## Foreword

This document provides responses to public comments received on the U.S. Environmental Protection Agency (EPA) “Standards of Performance for New, Reconstructed, and Modified Sources and Emissions Guidelines for Existing Sources: Oil and Natural Gas Sector Climate Review” proposals. Specifically, this document includes EPA’s responses to public comments received on the November 2021 Proposed Rule (86 FR 63110, November 15, 2021) and the December 2022 Supplemental Proposed Rule (87 FR 74702, December 6, 2022); hereinafter referred to as the November 2021 Proposal and the December 2022 Supplemental Proposal, respectively.

EPA received comments on these proposals via regulations.gov, mail, email, and during virtual public hearings. Hardcopies of all comments submitted are available at the EPA Docket Center Public Reading Room. Comments letters and transcripts of the virtual public hearings are also available electronically at <http://www.regulations.gov> by searching Docket ID No. EPA-HQ-OAR-2021-0317.

The high-level structure of this document includes this Foreword and a list of common acronyms and abbreviations used throughout the document; Volumes I and II (with individual Table of Contents); and Appendices that combined present a summary of comments received and EPA’s responses to those comments.

Volumes I and II of this document include the following:

- Volume I: *Standards of Performance for New, Reconstructed, and Modified Sources and Emissions Guidelines for Existing Sources: Response to Public Comments on the November 2021 Proposed Rule* (86 FR 63110, November 15, 2021).
- Volume II: *Standards of Performance for New, Reconstructed, and Modified Sources and Emissions Guidelines for Existing Sources: Oil and Natural Gas Sector Climate Review. Response to Public Comments on the November 2021 Proposed Rule and the December 2022 Supplemental Proposed Rule* (87 FR 74702, December 6, 2022).

Each of the volumes consists of a separate table of contents and an introduction presenting a high-level summary of the comments received on the applicable proposal. For links to Volumes I and II and Appendices, click below:

- [Volume I](#)
- [Volume II](#)
- [Appendices](#)

In addition, each volume includes several sections, with each section focusing on a different broad category of comments on the rule. Considering the large number of comments received on the proposals and the significant overlap between many comments, this document does not respond to each comment individually. Rather, EPA summarized and provided a single response to each significant argument, assertion, and question contained within the totality of comments.

Within each comment summary, EPA provides in parenthesis one or more lists of Docket ID Numbers (DCN(s)) for commenters who raised issues; however, these lists are not meant to be exhaustive, and EPA does not individually identify each commenter who made a certain point in all instances, particularly in cases where multiple commenters expressed essentially identical arguments. Note that the numbers provided in parenthesis reflect the last 4 digits of the DCN. For example, for this docket, the listed ID would be “xxxx” of EPA-HQ-OAR-2021-0317-xxxx.

EPA’s responses to comments are generally provided immediately following each comment summary. In some cases, EPA provided responses to specific comments or groups of similar comments in the preamble to the November 2021 Proposal (86 FR 63110, November 15, 2021 ), the December 2022 Supplemental Proposal (87 FR 74702, December 6, 2022), or the final rulemaking preamble. Similarly, there are some cases where responses refer the reader to another comment response within the document. Comment responses have individual IDs. For responses to comments presented in the Volume I and II Chapters, response IDs reflect the Volume number, Chapter number (or “A” for Appendix), and response number in chronological order presented in the Chapter. For example, “Response I-2-1” would be Volume I, Chapter 2, first response. For responses to comments presented in Appendix A – comment response IDs reflect that the response is in the Appendix by using and “A” prefix, the section number, and the response number in chronological order presented in the Appendix. For example, “Response A-1-3”, would be Appendix A, Section 1, third response. There is only one Appendix (Appendix A) to this Response to Comment (RTC) document that includes comments and responses. We also include abbreviated commenter identifiers after the individual IDs (i.e., XXXX-abbreviated identifier).

In many instances, responses presented in this RTC document also include cross-references to responses on similar or related issues located in the Regulatory Impacts Analysis (RIA) for the final rule and the Technical Support Document (TSD) for the final rule. Accordingly, this RTC document, together with the preamble to the final rule, the RIA for the final rule, the TSD for the final rule, and the rest of the administrative record should be considered collectively as the agency’s response to all the significant comments submitted on the proposed rules.

Comments were assigned to specific sections of this document based on an assessment of the principal subject of the comment; however, some comments inevitably overlap multiple subject areas. It is possible some responses in this RTC document may not reflect the language in the preamble and final rule in every respect. Where the response conflicts with the preamble or the final rule, the language in the final preamble and final rule should be used for purposes of understanding the scope, requirements, and basis of the final rule. Although portions of the preamble to the final rule are paraphrased in this document where useful to add clarity to responses, the preamble itself is the definitive statement of the agency’s rationale for the final rule. To the extent a response in this document could be construed as in conflict with the preamble or the final rule, the language in the final rule preamble and regulatory text supersedes what is included in this document and should be used for purposes of understanding the scope, requirements, and basis of the final rule.

| <b>Chapter 4. Overview of BSER, Control and Control Costs.....</b>                         | <b>I-4-1</b> |
| 4.1 Control of Methane and VOC Emissions in the Crude Oil and Natural Gas Source           |              |
| Category .....                                                                             | I-4-1        |
| 4.1.1 Best System of Emission Reduction (BSER) .....                                       | I-4-1        |
| 4.1.1.1 Periodic Revisions to BSER .....                                                   | I-4-1        |
| 4.1.1.2 Use of Non-Combustion Devices and Innovative Technologies .....                    | I-4-1        |
| 4.2 Control Costs of Standards.....                                                        | I-4-3        |
| 4.2.1 Natural Gas Savings .....                                                            | I-4-3        |
| 4.2.2 Cumulative Impact of All Oil and Natural Gas Sector Regulatory and Policy Actions... |              |
| .....                                                                                      | I-4-4        |
| 4.2.3 Cost Effectiveness Threshold for Methane.....                                        | I-4-5        |
| 4.2.4 Existing State Programs as a Basis for National Standards.....                       | I-4-6        |
| 4.2.5 Collaboration with States.....                                                       | I-4-8        |
| 4.2.6 Unquantified and Ancillary Benefits .....                                            | I-4-9        |
| 4.2.7 Other Cost Benefit Analysis Methodology Comments .....                               | I-4-9        |
| 4.3 Compliance Costs.....                                                                  | I-4-10       |

|                                                                                                        |              |
|--------------------------------------------------------------------------------------------------------|--------------|
| <b>Chapter 5. Control Devices .....</b>                                                                | <b>I-5-1</b> |
| 5.1 Flares .....                                                                                       | I-5-1        |
| 5.1.1 Emergency Flares Applicability Clarification .....                                               | I-5-1        |
| 5.1.2 Support Increased Regulation of Flaring .....                                                    | I-5-2        |
| 5.1.3 Oppose Increased Regulation of Flaring.....                                                      | I-5-5        |
| 5.1.4 Support Banning of Flaring/Non-Emergency Flaring .....                                           | I-5-8        |
| 5.1.5 Propane Fuel Fed Pilot Flares .....                                                              | I-5-17       |
| 5.1.6 Flare Design, Operation and Monitoring Requirements.....                                         | I-5-18       |
| 5.1.7 Flare Technology Requirement Recommendations (Including Monitoring Technologies).....            | I-5-23       |
| 5.1.8 Flare Recordkeeping and Reporting Requirements .....                                             | I-5-38       |
| 5.1.9 Standard Recommendations Based on Flare Size.....                                                | I-5-39       |
| 5.2 Other/All Combustion Devices .....                                                                 | I-5-42       |
| 5.2.1 Combustion Efficiency .....                                                                      | I-5-42       |
| 5.2.2 Control Technology Alternatives to Flaring .....                                                 | I-5-44       |
| 5.2.3 Monitoring Requirements .....                                                                    | I-5-45       |
| <b>Chapter 6. Environmental Justice (EJ) Implications and Stakeholder Outreach.....</b>                | <b>I-6-1</b> |
| 6.1 Environmental Justice and Impacts of Climate Change.....                                           | I-6-1        |
| 6.1.1 General Comments of Concern .....                                                                | I-6-1        |
| 6.1.2 Native American Environmental Justice Impacts.....                                               | I-6-5        |
| 6.1.3 Conducted EJ Analyses .....                                                                      | I-6-9        |
| 6.2 Environmental Justice Implications .....                                                           | I-6-12       |
| 6.2.1 Control of Emissions is Needed to Reduce EJ and Climate Impacts .....                            | I-6-12       |
| 6.2.2 Title VI of the Civil Rights Act .....                                                           | I-6-15       |
| 6.2.3 EPA’s EJ Analysis .....                                                                          | I-6-15       |
| 6.3 EJ Outreach and Engagement .....                                                                   | I-6-18       |
| 6.3.1 Need for Additional Communication and Outreach to Disadvantaged Communities.....                 | I-6-18       |
| 6.3.2 Community-Based Initiatives .....                                                                | I-6-18       |
| 6.4 Proposed Rule Will Result in Adverse Economic Impacts/Environmental Justice Economic Impacts ..... | I-6-19       |

