG and VOC standards for fugitive emissions components affected facilities in §60.5397b and alternative initial and continuous compliance requirements for covers and closed vent systems in §60.5416b. As provided in this section, owners and operators of affected facilities may choose to demonstrate compliance with these alternative standards in lieu of complying with the standards that would otherwise apply under §60.5397b and §60.5416b. If you choose to demonstrate compliance with the alternative GHG and VOC standards through periodic screening, you are subject to the requirements in paragraph (b) of this section. If you choose to demonstrate compliance through a continuous monitoring system, you are subject to the requirements in paragraph (c) of this section. The technology used for periodic screenings under paragraph (b) of this section or continuous monitoring under paragraph (c) of this section must be approved in accordance with paragraph (d) of this section.

Response II-5-213: EPA recognizes the commenters suggested language revisions to the final rule. EPA has made slight revisions to the regulatory text in §60.5398b to clarify what standards are covered by the alternative GHG and VOC standards for fugitive emissions components affected facilities and covers and closed vent systems. The opening of §60.5398b now states:

This section provides alternative GHG and VOC standards for fugitive emissions components affected facilities in §60.5397b and alternative continuous inspection and monitoring requirements for covers and closed vent systems in §60.5416b(a)(1)(ii) and (iii), (2)(ii) through (iv), and (3)(iii) and (iv).

Comment: Commenters (2363-CEMC, 2448-Project Canary) seek clarification about the timeframe rules that apply when an operator switches to using a continuous monitoring system from using another approved monitoring technology. Proposed §60.5398b(c)(3)(v) provides that operator must install and begin conducting monitoring with a continuous monitoring system.

Commenters (2363-CEMC, 2448-Project Canary) understand that this rule requires an operator switching from use of OGI cameras to a continuous monitoring system to begin operation of the continuous monitoring system no later than the date that the next OGI survey would have been required—whether for fugitive emissions components (§60.5397b) or for covers and closed vent systems (§60.5416b). The commenter would appreciate it if the agency could confirm this interpretation in the final rule.

Commenters (2363-CEMC, 2448-Project Canary) say that also, this provision does not address a scenario in which an operator switches from using an approved alternative periodic surveying method to using a continuous monitoring system. Accordingly, the commenters recommend the following revision:

No later than the final date by which the next monitoring survey required by §60.5397b(g)(1)(i) through (iv) would have been required to be conducted if you were previously complying with the requirements in §60.5397b and §60.5416b or §60.5398b.

Response II-5-214: EPA did not contemplate companies switching from a periodic screening alternative to a continuous monitoring alternative in the proposed rule, however we find the suggested revision to be overly restrictive since it could require a continuous system to be on-line within 30 days from the most recent periodic screening.

Therefore, for those owner or operators choosing to switch from the periodic screening alternative to a continuous monitoring alternative, you have within 120 days from your last screening event to conduct the site-specific baseline assessment and to initiate monitoring with your continuous monitoring system.

Comment: Commenters (2363-CEMC, 2448-Project Canary) are providing comment on the phrase “at least once every twelve-hour block.” While the commenters are supportive of the frequency for determining a valid mass emissions rate, they believe the proposal is ambiguous regarding allowable timeframes between reporting a valid emissions rate once every twelve-hour block. For example, some measurement systems are able to calculate mass emissions rate on a much more frequent basis. In such scenarios, two valid mass emissions rates could be calculated just minutes apart, meeting the proposed language as written. To provide compliance certainty, the commenter requests that EPA further clarify this language and specify if a minimum period of time is required between calculations of valid mass emissions rates during a twelve-hour block.

Commenter (2448-Project Canary) supports EPA’s proposal in §60.5398b(c)(1) to define continuous monitoring as the ability of a system to determine and record a valid mass emissions rate at least once every twelve-hour block. However, the commenter believes the term “valid mass emissions rate” should be defined more clearly as the language is vague and could be subject to varying interpretations. The commenter proposes the following:

“Valid Mass Emissions Rate” means any methane rate determined by the measurement system using system data within the prescribed operating ranges provided in the monitoring system approval. Data used to calculate a methane emissions rate that is outside the prescribed parameters shall invalidate that emissions rate.

Response II-5-215: EPA acknowledges the commenters’ support for the rule and the feedback. The 12-hour block is a minimum time frequency and if a system can measure a more frequent time block, they are allowed so long as that time resolution is maintained. How the block averages are determined for a system must be detailed as part of the advanced methane detection technology alternative test method process.

Comment: Commenters (2363-CEMC, 2448-Project Canary) provide two recommendations for revisions to regulatory text in §60.5398b(c). First, the reference to subparagraph (c)(1)(ii)(A) should reference subparagraph (c)(1)(iii)(A). Second, in the commenters’ view, the requirement in this section to “continuously collect the data” could result in confusion. The commenter’s concern is that the term “continuously collect” could be read colloquially, implying a perpetual requirement to collect data. However, paragraph (c)(1) —to which this text references— expressly defines “continuous monitoring” to establish a requirement for coverage in 12-hour blocks.

For these reasons, commenters (2363-CEMC, 2448-Project Canary) recommend revising §60.5398b(c)(1)(iii) as follows:

“(iii) The continuous monitoring system must ~~continuously~~ collect data as specified in paragraph (c)(1) of this section, except as specified in paragraphs (c)(1)(iii)(A) through (D) of this section.”

Response II-5-216: EPA recognizes the input and has chosen to finalize the provision as proposed. EPA has defined continuously as meaning the ability of a methane monitoring system to determine and record a valid methane mass emissions rate or equivalent of affected facilities at least once for every 12-hour block.

Comment: Commenters (2363-CEMC, 2448-Project Canary) support the inclusion of health checks for devices within the continuous monitoring system in §60.5398b(c)(1); however, believes that, as written, the requirement is overly prescriptive and unnecessary. This provision requires that continuous monitoring systems “must be confirmed for power and connectivity at least twice every six-hour block.” Such an “always-on” requirement may make sense for facilities subject to Compliance Assurance Monitoring (CAM) [40 CFR Parts 64, 70 and 71] or other continuous monitoring system requirements under non-methane-related regulations.

Commenters (2363-CEMC, 2448-Project Canary) indicate that sources subject to such requirements are of significant size and technical complexity so as to justify well-connected data transfer services, such as satellite or SCADA systems. As such, reliable connectivity and the ability to upload or send data is necessary due to the complexity of the facilities subject to these requirements. This includes large natural gas compressor stations, gas processing plants, refineries, and power plants.

Commenters (2363-CEMC, 2448-Project Canary) add, by contrast, production facilities and gathering and boosting facilities are significantly smaller in size, lower in complexity, more numerous and often constructed in areas with less reliable access to communication systems, often limited to commercial cellular networks. In some instances, especially in rural or remote locations, cellular service can be interrupted for periods of time, limiting the ability to upload data to a cloud-based system as frequently as is possible in areas with strong cellular coverage. If EPA imposes an “always-on” requirement for continuous monitors, it could disincentivize the use of such systems in some rural or remote areas that have substantial oil and gas production.

Moreover, commenters (2363-CEMC, 2448-Project Canary) say such an “always-on” requirement is not necessary to ensure environmental performance. An interruption in cellular service does not necessarily render a continuous monitoring system ineffective. During these situations, the continuous monitoring system is still operating, storing the data within the monitoring system until such time as the cellular connection is re-established. Once reconnection occurs, all data that wasn’t successfully uploaded will be “backfilled” to minimize, or eliminate, any data gaps.

While commenters (2363-CEMC, 2448-Project Canary) understand the importance of timely data to compare against action levels, they encourage the EPA to allow up to 24 hours of data to be backfilled. As amended, the provision would read as follows:

(ii) The health of the devices used within the continuous monitoring system must be confirmed for power and connectivity at least twice every six-hour block, provided that, if a device has the capability to backfill data during a connectivity disruption, the confirmation requirement for connectivity shall be once every 24-hour block.”

As shown in the table below, the percentage of data to be backfilled under such a rule would be less than 15 percent for the short-term action level and just over 1 percent for the long-term action level. Commenters (2363-CEMC, 2448-Project Canary) believe this process allows for connectivity issues outside of an operator’s control, while still providing adequate data to determine if an action level has been triggered within a reasonable period of time.

[Table shows for 12 hours backfilled, the Percent of Backfilled Data per Action Level Duration for a 7-day rolling average would be 7.1% and for a 90-day rolling average would be 0.6%, for 18 hours backfilled, the Percent of Backfilled Data per Action Level Duration for a 7-day rolling average would be 10.7% and for a 90-day rolling average would be 0.8%, and for 24 hours backfilled, the Percent of Backfilled Data per Action Level Duration for a 7-day rolling average would be 14.3% and for a 90-day rolling average would be 1.1%.]

Commenters (2363-CEMC, 2448-Project Canary) states accommodating this operational reality will still provide the operator and EPA with the information needed to take timely corrective action, even after a temporary interruption in service. In any event, to the extent that periodic surveying with OGI and Method 21 is the “best system of emission reduction” that has been “adequately demonstrated”, continuous monitoring will provide higher quality data than OGI and Method 21 even with interruptions in cellular service from time to time. As noted in a recent study; “While fixed duration emission events may not be detected and there can be time delays in detecting continuous infinite duration emissions events, the detection efficiencies for CM networks are greater than efficiencies for periodic short duration measurements such as monthly or quarterly inspections”.<sup>104</sup>

Response II-5-217: EPA acknowledges the commenters’ suggestions and have made some revisions to the alternative continuous monitoring approach as detailed in Section X.B.2 and XI.B.2 of the preamble of the final rule.

Comment: Commenter (2448-Project Canary) strongly supports the EPA’s inclusion of provisions in the Supplemental Proposal allowing operators to use advanced methane detection technologies for compliance purposes. However, the EPA has proposed to find that—at least at this time—periodic surveying with OGI and Method 21 is the “best system of emission reduction” that has been “adequately demonstrated.” There is substantial evidence that OGI and Method 21 systems fail to detect significant volumes of intermittent leaks that occur in between surveys, including leaks that qualify as “super-emitter” events. Additionally, as a recent study focusing on detection limits for OGI cameras indicates, “[o]verall detection rates from the camera-surveyor system are substantially lower than the detection rates estimated from studies focused solely on the camera performance...”<sup>105</sup> Further, the OGI surveyor experience level can also have a large impact on OGI use efficacy: “Study results indicate that OGI survey experience significantly impacts leak detection rate: Surveyors from operators/contractors who had surveyed more than 551 sites prior to testing detected 1.7 (1.5– 1.8) times more leaks than surveyors who had completed fewer surveys.”<sup>106</sup>

To the extent that it promotes greater deployment of continuous monitoring systems, the Final Rule will also advance several additional public policy objectives:

1. Making it possible, and incentivizing operators, to use alternative test methods is critical to the Agency’s ultimate goals for this rulemaking and for the impending rules for the Methane Emissions Reduction Program (MERP) and Subpart W established in §60113 of the Inflation Reduction Act. The MERP relies on methane intensity, which is why Congress also mandated in §60113 that the EPA update Subpart W to require “accurate” and “empirical” data. Advanced technologies, such as continuous monitoring solutions,

Sci. Technol.* 2020, 54, 18, 11506–11514, Publication Date: August 7, 2020. <https://pubs.acs.org/doi/full/10.1021/acs.est.0c01285>.

<sup>106</sup> *Id.*

provide the greatest temporal resolution, resulting in the most representative emissions profile and methane intensity of an oil and gas facility. Compliance with these new requirements is simply not achievable without advanced technologies and continuous monitoring. A February 2023 study summarizes this well:

“This work presents a real-world demonstration of how [continuous monitoring systems (CMS)] can be used to reconcile top-down measurements and bottom up inventories at the site-level. The Inflation Reduction Act requires accurate emissions estimates at this scale, and voluntary methane mitigation initiatives such as OGMP 2.0 require source- and site-level reconciliation of measurements with inventory estimates. While accurate basin-level emission estimates can be obtained through aerial surveys with large sample sizes, site-level estimates for individual operators require detailed temporal characterization of intermittent emission events. Information on such emission events, obtained through CMS in this work, will be critical for effectively creating site-specific measurement-informed inventories.<sup>107</sup>”

2. Expanded monitoring infrastructure will generate additional reductions of methane emissions and additional reductions of emissions of ozone-causing volatile organic compounds (VOCs). Both the methane and VOC reductions will have substantial health and welfare benefits for affected communities, thereby addressing important environmental justice goals.
3. Increasing deployment of continuous monitoring systems will help the EPA develop a more accurate methane emissions inventory for the entire oil and gas sector. In most cases, continuous monitoring systems provide the most complete picture of emissions and offer the greatest opportunity to achieve the nation’s methane reduction goals by 2030. Because continuous monitoring systems more accurately and frequently detect leaks, increased deployment of such systems will also allow resources for mitigation to be more effectively deployed, thereby increasing the emission reduction impact per dollar spent.
4. Increased deployment of advanced monitoring technologies across a variety of well sites will help develop valuable information for the EPA about the performance of different configurations of these technologies in different settings, which will provide EPA with information to develop specific guidance on the proper operation of these systems. Greater deployment is consistent with the EPA’s mandate to promote technological innovation.
5. EPA investment in continuous monitoring system infrastructure will ensure short-, medium and especially long-term effective emission measurement and reductions. As super-emitter events are reduced in the future with improved satellite and aerial technologies, unintentional basin emissions will be increasingly dominated by smaller sources, which are more effectively discovered through continuous monitoring systems.

---

<sup>107</sup> Daniels W, Wang J (L, Ravikumar A, Harrison M, Roman-White S, George F, et al. Towards multi-scale measurement-informed methane inventories: reconciling bottom-up inventories with top-down measurements using continuous monitoring systems. ChemRxiv. Cambridge: Cambridge Open Engage; 2023. This content is a preprint and has not been peer-reviewed <https://chemrxiv.org/engage/chemrxiv/article/details/63e526b9fcfb27a31f7c0a6c>.

Response II-5-218: EPA recognizes the commenter's support for the alternative continuous monitoring approach.

Comment: Commenter (2196-Private Citizen) references the following possible typos or reference errors:

- 60.5398b(c)(1)(i) The sensitivity of the system must be such that it can at least measure an order of magnitude less than the action-level defined in paragraph **(c)(4)(iii)** of this section.

Commenter (2196-Private Citizen) states there is no paragraph (C)(4)(iii), possibly meant (C)(4)(i) & (ii).

- 60.5398b(c)(1)(iii) The continuous monitoring system must continuously collect data as specified in paragraph (c)(1) of this section, except as specified in paragraphs **(c)(1)(ii)(A) through (D)** of this section.

Commenter (2196-Private Citizen) argues there is no paragraph (C)(1)(ii)(A) through (D), possibly meant (C)(1)(iii)(A) through (D).

Response II-5-219: EPA recognizes the commenter's input and EPA has made revisions to the final rule.

## **5.10 Alternative Test Method Approval**

### ***5.10.1 General Comments/Support***

Comment: Commenter (2355-CEC) respectfully recommends that EPA carefully assess proposed alternative test methods. Different types of advanced monitoring technologies may perform better or worse in different configurations, at different types of sites, and in different types of weather conditions. For these reasons, the commenter urges the Agency to make full use of its authorities to condition the approval of alternative test methods on specific work practices for use of those methods.

Response II-5-220: EPA recognizes the commenter's recommendations. The submissions requirements for alternative test methods are detailed in the final rule. EPA will be thoroughly reviewing all submitted materials to determine whether the alternative test method is appropriate for the specified application. This includes evaluation of technology limitations due to weather, site types, configurations, etc.

Comment: Commenter (2288-North Dakota Department of Environmental Quality) supports EPA's encouragement of new compliance methods provided EPA's review process is prompt and acknowledges the impact local climate conditions (North Dakota winters) may have on their accuracy and reliability.

Response II-5-221: EPA acknowledges the commenter's input. The submissions requirements for alternative test methods are detailed in Section X.B.3 and XI.B.3 of the preamble of the final rule. EPA will be thoroughly reviewing all submitted materials to determine whether the alternative test method is appropriate for the specified application and an evaluation of any potential limitations, such as weather conditions.

Comment: Commenter (DRAFT-154255-Colorado Air Pollution Control Division (CAPCD)) notes that Colorado has made significant progress in evaluating alternative monitoring methods for hydrocarbons and continues to participate in the ongoing development of equivalency frameworks to encourage effective deployment of alternative monitoring methods to detect both GHG and hydrocarbons.<sup>108</sup>

Response II-5-222: Thank you for your comments. EPA appreciates your efforts.

Comment: Commenter (1686/2345-GHGSat) agrees with EPA's proposal to require alternative technology to be catalogued as a Performance Test method as dictated by 40 CFR 60.8(b)(3). EPA should spearhead the vetting and qualification process due to the current diversity of alternative technologies and the lack of standardized methods and performance specifications. The commenter believes that the EPA should be the main approver of technology and use the Performance Test method stipulated in 40 CFR 60.8(b)(3), with the idea of eventually delegating authority to the States. For companies operating under the Federal Title V permit, this determination simplifies the permitting process and sets the basis for incorporating procedures for compliance. For entities not required to obtain a Federal Operating permit, the States should be able to authorize the use and implementation of alternative technologies, since the EPA will eventually grant delegating authority to the States.

Response II-5-223: EPA appreciates the support for the rule and the comments received. The submissions requirements for alternative test methods detailed in Section X.B.3 and XI.B.3 of the preamble of the final rule. EPA will be the main approver of technology and will be thoroughly reviewing all submitted materials to determine whether the alternative test method is appropriate for the specified application.

### ***5.10.2 Overall Recommendations and Clarifications to Streamline Approval***

Comment: Commenter (2316-ABB) urges EPA to consider establishing a rigorous and achievable minimum detection and quantification threshold and to highlight the importance of other performance parameters such as time response, linearity, overall accuracy (e.g., cross sensitivity, rates of false positives and false negatives), operational lifetime, and maintenance/calibration requirements. All requirements should be able to be met by commercially available technology.

Response II-5-224: EPA recognizes the commenter's recommendations. The submissions requirements for alternative test methods are detailed in Section X.B.3 and XI.B.3 of the preamble of the final rule. EPA will be thoroughly reviewing all submitted materials, including

---

<sup>108</sup> See Colorado's Approved Instrument Monitoring Method (AIMM) for oil & gas, <https://cdphe.colorado.gov/oil-and-gas-and-your-health/approved-instrument-monitoring-method-aimm-for-oil-gas>.

performance parameters, to determine whether the alternative test method is appropriate for the specified application.

Comment: Commenter (2433-EDF *et al.*) states prior to regulatory deployment, screening technologies and continuous monitoring technologies must be approved by EPA through a process that “will include consideration of the combination of the measurement technology and the standard protocol for its operation.” Both aspects are critical because the detection capability of a given technology can vary greatly depending on operating protocols and conditions. The alternative test method approval process must therefore assess technology performance under a wide variety of conditions representative of field conditions in diverse basins across the country. A technology should then be approved as meeting a specified detection threshold that it is capable of routinely and reliably achieving under a variety of conditions. The commenter supports EPA’s proposed approval process and provides the following general recommendations (more details can be found in the commenter’s letter):

- Eliminate conditional approval.
- Address basin- and site-specific requests through the AMEL process.
- Enable public participation.
- Define follow-up and repair requirements.

Response II-5-225: The EPA thanks you for your support and appreciates your recommendations. The final rule includes follow-up and repair requirements based on the spatial resolution of the technology as detailed in Section X.B.1 and XI.B.1 of the preamble of the final rule. Additionally, the final rule includes detailed submission requirements that will allow EPA to review the alternative test method technology and operational protocols.

Comment: Commenter (2326-AXPC) believes that EPA should not only rely on the ability to determine a mass emission rate when assessing alternative leak detection technologies due to the large discrepancies that can occur with mass conversion. EPA should also allow alternative leak detection technologies to use a background concentration and increase from that background level as a means to provide an action level for leak detection. The conversion of a detected concentration of methane to a mass emission rate is an added step in estimation that requires site-specific operational data/information that only the operator can provide. Testing of third-party data indicates that there can be a large discrepancy in the mass conversion. Alternative leak detection technologies can also identify a background concentration of molecules and base its action levels on an increase from that background level. This method of detection can be a reliable method of detecting and responding to leaks in real time and does not have some of the challenges presented by mass conversion based off of operator data and calculations.

Response II-5-226: Thank you for your comments. The final rule includes procedures for establishing site-specific baseline emission for the continuous monitoring systems and the action levels are based on mass emissions of methane over the site-specific baseline.

Comment: Commenter (2203-Ceres) notes that EPA should ensure that any testing is rigorous under a variety of conditions and supported by peer-reviewed and independent research.

Response II-5-227: Thank you for your recommendations. The submissions requirements for alternative test methods are detailed in Section X.B.3 and XI.B.3 of the preamble of the final rule. The following language has been added:

*“Published reports (e.g., scientific papers) produced by either the submitting entity or an outside entity evaluating the submitted measurement technology that has been independently evaluated. The published reports must identify either a site-level or aggregate detection threshold and be accompanied with sufficient supporting data to evaluate whether the performance metrics of the alternative testing procedures in paragraph (d)(3)(vi)(C) of this section are adequate and the data was collected consistent with those alternative testing procedures. The supporting data may be included in the published report or may be submitted separately.”*

Published reports should include peer-reviews journal articles and double- or triple-blind studies. As the commenter notes, testing of the alternative methane technology must be done under a variety of relevant environmental conditions.

Comment: Commenter (2213-Oxy) supports EPA’s proposal to streamline the use of these technologies through a pre-approved alternative screening approach in lieu of the proposed nine-month application process. The commenter supports the requirement to survey wellhead-only sites but the feasibility of surveying all of these locations requires the use of alternative technologies to satisfy the requirements. These alternative technologies need a streamlined approval process to allow for early adoption once the rule is finalized. Accordingly, the commenter encourages EPA to work with all stakeholders to further develop the proposed advanced measurement technology framework prior to issuing the final rules.

Response II-5-228: EPA thanks you for your support and comments. In the final rule, EPA has provided a framework for submission that is design to ensure all materials required by EPA are submitted so EPA can thoroughly review all materials.

Comment: Commenters (2363-CEMC, 2402-DGCC, 2448-Project Canary) recommend that the EPA make a limited modification to section 60.5398b(d)(1)(iv), which provides that the agency may require an operator using an approved alternative test method to demonstrate compliance with an OGI camera if the agency “finds reasonable grounds to dispute the results obtained” by the alternative test method.

Commenters (2363-CEMC, 2402-DGCC, 2448-Project Canary) note that this provision appears to assume that an operator that has opted to use an approved alternative test method will continue to have OGI cameras on-site and available. That might be the case if the alternative test method is a periodic surveying technology—because the Supplemental Proposal requires that use of such technologies is coupled with periodic OGI surveys. However, there is not a similar requirement for use of approved continuous monitoring systems.

For this reason, commenters (2363-CEMC, 2402-DGCC, 2448-Project Canary) recommend that the EPA integrate a “grace period” between the agency’s notification of dispute and the operator’s OGI camera survey. Such a period will make it possible for the operator to procure

OGI camera surveying services if it does not already have such services. The commenters recommended the following edits:

“(iv) If the Administrator finds reasonable grounds to dispute the results obtained by any alternative test method for the purposes of demonstrating compliance with a relevant standard, the Administrator may require you to demonstrate compliance according to §60.5397b for fugitive emissions components, affected facilities and §60.5416b for covers and closed vent systems within 30 days of the Administrator’s notification to you of disputed results.”

Response II-5-229: EPA disagrees with the commenters that a grace period is needed for this requirement. EPA has not stipulated that monitoring according to §60.5397b and §60.5416b must be performed if the Administrator finds reasonable grounds to dispute the results obtained by the alternative test method, only that it may be required. This decision will be made on a site-specific basis considering whether the dispute can be remedied in another manner, whether a different technology was deployed in the case of a periodic screening event, and the source of the dispute in the results. If the Administrator determines that the owner or operator must perform monitoring according to §60.5397b and §60.5416b, the Administrator is best suited to making that decision at the time of the dispute, considering factors such as the reason for the dispute, type of site and regulated components, and previous inspection results.

Comment: Commenter (2284-Kairos) echo the comments of the Methane Roundtable and others, who suggest that EPA focus its initial review and approval efforts on alternative technologies that have already been established as commercially and operationally viable so that the most promising technologies can be deployed as quickly as possible.

*Recommendation:* Prioritize technologies with high commercial readiness and potential for rapid deployment for approval and establish a streamlined review process for minor changes to approved technologies.

Response II-5-230: EPA thanks you for your recommendations. EPA has established rigorous submission requirements for readily available technologies as detailed in Section X.B.3 and XI.B.3 of the preamble of the final rule. No specific technology will be prioritized. Technologies will be reviewed as they are received. The review timeline is included in the final rule.

Comment: Commenter (2192-BSM) indicates that daily verifications are impractical and unnecessary for many screening technologies. Procedures for verifying measurement sensitivity, calibration intervals, etc. should be allowed to vary by technology. The commenter would recommend that technology specific operating procedures be included in the technology approval process.

Response II-5-231: Thank you for your comments and recommendations. The final rule includes requirements to submit standard operating procedures as well as alternative testing procedures for the technology. Both of these documents will be reviewed by EPA as part of our evaluation process.

Comment: In response to EPA's request for comment,<sup>109</sup> commenter (2298-Pioneer) echoes the Harvard Methane Roundtable comments and recommends EPA clarify information that companies must include in alternative test method applications. This is necessary to support EPA's ability to efficiently review and approve complete applications that demonstrate equivalent or better methane detection and reductions. In developing the final rule and any associated guidance, EPA should consider best practices and information required from methane detection approval processes in other jurisdictions.

Commenter (2298-Pioneer) provides the following example:

- EPA should clarify what information requestors should submit for EPA to approve the “operating window” and technology settings in which the specific test method will meet the matrix requirements.<sup>110</sup> The operating window within the work practice standards should prescribe the necessary environmental conditions in which operators may monitor with the specific test method including conditions related to weather, topography, daylight, windspeed, temperature, humidity, sunlight, and ground cover.
- EPA should require that companies submit at least two studies to demonstrate equivalency: (1) applied in the field and (2) under controlled conditions.<sup>111</sup> In guidance, EPA can specify certain testing facilities to conduct controlled testing.<sup>112</sup>
- EPA should require companies to submit information on the test method's ability to localize a leak detection and any other information to help EPA require appropriate response requirements to replace a full site wide OGI sweep.

Response II-5-232: Thank you for your recommendations. The submissions requirements for alternative test methods have been expanded and revised as detailed in Section X.B.3 and XI.B.3 of the preamble of the final rule in the final rule. EPA will be thoroughly reviewing all submitted materials to determine whether the alternative test method is appropriate for the specified application. This includes evaluation of technology limitations due to weather, site types, configurations, etc. The final rule also outlines requirements for submitting published reports evaluating the technology, supporting information and data verifying the technology meets the aggregate detection threshold(s), as well as supporting information verifying spatial resolution of the technology.

Comment: Commenters (2298-Pioneer, 2342-Harvard's Environmental and Energy Law Program (EELP)) also expect that as EPA undertakes review of any application, EPA may ask the company for additional information or clarifications. The commenters recommend EPA make clear that such a request during the review process will not restart the 270-day period or require an applicant to submit a new application. This clarification is consistent with EPA's practice. While the commenters support the proposed conditional approval process to avoid backlogging

---

<sup>109</sup> "The EPA solicits comment on the proposed information required to be submitted with the application of an alternative test method and whether the EPA should consider requiring any additional information." 87 Fed. Reg. 74702, 74746 (Dec. 6, 2022).

<sup>110</sup> See Colorado Approved Instrument Monitoring Methods (AIMM) Guidance & Procedures, p. 2.

<sup>111</sup> See AIMM Guidance & Procedures, p. 6; see also AL T-150 Approval Letter, pp. 4-8.

<sup>112</sup> See AIMM Guidance & Procedures, p. 6, suggesting the Methane Emissions Technology Evaluation Center (METEC) at Colorado State University may be used to conduct field testing.

effective advanced technologies, they encourage EPA to include a process for stakeholders to have notice of conditionally approved technologies and offer comments on their effectiveness and use.<sup>113</sup> For example, EPA could publish the application on its website with a statement that the test method will be conditionally approved by a certain date unless EPA receives substantive adverse comments.

Response II-5-233: EPA thanks you for your comments. The 270-day period will not restart if more information or supporting data is requested by EPA. The requestor will have the option to pull back their submission and resubmit at a later date if, for example, the requested information will require more than 270 days to hand over to the EPA. EPA will make all decisions related to approval and disapproval of alternative test methods based on the information that is provided in the submitted materials. If the submitted materials are incomplete or inadequate, the submission may be denied.

Comment: Commenters (2298-Pioneer, 2342-EELP) also recommend that once an application is approved, EPA provide a separate and expedited process to approve minor changes (*e.g.*, technology updates, etc.) to an approved technology without requiring a new application to submit a new alternative test method application. However, commenter (2342-EELP) also urges EPA to clarify that minor updates (*e.g.*, software updates) to an already approved technology that do not affect technology performance should not require EPA approvals.

Response II-5-234: EPA agrees with the commenter that minor updates to software that are intended to improve the Quality of Life (QoL) to improve workflow should not be subject to reapproval, however EPA does believe that changes to programming which would result in a substantive change in the output of a system must be subject to some level of re-approval. EPA has made revisions in the final rule to define when changes in software would trigger re-approval and to provide an expedited process for existing technology that has been previously approved.

Comment: In response to EPA's request for comment,<sup>114</sup> commenters (2342-EELP, 2363-CEMC, 2448-Project Canary) recommend EPA clarify information that companies requesting approval ("requestors") must include in alternative test method applications. This is necessary to support EPA's ability to efficiently review and approve complete applications that demonstrate equivalent or better methane detection and reductions. In developing the Final Rule and any associated guidance, EPA should consider best practices and information required from methane

---

<sup>113</sup> This recommendation is in response to EPA's request for comment: "The EPA is proposing a defined timeframe for review and determination of alternative test method requests by the Agency. The EPA is proposing to issue either an approval or disapproval in writing to the requestor within 270 days of receipt of the request, with a number of milestones for acknowledgement of receipt and initial reviews. [ ...] The EPA solicits comments on the proposed timeframe to review and approve alternative test methods and whether alternative timelines should be considered." 87 Fed. Reg. 74746.

<sup>114</sup> "The EPA solicits comment on the proposed information required to be submitted with the application of an alternative test method and whether the EPA should consider requiring any additional information." 87 Fed. Reg. 74702, 74746 (Dec. 6, 2022).

detection approval processes in other jurisdictions, including the Colorado Alternative Approved Instrument Monitoring Methods (AIMM) process.<sup>115</sup>

Response II-5-235: EPA has revised the rule as detailed in Section X.B.3 and XI.B.3 of the preamble of the final rule to clarify the required information that must be submitted when seeking approval.

Comment: Commenter (2227-Western Energy Alliance (WEA)) recommends that EPA establish a set of pre-approved alternative methane detection technologies. Also, the commenter recommends that validation of advanced methane detection technologies should be outside of the NSPS and EG.

Response II-5-236: EPA thanks you for your recommendations. EPA has established rigorous submission requirements for readily available technologies in the final rule. All technologies will undergo the same review process by EPA as the submissions are received.

Comment: Commenter (2193-California Air Resources Board (CARB)) urges EPA to include all approved advanced technology alternatives in the Emissions Measurement Center (EMC) website, not just the broadly applicable ones, to better streamline the 111(d) Plan implementation process.

Commenter (2193-CARB) states the Supplemental Rule includes that well sites and compressor stations may utilize alternative monitoring systems, optional advanced screening may be utilized, and that M21 inspections may be utilized in lieu of OGI monitoring for fugitive emissions.<sup>116</sup> Instead of indicating whether EPA intends to provide a list designating which alternative monitoring systems may be permissible, the Supplemental Rule states that "[w]hile there was widespread support of the concept of an alternative screening option, the EPA still does not have enough information to conduct the requisite BSER analysis for any specific advanced measurement technology to determine whether it would qualify as the BSER for detecting fugitive emissions."<sup>117</sup> Because this technology is not presently known, EPA has proposed sensitivity parameters based upon testing frequency for the level of emissions any proposed advanced technology would need to detect and discusses how best to utilize continuous monitoring systems.<sup>118</sup> However, with respect to the approval process, it only states that it wants to establish a system to streamline the approval of the alternative systems.<sup>119</sup> "Once an alternative test method or alternative technology has been approved, if it is broadly applicable, EPA will post it to the Emissions Measurement Center website" so other owner/operators who meet the requirements may utilize the technology as well, but "broadly applicable" is never

---

<sup>115</sup> See AIMM Guidance & Procedures, <https://oitco.hylandcloud.com/Pop/docpop/docpop.aspx>, and pending applications, <https://cdphe.colorado.gov/public-information/alternative-aimm-public-notices>; the Alberta Energy Regulator (AER) Alternative Fugitive Emissions Management Program (Alt-FEMP) and New Mexico Advanced Leak and Repair Monitoring (ALARM) program in New Mexico are other examples.

<sup>116</sup> 87 Fed. Reg. 74,709; 74,740 (Dec. 6, 2022).

<sup>117</sup> 87 Fed. Reg. 74,740 (Dec. 6, 2022).

<sup>118</sup> 87 Fed. Reg. 74,740-74,743 (Dec. 6, 2022).

<sup>119</sup> 87 Fed. Reg. 74,743-74,744 (Dec. 6, 2022).

defined.<sup>120</sup> This still leaves states the challenge of proposing regulations that accommodate a speculative, and likely redundant, application process.

Commenter (2193-CARB) continues, to further streamline the process, any already approved alternatives to OGI and M21 inspections should be maintained in the Emissions Measurement Center as a supplement to the presumptive standards by EPA to prevent unnecessary applications during the CAA 111(d) Plan drafting process. Broad applicability is unnecessary when the technology's requirements are being included on the website. While the commenter applauds EPA for its vision of allowing newer and better technology in the future, it does not make sense for entities to apply for approval of technologies that have already been approved for another entity. If states are to submit their plans in an efficient manner, there must be clear and consistent guidelines to follow in the presumptive standards.

Commenter (2193-CARB) goes further, maintaining the EMC website in this manner alleviates EPA from having to regularly approve or reject proposed alternatives on a case-by-case basis that EPA has already vetted and approved. Instead, states and entities can quickly check the website and determine a technology's applicability based on the requirements prior to considering whether an application is necessary. For instance, it appears from the proposed rule that quarterly OGI inspections are preferred, but quarterly M21 inspections or quarterly advance measurement technology inspections with OGI monitoring would both be approved alternatives that EPA may set requirements for in the Emissions Measurement Center website.<sup>121</sup> Clearly identifying the alternative inspection methods with the requirements, despite an analysis of whether they are "broadly applicable", as supplements to the presumptive standards provides the states a more expedient manner to determine whether a particular method is within the presumptive standards when drafting their CAA 111(d) Plans. A state's ability to determine presumptive standards quickly and efficiently with respect to facility inspection, without unnecessary applications, ensures well-drafted 111(d) Plans that better meet EPA's proposed EGs and therefore better reduce GHG and VOC emissions.

Response II-5-237: EPA recognizes the comment. All the alternative test methods (site-specific and broadly applicable) will be available to view on the submittal website. The submission and review process will be transparent, allowing the ability for users to search and view both site-specific and broadly applicable application materials (excluding CBI) that are approved, pending and denied.

Comment: Commenter (2326-AXPC) argues their failure to provide specific comments should not indicate support or lack of concern with a particular provision. The commenter supports many of the comments related to alternative leak detection technologies made by its fellow trade associations, particularly the API.<sup>122</sup> In general, the commenter does not believe that EPA's proposal provides a workable or efficient alternative leak detection program that operators could utilize in any significant way. The commenter and its members strongly support the ability to use alternative leak detection technologies under the rules and contend that many of these technologies are at least as effective as OGI because they can potentially capture more

---

<sup>120</sup> 87 Fed. Reg. 74,746 (Dec. 6, 2022).

<sup>121</sup> 87 Fed. Reg. 74,741-74,742 (Dec. 6, 2022).

<sup>122</sup> See API Supplemental Proposal Comments §3.0.

significant leaks more quickly and the screening technologies can obtain information on a greater percentage of facilities faster than an operator can accomplish with optical gas imaging. And more will come, as operators are working to further develop technological capabilities in this area. Thus, EPA's alternative leak detection program needs to be adopted in a manner that ensures that a range of technologies can be economically used now and that new technologies that become available can also be utilized. However, it must be structured significantly differently from the current alternative technology approval process to facilitate use of such devices.

Response II-5-238: EPA acknowledges the commenters input.

Comment: Commenter (2202-TXOGA) believes the rule should clarify that commercial availability of alternative technologies applies to underlying components and does not bind operators to purchase whole systems from third parties.

Commenter (2202-TXOGA) notes in the November 2021 proposal, EPA solicited data on the current detection sensitivity of commercially available methane detection technologies as deployed, as well as other data that could be used to support consideration of a different minimum detection threshold. In the proposed December 2022 changes, in an effort to streamline the approval process and reduce the time needed for processing these request for alternative test methods, EPA proposes pre-qualifications for those requesting approval of their technology; these pre-qualifications include; “(4) the technology must be commercially available, meaning it has been sold, leased, or licensed, or offered for sale, lease, or license, to the general public.” EPA is soliciting comments on how it has characterized the pre-qualifications in its proposal and whether any additional pre-qualifications may be appropriate. EPA must clarify that when it refers to the commercial availability of alternative leak detection technologies, it means that the underlying hardware components are “commercially available,” and that EPA does not mean that operators are bound to purchase certain whole package technologies from third parties that are approved by EPA. As industry practices and leak detection technology evolve, operators will likely be involved in the development of systems to more broadly detect and respond to emissions.

Commenter (2202-TXOGA) argues EPA needs to clarify the requirement for “commercially available” in a way that facilitates use of commercially available components in leak detection systems, while providing flexibility for operators to develop and build leak detection systems to fit varying operational scenarios. These could include systems that, while made up of commercially available components, may not be sold commercially as a whole package.<sup>123</sup>

Response II-5-239: EPA intent of the “commercially available” provision was a hedge to ensure only fully developed technology would be submitted to EPA for review and we did not consider owners and operators would develop their own proprietary solutions. EPA has revised the final rule to no longer include the commercially available requirements.

---

<sup>123</sup> This request is consistent with EPA's overall goal of advancing technologies, while also minimizing costs.

### ***5.10.3 Flexibility in Alternative Test Method (ATM) Process***

Comment: Commenters (2184-PSR, 2203-Ceres, 2213-Oxy, 2235-SLB, 2354-Business Roundtable, 2383-Baker Hughes) express support for EPA's proposal to streamline the use of alternatives technologies via an ATM approval process.

Commenter (2184-PSR) asks the EPA to provide industry flexibility to use innovative and cost-effective methane detection technologies, and a streamlined process for approving new detection methods as they become available.

Response II-5-240: The submission requirements for alternative methane measurement technology are outlined in Section X.B.3 and XI.B.3 of the preamble of the final rule. All alternative methane measurement technology for use in this NSPS and/or EG will be reviewed by the EPA.

Comment: Commenter (2354-Business Roundtable) observes that EPA has recognized that technology to detect methane emissions is rapidly advancing.<sup>124</sup> This success has been the result of timely Department of Energy and ARPA-E research funding, EPA voluntary programs in which many Roundtable members have participated, private-public research partnerships involving the oil and gas industry and the federal government, and U.S. businesses marshalling talent and resources to address the challenge of climate change. The result is that the U.S. leads the way in developing new technology to identify and reduce fugitive methane emissions. This technology is improving every day.

Commenter (2354-Business Roundtable) has long advocated for regulatory flexibility to encourage innovation and the development of cost-effective solutions to meet regulatory objectives.<sup>125</sup> Overly prescriptive, inflexible regulations discourage the development of innovative technologies that can generate greater emissions reductions and reduce compliance costs.

Commenter (2354-Business Roundtable) indicates that while EPA is to be commended for building in and clarifying regulatory flexibility to incentivize the introduction of newer, more effective and potentially less expensive technologies, the significantly elevated frequency required for utilizing alternative technologies and the process for approving these technologies is still more cumbersome and less predictable than it should be. The requirement to resubmit technology approval applications that require additional information following EPA's 270-day window for testing new technologies,<sup>126</sup> thereby resetting the 270-day clock, for example, will unnecessarily lengthen the approval process for new technologies. While the commenter appreciates the essential role EPA plays in ensuring only effective technologies are approved for use, more flexibility is needed if the objective is to accelerate the use of effective and efficient new technologies. If EPA decides additional information is required to support an application, a

<sup>124</sup> 86 Fed. Reg. 63147.

<sup>125</sup> Business Roundtable, *Achieving Smarter Regulation* (September 2011), available at: 2011\_09\_BRT\_Achieving\_Smarter\_Regulation.pdf

<sup>126</sup> Proposed regulatory text, §60.5398b(d), "Alternative Test Method."

better approach would be to stay the 270-day clock until the information is provided rather than require applicants to submit a new application and restart the review period.

Commenter (2354-Business Roundtable) urges EPA to provide a clearer, more expeditious and more certain pathway for the approval of innovative technologies that can be credibly verified to be as effective as those prescribed for leak detection and monitoring and consider technology needs for additional related rulemakings.

Response II-5-241: Thank you for your comments. Per the final rule, EPA will conduct a completeness review within 90 days of submission receipt. If the completeness requirements are not met, the requestor will be notified and may choose to revise the information and submit a new request. Section X.B.3 and XI.B.3 of the preamble of the final rule includes description of all submission requirements that are necessary for a submission to be considered complete.

Comment: Commenters (2363-CEMC, 2448-Project Canary) commend the EPA's ambition to streamline the approval process for proposed alternative test methods provided in §60.5398b(d), including acknowledgement of receipt of the request within 14 days and a completeness determination within 90 days of receipt. However, the commenters have concerns regarding the completeness determination process, and are providing the following comments.

Commenters (2363-CEMC, 2448-Project Canary) appreciate the EPA's planned completeness determination and notification process outlined in §60.5398b(d)(1)(ii); however, the commenters believe that without well-defined detail of the information EPA expects to see in a request for alternative test methods, there will be unnecessary delays within the approval process. Commenters (2363-CEMC, 2448-Project Canary) agree in concept with EPA's list of necessary information for consideration of an alternative test method provided in §60.5398b(d)(2) and §60.5398b(d)(3); however, the current proposal is vague when defining specific data necessary to review and approve a technology under these provisions.

As such, commenters (2363-CEMC, 2448-Project Canary) encourage the EPA develop, specific for technologies requesting an alternative test method under this subpart, a thorough and complete checklist of all information EPA will expect when considering a completeness determination, as well as final approval. A detailed checklist will help applicants ensure that all necessary information is included in each request, while expediting EPA review of said applications, helping streamline the approval process.

Commenters (2363-CEMC, 2448-Project Canary) are also providing comments regarding the initial review for completeness described in §60.5398b(d)(1)(ii). The requirement currently states:

If the request is deficient, meaning the requirements of in paragraphs (d)(2) and (3) were not met, the request will be denied, and the Administrator will notify the requestor in writing. The requestor may choose to revise the information and submit a new request for an alternative test method.

As written, if a request for approval were denied because it was deficient, the requestor would need to submit a new request for approval with appropriate revisions, restarting the 270-day conditional approval. Without a specific and detailed application checklist, as described above, commenters (2363-CEMC, 2448-Project Canary) believe there is too much ambiguity regarding what a request must include in order to be determined complete. This is particularly important because if a request is deemed incomplete, a completely new request must be submitted, inevitably delaying the process for approval of alternative technologies.

Commenters (2363-CEMC, 2448-Project Canary) also encourage EPA to provide reasonable timeframes for requestors to respond to questions and/or requests for additional information related to a request for an alternative test method, prior to denying such request. This clarification is consistent with EPA's practice. For example, in the ALT-150 approval letter, the requestor submitted additional information twice before approving the application.

For the reasons discussed above, commenters (2363-CEMC, 2448-Project Canary) recommend the following revision to §60.5398b(d)(1)(ii):

If the request is deficient, meaning the requirements of in paragraphs (d)(2) and (3) were not met, the request will be denied, and the Administrator will notify the requestor in writing. The requestor may choose to revise the information and submit a new request for an alternative test method. The new request will not restart the 270-day period provided in subparagraph (iii).<sup>127</sup>

Response II-5-242: EPA agrees that it is important to communicate our needs in order to streamline the review process. The final rule includes detailed submission requirements. A guidance document supplements the details outlined in the rule. It is the responsibility of the submitter to provide all of the required information. If the submitter fails to provide all the information requested by EPA, the request can be withdrawn by the submitter or, if necessary, denied by EPA. If the alternative method is resubmitted, the 270-day review period will restart at day 0. The review for completeness, done within 90 days, will give the submitter ample feedback regarding what information or data their submission is missing.

Comment: Commenters (2298-Pioneer, 2342-EELP, 2383-Baker Hughes, 2458-MiQ) urge EPA to incentivize operator use of advanced technologies by consistently improving its data inputs to better reflect advanced technologies' capabilities compared to BSER in realistic conditions. EPA should regularly issue guidance with the most recently approved modeling versions and peer-reviewed studies that requestors can use as inputs.

Response II-5-243: EPA acknowledges the input from the commenters.

Comment: Commenters (2298-Pioneer, 2342-EELP) state EPA should incentivize operator use of advanced technologies by consistently improving its data inputs to better reflect advanced technologies' capabilities compared to BSER in realistic conditions. Most importantly, EPA should clarify how it will conduct its review of applications to focus initial efforts on test methods that have already been established as commercially and operationally viable so that the

---

<sup>127</sup> See ALT-150 Approval Letter, p. 1.

most promising technologies can be deployed as quickly as possible. For example, EPA should consider how it might prioritize such applications and request information that might help expedite certain test methods, including other jurisdictional approvals, industry sponsors, and/or commercial availability.<sup>128</sup>

Response II-5-244: EPA thanks you for your comments. The final rule includes detailed submission requirements for alternative methane technology methods. All submissions will go through the same review process. Priority will not be given to any submissions.

Comment: Commenter (2458-MiQ) states to incentivize the continued adoption and use of advanced screening technologies, the commenter recommends that EPA dedicate resources to the testing and approval process for advanced monitoring technologies, per the process outlined in the supplemental proposal. OGI efficacy and inspection frequency should also be updated on an annual basis using applicable new research. This research could, for example, include studies of the comparative effectiveness of different monitoring technologies (both new and existing).

Response II-5-245: EPA recognizes the input from the commenter.

Comment: Commenter (2383-Baker Hughes) supports the alternative test method as defined in the proposed in NSPS Subpart OOOOb and EG Subpart OOOOc, believing these provisions will stimulate continuous improvement and innovation in emission detection and control technologies.

The commenter (2383-Baker Hughes) notes that innovation will be the key to cost-effectively reducing venting and fugitive emissions from the oil and gas sector. While technology and practices exist today to begin managing this issue, continued progress is necessary to drive the emission reductions necessary to make a material impact. The commenter believes EPA should ensure that regulations do not stand in the way of that innovation. Methane regulations must be designed to both foster and accommodate future innovative technologies and practices. Therefore, it is imperative that the approval process for new emission monitoring, quantification and mitigation technologies be efficient, flexible, well-defined, and open to a broad range of potential applicants including technology providers. The commenter believes the statement in §60.5398b meets the mark: “Any entity meeting the requirements in paragraph (d)(2) of this section may submit a request for an alternative test method.” The commenter is also supportive of the requirements in §60.5398b(d)(2) defining the eligibility for entities wishing to submit an alternative test method for consideration. These provisions support innovation from the range of potential companies and organizations developing commercial solutions to methane emission detection and measurement.

Response II-5-246: Thank you for your comments. EPA agrees that innovation and improvement is important. The final rule includes well defined submission requirements so a broad range of applicants can be reviewed by EPA as efficiently and effectively as possible.

---

<sup>128</sup> See AIMM Guidance & Procedures, p. 3-4.

#### ***5.10.4 FEAST Model Results, Matrix Approach, and State CAA 111(d) Plans***

Comment: Commenter (2235-SLB) recommends that in addition to the provided matrices, requestors be allowed the option to submit FEAST models with limited modifications to provide for combinations of alternative technology or threshold detection edge cases for review and approval under the alternative test method approval process included in the Supplemental Proposal.

Commenters (2298-Pioneer, 2363-CEMC, 2448-Project Canary) believe EPA should make clear that as part of alternative test method approval process, site-specific emission monitoring plans, or state CAA 111(d) plans, entities can use the most recent publicly available versions of FEAST and other models, as well as recent peer reviewed studies specific to basins within that state as modeling inputs. This way, EPA can ensure the requirements for advanced technologies reflects the best information available. For example, a state, or a group of states in a single basin, may want to submit a 111(d) plan that relies on basin specific emissions data to enable the deployment of advanced technologies best suited to reduce emissions in that area provided the emission reductions are consistent with BSER. EPA should clarify that states have the flexibility to incorporate such tailored modeling, subject to EPA approving such a plan as “satisfactory” in meeting the requirements of CAA section 111(d) and all other applicable equivalency requirements.

Response II-5-247: EPA acknowledges the input. EPA does not intend to evaluate any revisions to the matrix framework for the NSPS, however as part of the state plans in the EG, it would be appropriate for them to evaluate their own models, reflective of the oil and gas facilities found in their jurisdiction.

Comment: In response to EPA's request for comment,<sup>129</sup> commenters (2298-Pioneer, 2342-EELP) agree with EPA's recommendation to allow operators to utilize the matrix to comply with CAA section 111(h)(1) and to approve alternative test methods under 40 CFR §60.8(b)(3). Enabling operators to deploy technologies meeting the specifications of the matrix will encourage greater use of alternative test methods that can better detect emissions and therefore result in greater emission reductions than requiring operators to only use OGI or Method 21.

Commenters (2298-Pioneer, 2342-EELP) note EPA proposes the BSER for the fugitive emissions subcategory to be combinations of OGI and AVO work practice standards<sup>130</sup> under CAA section 111(h)(1).<sup>131</sup> The DC Circuit has indicated that "EPA may provide sources with multiple work practice compliance options if EPA demonstrates that at least one of these options is cost effective and 'expressly provides for the alternative in the standard.'"<sup>132</sup> Here, EPA

---

<sup>129</sup> “The EPA is soliciting comment on the use of this provision at 40 CFR 60.8(b)(3) for the approval of the alternative test method for an alternative technology for measurements within the proposed alternative periodic screening approach and the proposed alternative continuous monitoring approach.” 87 Fed. Reg. 74746.

<sup>130</sup> 87 Fed. Reg. 74708-09 (Dec. 6, 2022).

<sup>131</sup> Section 111(h)(1) of the Clean Air Act allows EPA to promulgate a work practice where “it is not feasible to prescribe or enforce a standard of performance.” 42 U.S.C.A. §7411(h)(1).

<sup>132</sup> 73 Fed. Reg. 78199, 78200 (Dec. 22, 2008) (citing *Arteva Specialties S.R.L., d/b/a KoSa v. EPA*, 323 F.3d 1088, 1092 (DC Cir. 2003)).

demonstrates that BSER is cost effective<sup>133</sup> and proposes an alternative work practice (AWP) of “periodic or continuous screening with advanced measurement technology instead of OGI and AVO monitoring according to minimum detection sensitivity of technology” (the “matrix”).<sup>134</sup> This voluntary AWP is supported by precedent, as EPA promulgated OGI as a voluntary AWP to Method 21 in 2008.<sup>135</sup> EPA established the 2008 OGI AWP using modeling to demonstrate equivalency to Method 21<sup>136</sup> and is proposing to establish the matrix AWP using modeling.<sup>137</sup>

Commenters (2298-Pioneer, 2342-EELP) state EPA also proposes to approve “alternative test methods” for the matrix under 40 CFR 60.8(b)(3),<sup>138</sup> which is supported by EPA's January 30, 2007 notice in the Federal Register describing the process the agency will use to issue broadly applicable major alternative test method approvals for NSPS.<sup>139</sup> This is distinguishable from the section 11(h)(3) AMEL process, which requires notice and an opportunity for public comment,<sup>140</sup> because the matrix- as a voluntary AWP- will be promulgated under EPA's general rulemaking authority and will have gone through a notice and comment,<sup>141</sup> and the test methods demonstrate compliance with that AWP.

Response II-5-248: EPA acknowledges the commenters support of the alternative test method process.

#### ***5.10.5 Minimum Application Requirements***

Comment: Commenter (1686/2345-GHGSat) agrees with the EPA that a pre-qualification process needs to be implemented. This process will set the preliminary expectations for each technology provider allowing them to prepare and align with the requirements. Commentary for each of the four characteristics is below:

1. Requestors are limited to any individual or organization located in or that has representation in the US. The commenter believes that, while in agreement with requestors needing to have representation in the United States, this point should be elaborated further, by clarifying this requirement as to which type of entity, number of employees in the US, and good track record with the Internal Revenue Service. Also, the EPA should explain what to do in case the company just started representation in the US. The EPA should establish a minimum residency/operating time in the United States or a mechanism to account for operating time in other countries.

---

<sup>133</sup> 87 Fed. Reg. 74727-35 (Dec. 6, 2022).

<sup>134</sup> 87 Fed. Reg. 74 708-09 (Dec. 6, 2022).

<sup>135</sup> See 73 Fed. Reg. 78200 (Dec. 22, 2008).

<sup>136</sup> 73 Fed. Reg. 78201 (Dec. 22, 2008).

<sup>137</sup> 87 Fed. Reg. 74741-43 (Dec. 6, 2022).

<sup>138</sup> 40 CFR §60.8(b)(3) requires that initial performance tests be conducted in accordance with the test methods “in each applicable subpart unless the administrator ... approves the use of an alternative method the results of which he has determined to be adequate for indicating whether a specific source is in compliance.”

<sup>139</sup> 72 Fed. Reg. 4257-03 (Jan. 30, 2007).

<sup>140</sup> 42 U.S.C.A. §741 l(h)(3).

<sup>141</sup> See 71 Fed. Reg. 17,403. EPA explained that the American Petroleum Institute requested EPA approve OGI as an AWP but did not “indicate if it was invoking EPA's general rulemaking authority or the AWP provisions of CAA section [ ] 111” so EPA “treated the request as being for a general rulemaking because APJ’s request was not specific to any single source category.”

2. Requestor must have a direct knowledge of the design, operation, and characteristics of the underlying technology. The commenter believes this requirement is valid and valuable, as it can prevent the rise of opportunistic companies with limited knowledge. Nonetheless, the EPA should establish a mechanism to validate the knowledge of the underlying technology. For example, the EPA should ask requestors to provide evidence of their participation in trade shows, peer and non-peer-reviewed articles, and/or presentations associated with the underlying technology.
3. The underlying technology must have been applied to methane measurements in the oil and gas production, processing, and/or transmission and storage sectors either domestically or internationally. The commenter believes that this requirement can be coupled with requirement #2, since it is imperative that requestors not only have the technical knowledge of the technology but also that the technology has been applied in the oil and gas sector.
4. The technology must be a commercial product, meaning it has been sold, leased, or licensed, or offered for sale, lease, or license, to the general public. The commenter believes this point is valid but requires clarification as to who the general public is. A literal interpretation may disqualify most of the technologies since the general public are not necessarily interested and/or able to procure any of these technological services. The commenter recommends removing “the general public” or to further add “the general public or industry”.