|                                                                                   |              |

## Chapter 1. Introduction

This document provides EPA's responses to public comments on the proposed *Standards of Performance for New, Reconstructed, and Modified Sources and Emissions Guidelines for Existing Sources: Oil and Natural Gas Sector Climate Review* published in the *Federal Register* on November 15, 2021, at 86 FR 63110.

Just over 472,000 public comments were received on the proposal. The EPA Docket Center consolidated mass mail campaigns, form letters and petitions into single DCNs, resulting in over 1,270 posted comments. (Note: Batches of substantially similar mass mail campaigns, form letters and petitions are considered as a single "unique" comment.). Each of these comments were reviewed and significant comments relevant to this action have been summarized and included in this document.

Of the more than 1,270 "unique" comment letters received over 62 percent originated from individual private citizens, 15 percent are from industry (including industry associations), 8 percent are from environmental and public advocacy groups, 6 percent are mass mail campaigns/petitions (representing nearly 470,000 individuals), 6 percent are from state, local, federal, and tribal governments/representatives, 3 percent are from other advocacy groups, including financial companies, and less than 1 percent are from academia.

In addition to public comment submissions to the Docket, EPA held a 3-day virtual public hearing, November 30, 2021, through December 2, 2021, to provide the public the opportunity to present comments and information on the Agency's proposed new source performance standards (NSPS) and emissions guidelines (EGs) to reduce methane and other harmful pollution from the oil and natural gas industry.

Nearly 300 speakers, from members of the public either representing themselves or speaking on the behalf of one or more organization or agency, provided oral testimony over the course of three days. Live, daily testimonies were recorded by a certified court reporter and documented in official transcripts. Emailed written copies of testimonies and other supporting information received were uploaded, separately to the Docket.

The public comment period for the proposed rule was first scheduled to close on January 14, 2022; however, EPA received several requests to extend the public comment period. Accordingly, EPA extended the deadline to submit comments by seventeen (17) days, to January 31, 2022. The comment period officially closed on January 31, 2022. A general overview of all the comments received follows in Sections 1.1 through 1.4 of this Chapter. More-detailed comments provided by these commenters (some of which are highlighted in the general overview) on the November 2021 Proposal have been summarized and included in Chapters 2 through 23 of this Volume I. Mass Mail Campaigns/Petitions

## 1.1 Mass Mail Campaigns/Petitions

Nearly 90 individual entries submitted to the Docket are categorized as mass mail campaign comments; representing roughly 470,630 of the more than 472,000 public submissions received by the Docket on the November 2021 Proposal (> 99 percent).

Mass mail campaigns can be classified as either mailers/form letters or petitions. For the purposes of this Response to Comment (RTC) document, mailers and form letters (including postcards) are comment submissions submitted by individual commenters, but present substantially similar (if not identical) remarks. These campaigns are typically sponsored by an organization/institution. Petitions are pre-written letters or statements (by a sponsoring agency/institution) requesting action that are signed by persons supporting what is stated in the pre-written letter or statement.

Under this proposal, mailers/form letters (including postcards) account for roughly 91 percent of the total number of mass mail campaign comments submitted to and identified by the Docket – representing more than 95,000 private citizens. Most contributors submitted templates provided by the known sponsoring organization(s) without change; however, it is worth noting that a few commenters customized the template(s) – e.g., to include statements describing personal experiences with deteriorating health. Petitions account for nearly 9 percent of the mass mail campaign comments identified and represent more than 373,900 private citizens.

Roughly 22 percent of mass mail campaign comments were prepared by an unknown sponsoring organization. The remaining campaigns were generated from various known groups and organizations representing a wide range of sectors, including academia, religion, and environmental/public advocacy. Most mass mail campaign comments received (over 40 percent) are sponsored by advocacy or interest groups, comprised of mainly faith-based organizations. At least one campaign, in support of the rule, represents 59 undersigned public representatives from the Commonwealth of Pennsylvania (last 4 digits of DCN-0995). (Note: Although a late submission, it is worth noting that at least one mass mail campaign (representing 88 individuals) was prepared and submitted in Spanish [last 4 digits of DCN-1454]).

It is worth noting that roughly 39 percent of comments prepared by “Private Citizens” included one or more mass mail campaign arguments; however, these comments varied enough to be considered as a separate entry by the Docket. These comments are summarized in section 1.4.1 of this Chapter (as part of the private citizen summary).

Mass mail comment campaigns uniformly support the proposed rule and applaud EPA’s efforts to reduce methane emissions/pollution from industrial sources (the oil and natural gas sector). Campaigns strongly believe that the proposed rule is an essential step forward towards protecting public health and tackling/mitigating climate change, and often argue the point that methane is over 80 times more potent than carbon dioxide. Many of the campaigns cite/reference the amount of methane emissions generated from the oil and gas sector (16 million metric tons) and warn that without immediate action, methane emissions and its impact on public health, primarily the health of vulnerable populations (e.g., children and communities

located near oil and gas industry operations) and the environment will continue to worsen.

While the campaigns agreed that, overall, the proposed rule is a step towards the right direction; nearly all urged the Agency to further strengthen the proposed rule. Requests repeatedly made include, for example:

- End routine flaring (except in emergency situations);
- Strengthen monitoring requirements for smaller, low-producing wells – increase the number of inspections;
- Maintain strong requirements for the deployment of zero-emitting controllers;
- Develop a process for the incorporation of monitoring data from third parties (e.g., a process that engages with frontline communities, educates and certifies community members and requires immediate follow-up on complaints filed by community leaders/members);
- Require monitoring and plugging of abandoned wells; and
- Reduce methane pollutions (using existing low-cost technologies) from the oil and natural gas industry by 65 percent by 2025.

More than 40 percent of the mass mail campaigns spoke directly on the issue of environmental justice. These campaigns were prepared by and represent roughly 12,600 black church leaders and community members, covering multiple states. These faith-based mailers express concerns that low-wealth communities and communities of color, particularly black communities, are disproportionately impacted by air pollution (methane emissions from the oil and gas industry) and climate change; stating that more than 1 million African Americans live within a half-mile of an existing natural gas facility.

Moreover, multiple campaigns explicitly reference methane pollution reduction requirements currently imposed by the states of Colorado and New Mexico, as examples of efficient and successful rulemakings, and encouraged the Agency to follow in these states' path and implement more stringent standards.

A list of campaigns received is provided in **Appendix B** to this document. Examples of a few of the mass comment campaigns can be found in **Appendix C** to this document.

## 1.2 General Support/Opposition

### Support

Roughly 74 percent (or more than 900 comments) of the unique written comments received support the general intent of EPA's proposed rule, *Standards of Performance for New, Reconstructed, and Modified Sources and Emissions Guidelines for Existing Sources: Oil and Natural Gas Sector Climate Review* published in the *Federal Register*, including one or more proposed requirements. Support for the proposed rules can be broken down by commenter type as follows: over 65 percent originated from individual private citizens (including mass mail campaign variations), 10 percent are from environmental and public advocacy groups, 10 percent are from industry (including industry associations), 9 percent are mass mail

campaigns/petitions, 4 percent are from state, local, federal, and tribal governments/representatives, 2 percent are from other advocacy groups (including financial companies), and less than 1 percent are from academia.

Commenters overwhelmingly believe that the proposed action is a significant step forward to combating climate change and its impacts (including economic productivity and social welfare), improving air quality, and protecting public health and the environment. Commenters remind that methane is a potent greenhouse gas (GHG) (traps about 80 times as much as heat as carbon dioxide) and point to the oil and gas industry as the biggest contributor. Several commenters expressed particular concern over the health and wellbeing of communities of color and tribal communities – which are often disproportionately impacted by harmful air pollution from oil and gas operations – and agree that the proposed rule could aid in addressing these environmental justice issues. Though commenters generally support the proposed rule and EPA’s efforts to reduce methane emissions, several of the commenters feel that the proposed changes do not go far enough and call on the EPA to further tighten rules surrounding the release of methane emissions from the oil and natural gas industry. In such cases, commenters highlighted instances where the rule could be improved upon and presented one or more recommendations to further strengthen requirements. Two central themes or requests included that the EPA end the practice of routine flaring at oil and gas operations (i.e., ban flaring, except for emergencies) and require regular monitoring at all smaller, high-polluting and leak-prone wells. While several commenters cite Colorado and New Mexico as examples of states with successful flaring and low-production well policies; overall, commenters stress that current regulations and voluntary actions achieved by the oil and gas industry alone are not enough to combat climate change and improve air quality and underscore the need for federal oversight.

### Oppose

Approximately 21 percent (or more than 250 comments, largely from private citizens, followed by industry/trade association representatives, government officials/organizations, nonprofit organizations and other advocacy groups) of the unique written comments received generally oppose one or more specific action. Generally, commenters worry that imposing additional regulations on the oil and gas industry, a sector which many believe is already over regulated, would significantly impact the economy – e.g., would slow U.S. economic growth, result in job losses, bankrupt small, local oil and gas producers, and create higher energy prices for consumers. Many of these commenters further argue that the proposed rule is an example of over-regulation and excessive federal government overreach. In most cases, commenters highlighted specific areas in the rule where they believe further improvements, or additional clarification are needed to correct requirements or language that they considered to be lacking.

Two commonly discussed areas of concerns include the reference to community involvement in identifying/detecting large-volume emission events and inclusion of marginal wells (or low production wells). Overall, commenters express that the reference to community involvement in identifying/detecting large-volume emission events is too vague and would lead to uninformed and untrained community members in and around oil and natural gas production operations. These commenters unanimously agree that the rule needs to be clear that untrained individuals

without appropriate safety equipment should not be visiting well sites or tank batteries to measure emissions; not only would they be trespassing on private property, but measuring emissions without training and without the proper equipment is dangerous. Similarly, commenters opposed the inclusion of marginal wells (or low production wells) in the proposed rule; claiming that emissions from these production operations are insignificant – marginal wells have a diminished capacity to emit methane. According to these commenters, marginal wells can become economically unviable for small independent drillers if new (inspection and repair) rules are too costly. These commenters generally remind the EPA that marginal wells historically have been exempted from complying with previous, similar regulations and many of the commenters feel that the Agency should maintain the exemption status.

Roughly 3 percent of the unique comments (over 35 comments, mostly from industry and government representatives) requested that EPA extend the public comment period for the proposed rule; citing that the amount of time granted to prepare and submit remarks is insufficient.

Approximately 3 percent (over 30 comments, primarily from private citizens) of the unique comments received, conveyed general concerns about the environment and/or public health but did not specifically comment on the proposed rules.

### **1.3 Summary of Public Hearing Comments**

As previously noted, the EPA held a virtual public hearing November 30, 2021, through December 2, 2021, to provide the public the opportunity to present comments and information on the Agency's proposed updates to NSPS and EGs to reduce methane and other harmful pollution from the oil and natural gas industry. Over the course of three days, nearly 300 speakers (roughly 100 speakers per day), from members of the public either representing themselves or speaking on the behalf of one or more organization or agency, provided oral testimony. Testimonies can be broken down by commenter type as follows: over 53 percent originated from environmental and public advocacy groups (including various nonprofits and faith communities), nearly 40 percent originated from individual private citizens (including students, retirees, community members and volunteers), 4 percent originated from industry (including industry associations), and 3 percent originated from government agencies representatives and elected officials. It is worth noting that some speakers prepared and submitted separate, more detailed comments to the Docket. These remarks are discussed elsewhere in this document. The public hearing transcripts for the virtual public hearing are accessible at [regulations.gov](https://www.regulations.gov) (see EPA-HQ-OAR-2021-0317-1528).

Environmental and public advocacy groups generally applauded EPA's efforts to reduce methane emissions/pollution from industrial sources (the oil and natural gas sector). Speakers strongly expressed that they believed that the proposed rule is a step towards the right direction and urged the Agency to finalize the strongest most comprehensive rule. While speakers agreed that the proposed rule would help protect public health and help mitigate climate change, some speakers suggested that the proposal, as written, could be further strengthened and proposed more protective standards – i.e., offered one or more recommendations aimed at achieving more comprehensive emissions reductions from oil and natural gas facilities, such as

supporting more frequent monitoring (quarterly instead of annually) and prohibiting the practice of routine flaring.

Private citizens testimonies echoed many of the remarks made by environmental and public advocacy groups, and at times also included personal accounts – experiences and a description of various environmental and health impacts resulting from climate change and/or exposure to air pollutants, including methane, from oil and gas facilities. Several of these speakers underscored the point and expressed ongoing frustration that the oil and gas industry is heavily subsidized even though the industry externalizes health and environmental costs. Many of these speakers, as well as of other private citizens suggested that the oil and gas industry cannot self-regulate, nor can we (private citizens) rely on volunteering efforts as a sole means to address climate change and adequately reduce methane and called on the EPA to finalize the strongest most comprehensive rule.

In general, industry representatives supported the intent of the proposed rule – reducing methane emissions – many of which, emphasized their company's commitment to protecting public health and the environment, as well as their commitment to participating in ongoing engagement efforts with community members, regulators, etc., to further reduce impacts from the oil and gas industry. A few industry speakers requested, informally, an extension of the public comment period (by an additional 30-, 60-, or 90- days); arguing the allotted time is too short to provide an adequate response. Other representatives identified one or more requirements in the rule which they specifically opposed, including for example, encouraging local residents and community members to evaluate and access onsite oil and gas equipment/identifying emissions at oil and gas locations. In this example, industry representatives warn against encouraging untrained public members that do not possess the right protective equipment to check equipment as they may get seriously injured. At least one industry representative (whose members operate natural gas compressors, stations, storage fields and interstate pipelines that will be subject to these rules in 46 of the 48 contiguous state) generally supported the revisions to NSPS OOOOa, as written, and offered thoughts specific to NSPS OOOOb and EG OOOOc. A few industry representatives noted the importance of the oil and gas industry to state economies (provide jobs), and at least one representative suggested that the proposed regulations are an attempt to bankrupt American oil and gas companies and do away with fossil fuels. In contrast, another industry representative expressed hope that the proposed rule will lead to innovative approaches to meeting emissions reduction challenges and briefly described available technologies that can be used – e.g., Airdar, a cousin to radar and sonar.

Speakers representing states, federal, local and tribal governments overwhelmingly supported the proposal and EPA's overall intent to limit/reduce methane pollution from oil and gas operations and urged the Agency to strengthen the proposed requirements to maximize climate and health benefits. These speakers agreed that methane emissions generated from oil and gas operations are harmful to public health and the environment, with at least one commenter underscoring the point that communities of color and/or low-income communities are disproportionately impacted. Another commenter reminded that some states' economies, such as theirs, are supported by (dependent on) tourism (including outdoor recreation activities) and expressed concerns over economic viability (impacts to diners, hotels, camping sites, etc.).