Response II-5-249: EPA acknowledges the commenters support of the alternative test method process and recognizes the suggestions made.

Comment: Commenter (1686/2345-GHGSat) believes that the EPA should provide an expected timeline to conduct a pre-screening resolution. Also, it needs to explain the next steps for requestors that are not able to meet the pre-screening requirements. These next steps should consider providing a timeline for requestors to reapply.

Commenter (2348-EWTC) notes that technology approval should include proof of results, including an accredited third-party’s validation, as they relate to detecting methane leak events, field-proven evidence, and technology validation accurately capturing events per a given range of detection and quantification thresholds that are not false events. As of today, it is common in the industry to use the METEC standard from the Colorado State University in Fort Collins.

Response II-5-250: EPA recognizes the input and Section X.B.3 and XI.B.3 of the preamble of the final rule detail the requirements for the alternative test method process.

Comment: Commenter (2226-Thermo Fisher) recommends EPA clarify the terms of the second pre-qualification regarding that the technology “must have been applied to methane measurements or monitoring in the oil and gas sector either domestically or internationally”. The commenter is unclear how a new technology can be demonstrated its application in the field without EPA designation. The commenter recommends the EPA establish a measurement technology testing facility where new technology can be demonstrated.

Response II-5-251: EPA designation is no required for use in the oil and gas sector. Only when the technology is used to demonstrate compliance with an applicable regulation under an NSPS and/or EG. This provision is in place to ensure EPA personnel will only evaluate technology that will be applied to the oil and gas sector.

Comment: Commenter (2226-Thermo Fisher) asks that EPA clarify the type of verifying information the Agency will be requesting under the proposed requirement requesting entities to provide “supporting information verifying that the technology meets the desired detection threshold(s) as applied in the field” as part of the application. For example, clarity on if the technology must be demonstrated under controlled laboratory conditions first.

Response II-5-252: EPA has expanded and revised the criteria for submitting an alternative test method request in this rule, as detailed in Section X.B.3 and XI.B.3 of the preamble of the final rule.

Comment: Commenter (2326-AXPC) says that EPA must clarify that when it refers to the commercial availability of alternative leak detection technologies, it means that the underlying hardware components are “commercially available”, and that EPA does not mean that operators are bound to purchase certain whole package technologies from third parties that are approved by EPA. As industry practices and leak detection technology evolve, operators will likely be involved in the development of systems to more broadly detect and respond to emissions. EPA must clarify the requirement for "commercially available" in a way that facilitates use of commercially available components in leak detection systems, while providing flexibility for operators to develop and build leak detection systems to fit varying operational scenarios. These could include systems that, while made up of commercially available components, may not be sold commercially as a whole package.

Response II-5-253: EPA intent of the “commercially available” provision was a hedge to ensure only fully developed technology would be submitted to EPA for review and we did not consider owners and operators would develop their own proprietary solutions. EPA has revised the final rule to no longer include the commercially available requirements.

Comment: Commenter (2333-LongPath) strongly recommends the following points be included in the list of required information for spatial coverage:

- What percentage of equipment is seen with each “scan”?
- How long does it take to achieve 100% coverage of all regulated equipment?
- Are there any systematic biases or blind spots in site coverage?

Response II-5-254: The intent of the spatial coverage is that you are able to measure emissions from 100% of the regulated equipment on site, EPA does not include requirements how this must be done and in reliant on the technology vendors to develop their processes so that an entire sites emissions are captured.

Comment: Commenters (2448-Project Canary, 2663-CEMC) urge the EPA to modify certain requirements of the alternative test method requirements that apply for non-entity operators. These requirements, which are found in proposed section 60.5398b(d)(2), imply that only technologies already in commercial use will be eligible for consideration. This could have the unintended effect of stifling, rather than encouraging, innovation.

Commenters (2448-Project Canary, 2663-CEMC) note proposed section 60.5398b(d)(2)(B)(ii)(B) provides that the “underlying technology” must have already been “applied to methane measurements or monitoring in the oil and gas sector either domestically or internationally.” And section 60.5398b(3)(2)(iii) requires that the underlying technology “must be commercially available, meaning that it has been sold, leased, or licensed, or offered for sale, lease, or license to the general public.” These are unreasonably limiting conditions. Notably, this proposed “commercially available” requirement imposes a higher standard on alternative test methods than the CAA section 111 test for determining whether a system is the “best system of emission reduction” that has been “adequately demonstrated.”

Commenters (2448-Project Canary, 2663-CEMC) state to be the BSER, it is not required that a technology “must be in actual routine use somewhere.”<sup>142</sup> Indeed, there are several instances in which the EPA has determined that a technology has been “adequately demonstrated” and qualifies as the BSER even where only pilot-scale data or projections were available. The Court of Appeals for the District of Columbia Circuit has upheld the validity of this approach.<sup>143</sup>

Commenters (2448-Project Canary, 2663-CEMC) argue if EPA does not require that a technology be in current commercial use to qualify as the BSER, it makes little sense for the agency to impose that requirement on what it intends to be innovative, technology-advancing alternatives to the BSER.

Response II-5-255: EPA has revised the commercially available provisions from the proposed rule as detailed in Section X.B.3 and XI.B.3 of the preamble of the final rule. The intent of the “commercially available” provision was a hedge to ensure only fully developed technology would be submitted to EPA for review.

Commenters (2448-Project Canary, 2663-CEMC) encourage the EPA to more clearly define “underlying technology” in this section. Their interpretation is that underlying technology means a physical methane detector technology which has been shown to adequately measure methane emissions, *e.g.*, laser-based, LiDAR, or metal oxide.

Commenters (2448-Project Canary, 2663-CEMC) state advanced methane emissions surveying and monitoring technologies are developing rapidly. Innovations are occurring at a brisk pace. The EPA should be open to considering as “alternative test methods” pre-commercial

---

<sup>142</sup> Portland Cement Ass’n v. Ruckelshaus, 486 F.2d 375, 391 (D.C. Cir. 1973) (emphasis added).

<sup>143</sup> See *Sierra Club v. Costle*, 657 F.2d 298, 363-64 (D.C. Cir. 1981) (upholding standard that no plant was then meeting either at pilot- or commercial-scale, based on projected improvement in scrubber technology), 380-84 (endorsing EPA’s use of operational data from small-scale plants to project utility-scale performance of baghouse technology); *Essex Chemical Corp. v. Ruckelshaus*, 486 F.2d 427, 440 (D.C. Cir. 1973) (concluding that EPA reasonably considered “prototype testing data” and vendor guarantees to determine that system was adequately demonstrated).

technologies that can demonstrate their effectiveness to EPA through field and pilot testing. Once the technologies are approved by the agency as scientifically accurate, then it will be up to the market to determine whether they are commercially viable.

Response II-5-256: As with the previous response, the requirements that the underlying technology or technologies must be readily available for use, is to ensure they have been properly and effectively evaluated in the field for use. The alternative test provision is for evaluating technologies that are ready to be used for compliance measurements, it is unlikely that EPA will consider any technology that has not previously gone through field or pilot testing.

Comment: Commenter (1686/2345-GHGSat) agrees with the EPA with conducting an initial and complete evaluation of each alternative technology applying for alternative test method recognition. Therefore, the pre-screening process should partially address the requirements of this evaluation. The commenter believes that an effective emissions detection system needs to simultaneously satisfy the following requirements:

1. Well-characterized detection limit based on a POD curve.
2. Well-characterized, high specificity (low rate of false positives).
3. Well- characterized quantification accuracy.

Commenter (1686/2345-GHGSat) is providing comments on each of the five requirements currently listed in this proposed rule (more specific information on these comments can be found in the commenter's letter).

1. The desired applicability of the technology (*i.e.*, site-specific, basin-specific or broadly applicable across the sector).
2. A description of the measurement system.
3. Supporting information verifying that the technology meets the desired detection threshold(s) as applied in the field.
4. A detailed description of the alternative testing procedure(s), including data quality objectives to ensure the detection threshold(s) are maintained and procedures for a daily verification check of the measurement sensitivity under field conditions.
5. Standard operating procedures consistent with the EPA's guidance and including safety considerations, measurement limitations, personnel qualification/responsibilities, equipment and supplies, data and record management, and quality assurance/quality control.

In addition to these requirements, commenter (1686/2345-GHGSat) believes that the agency should also indicate if the requestor needs to wait until a Notice of Availability has been published in the Code of Federal Regulations to start offering the service to meet regulatory requirements. The commenter understands that the publication of Notice of Availability in the Code of Federal Regulations could take time, so the commenter would like to propose that the EPA publishes any approved alternative test method in the EPA's Air EMC website. That way, operators that are interested in employing an alternative technology for regulatory purposes can identify the approved alternative test method by visiting the EPA's EMC website and confidently procure the approved services.

Response II-5-257: EPA has developed a web app to support the alternative test method process as found at <https://www.epa.gov/emc/oil-and-gas-alternative-test-methods>. A list of all approvals will be posted on this webpage.

Comment: Commenter (2340-Honeywell) believes that ATM approvals should use standardized, independent verifications of the accuracy of methane detection technologies, and should begin prior to the finalization of the rule. The alternative test method approval process should hold all continuous monitoring systems to similar, independently verified accuracy and reliability standards based on real-world deployment conditions so as to (a) ensure accurate emissions detection and equivalency to BSER, and (b) provide an even playing field for the validation of different technologies which may otherwise be biased by varying lab testing conditions. Further, the final rule should allow for streamlining of the alternative test method approval process (*e.g.*, by allowing submission of materials prior to publication of the final rule), given that approval is critical in order for technologies to be available to regulated parties as soon as possible.

Response II-5-258: EPA acknowledges the input from the commenter, EPA has expanded the and revised the required information a person must submit when requesting an alternative test method as described in Section X.B.3 and XI.B.3 of the preamble of the rule.

Comment: Commenters (2342-EELP, 2363-CEMC) indicate that as EPA evaluates these alternative test methods for equivalency, it is critical that EPA ensure that any approved work practice standards require operators to deploy the technology in scenarios that were evaluated by EPA. Therefore, EPA should require requestors to submit supporting materials that demonstrate the equivalency of the advanced technology in a range of operating conditions to ensure the technologies are deployed in a manner that appropriately detect emissions in the field under different conditions. The commenter recommends that EPA refine the information needed for considering and approving methane detection test methods to complete the test method standard operating procedures in EPA's preferred Environmental Monitoring and Management Council Methods Format:

- Most advanced methane detection technologies require numerous elements to confirm a detection, including specific technology hardware, procedures for using the technology to detect methane emissions, and software and procedures for processing resulting data from binary data to data that confirms a "detection". EPA should clarify which of these elements it is approving in an "alternative test method" and request information on each of those elements that it is intending to approve in the alternative test method.
- EPA should clarify what information requestors should submit for EPA to approve the "operating window" and technology settings in which the specific test method will meet the matrix requirements. The operating window within the work practice standards should prescribe the necessary environmental conditions in which operators may monitor with the specific test method including conditions related to weather, topography, daylight, windspeed, temperature, humidity, sunlight, and ground cover.
- EPA should clarify that the alternative test method applications must include technology-specific work practice standards that establish the deployment configuration to demonstrate equivalency. For example, continuous monitors will require information on

spatial location and number of sensors and aerial monitors will require information on how high above the site and how quickly the monitor can fly.

- EPA should require that companies submit results of testing to demonstrate equivalency through blind testing by a qualified third party applied under controlled conditions and in the field, and across a spectrum of emissions sizes. In guidance, EPA can specify certain testing facilities to conduct controlled testing.
- EPA should require companies to submit information on the test method's spatial and temporal coverage as well as its ability to localize an emission detection and any other information to help EPA require appropriate response requirements to replace a full site wide OGI sweep.

Response II-5-259: EPA acknowledges the input from the commenter, EPA has expanded the and revised the required information a person must submit when requesting an alternative test method as described in Section X.B.3 and XI.B.3 of the preamble of the rule.

Comment: Commenter (2405-Bridger) states the Proposed Rule enables the application of advanced technologies for regulatory compliance through approval as an alternative test method. Approval is contingent on demonstration that the “technology meets the desired detection [sensitivity] threshold(s) as applied in the field.”<sup>144</sup> The commenter encourages technology approval based on field performance and supports detection sensitivities being defined at 90% PoD. In addition, the commenter recommends that inputs used to determine equivalence between emissions monitoring approaches should also represent technology field performance. For OGI, studies under realistic but controlled conditions found that experienced surveyors achieved 90% PoD for ~135 g hr<sup>-1</sup> emission rates under the study conditions.<sup>145</sup> Meanwhile, less experienced surveyors never achieved 90% PoD at any emission rate studied. The study participants knew that there would be emissions to find and often exhibited a competitive spirit, which is different from field operations. The performance indicators from this study are different from the 60 g hr<sup>-1</sup> (100% PoD) detection threshold that was used for OGI within the FEAST simulations that supported equivalency demonstration in the Proposed Rule.<sup>146</sup> Updating this input could improve the correspondence between FEAST simulations and the real-world emissions reductions that can be achieved using OGI for emissions monitoring. An empirical study of emissions detected by Bridger's Gas Mapping LiDAR™ (GML) technology estimated that GML detected 18× the volume of emissions detected by OGI,<sup>147</sup> highlighting the importance of accurately representing the field performance of OGI to ensure that different emissions monitoring approaches are evaluated on a level playing field.

Response II-5-260: EPA acknowledges the input from the commenter, EPA has expanded the and revised the required information a person must submit when requesting and alternative test method as described in Section X.B.3 and XI.B.3 of the preamble of the rule.

#### ***5.10.6 ATM Approval Process***

Comment: Commenters (2336-CEMC, 2402-DGCC, 2448-Project Canary) emphasize that the effectiveness of the EPA's proposed program to allow and promote the use of advanced methane detection technologies will depend critically on the EPA's ability to efficiently and timely approve alternative test methods. Operators will not be comfortable investing in and using alternative technologies unless and until they have certainty that the technologies can be used for compliance. The commenters support the defined 270-day deadline for approvals of requests for alternative test methods.

Commenter (2298-Pioneer) expresses that the ATM approval process should enable expeditious and thorough review of advanced technologies. The commenter supports EPA's approach to approving advanced technology using the ATM approval process under 40 CFR §60.8(b)(3), which complements the matrix approach to enable use of advanced technologies. The commenter also supports EPA's proposal to conditionally approve applications within no more than 270 days to ensure that technologies can be deployed in a timely manner. However, to enable EPA's efficient review of applications, the commenter urges the agency to clarify, either in the Final Rule or in subsequent guidance, additional detail to ensure applicants provide EPA the information it will need to approve qualifying technologies as efficiently and expeditiously as possible.

Response II-5-261: EPA recognizes the commenter's support for the rulemaking. Detailed submission requirements are included in Section X.B.3 and XI.B.3 of the preamble of the rule.

Comment: Commenters (2283-Endeavor, 2301-U.S. Chamber of Commerce (USCC)) support EPA's proposal to allow operators to use a broader range of alternative technologies that goes beyond AVO inspections and OGI.<sup>148</sup> Such flexibility will spur continued innovation within the oil and natural gas sector. The commenter specifically supports EPA's proposal to allow approval of alternative test methods for alternative advanced technologies<sup>149</sup> and recommends that EPA work to create a fast and efficient system that allows for timely approvals that are not overly burdensome to those seeking approval.

Commenters (2254-PBPA, 2283-Endeavor, 2301-USCC) support EPA's proposal that others (not just owners/operators) be allowed to propose alternative test methods, they recommend shortening the EPA's approval deadline for applications from 270 days to 180 days in order to

---

<sup>148</sup> Id. at 74,741–44.

<sup>149</sup> Id. at 74,745–46.

further encourage innovation and prevent regulatory bottlenecks from stalling the use of new technologies.<sup>150</sup>

Commenter (2283-Endeavor) argues by shortening and simplifying the approval process, EPA can encourage new, cost-effective solutions that will benefit the environment, the economy, and the public. The commenter also supports EPA's proposal that others (not just owners or operators) be allowed to propose alternative test methods. Upstream producers frequently work with contractors for services, including for fugitive emissions monitoring, and it makes sense to allow entrepreneurs who wish to provide new, innovative services to be in a position to seek approval on their own.

Response II-5-262: EPA recognizes your support of the rule. The final rule includes detailed submission requirements, as described in Section X.B.3 of the preamble of the final rule. EPA has determined 270 days will provide enough time to rigorously evaluate the influx of all alternative methane technology requests and that expediting this timeline may be detrimental to the evaluation process.

Comment: Commenter (1686/2345-GHGSat) believes that the total proposed timeframe is adequate to conduct a thorough review and determination of the proposed alternative technology, which will then be translated into an alternative test method. Nonetheless, the commenter believes that the EPA should associate timelines for each of the different milestones the EPA is intended to establish. On that note, such milestones should be described a priori so that requestors can plan accordingly.

Commenter (1686/2345-GHGSat) suggests the creation of a parallel approval mechanism for requestors that have already been approved but now are bringing to the market an improved or new version of the technology. The idea is to streamline the process and fast track any applicable milestones that are not modified by the new technology.

Response II-5-263: EPA acknowledges the input from the commenter, EPA is finalizing two milestones in the process, a completeness of submittal checks at 90 days and the date in which the EPA must complete our evaluation, at 270 days. As it regards to modifications to an already approved technology, the same timetables are maintained, however EPA expects those evaluations to be concluded in a shorter time frame.

Comment: Commenter (2333-LongPath) strongly suggests that EPA define a process and maximum timeline for the approval of minor amendments to applications. The field of advanced technologies changes extremely rapidly, and operators need to continue to use the best-in-class of monitoring as it advances. Therefore, the commenter suggests a maximum time period of 30 to 60 days for approval of minor amendments, such as technology, algorithm, software, or methodological updates.

---

<sup>150</sup> Id. at 74,760–41 (expansion of applicants beyond owners and operators); id. at 74,746 (270-day deadline for conditional approval). Alternatively, the commenter (2301-USCC) recommends allowing for conditional approval of technologies EPA recognizes to be in wide-use during the 270-day approval period.

Response II-5-264: EPA acknowledges the input from the commenter, as it regards to modifications to an already approved technology, the same timetables are for initial approvals for modifications, however EPA expects those evaluations to be concluded in a shorter time frame.

Comment: Commenter (2227-WEA) notes that the concept and intent of the alternative periodic screening approach and survey matrices is sound. Operators appreciate the inclusion of the matrices, yet there is still concern that the proposed frequencies will not adequately promote the use of alternative technologies.

Commenter (2227-WEA) expresses concern with the proposed nine-month approval process for technologies especially when NSPS OOOOb becomes effective and the burden that could be created by multiple approaches. Operators may have to accommodate dual programs such as conventional OGI and an alternative technology, so pre-approval of alternative technologies would help alleviate what could be a significant burden. Validation of advanced methane detection technologies should be done quickly outside of the NSPS and EG, but to promote adoption of advanced technologies, the approval process should be streamlined, particularly for technologies EPA recognizes to be in wide use today. EPA should shorten the duration of review and approve such technologies or allow conditional approval of such technologies (without risk of retroactive non-compliance) until EPA has rendered its final decision.

Response II-5-265: All technologies must undergo the same review process. EPA has determined 270 days will provide enough time to rigorously evaluate the influx of all alternative methane technology requests and that expediting this timeline may be detrimental to the evaluation process.

Comment: Commenters (2254-PBPA, 2363-CEMC, 2402-DGCC, 2448-Project Canary) support the proposed approach of providing a “conditional approval” if the agency has not acted on a request by the 270-day deadline. This approach could allow an operator to go forward with use of an alternative test method with the understanding that the EPA has not yet taken final action on its review. It would also ensure that unforeseen agency delays do not impede deployment of these very promising technologies.

However, commenters (2363-CEMC, 2402-DGCC, 2448-Project Canary) note that the “conditional approval” concept will only meet the objective of promoting deployment if the risk to the operator is understood and manageable. To this end, the commenters urge the EPA to consider certain clarifications in proposed section 60.5398b(d)(1)(iii).

First, commenters’ (2363-CEMC, 2402-DGCC, 2448-Project Canary) understanding of the language in section 60.5398b(d)(1)(iii) is that the 270-day clock starts from the date of the “request” under section 60.5398b(d)(1), and not the date that the EPA determines “completeness” pursuant to section 60.5398b(d)(1)(ii). This approach is rational in the commenters’ view, and they urge the EPA to confirm this interpretation.

Second, commenters (2363-CEMC, 2402-DGCC, 2448-Project Canary) urge the agency to provide more detail on how “conditional approval” under section 60.5398b(d)(1)(iii) would

work. Absent this additional detail, operators may be reluctant to use methods subject to “conditional approval” status.

Commenters (2363-CEMC, 2402-DGCC, 2448-Project Canary) express that it is not clear what consequences follow if the EPA subsequently denies approval for an alternative test method that had “conditional approval” status. The commenters assume that such an agency action does not result in some form of retrospective liability for an operator that used the “conditionally approved” alternative test method in lieu of the requirements for fugitive emissions components affected facilities in §60.5397b and covers and closed vent systems in §60.5416b. Were such retrospective liability to apply, it would defeat the agency’s intentions for “conditional approval” because it is highly unlikely that any operator would use an alternative test method subject to that kind of risk. For these reasons, the commenters urge the EPA to make clear that an operator is not subject retrospective liability under such circumstances.

According to commenters (2363-CEMC, 2402-DGCC, 2448-Project Canary), operators will also want to know what prospective obligations they have in the event the EPA ultimately rejects a “conditionally approved” alternative test method. The commenter (2448-Project Canary) assumes that, in such a scenario, the operator must switch either to an approved alternative test method or to the OGI-based program required in §60.5397b or to closed vent systems as detailed in §60.5416b, as applicable. The commenter (2301-CEMC) urges the EPA to provide a reasonable grace period for the operator to modify and implement its plan for monitoring fugitive emissions, including obtaining needed equipment and contracting with service providers. For example, the EPA could establish a deadline identical to the deadline that applies under §60.5397b(f) for an initial monitoring survey of a new or modified well, *i.e.*, within 90 days of the agency’s notification.

Commenters (2363-CEMC, 2402-DGCC, 2448-Project Canary) add that a similar grace period should apply in the event that the EPA approves an alternative test method that had been subject to “conditional approval” but imposes work practice requirements that vary from the original alternative test method submittal. For example, the agency could approve a particular kind of continuous monitoring technology but require more sensors than operators were using pursuant to the “conditional approval.” In such circumstances, the operators could benefit from a period of time to obtain the additional sensors needed to ensure full compliance. Here again, a 90-day period would be appropriate.

Commenters (2363-CEMC, 2402-DGCC, 2448-Project Canary) urge the EPA to consider the foregoing clarifications and modifications to the “conditional approval” approach because they will meet the agency’s objectives of ensuring that unforeseen agency approval delays do not discourage operators from using highly promising advanced methane detection technologies. While any “conditional approval” inherently subjects an operator to some risk, the agency has an interest in ensuring that the risk is manageable.

In addition, as discussed in other sections in these comments, commenters (2363-CEMC, 2402-DGCC, 2448-Project Canary) request that the agency structure the approval process so that it is more streamlined for: (1) technologies already in commercial use and (2) technologies already approved by states.

Response II-5-266: EPA recognizes the commenter's input. The final rule includes detailed submission requirements, as described in Section X.B.3 and XI.B.3 of the preamble of the final rule. EPA has determined 270 days will provide enough time to rigorously evaluate the influx of all alternative methane technology requests and that expediting this timeline may be detrimental to the evaluation process.

Comment: Commenter (2333-LongPath) indicates that it has no fundamental concerns with the proposed timeframes. However, the commenter strongly discourages leaving an unlimited timeframe for programs to remain "conditionally approved." Operators require certainty of future use to invest in the installation of fixed monitoring infrastructure. Therefore, the commenter suggests a sunset period for conditional approvals after which time they are either fully approved in final form or rejected with specific guidelines for re-submission.

Response II-5-267: The final rule has maintained the "conditionally approved" provisions from the December 2022 proposal. EPA has determined 270 days will provide enough time to rigorously evaluate the influx of all alternative methane technology requests. We do not expect evaluations to extend beyond 270 and the time limit is there to ensure the EPA provides an action upon receiving a submittal.

Comment: Commenter (2428-API) argues that technologies should be available for use upon finalization of NSPS OOOOb and EG OOOOc. The commenter suggests that to facilitate adoption of alternative leak detection technologies, operators need options available beginning with finalization of the proposed rules. EPA's proposed 270-day review timeline means that technologies would likely not be approved until after the first AVO, OGI, or Method 21 inspection, since the initial inspection would be required 90 days after NSPS OOOOb is finalized. This gap may disincentive the use of alternative technologies as operators would already be required to implement the standard fugitive emissions monitoring program with AVO, OGI, and/or Method 21 inspections.

Commenter (2428-API) recognizes that EPA is unable to approve technologies until the rules are finalized, so the commenter proposes that alternative technology applications be granted conditional approval if they are submitted within 90 days after the final rule is published in the Federal Register (based on the proposed timelines for the initial AVO, OGI, or Method 21 surveys). This initial conditional approval period would allow for the immediate use of those alternative technologies to achieve initial compliance with NSPS OOOOb. An alternative to initial conditional approval could be extending the deadline for initial monitoring surveys from 90 day to one (1) year in §60.5397b(f) and §60.5398b(b)(2). Time beyond the 270-day conditional approval would be needed for operators to contract with vendors and conduct the initial surveys.

Commenter (2428-API) notes that operators would be able to use the conditionally approved technologies until EPA provides written disapproval to the requestor. Disapproval of a conditionally approved technology should not be considered a deviation for operators that used the technology while it was conditionally approved. Upon disapproval of a conditionally approved technology, operators would be able to comply with AVO, OGI, or Method 21 requirements or use another approved or conditionally approved alternative technology. EPA has

already proposed the idea of conditional approval for alternative technologies, so this idea could be extended to allow for technologies to be available for initial compliance. EPA could also utilize technologies approved by a state or another country (e.g., Colorado or Canada) as a starting point for initial conditional approval.

Response II-5-268: EPA recognizes the commenter's input. The final rule includes detailed submission requirements, as described in Section X.B.3 and XI.B.3 of the preamble of the final rule. EPA will start accepting submittals for these alternative test methods on the effective date of the rule, which is 60 days after the publication in the Federal Register.

EPA does not expect evaluations to extend beyond 270, however if EPA fails to decide by that time and a technology is considered conditionally approved, it may be used for compliance purposes. If a conditionally approved or approved technology is later found to be inadequate by the EPA and we have to rescind an approval, the preceding surveys or use of the technology I still considered valid.

Comment: In place of or in addition to initial conditional approval, commenter (2428-API) recommends that EPA prioritize review of initial alternative technology applications (submitted within 90 days after final rule is published in Federal Register) based on the following criteria:

- The technology is already approved for use by a state or another country. Approval by another agency means that the technology has been reviewed previously and is likely to meet EPA's proposed minimum detection threshold of  $\leq 30$  kg/hr (based on a probability of detection of 90%) as shown in Table 1 and Table 2 to NSPS OOOOb.
- The technology is already used by one or more operators for monitoring under voluntary efforts or regulatory programs. One potential measure could be the number of sites monitored in 2022 using the alternative technology under voluntary efforts or other regulatory programs.

Commenter (2428-API) adds that an initial conditional approval period and prioritization of review would allow for quicker adoption of alternative technologies and would also alleviate pressure from EPA to review a potential influx of applications upon rule finalization. Without these measures, EPA could be overwhelmed with applications, and the full 270-day review period would pass before the first technologies would be conditionally approved.

Comment: Commenter (2428-API) asks that EPA clarify how the review and conditional approval process will be implemented in the following ways:

- EPA should clarify that operators are able to use conditionally approved technologies until EPA provides written disapproval to the applicant.
- EPA needs to consider how to effectively notify operators when a conditionally approved technology is disapproved.
- EPA should also clarify that disapproval of a conditionally approved technology should not affect compliance for operators that used the technology while it was conditionally approved. Upon disapproval of a conditionally approved technology, operators would be

able to comply with AVO, OGI, or Method 21 requirements or use another approved or conditionally approved alternative technology.

Response II-5-269: The final rule has maintained the “conditionally approved” provisions from the December 2022 proposal. EPA has determined 270 days will provide enough time to rigorously evaluate the influx of all alternative methane technology requests. We do not expect evaluations to extend beyond 270 and the time limit is there to ensure the EPA provides an action upon receiving a submittal.

Comment: Commenter (2428-API) also asks that EPA elaborate on how deficiencies in an application will affect the proposed review timelines. For the initial 90-day review and final 270-day review, the proposed regulatory language implies that deficiencies in an application will result in disapproval and require the applicant to revise its request and restart this process. As with other application processes, agencies will typically issue requests for additional information with appropriate deadlines so that applicants can resolve deficiencies without restarting the entire application process. Forcing applicants to restart the process for any application deficiency would further delay the approval of alternative technologies for use by operators.

Response II-5-270: The information required for each submission is detailed in the final rule. It is the responsibility of the submitting entity to ensure they include all the requested information within 90 days of submission. The initial completeness review will provide feedback to the submitter regarding what information they are missing. If the submitter does not provide the request information within the 90 days of initial submission, the submitter may be asked to withdrawal their application or be denied. The intent of this process is to ensure as many applications as possible can be reviewed in a timely manner by EPA. Allowing submitters, the opportunity to delay submission of important information requested by EPA will slow the review process and may result in unnecessary conditional approvals.

Comment: Commenter (2284-Kairos) notes that EPA provided some guidance on the data requirements for alternative technologies to obtain approval to conduct regulatory inspections for the Proposed Rules. The commenter recommends EPA provide further detail on its expectations to streamline the review process for both technology developers and for the agency itself. This will lead to faster, more predictable outcomes that consume fewer resources on all sides.

Commenter (2284-Kairos) commissioned Highwood Emissions Management to develop a proposed framework for data needs to accurately assess alternative technology performance. The full document is available in Appendix A of the commenter’s letter, but the commenter provides a brief summary here. The goal is to balance the need for clear, transparent, and rigorous standards to ensure an aerial screening program will effectively and consistently eliminate emissions, without creating excessive administrative or technical burden for these programs. The commenter’s suggested aerial screening program framework follows a similar structure to the proposed Appendix K for OGI techniques. While the guidance provided by the commenter here is directly applicable to aerial screening surveys, many of the same data quality indicators, testing protocols, and documentation requirements will be relevant for other technology deployment methods (e.g., continuous monitoring systems).

Commenter (2284-Kairos) states the key elements are:

- Testing should be conducted with an independent third party where possible but is not explicitly required; all testing should be conducted using a well-documented, transparent plan with unbiased results and data quality indicators.
- Testing should be performed at the sensor model level– not every instrument of the same design needs to go through independent third-party testing. Note that this does NOT mean that an instrument can forgo calibration and maintenance necessary to ensure performance aligns with expected performance from the sensor model–technology developers must outline how they verify performance of additional sensors within the same model.
- Model testing shall establish probability of detection and an operating envelope including:
  - Flight parameters; and
  - Meteorological conditions.
- Technology developers shall establish an equipment calibration and maintenance schedule to regularly evaluate safety, hardware and software functionality, and data quality indicators.
- Each survey must have an operations plan that describes the following:
  - Pre-data acquisition instrument performance checks;
  - Pre-data acquisition software checks;
  - Pre-data acquisition operating envelope checks;
  - Pre-data acquisition data recording check; and
  - Plan for monitoring conditions throughout the survey.
- Documentation plan for the following:
  - Coverage of facilities;
  - Adherence to operating envelope; and
  - Survey results (*i.e.*, documentation of fugitive emissions or no emissions detected).
- Operator training requirements
- Data quality indicators to confirm instrument performance during the survey
- Recordkeeping
  - Documents to be maintained; and
  - Responsible party for each required piece of documentation.

The commenter (2284-Kairos) recommends that an alternative technology work practice that includes these elements will strike the correct balance of rigor and feasibility.

Response II-5-271: EPA recognizes the commenter’s input. The final rule includes detailed submission requirements, as described in Section X.B.3 and XI.B.3 of the preamble of the final rule.

Comment: Commenters (2307-Qube, 2363-CEMC, 2402-DGCC, 2448-Project Canary) note the Supplemental Proposal does not speak to how the agency will address minor changes to an already-approved Alternative Test Method. This silence could imply that an owner or operator

who wants to use a slightly upgraded version of an already-approved technology would need to go through the full approval process outlined in §60.5398b(d)(1).

Commenters (2307-Qube, 2363-CEMC, 2402-DGCC, 2448-Project Canary) note that minor upgrades to an approved technology should not trigger the full approval process. Such an approach would be inconsistent with the agency's objective of promoting the use of innovative technologies. For example, continuous monitoring system developers and vendors, including the commenter (2402-DGCC)'s members, regularly push out updated algorithms for the technology, thereby enhancing the system performance, such as speed of quantification calculations, exception handling, connectivity improvement, and many other potential upgrades. While these updates can be as frequent as several per year, the underlying quantification calculation methodologies and practices remain the same. Requiring such minor upgrades, which don't fundamentally alter the underlying quantification methodologies, to go through the full approval process is an inefficient use of resources for the regulator and the regulated community—and it could discourage owners and operators from implementing upgrades that offer better environmental performance.

Response II-5-272: See response II-5-273.

Comment: Commenters (2363-CEMC, 2402-DGCC, 2448-Project Canary) recommend that the agency adopt a streamlined approval process for minor upgrades to already-approved alternative test methods. First, the EPA could define a “minor change” or “minor upgrade” as any change in the hardware or associated software of a continuous monitoring system, which may improve, but will not degrade the system's ability to meet the requirements of §60.5398b(c). Changes in hardware or associated continuous monitoring system software that do not directly impact methane emissions quantification would not require subsequent approval from the EPA. Alternatively, EPA could approve these kinds of changes when they approve an alternative methodology application. A full approval process would be inconsistent with the realities of these kinds of technology upgrades.

Commenters (2363-CEMC, 2402-DGCC, 2448-Project Canary) say that if the agency determines it needs to have a separate approval process for minor upgrades, it could at least provide that such approvals subject to an expedited process, *e.g.*, 30 days instead of 270 days. As with the regular process, “conditional approval” would apply if EPA has not taken final action within the 60-day period (noting our recommended changes to the “conditional approval” requirements discussed in these comments).

Commenter (2235-SLB) encourages the EPA to include provisions to allow routine updates common in technologies deployment (such as software updates) to be made to approved technologies without retriggering the overall alternative technology review process.

Response II-5-273: EPA acknowledges the input from the commenters, as it regards to modifications to an already approved technology, the same timetables are for initial approvals for modifications, however EPA expects those evaluations to be concluded in a shorter time frame.

When it comes to upgrades of a system, EPA does not consider “quality of life” improvements to be a major change that would necessitate a re-submittal. Only when a major change is made to a system would a re-submittal be required including any change in the hardware that would affect a direct measurement (*i.e.*, methane concentration, wind vectors) or a change in the quantification calculation(s) that would result in a +/-5% change from the previously approved system, would a re-submittal be required.

Comment: Commenter (2405-Bridger) believes that third-party blind testing using standard protocols is necessary to provide confidence in the capabilities of methane sensing technologies. To ensure that the alternative test method approval process is transparent and upholds high scientific standards, blind testing by an approved third party should be required to demonstrate detection sensitivity. The METEC ADED initiative provides defined blind testing protocols for both continuous emissions monitoring systems and periodic screening methods. Adhering to ADED protocols presents an opportunity to achieve consistent and transparent technology approval.

Commenter (2405-Bridger) urges the EPA to require methane sensing technologies specified in alternative test method applications to demonstrate detection sensitivity performance through third-party blind testing using ADED protocols as part of approval requirements.

Response II-5-274: EPA acknowledges the recommendations. The final rule outlines requirements for published reports to be submitted as a part of the alternative technology request (see language below). While third party blind testing is not specifically required, it does represent strong supporting data. Additional guidelines regarding supporting evidence and data will be included in the guidance document.

*“Published reports (e.g., scientific papers) produced by either the submitting entity or an outside entity evaluating the submitted measurement technology that has been independently evaluated. The published reports must identify either a site-level or aggregate detection threshold and be accompanied with sufficient supporting data to evaluate whether the performance metrics of the alternative testing procedures in paragraph (d)(3)(vi)(C) of this section are adequate and the data was collected consistent with those alternative testing procedures. The supporting data may be included in the published report or may be submitted separately.”*

Comment: Commenter (2405-Bridger) believes that emission source localization capabilities should be demonstrated in the alternative test method application. Fundamental properties of methane sensing technologies include the ability to detect, localize, and quantify emissions. Localization capabilities should guide operators’ response to detection events. Efficiency is gained by being able to quickly confirm the presence of an emission, determine its cause, and initiate a response. Elsewhere in the commenter’s letter, the commenter urged the EPA to require onsite OGI follow up for periodic screening detection events only within the localization uncertainty of the methane sensing technology. Doing so requires localization precision and accuracy to be parameterized in the alternative test method application. Technologies used for periodic screening of emissions or continuous monitoring at individual well sites, compressor stations, and centralized production facilities should be able to localize emissions at least to the

site level. Improved localization capabilities should be reported as equipment group, equipment unit, and component-level precision. These designations have been accepted by the community<sup>151,152,153</sup> and should simplify onsite follow-up for detected emissions. For example, it would be simpler to use OGI to inspect an equipment group than determine a circle with a 50-foot radius that needs to be inspected. The ADED protocols that are mentioned throughout this letter provide a consistent and transparent approach to evaluating localization precision and accuracy. For a test method to be classified at a given level of localization precision, 95% of its detections should be correctly localized.

Commenter (2405-Bridger) urges the EPA to require demonstration of emission source localization capabilities for methane sensing technologies specified in alternative test method applications through third-party blind testing using ADED protocols.

Response II-5-275: EPA thanks you for your recommendations and agrees methane technology localization should be demonstrated. The final rule includes requirements for demonstrating whether a technology has facility-level spatial resolution, area-level spatial resolution, or component-level spatial resolution. The final rule also outlines different follow-up procedures based on the spatial resolution, or localization capabilities, of the technology.

Comment: Commenter (2405-Bridger) believes that methane sensing technologies need to reliably quantify emissions. In the proposed rules, mass emission rate action levels for the continuous monitoring approach assumes that the methane sensing technology accurately quantifies emissions. For example, if a fixed sensor system used for this approach returns average quantification values that are a factor of two lower than the true value, then the desired emissions reductions will not be achieved. Alternatively, if the quantification values are too high, then operators may waste time addressing negligible emissions. An alternative test method should not be approved by the EPA unless its capabilities are well represented. The commenter urges the EPA to require demonstration of emission rate quantification capabilities for technologies specified in alternative test method applications through third-party blind testing using ADED protocols.

Response II-5-276: EPA agrees that it is important to require all alternative methane technologies to demonstrate their emission rate quantification capabilities. The final rule details rigorous requirements for alternative test method submissions, including published reports and supporting data to demonstrate capabilities in the field.

Comment: Commenter (2405-Bridger) states that in order to provide stakeholders with assurance that emission monitoring achieves stated performance, monitoring methods should be routinely audited.

Commenter (2405-Bridger) notes operators, the EPA, and other stakeholders need assurance that emissions monitoring approaches continue to achieve their stated detection sensitivity. The commenter recommends that the EPA requires sensor operators to report anonymized emission rate measurements in the aggregate for each production basin on a yearly basis (past measured distributions should be a necessary, but not sufficient, requirement of approval). Reporting data for each basin individually is important because different basins can have very different characteristics including emission rate distributions, wind speeds, ground reflectivity, topography, and vegetation. After compiling data obtained from individual alternative test methods and generating emission rate distributions, statistical analysis can be performed to evaluate the detection sensitivity that was achieved during field operations.

Commenter (2405-Bridger) states measured emission rate distributions in a production basin can be fit to a suitable model probability density function (*e.g.*, functions describing lognormal or pareto distributions). At lower emission rates, where the number of emissions measured is less than the number expected based on the model probability density function, false negative detections are likely. The fit should only be applied to the part of the emission rate distribution for which the test method has a nearly 100% probability of detecting emissions. The commenter recently released a preprint of a scientific study where they performed similar statistical analysis of emission rate distributions.<sup>154</sup> The commenter refers the EPA to this publication for important details on the analytical approach.

Commenter (2405-Bridger) argues a statistical test on aggregate emission rate distributions is well suited for assessing detection sensitivity field performance for periodic screening approaches because it is simple and objective. Continuous monitoring systems may require alternative statistical analysis, but by collecting data, the EPA, operators, and other stakeholders will have the requisite inputs to objectively evaluate continuous monitor performance even if the analytical methods remain to be established.

Commenter (2405-Bridger) urges the EPA to audit the detection sensitivity achieved during field measurements taken by methane sensing technologies under approved alternative test methods. Next, the commenter recommends that the EPA requires sensor operators to report aggregate emission rate distributions which the EPA would use to evaluate the detection sensitivity achieved during field deployment on a yearly basis.

Response II-5-277: EPA recognizes the commenter's input and agrees that for many technologies, the detection threshold(s) will change based on environmental factors. EPA has revised the requirements for detection thresholds detailed in Section X.B.1, X.B.3, XI.B.1, and XI.B.3 of the preamble of the final rule.

---

<sup>154</sup> Kunkel, M. W. et al. Extension of Methane Emission Rate Distribution for Permian Basin Production Infrastructure by Aerial LiDAR. (2022).

Comment: Commenter (2403-PAO) observes that EPA states that it retains authority to rescind approvals of any alternative monitoring technology. It is unclear how EPA will view companies using a technology that EPA later rescinds approval. The commenter requests EPA clarify that companies using a technology that EPA later rescinds approval for will not be held in violation.

Response II-5-278: EPA recognizes the commenter's input; The final rule states EPA has 270 days to determine if a submitted request for an alternative test method meets the requirements for compliance. If a decision is not made after 270 days, the technology will be given conditional approval status. If an approved or conditionally approved method that is being used by a company is later determined to be inadequate for compliance, the company must find a new method. All previous use of the method when it was considered "approved" or "conditionally approved" will not constitute a deviation of the standard.

Comment: Commenter (2448-Project Canary) encourages the EPA to take into consideration continuous monitoring systems that have been approved for similar purposes under state regulatory programs, at a minimum to provide expedited approval of a technology. For example, CDPHE Alternative Approved Instrument Monitoring Method (Alt-AIMM) program includes an extensive equivalency, and technology feasibility review, to ensure approved continuous monitoring systems will meet the LDAR objectives, meeting or exceeding an already robust OGI camera LDAR inspection program.

Response II-5-279: All alternative test method proposals will be required to submit materials outlined in the final rule and will undergo the same approval process.

Comment: Commenter (2196-Private Citizen) comments on continuous monitoring, stating this option is truly an evolution or paradigm shift for LDAR programs whether upstream or downstream. Though, 1 AMEL has been approved for downstream. As this AMT matures, is developed and validated to ensure equivalent emissions reductions, the process or plan required in §60.5398b(c)(2) should at a minimum:

- Any leaks found using the OGI camera through the root-cause analysis should be quantified for Mass using the Hi Volume sampler. This mass data (and distance from sensors) is essential to verify veracity of the continuous monitoring system claims of mass resolution. As well as additional data that should be used to tweak algorithms (*i.e.*, the more real data used to adjust calculation, the smarter the algorithms are) used to establish mass at the sensor. This data is critical for the evolution of this technology as an established future alternative for LDAR.
- Require semiannual Human OGI process (Appendix K or as specified in §60.5397b) if the facility were normally required to be surveyed quarterly.
- And an annual Human OGI process (Appendix K or as specified in §60.5397b) if the facility were to normally require to be surveyed semiannually.

Response II-5-280: EPA recognizes the commenter's input.

Comment: Commenter (2451-Highwood Emissions Management and Analytics Inc. (HEMA)) believes the use of LDAR modeling as part of ATM technology approvals is critical to guarantee the performance of these solutions in a broad range of conditions.

Commenter (2451-HEMA) note that diverse tools exist for modeling the performance of methane detection and quantification technologies. Use of the tools in technology approvals at a national scale is critical to provide evidence for the value of technologies under broad representative conditions. Both conventional (OGI) and emerging alternative technologies perform differently under environmental and operational conditions. Key considerations include wind speed, temperature, precipitation, expected emissions profiles, site complexities, spatial coverage, topography, ground cover, cloud cover, and more. The METEC testing facility is a critical step in exploring the performance of technologies. However, it only provides one context for testing a solution. Simulation modeling is therefore needed to enable extrapolation of performance under a broad range of conditions to provide confidence that the proposed technology and work practice meet equivalency expectations. These tools, which include LDAR-Sim, FEAST, AroFEMP, and potentially others, have been thoroughly tested and have been integral for the adoption of all new technologies in an alternative LDAR context in Alberta and Colorado to date. These tools have also been vetted in the peer-reviewed literature and have been used by industry, non-profits, and voluntary initiatives to thoroughly understand technology performance before approval is issued.

The commenter states for consideration of specific technologies that do not fit within the context of the proposed screening matrix and prescribed continuous monitoring action levels, LDAR modelling should be a required approach for equivalency demonstration during the technology and work practice evaluation.

Commenter (2451-HEMA) states the EPA should be explicit in determining what exactly is required for a technology to be approved, what modeling parameters are needed, and what defaults should be expected. Relevant critical considerations include facilities in scope, production types, geographical coverage, temporal and spatial resolution, expected emissions distributions, leak production behavior, natural leak removal behavior, weather basis and assumptions, operational envelopes, required performance metrics from controlled testing, probability of detection mechanism, and follow-up, reporting, and repair timelines. In addition, as technology capabilities and methane distributions evolve with time, the commenter suggests approval requirements, published matrixes, and other prescribed details for alternative technology approval are re-evaluated as more data is collected and there is greater confidence in the field equivalency of these programs.

Commenter (2451-HEMA) notes while there has been considerable advancement in the capabilities of LDAR models, more work is needed to improve their functionality and cross-reference their results from field work. Furthermore, consensus is needed on how to perform the modeling for different regions and environmental contexts to ensure that “apples to apples” comparisons are being made during technology approval. There is also an important educational gap due to the novelty and complexity of these models. The commenter encourages the EPA to invest resources in the LDAR modeling community to enable greater understanding, consensus, and performance of LDAR models.

Response II-5-281: EPA thanks you for your comments and recommendations. The final rule details the submission requirements for alternative test methods. Submission requirements include details relating to model parameters, spatial resolution, assumptions, etc. Submissions will be reviewed by EPA to determine whether the alternative test method meets requirements and is adequate for indicating compliance.

EPA has detailed the advance methane detection technology alternative test method program in Section X.B.3 and XI.B.3 of the preamble to the final rule.

#### ***5.10.7 Inflation Reduction Act (IRA)***

Comment: Commenters (2363-CEMC, 2402-DGCC, 2448-Project Canary) state that the IRA provides support for the inclusion of the alternative test method provisions in the supplemental proposal. The text of IRA §60113 makes clear that Congress intends that there should be increasingly rigorous detection and quantification of methane emissions in the oil and gas sector. For example, §60113 requires EPA to levy the waste emissions charge on a per-ton methane intensity basis, which is not possible without highly accurate measurement of both emissions and throughput at affected facilities.

Commenters (2363-CEMC, 2402-DGCC, 2448-Project Canary) state that the Congressional emphasis on improved quantification can also be found in the directive to EPA to develop new and improved empirical methodologies for emissions reporting under the Subpart W program. This directive makes clear that continued reliance on emission factors under Subpart W is not appropriate. Under an emissions factor methodology, two facilities with widely disparate actual emissions but similar emission factors could incur equivalent waste emissions charge liability. Such an outcome would undermine the intent of Congress to incentivize reductions through a per-ton waste emissions charge.

Commenters (2363-CEMC, 2402-DGCC, 2448-Project Canary) add that Congress clearly intended EPA to use the funds appropriated under §60113 to financially support the deployment and adoption of the most rigorous available methane detection and quantification technologies. In particular, the appropriated funds provide a means for EPA to assist operators in progressing from periodic surveying with OGI cameras and Method 21 to more advanced and effective methane monitoring technologies.

Commenters (2363-CEMC, 2402-DGCC, 2448-Project Canary) say that the regulatory incentive of the alternative test methods may not be sufficient for some operators—including operators of marginal wells—for whom the costs of purchasing and operating such technologies exceed the costs of OGI cameras. Many operators already have established OGI inspection programs with company owned OGI cameras and personnel, and more frequent inspections will be additive to their current LDAR programs. In certain instances, the expansion of an existing LDAR program utilizing OGI cameras, even with the need for additional cameras and personnel, will cost less than the expenditures necessary to implement a CEMS program. The funds appropriated through §60113 can supplement the regulatory incentives in the proposed Clean Air Act §111 rules to bridge this gap.

Commenters (2363-CEMC, 2402-DGCC, 2448-Project Canary) state that §60113 clearly directs EPA to use funds to aid the deployment of advanced monitoring technologies, thereby lowering their costs and expanding their availability throughout the sector. For example, §60113 (a)(3)(B) requires EPA to ensure funds are dedicated to “improving and deploying industrial equipment and processes that reduce methane and other greenhouse gas emissions and waste.” And §60113 (a)(3)(C) directs the agency to use funds for “supporting innovation in reducing methane and other greenhouse gas emissions and waste from petroleum and natural gas systems.”

Commenter (2402-DGCC, 2448-Project Canary) submit comments on how the EPA should implement the IRA in its response to the EPA’s request for information on the implementation of the IRA’s MERP (Docket ID No. EPA-HQ-OAR-2022-0875) (RFI). The commenter incorporates their response to the RFI by reference and attached a copy in their comment letter.

Response II-5-282: EPA acknowledges the commenters’ input.

EPA has provided responses to similar comments in Chapter 9 - Inflation Reduction Act (IRA) and Methane Emissions and Waste Reduction Incentive Program (MERP) of the Response to Comment document.

Comment: Commenter (2355-CEC) states that the recently enacted IRA is considered the most significant climate legislation in U.S. history.<sup>155</sup> The IRA reflects congressional support for regulations and policies that incentivize and promote development of climate technologies for a variety of economic sectors. In light of the Infrastructure Investment and Jobs Act (IIJA) and the IRA, technologies for decarbonizing the power sector are forecast too rapidly advance. In developing rulemakings pursuant to CAA section 111, EPA has an opportunity to align its decision-making with that congressional intent and the changing landscape by exercising its authority to promulgate standards of performance that further encourage the development and deployment of technology.<sup>156</sup>

Commenter (2355-CEC) notes D.C. Circuit has developed a robust body of case law interpreting the term “standard of performance” under section 111.<sup>157</sup> Among the factors that EPA should consider in making a BSER determination is whether the standard would effectively promote further deployment or development of advanced technology.<sup>158</sup> EPA correctly echoes this in the Supplemental Proposal by including “advancement of technology” as one of the five factors it uses to determine which are the best systems.<sup>159</sup> While the BSER must be a system of emission

<sup>155</sup> See, e.g., White House, FACT SHEET: Inflation Reduction Act Advances Environmental Justice (Aug. 17, 2022), <https://www.whitehouse.gov/briefing-room/statements-releases/2022/08/17/fact-sheet-inflationreduction-act-advances-environmental-justice/> (“Most Significant Climate Legislation in U.S. History Delivers for Overburdened Communities”).

<sup>156</sup> See Greg Dotson & Dustin J. Maghamfar, The Clean Air Act Amendments of 2022: Clean Air, Climate Change, and the Inflation Reduction Act, 53 E.L.R. 10017, 10026, (2023) (“[T]he is funding provided by the IRA will allow EPA to increase the ambition of its CAA rulemakings, by lowering costs and demonstrating the feasibility of pollution control technologies.”).

<sup>157</sup> E.g., Portland Cement Ass’n v. Ruckelshaus, 486 F.2d 375, 391 (D.C. Cir. 1973) (noting that Congress did not intend to require that “the technology must be in actual routine use somewhere” and that “[t]he Administrator may make a projection based on existing technology”) (internal citations omitted).

<sup>158</sup> Sierra Club v. Costle, 657 F.2d 298, 347 (D.C. Cir. 1981).

<sup>159</sup> Supplemental Proposal, 87 Fed. Reg. at 74,820.

reduction that is “adequately demonstrated,” what is considered “adequately demonstrated” is rapidly changing as pollution control technologies are developed and deployed, especially in light of the funding and financial incentives of the IRA. Any suggestion that a system of emission reduction is adequately demonstrated only if it has been deployed on a commercial scale is inconsistent with the rate of technological advancements in the twenty-first century. In recent years, the amount of time between innovation and implementation has shortened significantly, and demonstration occurs much more quickly.

Commenter (2355-CEC) supports EPA’s approach of authorizing owners and operators to use advanced monitoring technologies by providing: (1) a performance matrix based on inspection frequency and minimum detection sensitivity and (2) a system by which owners and operators can propose individual advanced technologies that meet the specifications of the matrix as “alternative test methods” for approval by EPA. The commenter agrees with the Agency’s recommendation to allow owners and operators to use the matrix to comply with CAA section 111(h)(1) and to approve alternative test methods under 40 CFR 60.8(b)(3).

Commenter (2355-CEC) appreciates that EPA has determined that, for the fugitive methane emissions subcategory, combinations of OGI and AVO work practice standards should be the BSER.<sup>160</sup> However, technologies for detection of fugitive methane emissions are advancing rapidly. Certain technologies, used in accordance with specified work practices, can achieve better results and therefore result in greater methane emission reductions. Given the imperative under CAA section 111 for EPA to promote technological innovation, it is appropriate for the Agency to provide pathways for owners and operators to use such technologies for compliance.

Commenter (2355-CEC) adds that, in addition, the IRA includes a clear congressional directive to the EPA to promote deployment of advanced methane technologies.<sup>161</sup> Section 61103 of the IRA appropriates \$1.55 billion to EPA for such purposes as “improving and deploying industrial equipment and processes that reduce methane and other greenhouse gas emissions and waste<sup>162</sup>” and “supporting innovation in reducing methane and other greenhouse gas emissions and waste from petroleum and natural gas systems.<sup>163</sup>” EPA should complement these financial incentives with regulatory incentives.

Commenter (2355-CEC) states the approach EPA has outlined in the Supplemental Proposal is a valid use of the Agency’s authority to achieve the aim of increasing deployment of advanced methane detection technology. The D.C. Circuit has indicated that “EPA may provide sources with multiple work practice compliance options if EPA demonstrated that at least one of these options is cost effective and ‘expressly provides for the alternative in the standard.’”<sup>164</sup>

Commenter (2355-CEC) notes that the agency also proposes to approve “alternative test methods” that meet the thresholds of the matrix under 40 CFR 60.8(b)(3). The approach finds

<sup>161</sup> P.L. 117-169 (Aug. 22, 2022).

<sup>162</sup> Id. at section 60113(a)(3)(B).

<sup>163</sup> Id. at section 60113(a)(3)(C).

<sup>164</sup> 73 Fed. Reg. 78199-200 (citing *Arteva Specialties S.R.R.L., d/b/a KoSa v. EPA*, 323 F.3d 1088, 1092 (D.C. Cir. 2003)).

support in the Agency’s January 30, 2007, notice in the Federal Register outlining the process by which EPA will approve alternative test methods for NSPS. Once approved, such methods may be used any owner or operator for compliance.<sup>165</sup>

For these reasons, commenter (2355-CEC) agrees that EPA is appropriately using its authority to establish a system by which owners and operators may use advanced methane monitoring technologies as alternative test methods. Furthermore, the commenter strongly supports this approach as a means of promoting the deployment of these rapidly improving technologies.