## **1.4 Summary of General Positions by Commenter Type**

### ***1.4.1 Private Citizens***

#### Support

Most private citizens (approximately 77 percent of the “unique” comments received) generally support the proposed actions/revisions to the NSPS and EG for new and existing sources in the oil and natural gas sector. Similar to public submissions included as part of mass mail campaigns, several of the commenters express that while the proposed rule is a step in the right direction, they urge the Agency to go even further (*e.g.*, ban flaring and strengthen monitoring requirements). Several private citizen commenters specifically support the EPA regulating emissions of volatile organic compound (VOC) and methane emissions to address public health, environmental health and climate change concerns (and provided several examples to support their concerns).

#### Oppose

Approximately 19 percent of the “unique” comments received from private citizens generally oppose the proposed revisions to the NSPS and EG for new and existing sources in the oil and natural gas sector. Most of these commenters express that the oil and gas industry is already highly regulated, and warn that, if enacted, the proposed regulations would lead to economic hardships (*e.g.*, an increase in job losses, higher energy costs and increases in the cost of living in the United States) and production hardships (*i.e.*, cutting back domestic oil and gas production and the closing of small production facilities) that would be felt both, domestically and internationally. A few commenters also assert that the concept of climate change is not real and there is no climate crisis – methane is a natural occurring gas and is not problematic. Some commenters also question the benefits of the proposed rule as it relates to mitigating climate change, noting emission reductions imposed on domestic production in America does little to impact production or reduce methane emissions from other countries (*e.g.*, China and India).

#### Other

Approximately 4 percent of the comments received from private citizens include broad remarks about the environment, public health, etc., but do not comment specifically on the proposed requirements included in the Proposal.

Less than 1 percent of private citizens requested an extension to the public comment period – an additional 90 days to ensure appropriate time to review new regulations and accompanying documents, as well as to ensure that the EPA has sufficient time to review information.

### ***1.4.2 Academia***

Comments received from academia unanimously (100 percent) support EPA’s November 2021 Proposal. The commenters generally commend the Agency for their efforts to control methane

emissions from new and existing sources in the oil and gas industry and overwhelmingly agree that the proposed rule is an important step (in the right direction) to comprehensively protect public health (particularly at-risk, frontline communities and communities of color) and combat climate change (e.g., creating more frequent and more dangerous weather events); with many underscoring the point that oil and gas production is the largest industrial source of methane pollution in the U.S. One commenter referenced several studies that found correlations between living closer to more wells and more actively producing wells and increased risk of preterm birth, migraine headache, depression, and cardiovascular disease in Pennsylvania (Casey et al. 2016, Casey et al. 2018, Casey et al. 2019, Tustin et al. 2017, Rasmussen et al. 2016). These same studies also suggest that people of color are more likely to live closer to methane super-emitters, suggesting that reducing emissions from oil and gas wells is also an issue of environmental justice.

While commenters generally support the intent of the rule, nearly all believe that the November 2021 Proposal does not go far enough and urge the Agency to strengthen proposed requirements. Commenters propose one or more specific recommendations aimed at toughening EPA's final rule and maximizing net benefits. Recommendations offered are similar to suggestions made by other commenters, including private citizens – such as, end routine flaring, establish a meaningful and effective process that allows communities to report super-emitter events directly to the EPA, require regular monitoring at all smaller, leak-prone wells, require electric pumps at compressor stations and processing plants. At least one commenter maintains, as it relates to maximizing net social welfare, that the EPA should propose standards for additional sources (including abandoned and unplugged wells, flares, pipeline pigging operations, and tank truck loading operations) in the oil and gas sector.

#### ***1.4.3 Industry/Trade Association***

Industry support (including industry associations) for EPA's proposed actions is nearly split, with roughly 47 percent of the industry comments supporting one or more components of the proposed rule and nearly 45 percent opposing them.

##### **Support**

Overall, commenters in favor of the proposed amendments support EPA's efforts to protect public health and address climate change through reductions in methane emissions – which they echo is a major GHG – and are in support of reasonable methane regulations. Several industry commenters reiterate their commitment to measuring and mitigating methane emissions from their own operations and briefly discuss current efforts underway; adding that methane detection technologies have improved dramatically over the years.

A few industry commenters (many of which are vendors) provide product-specific equipment/material(s) and services offered (or sold) which they believe could be used to achieve EPA's methane emissions reduction goals.

There are also industry commenters, that, although they generally support the rule, request that EPA consider and avoid duplication or unnecessary administrative burdens in complying with state and federal standards. These commenters also request that the EPA consider some of the comprehensive regulatory and proactive operational approaches already underway in states, including New Mexico, and voluntary efforts/initiatives related to methane emissions that are currently underway throughout the natural gas supply chain.

### Oppose

Conversely, several industry commenters express opposition to one or more proposed requirements (approximately 44 percent) and maintain that the November 2021 Proposal is unnecessary; largely expressing that they believe that the industry sector is already overregulated. These commenters warn that additional regulations would significantly impact the economy.

Several industry commenters specifically object to what they say is the proposal's one-size-fits all approach, which the commenters contend fails to adequately account for impacts to small businesses – e.g., the cost of monitoring and implementation/compliance requirements, which they believe will burden many small business owners with unjustified costs leading to early plugging and abandonment of marginal wells that still have recoverable reserves. These commenters recommend, in general, that the EPA approve a longer implementation period of the rule for small businesses. At least one commenter warns that this early plugging and abandonment could cause a decline in U.S. domestic production nationwide resulting in increased dependency on foreign crude and natural gas, price increases to consumers for their energy and significant job losses across the oil and gas.

### Other

Approximately 8 percent of the industry comments requested an extension of the public comment period (anywhere from 30- to 60- to 90-days) for EPA's proposed rule (87 FR 74702, December 6, 2022); citing, in general, insufficient time to respond adequately and appropriately. Commenters unanimously agree that the complexity of the proposed rule, and its potential impact on operational requirements of numerous aspects of the natural gas and oil industry (not previously subject to regulation under the Clean Air Act (CAA), section 111(d)), suggests that sufficient (additional) time is needed to fully analyze the impact of the proposed regulations. Commenters further justify the need for additional time by noting the level and number of staff/members needed to fully analyze the proposed rule.

#### ***1.4.4 State/Local/Tribal/Federal Governments***

Roughly half (approximately 50 percent) of the comments submitted by government agencies and representatives (mostly comprised of states) generally support EPA's efforts to update, expand and strengthen the new source performance standards, or NSPS (proposed in November 2021 under CAA section 111(b)), for methane and other harmful pollutants (e.g., VOC

emissions) from new, modified, and reconstructed oil and natural gas operations, and to establish the EGs requiring regulation of methane from existing sources.

### Support

Overall, commenters that support the proposal agree that significantly reducing methane – a potent GHG – from the oil and natural gas industry will generate significant climate benefits as well as direct health benefits to communities harmed by local and regional emissions, including low-wealth, communities of color (including tribal communities). While commenters prepared and submitted individual, separate remarks on the proposed rule based on factors that are unique to their state or tribal community, a number of commenters offer technical comments and/or one or more recommendations aimed at further strengthening the rule that are identical to or resemble recommendations proposed by non-governmental representatives (including private citizens, environmental groups, etc.) – such as, limiting flaring to emergencies situations only, revising the proposed requirements for fugitive emissions monitoring and repair (increases in frequency), transitioning to zero-emitting technologies for controllers, eliminating venting of associated gas from oil wells, strengthening requirement for storage tanks, etc.

One commenter (representing 153 state and local air pollution control agencies) appreciates that the proposed rule would help state and local agencies in their efforts to achieve and maintain compliance with national ambient air quality standards (NAAQS) and is also supportive of the development of an example state plan and model rule language for each segment of the oil and gas industry that can be incorporated directly or by reference to meet EPA’s emission guidelines.

### Oppose

Over a quarter of the comments (approximately 27 percent, comprised mostly of states) submitted by state, local, federal and tribal governments claim that the proposed rule, as written, poses several problematic and concerning issues, and has the potential to substantially impact states and tribal communities. Specific concerns vary by commenter and commenter type. However, most commenters (including state and federal representatives and at least one commenter representing an association of local governments) express concerns that the amount of resources (cumulative costs) required to account for the anticipated increase in workload, in order to comply with and implement the proposed rule – e.g., in approving permits, reviewing monitoring data and reports, and ensuring compliance with the proposed emission guidelines for existing sources – will come at a significant cost to industry and states. Several state government commenters, particularly those home to oil and natural gas facilities, also express concern that the proposed actions would negatively impact production in their states, resulting in an increase in loss of jobs, as well as a reduction in state and federal revenues.

Several commenters also suggest that the November 2021 Proposal is redundant; highlighting that several states, including Colorado already have oil and gas regulations in-place that are comparable and, in some cases, more stringent than the proposed rule. These commenters

underscore the point that companies are currently making efforts to reduce methane emissions – e.g., via installing methane capturing systems, and warn against potentially getting in the way of innovation and investment in methane emissions reducing activities – by indirectly penalizing voluntary efforts and innovative solutions, through the addition of new regulatory burdens, which states and companies would not have been subject to had they not installed these innovative systems.

A few commenters objected to one or more specific actions pertaining to state plan development and implementation under the EG, and due to the complexity of the proposed EG, feel that they could benefit from further guidance.

In similar opposition, tribal commenters overwhelmingly express concerns that, if finalized as written, the proposed rule would unreasonably burden development of tribal energy resources. The commenters explain that the production of oil and gas on tribal lands has played a significant, historic role in tribal economic development – e.g., royalties/revenues used to fund, for example, critical resources, including housing, healthcare, and while they appreciate the intent of EPA’s effort, they ask that the Agency consider – and disclose – the full breadth of impacts it will have on tribal communities that rely (economically) on oil and gas production. Commenters remind, that as tribal communities, they face a set of unique challenges – e.g., resulting from the shared governance, and applaud the Agency for including options for tribes to exercise their inherent sovereignty by achieving Treatment as a State (TAS) and developing and implementing Tribal Implementation Plans (TIPs). Commenters ask that the EPA offer an expedited TAS and TIP development and approval process, and an expanded grant funding to assist with initial compliance costs and maximize limited tribal resources and staff capacity. Moreover, commenters also request that the Agency clarify, for example, whether a single federal plan would apply to all Indian reservations without TIPs or whether individual federal plans will be developed for each such Indian reservation.

#### Other

Remaining comments (approximately 22 percent, comprised predominately of state and federal representatives, and state and local air agencies and associations) ask that the EPA extend the public comment period (anywhere from 30- to 60- to 90-days); citing, in general, insufficient time to respond adequately and appropriately. Nearly all commenters reference the complexity of EPA’s November 2021 Proposal as the primary reason for requesting an extension.

### ***1.4.5 Environmental and Public Advocacy Groups***

#### Support

Comments (roughly 96 percent) from environmental and public advocacy groups overwhelmingly support the November 2021 Proposal and appreciate the Agency’s efforts to reduce methane emissions from oil and gas operations and urge the Agency to promptly finalize the proposal. Many of these commenters support and reiterate one or more proposed regulatory

changes also supported by non-environmental and public advocacy groups (including private citizens, industry, academia, etc.), including regulating oil and gas based on emissions – not on the amount of production from a particular well, requiring a zero-percent leak rate from controllers, prohibiting venting of methane, addressing leaks from storage tanks, providing an advanced screening approach for leak detection and remediation, and reducing emissions from maintenance activities, like liquids unloading.

Most commenters discuss climate change impacts, including its effect on public health (e.g., exposure to toxicity that cause asthma and other health problems) – particularly the health of minority and frontline communities/tribes, but while supportive of the Agency’s efforts to reduce emissions, many of the commenters echo feelings noted by other commenter types (including private citizens, academia, industry, etc.) that the proposed rule does not go far enough. These commenters collectively urge the EPA to pass the strongest possible regulations governing methane emissions in the oil and gas industry, and identify a number of regulatory areas (many of which have been discussed already), which they believe need tightening of the requirements to further limit emissions – i.e., regular monitoring should be conducted at all facilities, including those where site-level baseline methane emissions are below 3 tpy, address emissions from smaller storage tanks, prohibit routine flaring at oil and gas sites, incorporate emission monitoring by community groups, and require monitoring and plugging at abandoned and improperly plugged wells.

### Oppose

Remaining comments (roughly 2 percent) generally opposed the November 2021 Proposal. While specific concerns vary by commenter, at least one advocacy group questions how the Agency gauges the rule’s effectiveness; stating the proposed rule’s Regulatory Impacts Analysis (RIA) does not properly account for the standards’ impact on climate change.

### ***1.4.6 Other/Other Advocacy Groups***

#### Support

Comments (approximately 80 percent) received from other advocacy groups (mostly private equity/investment firms, but also includes union organizations) support the November 2021 Proposal and believe, in general, it is an important step in identifying sound investments needed to tackle climate change – to both reduce emissions and improve public health/air quality (would result in significant emission reductions from ozone precursors, air toxics etc.), as well as maintain economic stability.

Moreover, commenters in support of the November 2021 Proposal agree that companies need to increase investments in clean energy; many asserting that to ensure economic stability and achieve necessary financial returns, the world needs to transition to a more sustainable global economy. Nearly all these commenters echo one or more previously made concerns – e.g., methane is a potent GHG, and identify the changing climate as an extraordinary environmental

challenge with far-reaching economic, environmental, and societal implications that create risks (and opportunities) for companies and investors alike. These commenters agree, in general, that the need for stronger regulation of methane emissions from the oil and gas industry is necessary to help address this challenge and recommend that the EPA:

- Maintain strong requirements for the deployment of zero-emitting controllers;
- Maintain or expand strong leak monitoring and repair standards, including expanded use of advanced leak detection technologies;
- Expand upon the November 2021 Proposal to include all potentially significant sources of methane emissions, including smaller leak-prone wells, subject to emission standards;
- Sets a near-term end date for operators to cease routine flaring of natural gas at oil and gas facilities, as states like Alaska, Colorado and New Mexico have already done;
- Establish a transparent, credible and empirically based methane emissions reporting framework to improve the accuracy of reported methane emissions data, enabling investors to clearly differentiate between leaders and laggards;
- Regulate against orphan and abandoned wells, which are a significant source of methane emissions and a risk to public health and safety; and
- Incorporate community-based monitoring which is critical for those living closest to development.

One commenter (representing farmers union members) believes that the adoption of strong methane rules is critical to protecting rural communities and agricultural heritage. The commenter describes the impacts of climate change – e.g., severe droughts and floods, increases in range of pests, more disease overall and lower crop and livestock yields, etc., on agriculture, food, and related industries. At least one commenter states that the agriculture sector and related industries contributed to more than \$1.1 trillion to the U.S. economy in 2019 and provided 19.7 million full- and part time jobs in 2020.

### Oppose

Approximately 20 percent of commenters (comprised of financial firms) oppose the November 2021 Proposal as written; arguing that the EPA has not fully considered the impact of this proposed rule on small businesses. Commenters request that EPA consider a broader range of regulatory flexibilities to reduce the cost to small businesses in the supplemental proposal.