Response II-5-283: EPA recognizes the commenter’s support of the rulemaking. We acknowledge the desire to make the use of alternative technology the BSER, however EPA currently does not have the information necessary information to make that determination.

---

<sup>165</sup> 72 Fed. Reg. 4257-62 (Jan. 30, 2007). The alternative test method process is distinct from the section 111(h)(3) “alternative means of emission limitation” (AMEL) process. Under section 111(h)(3), each AMEL is subject to a notice-and-comment approval process—and may be used only at the facility for which it was approved. Here, by contrast, the matrix itself is the alternative work practice, promulgated through a rulemaking, and the alternative test methods simply demonstrate compliance with the matrix. Furthermore, approved alternative test methods may be used at multiple facilities.

## Chapter 6. Well Affected Facility and Associated Operations

### 6.1 Well Affected Facility

Comment: Commenter (2227-Western Energy Alliance (WEA)) states that the definition of a modification to an existing well should be simple and applied to the well affected facility to which a standard is applicable, not all operations involving that well facility. Though not defined by EPA, a new well would reasonably be assumed to be a well spudded after the proposed effective date of the rule. The commenter provides that a modification to an existing well should be a physical or operational change to the well that results in increased emissions. Consistent with new source performance standards (NSPS) OOOOa, the proposed NSPS OOOOb provides that a modification to an existing well occurs when an existing well undergoes a well completion with hydraulic fracturing or refracturing. The commenter does not support adding complexity to the established modification provisions for wells, such as liquids unloading operations on natural gas wells.

The commenter (2227-WEA) suggests the following:

- Make the determination of whether a modification has occurred at an existing well to be based on the changes that occur at the individual well affected facility and not in terms of all operations at the facility.
- Define a modification to an existing well as a physical or operational change that subsequently results in increased volatile organic compound (VOC) or methane emissions.
- Codify a categorical exclusion for well affected facilities subject to certain state or local associated regulations.
- Categorically exclude wildcat and delineation wells, and oil wells at sites with no natural gas takeaway capability from requirements to recover natural gas without a distinct requirement to demonstrate that takeaway is not feasible.

Response II-6-1: The well affected facility was defined in the supplemental proposal as a single well. This proposal greatly simplified the three well-related affected facilities proposed in the November 2021, which were (1) the well completion affected facility, (2) the associated gas affected facility, and (3) the well liquids unloading affected facility. The final rule retained this single simplified well affected facility definition. There are separate proposed standards for well completions, associated gas from oil wells, and gas well liquids unloading operations, all or some of which could apply to a well affected facility.

The definition of modification in the final rule is also very straightforward. Consistent with §60.14, a modification is when an existing well undergoes a physical or operational change results in increased emissions. The EPA believes that hydraulically fracturing or refracturing an existing well are the activities that result in an increase in emissions from a well, and thus these activities are specifically listed activities as modifications. The EPA agrees that a process change in other operations at the site do not constitute a modification of the well.

The EPA does not agree that wildcat and delineation wells should be categorically excluded from the well affected facility definition. However, the final rule does specifically exclude gas produced from wildcat and delineation wells from the definition of associated gas, effectively exempting them from the associated gas well requirements. The final rule also included separate provisions for wildcat and delineation well completions. The EPA does not expect wildcat and delineation wells to operate for an extended period which would require liquid unloading, so there are no special provisions under the liquids loading standards.

It is not appropriate to exempt wells from the NSPS if it is subject to state and local regulations. However, if the regulations include similar or more stringent requirements, the additional burden to comply with the NSPS should be minimal.

Comment: Commenter (2292-West Virginia Office of the Attorney General (WV AG) et al) suggests that the EPA is still defining “modification” in an exceptionally broad way. The commenter notes that breadth is particularly obvious when it comes to wells undergoing fracturing or refracturing, but the agency has also appeared to have left the door open for finding that liquids-unloading events could constitute “modifications,” too. 87 Fed. Reg. at 74,781-82. This redefinition, of course, would render the wells “new sources” subject to direct federal control. The commenter fails to see how these activities constitute “modifications” under either the CAA’s definition of the term or any ordinary understanding of it.

Response II-6-2: In the final rule the EPA has clarified that a liquids unloading event does not constitute a modification. This topic is discussed more in Section 6.4.1.2.

Comment: Commenter (2210- LANXESS Corporation) expresses concern that any well used to inject fluids could be interpreted as a “well affected facility” under 40 CFR 60.5365b regardless of source category. They point to the language indicating that a well affected facility, including a single well, where a “well” is defined in 40 CFR 63.5430b to mean “a hole drilled for the purpose of producing oil or natural gas, or a well into which fluids are injected” leading to this interpretation.

Response II-6-3: EPA has spelled out that the well affected facility applies to a single well “drilled for the purpose of producing oil or natural gas.” This makes it clear that wells into which fluids are injected are not well affected facilities.

Comment: Commenter (2218-Texas Commission on Environmental Quality (TCEQ)) requests that NSPS OOOOb include clear definitions for “oil well” and “gas well” to avoid ambiguity or confusion. States have different definitions of what is considered an oil well or a gas well. For example, the Texas Railroad Commission to Texas (RRC) defines cubic foot of gas, gas well, and oil well as follows:

“16 TAC [Texas Administrative Code] §3.79

(6) Cubic foot of gas or standard cubic foot of gas--The volume of gas contained in one cubic foot of space at a standard pressure base and at a standard temperature base. The standard pressure base shall be 14.65 pounds per square inch absolute, and the standard

temperature base shall be 60 degrees Fahrenheit. Whenever the conditions of pressure and temperature differ from the standard in this definition, conversion of the volume from these conditions to the standard conditions shall be made in accordance with the ideal gas laws, corrected for deviation.

(11) Gas well--Any well:

(A) which produces natural gas not associated or blended with crude petroleum oil at the time of production;

(B) which produces more than 100,000 cubic feet of natural gas to each barrel of crude petroleum oil from the same producing horizon; or

(C) which produces natural gas from a formation or producing horizon productive of gas only encountered in a wellbore through which crude petroleum oil also is produced through the inside of another string of casing or tubing. A well which produces hydrocarbon liquids, a part of which is formed by a condensation from a gas phase and a part of which is crude petroleum oil, shall be classified as a gas well unless there is produced one barrel or more of crude petroleum oil per 100,000 cubic feet of natural gas; and that the term "crude petroleum oil" shall not be construed to mean any liquid hydrocarbon mixture or portion thereof which is not in the liquid phase in the reservoir, removed from the reservoir in such liquid phase, and obtained at the surface as such.

(18) Oil well--Any well which produces one barrel or more crude petroleum oil to each 100,000 cubic feet of natural gas.”

Commenter (2218-TCEQ) states that the RRC currently monitors approximately 161,000 active oil wells and 87,000 active gas wells (as of December 2022). Without a clear definition of oil well or gas well, the commenter and RRC do not know which wells will be affected by the different requirements in NSPS OOOOb and emissions guidelines (EG) OOOOc (e.g., associated gas and liquids unloading requirements). Also, clarification is needed on the reference standard temperature and pressure in the definition of Gas to Oil Ratio in the proposed rule language.

Response II-6-4: EPA has chosen not to define oil wells or gas wells in NSPS OOOOb or EG OOOOc to avoid distinctions at the Federal level that are not the same across state programs.

## **6.2 Oil Wells with Associated Gas**

### ***6.2.1 Definition of Associated Gas***

Comment: Several commenters (2248-North Dakota Petroleum Council (NDPC), 2294-Ohio Oil & Gas Association (OOGA), 2326-American Exploration and Production Council (AXPC), 2360-Devon Energy, 2428-American Petroleum Institute (API) suggested that the EPA include a definition of “associated gas” and other related definitions in the proposed rules. Specific comments are provided in the following paragraphs.

Commenter (2248-NDPC) states that the EPA did not define “associated gas”. The commenter recommends that associated gas be defined as the gas that can be separated from the produced liquids in the first stage of separation at a pressure sufficient for it to flow into the gathering system.

Commenter (2360-Devon Energy) believes it is important for EPA and the regulated community to have a common understanding of the definition of associated gas. The commenter offers the following for consideration:

*Associated Gas* means the natural gas which originates at wells operated primarily for oil production and occurs either in a discrete gaseous phase at the wellhead or is released from the liquid hydrocarbon during the initial stage of separation after the wellhead.

Commenter (2428-API) points out that the EPA did not include a definition of associated gas within 40 CFR 60.5430b or 40 CFR 60.5430c, which they do not believe was EPA’s intent. The commenter believes that the language EPA uses in the preamble when describing associated gas<sup>1</sup>, with a few additional clarifications would be appropriate to clearly describe associated gas from oil wells for the purposes of new source performance standards (NSPS) OOOOb and emission guidelines (EG) OOOOc. The distinctions they provide in their suggest language explicitly determine which separator the requirements proposed in 40 CFR 60.5377b(a) would apply, providing clear transparency for the regulated community:<sup>2</sup>

*Associated gas* means the natural gas which originates at oil wells operated primarily for oil production and occurs either in a discrete gaseous phase at the wellhead or is released from the liquid hydrocarbon during the initial stage of separation after the wellhead.

Commenter (2326-AXPC) notes that the December 2022 supplemental proposal would apply standards to oil wells with associated gas at well affected facilities (or well designated facilities under EG OOOOc) but does not define the terms “oil well” or “associated gas.”<sup>3</sup> Without definition, the commenter contends that the applicability of the proposed standards is unclear. To avoid confusion in implementation and enforcement, the commenter urges EPA to define these terms as proposed below.

The commenter (2326-AXPC) expresses that the term “oil well” is ambiguous and needs definition to avoid unintended applicability. While EPA proposes to define “well” as a hole drilled for the purpose of producing oil or natural gas, or a well into which fluids are injected,<sup>4</sup> it does not propose to define oil well or gas well separately. Absent a clear and objective definition, the “oil well” associated gas standards might be interpreted to apply to gas wells, which as noted in the preamble of the December 2022 supplemental proposal, is not EPA’s intent.<sup>5</sup> Oil and

---

<sup>1</sup> 87 FR 74778.

<sup>2</sup> Without a clear definition, the commenter states that there is uncertainty of what gas EPA seeks to control. For example, some members debate if EPA meant to include flaring from storage vessels. By limiting to the first stage of separation, operators will clearly know what associated gas is applicable.

<sup>3</sup> Proposed 40 CFR 60.5377b, .5391c.

<sup>4</sup> Proposed 40 CFR 60.5430b, .5430c.

<sup>5</sup> 87 Fed. Reg. at 74,778.

natural gas wells produce natural gas and hydrocarbon liquids, and these liquids are generally characterized as crude oil or condensate depending on the jurisdiction or context. Regulatory authorities often look to the produced gas to hydrocarbon liquids ratio to define whether a well is an oil well or a gas well but do so inconsistently. The commenter provides that the Bureau of Land Management (BLM), in its Waste Prevention, Production Subject to Royalties and Resource Conservation proposed rule (“Waste Prevention Proposed Rule”),<sup>6</sup> defined “gas well” as,

a well for which the energy equivalent of the gas produced, including its entrained liquefiable hydrocarbons, exceeds the energy equivalent of the oil produced. Unless more specific British thermal unit (Btu) values are available, a well with a gas-to-oil ratio greater than 6,000 standard cubic feet (scf) of gas per barrel of oil is a gas well.<sup>7</sup>

The commenter (2326-AXPC) states that, like EPA’s proposals in NSPS OOOOb and EG OOOOc, BLM’s Waste Prevention Proposed Rule targets oil well associated gas flaring. The commenter proposes that EPA define oil well in the converse of how BLM proposes to define gas well, such that oil well is defined as:

a well for which the energy equivalent of the gas produced, including its entrained liquefiable hydrocarbons, is less than or equal to the energy equivalent of the oil produced. Unless more specific British thermal unit (Btu) values are available, a well with a gas-to-oil ratio less than or equal to 6,000 standard cubic feet (scf) of gas per barrel of oil is an oil well.

The commenter (2326-AXPC) believes this definition is objective and unambiguous and urges EPA to adopt this definition into the respective definitions of NSPS OOOOb and EG OOOOc. This definition is also consistent with how the U.S Energy Information Administration (EIA) defines oil well and gas well.<sup>8</sup> Further, the commenter concludes that using this definition will provide consistency across overlapping federal regulatory requirements and avoid conflicting regulatory requirements.

Commenter (2326-AXPC) adds that, without definition, the term “associated gas” could take on various meanings. The most literal interpretation could mean any gas associated with oil well production, which might include emissions from other NSPS OOOOb or EG OOOOc affected/designated facility types that EPA regulates in other sections of its proposal – e.g., collection of fugitive emissions components or storage vessels. EPA’s intent in the November 2021 proposed rule was to prioritize gas sales where a sales line is available, which suggests EPA’s intended target for these provisions is gas that could be routed to an available pipeline – i.e., produced gas generated in the first stage of separation. The commenter recommends that, to avoid ambiguity and potentially overlapping requirements under the proposed rule, EPA define “associated gas” consistent with this intent.

---

<sup>6</sup> 87 Fed. Reg. 73,588, 73,616 (Nov. 30, 2022).

<sup>7</sup> Id. at 73,616.

<sup>8</sup> See US Energy Information Administration, [The Distribution of US Oil and Natural Gas Wells by Production Rate], 3 (Dec. 2022) (using 6,000 scf of gas per barrel of oil to distinguish oil wells from gas wells).

The commenter (2326-AXPC) explains that the ability for an operator to inject gas into a pipeline is a function of the pipeline operating pressure and the pressure of the gas source immediately upstream of the pipeline connection. If the gas source's pressure exceeds the pipeline pressure, the gas can enter the pipeline (assuming the gas composition meets required specifications for the pipeline), but if the source pressure is equal to or less than the pipeline pressure, the gas cannot flow into the pipeline. At most production facilities, a mixed stream of liquids and gas leaves the wellhead and goes to a separation vessel where gas is separated from the liquids and routed offsite. In some cases, operators use a portion of this gas for on-site operations. The gas evolved from liquids in this first stage of separation has the highest pressure, and operators inject this gas into a pipeline where available and feasible. Further, the volume of gas evolved in the first stage is typically of much greater volume than gas evolved in subsequent stages of separation, and the gas evolved in subsequent stages of separation is generally not of sufficient pressure for injection into a pipeline. For the lower-pressure gas evolved in subsequent separation, injection into a pipeline often requires compression, which is a significant cost and often requires use of a combustion engine. Given the lower volumes generated in subsequent separation stages, compression is often uneconomical and accompanied by potential environmental disbenefit where gas compression emissions outweigh the emissions reductions achieved by transporting the gas offsite by pipeline as opposed to controlling it onsite. The environmental disbenefits become more pronounced as a well's production levels decrease over time. This is because the compressor's operation and associated emissions will remain relatively static over time, but the total gas evolved will decrease over time, meaning a similar amount of compression emissions will occur to achieve increasingly fewer emissions reductions over the life of the well.

Given EPA's intent to prioritize gas sales and, with respect to the gas evolved in later stages of production, the physical constraints and potential environmental disbenefits, the commenter (2326-AXPC, 3818-AXPC) proposes that EPA define "associated gas" as

the natural gas evolved from hydrocarbon liquids during the initial stage of separation following production from the wellhead. Associated gas does not include natural gas associated with well completion or downhole well maintenance activities.

Commenter (2294-OOGA) suggests that the definition of "associated gas" be limited to gas generated in the first stage of separation.

Response II-6-5: EPA agrees with the commenters that a definition of associated gas will facilitate understanding of the affected sources and the requirements related to managing associated gas. EPA included a definition of "associated gas" within the definitions section of this final rule and emissions guidelines. See 40 CFR 60.5430b and 40 CFR 60.5430c. The EPA has chosen not to define oil wells or gas wells in NSPS OOOOb or EG OOOOc to avoid distinctions at the Federal level that are not the same across state programs.

## 6.2.2 Proposed BSER – NSPS OOOOb

[**Note:** Most of the comments provided on the proposed BSER apply to both the NSPS OOOOb and EG OOOOc. For comments that specifically refer to EG OOOOc proposed applicability and BSER, see section 6.2.4 of this Chapter.]

### 6.2.2.1 Recovery of Associated Gas

Comment: Commenter (2433-Environmental Defense Fund (EDF) et al) suggests that EPA define best system of emission reduction (BSER) as associated gas recovery with allowances for specific circumstances of temporary flaring and venting. The commenter provides that the EPA’s current proposal permits using one of four gas recovery options to comply with its standard for associated gas at oil wells and includes a technical infeasibility exemption from the standard. The commenter recommends that EPA define the BSER as recovery of associated gas to (1) route into a gas gathering flow line or collection system to a sales line, (2) use as an onsite fuel source, (3) use for another useful purpose that a purchased fuel or raw material would serve, or (4) reinject into the well or inject into another well; unless one of a set of clearly defined circumstances exist where temporary flaring or venting would be applied.

The commenter (2433-EDF et al) states that the term “standard of performance” means a standard for emissions of air pollutants which reflects the degree of emission limitation achievable through the application of the best system of emission reduction which the Administrator determines has been adequately demonstrated.<sup>9</sup> In designating the BSER, EPA must first identify the various “systems of emission reduction” that have been “adequately demonstrated” for a given source category.<sup>10</sup> Of those systems, it must then select the “best,” taking into account the “extent of emission reduction” achieved by the system,” “costs,” “nonair quality health and environmental impacts,” “energy requirements,” and “technological innovation.”<sup>11</sup> EPA must set the standard at a level that is “achievable”<sup>12</sup> but reflects the “maximum practicable degree” of “control[.]”<sup>13</sup> Indeed, the commenter provides that the Clean Air Act (CAA) “requires that the standards [] maximize the potential for long term economic growth ‘by reducing emissions as much as practicable.’”<sup>14</sup> The commenter adds that Courts will generally uphold EPA’s designation of the BSER so long as it is not “exorbitantly costly in an economic or environmental way”<sup>15</sup> or “unreasonable.”<sup>16</sup>

EPA*, 513 F.2d 506, 508 (D.C. Cir. 1975)).

<sup>11</sup> 83 Fed. Reg. at 65433–34.

<sup>12</sup> *Id.*

<sup>13</sup> 116 Cong. Rec. at 42,385 (1970).

<sup>14</sup> *Costle*, 657 F.2d at 326.

<sup>15</sup> *Essex Chemical Corp.*, 486 F.2d at 433.

<sup>16</sup> *Costle*, 657 F.2d at 343.

Commenter (2433-EDF et al) points out that there are a variety of “systems” to reduce emissions from associated gas at oil wells that EPA has assessed, including the system set forth in its November 2021 proposal that would have allowed flaring at a 95 percent combustion efficiency rate if access to a sales line was not available. The commenter notes that other potential systems include those implemented by states such as Colorado and New Mexico.

Commenter (2433-EDF et al) states that of these systems, the “best” that has been “adequately demonstrated” after considering the “extent of emission reductions,” “costs” and “technological innovation,” among other factors, are those being implemented in Colorado and New Mexico. The commenter contends that these regulatory frameworks prohibit the routine flaring of associated gas and restrict flaring and venting to a set list of circumstances. As in EPA’s supplemental proposal, Colorado and New Mexico require operators to capture associated gas from oil wells and either route the gas to a sales line or put it to an alternative use. The alternative uses allowed in New Mexico largely overlap with those included in EPA’s supplemental proposal and include, among other things, power generation on lease, liquids removal on lease, reinjection for underground storage, and other alternative uses approved by the division.<sup>17</sup> For wells that are not connected to a pipeline, Colorado similarly allows operators flexibility to use other options to capture gas including to generate electricity or to process the gas to recover natural gas liquids, without venting or flaring.<sup>18</sup>

Commenter (2433-EDF et al) states that a standard based on approaches like those adopted in Colorado and New Mexico, which clearly limits and delineates circumstances where temporary flaring would be permitted, represents the “best system” for several reasons. For one, it would require gas recovery but contain reasonable exemptions for temporary flaring during certain activities that may require flexibility to vent or flare. Thus, this system would “reduc[e] emissions as much as *practicable*”<sup>19</sup> and reflect the “maximum *practicable* degree of control.”<sup>20</sup> The standard would permit technological flexibility by allowing the use of a multitude of abatement methods, including routing to a sales line, injection, or reinjection, use as onsite fuel, or use for another alternative purpose. And, as EPA notes in its supplemental proposal, technological innovation could potentially bring to the forefront more abatement methods that are not currently identified. Finally, the costs of a capture standard, as discussed above, are reasonable,<sup>21</sup> cost-effective, and in some instances are even profitable for operators.

Finally, commenter (2433-EDF et al) states that a system requiring capture using different technologies with allowances for temporary flaring or venting under certain circumstances has been “adequately demonstrated.” The commenter notes that Colorado, for example, passed its regulations after a lengthy stakeholder and rulemaking process. Numerous operators, including the largest producers in the Denver-Julesburg Basin – PDC Energy Inc. and Occidental Petroleum Corporation – participated in the rulemaking, as did the Colorado Oil and Gas Association, the Small Operator Society, and the American Petroleum Institute (API). The three largest producers in the Denver-Julesburg Basin expressed “general support” for the Colorado

<sup>18</sup> 2 Colo. Code Regs. § 404-1-903.d.(3).(E).

<sup>19</sup> See *Costle*, 657 F.2d at 326 (emphasis added).

<sup>20</sup> See 116 Cong. Rec. at 42,385 (1970) (emphasis added).

<sup>21</sup> See *Costle*, 657 F.2d at 343.

Oil and Gas Conservation Commission (COGCC) proposed rules and several noted that they shut in production facilities rather than flare or vent during instances of reduced gathering line pressure or limited takeaway capacity.<sup>22</sup> According to the commenter, none of these producers objected to the rule's prohibition on routine flaring or venting. Rather, their comments were limited to ensuring that the COGCC rules did not prohibit flaring or venting allowed by the Air Pollution Control Division (APCD).<sup>23</sup> And no party challenged the adoption of the rules once promulgated.

Further, to date, commenter (2433-EDF et al) states that the COGCC has granted only one variance from the prohibition on routine venting and flaring contained in R.903.(d)(3).<sup>24</sup> Similarly, the commenter provides that New Mexico's standards were developed during a lengthy stakeholder and rulemaking process that included input from the New Mexico Oil and Gas Association and OXY USA, and no party challenged the adoption of the rules once promulgated. Operator support for a standard that requires capture with narrow exemptions, the absence of challenges to the rules, and the minimal variances that have been granted in Colorado are evidence of the reasonableness of these measures. Operator practice also has shown such a standard is adequately demonstrated. Exxon, for example, has halted all routine flaring in the Permian Basin.<sup>25</sup> The Rystad report notes that most operators in Texas, North Dakota, New Mexico, Wyoming, and Colorado report low flaring volumes.<sup>26</sup> The commenter provides that those operators that have reduced flaring have done so through "a change in mindset from viewing flaring as a part of normal operations to viewing flaring as a constraint on operations."<sup>27</sup>

Because a standard that requires capture with a narrow set of exemptions is cost-effective, would reduce emissions to the greatest extent practicable, and has been adequately demonstrated, the commenter (2433-EDF et al) recommends that the EPA consider it to be the BSER.

Response II-6-6: EPA agrees in part with the commenter. In this final rule EPA has defined the best system of emission reduction (BSER) for new sources as associated gas recovery with limited allowances for specific circumstances of temporary flaring and venting. EPA has

<sup>27</sup> *Id.* at 80.

finalized a standard for new sources that will mostly require routing of associated gas to a sales line, or an alternative that achieves equivalent emissions reductions. As explained in sections X.F.2. and XI.F.2. of the final rule preamble, the standards for new sources do include limited circumstances that could result in flaring. For the reasons explained there, EPA still finds that these are necessary to include. For all modified and some existing sources, EPA is finalizing our proposal that could allow for routine flaring, but only in limited circumstances after a demonstration that the discussed zero emissions options are technically infeasible. For the reasons explained in Sections X.F.2. and XI.F.2. of the final rule preamble, EPA finds this appropriate. Lastly, in the context of existing sources, EPA's final EG OOOOc includes a subcategory for sources that produce less than 40 tpy methane of associated gas. The presumptive standard for the subcategory allows routine flaring without a showing of technical infeasibility because EPA's analysis conducted after reviewing comments on the supplemental proposal indicated that it is not reasonable with respect to cost to require these sources to route their associated gas to a sales line. See Sections X.F.2. and XI.F.2. of the final rule preamble for further explanation of this subcategory.

Comment: Commenter (2433-EDF et al) suggests that the BSER for associated gas should include routing to a sales line and gas recovery for other uses. They note that previous comments they provided for the 2021 proposal recommended EPA eliminate the harmful, polluting, and wasteful practice of routine flaring by determining that the "BSER for emissions from associated gas is to capture and sell, productively use or reinject the gas."<sup>28</sup> The commenter further advocates for EPA to require operators to "capture and route emissions to a sales line, to use it on-site for a productive purpose, or to preserve it through re-injection" and "carefully delineate when exemptions may apply."<sup>29</sup>

Commenter (2433-EDF et al) states that in both the November 2021 proposal and the December 2022 supplemental proposal, EPA determined the BSER for associated gas to be routing to a sales line.<sup>30</sup> However, in the December 2022 supplemental proposal, EPA agreed that alternative uses of the associated gas should be allowed, "as these options are equivalent in terms of emission reduction to the identified BSER." The commenter recommends that EPA clarify that the BSER for associated gas includes routing to a sales line and other gas recovery options. Specifically, the commenter recommends that EPA state that BSER includes the following four gas recovery options:

- Recover the associated gas from the separator and route the recovered gas into a gas gathering flow line or collection system to a sales line,
- Recover the associated gas from the separator and use the recovered gas as an onsite fuel source,
- Recover the associated gas from the separator and use the recovered gas for another useful purpose that a purchased fuel or raw material would serve, or

---

<sup>28</sup> 2022 Joint Environmental Comments, *supra* note 1, at 178.

<sup>29</sup> *Id.* at 181.

<sup>30</sup> 86 Fed. Reg. 63110, 63237–38.

- Recover the associated gas from the separator and reinject the recovered gas into the well or inject the recovered gas into another well.

For the second option encompassing “onsite use,” the commenter (2433-EDF et al) urges EPA to clarify that the onsite use must be one associated with oil and gas production. This is to ensure that the use is one EPA is familiar with and has authority to regulate so that unintended venting does not occur from unpermitted or uncontrolled sources. One example where this can occur cited by the commenter is cryptocurrency mining operations.

For the third option encompassing use for “another useful purpose,” commenter (2433-EDF et al) supports EPA’s interpretation encompassing emerging techniques that provide for an alternative use offsite, such as compressing gas and transporting it to a pipeline or processing plant. However, the commenter urges EPA to clarify that the use of associated gas for cryptocurrency mining operations does not qualify as a legitimate alternative use.

For the fourth option of reinjection/injection, commenter (2433-EDF et al) recommends that EPA remove any specific reference to “enhanced oil recovery.” The commenter explains that other preferable options exist for injected or reinjected gas, such as permanent storage in porous geological formations, and there is no reason to disallow or subordinate these alternatives. The commenter cites the Rystad report (included as Attachment W to their November 2021 proposal comments) demonstrates that storage is available in all the states primarily responsible for associated gas flaring, except for North Dakota. Notably, they report that saline aquifers are an alternative potential for storage in North Dakota.<sup>31</sup>

Commenter (2433-EDF et al) states that their November 2021 proposal comments provided detailed information regarding the cost-effectiveness and availability of these alternative options.<sup>32</sup> As stated in their prior comments, they believe “at least one or more of the best practices [including the compliance alternatives EPA proposes here] for gas capture and sale, productive use, or reinjection. . . are broadly available to operators at a reasonable cost in every basin and at every production level.”<sup>33</sup> Further comments provided on costs for these option are included in section 6.2.2.5 of this Chapter.

Response II-6-7: EPA believes that our final regulatory text largely captures the suggestions by the commenter with respect to requiring routing to a sales line, and offering non-flaring alternatives that achieve equivalent emission reductions. See 60.5377b for the final regulatory language.

EPA declines to modify “another useful purpose” in the way suggested by the commenter. EPA finds the suggestion to restrict the use to “be one associated with oil and gas production” to be overly prescriptive. EPA cannot predict the of ways that methane could be used to create other chemical feedstocks, or be used in the production of energy. EPA does not want to restrict the

---

<sup>31</sup> Rystad Energy, Cost of Flaring Abatement, at slide 67 (Jan. 31, 2022) [Hereinafter Rystad] (included in 2022 Joint Environmental Comments, supra note 1, as Attachment X.

<sup>32</sup> 2022 Joint Environmental Comments, supra note 1, at 185–89.

<sup>33</sup> Id. at 190.

future possibility of a useful alternative to flaring if that alternative achieves equivalent reductions.

EPA agrees that using the gas for another useful purpose is supported by the avoidance of emissions from flaring.

EPA agrees that reinjection should be an alternative to flaring, regardless of whether the recipient well is for enhanced oil recovery, because it is equivalent to routing to a sales line for methane reduction. As such, EPA has revised the option in the regulatory text.

With respect to cost-effectiveness data submitted by the commenter, EPA determined that the basis for these cost estimates lacked some details that EPA thought necessary to use them as the basis for a BSER analysis and they were not used in the BSER analysis. Please see Response II-6-19 of this Chapter and the TSD in the docket for more information.

Comment: Commenter (2301-U.S. Chamber of Commerce (USCC)) supports EPA's conclusion that "beneficial uses of the associated gas"—such as on-site use or reinjection into another well for enhanced oil recovery—should be deemed "equivalent" to the identified BSER of routing the gas to a sales line. For similar reasons, the commenter recommends that EPA allow a broad range of on-site beneficial purposes, without being prescriptive, to provide sufficient regulatory flexibility for future innovation.

Response II-6-8: EPA agrees with the commenter that options for beneficial use of the gas should be relatively unrestricted. EPA cannot predict the number of ways that methane could be used to create other chemical feedstocks, or be used in the production of energy available to the grid. EPA does not want to restrict the future possibility of a useful alternative to flaring when if that alternative achieves equivalent reductions.

Comment: Commenter (2315-New York State Department of Environmental Conservation (NYSDEC)) notes that the EPA requested comment on whether the proposed requirements will incentivize the sale or productive use of captured gas, and if not, inquired whether there are other methods that the EPA could use to incentivize or require the sale or productive use instead of flaring. In response, the commenter states that they support the creation of incentives or requirements to capture and use captured gas. The challenge is to understand, with relative certainty, what is being emitted prior to capture. The commenter recommends that EPA gather meaningful data about the emission sources prior to offering incentives.

Additionally, the commenter (2315-NYSDEC) states that they understand this solicitation to mean the proposal is attempting to regulate wells on private property or on lands currently regulated by the states. The commenter believes that a one-size-fits-all approach to regulating these wells will not result in more effective regulation because the conditions, construction, age, and other variables differ depending on the state and formation. They conclude by stating that these differences necessitate different approaches to regulating wells.

Response II-6-9: EPA agrees with the commenter that options to manage associated gas will not be universal. Recognizing this, EPA has developed a variety of approaches to new , modified,

and existing sources. See Response I-6-3 in this Chapter and Sections X.F.2. and XI.F.2. of the final rule preamble for EPA's full discussion of these different standards and the reasoning for each.

#### 6.2.2.2 Opposition to Elimination of the Option to Flare Associated Gas

Comment: Commenter (2428-API) recognizes the environmental benefit of eliminating the venting of associated gas from oil wells that do not currently recover gas to a sales line, for injection, or for onsite fuel as its primary use. However, the commenter disagrees with EPA's approach to the control standards proposed including the level of recordkeeping and reporting as they believe it far exceeds the normal level of compliance assurance typically expected from an NSPS. An initial analysis<sup>34</sup> of the impact of the rule on potential production conducted by the commenter indicates that if the final rule were to eliminate flaring of associated gas or is implemented in such a way that the practical effect is to eliminate flaring of associated gas, it could result in a substantial loss to production. The commenter asserts that they could not support such a restriction or implementation. Should the final rule either expressly or practically eliminate flaring of associated gas, the commenter states it could be technically infeasible and not cost effective.

Commenter (2428-API) states that the provisions for associated gas at oil wells that primarily recover associated gas to sales, for injection, or used for onsite fuel must be adequately delineated from associated gas from oil wells that do not have adequate or accessible gas gathering infrastructure. Specifically, the notion that "recovering associated gas from the separator and routing the recovered gas into a gas gathering flow line or collection system to a sales line" constitutes a control option as proposed under 40 CFR 60.5377b(a)(1) is exceptionally problematic since this explains standard business operations for thousands of wells producing a vital energy resource throughout the country. Including this option within the proposal creates tremendous administrative burden in maintaining the records proposed in 40 CFR 60.5420b(c), without generating environmental benefit as the gas is typically being captured to a sales line already. Selling natural gas is part of our business and this sets a uniquely unjustifiable precedent since operators are in the business to sell as much of the produced gas as possible. In the preamble (87 FR 74779), EPA states "In addition...a significant addition to the proposed rule is the establishment of requirements for situations when associated gas from an oil well that is primarily either routed to a sales line or used for another beneficial purpose is unable to utilize the gas in that manner due to gathering system or other disruptions." The commenter agrees that these wells should have special requirements for the sporadic, short periods of time that gas cannot be recovered, but the current provisions proposed in 40 CFR 60.5377b(a) do not adequately address associated gas that is typically recovered.

Commenter (2428-API) continues to support EPA's description of the proposed requirements for associated gas from oil wells in the November 2021 preamble description, but the commenter does not support the hierarchy of the compliance options and associated recordkeeping and

---

<sup>34</sup> The commenter contends that the EPA did not provide sufficient time to fully analyze the December 2022 supplemental proposal and its potential impacts as EPA did not grant their request for an extension of the comment period. The commenter notes that they will continue to evaluate the potential impacts of the December 2022 supplemental proposal.

reporting requirements as proposed and believe the requirements should be technology neutral. Specifically, the commenter supports:

- Recovering gas to sales in 40 CFR 60.5377b(a)(1).
- The beneficial use of the associated as onsite fuel proposed in 40 CFR 60.5377b(a)(2).
- Reinjection of the recovered gas into the well or injection of the recovered gas into another well for enhanced oil recovery proposed in 40 CFR 60.5377b(a)(4).
- Flaring the gas such that 95 percent control efficiency is achieved as proposed in 40 CFR 60.5377b(b).
- An annual reporting requirement focused on periods of venting.

One commenter (2248-NDPC) provides that approximately 99 percent of the gas that is intended to be sold in North Dakota is already connected to a gathering system. Five percent of that was flared due to pipeline issues. The commenter reports that there are many reasons why gas is preferentially flared over putting it into a gathering system. Some scenarios provided by the commenter are:

- A well could produce natural gas that contains hydrocarbon compounds that are not compatible with the nearby infrastructure (e.g., hydrogen sulfide (H<sub>2</sub>S), carbon dioxide (CO<sub>2</sub>), nitrogen (N), etc.). This is commonly called off-specification gas. Pipelines need to be made from materials that are compatible with the gas and additional equipment will need to be designed and constructed at the regional gas processing plant to be able to take the gas and process it to a pipeline quality specification.
- A well could turn sour over time (i.e., the Hydrogen sulfide in the gas will increase to levels that make it off specification and not saleable).
- Gathering systems and natural gas processing plants are often owned and operated by different companies (midstream). Extreme weather, electric power disruption, and accidents such as fire are just a few examples of force majeure where a midstream company temporarily or permanently shut in the gathering system and prevents the gas from being sold.
- Over time, that well pressure will drop. If it drops below the gathering line pressure, the associated gas will not flow into the gathering system.
- The third-party gatherer may take the system down for maintenance or repair.
- In North Dakota, our associated gas is considered “wet gas”. Wet gas contains a significant proportion of hydrocarbon compounds heavier than methane (e.g., ethane, propane, and butane). These compounds can be gaseous or liquid and gaseous in the reservoir. When wet gas is brought to the surface, these heavier hydrocarbons can condense out of the gas. This is especially true in winter months when the ground temperature is cooler. When these hydrocarbons condense out of the gas in the pipeline, the liquid hydrocarbons can collect in low spots in the pipeline, which reduces the effective diameter of the pipeline and results in a hydraulic constraint or reduce gas flow. Sending a pig down the pipeline is necessary to remove the liquids and hydraulic constraints.

Response II-6-10: EPA agrees with the commenter that the complete elimination of flaring of associated gas in all situations is not practical, for safety and other reasons. EPA therefore has

designed our final rule to prohibit long term flaring for some sources, while leaving options open to other sources to manage associated gas in ways that makes flaring less frequent. See Sections X.F.2 and XI.F.2 of the final rule preamble for discussion of the final standards for OOOOb as well as the final presumptive standards for OOOOc. In the context of existing sources of associated gas, EPA included a subcategory in the final emission guidelines for sources that produce 40 tpy or less of methane that allows those sources to flare routinely. In accordance with the final EG, existing sources that produce over 40 tpy of methane could also flare provided other options are technically infeasible. See 60.5377c for model rule text in OOOOc on this point. As alluded to above, EPA's final standards also allow for flaring where circumstances are not routine and flaring is the reasonable option for interim periods such as malfunctions or interruptions in sales line service. See section 60.5377b and 60.5377c for specific regulatory language described here. EPA believes that these various allowances for flaring address the bulk of commenters concerns. The finalized standards are not an absolute prohibition on flaring. EPA further points out that the standards in OOOOb will apply to certain new wells, such that only those new wells will be subject to standards that do not allow routine flaring. Wells where the gas is typically being captured to a sales line already would be considered existing wells that would not be subject until the state designates those as affected sources. Upon being designated facilities under OOOOc EG, EPA does not see a problem to continue routing to a sales line, and does not agree there is a recordkeeping burden for sources already meeting BSER. For those designated facilities that would find it to their advantage to use another option to BSER, there is likewise little significant burden in recordkeeping or reporting. The only instance of additional significant recordkeeping and reporting would be for those wells that produce more than 40 tpy methane but for which there is no feasible alternative to flaring. Given the substantive comments we received supporting our approach, we do not think there will be an overwhelming number of such cases, or that the due diligence burden of developing a record and submitting a demonstration of infeasibility is unreasonable.

As stated in the previous paragraph, EPA's final standards allow for flaring where circumstances are not routine and flaring is the reasonable option for interim periods such as malfunctions or interruptions in sales line service. One such provision is during those periods when the well produces off-specification gas. The souring of gas over time, or pressure drop of the gas going to the gathering system, could make the gas unsuitable for sales, and the operator would have to seek another non-flaring alternative for the gas, unless the overall production of the gas is below 40 tpy methane. Temporary interruptions in gas gathering for the reasons cited by the commenter are contemplated in the temporary provisions for an interruption in service which allow flaring of limited duration. Pigging operations are an issue related to maintenance of pipelines and are not directly related to associated gas from a separator at a well site.

Comment: Commenters (2168-Indiana Oil and Gas Association (INOGA), 2172-Kentucky Oil and Gas Association (KOGA)) believe that EPA needs to maintain flaring as an option. Many of the commenters' members produce oil with little associated gas. The gas production rate is too low to be able to justify the expense of routing to a sales line or even investing in the equipment to inject the gas back into the reservoir. Many times, the gas production rate is too low to be able to reliably operate an engine to produce power to operate surface equipment. They add that low production wells need to have the option to flare the gas as an environmentally acceptable

option. The commenters believe that eliminating this option would be an unnecessary burden on small businesses.

Commenters (2168-INOGA, 2172-KOGA) express that they understand EPA's perspective that gas should be sold or utilized when it is produced in a large enough volume to justify the expense, or the production is high enough to reliably operate surface equipment. They report that some of the commenters' members sell gas into the national gas market. Data that the commenters have gathered shows that the cost of connecting to a major gas transportation pipeline can cost tens of thousands of dollars, to hundreds of thousands of dollars. According to the commenters, the cost just to make the connection to the gas line for sales is more than the value of the gas that could be sold into the gas market. In addition, the cost to make the gas pipeline quality usually exceeds the value of the gas that might be sold into the gas market.

Commenters (2168-INOGA, 2172-KOGA) ask if industry and EPA work together to create a low complexity structure to be able to achieve EPA's goals of utilizing most of the gas without eliminating the option when no other option exists? Several of the commenters' members have expressed concern that the cost and experience needed to operate a combustion system is beyond their capability. The commenters report that many of the commenters' members do not have the expertise to be able to operate a combustion system safely and efficiently. They provide that operating a flare is a low cost, low technology method to efficiently eliminate gas that might otherwise be vented to the atmosphere.

Response II-6-11: See Response II-6-6 of this Chapter.

#### 6.2.2.3 Wildcat or Delineation Oil Wells

Comment: Commenter (2428-API) notes that, in their January 31, 2022, comment letter, they asked EPA to allow certain provisions for wildcat or delineation wells in its proposal with respect to the associated gas from oil well provisions. By nature, the commenter explains that these wells are typically located apart from other major oil developments including gathering infrastructure. In many instances an operator will not know or understand the composition of the gas until after the well is drilled. The commenter states that the EPA has acknowledged this fact within the definitions that have been published in 40 CFR 60.5430a and maintained in the proposed 40 CFR 60.5430b and 60.5430c where the terms are defined as:

*Wildcat well* means a well outside known fields or the first well drilled in an oil or gas field where no other oil and gas production exists.

*Delineation well* means a well drilled in order to determine the boundary of a field or producing reservoir.

In response to their January 31, 2022, comment letter, the commenter (2428-API) provides that the EPA stated (see 87 FR 74780):

The EPA believes that these situations could warrant an exemption or an alternative standard. However, this proposed rule does not include any exemptions or allowances for

these situations due to lack of specific sufficient information. Therefore, the EPA is interested in additional information on gas compositions of associated gas that would make it both unusable for a beneficial purpose and unable to be flared. The EPA is not only interested in why commenters feel these situations warrant an exemption from the associated gas standards as proposed, but also what methods are currently in use, or could be used, to minimize methane and [volatile organic compound] VOC emissions in these situations.

Like provisions within NSPS OOOOa for well completions, the commenter (2428-API) recommends that the EPA allow special considerations for handling associated gas since these activities are exploratory in nature and are typically not located near existing infrastructure. Wildcat or delineation wells will typically only produce for short period of time after flowback ends in order to complete well testing where the production flow rate is determined along with other parameters such as the gas composition before the well is shut-in or capped, which is regulated based on state protocols.<sup>35</sup> These wells are typically located in remote locations far from any form of permanent infrastructure thereby disallowing any beneficial reuse from a practical and logistical standpoint since the gas composition is not known.

As an example, the commenter (2428-API) states that, on the Alaskan North Slope, ice roads must be built to access locations where exploration activities are taking place because roads do not exist, and there is not access/connection to existing oil and gas infrastructure. As we described above, characteristics of associated gas from these wildcat/delineation wells is unknown and therefore it is not wise to use as an onsite fuel source. Currently under NSPS OOOOa and under proposed NSPS OOOOb, the initial well flowback is subject to the well completion operation requirements, which allow for use of a completion combustion device. After the flowback ends, the well undergoes cleanout and a well test (extended flowback) is conducted to determine reservoir characteristics. The commenter explains that there will still be open top tanks and a combustion device present; however, this equipment will only be utilized for a very short duration. The compliance requirements for both the provisions in 40 CFR 60.5377b(a) or 40 CFR 60.5412b do not allow for realistic implementation for such unique and short-term operations which are not permanently producing oil from a well.

According to the commenter (2428-API), since wildcat or delineation wells will typically cease production in well under 180 days<sup>36</sup>, a temporary or portable combustion device similar to those used to control emissions from well completions is appropriate to reduce volatile organic compound (VOC) and methane emissions. The commenter therefore requests EPA allow any associated gas produced from wildcat or delineation oil wells be routed to a completion

---

<sup>35</sup> EPA determined well testing “conducted immediately after well completion, is considered part of the well completion” for the purposes of reporting emissions under the Greenhouse Gas Reporting Program (see definition of Well Testing Venting and Flaring in 40 CFR 98.238).

<sup>36</sup> The commenter notes the initial performance test for enclosed combustion devices not tested by a manufacturer would not be required until within 180 days after initial startup or start of production. Wildcat or delineation wells typically do not produce for this long to warrant compliance with these provisions. Furthermore, they add that the duration of well testing flowbacks from wildcat and delineation wells can be limited to 30 days per other agency regulations/guidance, e.g., BLM’s NTL-4A guidance (and proposed Waste Prevention rule) generally limits this activity to 30 days, extension beyond 30 days requires additional approval by the agency.

combustion device (except in conditions that may result in a fire hazard or explosion, or where high heat emissions from a combustion device may negatively impact tundra, permafrost, or waterways). Due to the temporary nature of these activities, the commenter recommends that the control device compliance requirements mimic the requirements of control devices utilized for well completions affected facilities, i.e., operated with a reliable continuous pilot flame and no further compliance requirements.

The commenter (2428-API) suggests that the EPA add the following within 40 CFR 60.5377b:

For each wildcat or delineation oil well with associated gas at a well affected facility, capture and direct recovered associated gas from the separator to a completion combustion device, except in conditions that may result in a fire hazard or explosion, or where high heat emissions from a completion combustion device may negatively impact tundra, permafrost, or waterways. Completion combustion devices must be equipped with a reliable continuous pilot flame.

Commenter (2326-AXPC) suggests that EPA should allow operators to control associated gas from wildcat or delineation oil wells without justification of technical infeasibility or safety reasons. The commenter supports the American Petroleum Institute (API) suggested redline and supporting comments that would allow operators to utilize a temporary or portable combustion device similar to those used to control emissions from well completions to reduce VOC and methane emissions from wildcat or delineation oil well associated gas without justifying that sale, beneficial use, or reinjection is technically infeasible or unsafe.<sup>37</sup> As noted by API, these wells typically cease production within 180 days and are typically remotely located significant distances from natural gas pipelines. The commenter suggests including the following in 40 CFR 60.5377b and 60.5391c:

For each wildcat or delineation oil well with associated gas at a well affected facility, capture and direct recovered associated gas from the separator to a completion combustion device, except in conditions that may result in a fire hazard or explosion, or where high heat emissions from a completion combustion device may negatively impact tundra, permafrost, or waterways. Completion combustion devices must be equipped with a reliable continuous pilot flame.

Response II-6-12: EPA has defined associated gas to exclude gas from exploratory and wildcat wells, if and until those wells become producing oil wells with associated gas. See the definition of associated gas in 60.5430b.

Comment: Commenter (2227-WEA) states that wildcat and delineation wells, and oil wells located on sites with no natural gas takeaway infrastructure (pipeline) should be categorically excluded from requirements to recover natural gas. Associated gas from such wells may be captured for beneficial use (e.g., fuel), routed to a flare or otherwise combusted. Furthermore, a demonstration that it is not feasible to recover natural gas from oil wells with no pipeline

---

<sup>37</sup> See API Supplemental Proposal Comments § 4.5.

takeaway capacity for technical or safety reasons is an unnecessary burden and should not be required.

Response II-6-13: See Response II-6-12 of this Chapter.

Comment: Commenter (2248-NDPC) expressed that, in NSPS OOOOa, wildcat and boundary wells were exempt from the Reduced Emission Completion (REC) standards. The commenter suggests the EPA extend this exemption to the associated gas standard. The exploration of oil and natural gas begins in areas before the infrastructure can be designed, sized, and constructed. It's only after a field is proven, through the drilling of wells, that the quantity, quality, and economics of the oil and natural gas can be determined. For example, the commenter states that a company could drill a dry hole, and any money spent on the gathering system would be wasted.

Response II-6-14: See Response II-6-12 of this Chapter.

#### 6.2.2.4 Low Production Wells

Comment: Commenter (2172-KOGA) recommends that EPA maintain an exemption for low production wells. The commenter explains that many of the low production wells operate with low pressure and low gas to oil ratios, so the Potential to Emit (PTE) is significantly less than the PTE for higher production wells that were recently drilled. Illinois Basin crudes are typically undersaturated with associated gas. The initial gas to oil ratios is typically in the 300-400 cubic feet/ barrel of crude oil (bbl) range, while greater than 1,000 cubic feet/bbl in other basins. In older Illinois Basin waterfloods the gas to oil ratios is too low to reliably operate a separator. For example, an operator made a discovery in 1974 that produced 10 cubic feet per bbl upon initial production. This well is still producing with virtually no associated gas produced. According to the commenter, requiring additional regulations on this type of low production well is not cost effective and does not provide meaningful environmental benefits.

Response II-6-15: See Response II-6-6 of this Chapter where EPA describes the subcategory created for existing wells that produce up to 40 tpy methane.

Comment: Commenter (2294-OOGA) states that one of the critical flaws of the NSPS OOOO regulations, including NSPS OOOOb and EG OOOOc under the supplemental proposal, is the failure to properly account for the declining production of oil and natural gas from a well over time, and the corresponding decline in emissions in connection with various operational changes at the well site associated with the decline in production. While initial production at a well may be significant, it will deplete as the well ages and eventually become a low production well. According to the commenter, the failure to properly account for this change skews the fundamental basis of the entire NSPS OOOO program – i.e., the cost-effectiveness analysis for establishing the BSER for each source that is subject to the program. The commenter asserts that the magnitude of this fundamental flaw is most significant in the resulting EG OOOOc for existing sources, which have a disproportionate and detrimental impact on low production wells and small businesses.

Commenter (2294-OOGA) points out that a significant portion of the approximately 62,000 wells in Ohio meet the definition of a low production well (i.e., produce at or below 15 barrels of oil equivalent per day) and, in fact, produce far less. About 60 percent of the wells in Ohio involve private contractual relationships between the producer and landowner to take a limited amount of natural gas for the lessor's private domestic use. The commenter adds that this means that there are approximately 36,700 rural Ohio families who have direct access to natural gas because of operating oil and gas wells. Many of these wells are owned by a landowner or a small business. The commenter contends that the December 2022 supplemental proposal is replete with stringent emissions standards and related compliance requirements that are impractical, technically infeasible, cost-prohibitive, overly burdensome, and otherwise unreasonable. They state that the impacts of such requirements are disproportionately borne by small businesses and operators of low production wells.

Response II-6-16: EPA set BSER for new wells and set a different BSER for modified and designated wells. EPA set another BSER for designated wells that must manage 40 tpy or less of methane. EPA set this array of standards to reflect the determination, in general agreement with the commenter, that BSER would be different for wells across the category.

EPA is aware that over time well production will decline, and the associated level of associated gas may diminish over time as well. The standards do not prohibit that a source choose a different option over time if making a change from routing to a sales line to an alternative is in the interest of the source. EPA chose to set BSER for modified wells as routing to a sales line, but ultimately allowing the source to flare if other options were infeasible, as a reflection of the options that a modified well should have to manage associated gas.

#### 6.2.2.5 Cost/Benefit Analysis

Comment: Commenter (2428-API) states that based on their preliminary review of EPA's Supplemental Technical Support Document (TSD), the associated gas model plant analysis does not include assumptions reflective of actual proposed requirements. They provide the following comments on the model plant analysis:

- The EPA should consider model facilities that have existing control devices but now need to install the correct flow and other parametric monitoring equipment as this would be a type of model plant scenario not evaluated by the EPA.
- None of the beneficial reuse emerging technologies have been included within the model plant analysis. It is unclear how EPA has justified the inclusion of these technologies related to costs, feasibility or environmental benefit/disbenefit.
- EPA includes no costs associated with the technical demonstrations proposed. There are direct costs associated with the engineering certification process, whether companies support in-house engineers or leverage third parties. They note that they provided these costs to the EPA in previous comments they submitted, and they note that they estimated certifications to costs to be \$2,000 - \$9,000. Commenter (2428-API) notes in the commenter's January 31, 2022, letter, they stated:

“a more representative cost for installing a flare suitable to control associated gas would

be \$100,579, based on the average costs EPA uses for analyzing storage vessel controls.”.[1] We also stated, “that we did not include the costs from EPA’s Workbook ‘MP1 Plus Monitors.xlsx’ as this would have further increased results due to inclusion of costs for a flow monitor and calorimeter, which EPA did describe in the proposal. If EPA pursues requirements that involve monitors or other requirements such as meeting compliance with §60.18 (as EPA has solicited comment), then additional compliance costs will apply and should be included within EPA’s cost analysis.

Commenter (2428-API) states in the December 2022 supplemental proposal, EPA has proposed additional parametric monitoring but has not included these costs in the analysis.”

Response II-6-17: As the commenter points out, the EPA did not perform a detailed cost analysis for routing associated gas to a sales line. EPA has corrected this by performing a detailed cost analysis of routing to a sales line to set BSER. EPA set BSER for associated gas as routing to a sales line as the most effective means of reducing emissions at a reasonable cost. EPA also recognizes that routing to a sales line may not be a feasible or the most cost-effective option for every well with associated gas, and therefore provided for alternatives that achieved equivalent reductions. EPA did not base the BSER determination on the cost of flaring associated gas. See the TSD in the docket detailing EPA’s analysis of the cost of routing to sales. EPA has revised certain requirements for flaring operations. To respond to the comment regarding monitoring of existing affected sources and their control devices, see section X.H. and XI.H. for the reasons that EPA has increased monitoring requirements for combustion control devices to assure operators and regulators that controls operate at prescribed destruction efficiency.

As the commenter points out the EPA did not develop full cost analyses of the alternatives to BSER such as injection of the gas into the well or another well, using the gas as fuel, or converting the gas to CNG or LNG to be transported off-site, or another useful purpose. The EPA did not perform detailed cost analyses of those options because the standards do not require sources to adopt them. Sources may adopt them as acceptable alternatives to BSER when it is in the better interest of the source to do so. EPA did this in recognition that many of these techniques are already in use, that across the category not every well with associated gas can be regulated with one-size-fits-all BSER, and in those cases where connecting to a sales line is at the higher end of the cost spectrum, one of the alternatives is likely to be less costly than BSER. We received comments exactly to this effect.<sup>38</sup> While it is true that the analysis supporting a certification of infeasibility may cost in the range cited by the commenter, we have revised the requirement by not requiring that a licensed engineer perform and certify the analysis, but rather are allowing personnel with appropriate expertise to conduct the analysis.

Comment: Commenter (2446-Independent Petroleum Association of America (IPAA)) states that most of the studies used by EPA in the past and used to support these proposals are based on data predominantly taken prior to 2015 which means that it predates the NSPS OOOOa regulations and was at the beginning of the implementation of the NSPS OOOO regulations. The commenter reports that they have submitted information on this issue in prior comments demonstrating that the turnover in wells means that most of the existing source pool that exceeds 15 barrel of oil

---

<sup>38</sup> Rystad, *supra* note 394, at 11.

equivalent (boe)/day will be from NSPS OOOO and NSPS OOOOa well sites. The commenter states that the brunt of the impact of the EG will fall on low production wells. They state that, by the proposal using the November 2021 effective date, this creates the anomalous issue of requiring sources complying with prior NSPS requirements to replace equipment and processes at considerable expense to owners/operators under the EG. The commenter notes that the EPA has not evaluated the impact on the original BSER/cost-effectiveness evaluation and justification for various requirements under previously enacted NSPS for the Oil and Gas Industry.

Response II-6-18: EPA disagrees that EPA's proposed standards for associated gas are based exclusively on data from 2015. EPA developed the cost analysis based on industry data from 2014, 2015, and 2018 and was supplemented by data provided by industry after the supplemental proposal<sup>39</sup>.