## Chapter 2. Summary of Proposed Action for NSPS OOOOa

### 2.1 General Support

Comment: Several commenters (0437-New York Office of the State Comptroller, 0598-Countrymark Energy Resources, LLC (CER), 0756-Baker Hughes, 0820-Pioneer Natural Resources USA, Inc. (Pioneer), 0836-Domestic Energy Producers Alliance (DEPA); 0458-Maryland Department of the Environment (MDE), 0802-Kraken Oil and Gas LLC (Kraken), 1294-Ohio Clinicians for Climate Action (OCCA), 0817-GPA Midstream Association (GPA), 0938-Texas Oil & Gas Association (TXOGA), 0814-Independent Petroleum Association of America (IPAA) *et al.*, 1391-Interstate Natural Gas Association of America (INGAA)) provided general support for the proposed retention of certain aspects of the 2020 Technical Rule.<sup>1</sup> Commenter (0817-GPA) states that the changes made in the 2020 Technical Rule were sound, practical revisions designed to streamline the regulatory process while continuing to ensure that emissions were controlled appropriately. Commenter (0756-Baker Hughes) believes that the EPA's proposed revisions to NSPS OOOOa are necessary to ensure that important amendments made in the 2020 Technical Rule apply to NSPS OOOOa to address the technical and implementation issues that result from the CRA disapproval of the 2020 Policy Rule.<sup>2</sup>

Commenter (0802-Kraken) specifically supports EPA's action to reinstate the 2020 Technical Rule amendments to include:

- Fugitive emissions monitoring (initial monitoring requirements, monitoring frequency – compressor stations, monitoring frequency – well sites, low production well sites, schedule for repairing leaks).
- Fugitive emissions monitoring requirements and modifications (modifications of a well site that is a separate tank battery surface site).
- AMEL (incorporating state requirements, streamlining application requirements for using emerging technologies).
- Pneumatic pumps.
- Engineer certifications for CVS.
- Storage vessels (tanks).
- Other amendments (onshore natural gas processing plants, recordkeeping and reporting, well completions).

Similarly, commenter (0814-IPAA *et al.*) specifically supports the following 2020 Technical Rule amendment revisions to NSPS OOOOa:

- Allow the use of a separator at a nearby centralized facility or well pad that services the well affected facility during flowback, as long as the separator can be utilized as soon as it is technically feasible for the separator to function.

---

<sup>1</sup> “Oil and Natural Gas Sector: Emission Standards for New, Reconstructed, and Modified Sources Reconsideration,” 85 FR 57398 (Sept. 15, 2020) (“2020 Technical Rule”).

<sup>2</sup> “Oil and Natural Gas Sector: Emission Standards for New, Reconstructed, and Modified Sources Review,” 85 FR 57018 (Sept. 14, 2020) (“2020 Policy Rule”).

- The separator that is required during the initial flowback stage may be a production separator as long as it is also designed to accommodate flowback.
- Clarification to definition of “flowback” and what is not included in the definition of “flowback.”
- Changes and/or streamlining recordkeeping and reporting requirements.
- Expanding the technical infeasibility provision to apply to pneumatic pumps at greenfield sites.
- Clarification that boilers and process heaters are not considered control devices for purposes of the pneumatic pump standards. Nothing has changed within the industry to warrant EPA changing their initial determination.
- Allowing for the certification of technical infeasibility to be provided by a professional engineer (PE) or in-house engineer.
- The various changes and clarifications related to CVS. The commenter (0814-IPAA *et al.*) points out that the proposal inaccurately cites previous EPA conclusions with regard to optical gas imaging (OGI) monitoring of CVS at “no extra cost.” The cited reference makes no mention of cost and that consultants conducting emissions surveys add equipment to monitor at no extra cost.
- Exclusion of “wellhead only well site” or a well site that later becomes a wellhead only well site from fugitive emissions monitoring. The EPA should clarify if the wellhead is disconnected from the associated tank that the well is removed from the monitoring program.
- Extension of the initial monitoring of methane from well sites and compressor stations from 60 to 90 days.
- Clarification of requirements associated with the delay of repair requirements for fugitive methane emissions at well sites and gathering and boosting compressor stations and fugitive VOC and methane fugitive emissions at compressor stations in the transmission and storage segment.
- Revisions to the definition for startup of production as they relate to fugitive emissions at well sites.
- Exclusion of Class I and II Underground Injection Control (UIC) wells as a “well site” for NSPS OOOOa. EPA should also exclude Class II enhanced recovery wells from the monitoring requirements as well.
- Changes to the AMEL provisions.
- Alternative fugitive emissions standards based on equivalent state programs.
- Changes related to onshore natural gas processing plants.
- The “technical corrections and clarifications” present at 86 FR 63168-69.

Commenter (0820-Pioneer) is supportive of keeping the efficiencies in NSPS OOOOa that EPA included in the November 2021 Proposal. This applies to the streamlined leak detection and repair (LDAR) recordkeeping and reporting, PE certification flexibility, and especially the very helpful improvement to the Clean Air Act (CAA) 111(h) AMEL process. These efficiencies reduce unnecessary burden without negative environmental impacts, thus increasing the cost effectiveness of the NSPS OOOOa rulemaking. The commenter strongly urges EPA to provide these changes in the regulatory language of NSPS OOOOb and EG OOOOc as these technical changes are important for compliance with the rule. The commenter believes it is EPA’s intent to

retain these changes for these regulations and respectfully request that the language is included in the forthcoming regulatory language.

Commenter (0836-Domestic Energy Producers Alliance (DEPA)) specifically supported comments provided by 0814-IPAA *et al.*

Commenter (1391-INGAA) generally supports the following amendments to NSPS OOOOa:

- Extending the deadline for conducting initial monitoring from 60 to 90 days for both VOC and methane emissions at all well sites and compressor stations.
- Amending the NSPS OOOOa provisions associated with applications for use of an AMEL for methane work practice standards at well sites and gathering and boosting compressor stations and VOC and methane work practice standards at compressor stations in the transmission and storage segment.
- Finding that state fugitive emission standards for methane and VOCs in California, Ohio, Pennsylvania, and Texas for compressor stations in the transmission and storage segment are “equivalent with, if not better than, the Federal requirements.”
- Aligning the methane standards of NSPS OOOOa with the 2020 Technical Rule to allow certification of technical infeasibility by either a PE or an in-house engineer with expertise on the design and operation of the pneumatic pump.

The commenter (1391-INGAA) notes that all of these amendments made sense when they were done as part of the 2020 Technical Rule for the reasons expressed there, and they support extending these provisions to the transmission and storage segment and to methane emissions.

Commenter (0938-TXOGA) supports the EPA’s reinstatement of the 2020 Technical Rule provisions and states that although they believe that the effort may have been able to be accomplished via direct final rulemaking or under an exception to the Administrative Procedures Act (APA) notice and comment procedures, they state that it is helpful for the Agency to explain why it believes that the amendments are also appropriate for methane. The commenter notes that the emissions points and nature of the emissions are the same as for VOC, which means these provisions should be applied also to methane.<sup>3</sup> The commenter adds that the rulemaking record for the 2020 Technical Rule supports this conclusion.

---

<sup>3</sup> According to the commenter: “For example, EPA proposes in its standards for pneumatic pumps to align the requirement of certification of technical infeasibility by a qualified third-party Professional Engineer (PE) with the 2020 Technical Rule. TXOGA had supported this provision in the proposal for the 2020 Technical Rule, which allows this certification by either a PE or an in-house engineer, recognizing that in-house engineers have strong and direct knowledge about site design and control than a third-party PE. See 86 Fed. Reg. at 63,192. TXOGA supports this change and maintains that it should be interpreted to apply for all aspects of the Proposal. This flexibility should be equally applicable for all requirements associated with PE certifications under Quad Oa, Quad Ob, and Quad Oc, consistent with the original Quad Oa 2016 rulemaking, such as closed vent system design. See 81 Fed. Reg. 35,824, 35,883 (June 3, 2016) (“The Agency is convinced that an employee of a facility, who is a qualified professional engineer and who has been licensed by a state licensing board, would be no more likely to be biased than a qualified professional engineer who is not an employee of the owner or operator. The EPA has concluded that the programs established by state licensing boards provide sufficient guarantees that a professional engineer, regardless of whether he/she is ‘independent’ of the facility, will give a fair technical review.”).

Response I-2-1: EPA acknowledges the commenter's support for the proposed standards.

With regards to commenter's suggestions that EPA provide these changes in the regulatory language of NSPS OOOOb and EG OOOOc as these technical changes are important for compliance with the rule, EPA generally agrees and has retained the majority of the elements discussed in the 2021 proposal, which keeps certain aspects of the 2020 Technical Rule, including the corresponding regulatory amendments to NSPS OOOOa. These requirements are being finalized as proposed. For the few areas where EPA is finalizing provisions based on comments received, EPA has discussed these topics in section XI. Significant Comments and Changes to NSPS OOOOa and NSPS OOOO of the preamble to the final rule.

With regards to a commenter's point that EPA inaccurately cites previous EPA conclusions related to OGI monitoring of CVS at "no extra cost," EPA disagrees. In the 2021 proposal EPA stated that:

"We further incorporated the option for OGI monitoring because OGI is already being used for those sites that are subject to fugitive emissions monitoring and the CVS can readily be monitored during the fugitive emissions survey at no extra cost. 85 FR 57405.<sup>4</sup>".

This statement was based on information gathered for the 2020 Technical Rule, where EPA specifically indicated that it did not expect any additional costs associated with OGI monitoring of CVS, where the site was already subject to regular fugitive emissions monitoring requirements. Specifically, EPA stated the following in the 2020 Technical Rule:

"The EPA received comments recommending (1) retaining annual Method 21 as an option and (2) including OGI monitoring as an additional option because OGI is already being used to monitor fugitive emissions components at the well site and the CVS can readily be monitored at the same time.<sup>5</sup>"

With regards to a commenter's suggestions that EPA should clarify if the wellhead is disconnected from the associated tank that the well is removed from the monitoring program, EPA believes the regulatory text is clear on this point. 40 CFR §60.5397a(g)(5) specifies that:

"You are no longer required to comply with the requirements of paragraph (g)(1) of this section when the owner or operator removes all major production and processing equipment, as defined in § 60.5430a, such that the well site becomes a wellhead only well site. If any major production and processing equipment is subsequently added to the well site, then the owner or operator must comply with the requirements in paragraphs (f)(1) and (g)(1) of this section."

As specified in the existing regulatory provisions for NSPS OOOOa, if the well site becomes a wellhead only well site, the fugitive emissions monitoring requirements of 40 CFR §60.5397a(g) do not apply. The wellhead only well site would not be subject to fugitive emissions monitoring

---

<sup>4</sup> 86 FR 63162 (November 15, 2021).

<sup>5</sup> 85 FR 57405 (September 15, 2020).

but would have to report the change in status in the annual report as specified in §60.5420a(b)(7)(i)(D):

“For each collection of fugitive emissions components at a well site where during the reporting period you complete the removal of all major production and processing equipment such that the well site contains only one or more wellheads, you must include the date of the change to status as a wellhead only well site. Report the change in status in the annual report as specified in §60.5420a(b)(7)(i)(D).”

## 2.2 Applicability/Scope

Comment: Commenter (0928-American Public Gas Association (APGA)) states that because their members are small systems without access to significant resources to fully analyze complex rulemakings such as this, it is important that the scope of the rule be made as clear as possible. The commenter requests that EPA include the following underlined text in NSPS OOOOa at 40 CFR 60.5365a and in appropriate, corresponding sections of NSPS OOOOb and EG OOOOc (new text indicated by underlined text):

### **§60.5365a Am I subject to this subpart?**

You are subject to the applicable provisions of this subpart if you are the owner or operator of one or more of the onshore affected facilities listed in paragraphs (a) through (j) of this section, that is located within the Crude Oil and Natural Gas Production source category, as defined in § 60.5430, for which you commence construction, modification, or reconstruction.

Another commenter (0815-American Gas Association (AGA)) states that the wording at 40 CFR 60.5365a does not clearly describe the scope of the subpart or answer the question, “Am I subject to this subpart?” Similar to commenter (0928-APGA), this commenter (0815-AGA) states that a small gas utility or cooperative that does not have an environmental lawyer on staff may not understand that the rule applies only to facilities that are located within the Crude Oil and Natural Gas Production source category as defined in 40 CFR 60.5430a, and that they should turn to the definitions section toward the end of the rule to discover that the source category does not include operations inside and including the Local Distribution Company (LDC) custody transfer station, and then understand that the subpart only applies to facilities in the defined source category. The commenters state that clarifying language was added to 40 CFR 60.5365a in the 2020 Policy Rule. At a minimum, the commenter suggests that clarifying language be restored in NSPS OOOOa and included in the new scope provisions of NSPS OOOOb and EG OOOOc so that it is clear to anyone asking, “Am I subject to this subpart?” that facilities inside and including the LDC custody transfer station are not subject to the subpart.

Commenter (0815-AGA) urges EPA to include the following text in 40 CFR 60.5365a and the analogous scope sections of NSPS OOOOb and EG OOOOc: “You are subject to the applicable provisions of this subpart if you are the owner or operator of one or more of the onshore affected facilities listed in paragraphs (a) through (j) of this section, that is located within the Crude Oil

and Natural Gas Production source category, as defined in §60.5430a. Facilities located inside and including the LDC custody transfer station are not subject to this subpart.”

Response I-2-2: EPA agrees that, while the definitions section clearly defines the boundaries of the source category, additional clarification in the applicability section of the subpart, in particular with respect to LDC custody transfer, would further help sources to identify if they might be subject to any of the requirements in NSPS OOOOa. Therefore, the final rule includes the following introductory language at 40 CFR 60.5365a:

You are subject to the applicable provisions of this subpart if you are the owner or operator of one or more of the onshore affected facilities listed in paragraphs (a) through (j) of this section, that is located within the Crude Oil and Natural Gas source category, as defined in §60.5430a, for which you commence construction, modification, or reconstruction after September 18, 2015, and on or before December 6, 2022. Facilities located inside and including the Local Distribution Company (LDC) custody transfer station are not subject to this subpart.

Comment: Commenter (0763-Texas Commission on Environmental Quality (TCEQ) and the Railroad Commission (RRC)) states that the EPA should allow sites that were never subject to or no longer subject to NSPS OOOOa because of the 2020 Policy Rule sufficient time to comply with the NSPS OOOOa reinstated requirements. The commenter explains that the 2020 Policy Rule removed applicability of NSPS OOOOa requirements for transmission and storage facilities and for methane. They add that the congressional overturn of the 2020 Policy Rule and automatic reinstatement of the 2016 rules means that NSPS OOOOa again applies to these sources. The commenter suggests that additional time for compliance should be provided for sources that are not currently in compliance with the proposed requirements but are immediately subject to NSPS OOOOa upon reinstatement.

Response I-2-3: On June 30, 2021, President Joseph R. Biden, Jr. signed into law a joint resolution of Congress adopted under the CRA, disapproving the final EPA rule titled, “Oil and Natural Gas Sector: Emission Standards for New, Reconstructed, and Modified Sources Review,” 85 FR 57018 (September 14, 2020) (2020 Policy Rule). On that same date, EPA provided initial guidance to stakeholders, in the form of questions and answers, about the effect of the CRA resolution. Within that questions and answers (Q&A) document, EPA stated that “any new, modified, or reconstructed facility that would have been subject to the 2012 or 2016 NSPS (“affected facility”) but for the 2020 Policy Rule will immediately become subject to those NSPS.” Further, EPA stated that “the CRA resolution of disapproval does not explicitly address the deadline by which you must comply with the standards” and “EPA expects owners and operators of regulated sources to take immediate steps to comply with the applicable 2012 and 2016 standards.” See full Q&A document located at [https://www.epa.gov/system/files/documents/2021-07/qa\\_cra\\_for\\_2020\\_oil\\_and\\_gas\\_policy\\_rule.6.30.2021.pdf](https://www.epa.gov/system/files/documents/2021-07/qa_cra_for_2020_oil_and_gas_policy_rule.6.30.2021.pdf).