EPA agrees in part with the commenter regarding certain wells that produce low levels of associated gas. As explained in sections X.F.2. and XI.F.2. of the final rule preamble, EPA has included a subcategory in the final EG for wells that produce less than 40 tpy methane of associated gas.

Comment: Commenter (2433-EDF et al) states that in the November 2021 Proposal, EPA proposed to find that cost-effectiveness values up to \$1,970/short ton of methane reduced are reasonable. According to estimates by Rystad Energy, the costs of gas recovery options per metric ton of methane abated are well below the levels that EPA finds cost-effective.

- *Routing to a sales line*. The Rystad report shows that connecting wells to gathering infrastructure is not only highly cost-effective but profitable for operators, with an average net profit to operators of \$3.10 per thousand cubic feet (kcf) and average negative cost of \$162 per metric ton of methane flaring avoided.<sup>40</sup> Operators will pay between \$0.40 and \$0.80 per kcf handled by third party processing and gathering, netting profit after gas sales of \$2.70 to \$3.50 per kcf. This corresponds to a range of *negative \$141-183 per metric ton of methane abated*.<sup>41</sup> Gathering is an effective and available option for sites flaring any amount of gas.<sup>42</sup>
- *Onsite use*. Rystad estimates that on average, onsite use of gas nets a profit of \$8.60/kcf and \$449 per MT of methane flaring avoided, after accounting for cost savings from fuel switching.<sup>43</sup> For a site producing 50 kcf per day of associated gas, costs associated with onsite power generation include between \$1.90 to \$2.20 per kcf for a small power generator and between \$0.60 to \$1.70 per kcf for gas treatment, netting between \$7.70 to \$9.40 in profit per kcf.<sup>44</sup> This corresponds to a range of negative \$402-491 per metric ton

---

<sup>39</sup> Memorandum to the Docket, Record [call record for meeting with INGAA].

<sup>40</sup> Rystad, *supra* note 394, at 11.

<sup>41</sup> *Id.* at 45.

<sup>43</sup> Rystad, *supra* note 394, at 11.

<sup>44</sup> *Id.* at 50-51.

of methane abated.<sup>45</sup> Onsite use is an effective option for sites flaring a relatively small amount of gas (less than 100 kcf/day).<sup>46</sup>

- *Other beneficial use.* In the proposed rule, EPA categorizes CNG trucking as “another useful purpose.” Rystad’s report finds that on average, CNG trucking will cost operators \$1.8/kcf, or \$94 per metric ton of methane flaring avoided.<sup>47</sup> At a site producing 250 kcf per day of associated gas, costs associated with CNG include between \$0.60 to \$1.70 per kcf for gas treatment, \$0.30 to \$1.00 per kcf for compression, and \$2.60 to \$4.10 per for 200 miles of transportation, for a net cost after gas sales of between \$0.10 to \$3.40 per kcf.<sup>48</sup> This corresponds to a range of \$5 to \$177 per metric ton of methane abated. CNG is an effective option for sites flaring more than 250 kcf/day of gas and is scalable across a range of sites.<sup>49</sup>
- *Reinjection.* Reinjection for storage costs vary depending on various factors, but Rystad finds that on average, costs are \$3.4/kcf, and \$177 per metric ton of methane flaring avoided.<sup>50</sup> Costs associated with reinjection include between \$0.20 and \$0.60 per kcf for gathering and between \$0.20 and \$5.70 per kcf for storage, for a total cost between \$0.40 to \$6.30 per kcf.<sup>51</sup> This corresponds to a range of \$20 to \$329 per metric ton of methane abated. Reinjection is an effective option for sites flaring more than 350 kcf/day of gas.<sup>52</sup>

Commenter (2433-EDF et al) states that while EPA declined to quantitatively analyze these alternatives in the November 2021 TSD, stating, “the site-specific variabilities associated with the application of these control options are significant,”<sup>53</sup> and did not include a quantitative assessment of non-flaring abatement options in the 2022 TSD, the Rystad cost analysis estimates discussed above, which are broadly applicable across basins, offer a pathway to assessing costs and emissions reductions.

Commenter (2433-EDF et al) states that EPA quantitatively analyzed the use of a combustion control device to abate emissions from associated gas venting at five model plants in the December 2022 TSD.<sup>54</sup> Additionally, as Rystad notes, associated gas from nearby well pads could be aggregated together to increase the applicability of capture options.<sup>55</sup> As discussed, the commenter provides that all capture options are highly cost-effective based on cost per metric ton of methane flaring abated (and are even more cost-effective if assessed as abatement options for uncontrolled methane venting).

<sup>54</sup> Supplemental TSD, supra note 121, at chapter 6, attachment 7.

<sup>55</sup> Rystad, supra note 394, at 40.

Similarly, commenter (2408-CO-LGC) suggests that eliminating routine flaring is a cost-effective way to curb methane emissions. They refer to the above-cited environmental commenters submitted detailed analysis included in their comments submitted to the EPA on the November 2021 proposal documenting that the four-abatement options EPA proposes here are cost effective.<sup>56</sup> Specifically, they repeat:

- The Rystad report shows that connecting wells to gathering line infrastructure is not only highly cost-effective but profitable for operators, with an average net negative cost of \$3.10 per thousand cubic feet (mcf) and \$162 per MT of methane flaring avoided.<sup>57</sup>
- Rystad estimates that on average, on-site use of gas nets a profit of \$8.60/mcf and \$449 per MT of methane flaring avoided.<sup>58</sup>
- Rystad's report finds that on average, CNG trucking will cost operators \$1.8/kcf, or \$94 per MT of methane flaring avoided.<sup>59</sup> In the Proposed Rule, EPA views CNG trucking as falling into the "another useful purpose" category.
- Reinjection costs vary depending on various factors, but Rystad finds that on average, costs are \$3.4/mcf, and \$177 per MT of methane flaring avoided.<sup>60</sup>

Commenter (2408-CO-LGC) states that the costs of the abatement options are well below EPA's cost-effectiveness threshold. In the November 2021 Proposal and the 2022 Supplemental Proposal, EPA proposes to find that cost-effectiveness values up to \$1,970/ton of methane reduction are reasonable for controls identified as BSER.

Response II-6-19: EPA reviewed the Rystad report submitted by the commenter. EPA does not agree or disagree with the conclusions of the report on the cost-effectiveness of the alternatives to BSER. EPA does not need to agree or disagree to support our BSER determination. EPA analyzed routing to a sales line as BSER and concluded that in most cases for new wells, routing to a sales line is BSER. EPA also recognizes that some sources will seek alternatives to BSER where they find it to their advantage to use an alternative to BSER, for logistical, cost, or other reasons. The only justification required of an existing source is where every alternative is infeasible for technical or safety reasons, and the source determines that the only technical means of handling associated gas is to flare. This is an option available to modified and existing sources only after the alternatives have been documented to be infeasible. For sources that produce 40 tpy or less of associated gas, no justification is required to flare because our BSER analysis indicated that routing to a sales line was not reasonable for BSER even over short distances to a sales or gathering line.

Comment: Commenters (2168-INOGA, 2172-KOGA) believe that if industry was able to cost effectively transport the gas to a sales line and monetize the benefit, it would have been done

---

<sup>56</sup> Env't Def. Fund et al., Comments on Standards of Performance for New, Reconstructed, and Modified Sources and Emissions Guidelines for Existing Sources: Oil and Natural Gas Sector Climate Review, Dkt. <sup>60</sup> Rystad, Slide 11.

already. The challenge is that commercial gas lines are not in proximity to some the oil production. Industry has been sharing this information in our comments since 2015 when NSPS OOOOa was proposed.

Further, commenter (2168-INOGA) states that when industry proposes to construct a new gas pipeline to route the gas to sales (for environmental “benefit”), environmental groups oppose the project through litigation. The commenter notes that the EPA is maintaining this position; but has not supported the oil and gas industry through the process to provide take-away capacity to move the gas to market.

Commenters (2168-INOGA, 2172-KOGA) point out that much of the associated gas from low production wells does not meet the requirements to be sold on an interstate pipeline system. The gas may require water, nitrogen, carbon dioxide, and heavier hydrocarbons (ethane, propane, butane, pentane, and hexane) to be removed prior to being sold into the gas market. The cost to make the gas “pipeline spec” usually exceeds the benefit of selling the gas on the pipeline. The commenter provides that this is another example of where low production wells should be exempt from the proposed regulation.

Response II-6-20: See Response II-6-19 of this Chapter.

Comment: Commenter (2428-API) states the EPA seems to bias the data selected for baseline emissions to fit their expectation and not based on actual reported data. In section 6.3.1 of the technical support document the commenter reports that the EPA states:

There were 95 facilities/basins that reported associated gas venting emissions [through GHGRP subpart W data]. For each facility/basin, the number of wells venting is reported, along with the total methane vented from all wells. For each facility/basin, we calculated the average emissions per well. These average well emissions ranged from 0.015 tons per year (tpy) to over 2,400 tpy. Almost 20 percent of the facilities/basins had average well methane emissions less than 0.2 tons per year.

Explanations of the specific causes of emissions is not provided in the GHGRP subpart W outputs, but it would be expected that routine venting of associated gas would result in emissions greater than this level. In order to avoid selecting a well associated gas venting level that was unreasonably low, a weighted average well emissions level was calculated, using the total emissions from the facility/basin as the weighting factor. The result is an estimated average annual methane emissions level of 344 tpy. Applying the representative composition yields a representative VOC emissions level of 96 tpy.

Commenter (2428-API) states within these statements, EPA acknowledges that there are very low methane emissions generated from wells that only temporarily flare associated gas when the primary recovery method is not available (i.e., routing to sale, for injection, or used as onsite fuel). However, the commenter notes that the EPA in this proposal has not made the distinction between facilities that temporarily flare versus those that are truly stranded.

Response II-6-21: EPA is finalizing standards that do distinguish between facilities that temporarily flare gas for an interruption in service for routing to sales, for injection, or used of onsite fuel, apart from routine long-term flaring. In the finalized version of 40 CFR 60.5377b(c), EPA has specified reasons and periods that flaring may be used to achieve 95 percent control efficiency, unless a safety issue makes flaring unsafe. Each of these occurrences generates a record of deviation from the standard.

### **6.2.3 Proposed BSER - EG OOOOc**

[**Note**: Most of the comments provided on the proposed NSPS OOOOb also apply to EG OOOOc. For these comments, see section 6.2.2 of this Chapter. This section includes comments that specifically provided comments on the existing sources/EG OOOOc.]

#### 6.2.3.1 Opposition to Proposed EG OOOOc BSER

Comment: Commenter (2294-OOGA) suggests that the fundamental flaw in EPA's NSPS OOOO regulations has resulted in a misguided BSER determination for existing sources that effectively regulates existing sources the same as new and modified sources. The commenter states that the December 2022 supplemental proposal assumes that existing facilities can be retrofitted at a reasonable cost to meet the same emissions standards applicable to new and modified sources. The commenter contends that the EPA made a gross miscalculation in this regard. The commenter provides that many of their members lack the financial capital to retrofit existing sources with the equipment necessary to comply with the emissions standards under the supplemental proposal and/or do not have technical staff and legal advisors to assist with understanding and complying with the myriad of requirements that they will be subject to, including AVO inspections, conducting root cause analyses and fixing leaks, recordkeeping and reporting (not to mention the significant costs associated with conducting those activities). Even assuming operators could pay for costs to retrofit, the commenter explains that, as a well approaches the end of its useful life, there is a point at which it is no longer economic to make the necessary retrofits. Whereas EPA assumed compliance to be feasible and cost-effective, the commenter asserts that the reality is that the stringent emissions standards under the supplemental proposal will render many existing operations, particularly low production wells, economically infeasible and drive many small business and operators of low production wells out of business, including landowners of the approximately 5,300 wells that provide oil/gas to single-family residences in Ohio. [**Note**: For further comments received on low production well concerns, see sections 6.2.2.4 and 6.2.3.3 of this Chapter.]

Response II-6-22: While the scope of this comment is beyond associated gas requirements, EPA disagrees that differences in existing and new sources have not been considered in the development of NSPS OOOOb and EG OOOOc. This is particularly evident for associated gas, where the standards in the final NSPS OOOOb and the presumptive standards in EG differ considerably. Recognizing the barriers to retrofitting existing sites to route the associated gas to a sales line or use the gas for another beneficial purpose, the final EG OOOOc includes an allowance for owners and operators of existing wells to demonstrate the technical infeasibility and route the gas to a flare. For small low producing wells such as those described by the commenter, EPA recognized the cost burden the final EG OOOOc allows routing to a flare or

control device without a technical infeasibility demonstration. This is defined by the methane level containing the associated gas. Specifically, wells producing natural gas containing 40 tons of methane or less per year are eligible for this provisions.

Further, with regard to those wells that are approaching their remaining useful life, state agencies have the option to invoke the RULOF provisions and develop standards less stringent than the presumptive standards in EG OOOOc.

#### 6.2.3.2 Existing Well Site Considerations

Comment: Commenter (2283-Endeavor Energy) suggests that EPA should clarify the requirements for demonstrating that operational flaring is necessary and that the proposed flaring requirements do not apply to emergency flares. As with many of the other proposed requirements, the commenter is concerned that EPA's proposed provisions related to flaring do not reflect the realities of the environments in which the commenter and other producers operate. The commenter asserts that this is particularly true for existing sites. Under the Methane Proposal, EPA proposes that before associated gas can be flared, the owner or operator must submit a demonstration, certified by a professional engineer or other qualified individual, that a sales line is unavailable and other beneficial uses are not feasible for technical or safety reasons. The commenter explains that, for many of their existing wells, no sale line is readily available, and even if one was available, the volume of associated gas may be too low to reach a sales line. The commenter recommends that EPA reconsider this requirement for existing well sites, in recognition that the infrastructure is unlikely to be present to make such a requirement feasible.

Commenter (2283-Endeavor Energy) states that EPA's proposed provisions present several additional problems when applied to existing well sites. The commenter provides that many older, existing well sites in the Midland Basin do not have flares onsite, and it would present a significant capital expense to add a flare or similar control device at each existing well site. In addition, under the Methane Proposal, well owners or operators routing associated gas to a sales line that anticipate that there may be interruptions in the ability to route the associated gas to a sales line must provide a technical or safety demonstration in their annual report and install and operate a control device that achieves the required reduction during these temporary periods. The commenter states that this provision would effectively require a backup flare at every well site, which they say would impose substantial costs if applied to existing well sites. According to the commenter (and provided elsewhere in their comments), these requirements threaten to fundamentally alter the economics for these existing wells and could result in wells being shut in or abandoned. The commenter believes that the EPA should therefore consider the remaining useful life of these existing sources, as required by the CAA, and should not include these requirements in any finalized EGs.<sup>61</sup>

Response II-6-23: See Responses II-6-10 and II-6-21 of this Chapter.

---

<sup>61</sup> 42 U.S.C. §741 l(d)(I).

### 6.2.3.3 Low Production Wells

Comment: Commenter (2446-IPAA) provides comment on the implications of the EG on low production wells, where EPA's recurring conclusion that designated facilities under the EG should be the same as affected facilities under the NSPS fails to understand the implications of inherent production depletion on the economics and emissions from smaller wells. The commenter asserts that there are fundamental factors that are not adequately considered in the EPA assessments. As oil and natural gas wells undergo their inherent depletion, the reduced volumes of production limit the amount of emissions that can be generated. Within the well itself, one key factor is the reduction of the internal pressure of the well. Lower well pressure may compel actions like the addition of pumps to pull the liquids out of the well bore, as well as the addition of compressors to pull gas from the well bore. Even natural gas-powered pneumatic controllers and pumps may not be able to function if the well pressure drops below the level needed to run the controller or pump, and consequently the well does not produce as a function of negative pressure. As a result, well sites must be reconfigured to reflect their aging operations. All these factors also influence the magnitude – even the possibility – of emissions. A natural gas well with a booster compressor is typically operating under negative pressure - trying to pull gas from the well. As opposed "to leaking" the system would be pulling ambient air into the gas product stream, not having it leak from flanges and valves. As wells diminish, they do not necessarily operate – or emit – daily. Small wells may only operate a few days a week when the pumper comes to the site to operate the equipment to produce oil from a well bore that has slowly filled over the previous days. The commenter asserts that these factors affect the realistic design of regulations – including the potential definitions of designated facilities – that EPA has not addressed in the EG.

Response II-6-24: See Responses II-6-10 and II-6-21 of this Chapter.

### 6.2.3.4 EG OOOOc Regulatory Text

Comment: Commenter (2288-North Dakota Department of Environmental Quality (NDDEQ)) cites the proposed language in 40 CFR 60.5420c(c)(2)(ii)(B) which reads "[r]ecords of each change been [sic] made at the site since the original certification along with records of either a re-certification of why it is infeasible to comply with 40 CFR 60.5391c(a)(1), (2), (3), or (4) in accordance with 40 CFR 60.5391c(b)(2), or a statement that indicates compliance can now be achieved with 40 CFR 60.5391c(a)(1),(2), (3), or (4) and a description of specifically how compliance will be achieved." The commenter states it is unclear what type of change would require records to be kept under this requirement.

To avoid any confusion, the commenter (2288-NDDEQ) suggests the type of change requiring records to be kept should be explicitly defined, as in 40 CFR 60.5420c(b)(9)(ix) "change in the reported condition", or in 40 CFR 60.5415c(e)(1) "change in compliance method". Presumably, the commenter believes, the change required in 40 CFR 60.5420c(c)(2)(ii)(B) should refer to change "that would impact the ability to comply with §60.5391c(a)(1), (2), (3), or (4)", per 40 CFR 60.5420c(b)(3)(ii)(B)(1).

Additionally, commenter (2288-NDDEQ) points out that 40 CFR 60.5420c(b)(3)(ii)(B) appears to reference incorrect paragraphs. They note that it currently states, "[f]or each oil well with associated gas that complies by routing the gas to a control device that reduces methane emissions by at least 95.0 percent, the information in either paragraphs [40 CFR 60.5420c] (b)(4)(ii)(B)(1) or (2) of this section." Presumably, the commenter believes, since it is referencing its own paragraphs, it should instead reference "paragraphs [40 CFR 60.5420c](b)(3)(ii)(B)(1) or (2) of this section" instead.

Commenter (2237- North Dakota Industrial Commission (NDIC)) points out several of the same regulatory text concerns as commenter (2288-NDDEQ) does. For example, commenter (2237-NDIC) contends that the proposed language in 40 CFR 60.5420c(c)(2)(ii)(B) is confusing. It reads:

Records of each change been [sic] made at the site since the original certification along with records of either a re-certification of why it is infeasible to comply with §60.5391c(a)(1), (2), (3), or (4) in accordance with §60.5391c(b)(2), or a statement that indicates compliance can now be achieved with §60.5391 c(a)(1), (2), (3), or (4) and a description of specifically how compliance will be achieved.

The commenter (2237-NDIC) suggests that it is unclear what type of change would require records to be kept under this requirement. To avoid confusion, the commenter recommends that the type of change requiring records to be kept should be explicitly defined, as in 40 CFR 60.5420c(b)(9)(ix) "change in the reported condition", or in 40 CFR 60.5415c(e)(1) "change in compliance method". They also recommend that the type of change required in 40 CFR 60.5420c(c)(2)(ii)(B) should refer to change "that would impact the ability to comply with §60.5391c(a)(1), (2), (3), or (4)", per 40 CFR 60.5420c(b)(3)(ii)(B)(1).

Additionally, the commenter (2237-NDIC) states (as commenter 2288-NDDEQ does above) that 40 CFR 60.5420c(b)(3)(ii)(B) appears to reference incorrect paragraphs. It currently states:

For each oil well with associated gas that complies by routing the gas to a control device that reduces methane emissions by at least 95.0 percent, the information in either paragraphs (b)(4)(ii)(B)(1) or (2) of this section.

Since it is referencing its own paragraphs, the commenter (2237-NDIC) believes it should instead reference "paragraphs (b)(3)(ii)(B)(1) or (2) of this section".

Response II-6-25: The proposed provisions related to the recordkeeping requirement to document certain changes that trigger a re-assessment of the technical infeasibility have not been retained in the final rule. Rather, all associated gas wells that are allowed to routinely flare because they have demonstrated and certified the technical infeasibility of routing to a sales line and other beneficial uses are required to perform a new demonstration and re-certify technical infeasibility on an annual basis.

Comment: Commenter (2214- BlueCrest Alaska Operating, LLC (BlueCrest) ) requests clarification of 40 CFR 60.5420c(b)(3)(ii)(A) regulatory text. Does the identification of each

well that routes gas to a control device include unplanned facility upsets that result in well gas being routed to a flare when it is normally routed to a production facility?

Response II-6-26: See Response II-6-6 of this Chapter.

#### **6.2.4 Flaring**

[**Note:** In addition to the comments provided in this section, section 17.x of Chapter 17 includes general comments that support the banning of flaring of associated gas and use as a control device option for other affected/designated facilities subject to NSPS OOOOb and EG OOOOc.]

##### 6.2.4.1 Environmental and Human Health Implications of Flaring

Comment: Commenter (2392-Earthjustice et al) states that disparate air quality impacts are associated with flaring practices at oil and gas extraction facilities. These adverse health impacts are widespread and severe. The commenter reports that flaring of associated gas at oil wells produces black carbon particles, more commonly referred to as soot or particulate matter (PM). The respiratory impacts resulting from exposure to particulate matter can travel as far as 60 miles away from flaring sites.<sup>62</sup> Studies confirm a causal link between flaring and respiratory-related hospitalizations in North Dakota, where a recent study found that a 1 percent increase in the amount of flared natural gas in the state increases the respiratory-related hospitalization rate by 0.73 percent.<sup>63</sup> Therefore, the commenter urges EPA to strengthen the proposed rule to mitigate the above disparate impacts.

Commenter (2433-EDF et al) points out that flaring and venting also contribute a significant amount of methane emissions annually. In 2019, flaring emitted 86,000 metric tons of methane and venting emissions emitted 68,000 metric tons of methane. The commenter notes that these estimates likely underestimate methane emissions from associated gas flaring and venting, as they do not account for observed high rates of unlit and malfunctioning flares. The commenter reports that studies also demonstrate that emissions from flaring and venting cause severe health burdens on communities, especially disadvantaged communities like low-income populations, people of color, the elderly, and children.

A 2023 study by Boston University's School of Public Health, The University of North Carolina, and the commenter (2433-EDF et al) has analyzed the impacts of onshore oil and gas flaring and venting on air quality and health.<sup>64</sup> The commenter (2433-EDF et al) indicates that prior studies have indicated that oil and gas activity is associated with increased risk of adverse health events, but there was limited quantification of the health impacts that resulted from air pollution from flaring and venting activities. This study sought to fill this gap by quantifying ozone, fine particulate (PM<sub>2.5</sub>) and nitrogen dioxide (NO<sub>2</sub>) emissions from venting and flaring and attributing those emissions to particular health outcomes. Using a hybrid Visible Infrared Imaging

<sup>63</sup> Id.

<sup>64</sup> See Huy Tran et al., Onshore Oil and Gas Flaring and Venting Activities in the United States and their Impacts on Air Quality and Health (pre-publication slides) (Feb. 2023) (included as Attachment Q).

Radiometer Suite (VIIRS) and the National Emissions Inventory (NEI) based emissions inventory and applying Community Microscale Air Quality (CMAQ) and Benefits Mapping and Analysis Program (BenMAP)-R to assess air quality health impacts, the study found that in 2017, flaring and venting emissions from oil and gas operations resulted in 710 premature deaths, 73,000 asthma exacerbations among children, 210 instances of ozone national ambient air quality standards (NAAQS) exceedances, and over \$7.4 billion in health damages.<sup>65</sup> Critically, the commenter notes that the study has found that these health impacts disproportionately burden disadvantaged populations. Of the adult deaths and child asthma exacerbations caused by venting and flaring, one in three are among low-income populations, and one in five are in communities that are home to Native American populations.<sup>66</sup> The study also looks at specific pollutant emissions and their impacts. It finds that flaring and venting contributes to 50 percent of VOC emissions from oil and gas facilities across the continental U.S., 63.1 percent in Texas, 84.6 percent in North Dakota, 52 percent in New Mexico, 70.6 percent in Colorado, and 58.8 percent in Wyoming. And that ozone (O<sub>3</sub>) pollution from flaring and venting contributes to 230 deaths, 9,700 asthma exacerbations, and 110 respiratory hospitalizations annually.<sup>67</sup>

Commenter (2433-EDF et al) states that the 2023 study results complement previously published literature, including a 2022 study by Rice University and Clean Air Task Force, which looked at the health impacts related to black carbon emissions from flaring in the U.S.<sup>68</sup> This study used satellite flaring data from VIIRS and three separate reduced form models to assess flaring health impacts. It estimated that flaring from oil and gas operations emitted nearly 16,000 tons of black carbon in 2019, leading to 26-53 premature deaths that were directly attributable to air quality associated with flares, mostly in Texas, North Dakota, and New Mexico.

According to the commenter (2433-EDF et al), they conducted an additional analysis that focused on the impacts of flaring on disadvantaged communities living near oil and gas sites. To conduct this analysis, the commenter used Enverus data to identify wells with reported flaring in 2019 (available for the following states: TX, NM, CO, ND, MT, WY, and MS). By identifying wells with flaring, the commenter was able to identify the local communities that are impacted by the air pollution from these wells. Using the methodology described in Proville et. al. 2022,<sup>69</sup> the U.S. Census Bureau's American Community Survey 5-year estimates for 2015-2019,<sup>70</sup> and health data from the Centers for Disease Control and Prevention's Places dataset,<sup>71</sup> the commenter was able to estimate the populations living within a half mile radius of the previously identified wells using areal apportionment.

<sup>65</sup> Id. at 4–5.

<sup>66</sup> Id. at 5.

<sup>67</sup> Id. at 31.

<sup>68</sup> Chen Chen et al., Black Carbon Emissions and Associated Health Impacts of Gas Flaring in the United States, 13 *Atmosphere* 385 (Feb. 2022), <https://www.mdpi.com/2073-4433/13/3/385/htm>.

<sup>69</sup> Jeremy Proville et al., The demographic characteristics of populations living near oil and gas wells in the USA, 44 *Population Env't.* 1 (2022), <https://doi.org/10.1007/s11111-022-00403-2> (Attachment R of their comment submission).

<sup>70</sup> U.S. Census Bureau, 2015–2019 American Community Survey 5-year Estimates (2021) (retrieved from [https://www2.census.gov/geo/tiger/TIGER\\_DP/2019ACS/](https://www2.census.gov/geo/tiger/TIGER_DP/2019ACS/)).

<sup>71</sup> Centers for Disease Control and Prevention, Places: Local Data for Better Health, <https://www.cdc.gov/PLACES/> (last visited Feb. 13, 2023).

From this analysis, the commenter (2433-EDF et al) estimates there are roughly 240,000 people living within a half mile of a well with flaring. This includes approximately 19,000 children under the age of five, more than 28,000 older Americans over the age of 65, 110,000 people living in poverty, and almost 120,000 people of color, including 7,400 Native Americans and 94,000 Hispanic/Latinos. Because flaring data at the well level is only available for seven states, it is likely that these numbers are higher. Several of these demographic groups are over-represented in the population living in proximity to flaring, relative to the nation at large. For example, Native Americans live near actively flaring wells at rates 80 percent higher than the national average. Nationally, Hispanic/Latinos make up about 20 percent of the overall population, but 40 percent of those living near a flaring well identify as Hispanic/Latino. Among those near flaring, asthma, chronic obstructive pulmonary disease (COPD), coronary heart disease (CHD), and stroke are found at rates 4-8 percent higher than the rest of the country. Roughly 17,000 adults with asthma, 13,000 adults with COPD, 12,000 adults with CHD, and 6,500 adults who have experienced a stroke live within a half mile of a flaring well.

Commenter (2433-EDF et al) states that these results comport with previous findings, including a 2021 study by researchers at the University of California-Los Angeles (UCLA) and University of Southern California (USC) that found that more than half a million people in the U.S. live within a half mile of significant oil and gas flaring.<sup>72</sup> Of these people, the study found, 210,000 live near more than 100 flares, including a disproportionate number of black and indigenous people and other people of color.

The commenter (2433-EDF et al) asserts that these studies show the significant health impacts of flaring and that they disproportionately impact vulnerable communities. They highlight the critical need to address emissions from associated gas at oil wells. As noted in section I (A), EPA's proposal will reduce methane emissions from associated gas by roughly one million metric tons between 2023-2035. EPA standards could reduce associated gas methane emissions by an additional 400,000 tons (to at least 1.4 million tons)<sup>73</sup> over this period if strengthened as outlined below. Doing so will also substantially reduce the health impacts flaring has on local communities. Like flaring and venting emissions estimates, the commenter (2433-EDF et al) suggests these emission reductions estimates are likely undercounted as they do not account for reductions that could be achieved by reducing unlit and malfunctioning flares.<sup>74</sup>

Response II-6-27: While these comments encompass the impacts of flaring in general and are not limited to associated gas flaring, EPA points out that BSER for the final NSPS OOOOa and EG OOOOc is to route the associated gas to a sales line. In addition, the standards and presumptive standards also allow the use of other options that achieve the same level of emission reduction as routing to a sales line. Flaring is only allowed in limited circumstances. EPA believes that the final associated gas standards and presumptive standards will be effective in reducing the impacts of flaring such as those mentioned by the commenters.

---

<sup>72</sup> Lara J. Cushing et al., Up in smoke: characterizing the population exposed to flaring from conventional oil and gas development in the contiguous US, 16 Env't Rsch. Letters 034032 (Feb. 2021), <https://iopscience.iop.org/article/10.1088/1748-9326/abd3d4>.

<sup>73</sup> See infra section IV.A.

<sup>74</sup> See infra, section IV.B.

Comment: Commenter (1648-PA-Audubon) states methane flares present a hazard to birds from burning, entrapment in pipes or vents, or direct mortality from the flare. The flame emitted to burn off gas during a flaring event can attract birds, especially at night, explains the commenter, and birds may fly through the superheated gas or flame, resulting in feather damage which grounds the birds, or scalding of lungs and other tissues with inhalation. The commenter also reports that birds can also be killed or injured if they perch on burner pipes.

Response II-6-28: See Response II-6-27 of this Chapter.

Comment: Commenter (2502-RGISC) states that they conducted over 100 oil and gas inspections in the Eagle Ford shale and have seen firsthand how harmful methane pollution from the oil and gas industry is to health and the planet. The commenter states that on any given day a smoking flare, unlit flare, or leaking tanks could be spotted. The commenter states that there are communities along the Eagle Ford Shale, like Tilden, Texas, that smell of hydrocarbons, day in and day out, due to the sheer volume of gas being vented and flared.

Commenter (2028-WMCG) points to a study by a research team from the University of California, Los Angeles (UCLA) and University of Southern California (USC) which examined the relationship between poor birth outcomes and shale gas development in south Texas. The commenter explains that the study specifically considered proximity to flaring events, studied the birth outcomes from mothers exposed to the most flaring events, based on satellite observations, within a five-kilometer radius of their homes during pregnancy and compared them to the birth outcomes from mothers who were not exposed to flaring events during their pregnancies. Between these two groups the researchers saw 50 percent higher odds of preterm birth and shorter gestation in the group exposed to flares<sup>75</sup>.

Commenter (2028-WMCG) also points out that the Ventura County Air Pollution Control District, in California has estimated that the following air pollutants may be released from natural gas flares: benzene, formaldehyde, polycyclic aromatic hydrocarbons (PAHs, including naphthalene), acetaldehyde, acrolein, propylene, toluene, xylenes, ethyl benzene and hexane. The commenter adds that researchers in Canada have measured more than 60 air pollutants downwind of natural gas flares, states the commenter and deadly hydrogen sulfide and radon-226 has also been shown to exist in shale gas.

Commenter (2028-WMCG) provides that in 2014, a four-part investigation by the San Antonio Express-News found that natural gas flaring in the Eagle Ford Shale in 2012 contributed more than 15,000 tons of VOCs and other contaminants to the air of southern Texas—which is roughly equivalent to the pollution that would be released annually by six oil refineries.

Commenter (2352-ETRPC) notes Texas accounts for 47 percent of vented and flared natural gas in the U.S, and the commenter states they have seen firsthand how harmful that pollution can be. The commenter includes examples of interviews they conducted across the Permian Basin from people living and working in the region, including ranchers, oil and gas attorneys, and others

---

<sup>75</sup> Cushing et al., 2020.

with industry ties. The commenter states that they are posting these example interviews at EnvironmentTexas.org.

Commenter (2352-ETRPC) provides that Dr. Edward Brooks, a physician and specialist in immunology, has also expressed concerns with health impacts in communities located close to a refinery or high production area. The commenter warns that flaring releases compounds, such as benzene, a known carcinogen or toluene, a neurotoxin. The commenter refers to a recently published study examining the Eagle Ford Shale region that found that “pregnant women who lived near areas where flaring is common had 50 percent greater odds of giving birth prematurely than those who did not.”

Response II-6-29: See the Response II-6-27 of this Chapter.

Comment: Commenters (1620-EEN, 2039-CPLV) states that when companies rush to extract oil, many forgo investments necessary to capture and sell methane and instead flare it as a waste product, emitting a host of climate and health-harming pollutants. The commenter warns that flares have been found to malfunction or fail entirely, spewing methane directly into the atmosphere. Commenter (2039-CPLV) asserts that reducing venting and flaring will significantly decrease methane, an extremely potent GHG, as well as smog-causing VOC emissions and carcinogens.

Response II-6-30: See Response II-6-27 of this Chapter.

#### 6.2.4.2 Exclusion/Limitation of Flaring

Comment: Commenters (1611-ELPC, 1620-EEN, 1633-NRDC, 1643-ORVI, 1644-YECA, 1648-PA Audubon, 1651-CJM, 1658-PDT, 2028-WMMCG, 2036-NPCA, 2152-CALSTRS, 2156-CCGD, 2164-NAM, 2174-Progress MI, 2185-NY CRF, 2190-M/H Investments, 2191-Boston Trust, 2195-EHP, 2199-RMFU, 2203-Ceres, 2206-L&G Investment, 2215-WVRC et al Rivers, 2217-RACRJ, 2236-PA PSR, 2242-SGI, 2250-NRPE et al, 2278-Springfield NAACP, 2285-Bailard, 2287-ICCR, 2289-Galilee Baptists, 2299-NEI Investments, 2303-NTAA, 2335-Loren Karro, 2352-ETRPC, 2356-Earthworks et al, 2364-CleanEarth4Kids, 2365-CA CA, 2388-ExxonMobil, 2394-Earthworks, 2404-DRC, 2407-Methane Action, 2410-CA AG et al, 2420-WHPCA, 2422-WLN, 2424-As You Sow, 2429-WOC, 2441-HAWC, 2447-CALN, 2459-BMO Global Assets, 2461-CRS, 2466-KM, 2502-RGISC, 2766-1000 Grandmothers, 3418-Maine Solar Energy Association) urge the EPA to build on the proposed framework to address flaring by ensuring that operators at wells capture associated gas and limit flaring of that gas to instances in which it is necessary for safety or maintenance reasons. Many commenters point to flaring regulations in Colorado and New Mexico and ask the EPA to reflect those regulations in the proposed rule.

Commenter (2447-CALN) states that communities of color have been shown to experience disproportionate exposure to natural gas flaring.<sup>76</sup> If flaring must occur, the commenter states it

---

<sup>76</sup> Johnston, Jill E., Khang Chau, Meredith Franklin, and Lara Cushing. "Environmental Justice Dimensions of Oil and Gas Flaring in South Texas: Disproportionate Exposure among Hispanic Communities." *Environmental Science & Technology* 54, no. 10 (May 19, 2020): 6289-98. <https://doi.org/10.1021/acs.est.0c00410>.

should continuously meet the 95 percent threshold in terms of reductions of methane and VOCs and it should never be considered a long-term solution. The commenter recommends that the EPA carefully weigh the benefits of requiring owners and operators capturing gas for "beneficial" uses such as on-site power or reinjecting into wells for enhanced oil recovery with the potential climate, safety, and environmental justice impacts of these measures.

Commenter (2028-WMMCG) believes that the current proposal does not go far enough. The commenter is concerned that the current draft would continue to allow unnecessary gas flaring and venting if a company claims it is unable to capture and repurpose gas. The commenter states that EPA's proposal that ensures flares meet requirements for good flare performance, including the requirement to continuously monitor the flare to ensure that a pilot flame burns at all times are wholly insufficient because flaring is toxic and a hazard to public health.

Response II-6-31: See Response II-6-27 of this Chapter.

Comment: Commenter (2433-EDF et al) strongly supports EPA's exclusion of flaring as a compliance option for reducing associated gas from oil wells. But while flaring is no longer a compliance option, operators nonetheless can flare if they demonstrate that each of the gas recovery options is not technically feasible or safe. This is true for operators of new and existing wells. Moreover, the commenter adds that the EPA does not propose to limit the volume or amount of time an operator can flare upon submission of its technical infeasibility demonstration. The commenter description of their concerns with the technical infeasibility exception are presented below. In particular, the commenter urges EPA to revise the standard to limit the instances when an operator may flare temporarily by replacing the proposed technical infeasibility exemption with a set of clearly delineated circumstances in which temporary flaring or venting may be warranted.

Commenter (2433-EDF et al) states that the technical infeasibility exemption, as proposed, does not distinguish between instances when an operator seeks to flare on a routine, ongoing basis, and those instances when an operator seeks to flare on a temporary basis. This is one example of the over-breadth of the exemption. According to the commenter, as these and prior comments demonstrate, ongoing, routine flaring is rarely, if ever, a necessary part of operations. Furthermore, the commenter contends that the technical infeasibility exemption presents enforcement challenges. Below the commenter describes the reasons why they believe this exemption is overly broad.

First, commenter (2433-EDF et al) suggests safety concerns are by their nature temporary and would never give rise to the need to flare indefinitely. EPA should therefore require that any safety-related flaring cease when the safety concern no longer exists.

Second, commenter (2433-EDF et al) suggests routine flaring from new wells can never be justified due to the technical infeasibility of some alternative. As discussed in both the Rystad report and the expert report of Tom Alexander, the commenter states that routine flaring is readily preventable at new wells with proper planning and coordination between upstream and

midstream operators.<sup>77</sup> The commenter adds that the Rystad report makes clear that the main drivers of flaring are timing of well hookups and infrastructure capacity.<sup>78</sup> An operator has complete control over decisions regarding where and when to drill a new well and when to complete or put such a well into production.<sup>79</sup> As such, the commenter states that operators of new wells have the ability to address both timing and infrastructure capacity challenges.

Third, commenter (2433-EDF et al) states that routine flaring from existing wells is also avoidable or preventable.<sup>80</sup> In the event an existing well is not currently connected to a gathering line, cost-effective options in addition to routing to a gathering line are available, including converting the associated gas to compressed natural gas (CNG), using it to replace a different fuel source for onsite fuel purposes, converting the gas to electricity, or injection or reinjection.<sup>81</sup> The commenter notes that prudent operators are prepared for events that can result in loss of takeaway capacity such as midstream and downstream interruptions, changes in gas composition requirements, and changes in line pressure.<sup>82</sup> The commenter contends that such operators can quickly employ one of the alternative abatement options EPA proposes.<sup>83</sup>

Commenter (2433-EDF et al) suggests that in the event an operator loses its connection to a gathering line without warning due to events outside its control, a limited exception for flaring during the upset condition can address an operator's need to flare temporarily (discussed further below).<sup>84</sup> Operators can also temporarily shut in wells if time is needed to restore access to a pipeline or make arrangements for alternative gas recovery. The commenter states that shutting in wells does not necessarily harm the productivity of a well and may, in some instances, enhance performance.<sup>85</sup> Additionally, the commenter notes that the CAA section 111(d) implementation process as proposed gives operators of existing wells significant time (i.e., approximately four-and-a-half years after rule finalization) to implement one of the four approved alternative uses for associated gas. In those rare instances when an operator of an existing well is unable to capture, put to beneficial use, or inject or reinject associated gas after this lengthy runway due to truly unique and extenuating circumstances, it may request a variance in a state plan pursuant to the remaining useful life and other factors (RULOF) provisions.

Fourth, commenter (2433-EDF et al) believes the exemption presents enforcement challenges. While an operator's demonstration of technical infeasibility must be signed and certified as to its truth, accuracy, and completeness, the commenter provides that there is no requirement that EPA review and approve this demonstration prior to an operator flaring. Rather, operators must retain records of the certified demonstration and provide it to EPA as part of annual reporting. This

---

<sup>80</sup> Expert Report of Thomas Alexander, *supra* note 435, at 4.

<sup>81</sup> 2022 Joint Environmental Comments, *supra* note 1, at 187; Expert Report of Thomas Alexander, *supra* note 435, at 4.

<sup>82</sup> Expert Report of Thomas Alexander, *supra* note 435, at 4.

<sup>83</sup> *Id.*

<sup>84</sup> *Id.* at 4-5.

<sup>85</sup> *Id.* at 3.

raises the possibility that flaring will occur in the absence of a full, accurate, complete, or otherwise adequate demonstration.<sup>86</sup> In order for EPA to identify any problems or shortcomings in the certified demonstration, it must review the operator's documentation, but this review will necessarily occur after an operator has flared, potentially for a considerable amount of time. The commenter states that this opens the door to extended periods of flaring in violation of the rules.

Response II-6-32: See Responses II-6-10 and II-6-21 of this Chapter. EPA disagrees that it is necessary for EPA to review each demonstration by a facility that BSER and the alternatives are infeasible, and therefore the sources must flare associated gas. EPA has delegated authority to permitting agencies that have capacity to oversee sources in their jurisdiction.

Comment: Commenter (2410-CA AG et al) urges EPA to adopt NSPS and EG that effectively prohibit routine flaring of associated gas from new and existing oil wells, with the only exceptions related to safety and emergencies, by requiring owners or operators to capture all or most of the gas. Flaring is a major source of emissions of many harmful air pollutants. When functioning properly, flares emit large amounts of CO<sub>2</sub> and nitrogen oxides (NO<sub>x</sub>). When malfunctioning, which is common, they emit substantial amounts of methane, VOC, and hazardous air pollutants (HAP) directly into the atmosphere.<sup>87</sup> The commenter recommends that EPA should follow the states' (noted CA and NM state requirements) lead and prohibit routine flaring of associated gas from new and existing oil wells except in very limited cases such as emergencies and for safety reasons. If EPA continues to allow flaring of associated gas for technical feasibility reasons, the commenter contends that EPA should also take steps to disallow the indefinite continuation of routine flaring. The commenter believes that it would be appropriate to limit the allowable time for flaring to 12 months. If after 12 months an owner or operator does not connect its facility to a gathering line or otherwise put gas to beneficial use, EPA should require the operator to shut in a well until it is connected to a gathering line, or the gas is put to beneficial use.

At a minimum, the commenter (2410-CA AG et al) requests EPA further strengthen flaring restrictions to ensure that the need to flare is well-documented, continues to be necessary, and does not become routine. The commenter asserts that the EPA should require more frequent certifications than annual reports to demonstrate why all potential beneficial uses, including emerging techniques, are not feasible due to technical or safety reasons. When there is any change in circumstances, they add that owners and operators should be required to perform a more thorough analysis and engineering certification comparable to the initial certification required once an owner or operator becomes subject to the rule. For instance, the commenter agrees, as EPA suggests, that it would be appropriate to require an owner or operator to provide an additional engineering certification that flaring is the only option where a new gathering pipeline is installed within a certain distance of an oil well.

---

<sup>86</sup> Expert Report of Thomas Alexander, *supra* note 435, at 6-7.

<sup>87</sup> See, e.g., Environmental Defense Fund, Permian Methane Analysis Project, available at <https://data.permianmap.org/pages/flaring> (finding in seven random surveys of routine-flaring sites, flare malfunctions ranged from 3.3 percent to 11.5 percent and when expanded to all well sites, including lower-production wells, flare malfunctions jumped from 29 percent to 36 percent).

Response II-6-33: See Responses II-6-10 and II-6-21 of this Chapter.

Comment: Commenter (2392-Earthjustice et al) strongly supports EPA's proposed requirement that owners and operators of oil wells with associated gas must capture that gas and route it to a sales line. However, they believe that the EPA can and should take further steps to eliminate routine flaring. They assert that the EPA should replace the broad technical infeasibility exception that would allow operators to continue routinely flaring with narrowly defined exemptions applicable only to short-term and temporary flaring. Alternatively, they add that EPA should revise and strengthen the certified technical infeasibility demonstration by requiring independent third parties to conduct the demonstration and requiring additional documentation to prove that no other gas recovery options are available.

Commenter (2392-Earthjustice et al) states that enacting these recommended improvements will reduce rates of routine flaring that disproportionately impact tribal communities, like those of the Fort Berthold Reservation in North Dakota, as well as Black and Latine communities. The commenter contends that action to significantly reduce dangerous air emissions from these sources will result in major air quality and health benefits for the communities of color living near these sources.

Response II-6-34: See Responses II-6-10 and II-6-21 of this Chapter. EPA disagrees that it is necessary for a third party to verify an analysis showing that BSER and the alternatives are infeasible. The operator is ultimately responsible for a credible study of feasibility and has the option to enlist a third party or use personnel from their organization qualified to determine the feasibility of BSER or the alternatives. The demonstrations of feasibility will be subject to review by state permitting agencies with the requisite expertise to review the demonstrations to determine their credibility.

Comment: Commenter (2365-Climate Action California) argues that oil companies should be required to work out arrangements with pipeline companies/contractors and gas processing plants to ensure that their associated gas can be transported away and sold. They add that being able to flare this excess gas should not be an option.

The commenter (2365-Climate Action California)) explains that most routine flaring occurs at oil wells that are unable to pipe their associated gas to a sales line, either because they are 1) not connected to a natural gas gathering pipeline, or 2) the local pipeline or the downstream processing plant has insufficient capacity to collect or use its gas, or 3) the gathering pipeline is experiencing maintenance problems. In other words, the flaring problem is created by a lack of off-site infrastructure. How can the EPA's final rule contribute to solving this problem? They suggest the following:

- A start would be to require that all oil well applications for a permit to drill (APDs) include a waste minimization plan indicating how the owner plans to minimize the need for venting and flaring associated gas. Plans indicating how a well will be connected to a gathering pipeline should be a condition of receiving approval if other nearby, worthwhile uses for the gas are not feasible.

- If the waste minimization plan will not prevent most flaring, the EPA should have the authority to delay approval until all associated gas can be used on site or removed for some productive use.
- If the gathering lines are already operating at capacity, the applicant could apply for approval for construction of a new gathering line. If the downstream processing plant is at capacity application approval should be delayed until more capacity comes on line.
- The commenter recommends that flaring of associated gas beyond a certain minimum level be disallowed, and hence subject to financial penalties. Since the EPA has chosen not to ban routine flaring, it must make it expensive. Penalties or fines should be large enough to push oil producers to work out infrastructure solutions. Oil companies will only devote time to solving their infrastructure problem if it is costly not to do so.

Commenter (2365-Climate Action California) refers EPA to the Bureau of Land Management (BLM) Proposed Rule on Waste Prevention, Production Subject to Royalties and Resource Conservation published on November 30, 2022. Section 3162.3-1 covers Drilling Applications and Plans and Section 3179.8 covers Oil-Well Gas.

Commenter (2365-Climate Action California) states that most of the flaring from BLM-managed oil and gas leases occurs at oil wells that are connected to a gas pipeline with insufficient takeaway capacity for the well(s) connected to the pipeline. The commenter explains that when the gas pipeline associated with an oil well becomes overwhelmed, the well is “kicked off” the pipeline and the operator is faced with a choice: flare the associated gas to continue oil production unabated or curtail oil production in order to conserve the associated gas.” While the royalty rate of 16.67 percent may not result in producers temporarily halting production, they note that, it at least provides an incentive to reduce flaring.

Commenter (2365-Climate Action California) states that the BLM proposal exempts the following emissions from royalties: emergency venting or flaring for up to 48 hours, gas used or consumed within a lease area and gas “unavoidably lost”. This last category includes well completions, production testing and downhole well maintenance. Neither the emergency nor the unavoidably lost category includes recurring equipment failures, inadequate equipment capacity, failure to limit production when it exceeds capacity of equipment, pipeline, or gas plant to handle—or exceeds sales contract volumes, scheduled maintenance, or operator negligence. (Section 3179.105)

- The BLM proposal requires that all applications for an oil well drilling permit (APDs) include a waste minimization plan (Section 3162.3-1(j)). “The waste minimization plan would need to demonstrate how the operator plans to capture associated gas upon the start of oil production, or as soon thereafter as reasonably possible, including an explanation of why any delay in the capture of the associated gas would be necessary.” This rule will enable the BLM to determine the likely amount of flaring should the drilling permit be issued. The BLM can defer action on the permit application by informing the applicant what additional steps must be taken to reduce the likelihood of flaring (Section 3162.3-1(k)).
- The BLM proposal sets a royalty-free flaring limit of 1050 thousand cubic feet (Mcf) per month per lease, flaring above this limit would be subject to a 16.66 percent royalty rate.

(Section 3179.8(a)) The BLM estimates that this flaring limit would make approximately 85 percent of flared volumes royalty-bearing. The BLM proposal also gives the BLM authority to curtail production of oil if flaring gas exceeds 4000 Mcf per month for 3 consecutive months. (Section 3179.8 paragraphs (b) and (c)).

- The BLM's proposed rule includes the authority to fine a producer \$1000 immediately on discovery that a flare is not lit. (Section 3179.6(b)) EPA should have similar authority.

Commenter (2365-Climate Action California) continues by stating that an EPA requirement that oil drilling permit applications include a plan to minimize venting or flaring associated gas should bring with it the agency's authority to delay permit approval until further steps are taken to reduce the need for routine flaring. If a lack of pipeline capacity occurs for a producing oil well and the owner does not want to temporarily curtail production, EPA would be able to impose time and volume limits on gas flaring and fine producers at the same rate the BLM is proposing. The commenter contends that, since the EPA chose not to ban routine flaring and venting, it needs to make flaring and venting more costly for producers.

A recent EDF study of gathering line methane emissions in the Texan Permian Basin<sup>88</sup> estimated them to be 14 times the EPA national inventory estimate. Fortunately, gas gathering pipelines came under federal oversight in November 2021. The Department of Transportation's Pipeline and Hazardous Materials Safety Administration (PHMSA) should now be receiving annual reports on all safety incidents. Commenter (2365-Climate Action California) recommends that the EPA work with PHMSA to determine how maintenance on existing gathering pipelines can be improved to reduce pipeline shutdowns and methane emissions, and how insufficient capacity in gathering pipelines can be corrected. The commenter further recommends that the EPA strategize with the Department of Energy (DOE) to determine how offsite infrastructure improvements can reduce the need to flare, especially in the Permian Basin.

Response II-6-35: See Responses II-6-10 and II-6-21 of this Chapter. It is beyond the scope of the NSPS to address safety concerns under the jurisdiction of PHMSA, or to address gathering capacity directly. To the commenter's suggestion that EPA collaborate with the DOE, the commenter does not specify which offsite infrastructure that EPA should collaborate on.

Comment: Commenter (2453-Carbon Mapper-RMI) states that under the supplemental proposal, EPA is proposing to require operators and owners to prioritize alternative beneficial reuse options for associated gas from oil wells utilizing a hierarchy of standard control options, and all options must be exhausted prior to resorting to flaring at a site via requesting a variance. The first demonstration and request for variance would require certification by a professional engineer or approved equivalent, and subsequent reports would require simply reporting whether circumstances have changed regarding the need to flare. The commenter notes that the EPA also seeks comment on details and triggers required to continue and/or re-analyze granted variances.

As the impetus for the rule is prevention of the indefinite use of flaring, the commenter (2453-Carbon Mapper-RMI) supports that flaring variances last for a finite period and/or volume (whichever is reached first). New usable sales pipelines or other infrastructure, feasible delivery

---

<sup>88</sup> <https://blogs.edf.org/energyexchange/2022/10/04/research-shows-gathering-pipelines-in-the-permian-basin-leaking-14-times-more-methane-than-officials-estimate/>.

points for compressed gas, technology, or discoveries in additional beneficial uses may present themselves as available later in the asset's life. As proposed in the rule, the commenter also supports that such triggers (variance age, volume flared, or new developments/innovations) should trigger a new, full, and certified review similar to original variance requests.

Commenter (2453-Carbon Mapper-RMI) adds that they support EPA requiring operators to attempt to access an existing sales line, the preferred standard control option, and facilitate alternative off-site transport and use of associated gas. Furthermore, since sites operate for decades and sales lines are typically not under the control of the well owners and operators, the commenter recommends that operators include an attempt to collaborate with gathering system owners regarding both upcoming or proposed sales line projects and production projects, as this may inform and optimize sales lines route engineering. If enough operators collaborate with gathering system owners, gathering system owners may respond to the demonstrated need of sales pipelines in unserved/underserved areas. Otherwise, they note that pipelines may not be developed due to a lack of discussion and identification of opportunity.

The commenter (2453-Carbon Mapper-RMI) states that the supplemental proposal and the existing regulations do not contain provisions to directly validate or verify destruction efficiency unless a flare is detected as part of the Super-Emitter Response Program. The commenter recommends that EPA remain abreast of studies and data available that would indicate improvements in flare performance based on requirements. Furthermore, they add that the supplemental proposal requires use and performance monitoring of a pilot flame used for flaring at all times, "unless a demonstration has been made that the [net heating value] NHV of the inlet gas to the flare consistently exceeds the operating limit established in the rule." The commenter believes, similar to the above discussion regarding flaring variances, that this demonstration should be subject to a time- and/or volume-based limitation and should require re-submittals to ensure that original conditions granting such an exception persist.

Response II-6-36: See the response to II-6-10 and II-6-21. Regarding flare requirements, the commenter is incorrect that a pilot flame must be monitored unless a demonstration is made that the NHV of the inlet gas is consistently above the required limit. The December 2022 Supplemental Proposal required flare pilot flames to be monitored at all times. In the final rule, we have augmented this monitoring by requiring an alert to the control room whenever the pilot flame is not lit. Additionally, in the final rule we have added a requirement that the pilot flame does not need to be monitored if the owner or operator is approved for an alternative test method that continuously monitors the combustion efficiency of the flare. Regarding the inlet gas NHV demonstration that can be used in lieu of continuously monitoring the NHV of the inlet gas to the flare, in the final rule we have added an ongoing five-year sampling requirement to ensure the inlet gas NHV remains sufficiently high. These requirements are discussed in more detail in Sections X.H and XI.H of the preamble to the final rule.

Comment: Commenter (2408-CO-LGC) reiterates the comments they previously submitted to EPA on its initial proposal which called for a nation-wide ban on the wasteful and unnecessary practice of routine flaring. By routine flaring the commenter means ongoing, continuous flaring in the absence of a method for capturing and selling, putting to beneficial use, or storing

associated gas.<sup>89</sup> The commenter points out that leading state examples and the commitments made by multiple operators demonstrate eliminating routine flaring is feasible and cost effective.

As the commenter (2408-CO-LGC) contends that their prior comments made clear, Colorado and New Mexico have largely banned this pernicious practice and the commenter urges EPA to do the same. Colorado's rule provides: "[V]enting and Flaring of natural gas represent waste of an important energy resource and pose safety and environmental risks. Venting and Flaring, except as specifically allowed in this Rule 903, are prohibited."<sup>90</sup> Similarly, New Mexico's rule provides: "[V]enting or flaring of natural gas during drilling, completion, or production operations that constitutes waste as defined in 19.15.2 NMAC is prohibited. The operator has a general duty to maximize the recovery of natural gas by minimizing the waste of natural gas through venting and flaring. During drilling, completion and production operations, the operator may vent or flare natural gas only as authorized [through specific regulations]."<sup>91</sup> The commenter adds that Alaska has also largely banned this practice, allowing operators to flare only during specific, narrowly conditioned exceptions.<sup>92</sup>

Commenter (2408-CO-LGC) also notes that that numerous operators have committed to eliminate routine flaring as part of the World Bank's Zero Routine Flaring by 2030 Initiative. To date, 54 oil companies and 34 governments have endorsed the "Zero Routine Flaring by 2030" Initiative. Based on satellite estimates and publicly reported flaring data, together the endorsers represent around 60 percent of global flaring.<sup>93</sup> The commenter adds that Exxon Mobil recently announced a commitment to end routine flaring while also expressing support for regulations banning this wasteful practice.<sup>94</sup>

Commenter (2408-CO-LGC) urges EPA to revise its proposal to prohibit routine flaring by requiring operators use one of the four gas recovery abatement methods included in EPA's proposal. They suggest that EPA allow for flaring only during explicit, narrowly tailored, and time-limited, exemptions. They believe that, by doing so, it would more clearly and unequivocally prohibit pollution stemming from routine flaring, as well as enhance the enforceability of the rule.

Specifically, commenter (2408-CO-LGC) urges EPA to abandon the broad, unclear technical infeasibility exemption and instead delineate those instances in the rule where temporary flaring is allowed, subject to reasonable, limitations. According to the commenter, doing so is consistent with the approach in Colorado and New Mexico.

<sup>94</sup> Reuters, Exxon Halts Routine Gas Flaring in The Permian, Wants Others to Follow (Jan. 24, 2023), <https://www.nasdaq.com/articles/exclusive-exxon-halts-routine-gas-flaring-in-the-permian-wants-others-to-follow>

The commenter (2408-CO-LGC) explains that, during an upset condition operators may need to flare or vent for a limited period. Notably, upset conditions are conditions outside of the control of an operator that can interrupt the ability of the operator to comply with the proposed standard. An example of an upset condition is temporary loss of connection to, or ability to route gas to, a gathering system. EPA has determined that interruptions of an operator's ability to route gas to a gathering system constitute a technical or safety reason that can justify flaring and is taking comment on requirements to address this circumstance.<sup>95</sup> The commenter agrees that interruptions to an operator's connection to a gathering system can result in the need for operators to flare on a temporary basis. However, they believe that routine flaring is avoidable and should not be permitted during these circumstances.

Commenter (2408-CO-LGC) provides that both Colorado and New Mexico allow operators to flare or vent gas for a short period of time during upset conditions or emergencies which include temporary unavailability of access to a gathering line. They explain that the Colorado rules provide a concise, clear definition of upset condition combined with a limit on the amount of time an operator may flare or vent during such circumstances. Colorado allows operators to vent or flare for up to 24 cumulative hours during an upset condition while New Mexico allows operators to vent or flare for up to 8 hours during an emergency. Loss of a connection to a pipeline qualifies as an upset condition under the Colorado rules and an emergency under the New Mexico rules.

The commenter (2408-CO-LGC) continues to explain that Colorado's definition of an Upset Condition is "a sudden unavoidable failure, breakdown, event, or malfunction, beyond the reasonable control of the Operator, of any equipment or process that results in abnormal operations and requires correction." This definition does not include "an operator's negligence, failure to install appropriate equipment, or failure to perform scheduled maintenance."<sup>96</sup> Colorado limits venting and flaring to a period necessary to address the upset, not to exceed 24 cumulative hours and requires operators maintain records of the date, cause, estimated volume of gas flared or vented, and duration of each upset condition.<sup>97</sup> This definition includes "sudden unplanned lack of pipeline capacity."<sup>98</sup> Accordingly, Colorado allows operators to vent or flare associated gas in the event that disruptions to a gathering system interrupt the ability of an operator to route associated gas to a sales line, but only up to 24 cumulative hours.<sup>99</sup>

<sup>95</sup> 87 Fed. Reg. at 74,780.

<sup>96</sup> COGCC SBP, 800/900/1200 Rule Series, p.76, available at <https://drive.google.com/drive/u/0/folders/1kTZUgXmhVpOy4gEZ2tSOYVDDvYXupzvA>.

<sup>97</sup> 2 Colo. Code Regs. § 404-1-903(d)(1)(A).

<sup>98</sup> COGCC SBP, 800/900/1200 Rule Series, p.76.

<sup>99</sup> Colorado also allows operators to request approval to flare for a longer period, up to 12 months, in the event of loss of access to a gathering line due to unforeseen circumstances outside of the operator's control. An operator may only request approval once, however. To avail itself of this option, an operator must request permission to flare within 30 days of loss of access to a gathering line and cannot flare unless approval is granted. This request must be accompanied by detailed information demonstrating why the well cannot be connected to infrastructure, when the well will be connected to infrastructure, options for using the gas, including to generate electricity, gas processing to recover natural gas liquids, or other options for using the gas, an estimate of the volume and content of the gas to be flared and a gas analysis. 2 Colo. Code Regs. § 404-1-903.d.(3).

The commenter (2408-CO-LGC) adds that New Mexico similarly allows for temporary venting or flaring during an emergency. An emergency means “a temporary, infrequent, and unavoidable event in which the loss of natural gas is uncontrollable or necessary to avoid a risk of an immediate and substantial adverse impact on safety, public health, or the environment” other than in certain exceptions. One such exception is “venting or flaring of natural gas for more than eight hours after notification that is caused by an emergency, an unscheduled maintenance, or a malfunction of a natural gas gathering system.”<sup>100</sup> In other words, they explain that an upstream operator may vent or flare during a temporary, infrequent, and unavoidable event involving loss of connection to a sales line provided the midstream operator notifies the producer of the disruption to the operator of the sales line. However, an upstream operator cannot vent longer than 8 hours in this circumstance.<sup>101</sup> The commenter recognizes that there may be instances when an operator loses connection to a sales line for reasons other than during an emergency of upset condition, such as where the midstream operator ceases to operate the gathering line or where the demand for the gathering line exceeds its capacity. The commenter does not believe flaring or venting should be permitted in these circumstances. These are foreseeable risks that prudent operators can and should plan for. As discussed above, prudent operators should have equipment in place to utilize associated gas for other beneficial purposes (e.g., compression for conversion of natural gas to CNG) in the event of a loss of takeaway capacity. New Mexico does not allow operators to vent or flare during non-emergency losses of takeaway capacity.<sup>102</sup> An operator’s failure to limit production when the production rate exceeds the capacity of the related equipment or natural gas gathering system, or exceeds the sales contract volume of the natural gas, do not constitute emergencies during which an operator may vent or flare.<sup>103</sup> Colorado contains a limited exception that allows operators to request permission to flare in the event of loss of connection to a sales line, but this exception is only available once to an operator, and to qualify for it an operator must demonstrate there are no alternative options available to recover the gas.<sup>104</sup> The commenter states that they do not believe such an exception is warranted with proper planning.

The commenter (2408-CO-LGC) recommends EPA limit flaring (or venting) during an upset condition not to exceed 24 cumulative hours per R.903.d.(1)(A). This would apply in those instances where a disruption to a gathering system or other event causes an interruption to an operator’s ability to route the gas to a sales line.

Specifically, commenter (2408-CO-LGC) urges EPA to abandon the broad, unclear technical infeasibility exemption and instead delineate those instances in the rule where temporary flaring is allowed, subject to reasonable, limitations. The commenter notes that doing so is consistent with the approach in Colorado and New Mexico.

Commenter (2408-CO-LGC) Another circumstance that may give rise to an operator’s need to vent or flare on a temporary basis is during the commissioning of pipelines, equipment, or facilities. New Mexico allows operators to vent or flare temporarily during pipeline equipment or

---

<sup>100</sup> N.M. Code R. §19.15.27.7.H.

<sup>101</sup> Id. at § 19.15.27.7.H.(4).

<sup>102</sup> Id. at § 19.15.27.7.H.(4).

<sup>103</sup> Id.

<sup>104</sup> 2 Colo. Code Regs. § 404-1-903.d.(3).

facilities commissioning.<sup>105</sup> New Mexico limits waste during this activity to “only for as long as necessary to purge introduced impurities.”<sup>106</sup> When starting up operation of new equipment, there is often water (used to hydro test) or solids (from stimulation flowback) that need to be purged from the equipment or pipeline. This can only be done by releasing this gas with untreatable impurities to atmospheric tanks which allows for the small volumes of gas to also be released until a stable hydrocarbon stream is achieved. While New Mexico does not limit the amount of time an operator may need to vent or flare during this exception, operators have an incentive to limit venting or flaring to a minimum as the sooner they connect the well to a gathering line, the sooner they are able to route the gas to sales.

In addition, the commenter (2408-CO-LGC) provides that operators may also need to flare temporarily where an operator is connected to a sales line, but natural gas does not meet pipeline specifications, and where the other three compliance options are also unavailable.<sup>107</sup> This occurs where impurities such as nitrogen are present in the associated gas and thus the gas cannot safely be sent to the sales line. New Mexico requires the operator take specific steps to limit flaring during this circumstance as follows:

Operators must analyze gas samples twice a week to determine if pipeline specifications have been achieved; must route gas into gathering pipelines when pipeline specifications are met and must provide pipeline specs and NG analyses to division upon request.<sup>108</sup>

The commenter (2408-CO-LGC) notes that New Mexico does not include a specific time-limit for this exemption. However, per the example above, operators have a profit incentive to limit flaring or venting.

The commenter (2408-CO-LGC) provides that another exemption provided is during active or required maintenance. Both Colorado and New Mexico allow for temporary venting and flaring during maintenance activities. Colorado specifies that maintenance must be active and required “to clarify that while venting can be permitted while the maintenance activity is ongoing (for example, while personnel are on-site and performing the maintenance), venting during periods between discovery of the need for maintenance and the performance of the maintenance remains prohibited.”<sup>109</sup> Colorado requires operators use best management practices to minimize venting during maintenance and repair activity. New Mexico similarly allows venting or flaring during repair and maintenance, including blowing down and depressurizing production equipment to perform repair and maintenance.<sup>110</sup> The commenter recommends that EPA allow flaring and venting during active and required maintenance activities, provided not otherwise prohibited by EPA or state rules.

Commenter (2408-CO-LGC) states that Colorado and New Mexico also allow for temporary flaring during production tests and production evaluations. Colorado defines a production test to

<sup>110</sup> N.M. Code R. § 19.15.27.8.

mean “a test for determination of a reservoir’s ability to produce economic quantities of oil or gas.”<sup>111</sup> Colorado defines a production evaluation as “an evaluation of production potential for determination of requirements for infrastructure capacity and equipment sizing.”<sup>112</sup> Colorado allows venting or flaring during both events, but only subject to pre-approval from the Director. If the operator has obtained approval, the rules permit venting or flaring up to a period not to exceed 60 days.<sup>113</sup> New Mexico limits venting or flaring during a production test for a period not to exceed 24 hours absent approval for a longer test period.<sup>114</sup> The commenter recommends that EPA allow venting or flaring during this exception yet limit the duration of 24 hours as Colorado has done.

Commenter (2408-CO-LGC) adds that limited venting or flaring may also occur when operators conduct monitoring activities to inspect downhole well integrity. Colorado and New Mexico allow operators to vent or flare during bradenhead monitoring.<sup>115</sup> Per the Statement of Basis and Purpose for Colorado’s rule, bradenhead monitoring activities should be limited to 30 minutes.<sup>116</sup> New Mexico allows operators to conduct packer leakage tests, which is another form of downhole monitoring.<sup>117</sup> In both instances, the commenter suggests that venting and flaring be limited to 30 minutes.

Response II-6-37: See section XI.F.2 of the final rule preamble for a comprehensive discussion of EPA’s BSER determination for the final rule.

Comment: Commenter (2452-Hess, 3843-Hess) recommends that EPA should align any requirements relating to routine flaring of associated gas with the World Bank’s zero routine flaring initiative by using consistent definitions and concepts. EPA has noted that it “is taking comment on steps the Agency should consider taking to disallow the indefinite continuation of routine flaring.” The commenter agrees with EPA that flaring during production operations should be minimized. The commenter recently endorsed the World Bank’s “Zero Routine Flaring by 2030” initiative and has set a target to eliminate routine gas flaring (consistent with the World Bank’s definitions) at all our operated production sites by the end of 2025, five years ahead of the World Bank’s commitment date. To support the achievement of this objective, the commenter continues to focus on the buildout of gas infrastructure in the Bakken and consider additional flare reduction initiatives globally. However, the commenter is concerned that the associated gas requirements in the Supplemental Proposal unnecessarily restrict innovative, cost-effective, and performance-based approaches to emissions reductions and create regulatory uncertainty.

Commenter (2452-Hess) believes that flaring of associated gas should be defined and regulated in a way that is consistent with the World Bank’s “Zero Flaring by 2030” initiative, which defines routine flaring as “flaring that occurs during the normal production of oil, and in the

<sup>112</sup> 2 Colo. Code Regs. § 404-1-100-14.

<sup>113</sup> 2 Colo. Code Regs. § 404-1-903.d.(1)(C).

<sup>114</sup> N.M. Code R. § 19.15.27.8.D.(4)(k).

<sup>115</sup> N.M. Code R. § 19.15.27.8.D.(4)(i).

<sup>116</sup> COGCC SBP, 800/900/1200 Rule Series, p.86.

<sup>117</sup> N.M. Code R. § 19.15.27.8.D.(4)(j).

absence of sufficient facilities to utilize the gas onsite, dispatch it to a market or reinject it.”<sup>118</sup> The World Bank approach acknowledges that the appropriate time to restrict flaring is after the well begins normal production. Gas capture needs during initial production operations can vary significantly depending on well-specific conditions, which may require flaring. In contrast, they note that once a facility has reached a state of normal production, gas capture needs are more predictable, and operators can better avoid flaring scenarios. As currently written, the restrictions on associated gas in the Supplemental Proposal apply throughout production operations, without any consideration of the different circumstances that may necessitate flaring. According to the commenter, this lack of distinction is inconsistent with the commonsense approach adopted by the World Bank and ignores practical considerations on-site. The commenter asserts that the EPA should not apply a single approach to the treatment of associated gas during the entirety of production operations.

Further, commenter (2452-Hess) points out that EPA’s proposed language allows flaring for “technical or safety reasons,” but does not provide operators with an understanding of what types of activities may qualify. In contrast, the World Bank’s proposal expressly acknowledges on-site realities and excludes safety flaring and non-routine flaring. As the World Bank notes in its FAQ, “safety flaring is both small in volume and essential for the safe operation of oil and gas production facilities. Non-routine flaring is often unforeseen in nature. For example, the commenter explains that it could be due to issues with the operation of the facility, and as such is hard to mitigate.”<sup>119</sup> Examples of safety flaring include blow downs to prevent overpressure, pilot flame gas, purge/fuel gas, gas containing H<sub>2</sub>S, and gas with high levels of volatile organic compounds (VOC) other than methane.<sup>120</sup> The commenter adds that non-routine flaring is typically intermittent and of short duration. It can include activities like temporary failure of equipment, failure of customer facilities that prevents receipt of gas, startup and shutdown activities, maintenance activities, process upsets, construction activities and facility modifications, and well testing, among other things.<sup>121</sup> The World Bank’s express exclusions for safety and non-routine activities better reflect operational constraints and provide more guidance to operators than EPA’s undefined “technical or safety reasons” throughout the Supplemental Proposal.

In addition, commenter (2452-Hess) states that while EPA’s preamble suggests an intent to view these stages separately, the plain language of 40 CFR 60.5377b applies to “each oil well with associated gas at a well affected facility.” Absent a clear distinction, the commenter suggests that this appears to conflict with the well completion obligations at proposed 40 CFR 60.5375b, which establish different requirements for flaring. Different regulatory and operational considerations apply during flowback. To avoid confusion in implementation, the commenter requests that EPA clarify that the requirements of 40 CFR 60.5377b only apply during

<sup>118</sup> See Global Gas Flaring Reduction Partnership Gas Flaring Definitions (June 29, 2016), available at World Bank Document.

<sup>119</sup> See World Bank, Zero Routine Flaring by 2030 (ZRF) Initiative Frequently Asked Questions and Answers, available at <https://www.worldbank.org/en/programs/zero-routine-flaring-by-2030/qna#37>.

<sup>120</sup> See Global Gas Flaring Reduction Partnership, Gas Flaring Definitions (June 29, 2016), available at World Bank Document.

<sup>121</sup> Id.

production operations and do not apply during the well completion operations covered by 40 CFR 60.5375b.

While the commenter (2452-Hess) states they are committed to reducing routine flaring, they believe that EPA should align its regulations with the World Bank's initiative, rather than what is currently proposed. They state that this approach is consistent with the U.S existing endorsement of the World Bank initiative and commitment to "provide a legal, regulatory, investment and operating environment that is conducive to upstream investments and to the development of viable markets for utilization of the gas and the infrastructure necessary to deliver the gas to these markets."<sup>122</sup> According to the commenter, adopting the World Bank's proposed definition of routine flaring is a logical next step in support of this commitment. They add that it would also reduce the concerns discussed above and would encourage operators to continue to pursue voluntary emissions reduction initiatives, such as the World Bank's Zero Routine Flaring Initiative.

Commenter (3843-Hess) reports that many companies are already committed to that effort, as is the U.S. government.

Response II-6-38: See Responses II-6-10 and II-6-21 of this Chapter. EPA carefully reviewed and considered The World Bank initiative information. Much of the final rule is consistent with the World Bank approach.

Comment: Commenters (1646-Commission Shift (CS), 2329-LSC-Sierra Club, 2352-Environment Texas Research and Policy Center (ETRPC) express concerns with oversight of oil and gas operations. Commenter (1646-CS) is concerned with a lack of transparency within the organization and believes the RRC has allowed oil and gas companies to disregard venting and flaring limits and well plugging requirements, to the detriment of health and safety. The commenter believes that the elected officials at the RRC have no reason to listen to the commenter's most vulnerable community members, stating that oil and gas companies have far too much influence over the agency.

Commenter (2352-ETRPC) states that over the last five years, the RRC has granted operators an average of about 4,800 flaring permits annually. In 2021, the commenter states that 68 billion cubic feet of gas were flared. The commenter cites to an interview with an oil and gas attorney, where concern was raised about state oversight, and concludes that EPA must use its federal authority to ensure enforcement. Further, the commenter wants to ensure that operators at wells capture gas and limit flaring to when it is necessary for safety or maintenance reasons. Commenter (1646-CS) requests EPA to finalize a strong methane rule without delay to ensure strong federal methane standards to protect health and slow climate change.

Commenter (2329-LSC-Sierra Club) states while Texas' laws limit flaring and venting, the commenter believes the regulations are filled with loopholes, and the RRC routinely grants exceptions to the limitations. Between FY 2009 and FY 2020, the commenter explains that more than 27,000 exceptions were granted to allow oil and gas operations to flare. The commenter

---

<sup>122</sup> See World Bank, Zero Routine Flaring by 2030 Initiative Text, available at <https://www.worldbank.org/en/programs/zero-routine-flaring-by-2030/initiative-text>.

states it is important to note that under Texas laws, venting is allowed during the first 10 days of drilling oil and gas wells and have dozens of other exceptions in the Natural Resource Code. The commenter notes there have been some improvement in the last few years because of community pressure, including enhanced review and publishing the flaring exceptions online. Still, even with more attention, the commenter reports that between January 1, 2022, to January 1, 2023, about 3,700 exceptions were granted, with millions of pounds of methane being released into the atmosphere, explains the commenter.

Commenter (2502-Rio Grande International Study Center (RGISC)) states that while the RRC reports that the percentage of natural gas flared compared to the natural gas produced from oil and gas wells in Texas dropped from 2.28 percent to 0.65 percent in May 2021; the flaring data is coming from self-reporting operators, who the commenter believes traditionally do not operate in good faith. Regarding self-reporting, the commenter believes this also leads to the underreporting of emissions events and other malfunctions regulated by the Texas Commission of Environmental Quality (TCEQ). The commenter cites to a 2021 TCEQ annual enforcement report, where 5,362 incidents were reported as “excess emissions events,” but the reports shows that TCEQ issued findings in only 16 percent of those cases, and of those, it ordered corrective measures in only 19.

Commenter (2236-Physicians for Social Responsibility Pennsylvania (PSR-PA)) expresses similar concerns about self-reporting and enforcement. The commenter states that intentional gas flaring and venting in addition to accidental leaks are dangerous for communities as well as the climate. The commenter believes that existing regulations are not adequate and expresses concern with self-reporting and proper oversight and enforcement. The commenter suggests that EPA strengthen the rules and urges EPA to address permit violations.

Response II-6-39: EPA notes the concerns of the commenters related to the Texas RRC program. EPA has no jurisdiction over these regulations or their enforcement. Further, while the requirements of the final federal standards and presumptive standards may be incorporated into permits, violations of air quality or other types of permits are not under the statutory authority of these regulations.

However, the final NSPS OOOOb and EG OOOOc include rigorous compliance provisions, including monitoring, recordkeeping, and reporting, that will hold owners and operators accountable to ensure that the applicable requirements are met.

#### 6.2.4.3 Technical Infeasibility Exemption and Determination Requirements

Comment: Commenters (2028-Westmoreland Group (WMCG, 2039-Citizens to Preserve Ligonier Valley, Inc. (CPLV)) requests that EPA provide clarity on when it is technically feasible to flare due to lack of gathering lines-- how the agency will evaluate and approve/deny venting and flaring applications from operators, including what role states will have.

Response II-6-40: EPA cannot predict every possible reason that an alternative to BSER would be infeasible. For this reason EPA has required that qualified technical personnel certify any final determination because the factors may be site-specific, specific to the alternatives being

evaluated, and require detailed knowledge of the site location. The alternatives that EPA has offered are broad categories of non-emitting alternatives or activities that emit equivalent to BSER. Each of the options could have their own unique factor of infeasibility. A site may be unable to reinject the gas because the geology of the site may not be suitable for permanent reinjection. A site may not be able to access or construct a gathering line because it is surrounded or within jurisdictions where right of way will not be granted because of land use restrictions, historic preservation restrictions, or laws and ordinances to protect cultural resources.<sup>123</sup> A site may not be able to capture and convert the gas to compressed or liquid natural gas because the site itself is an existing facility and may not have physical space appropriate or sufficient to construct and operate such an operation, or may be so remote as to make regular or all-season truck traffic infeasible on access roads. While each of these factors could make an option infeasible, none of the examples we have provided likely apply to all of the alternatives. Where one alternative may be infeasible, two other alternatives could be feasible, but may have different capital and operating costs, and different cost mitigation projections based on the volume and quality of gas that could be captured or used. EPA chose not to be more prescriptive because as industry has stated repeatedly in comments to this proposal, conditions will vary across geography, age of facilities, types of wells, and volume of associated gas to be handled.

Comment: Commenter (2433-EDF et al) has considerable concerns with the proposed technical infeasibility exemption and accompanying infeasibility demonstration. However, should EPA retain a technical infeasibility exemption, the commenter states that the agency must improve the rigor and enhance the enforceability of the exemption by: (1) limiting flaring to instances of physical impossibility; (2) requiring pre-approval of any flaring occurring under the technical feasibility exemption, or at least public notification of such flaring; (3) requiring that an independent third party submit the technical infeasibility certification; (4) requiring operators to submit detailed, certified technical infeasibility documentation at least annually if they intend to flare; and (5) require additional records of flaring events.

As discussed above in a previous comment, commenter (2433-EDF et al) does not believe there are ever any instances where an operator must flare routinely due to technical infeasibility or safety. As such, the commenter recommends that EPA prevent pollution from routine flaring by requiring gas recovery except in the temporary, limited circumstances discussed above. However, if EPA nonetheless finalizes a technical infeasibility exemption that allows an operator to flare based on a certified demonstration of technical infeasibility, the commenter argues that the agency must limit the exemption by clearly delineating the “technical” reasons that would justify flaring in lieu of the four gas recovery options.

First, commenter (2433-EDF et al) suggests that EPA must make clear that a demonstration based on a claim that the four abatement options are not economical at a particular site is not sufficient or relevant. EPA has not proposed an exemption based on economic infeasibility. As discussed above, the commenter states that gas recovery options are cost-effective at a variety of sites. The commenter adds that the EPA clarifies elsewhere (e.g., in its well completion

---

<sup>123</sup> See for example 25 CFR § 169.123 (a)(2) at [<https://www.ecfr.gov/current/title-25/chapter-I/subchapter-H/part-169/subpart-C/subject-group-ECFR7b7105daa80dc3a/section-169.123>].

requirements) that technical infeasibility does not include economic infeasibility, but rather is limited to circumstances like lack of infrastructure, engineering issues, and safety concerns.<sup>124</sup>

Second, the commenter (2433-EDF et al.) adds that the EPA must require operators to demonstrate the physical impossibility of each of the gas recovery options to claim the exemption to flare. The commenter provides potential physical impossibility demonstrations below for each abatement method:

- *Gathering Lines.* In order to claim that routing associated gas to sales lines is not technically feasible, an operator should be required to show that it is physically impossible to connect to a gathering line and that the operator used best efforts to do so. Thus, for example, constraints that can be overcome with timing considerations (e.g., delaying completion or production of wells), compression (e.g., adding compressors to boost low-pressure gas in order to add the gas to higher-pressure pipelines) or proper planning are not sufficient to demonstrate that access to a gathering line is technically infeasible.<sup>125</sup> In these instances, lack of access to a gathering line is technically feasible because it is physically possible to route gas to the line with some timing revisions or the addition of compression at the well site.
- *Another Useful Purpose.* To demonstrate that it is not technically feasible to use gas for another useful purpose that a purchased fuel or raw material would serve, such as conversion of associated gas to CNG, an operator must show that it is physically impossible to use the gas for another useful purpose. CNG transport services are widely available<sup>126</sup> and must be considered as another potential useful purpose in all flaring demonstrations. To demonstrate this option is not technically feasible an operator must show that it is physically impossible to convert associated gas to CNG at the wellsite due to physical or technical constraints and/or that CNG transport in the region is not available.
- *Onsite Fuel.* An operator must show that there is no way to use the associated gas as an onsite fuel source to demonstrate that this abatement option is technically infeasible. As our prior comments demonstrated<sup>127</sup> operators have options for using associated gas as an onsite fuel source, including use for onsite power needs (e.g., replacing diesel with associated gas) or using associated gas to power a small electricity generation plant that sends power to the grid. Thus, an operator would need to demonstrate that neither option is available either because an operator has no onsite power needs or power needs have been met with less gas than produced, there is insufficient associated gas to support a small electricity generation plant, or there is no local demand for the power, even if generated.
- *Reinjection.* To demonstrate that reinjection is technically infeasible, an operator must demonstrate that there is no subsurface reservoir or other storage available for reinjection.

<sup>124</sup> U.S. Environmental Protection Agency, Oil and Natural Gas Sector: Emission Standards for New, Reconstructed, and Modified Sources, Final Rule, 81 Fed. Reg. 35824 (June 3, 2016), <https://www.govinfo.gov/content/pkg/FR-2016-06-03/pdf/2016-11971.pdf>.

<sup>125</sup> See e.g., Expert report of Thomas Alexander, *supra* note 435, at 7 (discussing efforts in North Dakota to find innovative methods of transporting oil to market in the absence of sufficient oil pipeline capacity).

<sup>126</sup> 2022 Joint Environmental Comments, *supra* note 1, at 187.

<sup>127</sup> *Id.* at 67; Expert report of Thomas Alexander, *supra* note 435, at 7.

Porous subsurface reservoirs are readily available in all states responsible for the majority of associated gas flaring, with the possible exception of North Dakota.<sup>128</sup> There is potential, however, for reinjection into saline aquifers in North Dakota.<sup>129</sup>

Response II-6-41: The final rule diminishes the prevalence of the infeasibility determinations and certifications and only allows routine flaring with a technical infeasibility determination and certification in circumstances where the well was drilled prior to the knowledge or expectation of a prohibition on routine flaring. Specifically, these circumstances are existing wells (addressed by the presumptive standards in EG OOOOc), new wells for which construction commenced after the December 6, 2022, supplemental proposal and the final rule, and modified or reconstructed wells. More discussion of this topic is provided in section XI.F.2.g of the final rule preamble.

Comment: Commenter (2433-EDF et al) recommends that EPA require certification by an independent third party. EPA has proposed to allow certification by either a professional engineer or a “qualified individual with expertise in the uses of associated gas.”<sup>130</sup> Notably, per EPA’s proposal, an operator could use an in-house engineer, other qualified individual, or a contractor. However, the commenter notes that there is no requirement that the individual be independent from the operator. Certification by an independent third party, rather than a professional engineer or a “qualified individual with expertise in the uses of associated gas,” either of whom could be an in-house individual or a person with significant ties to the company, will enhance the credibility and reliability of the report.<sup>131</sup> Certification by an independent third party of all demonstrations seeking a flaring exception is necessary to ensure a robust, complete, and accurate demonstration of the reasons underlying the flaring request.

Commenter (2433-EDF et al) requests that EPA should further clarify that both the certifier and the owner/operator may be subject to penalties for submission of a fraudulent or significantly flawed certification. The commenter notes that this clarification is consistent with EPA’s proposal for pneumatic pumps. EPA proposes to include a technical infeasibility exemption from the zero-emission pneumatic pump standard, provided an operator submits a demonstration certified by a qualified professional engineer or in-house engineer with relevant experience. EPA notes that it “is committed to ensuring that this technical infeasibility provision is not abused or used as a loophole . . .,” pointing to the potential for enforcement actions to be levied against both the owner/operator and certifier upon submission of a “fraudulent, or significantly flawed” certification. The commenter urges EPA to clarify that this same potential penalty is applicable to the submission of “fraudulent, or significantly flawed” certifications in the context of associated gas at the affected well facility, if EPA retains the technical infeasibility exemption.

Commenter (2433-EDF et al) suggests that operators seeking to routinely flare must submit a thorough analysis and engineering certification comparable to the initial certification each year.

---

<sup>128</sup> Rystad, *supra* note 394, at 67.

<sup>129</sup> *Id.* at 67; Expert report of Thomas Alexander, *supra* note 435, at 7.

<sup>130</sup> Proposed 40 C.F.R. § 60.5377b(b).

<sup>131</sup> Maureen Lackner & Kristina Mohlin, *Env’t Def. Fund, Certification of Natural Gas with Low Methane Emissions: Criteria for Credible Certification Programs* 11 (2022), [https://blogs.edf.org/energyexchange/files/2022/05/EDF\\_Certification\\_White-Paper.pdf](https://blogs.edf.org/energyexchange/files/2022/05/EDF_Certification_White-Paper.pdf) (Attachment W).

The commenter recommends that this demonstration should include the same information as the initial demonstration, namely a detailed analysis documenting the technical infeasibility or safety reasons for the infeasibility and an explanation as to why none of the four gas recovery options are technically feasible or safe. This demonstration must also be certified by an independent third party.

Response II-6-42: As discussed at length in the proposed amendments to NSPS OOOOa published on October 15, 2018 (83 FR 52079), EPA determined that the use of in-house engineers to assess feasibility is appropriate. This concept is maintained in this final rule and emission guidelines.

EPA agrees with the commenter that annual re-evaluation and re-certification of the technical infeasibility of routing the associated gas to a sales line or for another beneficial purpose is warranted. The technical infeasibility determination and certification requirements are discussed in Section XI.F.2.g of the final rule preamble.

Comment: Commenter (2428-API) does not support the requirement to make an infeasibility demonstration and safety and technical certification statements in order to use a flare to reduce these emissions; especially at oil wells that are connected to gas gathering infrastructure and only temporarily flare gas when unable to sell the gas. The commenter notes that in the proposed rule, EPA even uses controlling associated gas with a control device such as a flare as justification for the storage vessel requirements “...these sites also may be subject to standards for oil well with associated gas and the compliance burden is shared between those affected facilities to ensure emissions from both storage vessels and oil wells with associated gas are reduced by 95 percent.” According to the commenter, this statement is evidence of EPA’s clear expectations of the use of flares at oil well facilities that may have associated gas, making the need for these additional demonstrations arbitrary.

Since EPA has already acknowledged in the preamble that situations where a well is configured to route gas to sales or for reinjection can no longer recover the gas for its primary use and need to route gas to a flare do occur and are outside the control of the well operator, the commenter (2428-API) also does not support making technical or safety demonstrations where disruptions or interruptions in the gas gathering infrastructure result in the need to route the associated gas to a control device for temporary periods. For wells that primarily recover gas for reinjection, conducting compressor maintenance may necessitate temporary periods of flaring. This is reasonable given that a facility is designed with a certain configuration for handling the disposition of associated gas and it is unreasonable to expect facilities to design for multiple uses based on emerging technologies before they can resort to flaring, especially during these short intermittent periods. Any retention of technical demonstrations, for wells that do not primarily recover associated gas, should include economic viability.

Response II-6-43: EPA agrees with this commenter, and the final rule allows the temporary flaring of associated gas when the gas cannot be routed to the sales line or used for the other primary beneficial purpose. See the response to II-6-6 and Section XI.F.2.f of the final rule preamble.

Comment: Commenter (2326-AXPC) suggests that the BSER opt-out should include economic factors in addition to technical feasibility or safety. The commenter reports that the EPA concedes that it is proposing multiple regulatory requirements whose implementation would be so burdensome that they would be “technically infeasible” for some set of affected facilities. EPA thus gives affected facilities the ability to “opt out” of the performance standard if the affected facility can show that compliance with the performance standard would be infeasible for technical or safety reasons. As explained below, the commenter contends that “technically infeasible” is a misnomer and EPA should explicitly include economic factors in addition to a technical feasibility analysis.

Commenter (2326-AXPC) states that within EPA’s NSPS OOOOb/EG OOOOc regulations, EPA provides opt out for their regulatory requirements such as the ability to use an emissions control device to handle associated gas,<sup>132</sup> the continued use of pneumatic pumps driven by natural gas,<sup>133</sup> and the use of emitting gas well unloading methods.<sup>134</sup> Unfortunately, according to the commenter, EPA does not provide any information within the rule on how an affected facility is expected to demonstrate that the regulatory provision in question is “technically infeasible” in their case, other than a requirement that a professional engineer or other qualified individual so certify.

Because there is no explanation of technical infeasibility within the rulemaking, the commenter (2326-AXPC) evaluated what EPA has done in other CAA programs. For example, EPA’s regulations related to best available retrofit technology (BART) determinations under the regional haze program include some insight into how EPA might evaluate technical feasibility considerations.<sup>135</sup> According to EPA’s BART regulations:

Control technologies are technically feasible if either (1) they have been installed and operated successfully for the type of source under review under similar conditions, or (2) the technology could be applied to the source under review. Two key concepts are important in determining whether a technology could be applied: “availability” and “applicability.” As explained in more detail below, a technology is considered “available” if the source owner may obtain it through commercial channels, or it is otherwise available within the common sense meaning of the term. An available technology is “applicable” if it can reasonably be installed and operated on the source type under consideration. A technology that is available and applicable is technically feasible.<sup>136</sup>

Commenter (2326-AXPC) believes that while these regulations provide more context than EPA’s proposed NSPS OOOOb/EG OOOOc regulations, the BART regulation conflates economic factors and technical feasibility and does not specifically account for other factors related to potential implementation that may be critical to compliance. The “available” concept is inherently an economic concept as it relates to whether the item is commercially available

---

<sup>132</sup> See, e.g., Proposed 40 CFR 60.5377b(b)(2).

<sup>133</sup> See, e.g., id. 40 CFR 60.5393b(c).

<sup>134</sup> See, e.g., id. 40 CFR 60.5376b(c)(2)(ii)(B)(2).

<sup>135</sup> See 40 C.F.R. Part 51, Appendix Y.

<sup>136</sup> Id. Appendix Y(D)(1).

– *i.e.*, that the price is at such a level that it can be produced commercially. If EPA was truly looking at considering technical feasibility without regard to economic viability, whether a technology is commercially available would be irrelevant. And to do so here, would be inappropriate, particularly given the definition of standard of performance. Under CAA section 111(a)(1), the commenter provides that a standard of performance means a standard for emissions of air pollutants which reflects the degree of emission limitation achievable through the application of the best system of emission reduction (considering the cost of achieving such reduction and any non-air quality health and environmental impact and energy requirements) the Administrator deems has been adequately demonstrated.<sup>137</sup>

By providing an opt-out, the commenter (2326-AXPC) states that the EPA inherently recognizes that BSER cannot be met at every facility. Thus, in making the demonstration that use of the opt out is appropriate, the costs of achieving such emissions reduction should be considered. Further, because EPA may only include standards that are determined to be adequately demonstrated, they believe that technical feasibility must include considerations such as: ability to access electrical power; landowner access; other local or state regulatory requirements; and other considerations that limit the ability to comply with the standard of performance. In other words, they believe that technical feasibility must include considerations beyond just physical impossibility. Anything that would preclude or hinder implementation of the regulations should be included in a consideration of feasibility – whether technical, economic, or some other appropriate consideration. However, the commenter states that the EPA should be explicit that economics is to be considered in the feasibility analysis – as technical feasibility alone is insufficient.

Instead of EPA conflating technical feasibility and economic considerations, as it does in the Supplemental Proposal, the commenter (2326-AXPC) reports that the EPA in its final rule should transparently state that economic factors must be part of an affected facility’s ability to opt out of the regulatory requirement, in addition to whether installation and operation of the regulatory requirement is technically feasible and safe. The commenter therefore recommends that EPA adopt general standards for opting out of EPA’s performance standards or in instances where EPA has provided an opt out. Specifically, the commenter (2326-AXPC) suggests that an affected facility be able to opt out of the standard of performance if any of the following apply:

- The performance standard cannot reasonably be installed and operated at the affected/designated facility including due to technical feasibility, safety concerns, or physical impossibility;
- The cost of compliance with the performance standard would result in the affected/designated facility having a cost-effectiveness greater than \$5,540 per ton of VOCs or \$1,970 per ton of methane or the well is no longer able to economically operate; or
- The cost of compliance with the performance standard would be so great that it would result in the affected/designated facility no longer being able to economically operate.

---

<sup>137</sup> 42 U.S.C. § 7411(a)(1).

In addition to the above, commenter (2326-AXPC) recommends EPA provide detailed information on what affected facilities can show to meet the requirements for opting out of a control requirement.

Response II-6-44: EPA disagrees that economic feasibility should be a factor in defining an “opt out” for the BSER requirements. As required by section 111(d) of the Clean Air Act, EPA considered the emission reduction, and the cost of achieving such reduction and any non-air quality health and environmental impact and energy requirements in determining BSER. The commenter cites BART, but those requirements are in response to a different statutory authority.

While the EPA does not consider many of the factors cited by the commenter to reflect economic viability, they do represent criteria that could be considered as part of a technical infeasibility determination. Examples of such criteria include landowner access; other local or state regulatory requirements; and other considerations that limit the ability to comply with the standard of performance. These criteria are not limited to physical impossibility.

Comment: Commenter (2326-AXPC) requests that for wells where the operator has designed and configured the separator to recover and sell or beneficially use associated gas, EPA remove the requirement to provide an infeasibility or safety justification for controlling associated gas when the primary means of disposition is temporarily unavailable. For these configurations, the commenter supports controlling the gas by using a permanent control device that meets the applicable control device requirements during periods when the primary means of disposition is unavailable. In the scenario where control is temporarily necessary, the operator would route the gas to the control device as soon as practicable. The commenter states that this is consistent with EPA’s acknowledgment in the preamble that the primary means of disposal may become temporarily unavailable for reasons outside the operator’s control and that EPA’s expectation is that the operator installs a permanent control device for these periods of temporary control. According to the commenter, requiring a certified justification in this scenario is overly burdensome with no corresponding environmental benefit.

The commenter (2326-AXPC, 3818-AXPC) proposes that EPA remove the requirement in 40 CFR 60.5377b(b)(1) and 60.5377c(b)(1) to provide a certified justification for controlling associated gas where the operator complies with 40 CFR 60.5377b/60.5377c (a)(1), (2), (3), or (4) during normal operations and temporarily controls associated gas when the primary method of disposition is unavailable.

Additionally, commenter (2326-AXPC) proposes eliminating the requirement to justify use of control in many circumstances. However, where a justification continues to be required, the commenter provides the following additional comments regarding economic viability. These comments are in addition to the comments they provide in their comment letter which addresses these considerations more generally. The commenter fully supports the concept of prioritizing the sale or beneficial use of associated gas as opposed to controls where markets exist and disposition into those markets is economically viable. However, they contend that the EPA must allow operators to control associated gas where no viable gas market exists, considering the commercial availability of a gas sales pipeline or other potential market and site economics to deliver gas to market. The commenter provides that this is consistent with the World Bank’s

“Zero Routine Flaring by 2030” initiative, in which some of the commenter’s members are participants. This global initiative encourages operators “to implement economically viable solutions to eliminate [routine] flaring as soon as possible.”<sup>138</sup> While a use may be technically feasible, they state that it may not be commercially viable, as discussed elsewhere in their comments.

Commenter (2326-AXPC) states that in addition to commercial availability/viability, a potential gas disposition method must be economically viable. For example, a remote well site operator could identify a pipeline with sufficient capacity, but the closest pipeline with sufficient takeaway capacity may be 100 miles away. And the cost to build, maintain, and operate the connecting pipeline may well exceed the total value of the gas that could be sold. Further, the additional infrastructure development is not without environmental impacts – *e.g.*, the impacts associated with the construction and installation of the pipeline. While it would be technically feasible to build this connecting pipeline, it is not an economically viable solution – *i.e.*, a cost-effective solution, as noted by EPA.<sup>139</sup> The commenter suggests that, to ignore economic viability would result in a rule that does not provide “achievable, cost-effective measures to significantly reduce methane and VOC emissions, consistent with the requirements of section 111 of the CAA.”

Commenter (2326-AXPC) believes that not only is it good policy to consider a control measure’s economic viability, but CAA section 111 requires it, as evidenced by its plain language and EPA’s many references to the Proposal’s cost-effectiveness. As noted in the regulatory impact analysis (RIA), which explicitly excludes any substantive analysis of the cost-effectiveness of EPA’s proposed oil well associated gas requirements, control of associated gas is appropriate where an operator does “not produce a large enough quantity of associated gas to offset the capital necessary to install” the infrastructure necessary to sell gas or use it in another beneficial way.<sup>140</sup> According to the commenter, inherent in this suggestion is the notion that economic considerations play a role in determining the feasibility of selling or using gas for a beneficial purpose.

Commenter (2326-AXPC, 3818-AXPC) proposes that EPA revise the proposed 40 CFR 60.5377b(b), and the corresponding EG OOOOc provision, as follows (underlined text indicates new text and struck out text indicates deleted text):

(b) If you demonstrate that it is not feasible to comply with paragraph (a)(1), (2), (3), or (4) of this section due to technical, economic, lack of commercial availability, or safety reasons in accordance with paragraphs (b)(1) through (3) of this section, you must route the associated gas to a control device that reduces methane and VOC emissions by at least 95.0 percent. The associated gas must be routed through a closed vent system that

<sup>138</sup> The World Bank, [Global Initiative to Reduce Gas Flaring: “Zero Routine Flaring by 2030”, available at] <https://thedocs.worldbank.org/en/doc/a903b5e6456991faf3b5e079bba0391a-0400072021/related/ZRF-Initiative-text-list-map-103.pdf> (emphasis added).

<sup>139</sup> See 2022 RIA at 153.

<sup>140</sup> See 2022 RIA at 26, 153.

meets the requirements of §60.5411b(a) and (c) and the control device must meet the conditions specified in §60.5412b(a), (b) and (c).

(1) In order to demonstrate that it is not feasible to comply with paragraph (a)(1), (2), (3), or (4) of this section, you must provide a detailed analysis documenting and certifying the technical, economic, lack of commercial availability, or safety reasons for this infeasibility. The demonstration must address the technical, economic, lack of commercial availability, or safety infeasibility for all options identified in (a)(1), (2), (3), and (4) of this section. ~~With regard to compliance with paragraph (a)(3) of this section, another useful purpose that a purchased fuel or raw material would serve includes, but is not limited to, methane pyrolysis, compressing the gas for transport to another facility, conversion of gas to liquid, and the production of liquified natural gas.~~ Documentation of these demonstrations must be maintained in accordance with §60.5420b(c)(3)(ii). If the primary means of disposition of oil well associated gas is one of the options identified in (a)(1), (2), (3), and/or (4) of this section, you do not need to complete, certify, or document the detailed analysis in this section to utilize temporarily the option in §60.5377b(b).

(2) This demonstration must be certified by a professional engineer or another qualified individual with expertise in the uses of associated gas. The following certification, signed and dated by the qualified professional engineer or other qualified individual shall state: “I certify that the assessment of technical, economic, lack of commercial availability, and safety infeasibility was prepared under my direction or supervision. I further certify that the assessment was conducted, and this report was prepared pursuant to the requirements of §60.5377b(b)(1). Based on my professional knowledge and experience, and inquiry of personnel involved in the assessment, the certification submitted herein is true, accurate, and complete.”

Response II-6-45: EPA agrees with this commenter, and the final rule allows the temporary flaring of associated gas when the gas cannot be routed to the sales line or used for the other primary beneficial purpose. See the response to II-6-6 and Section XI.F.2.f of the final rule preamble.

Comment: Commenter (2326-AXPC) suggests that if a justification is required for the temporary control of associated gas, EPA should allow operators to develop a gas capture plan for the similarly simulated oil wells with associated gas. The commenter proposes eliminating the requirement to justify use of control in many circumstances.

However, where a justification continues to be required, the commenter provides the following additional comments regarding such justifications. EPA proposes that operators prioritize the sale, use, or injection of crude oil well associated gas over use of a control device to reduce emissions, and where an operator must control associated gas emissions because it is technically infeasible or unsafe to sell, use, or inject associated gas, it must justify and certify why. This requirement applies to “each oil well with associated gas at a well affected [or “designated”

under EG OOOOc] facility,”<sup>141</sup> meaning the certification requirement would apply on a well-by-well basis. If the exemption from justification proposed by the commenter is not adopted, this may require hundreds or thousands of certifications that would be unnecessarily onerous where similarly situated oil wells must control associated gas emissions to comply with the oil well associated gas provisions, even where control is limited to temporary situations.

Commenter (2326-AXPC) states that because regional circumstances often dictate associated gas disposition, an operator may comply with the associated gas standards in the same manner for all or many wells in a region, and where the primary means of compliance is unavailable, the operator is likely to use the same alternative method(s) of compliance for all similarly situated wells. For example, where gas pipeline takeaway is readily available in a region, the operator will dispose of natural gas produced from all wells in the region into the pipeline and route gas to control when the pipeline is temporarily unavailable. For these similarly situated wells, it would be most efficient for the operator to use one document that covers all wells to identify the primary compliance approach – *e.g.*, pipeline injection – and the technical infeasibility or safety justification for controlling gas when the primary compliance approach is unavailable.

Commenter (2326-AXPC) proposes that, as an alternative to a well-by-well certification requirement, operators may develop a system-wide gas capture plan that would cover all similarly situated oil wells – *e.g.*, oil wells that share a common gas gathering system or other appropriately representative grouping. Under this plan, operators would identify the primary means of complying with §§60.5377b(a) or 60.5391c(a), as applicable, and where the operator must control associated gas because the primary means of associated gas disposition is technically infeasible or unsafe, the operator would provide a commonly applicable justification. For example, as EPA identifies in the preamble, interruptions to the gas gathering system may affect an operator’s ability to sell gas. In these instances where operators dispose of associated gas via pipeline, operators are unlikely to have the infrastructure available to use the gas for another purpose or to reinject the gas, leaving control as the only other feasible option. In response to the commenters that identified this potential issue, EPA proposes that operators “provide a technical or safety demonstration in their annual report and install and operate a control device that achieves the required reduction during these temporary periods.” The same logic would apply for operators that use gas for a beneficial purpose or re-inject gas. Like with gas sent to pipeline, a beneficial use or re-injection may become unavailable without notice, and the operator must instead control the gas.

Commenter (2326-AXPC) states that applying the gas capture plan approach, the operator would identify pipeline injection as the primary compliance method for all wells covered by the gas capture plan, and when pipeline disposition is technically infeasible – *e.g.*, due to capacity constraints or pipeline downtime, the operator would comply with 40 CFR 60.5377b(b) by controlling the associated gas with a control device meeting all applicable NSPS OOOOb requirements. The commenter adds that an operator would provide the justification of technical infeasibility that is commonly applicable to all wells covered by the gas capture plan, and no well-by-well justification would be required. Under this gas capture plan approach, operators would maintain records of compliance with the gas capture plan and report compliance in a similar manner as currently proposed. Using the example above, if the operator vents gas rather

---

<sup>141</sup> See Proposed 40 C.F.R. §§60.5377b(a), .5391c(a).

than controls it, the operator would maintain records of this event and report its occurrence in the annual report. Similarly, operators that control associated gas during a reporting period would provide a copy of the gas capture plan's justification applicable to the well(s) that required associated gas control during the reporting period.

Just as with the proposed requirement to consider changes that would impact an operator's ability to comply with the requirements to sell, use, or re-inject associated gas, the commenter (2326-AXPC) proposes that operators that routinely or periodically control associated gas under a gas capture plan would consider and report on any changes in the region that impact the operator's ability to comply with the requirement to sell, use, or re-inject associated gas.

To summarize, commenter (2326-AXPC) requests that EPA add language to the oil well associated gas provisions that would allow operators to develop a gas capture plan for similarly situated oil wells with associated gas. The commenter recommends that operators must develop and maintain records of the gas capture plan, which must identify the primary method(s) of gas disposition, and where control of associated gas is necessary on a permanent or temporary basis, the operator must justify the technical infeasibility and/or safety justification for controlling the gas, with such justification to apply to all wells covered by the gas capture plan. The commenter adds that operators using a gas capture plan would maintain records and report under a framework similar to the December 2022 supplemental proposal's recordkeeping and reporting requirements.

Response II-6-46: EPA agrees with this commenter, and the final rule allows the temporary flaring of associated gas when the gas cannot be routed to the sales line or used for the other primary beneficial purpose. See the response to II-6-6 and Section XI.F.2.f of the final rule preamble.

Comment: Commenter (2294-OOGA) expresses that, under the December 2022 supplemental proposal, associated gas cannot be routed to a flare or other combustion device unless the owner or operator demonstrates that each of the four compliance options are infeasible due to technical or safety reasons, and that demonstration is approved by a certified professional engineer. The commenter notes that this is a significant change from the November 2021 proposed rule that places additional burden on operators which may be unworkable as a practical matter.

Response II-6-47: EPA acknowledges the difference in the November 2021 proposal and the December 2022 supplemental proposal, as discussed in the supplemental proposal preamble. EPA disagrees that the final rule is unworkable as a practical matter and maintains that it provides reasonable requirements with provisions that allow for situations when the complying with the primary standard is technically infeasible.

Comment: Commenter (2403-The Petroleum Alliance of Oklahoma (PAO)) contends that, for those situations where the operator is connected to a sales line and there are instances where the gas needs to be routed intermittently to a control device for equipment maintenance, repairs, emergencies or other similar situations, this type of flaring should not have to undergo repeated onerous infeasibility determinations and detailed recordkeeping requirements. A one-time feasibility determination should suffice. The commenter suggests that the requirement to have a

certified professional engineer conduct the feasibility analysis is excessive as well. In-house engineers with the knowledge, experience and understanding of the site conditions should be allowed to conduct the technical infeasibility demonstration. Also, the commenter states that the EPA should recognize the characteristics and limitations of low producing, marginal wells. The production of these wells is declining. Repeated, onerous technical infeasibility analysis, and detailed recordkeeping should be eliminated in the final rule.

Response II-6-48: EPA agrees with this commenter, and the final rule allows the temporary flaring of associated gas when the gas cannot be routed to the sales line or used for the other primary beneficial purpose. See the response to II-6-6 and Section XI.F.2.f of the final rule preamble. EPA disagrees however, that repeated infeasibility determinations should be eliminated. In fact, if an option becomes available where an owner or operator is able to sell or utilize the associated gas for a beneficial purpose, that may increase the economic viability of the well and extend its life.

Comment: Commenter (2247-Ohio Environmental Protection Agency (OHEPA)) states that, under paragraph (b) of 40 CFR 60.5391c (What GHG standards apply to oil wells with associated gas at well designated facilities?) [also applies to parallel provisions under NSPS OOOOb], does “feasible” mean just technically feasible, economically feasible or both? If economic feasibility needs to be assessed, what factors or thresholds should be considered?

Response II-6-49: EPA believes that it has been quite clear that feasibility is based on technical feasibility and not economic feasibility.

Comment: Commenter (2348-Energy Workforce & Technology Council (EWTC)) suggests that a “qualified individual” for production systems should have a background in process and/or petroleum engineering, with experience operating and/or starting up production facilities in the field. Qualified persons for other activities, such as drilling and completions, would require expertise and field experience in these respective areas.

Response II-6-50: The final rule allows a technical infeasibility determination to be certified by either a professional engineer or another qualified individual with expertise in the uses of associated gas. The type of professional described by the commenter would qualify as such an individual.

Comment: Commenters (2028-WMCG, 2039-CPLV) suggest that rather than applying for an exception which increases emissions, companies could instead apply for assistance in avoiding concentrated, high emission pollution incidents. By way of example, the commenters state that “blowdowns” are a significant source of air pollution in Pennsylvania and believes their frequency is routinely underestimated by the Pennsylvania Department of Environmental Protection (DEP) in air pollution permits. The commenters point out that most industrial rules are focused on annual pollution levels at a specific facility, but concentrated pollution events like blowdowns result in acute exposures to air pollution that increase the likelihood of respiratory damage or other health effects. The commenters provide that EPA has advocated for equipment that would reduce air pollution from blowdowns since 2012 and they believe EPA must take an

active role in the application of these pollution reduction technologies, specifically with the \$1.55 billion allocated to EPA in the methane emissions reduction program (MERP).

Response II-6-51: This comment is outside the scope of this regulatory action.

#### 6.2.4.4 Support Approaches Taken by Colorado and New Mexico for Temporary Flaring

Comment: Commenter (2433-EDF et al) recommends the replacement of the “technical infeasibility” exemption with clearly delineated circumstances for temporary flaring. Rather than include a technical infeasibility exemption, the commenter recommends that EPA require oil wells to capture associated gas by utilizing one of the four recovery options, except in specific, narrowly defined circumstances when a well may be permitted to flare on a temporary basis. In doing so, EPA can follow the approach taken by Colorado and New Mexico to address routine flaring. Both states prohibit venting or flaring other than in enumerated exceptional situations. EPA can apply these exemptions nationally because “[t]he types of reservoir traps, reservoir drives, subsurface geology, structures, production technologies, infrastructure buildouts, availability of services and supplies are all very similar across producing areas.”<sup>142</sup> A time-limited or otherwise narrow exemption to utilizing one of EPA’s approved gas recovery options may be justified in the following circumstances, each discussed in more detail below: upset conditions; pipeline, equipment, or facilities commissioning; initial production where gas does not meet pipeline specifications and where an operator is connected to a gathering line; active and required maintenance; production evaluation and production tests; Bradenhead monitoring; and packer leakage tests.<sup>143</sup>

To assist with compliance and enforcement, the commenter (2433-EDF et al) suggests that EPA require that operators maintain records of the date, cause, estimated volume of gas flared or vented, and duration of each event it seeks to justify under one of the exemptions.<sup>144</sup> Below, the commenter discusses circumstances where EPA may consider exemptions from its capture requirements in which flaring is authorized.

Commenter (2433-EDF et al) suggests that capture may be technically infeasible or unsafe for a limited amount of time during upset conditions, which are emergency circumstances outside of the control of an operator that can interrupt its ability to comply with the proposed standard. An example of an upset condition is a temporary, unplanned loss of connection to, or ability to route gas to, a gathering system. The commenter notes that the EPA has determined that interruptions of an operator’s ability to route gas to a gathering system constitute a technical or safety reasons that can justify flaring. It is critical that EPA permit only temporary flaring during these circumstances and establish clear time limitations during which it may be permitted. Both Colorado and New Mexico allow operators to flare or vent gas for a short period of time during upset conditions or emergencies, including temporary unavailability of access to a gathering line. The commenter states that the Colorado rules provide a concise, clear definition of this circumstance, while also limiting the length of time an operator may flare or vent during such circumstances. Colorado’s definition of an “Upset Condition” is “a sudden unavoidable failure,

---

<sup>142</sup> Expert Report of Thomas Alexander, *supra* note 435, at 3.

<sup>143</sup> *Id.* at 4–6.

<sup>144</sup> See e.g., 2 Colo. Code Regs. §404-1-903.d.(2) (2023).

breakdown, event, or malfunction, beyond the reasonable control of the Operator, of any equipment or process that results in abnormal operations and requires correction.”<sup>145</sup> Notably, per the Statement of Basis and Purpose for the rule, this definition does not include “an operator’s negligence, failure to install appropriate equipment, or failure to perform scheduled maintenance.”<sup>146</sup>

Furthermore, commenter (2433-EDF et al) points out that Colorado limits venting and flaring during upset conditions to a period necessary to address the upset, not to exceed 24 cumulative hours, and requires operators to maintain records of the date, cause, estimated volume of gas flared or vented, and duration of each upset condition.<sup>147</sup> Per the Statement of Basis and Purpose for the rule, Colorado’s definition of an upset condition also include sudden lack of pipeline capacity.<sup>148</sup> Accordingly, Colorado allows operators to vent or flare associated gas in the event that unplanned disruptions to a gathering system interrupt the ability of an operator to route associated gas to a sales line, but only up to 24 cumulative hours.

Commenter (2433-EDF et al) states that New Mexico similarly allows for temporary venting or flaring during an emergency. An emergency means “a temporary, infrequent, and unavoidable event in which the loss of natural gas is uncontrollable or necessary to avoid a risk of an immediate and substantial adverse impact on safety, public health, or the environment” other than in certain exceptions.<sup>149</sup> One such exception is “venting or flaring of natural gas for more than eight hours after notification that is caused by an emergency, an unscheduled maintenance, or a malfunction of a natural gas gathering system.”<sup>150</sup> In other words, an upstream operator may vent or flare during a temporary, infrequent, and unavoidable event involving loss of connection to a sales line provided the midstream operator notifies the producer of the disruption to the operator of the sales line. However, an upstream operator cannot vent longer than 8 hours in this circumstance.<sup>151</sup>

Commenter (2433-EDF et al) recommends EPA limit flaring or venting during an upset condition to not more than 24 cumulative hours, in line with the Colorado rules. This would apply in those instances where a disruption to a gathering system or other event causes an interruption to an operator’s ability to route the gas to a sales line. Prudent operators should be prepared to recover gas in the event of sudden loss of takeaway capacity.<sup>152</sup> Specifically, while short-term flaring may be necessary to allow the operator to make alternative arrangements for the disposition of associated gas, prudent operators can quickly deploy alternative uses of the gas such as onsite use, compression for CNG, or injection.<sup>153</sup> Because of this the commenter does

<sup>153</sup> *Id.*

not believe EPA should include a separate exemption for loss of takeaway capacity that would permit flaring or venting in excess of 24 hours.

Response II-6-52: EPA considered these state rules in the development of the final rule requirements rule requirements for temporary flaring and venting.

Comment: Commenter (2433-EDF et al) discusses circumstances where EPA may consider exemptions from its capture requirements in which flaring is authorized. One circumstance that may give rise to an operator's need to flare on a temporary basis is the commissioning of pipelines, equipment, or facilities.<sup>154</sup> The commenter provides that New Mexico allows operators to flare temporarily during these circumstances,<sup>155</sup> and even then "only for as long as necessary to purge introduced impurities."<sup>156</sup> An operator may need to flare temporarily when it is first connecting to a pipeline that has just been constructed if the pipeline was cleaned out with substances that the midstream operator does not want in the gas.<sup>157</sup> With proper coordination between midstream and downstream operations, operators can substantially mitigate any lost production of oil and avoid unnecessary flaring of associated gas.<sup>158</sup> If carefully applied, the commenter contends that this limited exemption will not give rise to significant emissions; "flaring during this exemption will often be of very short duration," since it does not take long to "clear impurities from equipment, facilities or pipelines."<sup>159</sup>

Commenter (2433-EDF et al) also suggests that operators may also need to flare temporarily where an operator is connected to a sales line, but natural gas does not meet pipeline specifications and the other three gas recovery options are also unavailable.<sup>160</sup> This occurs where impurities such as oxygen or nitrogen are present in the associated gas and thus the gas cannot safely be sent to the sales line.<sup>161</sup> New Mexico requires the operator take specific steps to limit flaring during this circumstance. Operators must analyze gas samples twice a week to determine if pipeline specifications have been achieved, and must route gas into gathering pipelines when pipeline specifications are met.<sup>162</sup> Operators must also provide pipeline specifications and gas analyses to the agency upon request.<sup>163</sup> The amount of time an operator may need to flare in order to clean up associated gas prior to routing to sales should be short, with the specific timeframe varying depending on the reservoir characteristics and composition of the hydraulic fracturing fluid. On average, an operator may need to flare for as little as two days to a week.<sup>164</sup> Requiring an operator to take frequent samples of gas composition is imperative so that it can begin routing gas to sales as quickly as possible once impurities have been removed. The New

<sup>159</sup> Id.

<sup>160</sup> Id. at 6-7; N.M. Code R. § 19.15.27.8.D.(4)(l) (2023).

<sup>161</sup> Expert report of Thomas Alexander, supra note 435, at 6-7.

<sup>162</sup> N.M. Code R. § 19.15.27.8.D.(4)(l) (2023).

<sup>163</sup> Id.

<sup>164</sup> Expert report of Thomas Alexander, supra note 435, at 5.

Mexico requirement that operators sample twice a week is quite reasonable, and prudent operators will likely sample more frequently since there is a profit incentive to doing so.<sup>165</sup>

Commenter (2433-EDF) states that both Colorado and New Mexico allow for temporary venting and flaring during active and required maintenance activities. The commenter explains that Colorado specifies that maintenance must both be active and required, clarifying that "while venting can be permitted while the maintenance activity is ongoing (for example, while personnel are on-site and performing the maintenance), venting during periods between discovery of the need for maintenance and the performance of the maintenance remains prohibited."<sup>166</sup> Colorado also requires operators to use best management practices to minimize venting during maintenance and repair activity, and Colorado is currently phasing in requirements that midstream operators capture hydrocarbons from blowdowns of compressors and other equipment at compressor stations and gas processing plants<sup>167</sup> - once fully phased in, Colorado midstream operators may no longer flare gas from depressurization of equipment for routine maintenance. New Mexico similarly allows venting or flaring during repair and maintenance, including blowing down and depressurizing production equipment to perform repair and maintenance.<sup>168</sup> The commenter recommends that EPA allow flaring during active and required maintenance activities, which includes blowing down and depressurizing production equipment.<sup>169</sup>

Commenter (2433-EDF et al) adds that Colorado and New Mexico both allow for temporary flaring during production tests and production evaluations. Colorado defines a "Productivity Test" to mean "a test for determination of a reservoir's ability to produce economic quantities of oil or gas."<sup>170</sup> Colorado defines a "production evaluation" as "an evaluation of production potential for determination of requirements for infrastructure capacity and equipment sizing."<sup>171</sup> Colorado allows venting or flaring during both events, but only subject to pre-approval. If the operator has obtained approval, the rules permit venting or flaring for a period not to exceed 60 days.<sup>172</sup> New Mexico limits venting or flaring during a production test for a period not to exceed 24 hours absent approval for a longer test period.<sup>173</sup> The commenter recommends EPA allow flaring during production and evaluation tests but limit the duration of these emissions events to 24 hours, as New Mexico has done, unless the operator obtains pre-approval to flare for a longer period of time. There may be instances, based on reservoir characteristics and the amount of knowledge an operator has about the reservoir's productivity, that an operator may need to flare for longer than 24 hours,<sup>174</sup> but in no event should flaring during this exemption exceed 60 days.<sup>175</sup>

Commenter (2433-EDF et al) also acknowledges that venting may be necessary for safety as previously acknowledged.<sup>176</sup> In addition, operators may need to vent for a very brief period during downhole monitoring activities, namely when monitoring the downhole pressure during bradenhead monitoring and packer leakage tests. The commenter reports that both Colorado and New Mexico allow operators to vent or flare during bradenhead monitoring.<sup>177</sup> Colorado limits bradenhead monitoring to 30 minutes.<sup>178</sup> New Mexico also allows operators to flare or vent during packer leakage tests.<sup>179, 180</sup>

Response II-6-53: EPA considered these state rules in the development of the final rule requirements rule requirements for temporary flaring and venting.

Comment: Commenter (2433-EDF et al) suggests that EPA should require pre-approval of requests to flare based on claims of technical infeasibility. Doing so would enhance oversight and reduce abuse that could otherwise occur without pre-approval.

Commenter (2433-EDF et al) states that in Colorado, operators may flare gas during completion operations with specific written approval of the operator's gas capture plan.<sup>181</sup> Alternatively, the operator may submit a form which explains why flaring is necessary to complete the well and will minimize adverse impacts to public health, safety, welfare, the environment, and wildlife resources; estimates the anticipated flaring volume and duration; and explains its plan to connect the facility to a gathering line or otherwise utilize the gas in the future. The operator's plan may be approved, through a form requesting permission to flare during completion, if it is determined that the flaring is necessary to complete the well and the operator will minimize adverse impacts to public health, safety, welfare, the environment, and wildlife resources.<sup>182</sup> In addition, Colorado requires pre-approval and documentation supporting the request for flaring in the event that an operator loses access to a gathering line.

In either instance, commenter (2433-EDF et al) suggests that EPA require public disclosure of flaring activities. Colorado requires notification of planned flaring, no later than two hours before flaring, as well as subsequent (and no later than 12 hour) notice of flaring due to upset conditions.<sup>183</sup> New Mexico requires notice of venting or flaring exceeding 50 Mcf resulting from an emergency or malfunction, or that lasts eight hours or more within a 24-hour period.<sup>184</sup>

Finally, commenter (2433-EDF et al) recommends additional recordkeeping and reporting requirements to bolster the enforceability of the demonstration and prevent abuse of the

<sup>182</sup> Id.

<sup>183</sup> 2 Colo. Code Regs. § 404-1-903.a.(1),(2).

<sup>184</sup> N.M. Code R. § 19.15.27.8.G.(1) (2023).

exemption. These recommendations are based on requirements in Colorado<sup>185</sup> and New Mexico.<sup>186</sup> Specifically, the commenter recommends that operators' initial and annual demonstrations include an estimate or measurement of the volume and content of vented or flared gas. This information should also be provided in the operator's annual report. As Colorado regulators have found, the commenter states that requiring records of the estimated duration and time of flaring helps prevent abuse and enhances enforcement.<sup>187</sup> The commenter adds that flaring data should also be publicly disclosed.

Response II-6-54: EPA concluded that pre-approval of flaring activity provides an excessive burden on both the owners and operators and the Agency, so the final rule does not include such provisions. The final rule does include specific circumstances and time frames when temporary flaring is allowed. Specifically, these are:

- For equal to or less than 24 hours during a deviation caused by malfunction causing the need to flare.
- For equal to or less than 24 hours during repair, maintenance including blow downs, a bradenhead test, a packer leakage test, a production test, or commissioning.
- For (a)(1) and (b)(1), through the duration of a temporary interruption in service from the gathering or pipeline system, or 30 days, whichever is less.
- For 72 hours from the time that the associated gas does not meet pipeline specification, or until the associated gas meets pipeline specifications, whichever is less.

These provisions are at §60.5377b((d)(1) through (4) and §60.5391c((c)(1) through (4) of EG OOOOc.

Comment: Commenter (2428-CO-LGC) asserts that the technical infeasibility exemption places a significant compliance monitoring burden on EPA, or states with delegated air quality programs such as Colorado. While an operator's certified demonstration must be signed and certified as to its truth, accuracy and completeness, there is no requirement that EPA review and approve this demonstration prior to an operator flaring. Rather, operators must retain records of the certified demonstration and provide it to EPA as part of annual reporting. According to the commenter, this raises the possibility that flaring will occur in the absence of a truthful, accurate, complete, or otherwise adequate demonstration. For EPA to identify any problems with the certified demonstration, EPA must review the operator's certified demonstration – this review will necessarily occur after an operator has flared, and even routinely flared for potentially a considerable amount of time. The commenter states that this opens the door to extended periods of flaring and pollution in violation of the rules.

Response II-6-55: The points made by the commenter appear to be somewhat contradictory. They are expressing concern over the burden placed on EPA and delegated agencies with the proposed infeasibility structure while also suggesting approval of each infeasibility determination prior to flaring being allowed, which would increase the burden. EPA believes that

---

<sup>185</sup> 2 Colo. Code Regs. § 404-1-903.d.(2) (2023).

the severe penalties that could be imposed on both the owner operator and the engineer that signs the certification are a sufficient deterrent for fraudulent infeasibility claims.

#### 6.2.4.5 Control Device Requirements (Inclusive of Flares)

Comment: Commenter (2433-EDF et al) states that in situations where flaring occurs, operators would be required to route associated gas through a closed vent system that meets the requirements proposed at 40 CFR 60.5411b(a) and (c) to a control device that reduces emissions by at least 95 percent and meets the conditions of 40 CFR 60.5412b(a)-(c).<sup>188</sup> The commenter strongly supports these requirements, which the commenter believes are critical for addressing the commonly-observed problems from inefficient, malfunctioning, and unlit flares. Below, the commenter explains why EPA's proposed control device requirements are necessary and suggest additional improvements.

Commenter (2433-EDF) states that the problem of unlit and malfunctioning flares is a well-documented and prevalent issue that is a significant source of methane emissions. EDF scientists have assessed flare performance in the Permian Basin with a series of helicopter-based infrared camera surveys.<sup>189</sup> Based on over 1,000 flare observations, approximately 5 percent of large flares are unlit and venting gas at any given time, and another 5% have visible slip of methane or other hydrocarbons—meaning the flare is only partially combusting the methane and the rest is escaping to the atmosphere.<sup>190</sup> On-the-ground flare combustion efficiency is thus much worse than EPA has assumed and what regulatory standards require.<sup>191</sup> Flares are consequently one of the largest sources of methane in the Permian Basin, and the latest surveys have found even worse performance among smaller, intermittent flares.<sup>192</sup>

Commenter (2433-EDF) states that other recent studies have confirmed that unlit or malfunctioning flares are one of the largest sources of methane emissions.<sup>193</sup> A study consisting of in situ measurements of lit flares found an average combustion efficiency of 91 percent for flares in the Permian Basin.<sup>194</sup> When accounting for unlit flares, the study that found average efficiencies of flares across major production basins range between 85 percent and 93 percent.<sup>195</sup> Multi-basin research has identified unlit flares across the entire country, and a Permian Basin study using flights conducted in 2020 found 5 percent of all active flares were unlit.<sup>196</sup>

Commenter (2433-EDF) states that improved control device performance is feasible and already required by leading states. For example, the commenter reports that Colorado requires operators

<sup>196</sup> David R. Lyon et al., Concurrent Variation in Oil and Gas Methane Emissions and Oil Price During the COVID-19 Pandemic, 21 Atmos. Chem. Phys. 6605 (2021), <https://acp.copernicus.org/articles/21/6605/2021/>.

to use an enclosed combustion device with a design destruction efficiency of at least 98 percent for hydrocarbons.<sup>197</sup> And New Mexico requires control devices used to abate well completion emissions either meet a 95 percent or 98 percent destruction efficiency. Specifically, if an operator uses an enclosed combustion device or thermal oxidizer, the destruction efficiency must be at least 98 percent for hydrocarbons.<sup>198</sup> If operators use a different type of control device (e.g., a flare), it must have a control efficiency of at least 95 percent for hydrocarbons.<sup>199</sup>

Commenter (2433-EDF) strongly supports EPA's improved control device requirements, which the commenter believes will help address the serious problems posed by unlit and malfunctioning flares. By using the pilot and flow monitoring devices in combination with one another, the commenter states that operators will be able to measure the amounts of combusted and vented gas during periods in which the flare is unlit. In 2021, only 20 percent of flare units across in the Permian basin across all industry segments had continuous flow monitoring according to the Greenhouse Gas Reporting Program (GHGRP).<sup>200</sup> The proposed requirements will improve the accuracy and reliability of the reported data, while enabling operators to timely address flare malfunctions. The commenter contends that the addition of continuous monitoring requirements of the pilot light and gas flow rate are significant and low-cost improvements that will help ensure proper combustion and will also support EPA improving the reporting of unlit flare emissions.

Commenter (2433-EDF) points out the two exemptions to the flow rate requirement that the EPA has provided. The first is available if an engineering assessment of the sources vented to the flare indicates that the maximum gas flow rates would not exceed the maximum flare tip velocity. The second is available if a backpressure preventer is installed which is set to operate at or above the minimum inlet gas flow rate. While ensuring gas flow rates are below the maximum flare tip velocity will help maintain efficient combustion, the commenter believes that the engineering assessment and subsequent exemption from the flow monitoring requirement hampers EPA's ability to quantify and address emissions from unlit flares. The commenter states that only when both the pilot light and gas flow of the flare stack are continuously monitored can operators accurately report the amount of gas emitted while a flare is unlit. Given the high rate of unlit flares in the Permian,<sup>201</sup> Eagle Ford, and Bakken formations,<sup>202</sup> flow monitoring of flares is necessary in all cases. The commenter urges EPA to ensure that in all circumstances, both continuous monitoring of the pilot light and the flow rate occur, which are necessary to enabling an accurate and empirical assessment of flared gas emissions and an understanding whether flares are unlit. The commenter believes there should be no exemptions from these two requirements given the high rate of observed unlit flares.

Commenter (2433-EDF) also supports the requirements for no visible emissions and monthly monitoring using Method 22. The commenter adds that EPA could also consider alternative

<sup>201</sup> Lyon et al., Concurrent Variation, *supra* note 527.

<sup>202</sup> Plant et al., *supra* note 174.

monitoring technologies and methods that would achieve equivalent or superior results. The commenter believes this monitoring requirement, paired with the control device monitoring the commenter recommends during leak detection and repair (LDAR) surveys described in Section IV.B of their comment letter, will help ensure that unlit and malfunctioning flares are quickly detected and returned to compliant operating status. The commenter contends that Method 22 monitoring can be conducted at the same time as LDAR surveys and therefore poses little-to-no additional burden on operators.

Response II-6-56: EPA acknowledges the support of the commenters, as well as the concerns related to flaring. The final rule only allows routine flaring of associated gas in limited circumstances, so it will effectively reduce the amount of flaring in the US. The final rule also includes enhanced compliance requirements to ensure that flares are operating properly. This is discussed in more detail in Section 17.2 of this document.

Comment: Commenter (2218-TCEQ) supports the continued use of 40 CFR 60.18 requirements and monitoring to demonstrate 98 percent destruction efficiency for flares and vendor information for other control devices. The commenter's authorization mechanisms for flares closely match 40 CFR 60.18 requirements and allow for the use of an automatic pilot. The commenter recommends that the use of an automatic pilot continues to be an option for non-pressure-assisted flares. Also, the commenter notes that many remote sites only have field gas as an option to use in a continuous pilot. Field gas may have a high concentration of hydrogen sulfide, so using a continuous pilot in these situations may lead to increased emissions of hydrogen sulfide and sulfur dioxide. In addition, the commenter states that the remoteness of and lack of electricity for some sites may present logistical barriers complicating or preventing the implementation of continuous monitoring. The commenter supports the use of temporary control devices for situations when associated gas could not be routed to a sales line or used for other beneficial purposes. The commenter explains that some sites may have permanent control devices for these scenarios; however, temporary controls can be used to minimize emissions during planned maintenance, startup, and shutdown activities. Emissions from these temporary controls are permitted as an alternate operating scenario, as a part of normal operations.

Response II-6-57: The final rule includes enhanced compliance provisions to ensure that flares meet the requirements in §60.18. This applies both to flares used to routinely reduce associated gas emissions, as well as flares that are used temporarily when the primary option (e.g., routing to sales or other beneficial use) is unavailable. However, as final NSPS OOOOb rule addresses emissions of VOC and methane, and the final presumptive standards in EG OOOOc address methane emissions, emissions of hydrogen sulfide and sulfur dioxide created in the flare are not covered.

Comment: Commenter (2237-NDIC) states that for control devices used to comply with emissions standards at well facilities in cases where associated gas is not otherwise sold or routed to a beneficial use, the supplemental proposal requires a full Method 25A test for the control device to determine the 95 percent methane reduction requirement in 40 CFR 60.5412c(a)(1)(i). The commenter has previously commented that due to issues with sales line access that control devices are required by state law at sites even if a sales line is available, in

case of situations where access is cutoff due to pipeline maintenance/emergencies, pressure issues, or lack of takeaway capacity within the pipeline itself.

Commenter (2237-NDIC) states that North Dakota state law requires that organic compounds gases and vapors be burned by a flare or an equally effective control device (except when from an emergency vapor blowdown system or emergency relief system), so essentially every well site that could emit "organic compounds gases and vapors" (North Dakota Administrative Code Chapter 33.1-15-07-02) has a flare of some type.

Commenter (2237-NDIC) states that is concerned that the testing requirements would put an undue burden on operators operating what is essentially a backup device to safely dispose of the gas and prevent venting during such upsets and other temporary disruptions. The commenter requests that control devices used temporarily when associated gas cannot be sold or otherwise routed for beneficial use be exempted from the operational and performance testing requirements.

Response II-6-58: Based on comments received and information available to the Agency, EPA clearly understands that in situations where the associated gas is routed to a sales line or used for another beneficial purpose, situations occur that will cause the primary option of using the associated gas to be unavailable. As discussed in response to many other comments in this section, the final rule allows the associated gas to be routed to a flare or control device in these temporary situations. However, it is evident from the comments that this is not a rare or uncommon situation. Given the potential frequency of such occurrences, and the potential significant level of cumulative emissions, EPA concluded that is necessary to ensure that the flare or control device to which the associated gas is temporarily routed is operating properly and is achieving the desired reduction in emissions. Therefore, no change was in the final rule in response to this comment.

Comment: For wells where associated gas from the separator is designed and configured to be recovered, commenter (2428-API) supports simplification of the requirements that focus on the short periods of time when gas is not recovered for sale, injection, or reuse. Specifically, the commenter supports flaring the gas by using a permanent or temporary control device that achieves 95 percent efficiency during periods of time when the associated gas is routed to the control device. In this scenario when a well that is configured to route gas to sales or for reinjection can no longer recover the gas for its primary use, the gas should be immediately routed to the flare as soon as practicable, without the need for a technical infeasibility demonstration.

Response II-6-59: The final rule is consistent with the concepts suggested by the commenter. See Response II-6-6 in this Chapter and Section XI.F.2.f of the final rule preamble.

Comment: Commenter (2360-Devon Energy) encourages EPA to distinguish between “routine” and “non-routine” flaring events. While the commenter believes it is appropriate to restrict the routine flaring of associated gas, if the ability exists to provide a demonstration of infeasibility for unique circumstances, non-routine flaring may occur due to any number of extenuating circumstances beyond the reasonable control of the operator. The commenter encourages EPA to

consult with operators to properly characterize or define “routine” and “non-routine” flaring of associated gas in the final rule and allow for more streamlined notifications in situations where “non-routine” flaring may occur.

Commenter (2409-BP America Incorporated (BP)) urges EPA to consider defining routine and non-routine flaring to account for circumstances where flaring devices are being used to combust emissions that would otherwise be vented, particularly where EPA seeks to limit the scope of safety flaring for non-routine purposes by narrowly defining permissible scenarios for safety flaring.

Commenter (2394-Earthworks) urges EPA to eliminate pollution from routine flaring except in emergency situations and to define the term “emergency” clearly and narrowly. The commenter recommends that exemptions only be applicable to only short-term and temporary flaring. They further recommend that EPA also consider adding a certified technical infeasibility demonstration that requires an independent third party to conduct the demonstration and should require additional documentation to prove that no other gas recovery options are available.

Response II-6-60: The final rule has distinguished routine flaring and temporary flaring, and temporary flaring is allowed in specified situations. See the responses to II-6-54 and II-6-6 and Section XI.F.2.f of the final rule preamble.

Comment: Commenter (2241- Utah Department of Natural Resources (UDNR)) states that there is no need for further federal regulations, as the state already has rules in place for managing methane emissions. In creating an overlay to this state rule, the EPA will only create a difficult process of state approval and enforcement of its own requirements, states the commenter. By way of example, the commenter explains that Utah has specific rules governing the venting and flaring of associated gas from oil wells.<sup>203</sup> The commenter explains that the rule has been in place for nearly 40 years (with only minor modifications) and the state’s petroleum industry has adapted well to the requirements of the rule. Further, the commenter states that owners and operators understand that the Utah Division of Oil, Gas and Mining (DOGM) will work collaboratively to offer reasonable solutions to gas venting/flaring situations that both prevent waste of resource while economically producing from wells that may otherwise sit idle or be plugged prematurely.

Response II-6-61: EPA appreciates the robustness of Utah’s state rules to reduce methane emissions and applauds these efforts. However, the NSPS OOOOb and EG OOOOc are national-level rules developed under the authority of the Clean Air Act. When Utah is adopting the emission guidelines in EG OOOOc into their state rules, strong state regulations will make adoption of state guidelines less disruptive for operators than would otherwise be the case in the absence of such standards.

---

<sup>203</sup> See Utah Administrative Code R649-3-20, Gas Flaring or Venting.

#### 6.2.4.6 Compliance Timeframe for Flaring Restrictions

Comment: Commenter (2360-Devon Energy) reports that they are actively working to reduce flaring of associated gas across each of its operating areas and has committed to eliminate routine flaring, as defined by the World Bank, by 2030. Since the commenter's standard practice is to only bring wells online where adequate sales line capacity exists, the commenter supports the restriction of the routine flaring of associated gas from oil wells that are considered "new" sources. The commenter encourages, however, the EPA to recognize the infrastructure challenges that may affect "existing" sources, and suggests 2030 as an appropriate compliance timeframe, consistent with the World Bank, which many operators already commit to or align with in voluntary initiatives.

Response II-6-62: EPA greatly appreciates the efforts by this commenter to pro-actively eliminate routine flaring in the absence of a federal regulation or guidelines. The final rule is consistent with the approach being taken by this company and therefore, should not impose restrictions that were not already being undertaken by the company to improve the environment.

#### ***6.2.5 Beneficial Use/Useful Purpose***

Comment: Commenter (2254-Permian Basin Petroleum Association (PBPA)) states that for wells producing associated gas, BSER is routing to a sales line, onsite use of gas and other "useful purposes" according to the proposed rule. The commenter contends that the EPA lacks authority in the CAA to render judgments on "useful purposes." After all, if an operator burns gas in a flare that has a 98 percent efficiency or burns it as fuel in a generator that also has a 98 percent efficiency, those circumstances have the same emissions. The commenter suggests that EPA leave to state agencies with jurisdiction over control of state resources what "useful purposes" or "beneficial uses" are. With that being said, the commenter believes EPA should allow a broad range of onsite beneficial purposes, and the commenter supports EPA's conclusion that "beneficial uses of the associated gas"—such as on-site use or reinjection into another well for enhanced oil recovery—should be deemed "equivalent" to the identified BSER of routing the gas to a sales line. To ensure consistency with corresponding state regulations, the commenter suggest that EPA could draw upon state definitions of beneficial purposes, such as those used in New Mexico.<sup>204</sup>

Response II-6-63: EPA points out a significant flaw in the commenter's example. If the associated gas is flared and a generator is also used onsite, there will be emissions resulting from both the combustion of the associated gas in the flare and the combustion of the fuel for the generator. Thus, if the associated gas is used as the fuel for the generator the emissions will be 50 percent less.

Also, while EPA disagrees with the assertion by the commenter regarding EPA's authority, we do believe that limitations should not be placed on "beneficial use". The specific uses that were specified in §60.5377b(b)(2) of the proposed rule and §60.5391c(b)(1) of the emission guideline

---

<sup>204</sup> 19.15.27.9 NMAC.

(methane pyrolysis, compressing the gas for transport to another facility, conversion of gas to liquid, and the production of liquified natural gas) have not been retained in the final rule.

Comment: Commenter (2326-AXPC) suggests that the EPA not require consideration of predetermined beneficial uses for oil well associated gas, and, if EPA retains such a list, any included beneficial use must be commercially viable. The commenter states that the EPA proposes that operators must certify that use of “recovered gas for another useful purpose that a purchased fuel or raw material would serve” is not feasible “due to technical or safety reasons” before the operator may control associated gas onsite. They add that EPA proposes the feasibility analysis must include consideration of using gas for “methane pyrolysis, compressing the gas for transport to another facility, conversion of gas to liquid, and the production of liquified natural gas.” The commenter fully supports the beneficial use of natural gas where reasonably feasible and cost-effective and further supports development of additional technologies that would provide a broader range of potential beneficial uses. The commenter believes that the EPA’s inclusion of a predetermined list of uses suggests EPA has determined each of these beneficial uses is technically feasible, commercially available, and appropriately included as part of associated gas BSER. The commenter contends that, EPA, however, has provided no support for this apparent determination.

Accordingly, commenter (2326-AXPC) requests that EPA remove this list of beneficial uses. Further, to the extent EPA maintains such a list of beneficial uses, the commenter requests that EPA remove any unproven “emerging technologies.” The commenter states that CAA section 110(j) provides the appropriate pathway for sources to evaluate emerging technologies to meet NSPS. According to the commenter, requiring evaluation of unproven emerging technologies sidesteps both the BSER demonstration and the CAA section 110(j) process in violation of the CAA.

In the preamble, the commenter (2326-AXPC) reports that the EPA solicits comment on potential emerging technologies that could expand the universe of beneficial gas use and provides two examples of what it considers to be emerging technologies – methane pyrolysis and condensing gas and transporting it to other sites for use. They add that the EPA cites two comments in support of these emerging technologies. One commenter – a company in development of a methane pyrolysis solution – suggests that EPA should adopt methane pyrolysis as an express useful purpose in the rule but precedes this suggestion with an admission that its methane pyrolysis solution is neither scaled nor readily available for implementation. The commenter then requests that EPA grant a performance standard waiver for its unproven technology.<sup>205</sup> In fact, the commenter indicates its technology is in early stages of testing and has not been tested in a field setting.

Commenter (2326-AXPC) fully supports development of methane pyrolysis as a commercially scaled and available technology to reduce gas flaring; however, it is not commercially available today, and EPA should not require every beneficial use analysis to evaluate such an unproven solution. While one-off methane pyrolysis use may be technically possible, the commenter notes that methane pyrolysis is not a commercially feasible solution on the scale of implementation that may be required under this proposed rule. The commenter believes that the EPA’s express

---

<sup>205</sup> See Document ID No. EPA-HQ-OAR-2021-0317-0594, -0595.

inclusion of it as a beneficial use in the final rule suggests methane pyrolysis is feasible (including on a commercial scale), while it is not, and would provide a windfall to this commenter.

The company supporting methane pyrolysis suggests a couple of pathways for approving the use of its methane pyrolysis technology – a CAA section 110(j) waiver and a commercial demonstration permit. Commenter (2326-AXPC) encourages the company to evaluate these paths; however, they believe that neither is a pathway to including its product as a required consideration in a NSPS or EG control evaluation.

Regarding condensing gas and transporting it offsite for use, EPA cites one comment that makes no mention of condensing gas. The commenter (2326-AXPC) notes that they can only guess that EPA means to reference the one sentence in the comment that suggests gas can be compressed and trucked to a processing plant or other location with no support for whether this solution is feasible or safe.

While commenter (2326-AXPC) believes that EPA should not expressly include any enumerated beneficial use and leave operators to determine the universe of beneficial uses reasonably available, if EPA includes any list of beneficial uses, the commenter requests that EPA remove technologies that are not proven and/or commercially available, including methane pyrolysis and condensing gas and transporting it offsite. The commenter states that including these technologies in a list of feasible beneficial uses that operators must consider in every associated gas control analysis sidesteps the requisite BSER analysis in violation of the CAA.

With respect to converting gas to liquid, commenter (2326-AXPC) provides that current gas liquefaction technology is capable of converting only the heavier-end gaseous hydrocarbons to liquid, requiring the control of methane and potentially other lighter-end hydrocarbons that remain in the gaseous phase following processing. Thus, gas to liquid conversion will not provide for complete use of the gas stream. Additionally, the equipment necessary to process gas to liquids is expensive to deploy and maintain and of limited commercial availability. While gas to liquid conversion may be viable in some instances, it is not a universally viable solution. Accordingly, the commenter requests that EPA remove gas to liquids conversion from the list of beneficial uses that operators must consider.

Finally, commenter (2326-AXPC) states that the EPA includes the production of liquified natural gas in its list of beneficial uses. While operators have removed natural gas liquids from field gas using equipment deployed to or near well sites, the commenter reports that this equipment has proven to be an unreliable permanent solution for several reasons, including vendor availability and safety. The commenter supports the expanded utilization of equipment that can extract natural gas liquids from field gas in the upstream sector; however, they believe it unnecessary to expressly include this as a consideration in a technical infeasibility analysis. Accordingly, the commenter requests that EPA remove the production of liquified natural gas from the list of required beneficial use considerations.

Response II-6-64: We agree with the commenters that limitations should not be placed on “beneficial use”. The specific uses that were specified in §60.5377b(b)(2) of the proposed rule

and §60.5391c(b)(1) of the emission guideline (methane pyrolysis, compressing the gas for transport to another facility, conversion of gas to liquid, and the production of liquified natural gas) have not been retained in the final rule.

Comment: Commenter (2428-API) suggests that using associated gas as purge or pilot gas for a control device should be considered beneficial use. Pilot and/or purge gas allow flares and other control devices to operate safely and effectively to reduce emissions. Furthermore, the commenter notes that the NSPS OOOOb and EG OOOOc require flares and enclosed combustion devices to have a continuously burning pilot flame when the flare is in use. Enclosed combustion devices are also required to maintain a minimum inlet flow rate, which may require supplemental fuel. In other words, pilot and purge gas are part of the fuel requirements for a flare or enclosed combustion device and are not controlled vent streams.

Since the use of associated gas as an onsite fuel source is one of the proposed beneficial use options in 40 CFR 60.5377b(a)(2), the commenter (2428-API) requests that EPA clarify that purge or pilot gas for a control device is considered part of onsite fuel use as shown in the following suggested edit to 40 CFR 60.5377b(a)(2) (underlined text indicates new text):

Recover the associated gas from the separator and use the recovered gas as an onsite fuel source, which may include using the recovered associated gas as purge or pilot gas for a control device or flare.

As an alternative, the commenter (2428-API) suggests that EPA could clarify that purge or pilot gas for a control device is considered a useful purpose option under 40 CFR 60.5377b(a)(3).

Response II-6-65: As discussed in Responses II-6-63 and 64 of this Chapter, EPA has removed the specific list of beneficial uses of associated gas that must be evaluated to allow innovative solutions and emerging technologies. However, in general, EPA does not believe that using the associated gas as a purge or pilot gas for a control device is an acceptable option. This represents a significant potential loophole via which associated gas could be routed to a flare or combustion device. However, the EPA recognizes that there could be limited circumstances where this represents a legitimate beneficial use. For example, if the volume of associated gas is very low and equivalent to the amount of pilot gas that would otherwise be used for the flare. Therefore, the final rule does not specifically prohibit this usage. However, EPA would heavily scrutinize any such usage.

Comment: Commenter (2248-NDPC) suggests that the EPA adopt a broad definition of beneficial use, and use the list as suggested possible beneficial uses and not be prescriptive. There are a lot of variables in the different oil and gas regions (e.g., weather, formations, distance to populated areas) that may make one beneficial use more effective than others. For example, in North Dakota, the weather is extreme. The formation is very tight and thin and not conducive to permanent storage of natural gas. There may not be nearby population centers that could take advantage of additional power generation. There may be other technologies that can be deployed to take advantage of waste heat from the flare gas to generate power for onsite use (e.g., Thermo Electric Generation).

Response II-6-66: As discussed in Responses II-6-63 and 64 of this Chapter, EPA has removed the specific list of beneficial uses of associated gas that must be evaluated to allow innovative solutions and emerging technologies.

Comment: Commenter (2218-TCEQ) supports emerging technologies as potential methods for controlling emissions from oil and gas facilities and recommends that the rules allow the use of emerging technologies as a recognized method of achieving a beneficial use for associated gas. The commenter reports that some companies use the associated gas as fuel for electric generating units or compress the gas and send it to another site for processing. The commenter believes that useful purpose should include, but not be limited to, uses or purposes that a purchased fuel or raw material would serve. The commenter also believes that useful purpose should not be explicitly defined in the rule language, and that the owner or operator can provide a demonstration or certification that they meet this criterion. Due to the unpredictable nature of technological advancement, the commenter believes it would be shortsighted for EPA to limit this aspect of the rule to only narrowly defined or specified processes or technologies. Certain technologies for reducing methane and other greenhouse gas emissions, such as gas compression for offsite transport, can also result in collateral emissions of other regulated pollutants which are subject to NAAQS.

Response II-6-67: As discussed in Responses II-6-63 and 64, EPA has removed the specific list of beneficial uses of associated gas that must be evaluated to allow innovative solutions and emerging technologies.

Comment: Commenter (2283-Endeavor Energy) generally supports EPA's conclusion that "beneficial uses of the associated gas" such as on-site use or reinjection into another well for enhanced oil recovery-should be deemed "equivalent" to the identified BSER of routing the gas to a sales line, and recommends that EPA allow a broad range of on-site beneficial purposes in recognition that operators will need flexibility to pick the best option for their operations based on the particular well site.

Response II-6-68: As discussed in Responses II-6-63 and 64, EPA has removed the specific list of beneficial uses of associated gas that must be evaluated to allow innovative solutions and emerging technologies.

Comment: Commenter (2175-Crusoe Energy) recommends that their digital flare mitigation system (DFM) be included as an example of an emerging technology. The Proposal includes several examples of emerging technologies based on information provided by commenters in response to the November 2021 proposal. Specifically, EPA notes, "[e]xamples of such emerging technologies provided by commenters include methane pyrolysis and condensing the gas and transporting it to other sites for use." The commenter provides that their DFM technology is comparable to these provided examples as it also converts gas that would otherwise be flared into energy that can be used for high-powered computing. The DFM reduces methane emissions at a 99.9 percent efficiency, compared to an average combustion efficiency of only 91–93 percent in a flare, while simultaneously decreasing the carbon footprint of high-performance computing and removing datacenter load from the grid. The commenter states that

their DFM technology therefore provides a two-pronged emissions avoidance and can typically do so without cost to producers.

In addition, the commenter (2175-Crusoe Energy) explains that DFM technology provides additional environmental benefits. By reducing flaring and methane emissions, the commenter states it also helps to reduce levels of criteria air pollutants such as nitrous oxides (NO<sub>x</sub>), carbon monoxide (CO), and VOCs, which are linked to adverse human health effects. Relative to flaring, the DFM results in a 74 percent reduction in NO<sub>x</sub> emissions, a 95 percent reduction in CO emissions, and a 99 percent reduction in VOC emissions. Lower levels of methane emissions and these air pollutants also reduce the amount of ground-level ozone and improves air quality. By reducing these air emissions, the commenter notes that DFM further benefits the environment and advances EPA's environmental justice initiatives of reducing overall emissions in affected communities.

Commenter (2175-Crusoe Energy) concludes by requesting that DFM and similar technologies be considered an example of another beneficial use and that EPA provide clear guidance for operators and the states in any final rule so they know with certainty.

Response II-6-69: EPA agrees that the DFM system described by the commenter offers promise as beneficial use option for associated gas to eliminate the routine flaring or venting of associated gas. However, this statement does not indicate that EPA completely endorses DFM as an alternative to routing to a sales line for all applications. The commenter compares the impacts of DFM for a flare, which is not appropriate. An acceptable beneficial use must be comparable to routing to a sales line or using it as an onsite fuel source.

Comment: Commenter (2175-Crusoe Energy) points out that in the proposal, EPA notes that it interprets the third criterion, "used for another useful purpose", to include emerging techniques but is soliciting comment whether an additional criterion should be added to make this clear." The commenter responds to this solicitation by stating that they do not think additional criteria are necessary and is of the belief that the agency should leave the standard open and flexible to allow for future innovation that it may not be able to predict at this time. So long as a technology appears beneficial and can meet the BSER standard, the commenter believes it should qualify as a beneficial use. According to the commenter, rigid requirements or a complicated approval process would only stymie innovation. The commenter notes that many of the benefits achieved by current technologies (such as cloud computing) may not have even been considered 10 or 15 years ago, and many new benefits or uses for stranded gas may emerge in the upcoming years. To best address the climate crisis, the oil and gas industry needs new, innovative solutions in real time. The commenter contends that, given how time intensive it is for EPA to revise regulations or even to issue guidance as new technologies develop, it would be best for the agency, industry, and the environment if EPA's final rule allows broad latitude for new technologies to develop and help address emissions in the future.

Commenter (2175-Crusoe Energy) states that EPA's decision to confirm that the "used for another useful purpose" criterion includes emerging technologies is also consistent with the text and purposes of the CAA. The commenter provides that CAA section 111(a) of the Act provides that BSER should be determined after considering a variety of factors, including the cost of

emissions reductions, energy requirements, and health and environmental impacts. The D.C. Circuit has interpreted section 111(a) of the Act as authorizing EPA to “embrace[] consideration of technological innovation as part of [the BSER] balance” and as encouraging EPA to promote “the stimulation of technologies.” The commenter adds that the legislative history of the CAA likewise confirms that Congress intended BSER to “encourag[e] the development of innovative technological means of achieving equal or better degrees of control.” Indeed, Congress was so concerned with ensuring that EPA did “not stymie technological innovation” that it developed several pathways through which emerging technologies could be deployed even if they do not yet meet all BSER requirements, including, among other things, technology waivers under CAA section 111(j) and permitting the use of commercial demonstration permits.

Commenter (2175-Crusoe Energy) states that their DFM technology is already sufficient to satisfy the proposed 95 percent BSER, meaning that no waiver or demonstration permit would be needed. But the fact that Congress elected through CAA sections 111(a) and 111(j) to promote technological innovation confirms that EPA, when it promulgates any final rule, should make it unmistakably clear that (1) emerging technologies can be used to satisfy the “used for another useful purpose” component of BSER and (2) Crusoe’s DFM technology is a promising example of just such a “useful purpose.” Especially given the significant level of ongoing technological innovation in this area, the commenter believes that the EPA should use this opportunity to clarify that, unlike in generations past, terms like “beneficial use” and “another useful purpose” need not refer exclusively—or even primarily—to reallocating stranded gas for use as an onsite fuel source for the processing of other hydrocarbons. According to the commenter, the EPA should instead take advantage of its power to set flexible standards by crafting forward-looking, open-ended regulations that will encourage the use of DFM and other like technologies.

As explained above, commenter (2175-Crusoe Energy) does not believe that additional criteria are necessary or appropriate. However, to the extent EPA does include such criteria, the commenter states that their DFM technology should qualify because, as discussed above, it can demonstrate meeting the 95 percent emissions reduction rate, creates a beneficial use for gas, has been proven viable in the field, and is safe, reliable, and commercially available. The commenter therefore asks EPA to make clear in the preamble that DFM or similar technologies meet EPA’s criteria to avoid regulatory uncertainty.

Response II-6-70: EPA agrees that the rule should allow and encourage the use of emerging technologies to use the associated gas in a beneficial manner to avoid venting or flaring. However, the commenter has mischaracterized the BSER determination. BSER, for both new and existing sources, was determined to be routing to a sales line. As discussed in the supplemental proposal preamble (87 FR 74779), the EPA determined that beneficial uses of the associated gas for options that are equivalent in terms of emission reduction to the identified BSER. Therefore, as discussed in Response II-6-69, it is not appropriate to compare DFM or any other potential option to a flare, but rather it must be compared to routing to a sales line or using as an on-site fuel source.

Comment: Commenter (2175-Crusoe Energy) agrees with the recommendation that a list of examples should be included in the final rule for the purpose of regulatory clarity. The commenter would also request that DFM technology be included in any such list in the final rule.

They add that it should be made clear that this list should not be interpreted as exclusive or exhaustive, but rather intended to give operators and states examples of beneficial uses that EPA would accept in compliance with the standards of performance. Should EPA determine not to include such a list of examples, the commenter believes it should instead provide a clear and streamlined way for other beneficial uses to be pre-approved. This way, the regulated community will be better prepared to make the investments necessary to comply with the rule, new innovations with climate benefits will not be stymied by a time-consuming regulatory approval process, and EPA staff will not be overwhelmed with new administrative burdens.

Commenter (2175-Crusoe Energy) encourages EPA to provide the same list of emerging technologies as examples that states may use in their EGs. The commenter suggests that this should be done to provide clarity and consistency to the regulated community and to states as they develop their EGs.

Response II-6-71: See Responses II-6-69 and 70 of this Chapter.

Comment: Commenter (2175-Crusoe Energy) supports EPA’s proposal to use a BSER that allows for innovative solutions. According to the World Bank’s Global Gas Flaring Tracker Report, 144 billion cubic meters (bcm) of natural gas was flared in 2021. The commenter explains that much gas “could have potentially generated some 1,800-Terawatt hours (TWh) of energy—almost two-thirds of the European Union’s net domestic electricity generation.” Instead, it was burned away with no discernible value or purpose. However, the commenter suggests that the biggest problem with flaring is that it does not fully combust the methane in this wasted gas. As EPA has reported, over a 20-year timeframe, methane is over 80 times more potent than carbon dioxide as a greenhouse gas (GHG). “Oil and natural gas operations are the nation’s largest industrial source of methane,” and that methane “is responsible for approximately one-third of current warming resulting from human activities.” The commenter reports that Environmental Defense Fund’s Permian Methane Analysis Project found that three times more methane is leaked in the Permian Basin than EPA estimates. Most recently, a University of Michigan study of more than 300 flares found that flaring releases five times more methane in the U.S. than previously estimated.

Commenter (2175-Crusoe Energy) strongly supports EPA’s Proposal to broadly expand what is considered a “beneficial use”. While regulation plays an important role in limiting methane emissions, the commenter supports EPA’s approach of encouraging new technologies, private innovation, and site-specific solutions (particularly when a sales line is not available). This approach will help foster economic growth and energy security in an environmentally beneficial way during our energy transition.

Response II-6-72: See Responses II-6-69 and 70 of this Chapter.

Comment: Commenter (2257-Michigan Oil and Gas Association (MOGA)) provides discussion regarding the innate issues regarding bringing associated gas to a “useful purpose rather than flared”. The commenter notes that every producer would like the ability to sell all produced assets. On most occasions, the commenter states that the ability and cost are not feasible because of conflicting regulations, landowner & community objections, production sharing contract

(PSC) restrictions, and the associated cost of pipeline metering, compression, and transfer gate installation. The commenter explains that many wells drilled in the U.S. are not located at convenient spots. The inconvenient locations are in rural locations such as farmland, forests, and sparsely populated areas. Because these areas are remote and often isolated, transmission or gathering lines that collect gas are located closer to major distribution areas. The natural gas produced in these remote areas is referred to as “stranded gas”. The term “stranded” is used because the value of the gas will not pay for the pipeline needed to move the gas to a distribution line. If multiple wells are in a micro-geographic region, then connecting the flowlines to a distribution point, may justify the installation. However, landowners may object to having flowlines in their fields and local communities may not want subsurface piping down road easements, crossing driveways and stream crossings. So, the natural gas stays stranded, except for wellsite fuel or power generation. The commenter requests that the EPA discuss and clarify whether the Biden Administration is proposing financial, regulatory, and political support necessary to install natural gas lines to move stranded gas to a “useful purpose rather than flared”?

Response II-6-73: As discussed in the preamble for the final rule (Section XI.F.2), EPA recognizes that many wells were originally drilled in locations without the knowledge or expectation of a requirement that prohibits routine flaring. In these situations, the final emission guidelines and regulation allow the routing of the associated gas to a flare or control device if a demonstration is made (accompanied by a certification) that it is technically infeasible to route the associated gas to a sales line or use it for another beneficial purpose or inject or reinject it. Specifically, this is the case for existing wells under EG OOOOc modified and reconstructed wells under NSPS OOOOb, and new wells for which construction was commenced between the December 22, 2022, supplemental proposal and the date of publication of the final rule.

For new sources for which construction commences after the effective date of the rule, EPA concluded that, with the full knowledge and understanding of the final rule, owners and operators can plan ahead to ensure that one of the non-flaring options can be utilized. Therefore, the option to routinely flare is not allowed for new wells. Note that there is one caveat to this routine flaring prohibition is that new wells that commence construction for the first 6 months after the effective date of the final rule are allowed to routinely flare for a 2-year period, after which routine flaring is not allowed.

Comment: Commenter (2427-Utah Petroleum Association (UPA)) recommends that operators be allowed to use associated gas as an onsite fuel source and for onsite beneficial uses regardless of available gas takeaway pipeline capacity. The preamble to the supplementary proposal indicates that associated gas must be routed to a sales line and that only if access to a sales line is not available, the gas can be used as an onsite fuel source. However, the commenter believes that the final rules must allow use as an onsite fuel source and for onsite beneficial uses in any event, regardless of access to an available sales line or to available sales line capacity.

Commenter (2427-UPA)) states that oil and gas operations in the Uinta Basin do not have widely available access to electricity, and creating access would be very costly in most cases or not practical in other cases. Additional research into the feasibility of using solar power as a replacement for line electricity in the Uinta Basin has revealed that batteries will not charge or

operate successfully at some of the colder temperatures experienced in the Uinta Basin. For example, in Vernal, Utah, 21 days in January 2019 had low temperatures of 10 degrees Fahrenheit or lower and 22 days in the month had daytime high temperatures below freezing. 10 However, charge acceptance of batteries decreases at the cold temperatures and forcing high current to the batteries can build up pressure causing explosions of sealed batteries.<sup>11</sup>

Commenter (2427-UPA)) states that due to the waxy nature of the crude oil, operators must heat the separators and storage vessels to maintain the crude oil in a liquid and pumpable state. With the lack of available electricity, operators use associated gas to fire these heaters. Due to the lack of available electricity, operators also use associated gas to power the pump jack engines used for oil production. Operators also use associated gas to power other generators, wherever needed.

Moreover, commenter (2427-UPA)) states that if the final rule requires zero emissions pumps and controllers, the number of generators may increase; operators may need to use associated gas to operate engines needed for compressed air or to power local electricity generators to replace gas currently used to operate these devices. The use of associated gas in these manners is essential to efficient and successful production in the Uinta Basin. According to the commenter, these practices must be allowed to continue regardless of gas pipeline takeaway availability.

The commenter (2427-UPA) suggests that the regulatory language for NSPS OOOOb appears to allow these essential uses of associated gas in section 40 CFR 60.5377b. Similarly, they add that the language for EG OOOOc also appears to allow these essential uses of associated gas. The commenter supports the regulatory language as written in both rules. The commenter believes that any changes to this language to match the more restrictive wording of the preamble would severely restrict operations in the Uinta Basin and be detrimental to the economics of operation.

Response II-6-74: It EPA's intent that associated gas could be used as an onsite fuel source and for onsite beneficial uses regardless of available gas takeaway pipeline capacity. In the proposed rule any of the options listed in §60.5377a(a)(1),(2), (3) or (4) are equally acceptable compliance options. This is retained in the final rule, as well as in the EG OOOOc at §60.5391(a)(1) through (4).

### ***6.2.6 Allowance for Venting of Emissions***

Comment: Commenter (2241-Utah Department of Natural Resources (UDNR)) states that, for many operators, the decision to flare is largely dependent on the oil-to-gas price ratio, and the cost to capture and process the gas.<sup>206</sup> The commenter explains that while the added costs of flaring are likely the cheaper option when compared to the added costs of capturing, processing and sending the gas through a sales line (as this would require the construction of miles and miles of additional collection and distribution lines), there are still added costs, safety concerns, and other complexities associated with flaring. As such, the commenter would encourage that

---

<sup>206</sup> U.S. DOE, Developing Technologies for Upcycling Associated Gas into Higher-Value Products, U.S. Department of Energy, available at: <https://www.netl.doe.gov/sites/default/files/2020-12/Upcycling-Associated-Gas-into-Higher-Value-Products-12-2020.pdf> (2020).

exceptions be added to the proposed rule allowing for venting in certain situations where neither flaring nor redirecting gas to a sales line is a feasible option (such as on remote public lands).

Response II-6-75: EPA does not believe there are any circumstances that warrant routine venting of associated gas. Thus, there are no such allowances in the final rule. EPA does recognize, however, that there are temporary reasons that venting may be necessary. Thus, in the final rule and emission guidelines, venting is allowed under the following circumstances and for the specific durations.

- For up to 12 hours per incident to protect the safety of personnel.
- For up to 30 minutes per incident during bradenhead monitoring.
- For up to 30 minutes per incident during a packer leakage test.

However, the final rule and emission guidelines only allow such venting for a total of 24 hours each calendar year. For more information, see the discussion in section XI.F.2.f of the final rule preamble.

Comment: Commenter (2433-EDF et al) touches on circumstances where venting may be warranted. The commenter acknowledges that venting may be necessary for safety.<sup>207</sup> In addition, they add that operators may need to vent for a very brief period during downhole monitoring activities, namely when monitoring the downhole pressure during bradenhead monitoring and packer leakage tests. The commenter reports that both Colorado and New Mexico allow operators to vent or flare during bradenhead monitoring.<sup>208</sup> Colorado limits bradenhead monitoring to 30 minutes.<sup>209</sup> New Mexico also allows operators to flare or vent during packer leakage tests.<sup>210,211</sup>

Response II-6-76: As discussed in Response II-6-75, the final rule allows temporary venting in specified circumstances,

### ***6.2.7 Access to a Sales Line***

Comment: Commenter (2248-NDPC) suggests that, when soliciting comments on what the definition of “access to a sales line” should be, the commenter reminds the EPA that in most cases, the midstream company that designs, builds, and operates the gas gathering system (sales line) and gas processing plants is not the same as the well owner and operators, landowners, and mineral lease owners. One entity has little control over the other. In addition to commercial availability/viability, a potential gas disposition method must be economically viable. For example, the commenter explains that a remote well site operator could identify a pipeline with sufficient capacity, but the closest pipeline with sufficient takeaway capacity maybe 100 miles away. The cost to build, maintain, and operate the connecting pipeline may well exceed the total

---

<sup>207</sup> 2022 Joint Environmental Comments, supra note 1, at 181.

<sup>208</sup> N.M. Code R. § 19.15.27.8.D.(4).(i).

<sup>209</sup> Colo. 800/900/1200 SBP, supra note 450, at 86.

<sup>210</sup> N.M. Code R. § 19.15.27.8.D.(4).(j).

<sup>211</sup> Expert report of Thomas Alexander, supra note 435, at 6.

value of the gas that could be sold. According to the commenter, while it would be technically feasible to build this connecting pipeline, it is not an economically viable solution.

Commenter (3845-ND Congress) reports that energy producers must manage increasing volumes of gas associated with oil production, and the proposed rule's restrictions on flaring of associated gas would disproportionately impact operators in ND. While natural gas pipeline capacity in the state has grown over the years, based on the remote nature of operations, there are still cases where natural gas pipelines are not readily available, particularly on federal and tribal lands where permitting issues impede infrastructure deployment. Even when available, they add that issues such as product incompatibility with infrastructure, third-party maintenance, market conditions, or extreme cold weather can all restrict an operator's ability to send gas to pipelines for sales. Similarly, the unique geography and extreme cold weather in the region can make other beneficial uses of the gas infeasible.

In some cases, the commenter (3845-ND Congress) contends that an alternative to flaring may impose greater costs than the value of the gas itself. In such situations, operators cannot be expected to forgo flaring which eliminates 98 percent or more of the methane. To do so would be inconsistent with the mandate of the CAA, which expressly requires consideration of costs by EPA when establishing NSPS. As a result, the commenter believes that EPA's approach will leave many operators with no option but to shut-in production. According to the commenter, any reduction in production would also reduce royalties, directly impacting the livelihoods of North Dakotans and members of the Three Affiliated Tribes that rely on this key source of revenue. Further, the commenters note that, if operators are unable to comply with EPA's burdensome regulations in North Dakota, they may shift operations out of state, drastically reducing production and associated income.

Lastly, the commenter (3845-ND Congress) reports that, in fiscal year 2022, taxes on North Dakota oil and gas operations generated over two billion dollars to fund services for the people of North Dakota. These revenues support schools, infrastructure, improvements such as flood control projects, environmental reclamation activities, and tax relief for residents throughout the state. According to the commenter, any regulation that reduces or disincentivizes production operations will reduce available funds for these important efforts and harm North Dakotans.

Response II-6-77: EPA recognizes that situations exist for many existing wells that make routing the associated gas to a sales line or for one of the other approved purposes may be infeasible. For that reason, the final emission guidelines allow owners and operators to routinely route the associated gas from an existing well to a flare or control device, provided that they demonstrate it is technically infeasible to route it to sales line, use it as a fuel or for another beneficial purpose, or inject or re-inject it. The final rule does not, however, allow the routine flaring of associated gas from new wells. Therefore, moving forward, owners and operators of wells to be drilled in North Dakota (and elsewhere) will need to plan ahead so that the associated gas may be used for one of the approved purposes.

EPA points out that the commenters are overlooking the value of the options to BSER that EPA is allowing. When considering the economics of the well, it would be inappropriate for EPA to set BSER based only on "the total value of the gas that could be sold." In the example of a 100

mile gathering line, it is likely that it would be in the interest of the source to employ one of the alternatives to BSER.

Comment: Commenter (2414-Carbon Mapper and RMI (CM-RMI)) agrees that flaring variances last for a finite period and/or volume (whichever is reached first). The commenter explains that new usable sales pipelines or other infrastructure, feasible delivery points for compressed gas, technology, or discoveries in additional beneficial uses may present themselves as available later in the asset's life. The commenter also supports that such triggers (variance age, volume flared, or new developments/innovations) should trigger a new, full, and certified review similar to original variance requests.

Commenter (2414-CM-RMI) supports EPA in requiring operators to attempt to access an existing sales line, the preferred standard control option, and facilitate alternative off-site transport and use of associated gas. Furthermore, since sites operate for decades and sales lines are typically not under the control of the well owners and operators, the commenter recommends that operators include an attempt to collaborate with gathering system owners regarding both upcoming or proposed sales line projects and production projects, as this may inform and optimize sales lines route engineering. The commenter notes that, if enough operators collaborate with gathering system owners, gathering system owners may respond to the demonstrated need of sales pipelines in unserved/underserved areas. Otherwise, the commenter suggests that pipelines may not be developed due to a lack of discussion and identification of opportunity.

Response II-6-78: For existing associated gas wells, along with reconstructed or modified wells and those that commenced construction between the supplemental proposal and the final rule, owners and operators are allowed to routinely route the associated gas to a control or flare if a demonstration is made that it is technically infeasible to route to sales or one of the other approved options. However, consistent with the recommendations by the commenters, the final rule requires that this determination and certification be revisited every year because solutions, such as the building of new infrastructure, could have occurred.

## 6.3 Well Completions

### 6.3.1 Applicability

Comment: Commenter (2408-CO LGC) recommends that EPA extend its reduced emission completion (REC) requirements to non-hydraulically fractured wells, as is the case in Colorado<sup>212</sup> and New Mexico.<sup>213</sup> The commenter notes that, per the Statement and Basis for Colorado's rules "the Commission intends for its reduced emission completion standards to apply to all wells, regardless of whether they are hydraulically fractured."<sup>214</sup> New Mexico's rules similarly apply to all wells.<sup>215</sup> The commenter contends that the EPA gives no reason for exempting non-hydraulically fractured wells from controlling emissions during completions.

---

<sup>212</sup> Id. at 903.c.(1).

<sup>213</sup> N.M. Code R. §19.15.27.8.C.

<sup>214</sup> COGCC SBP, 800/900/1200 Rule Series, at p. 81.

<sup>215</sup> N.M. Code R. §19.15.27.8.C.

Response II-6-79: The EPA has not extended the REC requirements that apply to hydraulically fractured wells to non-hydraulically fractured wells in the NSPS OOOOb final rule. The EPA does not have information to support the extension of well completion REC requirements to non-hydraulically fractured wells under NSPS OOOOb.

### ***6.3.2 Well Completions Requirements***

Comment: Commenters (2408-CO LGC, 2433-EDF et al) request that EPA follow Colorado's and New Mexico's example and prohibit venting during the initial flowback stage of completions.

The commenters (2408-CO LGC, 2433-EDF et al) specifically recommend that EPA follow the example set by Colorado and New Mexico, which require control of venting during initial flowback. They provide that the Colorado Air Quality Control Commission requires operators route flowback to enclosed flowback vessels after drill-out, and route emissions from flowback vessels to a device that achieves “a hydrocarbon control efficiency of at least 95%” or to a combustion device with “a design destruction efficiency of at least 98% for hydrocarbons.”<sup>216</sup> Colorado Oil and Gas Conservation Commission rules further require that operators “enclose all [f]lowback vessels...” and adhere to the Air Quality Control Commission rules requiring the use of enclosed and controlled flowback vessels.<sup>217</sup>

The commenters (2408-CO LGC, 2433-EDF et al) add that as part of the development of the Air Quality Control Commission rule, the Colorado Department of Public Health, and the Environment (CDPHE) conducted a cost-benefit analysis and found its completion requirements were incredibly cost effective, even assuming a worst-case scenario. To estimate the costs of its rule, Colorado assumed operators needed 10 to 15 500 barrel of crude oil (bbl) flowback vessels at a multi-well production facility. The CDPHE assumed new storage vessels would cost \$30,500 and used storage vessels would cost between \$7,000 and \$19,000; \$1,000 in one-time costs; and \$500 in annual operation and maintenance costs, assuming a 15-year lifespan for flowback tanks. Colorado found its annualized cost per flowback tank would be \$4,830 and, assuming an average of 12 flowback tanks, the annualized costs per wellsite are \$57,958.<sup>218</sup>

Commenter (2433-EDF et al) notes that they reviewed Colorado's estimate and found that it was reasonable and even likely conservative, as it represented a “‘worst-case cost effectiveness estimate’ because it assumed an operator would use the 12 flowback tanks only once, at one well site. According to the commenter, it is more likely operators would use the same flowback tank at multiple wells for the lifetime of the tanks.”<sup>219</sup> Relying on the CDPHE cost-effectiveness analysis, the commenter evaluated the policy prohibiting venting during the initial flowback

<sup>218</sup> CDPHE, Air Quality Control Commission, Cost Benefit Analysis for Proposed Revisions to AQCC Regulation No. 7, p. 23 (September 4, 2020), available at [https://downloads.regulations.gov/EPA-HQ-OAR-2021-0668-0758/attachment\\_5.pdf](https://downloads.regulations.gov/EPA-HQ-OAR-2021-0668-0758/attachment_5.pdf).

<sup>219</sup> New Mexico Env. Improvement Board, In the Matter of Proposed New Reg. 20.2.50 NMAC-Oil and Gas Sector-Ozone Precursor Pollutants No. EIB 21-27 (R), Direct Testimony of Thomas Alexander, at 14 (2021)

stage in New Mexico.<sup>220</sup> The analysis found that controlling emissions during the initial flowback stage could be implemented at a cost of \$53.79 per ton methane. The commenter also estimated the cost-per-ton to reduce VOC emissions under this policy. Using the statewide average methane-to-VOC ratio for completions, the commenter estimated the cost effectiveness to be \$259.48 per ton VOC reduced. As such, the commenter contends that requiring control of emissions during the initial flowback stage is overwhelmingly cost-effective.<sup>221</sup>

Commenter (2408-CO LGC) notes that New Mexico similarly requires operators “collect and control emissions from each flowback vessel...” and route emissions to a control device that achieves a hydrocarbon control efficiency of at least 95 percent.<sup>222</sup> Operators must ensure that the control device “operates as a closed vent system...and that unburnt gas is not directly vented to the atmosphere.”<sup>223</sup>

Commenter (2433-EDF et al) states that a key difference between the New Mexico and Colorado rules is that New Mexico does not require flowback vessels to be “vapor tight” but rather requires them to deploy a control that operates as a closed vent system (CVS).<sup>224</sup> The commenter believes this slight variation in the requirements is appropriate, as concerns have been raised that the vapor tight language raises safety concerns.<sup>225</sup>

Response II-6-80: The EPA disagrees with the commenters that the NSPS OOOOb final rule should follow Colorado’s and New Mexico’s example and prohibit venting during the initial flowback stage of well completions. The EPA has maintained the December 2022 Supplemental Proposal requirements. Under 40 CFR 60.5375b (proposed and final rule text), operators must capture emissions during the separation flowback period of each well completion, unless it is technically infeasible to do so. The owner or operator must direct captured emissions from the separator into a gas flow line or collection system, re-inject the recovered gas into the well or another well, use the recovered gas as an on-site fuel source, or use the recovered gas for another useful purpose that a purchased fuel or raw material would serve. The rule provision for use of captured gas for “any useful purpose” provides flexibility such as use for mobile natural gas refrigeration units or natural gas generators for onsite electricity. Under the final rule, only if these options are not technically feasible (which may include the lack of infrastructure and gathering line concerns) would captured emissions be routed to a completion combustion device. Owners or operators also have a general duty to safely maximize resource recovery and minimize releases to the atmosphere during flowback and subsequent recovery.

<sup>223</sup> N.M. Code R. §20.5.20.127.B.(1)(2).

<sup>224</sup> N.M. Code R. §20.5.20.127.B.(2) (2023).

<sup>225</sup> N.M. Env’t Improvement Bd., In the Matter of Proposed New Reg. 20.2.50 NMAC-Oil and Gas Sector-Ozone Precursor Pollutants No. EIB 21-27 (R), Notice of Intent to Present Rebuttal Technical Testimony on Behalf of Oxy USA Inc., Testimony of Danny Holderman, Ex. 2, pp. 3-4 (2021).

Comment: Commenter (2213-Occidental (Oxy)) provides that they implement RECs to capture gas at the wellhead during completions and minimize releases to the atmosphere. They note that they plan their drilling programs and facilities in tandem to deploy the necessary infrastructure in advance of well completion so that methane and other emissions can be captured and sent to processing facilities and pipelines for sale. The commenter believes a framework could be adopted prospectively for the well completion section of the rule that applies many of these same principles in order to reduce/eliminate the need for flaring.

Response II-6-81: Ideally, most owners or operators plan their drilling programs and facilities similarly to reduce/eliminate the need for flaring. The NSPS OOOOa and NSPS OOOOb rules are structured to only allow for venting/flaring of releases during completions where it is technically infeasible to capture emissions from the separator into a gas flow line or collection system, re-inject the recovered gas into the well or another well, use the recovered gas as an on-site fuel source, or use the recovered gas for another useful purpose that a purchased fuel or raw material would serve. Owners or operators have a general duty to safely maximize resource recovery and minimize releases to the atmosphere during flowback and subsequent recovery.

Comment: Commenter (2177-Ute Indian Tribe) recommends that EPA remove the following notification requirement, stating that it is not appropriate to require a well completion notification in the regulation:

If you own or operate a well affected facility, you must notify the Administrator no later than 2 days prior to the commencement of each well completion operation listing the anticipated date of the well completion operation. The notification shall include contact information for the owner or operator; the United States Well Number; the latitude and longitude coordinates for each well in decimal degrees to an accuracy and precision of five (5) decimals of a degree using the North American Datum of 1983; and the planned date of the beginning of flowback. You may submit the notification in writing or in electronic format. If you are subject to state regulations that require advance notification of well completions and you have met those notification requirements, then you are considered to have met the advance notification requirements of this paragraph.

Response II-6-82: The EPA disagrees with the commenter that the cited notification requirement is not appropriate and has not made the commenter's recommended change in the final rule. This notification has been required under NSPS OOOOa for several years without issue and is maintained in NSPS OOOOb. As required (and noted above), if an owner or operator is subject to state regulations that require advance notification of a well completion and you meet that requirement, then you are considered to have met the advance notification requirements of NSPS OOOOb.

### ***6.3.3 Technical Infeasibility Exception***

Comment: Commenters (2408-CO LGC, 2433-EDF et al) urge EPA to remove the technical infeasibility exception for the separation flowback stage as Colorado and New Mexico have done.

Commenter (2408-CO LGC) contends that broad, undefined technical infeasibility exemptions open the door to abuse and present enforcement challenges and notes that neither New Mexico nor Colorado includes a technical infeasibility exemption in its completion rules.<sup>226</sup> The commenter notes that New Mexico requires operators capture and route natural gas from separation equipment to a flowline or collection system or use the gas on-site.<sup>227</sup> New Mexico permits flaring only if necessary for safety<sup>228</sup> or temporarily if natural gas does not meet gathering pipeline quality specifications.<sup>229</sup> The commenter adds that Colorado similarly only permits flaring with pre-approval<sup>230</sup> or if necessary to ensure safety during an upset condition.<sup>231</sup> The commenter provides that safety flaring during an upset condition is limited to 24 hours.<sup>232</sup>

Commenter (2433-EDF et al) suggests that combustion only be allowed during an upset condition, as New Mexico has required.<sup>233</sup> The commenter maintains that this will help ensure that the technical infeasibility exception is not misused, and ensure operators are using equipment that is appropriately sized for the needs of the flowback scenario.<sup>234</sup> The commenter also recommends EPA define "Upset Condition" to mean "a sudden, unavoidable failure, breakdown, event, or malfunction beyond the reasonable control of the operator that substantially disrupts operations but does not include a failure or breakdown that is caused entirely or in part by poor maintenance, careless operation, or other preventable equipment failure or breakdown." The commenter notes that the definition draws from the definition of "Upset Condition" in Colorado<sup>235</sup> and the definition of malfunction in the New Mexico rules.<sup>236</sup>

Response II-6-83: The EPA has not eliminated the REC technical infeasibility exception for the separation flowback stage in the NSPS OOOOb final rule. Please see section VI.E.2 of the preamble to the 2016 NSPS OOOOa final rule<sup>237</sup> for a discussion of the reason for the technical infeasibility exemption. In the 2016 NSPS OOOOa final rule, the EPA strengthened the documentation and recordkeeping requirements in order to claim the technical infeasibility

exemption, and EPA continues to believe that there are instances where performing a REC is technically infeasible and the rule needs to allow for relief in those instances.

#### ***6.3.4 Definition of Hydraulic Fracturing - Well Completions***

Comment: Commenter (2179-Kansas Independent Oil & Gas Association (KIOGA)) is concerned with the definition of “hydraulic fracture.” The commenter believes well completions performed in Kansas, and other similar areas, do not meet EPA's definition of hydraulic fracturing for various geologic and engineering reasons. The commenter recommends that the definition in NSPS OOOOa be amended to explicitly exclude conventional wells from the regulation because the work performed does not meet the definition provided in the regulation. The commenter notes that operations in Kansas do utilize pressurized fluids that contain water, proppant, and/or chemicals, however most of the operations use a process that neither penetrates tight formations like shale or coal, nor require high rate, extended flowback. They explain that most Kansas operations result in little to no flowback from formations with higher quality reservoir properties than shale or coal. According to the commenter, ignoring those two facts discounts two thirds of the definition as outlined by 40 CFR 60.5430a. The commenter contends that enforcing this regulation based on "the process of directing pressurized fluids" alone; but not based on the type of formation or subsequent flowback directly ignores the criteria outlined by this regulation.

The commenter (2179-KIOGA) states that these two criteria were included in the definition of hydraulic fracturing, as pertaining to this regulation, to distinguish the varying completion styles of small, vertical, conventional drilling targets from large, horizontal, tight, unconventional drilling targets (such as shale and coal). The commenter also assumes that this distinction was developed due to the difference in potential greenhouse gas (GHG) emissions from the dissimilar formation types and completion styles. While the amount of GHGs emitted from each reservoir type has yet to be quantified, the commenter assumed the GHG emissions will be proportional to the amount of hydrocarbons produced (i.e., the more oil and gas a well produces has the potential to produce greater amounts of GHGs that well may emit). According to the commenter, the average Estimated Ultimate Recovery (EUR) for vertical wells in Kansas is 20,000-30,000 bbl/well, where shale wells yield much higher EURs. Per Energy Information Administration (EIA) data, the average EUR is 168,000 bbl/well for an Eagleford shale well and 243,000 bbl/well for an Eastern Bakken well. Based on these numbers, a typical Kansas well will yield — 10 percent of the oil, and theoretically 10 percent of the GHGs, of a typical oil shale well. The commenter further compares typical reservoir and completion parameters for tight shale formations and for conventional formations targeted in Kansas, indicating that many of the terms mentioned in the definition provided in 40 CFR 60.5430a are also included as a comparison between wells drilled in Kansas and by operators targeting tight, unconventional, shale formations.

Regarding geologic criteria, the commenter (2179 - KIOGA) states that most reservoirs within Kansas produce from reservoirs that do not constitute tight formations, such as shale or coal formations, as defined within the standards of the EPA. According to the commenter, the formations targeted are conventional reservoirs that are different from unconventional shales and coals for four main reasons:

1. *Grain size* - Reservoirs in Kansas are carbonates and sandstones rather than shale or coal. The Wentworth grain size classification categorizes sands as being larger than 0.0625 millimeters (mm) while clays (main component of shale) are categorized as grains smaller than 0.0039 mm, more than ten times smaller than the finest-grain, conventional reservoir in Kansas. Furthermore, coal is not composed of consolidated grains, but rather consolidated, thermally mature organic matter.
2. *Organic content* - The shales and coals exploited outside of Kansas are targeted due to their organic content. Coal is composed of nearly 100 percent total organic content (TOC) whereas productive shales are typically greater than 2 percent TOC. Many of the major producing shales have much higher TOCs, some exceeding 10 percent. The conventional reservoirs in Kansas have only trace amounts of TOC at best. The TOC content is very important in shale and coal because the hydrocarbons being targeted are located within the porosity of the organic matter. Producing the hydrocarbons from the organic matter requires large hydraulic fracturing stimulation.
3. *Permeability* - In Kansas reservoirs permeability in locations is generally measured in millidarcies, and some are measured in darcies; while in shale reservoirs, permeability is measured in nano-darcies. The difference between a millidarcy and a nano-darcy is six orders of magnitude ( $10^{-3}$  vs.  $10^{-9}$  darcies, respectively). Because the permeability and nature of the formation types vary so much, the two reservoir types require two different analytical methods in order to measure rock properties.
4. *Producibility* - The finer grain size, nanoscale organic porosity, and low permeability of shale and coal require extended reach laterals with extensive fracturing to increase permeability over large drainage areas to achieve economical flow rates. Reservoir fluid flow typically does not occur outside of the stimulated rock volume. The larger grain size and higher permeability of the conventional reservoirs of Kansas require much less stimulation, and typically a much smaller drainage area, to achieve economical flow rates. Reservoir fluid flow will occur outside of the stimulated rock volume in the more permeable Kansas reservoirs.

Response II-6-84: Similar comments were received on the November 2021 NSPS OOOOb proposal. See response to these similar comments in Volume I, Chapter 16, Response I-16-1 of this RTC.

## **6.4 Liquids Unloading Operations**

### **6.4.1 Applicability**

#### **6.4.1.1 Affected Facility Definition**

Comment: Commenters (2248-NDPC, 2258-MSD, 2446-IPAA) consider the current definition of liquids unloading operations to be unclear. Commenter (2248-NDPC) requests clarification whether well liquids unloading operations only apply to gas wells as described in 40 CFR 98.

Commenter (2326-AXPC) appreciates the following changes or clarifications by EPA: (1) clarification of that the liquids unloading requirements apply to gas wells; (2) removing the

overly expansive modification trigger for well liquids unloading; and (3) removal of “design” as the determination of whether a well liquid unloading activity must comply with the requirements.

Commenter (2258- Marcellus Shale Coalition (MSC)) contends that EPA is attempting to use the proposed regulation to significantly increase their understanding of gas well liquid unloading by including an overly broad and poorly defined affected facility definition and by including wells that do not vent during liquid unloading. The commenter notes that EPA defines liquid unloading as: “*Liquid unloading* means the unloading of liquids that have accumulated over time in gas wells which are impeding or halting production.” According to the commenter, this broad definition will lead to a variety of interpretations concerning which production techniques, among the dozen or so employed in industry, this should apply to. The commenter provides that this will lead to poor consistency in the interpretation of what type of production techniques constitute liquid unloading which will create regulatory compliance uncertainty among reporters. The commenter contends that EPA acknowledges this by specifically asking the following “U.S. EPA has yet to reach a conclusion on whether certain types of liquids unloading events could be an operational change to a well. The EPA is therefore requesting comment on operational scenarios where a well liquids unloading event could constitute a modification.”

The commenter (2258-MSC) explains that liquid unloading techniques will change over the potential 30 or more years in the producing life of wells. Venting may be required at a particular time in a well’s life; however subsequent techniques may not vent as future unloading techniques evolve. For example, the commenter notes that the installation of a field wide gas lift system, or the addition of wellhead compression, or the reduction in gathering line pressures may occur in the later phases of well life that may not vent during liquid unloading. The commenter considers EPA’s attempt to use their current definition of liquids unloading for source applicability to be ambiguous. The commenter states that each type of liquid unloading activity may require a unique and thorough assessment to formulate appropriate regulations as potential emission sources. The commenter recommends EPA better understand these differences and develop regulations with enough specificity to avoid such ambiguity.

Due to the factors discussed, the commenter (2258-MSC) requests that EPA more narrowly define liquids unloading operations to clarify those activities regulated rather than all unloading activities as currently proposed. The commenter suggests defining liquids unloading operations as those operations that vent to the atmosphere. The commenter states that this action would clearly define the source and limit the recordkeeping to the liquid unloading events that vent to the atmosphere.

Commenter (2446-IPAA) notes that EPA is attempting to use the proposed regulation to significantly increase their understanding of the gas well liquid unloading by including an overly broad and poorly defined affected facility definition and by including wells that do not vent during liquid unloading. The commenter provides that EPA’s definition of liquid unloading is broad and will lead to a variety of interpretations concerning which production techniques, among the dozen or so employed in industry, this should apply to. The commenter contends that this will lead to poor consistency in the interpretation of what type of production techniques constitute liquid unloading which will create regulatory compliance uncertainty among reporters. The commenter states that EPA acknowledges this by specifically asking the following "EPA has

yet to reach a conclusion on whether certain types of liquids unloading events could be an operational change to a well. The EPA is therefore requesting comment on operational scenarios where a well liquids unloading event could constitute a modification."<sup>238</sup>

Response II-6-85: In the December 2022 Supplemental Proposal, rather than including three separate definitions for well affected facilities (as initially proposed in the November 2021 Proposal) for (1) oil wells with associated gas, (2) gas wells that undergo liquids unloading, and (3) wells that undergo completions, the EPA proposed a single definition for a well affected facility, which was defined as a single well, in the proposed NSPS OOOOb. In the December 2022 Supplemental Proposal, the EPA proposed that, in addition to 40 CFR 60.14, a “modification” of an existing well occurs when an existing well is hydraulically fractured or hydraulically refractured. Nonetheless, EPA solicited comment in the December 2022 Supplemental Proposal on whether there are operational scenarios where a liquids unloading event could potentially constitute a modification. Based on comments received, the EPA has finalized what was proposed in the December 2022 Supplemental Proposal (*i.e.*, in addition to 40 CFR 60.14, a “modification” of an existing well occurs when an existing well is hydraulically fractured, or hydraulically refractured). See section 6.4.1.2 of this Chapter for specific comments received and EPA’s responses on what constitutes a “modification” for well affected facilities that undergo liquids unloading. While a well affected facility that has been modified (*e.g.*, refractured) would include non-venting liquids unloading events, minimal recordkeeping and reporting requirements would apply to owners or operators of well affected facilities that do not vent during liquids unloading.

With regards to the commenter that requests clarification on whether well liquids unloading operation requirements only apply to gas wells as described in 40 CFR 98. The final rule text has been clarified to specifically state that liquids unloading operation requirements only apply to gas wells.

See sections X.F.1 and 3 of the preamble to the final rule which details EPA’s final standards related to well affected facilities/designated facilities and liquids unloading requirements. See section XI.F.1 and 3 of the preamble to the final rule for the basis for any changes made from the December 2022 Supplemental Proposal and final rule related to liquids unloading as an outgrowth of significant comments.

Comment: Commenters (2227-WEA, 2238-Southeastern Ohio Oil and Gas Association (SOOGA), 2254-PBPA, 2258-MSA, 2294-OOGA, 22391-Chesapeake Energy, 446-IPAA) assert that EPA should only regulate unloading operations that vent emissions.

Commenter (2238-SOOGA) requests that, with respect to the emissions standards for liquids unloading, EPA clarify that unloading which does not result in venting to the atmosphere should not be an affected facility, and that EPA include feasibility language from the preamble in the regulatory text.

---

<sup>238</sup> 87 FR 74782.

Commenter (2227-WEA) provides that operators conducting liquids unloading operations with zero methane and volatile organic compound (VOC) emissions should not be subject to burdensome recordkeeping, reporting and other requirements. The commenter asserts that the rule should only apply to venting during liquids unloading. The commenter adds industry innovated to address the environmental problem of venting during liquids unloading, yet EPA is disincentivizing this innovation. Malfunctions of designed zero-emissions liquids unloading events would be addressed with designed venting events, with required best management practices (BMPs) that minimize emissions, and recordkeeping and reporting.

Commenter (2258-MSD) contends that the implementation of the rule would be easier if the standards only applied to wells that vent. The commenter suggests EPA develop emission requirements for facilities that vent emissions, not for facilities that would only vent emissions if something goes wrong or not as planned. In these situations, the commenter recommends EPA develop separate requirements that would apply.

Commenter (2391-Chesapeake Energy) notes that in the November 2021 proposal, EPA solicited comments on two approaches to defining the affected facility. The first approach defined the affected facility as every well that undergoes liquids unloading, while the second approach defined the affected facility as every well that undergoes liquids unloading using a method that is not designed to eliminate venting. 87 Fed. Reg. at 74781. Although numerous commenters supported the second option, EPA now proposes, in the December 2022 proposal, regulatory text implementing the first option.

The commenter (2391-Chesapeake Energy) opposes this approach because it imposes burdensome recordkeeping and reporting obligations on owners or operators in exchange for no environmental benefit for well unloading activities that do not vent. For example, owners or operators of well affected facilities where gas well liquids unloading occurs must submit annual reports (1) identifying the well affected facility; (2) disclosing the number of gas well liquid unloading operations that occurred there during the reporting period; (3) describing the unloading operation method used each time; and (4) reporting any deviations in detail along with corrective actions. See e.g., proposed 40 CFR 60.5410b(b) and 60.5415b(b). When unloading operations do not result in any vented emissions, these reports serve no purpose.

To avoid this result, the commenter (2391-Chesapeake Energy) recommends that the EPA clarify the standards for gas well liquids unloading operations apply only to those operations that result in emissions to the atmosphere. This action would appropriately limit the recordkeeping and reporting obligations, and it would still allow EPA to gather compliance information for a well that vents to the atmosphere during liquid unloading. The commenter adds that the EPA should also make similar changes to proposed 40 CFR 60.5390c in EG 0000c.

Response II-6-86: In the December 2022 Supplemental Proposal, rather than including three separate definitions for well affected facilities (as initially proposed in the November 2021 Proposal) for (1) oil wells with associated gas, (2) gas wells that undergo liquids unloading, and (3) wells that undergo completions, the EPA proposed a single definition for a well affected facility, which was defined as a single well, in the proposed NSPS 0000b. In the December 2022 Supplemental Proposal, the EPA proposed that, in addition to 40 CFR 60.14, a

“modification” of an existing well occurs when an existing well is hydraulically fractured or hydraulically refractured. Nonetheless, EPA solicited comment in the December 2022 Supplemental Proposal on whether there are operational scenarios where a liquids unloading event could potentially constitute a modification. Based on comments received, the EPA has finalized what was proposed in the December 2022 Supplemental Proposal (*i.e.*, in addition to 40 CFR 60.14, a “modification” of an existing well occurs when an existing well is hydraulically fractured, or hydraulically refractured). See section 6.4.1.2 of this Chapter for specific comments received and EPA’s responses on what constitutes a “modification” for well affected facilities that undergo liquids unloading. While a well affected facility that has been modified (*e.g.*, refractured) would include non-venting liquids unloading events, minimal recordkeeping and reporting requirements would apply to owners or operators of gas well affected/designated facilities that do not vent during liquids unloading.

For unloading technologies or techniques that eliminate venting of emissions during liquids unloading events, the final rule requires minimal recordkeeping and reporting.

For unloading technologies or techniques that could result in venting to the atmosphere, the final rule requires work practices be followed. Specifically, the final rule requires that owners or operators employ and document best management practices to minimize or eliminate venting of methane and VOC emissions for each gas well liquids unloading operation.

See sections X.F.1 and 3 of the preamble to the final rule which details EPA’s final standards related to well affected facilities/designated facilities and liquids unloading requirements. See section XI.F.1 and 3 of the preamble to the final rule for the basis for any changes made from the December 2022 Supplemental Proposal and final rule related to liquids unloading as an outgrowth of significant comments.

Comment: Commenter (2433-EDF et al.) supports the November 2021 proposal’s Option 1 in defining affected facilities to cover all wells undergoing liquids unloading as a critical requirement to ensure that operators do not simply claim to conduct liquids unloading events with zero emission techniques, when in reality venting is occurring. The commenter notes that EPA has recognized, “under some circumstances venting could occur when a selected liquids unloading method that is designed to not vent to the atmosphere is not properly applied (*e.g.*, a technology malfunction or operator error).”<sup>239</sup> The commenter contends that in some cases, the malfunction or error could be so great that it results in venting 100 percent of the gas intended to be captured. Because of this, the commenter states EPA must require recordkeeping so it is aware of these events and overall emissions, and to build an understanding of what causes these errors and how they can be prevented. The commenter recommends EPA finalize Option 1 and require operators of all wells undergoing liquids unloading to maintain records of the number of unloading events that occur, the method used, and any venting that occurred.

Response II-6-87: In the December 2022 Supplemental Proposal, rather than including three separate definitions for well affected facilities (as initially proposed in the November 2021 Proposal) for (1) oil wells with associated gas, (2) gas wells that undergo liquids unloading, and

---

<sup>239</sup> 86 Fed. Reg. at 63179.

(3) wells that undergo completions, the EPA proposed a single definition for a well affected facility, which was defined as a single well, in the proposed NSPS OOOOb. In the December 2022 Supplemental Proposal, the EPA proposed that, in addition to 40 CFR 60.14, a “modification” of an existing well occurs when an existing well is hydraulically fractured or hydraulically refractured. Based on comments received, the EPA has finalized what was proposed in the December 2022 Supplemental Proposal (i.e., in addition to 40 CFR 60.14, a “modification” of an existing well occurs when an existing well is hydraulically fractured, or hydraulically refractured). See section 6.4.1.2 of this Chapter for specific comments received and EPA’s responses on what constitutes a “modification” for well affected facilities that undergo liquids unloading. While a well affected facility that has been modified (e.g, refractured) would include non-venting liquids unloading events, minimal recordkeeping and reporting requirements would apply to owners or operators of well affected facilities that do not vent during liquids unloading.

For unloading events that result in venting to the atmosphere, the final rule requires owners or operators of well affected facilities/well designated facilities employ best management practices to minimize venting of methane and VOC emissions for each gas well liquids unloading operation, in addition to having to comply with the associated recordkeeping and reporting requirements. Where liquids unloading events were conducted using a technology/technique that eliminates venting to the atmosphere, the final rule only requires owners and operators to report the identification of the well along with the non-venting technology or technique used in their annual report. Where unplanned venting occurs from these wells during a compliance period, an owner or operator would be required to follow their best management practices plan for such events and comply with the associated recordkeeping and reporting requirements for those events.

See sections X.F.1 and 3 of the preamble to the final rule which details EPA’s final standards related to well affected facilities/designated facilities and liquids unloading requirements. See section XI.F.1 and 3 of the preamble to the final rule for the basis for any changes made from the December 2022 Supplemental Proposal and final rule related to liquids unloading as an outgrowth of significant comments.

#### 6.4.1.2 Modification – Specific to Liquids Unloading

Comment: Commenters (2218-TCEQ-RRC, 2227-WEA, 2348-EWTC) consider there to be cases where unloading operations would be considered a modification, but do not support this rule to cover all unloading operations.

Commenter (2326-AXPC) requests that EPA remove the overly expansive modification trigger for well liquids unloading.

Commenter (2177-Ute Indian Tribe) notes that the EPA requested comment on whether the following are operational scenarios where a well liquids unloading event could constitute a “modification”:

- (1) the first time, in the life of the well, that well liquids unloading occurs,
- (2) the first time, after fracturing or refracturing a well, that well liquids unloading occurs,
- (3) a change in the type or method of well liquids unloading, or
- (4) ongoing liquids unloading as part of a regular operational schedule. The commenter recommends that EPA omit this condition, stating that well liquids unloading events are routine operations of a well and should not constitute a "modification".

Commenter (2218-TCEQ-RRC) agrees with EPA that a modification for well liquids unloading can include (1) the first time, in the life of the well, that well liquids unloading occurs, (2) the first time, after fracturing or refracturing a well, that well liquids unloading occurs, or (3) a change in the type or method of well liquids unloading. The commenter contends that ongoing liquids unloading would not be considered a modification, because it is not a physical or operational change to an existing facility.

Commenter (2348-EWTC) notes that intermittent emissions may constitute a modification in the example of liquids being unloaded from storage tank to truck which is captured in “ongoing liquids unloading as part of a regular operational schedule.”

Response II-6-88: As noted by commenters, the EPA requested comment on whether the following are operational scenarios where a well liquids unloading event could constitute a “modification”:

- (1) the first time, in the life of the well, that well liquids unloading occurs,
- (2) the first time, after fracturing or refracturing a well, that well liquids unloading occurs,
- (3) a change in the type or method of well liquids unloading, or
- (4) ongoing liquids unloading as part of a regular operational schedule.

While some commenters note that these operations could constitute a modification to a well, others assert that ongoing liquids unloading is routine maintenance and not a physical or operational change to an existing facility and would not constitute a “modification”.

Based on comments received, the EPA has finalized what was proposed in the December 2022 Supplemental Proposal (*i.e.*, in addition to 40 CFR 60.14, a “modification” of an existing well occurs when an existing well is hydraulically fractured, or hydraulically refractured). The EPA, for purposes of regulation, has determined that a “modification” of a well does not include (1) the first time, in the life of the well, that well liquids unloading occurs, (2) a change in the type or method of well liquids unloading, or (3) ongoing liquids unloading as part of a regular operational schedule.

While a well affected facility that has been modified (*e.g.*, refractured) would include non-venting liquids unloading events, minimal recordkeeping and reporting requirements would apply to owners or operators of well affected facilities that do not vent during liquids unloading. Comment: Commenters (2172-KOGA, 2179-KIOGA, 2205-Kriebel Well, 2254-PBPA, 2283-Endeavor Energy) do not believe that liquids unloading is an operational change and should not be considered a modification.

Commenter (2254-PBPA), in response to whether the operating scenarios EPA solicited comment on should be considered a modification, PBPA provides the following comments:

- (1) No. Conducting the operation that the facility is designed to conduct should not be considered a modification.
- (2) No. The act of unloading, whether before or after fracturing/refracturing, should not be considered a modification.
- (3) No. A change in the method of well unloading does not necessarily increase emissions or result in additional pollutants being emitted and should, therefore, not be considered a modification, in and of itself.
- (4) No. Such operations are part of regular operations and the life of the well. Precisely because of this, they should not be considered modifications.

Commenter (2254-PBPA) requests that EPA adhere to a plain English definition of “modification.” The commenter contends that an ongoing operation does not meet the commonsense definition of a “modification.” Moreover, they suggest that, given how commonplace liquids unloading is in upstream operations, the first occurrence of a liquids unloading event and ongoing liquids unloading cannot represent a “modification” as that term is generally understood and applied under the CAA’s NSPS.

While the commenter (2254-PBPA), and its members concede that some changes in the type or method of well liquids unloading operations might meet existing CAA requirements for a “modification,” to the extent EPA seeks to regulate these types of changes under any final NSPS for methane emissions from the oil and gas sector, the commenter asserts that the EPA needs to provide clear guideposts to the regulated community. As an example, the commenter notes that, in Texas and New Mexico, changes to liquid unloading operations are considered a modification, only if such changes result in increased emissions. The commenter suggests a similar approach be implemented.

Commenter (2172-KOGA) states that liquids unloading is not an operational change and should not be considered a modification. The commenter contends that the only operational change that could be considered a modification would be when equipment is added to a well to unload liquids. Even then, the commenter explains that most of that will be downhole with an insignificant number of components added to the above ground wellhead, resulting in a wellsite that could still be considered a “single wellhead well site” or a “small wellhead”. The commenter adds that wells that unload liquid and do not vent to the atmosphere should be considered

similarly to EPA's "single wellhead well site" or proposed "small well wellsite" for fugitive emissions surveys utilizing audio, visual or olfactory (AVO) monitoring on a quarterly schedule. The commenter notes that an operator with wells that unload liquid without venting to the atmosphere should not be required to report its unloading events. According to the commenter, many small operators operate wells with plunger lift and other systems that remove liquids from their wells' wellbores without venting. To require those operators to report those unloading events would be a significant burden on those operators, especially with wells that might unload multiple times a day. The commenter adds that EPA's understanding that single well wellheads are not regularly visited is incorrect. In fact, they report that most gas wells operated by small operators that have automated liquid removal systems, whether vented to the atmosphere or not, are regularly visited by the operator's personnel, often daily. The commenter provides that EPA's concern that there might be some type of equipment failure during an automated liquid unloading event resulting in a methane release to the atmosphere can be tempered in that sites with those potential failures are visited very regularly allowing for any failure to be noticed, stopped, and corrected quickly.

The commenter (2179-KIOGA) urges EPA to reconsider its determination that each liquids unloading event represents a modification, making the well subject to new source standards for purposes of liquids unloading standards. The commenter notes that oil and natural gas wells produce the largest volume at the time they are initially drilled; followed by a declining curve over time. Depending on when the liquid unloading event occurs, the production would only return to where it should have been on the declining production curve assuming the liquid unloading event was successful. The production never increases to the volume the wells observed early in the production curve for a new well. Therefore, the commenter asserts that liquid unloading events are considered normal operation for well operators.

Commenter (2205-Kriebel Well) is concerned with the liquid's unloading process that is currently being considered, particularly, "EPA has yet to reach a consensus on whether certain types of liquids unloading events could be all operational change to a well." The commenter states that efficient capture and full payment for our product is critical for the sustainability of the business. Therefore, liquids unloading events do not exceed that which is necessary to produce at marginal wells. The commenter states that through any unloading event, the wells are neither modified nor are their connections to oil and gas bearing reservoirs altered.

Commenter (2283-Endeavor Energy) notes that ongoing liquids unloading does not meet the common-sense definition of a "modification," and given how commonplace liquids unloading is in upstream operations, the first occurrence of a liquids unloading event and ongoing liquids unloading cannot represent a "modification" as that term is generally understood and applied under the CAA. The commenter contends that this reinforces why liquids unloading does not fit properly within the NSPS OOOOb or EG OOOOc framework and should be removed.

Response II-6-89: As noted by commenters, the EPA requested comment on whether the following are operational scenarios where a well liquids unloading event could constitute a "modification":

- (1) the first time, in the life of the well, that well liquids unloading occurs,
- (2) the first time, after fracturing or refracturing a well, that well liquids unloading occurs,
- (3) a change in the type or method of well liquids unloading, or
- (4) ongoing liquids unloading as part of a regular operational schedule.

While some commenters note that these operations could constitute a modification to a well, others assert that ongoing liquids unloading is routine maintenance and not a physical or operational change to an existing facility and would not constitute a “modification”.

Based on comments received, the EPA has finalized what was proposed in the December 2022 Supplemental Proposal (i.e., in addition to 40 CFR 60.14, a “modification” of an existing well occurs when an existing well is hydraulically fractured, or hydraulically refractured). The EPA, for purposes of regulation, has determined that a “modification” of a well does not include (1) the first time, in the life of the well, that well liquids unloading occurs, (2) a change in the type or method of well liquids unloading, or (3) ongoing liquids unloading as part of a regular operational schedule.

While a well affected facility that has been modified (e.g, refractured) would include non-venting liquids unloading events, minimal recordkeeping and reporting requirements would apply to owners or operators of well affected facilities that do not vent during liquids unloading.

Comment: Commenter (2433-EDF) notes that in the supplemental proposal, EPA has proposed to revise the “modification” definition for a liquids unloading affected facility to apply to a single well that undergoes hydraulic fracturing or refracturing. Previously, EPA had proposed that a “modification” be defined as a well liquids unloading event. The commenter urges EPA to reconsider this change and notes that they supported the previously proposed definition that a well liquids unloading event constitutes a modification.

Response II-6-90: The EPA requested comment on whether the following are operational scenarios where a well liquids unloading event could constitute a “modification”:

- (1) the first time, in the life of the well, that well liquids unloading occurs,
- (2) the first time, after fracturing or refracturing a well, that well liquids unloading occurs,
- (3) a change in the type or method of well liquids unloading, or
- (4) ongoing liquids unloading as part of a regular operational schedule.

While a few commenters note that these operations could constitute a modification to a well, others assert that ongoing liquids unloading is routine maintenance and not a physical or operational change to an existing facility and would not constitute a “modification”.

Based on comments received, the EPA has finalized what was proposed in the December 2022 Supplemental Proposal (*i.e.*, in addition to 40 CFR 60.14, a “modification” of an existing well occurs when an existing well is hydraulically fractured, or hydraulically refractured). The EPA, for purposes of regulation, has determined that a “modification” of a well does not include (1) the first time, in the life of the well, that well liquids unloading occurs, (2) a change in the type or method of well liquids unloading, or (3) ongoing liquids unloading as part of a regular operational schedule.

In addition to liquids unloading being considered routine maintenance for the source category, defining each liquids unloading event as a “modification” would mean that an ongoing/routine liquids unloading operation would constitute a “modification”, which is impractical.

#### ***6.4.2 Proposed Best System of Emission Reduction (BSER)***

##### **6.4.2.1 Proposed Well Liquids Unloading Requirements**

Comment: Commenters (2258-MS, 2446-IPAA) states that the proposed regulation, as it pertains to wells that do not vent during liquids unloading, seems more like an Information Collection Request (ICR) than a regulation to control emissions. The commenters recommend EPA develop regulations specific to each type of liquid unloading technique and that EPA ensure regulations are consistent with the other forms of regulations associated with the equipment and techniques that could be part of these unloading activities. The commenters assert that if EPA requires further understanding of these techniques, they should not use this regulation to acquire such information by requiring significant reporting burdens for activities with no emissions.

Response II-6-91: See sections X.F.1 and 3 of the preamble to the final rule which details EPA’s final standards related to well affected facilities/designated facilities and liquids unloading requirements. For unloading events that result in venting to the atmosphere, the final rule requires owners or operators of well affected facilities/well designated facilities employ best management practices to minimize venting of methane and VOC emissions for each gas well liquids unloading operation, in addition to having to comply with the associated recordkeeping and reporting requirements. Where liquids unloading events were conducted using a technology/technique that eliminates venting to the atmosphere, the final rule only requires owners and operators to report the identification of the well along with the non-venting technology or technique used in their annual report. Where unplanned venting occurs from these wells during a compliance period, an owner or operator would be required to follow their best management practices plan for such events and comply with the associated recordkeeping and reporting requirements for those events.

See section XI.F.1 and 3 of the preamble to the final rule for the basis for any changes made from the December 2022 Supplemental Proposal and final rule related to liquids unloading as an outgrowth of significant comments.

Comment: Commenter (2326-AXPC) states that EPA’s proposed BSER is to have no emissions to the atmosphere and that non-emitting equipment or activities be subject to what they contend are burdensome recordkeeping and reporting requirements that would have no corresponding environmental benefit. The commenter provides that the issue is whether CAA section 111(b) and/or CAA 111(d) authorize EPA to set performance standards that ensure the intended regulatory target is not a “stationary source.” The commenter notes that the CAA’s standards of performance – both CAA sections 111(b) and (d) – provide EPA authority to regulate categories of “stationary sources,” and define a stationary source as “any building, structure, facility, or installation which emits or may emit any air pollutant.”<sup>240</sup> The commenter contends that this plain language of the statute requires that a stationary source emit, or have the potential to emit, to the atmosphere. While “stationary source” may apply as broadly as an entire well site, for example, EPA’s historic implementation of CAA section 111(b) has been to more narrowly regulate “affected facilities” – typically a type of equipment or activity – which the commenter believes fits within CAA section 111’s definition of stationary source. The commenter suggests that, given the statute’s plain language, it is outside of EPA’s authority to regulate non-emitting equipment or activities under CAA section 111 because any such equipment or activity is not a “stationary source.”

The commenter (2326-AXPC) provides that EPA proposes BSER that would result in no VOC or methane emissions from gas well liquids operations. Thus, compliance with EPA’s proposed BSER ensures that gas well liquids operations are not “stationary sources” because compliance will not, and could not, result in emissions. The commenter maintains that this exceeds EPA’s authority granted under CAA section 111.

Response II-6-92: See sections X.F.1 and 3 of the preamble to the final rule which details EPA’s final standards related to well affected facilities/designated facilities and liquids unloading requirements. Where liquids unloading events were conducted using a technology/technique that eliminates venting to the atmosphere, the final rule only requires owners and operators to report the identification of the well along with the non-venting technology or technique used in their annual report. Where unplanned venting occurs from these wells during a compliance period, an owner or operator would be required to follow their best management practices plan for such events and comply with the associated recordkeeping and reporting requirements for those events. See section XI.F.1 and 3 of the preamble to the final rule for the basis for any changes made from the December 2022 Supplemental Proposal and final rule related to liquids unloading as an outgrowth of significant comments.

Comment: Commenters (2348-EWTC, 2383-Baker Hughes (BH)) state that there are significant opportunities to reduce emissions associated with liquids unloading despite the diversity of circumstances and technologies involved.

Commenter (2348-EWTC) provides that one means of facilitating reductions in methane emissions generated by liquids unloading is to deploy advanced methods that reduce the frequency of unloading events. For example, there are artificial lift solutions that use advanced analytics and “smart” edge technology to boost production and reduce associated methane emissions from oil and gas wells. The commenter notes that during one recent three-month pilot

---

<sup>240</sup> 42 U.S.C. §7411(a)(3) (emphasis added).

project in the Haynesville Shale using one artificial lift solution across 10 wells, the operator's gas production increased by 5 percent and well unloading events decreased by 94 percent. The commenter believes BMPs should include technologies that reduce the frequency of events as a means of reducing overall emissions.

Commenter (2383-BH) describes ProductionLink™ Edge, an integrated production optimization platform providing real-time transmission and monitoring of artificial lift operational data. In 2021, natural gas producer Vine Energy deployed ProductionLink™ Edge across 100 natural gas wells in Louisiana's Haynesville Shale. This follows a three-month joint pilot project in Haynesville Shale using the artificial lift solution across 10 wells, during which Vine's gas production increased by 5 percent and well unloading events decreased by 94 percent, which in turn reduced methane emissions. The commenter notes that 40 CFR 60.5376b(d) and 60.5390c(d) define the minimum requirements for a BMP plan to minimize venting of methane and VOC emissions from liquids unloading events for operators seeking an exemption from the zero-emission standard defined in 40 CFR 60.5376b(b) and 60.5390c(b). The commenter recommends that, given the commercial availability of ProductionLink™ Edge and other such solutions, EPA include the following to the list of the requirements at 40 CFR 60.5376b(d) and 60.5390c(d).

- (5) Document technology and operating practices employed to reduce the need and frequency of liquids unloading events at a well affected facility.

The commenter (2383-BH) states that production optimization represents a BMP for capable of delivering cost-effective efficiency improvements and significant methane and VOC emission reduction.

Response II-6-93: The EPA appreciates the feedback and information provided by commenters. See section X.F.1 and 3 of the preamble to the final rule for details on EPA's final standards and XI.F.1 and 3 for the basis for any changes made from the December 2022 supplemental proposal and final rule related to liquids unloading as an outgrowth of significant comments.

#### 6.4.2.2 Zero Emissions Standard

Comment: Commenters (2218-TCEQ, 2248-NDPC, 2283-Endeavor Energy, 2326-AXPC, 2428-API) are concerned with the feasibility and burden a zero-emission standard would have on oil and gas operations.

Commenter (2218-TCEQ) asserts that the proposed rule's zero emission limit is an extremely costly and potentially unrealistic standard for rural gas well sites with typical well liquids loading and unloading operations to meet (since it may not be possible to eliminate the emission of every loading and unloading methane molecule). To achieve compliance with this standard, the commenter anticipates that industry would have to install expensive vacuum inducing, vapor tight loading, and potentially vapor tight disconnection equipment at each Texas gas well site that loads liquids (and may still not be able to eliminate every molecule of potential methane emissions). The commenter recommends that EPA consider the economic feasibility in

establishing a 40 CFR 60.5390c control limit and replace the zero-emission standard with a more cost-effective and realistic one.

Commenter (2248-NDPC) states that, as they communicated to EPA in their comments on the November 2021 proposal, well liquids unloading is a complex topic that has historically been difficult to address from a regulatory perspective because there are numerous misconceptions about why and how this activity is conducted. While the commenter supports EPA's inclusion of well liquid unloading operations as an affected facility, the commenter asserts that the regulation should be based solely on the work practice standard outlined in 40 CFR 60.5376b(c)(2) and (d) and should not include a zero-emission limit as provided in 40 CFR 60.5376b(b).

Commenter (2283-Endeavor Energy) states that liquids unloading is a daily occurrence for many operators and the proposal's requirements simply ignore the realities of these operations and are therefore arbitrary and capricious. The commenter notes that EPA proposes a zero-emission standard for liquids unloading at existing wells. Where it is technically infeasible or not safe to meet the zero-emission standard, EPA proposes to require that owners and operators employ best management practices to minimize venting. The commenter provides that they would need to install closed loop systems, low-pressure flares, or another control device to meet the zero-emission standard for liquids unloading at well sites and expect that many other producers in the Midland Basin would have to do the same. The commenter considers these kinds of capital expenses and retrofitting of sites-particularly at existing well sites-can fundamentally change the economics of the site. The commenter recommends that EPA remove this requirement entirely, or at the very least remove it from any finalized EGs so that it does not apply to existing sites.

Commenter (2326-AXPC) requests removal of the zero emissions standard and associated recordkeeping and reporting requirements such that NSPS OOOOb/EG OOOOc standards apply only where the operator intends that a gas well liquids unloading operation will result in methane and/or VOC emissions to atmosphere. The commenter contends that excluding non-emitting gas well liquids unloading activities from regulation would not impact the standards for those unloading events that emit to atmosphere.

Commenter (2428-API) does not support the provisions proposed in 40 CFR 60.5376b(b) establishing a zero-emission limit on liquid unloading operations. They believe that a zero-emission limit creates an undue burden of compliance when EPA has acknowledged it is known that not every liquid unloading operation can technically or safely meet the zero-emission limit. The commenter states that this undue burden is compounded when considering the logistical and practical implementation of the associated proposed recordkeeping, reporting and certification statements.

Response II-6-94: The EPA has not finalized its December 2022 proposal to require owners and operators to employ techniques or technologies that eliminate methane and VOC emissions, unless it was technically infeasible or not safe to meet the zero emissions standard. See section X.F.1 and 3 of the preamble to the final rule for details on EPA's final standards and XI.F.1 and 3 for the basis for any changes made from the December 2022 supplemental proposal and final rule related to liquids unloading as an outgrowth of significant comments. Specifically, see section XI.F.3.a response to this and other comments received on EPA's proposed December

2022 Supplemental zero-emissions standard and section XI.F.3.b on EPA's proposed December 2022 Supplemental recordkeeping and reporting requirements.

Comment: Commenter (2326-AXPC) suggests that, by defining well liquids unloading events to mean only those wellbore liquid removal events that are intended vent to atmosphere, EPA would avoid regulating events or operations that do not have any emissions to atmosphere. The commenter believes that such a framework is much more consistent with EPA's legal authority – which does not extend to equipment or operations that do not have emissions releases. In connection with this creation of a definition for well liquids unloading event, the commenter recommends that the EPA eliminate use of the term zero emissions or zero emissions standard in reference to wellbore liquids removal. The commenter notes that API recommends removal of the requirement to demonstrate that an operator cannot preclude venting to the atmosphere.<sup>241</sup> The commenter supports that position. However, the commenter states that, if EPA retains those requirements, then EPA should only require: (1) maintaining documentation that the operator cannot preclude venting to the atmosphere due to technical, safety or economic considerations; and (2) the implementation of BMPs where that demonstration has been made. Importantly, the commenter expresses that they believe that wellbore liquids removal operations that are routed to combustion device or a flare do not “vent to atmosphere.” In fact, routing emissions from wellbore liquids removal operations to a combustion device or a flare may (in certain circumstances) be the best mechanism to reduce emissions from well liquids unloading. By using the term “zero emissions,” which EPA has indicated in other contexts that combustion devices do not fall into, they believe that the EPA has limited the value and usefulness of this control methodology. Thus, the commenter contends that wellbore liquids removal operations that are routed to a combustion device should not be considered to be venting to the atmosphere, and under their suggested proposal, would not be considered well liquids unloading. The commenter recommends that EPA clarify in the final rule that well liquids unloading being routed to a control device is not intended to vent and thus not subject to the well liquids unloading requirements.

Response II-6-95: The EPA has not finalized its December 2022 proposal to require owners and operators to employ techniques or technologies that eliminate methane and VOC emissions, unless it was technically infeasible or not safe to meet the zero emissions standard. See section X.F.1 and 3 of the preamble to the final rule for details on EPA's final standards and XI.F.1 and 3 for the basis for any changes made from the December 2022 supplemental proposal and final rule related to liquids unloading as an outgrowth of significant comments. Specifically, see section XI.F.3.a response to this and other comments received on EPA's proposed December 2022 Supplemental Proposal zero-emissions standard and section XI.F.3.b on EPA's proposed December 2022 Proposal Supplemental recordkeeping and reporting requirements.

Comment: Commenter (2446-IPAA) states EPA needs to define more clearly what would be considered "zero emitting". According to the commenter, routing of vented emissions to a flare or a control device should be considered zero-emitting in this context as it is often the best solution for emission reduction.

---

<sup>241</sup> API Supplemental Proposal Comments Section 9.3.

Response II-6-96: The EPA disagrees that routing vented emissions to a flare or a control device should be considered zero-emitting. Flare/control devices are not zero-emitting (*i.e.*, do not control 100 percent of the vented emissions on a continuing basis and flares/combustors create secondary emissions).

The EPA has not finalized its December 2022 proposal to require owners and operators to employ techniques or technologies that eliminate methane and VOC emissions, unless it was technically infeasible or not safe to meet the zero emissions standard. Additionally, the final standards/presumptive standards have been revised to allow owners or operators the option to comply with the GHG and VOC standards by reducing methane and VOC emissions from each gas well liquids unloading event by 95 percent by routing emissions to a control device via a closed vent system (CVS). See Volume I of this Response to Comment Document, Chapter 12, Response I-12-20 for a response to comments requesting this option.

See section X.F.1 and 3 of the preamble to the final rule for details on EPA's final standards. See also section XI.F.3.a response to comments received on EPA's proposed December 2022 Supplemental Proposal zero-emissions standard.

Comment: Commenter (2177-Ute Indian Tribe) requests that an exception to the zero emissions standard be allowed for smaller producing wells where compliance with the zero-emission standard for gas well liquids unloading would be uneconomic to the point of it being less expensive to shut-in the well.

Response II-6-97: The EPA has not finalized its December 2022 proposal to require owners and operators to employ techniques or technologies that eliminate methane and VOC emissions, unless it was technically infeasible or not safe to meet the zero emissions standard. See section X.F.1 and 3 of the preamble to the final rule for details on EPA's final standards and XI.F.1 and 3 for the basis for any changes made from the December 2022 supplemental proposal and final rule related to liquids unloading as an outgrowth of significant comments.

The EPA has not finalized its December 2022 proposal to require owners and operators to employ techniques or technologies that eliminate methane and VOC emissions, unless it was technically infeasible or not safe to meet the zero emissions standard. See section XI.F.3.a response to this and other comments received on EPA's proposed December 2022 Supplemental Proposal zero-emissions standard and section XI.F.3.b on EPA's proposed December 2022 Proposal Supplemental recordkeeping and reporting requirements.

#### 6.4.2.3 Certification of Non-Zero Emitting Liquids Unloading Method

Comment: Commenters (2258-MS, 2294-OOGA, 2326-AXPC, 2428-API, 2446-IPAA) request EPA include economic feasibility in addition to the technical and safety reasons described in the proposal.

Commenter (2258-MS) asserts that the proposed certification language needs to include not only technical and safety reasons but should also include economic feasibility as well, as follows:

I certify that the technical, economic and safety infeasibility justification of needing to use a non-zero emitting liquids unloading method for all liquids unloading events at the well-affected facility was prepared under my direction or supervision. Based on my professional knowledge and experience, and inquiry of personnel involved in the infeasibility justification, the certification submitted herein is true, accurate, and complete.

Commenter (2294-OOGA) notes that the preamble to the supplemental proposal allows for economic feasibility determinations when utilizing liquids unloading methods that vent to the atmosphere: “Additionally, for wells that utilize methods that vent to the atmosphere, the proposed rule would require: “(1) Documentation explaining why it is infeasible to utilize a non-venting method due to technical, safety, or economic reasons.”<sup>242</sup> However, the commenter points out that the rule text makes no mention of economic feasibility, limiting infeasibility determinations to technical and safety-related justifications. The commenter provides that this apparent limitation on feasibility determinations in the rule text is unreasonable and renders the infeasibility demonstration impractical. According to the commenter, a technical feasibility review can take a significant amount of time to complete. The review time would result in lost production due to the well having to be shut in. For an operator to keep pace with required well unloads, significant additional staffing would be needed to complete the required reviews. Additionally, the commenter provides that there are very few scenarios that an engineer or qualified professional would certify a technical or safety infeasibility justification. Without a certified justification and allowance for unloading without a zero emissions method, wells would ultimately just be shut in until the well rebuilt pressures to produce on its own, resulting in lost production or the well never returning to production. The commenter urges EPA to revise the rule text to include economic infeasibility as a justification for needing to use a non-zero emitting liquids unloading method. The commenter maintains that this would provide necessary additional opportunities for justifying the use of a non-zero emitting liquids unloading method, especially for low producing wells.

Commenters (2258-MSD, 2446-IPAA) recommend EPA provide additional supporting documentation about what would be considered acceptable “written justification”. Commenters point out that EPA does not provide examples of what level of detail a certifier should use, provides no minimum set of requirements, no specific economic input criteria, and has created a level of ambiguity regarding this very exacting statement. The commenters add that professional engineers or another qualified individual with expertise in liquids unloading operations will be reluctant to provide such a statement without more specificity about the criteria for such a statement. If EPA cannot provide such detail, the commenters contend that there will be considerable challenges within the industry for qualified certifiers and this requirement should therefore be withdrawn.

Commenter (2326-AXPC) requests EPA revise the language in the regulations to be consistent with its preamble. In the preamble, EPA states that: “for wells that utilize methods that vent to the atmosphere, the proposed rule would require: (1) Documentation explaining why it is infeasible to utilize a non-venting method due to technical, safety or economic reasons....” However, the commenter notes that EPA does not include “economic” considerations in the rule

---

<sup>242</sup> 87 FR 74782.

language. The commenter notes that the rule language currently references only “technical or safety reasons.” Consistent with EPA’s preamble, the commenter states EPA should revise the rule to reference “technical, safety, or economic reasons.” The commenter also provides that inclusion of “economic” is also critical considering the framework for the NSPS.

Commenter (2428-API) states one of the legal flaws in EPA’s opt-out scheme is that technical feasibility is the only governing criterion. The commenter provides that the cost of implementing the default zero-emitting standard is not a consideration. As a result, the proposed opt-out approach unlawfully evades the obligation that cost must be considered in prescribing CAA section 111 standards of performance. The commenter contends that this flaw is easily cured by including cost as a consideration in implementing the opt-out provisions.

Response II-6-98: The EPA has not finalized its December 2022 proposal to require owners and operators to employ techniques or technologies that eliminate methane and VOC emissions, unless it was technically infeasible or not safe to meet the zero emissions standard. As discussed under section X.F.3.a of the final rule preamble states, the EPA has determined that the intermittent and necessary nature of the variable methods and technologies employed to unload liquids and the unpredictable nature as to when it may be necessary to vent emissions makes a work practice standard more practical for liquids unloading operations than a zero-emissions standard. As a work practice standard, the engineering certification statement required under the December 2022 Supplemental Proposal that required an explanation of why it is infeasible to utilize a non-venting method due to technical, safety, or economic reasons is unnecessary and has been removed from the final rule.

Comment: Commenters (2172-KOGA, 2403-PAO, 2428-API) provide comments regarding who would conduct the technical infeasibility analysis, particularly given the concerns of certification via a professional engineer.

Commenter (2172-KOGA) states that EPA’s proposed requirements for wells with liquid unloading operations that do vent to the atmosphere are to 1) document “why it is infeasible to utilize a non-venting method due to technical, safety, or economic reasons”, 2) BMP to minimize venting, 3) documenting BMPs were followed, and 4) submission of an annual report that includes the number of unloading events during the year and the number of events that “did not follow the BMPs” are justifiable as long as the EPA does not require any documentation or BMP’s to be compiled by a “Registered Professional Engineer”. The commenter contends that the operator of a well that vents to the atmosphere while liquids are unloaded should be allowed to document “why it is infeasible to utilize a non-venting method” of liquid unloading for their own well. Small wells, producing 10 thousand cubic feet (Mcf)/day or less that need to be bailed once every year or two to remove fluid built up over the pay zone, cannot afford to have a professional engineer sign off on its liquid unloading methodology, especially since it has probably been done the same way for the last several decades. The commenter is concerned that this would be a heavy economic burden on operators of legacy producing properties and other low-cost operations.

Commenter (2403-PAO) states that the technical infeasibility analysis demonstrating that well liquids unloading cannot be achieved with zero emissions can be conducted by a qualified

professional engineer or an in-house engineer. The commenter requests EPA clarify that technical infeasibility for liquids unloading can be accomplished by a professional engineer or an inhouse engineer.

Commenter (2428-API) contends that the express threat of possible personal liability on the part of certifiers will limit the number of individuals willing to make the needed certifications, particularly considering the uncertainties about what will be needed as a practical matter to demonstrate “technical infeasibility.” The commenter adds that the clear opportunity and possibility of second guessing will be further material disincentives.

Response II-6-99: The EPA has not finalized its December 2022 proposal to require owners and operators to employ techniques or technologies that eliminate methane and VOC emissions, unless it was technically infeasible or not safe to meet the zero emissions standard. As discussed under section X.F.3.a of the final rule preamble states, the EPA has determined that the intermittent and necessary nature of the variable methods and technologies employed to unload liquids and the unpredictable nature as to when it may be necessary to vent emissions makes a work practice standard more practical for liquids unloading operations than a zero-emissions standard. As a work practice standard, the engineering certification statement required under the December 2022 Supplemental Proposal that required an explanation of why it is infeasible to utilize a non-venting method due to technical, safety, or economic reasons is unnecessary and has been removed from the final rule.

#### 6.4.2.4 Best Management Practices (BMPs)

Comment: Commenter (2428-API) supports the proposed alternative measures outlined in 40 CFR 60.5376b(c)(2) and (d), which provide a clear and rational work practice standard based on BMPs that achieve the intent to reduce emissions from liquid unloading of gas wells. The commenter believes that these provisions should be considered BSE and should not be considered an exception to the standard as currently proposed in 40 CFR 60.5376b(c).

The commenter (2428-API) appreciates EPA’s recognition that solely imposing an absolute requirement would constitute an unwarranted prohibition on necessary operations that in many situations could severely halt natural gas production. For some situations, a certain unloading technique may reduce emissions, but the same option might increase emissions if applied on another well with differing characteristics. The commenter contends that the work practice standards proposed in 40 CFR 60.5376b(d) allow operators the flexibility needed to minimize emissions from well liquid unloading, while allowing for unexpected situations or outcomes that may occur during the unloading operation that might result in a minimal amount of emissions to be vented.

Response II-6-100: The comment is a supportive comment of the December 2022 Proposal for best management practices. The EPA has maintained the best management practice requirements proposed in the December 2022 Supplemental Proposal. For unloading technologies or techniques that result in venting to the atmosphere, the final rule requires that owners or operators employ best management practices that meet minimum specified criteria to minimize venting of methane and VOC emissions for each gas well liquids unloading operation. Unloading

events that employ non-venting liquids unloading technologies and techniques that do not result in venting of methane and VOC emissions to the atmosphere are not subject to best management plan requirements and the associated recordkeeping and reporting requirements under the rule. An owner or operator of a well affected facility that employs non-venting liquids unloading technologies and techniques is only required to comply with minimal recordkeeping and reporting requirements. In instances where there may be an unplanned venting event, that event would be subject to the best management practices to minimize venting of emissions and the associated recordkeeping and reporting requirements.

Additionally, the EPA has not finalized its December 2022 proposal to require owners and operators to employ techniques or technologies that eliminate methane and VOC emissions, unless it was technically infeasible or not safe to meet the zero emissions standard. See section X.F.1 and 3 of the preamble to the final rule for details on EPA's final standards and XI.F.1 and 3 for the basis for any changes made from the December 2022 supplemental proposal and final rule related to liquids unloading as an outgrowth of significant comments. Specifically, see section XI.F.3.a response to this and other comments received on EPA's proposed December 2022 Supplemental zero-emissions standard.

Comment: Commenter (2433-EDF et al) recommends that EPA limit permissible circumstances in which liquids unloading can be conducted without zero emissions and require rigorous documentation of why venting had to occur. The commenter notes that the EPA has proposed allowing venting if "it is technically infeasible or not safe to perform liquids unloading with zero emissions," in which "an owner or operator [must] establish and follow [best management practices] to minimize methane and VOC emissions during liquids unloading events to the extent possible."<sup>243</sup> EPA does not intend to "dictate all of the specific practices that must be included," but rather "would specify minimum acceptance criteria required for the types and nature of the practices."<sup>244</sup> The commenter contends that this is too nebulous and is likely to result in regular venting, followed by operators checking off a handful of best practices. The commenter suggests that EPA should instead clearly define best practices, list them in hierarchical order, and require operators to follow the practices or otherwise provide rigorous documentation as to why they could not do so.

Response II-6-101: The EPA has not finalized its December 2022 proposal to require owners and operators to employ techniques or technologies that eliminate methane and VOC emissions, unless it was technically infeasible or not safe to meet the zero emissions standard. See section X.F.1 and 3 of the preamble to the final rule for details on EPA's final standards/presumptive standards and XI.F.1 and 3 for the basis for any changes made from the December 2022 supplemental proposal and final rules related to liquids unloading as an outgrowth of significant comments. Specifically, see section XI.F.3.a response to this and other comments received on EPA's proposed December 2022 Supplemental zero-emissions standard. The EPA has determined that, because of the intermittent and necessary nature of allowing for variable methods and technologies employed to unload liquids, and the often-unpredictable timing as to when owners and operators may need to vent emissions, a work practice standard is more appropriate than an emissions standard for liquids unloading operations. Because of the varied

---

<sup>243</sup> 86 Fed. Reg. at 63179.

<sup>244</sup> Id.

techniques or technologies that could be employed and the differing circumstances that could exist for a well affected/designated facility, the EPA continues to not dictate specific best practices and has maintained the proposed December 2022 Supplemental Proposal minimum criteria to be included in a BMP plan and implemented to meet the final standards/presumptive standards:

- (1) Include steps that create a differential pressure to minimize the need to vent a well to unload liquids,
- (2) Include steps to reduce wellbore pressure as much as possible prior to opening the well to the atmosphere,
- (3) Unload liquids through the separator where feasible, and
- (4) Close all wellhead vents to the atmosphere and return the well to production as soon as practicable.

See section XI.F.3.a response to comments on EPA’s proposed December 2022 Supplemental Proposal zero-emissions standard and section XI.F.3.b on EPA’s response to comments on EPA’s proposed December 2022 Proposal Supplemental Proposal recordkeeping and reporting requirements.

#### ***6.4.3 Liquids Unloading Definition***

Comment: Commenter (2428-API) states that additional clarification to the proposed definition of liquids unloading is warranted. The commenter provides that other well maintenance and workover activities may occur on a well that are distinctly different, require separate specialized equipment and operation, and are reported differently in federal and state GHG inventories from well liquids unloading. The commenter requests EPA explicitly provide clarification to address these distinctions, within the definition for “liquids unloading” so not to confuse other activities that might occur at a well with the liquids unloading operation provisions as proposed. The commenter provides suggested clarifications to the definition of liquids unloading under 40 CFR 60.5430b and 40 CFR 60.5430c is as follows (underlined text indicates new text):

*Liquids unloading* means the unloading of liquids that have accumulated over time in gas wells, which are impeding or halting production. Routine well maintenance activities, including workovers, screenouts, coil tubing cleanouts, or any other activity that requires a rig or other machinery are not considered liquids unloading.

Response II-6-102: The commenter’s suggested clarifying language edits to the “liquids unloading” definition meet EPA’s intent and the suggested clarifying edits have been made to 40 CFR 60.5430b and 40 CFR 60.5430c.

#### ***6.4.4 Recordkeeping and Reporting Requirements***

Comment: Several commenters (2227-WEA, 2238-SOOGA, 2294-OOGA, 2326-AXPC, 2391-Chesapeake Energy, 2428-API) request that EPA not require recordkeeping and reporting of non-venting liquids unloading events.

Another commenter (2258-MSC) requests the removal of reporting requirements that do not provide valuable emissions-related information.

Response II-6-103: The EPA has not finalized its December 2022 proposal to require owners and operators to employ techniques or technologies that eliminate methane and VOC emissions, unless it was technically infeasible or not safe to meet the zero emissions standard. See section X.F.1 and 3 of the preamble to the final rule for details on EPA's final standards/presumptive standards and section XI.F.3.a of the preamble to the final rule for EPA's response to comments on EPA's proposed December 2022 Proposal Supplemental Proposal recordkeeping and reporting requirements.

Comment: Commenter (2428-API) recommends that proposed recordkeeping and reporting for liquids unloading operations be simplified into a manageable framework for operators and streamlined for liquid unloading operations that vent to atmosphere. The commenter notes that the information proposed by EPA within 40 CFR 60.5420b and 40 CFR 60.5420c for the recordkeeping and reporting as it pertains to liquid unloading operations is focused on an operator tracking and certifying techniques and less focused on allowing an operator to perform the necessary procedures to unload liquids accumulated within the wellbore and maintain natural gas production with as minimal emissions as possible. To address this shortfall, the commenter suggests EPA define the data operators, track per unloading operation, and remove all superfluous records that generate additional burden for the operator and EPA without added environmental benefit. The commenter provides that these suggestions assume that liquid unloading operations are to be conducted using a work practice standard.

Furthermore, commenter (2428-API) provides that the current proposed recordkeeping requirements do not offer a reasonable framework for operators to maintain compliance assurance. In fact, the commenter states that the EPA has included a certification by professional engineer for every instance a well unloading operation vents emissions to atmosphere in 40 CFR 60.5420b(c)(2)(ii)(B) and 40 CFR 60.5420b(b)(3)(ii)(B) based on the proposed zero emissions limit standard. The commenter notes that this may not be known to an operator until the liquid operation is taking place based on a variety of parameters. For context, the commenter states that a single well affected facility may undergo multiple liquid unloading operations in a single compliance period. For example, one well may necessitate an unloading schedule of four times in a year. Based on best management procedures, three (3) of these events may occur with zero emissions, while one (1) of the events might vent to atmosphere for a short duration using the same technique. The commenter considers the justification provisions in 40 CFR 60.5420b(c)(2)(ii)(B) to be untenable when the same technique used on a well may result in zero emissions during some liquid operations, but not during all liquid unloading operations in the same compliance period. The commenter asserts that the fact is that in some instances a well liquid unloading operation may need to vent emissions for short duration, sometimes as little as

30 minutes, to safely perform the liquid unloading operation. The commenter therefore requests:

1. EPA remove the additional engineering certification statements under the guise of technical demonstrations. These additional certifications would be unnecessary if the standard followed a work practice procedure.
2. Limit recordkeeping and reporting to liquid unloading operations that result in emissions only. This would reduce the administrative burden for thousands of liquid unloading operation events. This is also consistent with how both Colorado and New Mexico have organized recordkeeping and reporting for their state regulations.

The commenter (2428-API) recommends that EPA streamline and simplify the recordkeeping and reporting for liquid unloading operations as follows:

For each gas well affected facility that conducts liquids unloading operations during the reporting period that resulted in emissions vented to the atmosphere:

- US Well ID
- The number of liquids unloading events during the year that resulted in emissions.
- The date and time of each liquid unloading operation where venting occurred.
- The duration of venting in hours.
- Reason venting occurred.

Additionally, the commenter (2428-API) requests that recordkeeping for liquid unloading operations include the following:

Documentation of your best management practice plan developed under paragraph §60.5376b(d). You may update your best management practice plan to include additional steps which meet the criteria in §60.5376b(d).

Response II-6-104: The EPA has not finalized its December 2022 proposal to require owners and operators to employ techniques or technologies that eliminate methane and VOC emissions, unless it was technically infeasible or not safe to meet the zero emissions standard. See section X.F.1 and 3 of the preamble to the final rule for details on EPA's final standards/presumptive standards and section XI.F.3.a of the preamble to the final rule for EPA's response to comments on EPA's proposed December 2022 Proposal Supplemental Proposal recordkeeping and reporting requirements.

With regards to the commenter that requests that recordkeeping for liquid unloading operations include documentation of the best management practices plan, the December 2022 Supplemental Proposal included this language in 40 CFR 60.5420b and 40 CFR 60.5420c, and it is maintained in the final rule, with the exception that the cited language is 40 CFR 60.5376b(c) [not 40 CFR 60.5376b(d)] in NSPS OOOOb, and 40 CFR 60.5390c(c) in EG OOOOc.

Comment: Commenter (2248-NDPC) also requests that the recordkeeping and reporting requirements be amended to be a workable framework for operators to assure compliance including removal of the certification statement by an engineer in every instance that venting

may occur. They also add that the applicability for liquid unloading operations must be designated as the date of the supplemental proposal as the recordkeeping requirements were not explicitly known for each event that occurred prior to the publication. The commenter notes that much of the recordkeeping elements proposed in the December 2022 proposal, including the certification statement by engineer, was not anticipated based on the descriptions in the November 2021 proposal. According to the commenter, operators should not be penalized for failing to have records and certification statements for events that occurred before the particular data elements were made known as being required.

Response II-6-105: The EPA has not finalized its December 2022 proposal to require owners and operators to employ techniques or technologies that eliminate methane and VOC emissions, unless it was technically infeasible or not safe to meet the zero emissions standard.

See section X.F.1 and 3 of the preamble to the final rule for details on EPA's final standards/presumptive standards and section XI.F.3.b of the preamble to the final rule for EPA's response to comments on EPA's proposed December 2022 Proposal Supplemental Proposal recordkeeping and reporting requirements.

Comment: Commenter (2326-AXPC) argues that the EPA should not require recordkeeping or reporting for each well liquid unloading operation conducted during the year unless EPA has defined well liquid unloading operation to mean only those well liquid unloading operations intended to vent to atmosphere. As the commenter noted in their comments on the November 2021 proposal, they continue to support EPA's original "Option 2" and feel strongly that EPA's Option 1 (selected in the December 2022 Supplemental Proposal by EPA) has significant practical and legal implications. As EPA recognizes in its supporting documentation, the commenter reports that one primary methodology that may be used to reduce or eliminate venting from removal of liquids of gas wells is a plunger lift. In most operational scenarios, a plunger lift will assist with liquid removal from the wellbore without any venting to the atmosphere. The plunger lift will operate on either a set cycle or may operate based upon pressures reflected in the well bore. However, not all plunger lifts are designed to or have the necessary equipment on site to track each cycle of the plunger lift. Thus, the commenter explains that the EPA's proposal could require installation of equipment to track the plunger cycles while providing no emissions reductions benefits. The commenter notes that the EPA has not fully evaluated the cost of installing and operating such tracking equipment in its cost-benefit analysis, and given that there will be no emissions benefits, EPA cannot show that such a requirement would be cost-effective. They note that this is only one example. The commenter adds that even where equipment is available to track the number of wellbore liquids removal events that do not vent to atmosphere, the operational costs of undertaking that tracking are considerable and the data collected will be significant. According to the commenter, EPA has provided no reasonable explanation for its need to obtain and track data relating to the number of wellbore liquids removal events that do not vent to atmosphere. And EPA provides virtually no explanation for its decision to stick with Option 1, other than the fact that "malfunctions" can result in vented emissions from liquids removal operations that would otherwise meet the zero emissions standard. The commenter states that the EPA has no basis for concern with respect to malfunctions as it has implemented a robust AVO and optical gas imaging (OGI) inspection

program that would be expected to identify wells that have emissions during liquids removal that were not expected or intended.

The commenter (2326-AXPC) concludes that one simple solution to this problem is to define well liquids unloading to mean only those wellbore liquids removal events that are intended to vent to atmosphere. By defining well liquids unloading in such a manner, the commenter believes that the EPA would not only encourage operators to find solutions that eliminate venting and will ensure that operators not only implement certain emission reduction requirements to reduce venting to atmosphere but would also record and report on those instances that do result in venting to the atmosphere.

Response II-6-106: The EPA has not finalized its December 2022 proposal to require owners and operators to employ techniques or technologies that eliminate methane and VOC emissions, unless it was technically infeasible or not safe to meet the zero emissions standard.

See section X.F.1 and 3 of the preamble to the final rule for details on EPA's final standards/presumptive standards and section XI.F.3.b of the preamble to the final rule for EPA's response to comments on EPA's proposed December 2022 Proposal Supplemental Proposal recordkeeping and reporting requirements.

Comment: Commenter (2446-IPAA) cites the EPA referenced study by Dr. Allen, University of Texas, Environmental Science & Technology, December 9, 2014, *Methane Emissions from Process Equipment at Natural Gas Production Sites in the United States: Liquids Unloadings*, "[s]ome wells with plunger lifts are automatically triggered and unload thousands of times per year." The commenter states that just a single well with thousands of unloading events per year, would create a significant reporting burden, and when wells do not vent this reporting should not be required.

Response II-6-107: The EPA has not finalized its December 2022 proposal to require owners and operators to employ techniques or technologies that eliminate methane and VOC emissions, unless it was technically infeasible or not safe to meet the zero emissions standard. Where liquids unloading events were conducted using a technology/technique that eliminates venting to the atmosphere, the final rule only requires owners and operators to report the identification of the well along with the non-venting technology or technique used in their annual report. Where unplanned venting occurs from these wells during a compliance period, an owner or operator would be required to follow their best management practices plan for such events and comply with the associated recordkeeping and reporting requirements for those events.

See section X.F.1 and 3 of the preamble to the final rule for details on EPA's final standards/presumptive standards and section XI.F.3.b of the preamble to the final rule for EPA's response to comments on EPA's proposed December 2022 Proposal Supplemental Proposal recordkeeping and reporting requirements.

Comment: Commenter (2214-(BlueCrest)) suggests that the following citation be checked for correct cross referencing: 40 CFR 60.5420b(c)(2)(ii)(B).

Response II-6-108: 40 CFR 60.5420b(c)(2) has been revised and the cross- reference issue identified by the commenter is not included in the final rule.

#### ***6.4.5 Existing State and Federal Requirements***

Comment: Commenter (2227-WEA) believes that natural gas well liquids unloading operations subject to emission standards promulgated by a state or local authority should be excluded from federal regulation. For example, and as acknowledged by EPA, Colorado Air Quality Control Commission Regulation No. 7, Part D, Section II.G.1.d., Title 20, Chapter 2, Part 50 of the New Mexico Administrative Code (20.2.50.117 NMAC) and other state and local regulations include emission standards for natural gas well liquids unloading operations. The commenter notes that both New Mexico and Colorado only require recordkeeping and reporting associated with unloading events involving the release of emissions.

Additionally, the commenter (2227-WEA) notes that the proposed rules provide procedures for the submittal and approval of alternative means of emission limitation (AMEL) for complying with fugitive emissions standards based on programs under state, local, or tribal authorities for the fugitive emissions components affected facility. The commenter recommends that EPA, at a minimum, should apply a similar procedure to natural gas well liquids unloading operations which are also regulated by some states. However, the commenter states that the current AMEL process is overly burdensome and time-consuming, and a categorical exclusion should be codified in the final standards for affected facilities currently subject to certain state and local regulations. The commenter concludes that future regulations promulgated by a federal, state, or tribal authority would be subject to the AMEL process.

Response II-6-109: The EPA has not finalized its December 2022 proposal to require owners and operators to employ techniques or technologies that eliminate methane and VOC emissions, unless it was technically infeasible or not safe to meet the zero emissions standard. Under the final standards/presumptive standards Where liquids unloading events were conducted using a technology/technique that eliminates venting to the atmosphere, the final rule only requires owners and operators to report the identification of the well along with the non-venting technology or technique used in their annual report. Where unplanned venting occurs from these wells during a compliance period, an owner or operator would be required to follow their best management practices plan for such events and comply with the associated recordkeeping and reporting requirements for those events.

See section X.F.1 and 3 of the preamble to the final rule for details on EPA's final standards/presumptive standards and sections XI.F.1 and 3 of the preamble to the final rule for EPA's response to comments on EPA's proposed December 2022 Proposal Supplemental Proposal zero emissions standard/presumptive standards and recordkeeping and reporting requirements.

The EPA disagrees with the commenter that a categorical exclusion should be codified in the final standards for affected facilities currently subject to certain state and local regulations. The EPA reviewed both the New Mexico and Colorado requirements when developing the final standards/presumptive standards for liquids unloading operations. While, for example, both New

Mexico and Colorado only require recordkeeping and reporting associated with unloading events involving the release of emissions, the final NSPS OOOOb and EG OOOOc standards/presumptive standards also require minimal recordkeeping and reporting where a technology/technique is used that eliminates venting to the atmosphere. Under the final rule requirements, an owner or operator needs to report the identification of the well along with the non-venting technology or technique used in their annual report.

An owner or operator also has the option to follow the procedures of 40 CFR 60.5399b for the submittal and approval of AMEL for complying with the GHG and VOC NSPS OOOOb work practice standards for liquids unloading operations. Additionally, states can consider RULOF to support the need for alternative compliance options under EG OOOOc in their state plans. See section XIII.C.3 (Remaining useful life and other factors (RULOF)) of the final rule preamble for a summary of the RULOF provisions that have been finalized in the subpart Ba rulemaking (codified at 40 CFR part 60, subpart Ba).

Comment: Commenter (3839-AOGA) reports that the Alaska Oil and Gas Conservation Commission (AOGCC) and the Bureau of Land Management (BLM) implement regulatory requirements which diminish or eliminate venting during liquids unloading events. The commenter requests that EPA revise its proposal to deem that Alaska's operators meet the proposed control requirements under NSPS OOOOb when operators have satisfied requirements under the AOGCC and BLM. The commenter explains that there is precedence for AOGA's request. They refer to the notification, reporting, and recordkeeping requirements found at 40 CFR 60.5420a(2)(ii), which states, "if an operator is subject to state regulations that require advanced notification of well completions, and the [operator] has met those requirements, then the [operator] is considered to have met the advanced notification requirements of the rule." Similarly, the commenter urges that the EPA's rule be revised to state, "if an operator is subject to state regulations for venting during liquids unloading, and the operator has met those requirements, then the operator is considered to have met the control requirements under Subpart OOOOb." According to the commenter, revising the EPA's proposal in this suggested manner will allow the EPA to meet its venting and flaring goals while avoiding duplicative regulatory schemes where no environmental benefits would result.

Response II-6-110: The EPA has not finalized its December 2022 proposal to require owners and operators to employ techniques or technologies that eliminate methane and VOC emissions, unless it was technically infeasible or not safe to meet the zero emissions standard. See section X.F.1 and 3 of the preamble to the final rule for details on EPA's final standards/presumptive standards and sections XI.F.1 and 3 of the preamble to the final rule for EPA's response to comments on EPA's proposed December 2022 Proposal Supplemental Proposal zero emissions standard/presumptive standards and recordkeeping and reporting requirements.

The EPA disagrees that the NSPS OOOOb should be revised to deem that Alaska's operators meet the proposed liquids unloading requirements under NSPS OOOOb when operators have satisfied requirements under the AOGCC and BLM. However, an owner or operator may follow the procedures of 40 CFR 60.5399b for the submittal and approval of AMEL for complying with the GHG and VOC NSPS OOOOb work practice standards for liquids unloading operations. Additionally, states can consider RULOF to support the need for alternative compliance options

under EG 0000c in their state plans. See section XIII.C.3 (Remaining useful life and other factors (RULOF)) of the final rule preamble for a summary of the RULOF provisions that have been finalized in the subpart Ba rulemaking (codified at 40 CFR part 60, subpart Ba).

Comment: Commenter (2220-Wyoming Department of Environmental Quality (WDEQ)) reports that much of Wyoming's mineral estate is managed by federal agencies such as the BLM. Wyoming receives significant revenue from severance and other taxes paid on oil and gas production. In the supplemental proposal, the commenter states that the EPA expanded its proposed NSPS 0000b standards pertaining to well liquids unloading operations to include zero VOC and methane emissions requirements for liquid unloading to EG 0000c for existing wells. According to the commenter, these requirements conflict with existing BLM regulations that require direct measurement of liquids from tanks. The commenter states that it is technically infeasible for operators to undertake these direct measurements, which involve opening thief hatches, while maintaining a zero-emission standard. Furthermore, they add that there are technical safety concerns pertaining to zero-emissions liquid unloading involving scenarios where oxygen could get into the tank. Although EPA does include a provision that, in the event of technical infeasibility, an owner or operator would establish and follow BMPs to minimize methane and VOC emissions, the commenter states that these potentially conflicting requirements nevertheless could discourage operators from undertaking production on federal lands in Wyoming. The commenter asserts that the EPA needs to consult with BLM about the supplemental proposal, and EPA should ensure the two agencies' regulations do not conflict.

Commenter (2220-WDEQ) provides that Wyoming already imposes stringent, 98-percent control requirements for well liquids unloading operations and the state would be disproportionately impacted if the EPA discourages production on federal lands by imposing onerous new regulations. A significant amount of oil and gas production occurs on federal lands in Wyoming. Between 2003 and 2019, Wyoming has consistently ranked second in the nation in federal oil production, trailing only New Mexico. Over the same timeframe, they report that Wyoming has been the national leader in federal natural gas production by a wide margin.<sup>245</sup> Two-thirds of the state's natural gas is produced on federal lands leased by energy companies.<sup>246</sup> As such, they contend that there are potential negative ramifications for Wyoming's economy if the proposed rule discourages production on federal lands.

The commenter (2220-WDEQ) argues that the proposed NSPS 0000b and EG 0000c standards ultimately could result in operators reconsidering locating in Wyoming and instead locating in states that would not experience similar conflicting technical requirements because the majority of their production does not take place on federal lands. In addition to Wyoming's state-level concerns, they note that it is also worth pointing out that the federal government also could see its mineral revenues impacted if operators choose to relocate from federal lands. The commenter urges the EPA to reconsider how its zero-emission requirements conflict with BLM's

---

<sup>245</sup> "The Fiscal and Economic Impacts of Federal Onshore Oil and Gas Lease Moratorium and Drilling Ban Policies." Dr. Timothy J. Considine, Professor of Energy Economics, School of Energy Resources, University of Wyoming. Dec. 14, 2020. <https://www.wyoenergy.org/wp-content/uploads/2020/12/Final-Report-Federal-Leasing-Drilling-Ban-Policies-121420.pdf>.

<sup>246</sup> U.S. Energy Information Administration, Wyoming State Profile and Energy Estimates, <https://www.eia.gov/state/analysis.php?sid=WY>.

direct measurement requirements before promulgating its final rule and consider including an exemption for operators located on federal lands.

Response II-6-111: The EPA has not finalized its December 2022 proposal to require owners and operators to employ techniques or technologies that eliminate methane and VOC emissions, unless it was technically infeasible or not safe to meet the zero emissions standard. For unloading technologies or techniques that result in venting to the atmosphere, the final rule requires that owners or operators employ best management practices that meet minimum specified criteria to minimize venting of methane and VOC emissions for each gas well liquids unloading operation. Unloading events that employ non-venting liquids unloading technologies and techniques that do not result in venting of methane and VOC emissions to the atmosphere are not subject to best management plan requirements and the associated recordkeeping and reporting requirements under the rule. An owner or operator of a well affected facility that employs non-venting liquids unloading technologies and techniques is only required to comply with minimal recordkeeping and reporting requirements. In instances where there may be an unplanned venting event, that event would be subject to the best management practices to minimize venting of emissions and the associated recordkeeping and reporting requirements. The EPA believes that the final work practice standard and associated recordkeeping and reporting requirements will incentivize owners or operators of well affected facilities and well designated facilities to minimize or eliminate the venting of emissions to the maximum extent possible during liquids unloading events.

Based on changes made in the final NSPS OOOOb standards and EG OOOOc presumptive standards for liquids unloading operations, any conflicts with the December 2022 Supplemental Proposal zero emissions standard because of other rule requirements that could result in some venting to the atmosphere from a well affected facility conducting liquids unloading would be resolved. Additionally, states can consider RULOF to support the need for alternative compliance options under EG OOOOc in their state plans. See section XIII.C.3 (Remaining useful life and other factors (RULOF)) of the final rule preamble for a summary of the RULOF provisions that have been finalized in the subpart Ba rulemaking (codified at 40 CFR part 60, subpart Ba).

See section X.F.1 and 3 of the preamble to the final rule for details on EPA's final standards/presumptive standards and sections XI.F.1 and 3 of the preamble to the final rule for EPA's response to comments on EPA's proposed December 2022 Supplemental Proposal zero emissions standard/presumptive standards and recordkeeping and reporting requirements.

## **6.5 Technical Infeasibility**

Comment: Commenter (2428-API) states the proposed certification requirements are unreasonably onerous because, in each case, the certifying individual must essentially prove a negative – that the otherwise applicable zero-emissions approaches are “technically infeasible.” The commenter notes that there is no definition of technical infeasibility in the proposed rules, but the words could be construed as setting an exceedingly high bar, such that a given non-emitting technique is “infeasible” based solely on a technical assessment of whether it can

theoretically be physically applied in the given situation. So, for example, the commenter suggests that might require a non-emitting technology to be applied because it is technically theoretically possible, even though it would be inordinately expensive. The commenter believes that this outcome would not be lawful because it would violate the statutory requirement that BSER and the corresponding standard of performance must be cost effective.

Should EPA retain the requirement for case-specific certifications, commenter (2428-API) requests that EPA revise the required certification. The proposed regulatory text of each certification includes the following sentence: “Based on my professional knowledge and experience, and inquiry of personnel involved in the assessment, the certification submitted herein is true, accurate, and complete.”<sup>247</sup> The commenter requests that this be revised to specify that the certification is based on “reasonable inquiry,” as is required for certifications under the Title V operating permit program. The commenter suggests that the revised certification could read as follows: “Based on reasonable inquiry, including application of my professional knowledge and experience and inquiry of personnel involved in the assessment, ....” The commenter contends that a “reasonable inquiry” standard would not shield a certifier from outright fraud but would provide more latitude for reasonable differences of opinion as to technical infeasibility.

And, in any event, the commenter (2428-API) states that a “technical infeasibility” standard allows for second guessing by regulators or citizen enforcers, which invites a “battle of the experts” in potential enforcement actions. The commenter contends that this diminishes the possibility that the opt outs can be implemented with reasonable certainty.

Rather than creating opt outs that require case-specific certification, the commenter (2428-API) recommends EPA establish the opt outs in the final regulation as regulatory alternatives that may be employed if specified criteria in the rule are met. The commenter notes that this is the usual method of prescribing standards of performance and regulatory compliance alternatives, and it would not be difficult for EPA to structure the rule in this fashion.

Commenter (2326-AXPC) requests that BSER exceptions should include economic factors in addition to technical feasibility or safety. The commenter notes that the EPA concedes that it is proposing multiple regulatory requirements whose implementation would be “technically infeasible” for some set of affected facilities. In such cases, the EPA gives affected facilities the ability to “opt out” of the performance standard if the affected facility can show that compliance with the performance standard would be infeasible for technical or safety reasons. As explained below, the commenter believes that “technically infeasible” is a misnomer and EPA should explicitly include economic factors in addition to a technical feasibility analysis.

Within EPA’s NSPS OOOOb/EG OOOOc regulations, the commenter (2326-AXPC) provides that the EPA includes opt out for their regulatory requirements such as the ability to use an emissions control device to handle associated gas,<sup>248</sup> the continued use of pneumatic pumps

---

<sup>247</sup> See, e.g., 40 CFR 60.5377b(b)(2).

<sup>248</sup> Proposed 40 CFR 60.5377b(b)(2).

driven by natural gas,<sup>249</sup> and the use of emitting gas well unloading methods.<sup>250</sup> The commenter states that elsewhere in their comments (section II.D.i of their comments) they provide at least one additional recommendation of an opt out with respect to pneumatic controllers. Unfortunately, the commenter expresses that EPA does not provide any information within the rule on how an affected facility is expected to demonstrate that the regulatory provision in question is “technically infeasible” in their case, other than a requirement that a professional engineer or other qualified individual so certify.

Because there is no explanation of technical infeasibility within the rulemaking, the commenter (2326-AXPC) evaluated what EPA has done in other CAA programs. For example, they note that the EPA’s regulations related to best available retrofit technology (BART) determinations under the regional haze program include some insight into how EPA might evaluate technical feasibility considerations.<sup>251</sup> According to EPA’s BART regulations:

Control technologies are technically feasible if either (1) they have been installed and operated successfully for the type of source under review under similar conditions, or (2) the technology could be applied to the source under review. Two key concepts are important in determining whether a technology could be applied: “availability” and “applicability.” As explained in more detail below, a technology is considered “available” if the source owner may obtain it through commercial channels, or it is otherwise available within the common sense meaning of the term. An available technology is “applicable” if it can reasonably be installed and operated on the source type under consideration. A technology that is available and applicable is technically feasible.<sup>252</sup>

The commenter (2326-AXPC) suggests that, while these regulations provide more context than EPA’s proposed NSPS OOOOb/EG OOOOc regulations, the BART regulation conflates economic factors and technical feasibility and does not specifically account for other factors related to potential implementation that may be critical to compliance. The commenter states that the “available” concept is inherently an economic concept as it relates to whether the item is commercially available – i.e., that the price is at such a level that it can be produced commercially. The commenter contends that, if EPA was truly looking at considering technical feasibility without regard to economic viability, whether a technology is commercially available would be irrelevant. And to do so here, would be inappropriate, particularly given the definition of standard of performance. Under CAA section 111(a)(1), standard of performance means

a standard for emissions of air pollutants which reflects the degree of emission limitation achievable through the application of the best system of emission reduction (taking into account the cost of achieving such reduction and any nonair quality health and

<sup>249</sup> Proposed 40 CFR 60.5393b(c).

<sup>250</sup> Proposed 40 CFR 60.5376b(c)(2)(ii)(B)(2).

<sup>251</sup> 40 CFR Part 51, Appendix Y.

<sup>252</sup> Appendix Y(D)(1).

environmental impact and energy requirements) the Administrator deems has been adequately demonstrated.<sup>253</sup>

By providing an opt-out, the commenter (2326-AXPC) believes that the EPA inherently recognizes that BSER cannot be met at every facility. Thus, in making the demonstration that use of the opt out is appropriate, the costs of achieving such emissions reduction should be taken into account.

Further, because EPA may only include standards that are determined to be adequately demonstrated, the commenter (2326-AXPC) contends that the technical feasibility for the opt-out provisions in NSPS OOOOb/EG OOOOc, technical feasibility must include considerations such as: ability to access electrical power; landowner access; other local or state regulatory requirements; and other considerations that limit the ability to comply with the standard of performance. In other words, technical feasibility must include considerations beyond just physical impossibility. According to the commenter, anything that would preclude, or hinder implementation of the regulations should be included in a consideration of feasibility – whether technical, economic, or some other appropriate consideration. However, they recommend that EPA be explicit that economics is to be considered in the feasibility analysis – as technical feasibility alone is insufficient.

The commenter (2326-AXPC) provides that they discuss the specific concept that commercially unavailable technologies should not be considered technically feasible in further detail with respect to EPA’s proposed oil well associated gas standards elsewhere in their comments (section II.A.iii of their comment letter).

Instead of EPA conflating technical feasibility and economic considerations, as the commenter (2326-AXPC) suggests that the EPA does in the December 2022 proposal, they recommend that EPA in its final rule transparently state that economic factors must be part of an affected facility’s ability to opt out of the regulatory requirement, in addition to whether installation and operation of the regulatory requirement is technically feasible and safe.

The commenter (2326-AXPC) recommends that EPA adopt the following general standard for opting out of EPA’s performance standards or apply this type of standard in instances where EPA has provided an opt out.

An affected facility may opt out of the standard of performance if any of the following apply:

- The performance standard cannot reasonably be installed and operated at the affected/designated facility including due to technical feasibility, safety concerns, or physical impossibility;
- The cost of compliance with the performance standard would result in the affected/designated facility having a cost-effectiveness greater than \$5,540 per ton of VOCs or \$1,970 per ton of methane or the well is no longer able to economically operate; or

---

<sup>253</sup> 42 U.S.C. §7411(a)(1).

- The cost of compliance with the performance standard would be so great that it would result in the affected/designated facility no longer being able to economically operate.

In addition to the general standard provided above, the commenter (2326-AXPC) also request that EPA provide detailed information on what affected facilities can show to meet the requirements for opting out of a control requirement.

In a later comment submission provided by the commenter (3818-AXPC) the commenter expressed serious concerns about the certification requirements for technical infeasibility demonstrations. For example, the commenter notes that the proposal discusses potential for criminal liability related to the technical feasibility demonstration for use of control devices to handle associated gas. The commenter reiterated their position that the CAA already has provisions for knowing criminal violations related to false statements, which includes reference to false material statement, representation, or certification in/omits material information from/alters, conceals, or fails to file or maintain a document filed or required to be maintained under the CAA. The commenter asserts that while they appreciate EPA's recognition that non-emitting approaches are not always practicable and the provision for an alternate path for those situations, we are concerned the potentially punitive nature of these certification requirements will be insurmountable. Not only would the certifier have to prove a negative, that a non-emitting technique is not feasible, they risk personal liability to themselves and their families if their opinion is disagreed with or if a mistake is made, which may not be of their making. It is unlikely that any individual would take such a risk and we argue it is unreasonable and unnecessary to do so.

As a solution, the commenter (3818-AXPC) supported language recommended by API in their comments (copied below).

If EPA retains the requirement for case-specific certifications, EPA should revise the required certification. The proposed regulatory text of each certification includes the following sentence: "Based on my professional knowledge and experience, and inquiry of personnel involved in the assessment, the certification submitted herein is true, accurate, and complete." See, e.g., § 60.5377b(b)(2). This should be revised to specify that the certification is based on "reasonable inquiry," as is required for certifications under the Title V operating permit program. The revised certification could read as follows: "Based on reasonable inquiry, including application of my professional knowledge and experience and inquiry of personnel involved in the assessment, ...." A "reasonable inquiry" standard would not shield a certifier from outright fraud but would provide more latitude for reasonable differences of opinion as to technical infeasibility.

Response II-6-112: The EPA agrees with the commenter that adding "reasonable inquiry" to the statement of certification may alleviate the concern that the effort to explore alternatives to BSER could be unfairly questioned by permit reviewers.

The EPA received data and comments supporting the determination that BSER is routing to a sales line, so long as an operator may with reasonable effort choose a better alternative for their specific physical or operating environment. The analysis that EPA performed to determine the

cost of implementing BSER makes clear that associated gas is a marketable product when the determinants for routing to a sales line are favorable, when the well is new and plans to extract and market the product can be customized as it comes on-line. We believe the commenter's concern is focused on existing production where the location and logistical concerns limit the options available. The EPA accommodated those concerns by allowing reconstructed wells to flare where alternatives are infeasible. The EPA considered that the physical space to operate a non-flaring alternative may be unavailable or that the logistics of routing to sales may be insurmountable even with reasonable time and effort. Other commenters suggested that injecting the associated gas into the well or other well would not always be viable. The EPA points out that based on the 2021 proposal, we are already relying on delegated authorities to make determinations on site-specific facts within their jurisdictions to determine the credibility of a reasonable effort to use non-flaring alternatives to use or dispose of associated gas.

The EPA also subcategorized wells with low levels of associated gas to allow them to flare without making a showing that other alternatives are infeasible. This completely addresses the concerns of operators with exceedingly small amount of gas to dispose. This subcategory should also alleviate some concern regarding the effort required of delegated authorities to make these determinations.

## Chapter 7. Process Controllers

### 7.1 NSPS OOOO and EG OOOOc Affected Facility Definition

#### *7.1.1 Support for EPA Proposed Affected Facility Definition*

Comment: Several commenters (1581-Kathairos Solutions US, Inc. (Kathairos), 2410- California Office of the Attorney General (CA AG) et al, 2433- Environmental Defense Fund (EDF) et al, 2wed446- Independent Petroleum Association of America (IPAA)) provide support for EPA's December 2022 proposed pneumatic controller affected facility definition. Some of the specific comments provided are included in the following paragraphs.

Commenter (2410-CA AG et al) supports EPA's proposed definition of pneumatic controller affected facilities to include the collection of natural gas-driven pneumatic controllers at a site instead of each individual natural gas-driven controller. The commenter further supports EPA's proposal to include: (1) controllers where the emissions are collected and routed to gas-gathering flow line or collection system to a sales line or used as an onsite fuel source and (2) self-contained natural gas pneumatic controllers.

Commenter (2446-IPAA) supports EPA's proposed definition of affected facility opposed to defining each individual natural gas-driven pneumatic device as an affected facility.

Commenter (2433-EDF et al) states that EPA properly defines the affected facility as all controllers at a site for new, modified, and reconstructed facilities, including "modification" and "reconstruction", site-wide pneumatic controller affected facility definition, the two-year window, the inclusion of routed and self-contained controllers, and intermittent controllers.

The commenter (2433-EDF et al) supports EPA's application of "modification" and "reconstruction" in this context, and its conclusion that a modification or reconstruction would result in all controllers at a site becoming a new pneumatic controller affected facility subject to new source performance standards (NSPS) OOOOb. The commenter adds that they believe EPA has reasonably defined an "affected facility" as the collection of controllers at a site. And in applying this definition, EPA's clarification that all controllers at a facility become subject to NSPS OOOOb after the addition of one or more pneumatic controllers is accurate, since doing so would be a physical change resulting in increased emissions. They contend that this is the definition of "modification" under the Act and would necessitate the conversion of all controllers at the site to zero-emission technologies.

According to the commenter (2433-EDF et al), EPA's interpretation of the 2-year 50 percent threshold for the definition of "reconstruction" aligns with the Clean Air Act's (CAA's) "reconstruction" definition, which means the replacement of components of an existing facility to such an extent that "the fixed capital cost of the new components exceeds 50 percent of the fixed capital cost that would be required to construct a comparable entirely new facility." In accordance with this definition, it is reasonable for EPA to equate replacing 50 percent of controllers at a site with 50 percent of the fixed capital costs required to construct an entirely new facility. If the affected facility is all controllers at a site, which, as explained previously, is

appropriate, then 50 percent of the cost to construct an entirely new “facility” would amount to replacing 50 percent of controllers at the site. Since individual controllers are likely to have comparable replacement costs, it is reasonable to assume that there would be a one-to-one correlation between the percentage of controllers being replaced at a site and the percentage of the fixed capital cost that would be required to construct an entirely new comparable facility. Without a two-year window, operators could create multiple replacement programs below the 50 percent threshold over the course of several years (e.g., 20 percent in October 2026, and 30 percent in September 2028) to avoid compliance with NSPS OOOOb. The commenter notes that allowing this loophole would undermine Congress’ intent that air quality be enhanced over the long term with the turnover of polluting equipment, and with the intent of the EPA’s reconstruction provisions. They add that the two-year period provides a reasonable method of determining whether an owner of an oil and natural gas site with pneumatic controllers is proposing an extensive controller replacement that the exact type of program 40 CFR 60.1 was intended to regulate. The two-year time frame also recognizes that it is more cost effective to replace larger chunks of controllers rather than initiate several, smaller replacement programs.

Response II-7-1: These comments are supportive comments on an aspect of the December 2022 Supplemental Proposal that has remained unchanged in the final rule; as such, no response is required.

Comment: Commenter (2433-EDF et al) supports EPA’s decision to include intermittent vent controllers in its proposed standards. The commenter notes that the Carbon Limits 2021 tool shows that converting to zero-bleed remains cost-effective even for sites with just one intermittent controller, especially when considering multi-pollutant costs. The commenter also supports EPA’s response to industry comments that emissions reductions from intermittent vent controllers are already captured in EPA’s cost analysis for the proposed leak detection and repair (LDAR) requirements. As EPA notes, the average emission factor that the EPA uses considers low-emitting properly operating controllers, as well as those that are not operating properly and that are venting during idle, and EPA finds that factor is the correct factor to represent the “uncontrolled” emissions from the universe of intermittent vent controllers. Additionally, these devices are not accounted for in EPA’s modeling of the LDAR provisions.

The commenter (2433-EDF et al) adds that inclusion of intermittent controllers is essential because EPA estimates that over 1.5 million metric tons of methane – 71 percent of emissions from pneumatic controllers - are from intermittent vent controllers. The commenter also supports EPA’s conclusion that using one intermittent controller should not exempt an operator from the standard. The commenter notes that the EPA’s own cost analysis demonstrates the cost-effectiveness of the standard with one controller on-site. The commenter also notes that the Carbon Limits 2021 tool shows that converting to zero-bleed remains cost-effective even for sites with just one intermittent controller, especially when considering multi-pollutant costs.

Response II-7-2: These comments are supportive comments on an aspect of the December 2022 Supplemental Proposal that has remained unchanged in the final rule; as such, no response is required.

### 7.1.2 Request for Related Definitions/Other Clarifications

Comment: Commenter (2399- GPA Midstream Association (GPA)) proposes the following changes to the definitions of certain terms (underlined text indicates new text and struck-out text indicates deleted text):

- *Intermittent vent natural gas-driven pneumatic controller* means a process control device that uses natural gas and ~~natural gas-driven pneumatic controller~~ that is not designed to not have a continuous bleed rate but is instead designed and operated to only release natural gas to the atmosphere as part of the actuation cycle.
- *Non-natural gas-driven pneumatic controller* means ~~an automated~~ process control device that utilizes instrument air or hydraulic fluid as the motive force to change valve position.
- *Pneumatic controller* means ~~an automated instrument~~ process control device used for maintaining a process condition such as liquid level, pressure, delta-pressure, or temperature by changing valve position.
- *Self-contained pneumatic controller* means a natural gas-driven pneumatic controller ~~in which the motive gas is not vented to the atmosphere but captured in a closed vent system for process use or control such that there are no direct methane or VOC emissions from the controller~~ that releases gas into the downstream piping and not to the atmosphere, resulting in zero methane and VOC emissions.

Commenter (2428 - American Petroleum Institute (API)) proposes the following changes to the definitions of certain terms (underlined text indicates new text and struck out text indicates deleted text):

- *Bleed rate* means the rate in standard cubic feet per hour at which natural gas is continuously vented (bleeds) from a fixed orifice in a pneumatic controller.
- *Continuous bleed* means a natural gas-driven pneumatic controller that is designed with a continuous flow of ~~pneumatic supply natural gas from to a fixed orifice pneumatic controller.~~
- *Non-natural gas-driven pneumatic controller* means an automated process control device that utilizes instrument air or hydraulic fluid as the motive force to change valve position. ~~Instrument that is actuated using other sources of power than pressurized natural gas; examples include solar, electric, and instrument air.~~
- *Pneumatic controller* means an automated instrument that manipulates a valve's position with pressurized gas to used for ~~maintaining~~ a process condition such as liquid level, pressure, delta pressure and temperature.
- *Self-contained pneumatic controller* means a natural gas-driven pneumatic controller in which the motive gas is not vented to the atmosphere but captured ~~releases gas into the downstream piping for process use, sales, or control such that there are no direct methane or VOC emissions from the controller.~~ , resulting in zero methane and VOC emissions