## 2.3 Well Completions - Hydraulic Fracturing

Comment: Commenter (0577-Kansas Independent Oil & Gas Association (KIOGA)) believes well completions performed in Kansas, and other similar areas, do not meet EPA's definition of hydraulic fracturing for the geologic and engineering reasons provided below. The commenter recommends that the definition in NSPS OOOOa be amended to explicitly exclude conventional wells from the regulation because the work performed does not meet the definition provided in the regulation. The commenter notes that operations in Kansas do utilize pressurized fluids that contain water, proppant, and/or chemicals. However, they explain that the majority of the operations use a process that neither penetrates tight formations like shale or coal, nor require high rate, extended flowback. According to the commenter, most Kansas operations result in little to no flowback from formations with higher quality reservoir properties than shale or coal. The commenter states that ignoring those two facts discounts two thirds of the definition as outlined by 40 CFR 60.5430a. The commenter provides that enforcing this regulation based on "the process of directing pressurized fluids" alone; but not based on the type of formation or subsequent flowback directly ignores the criteria outlined by this regulation. They infer that these two criteria were included in the definition of hydraulic fracturing, as pertaining to this regulation, to distinguish the varying completion styles of small, vertical, conventional drilling targets from large, horizontal, tight, unconventional drilling targets (such as shale and coal).

The commenter (0577-KIOGA) assumes that this distinction was developed due to the difference in potential greenhouse gas emissions from the dissimilar formation types and completion styles. They explain that, while the amount of greenhouse gases emitted from each reservoir type has yet to be quantified, the commenter assumes the greenhouse gas emissions will be proportional to the amount of hydrocarbons produced (*i.e.*, the more oil and gas a well produces has the potential to produce greater amounts of greenhouse gases that well may emit). The commenter reports that the average estimated ultimate recovery (EUR) for vertical wells in Kansas is 20,000-30,000 barrels of crude oil (bbl)/well, where shale wells yield much higher EURs. Per Energy Information Administration (EIA) data, the average EUR is 168,000 bbl/well for an Eagleford shale well and 243,000 bbl/well for an Eastern Bakken well. Based on these numbers, the commenter states that a typical Kansas well will yield about 10 percent of the oil, and theoretically 10 percent of the greenhouse gas, of a typical oil shale well. The commenter provides a table [Table 7 of their comment letter (page 13)] that presents a comparison of typical reservoir and completion parameters for tight shale formations and for conventional formations targeted in Kansas. The commenter notes that many of the terms mentioned in the definition provided in 40 CFR 60.5430a are also included as a comparison between wells drilled in Kansas and by operators targeting tight, unconventional, shale formations.

Commenter (0598-CER) expresses that they continue to advocate that the conventional wells that utilize low pressure, small volumes of water and proppant, and have a short flowback period (*i.e.*, hours or minutes) were not originally intended to be covered in the 2016 NSPS. The commenter recommends that the original definition of "hydraulic fracturing" be maintained from the 2016 NSPS and that the wells that do not meet this definition be exempt from NSPS OOOOa (and NSPS OOOOb, and EG OOOOc). The commenter states that their recommendation is based on the much lower potential to emit (PTE) from wells that do not experience the high-volume, high-pressure fracture stimulation events that are utilized for the unconventional wells.

Response I-2-4: The definition of “hydraulic fracturing” in 40 CFR 60.5430a of NSPS OOOOa is not being reconsidered or amended under this action. NSPS OOOOa defines hydraulic fracturing as follows:

*Hydraulic fracturing* means the process of directing pressurized fluids containing any combination of water, proppant, and any added chemicals to penetrate tight formations, such as shale or coal formations, that subsequently require high rate, extended flowback to expel fracture fluids and solids during completions.

For comments and responses on well completions and associated definitions (including the hydraulic fracturing definition) leading to the inclusion of this definition in the final 2016 NSPS subpart OOOOa rule, see Docket ID No. EPA-HQ-OAR-2010-0505-7632, Chapter 3. Well Completions.

## **2.4 Fugitive Emissions**

### ***2.4.1 Low Production Wells***

Comment: Commenter (0458-MDE) supports enhanced monitoring for low-production well sites. The commenter suggests the smaller wells could have as much, or more, fugitive and vented emissions as they are less monitored and maintained.

Conversely, commenters (0577-KIOGA, 0803-Ohio Oil & Gas Association (OOGA), 0824-Wyoming Department of Environmental Quality (WDEQ), 0464-Muskegon Operating Company LLC (MOPC)) object to the proposal to repeal the amendments in the 2020 Technical Rule that exempted low production well sites from monitoring fugitive emissions under the NSPS (86 FR 63118).

Commenter (0803-OOGA) urges the EPA to retain the exemption for low-production wells. The commenter states that a significant portion of the more than 61,000 wells in Ohio meet the definition of a low production well (*i.e.*, produce at or below 15 barrels of oil equivalent (boe)/day) and, in fact, produce on average far less than 15 boe/day. Notwithstanding the commenter’s objection to removing the exemption for low production wells, the commenter contends that the EPA’s proposed site-level baseline methane estimate methodology to determine whether a well site is subject to the fugitive emissions monitoring requirement is flawed for several reasons.

Commenter (0810-Petroleum Alliance of Oklahoma (PAO)) recommends that the EPA first determine if marginal well emissions warrant regulation. The commenter explains that when EPA developed its NSPS OOOOa regulation for oil and gas, it had no emissions profile for marginal/low production wells; however, EPA proceeded to regulate them with a limited data set. Currently, the commenter notes that the EPA still has a limited data set that does not fully characterizes these types of wells. The commenter notes that the Department of Energy (DOE) is conducting a study to better characterize emissions from these types of wells (expected to be publicly available in early 2022). The commenter states that Executive Order 13990 requires the Federal Government, “...be guided by the best science and be protected by processes that ensure

the integrity of Federal decision-making.” As such, the commenter recommends that the EPA defer regulating marginal/low production wells until this report is available for review or collect additional data to fully determine the emissions profile of these types of wells, determine if requirements are needed, and if needed, develop an appropriate regulatory program.

Commenter (0763-TCEQ/RRC) suggests that removing the exemption for low producing wells from quarterly fugitive emission monitoring in NSPS OOOOa could result in tens of thousands of additional affected facilities and/or projects establishing PTE below affected source emission levels. The commenter adds that changing this requirement may also result in some facilities becoming an affected facility retroactively.

Commenter (0824-WDEQ) states that the proposed rule repeals amendments to the 2016 NSPS OOOOa in the 2020 Technical Rule that exempted low production well sites from monitoring fugitive emissions. The commenter adds that it also requires low production well sites to undertake semiannual monitoring of VOC and methane emissions. Furthermore, under EPA's proposed NSPS OOOOb and EG OOOOc requirements, the commenter notes that well sites with total site-level baseline methane emissions of 3 tons per year (tpy) or greater would trigger requirements for quarterly OGI or EPA Method 21 monitoring. They add that these requirements would affect many stripper wells in Wyoming (defined by the Wyoming Oil and Gas Conservation Commission (WOGCC) as wells that produce an average of 15 bbl or less per day) and some very small-scale, independent well site operations that strictly operate on a single owner's private property. According to the WOGCC, Wyoming has approximately 6,524 stripper wells. The commenter is concerned about the potential adverse economic impacts of these proposed regulations upon individual operators and the greater economy of the State of Wyoming and states that the economic impacts outweigh the indeterminate and potentially marginal environmental benefits of the proposal. They add that the cost of compliance with these requirements is simply unworkable for many smaller operators in Wyoming and some have already expressed concerns to WDEQ that they will go out of business due to the proposed requirements. The commenter (0824-WDEQ) suggests that the EPA prematurely proposed these requirements for marginal well sites without having thoroughly evaluated the emissions or the costs to control those emissions from those marginal sites. The commenter notes that they are aware that at least one study is underway to evaluate methane emissions from marginal wells,<sup>6</sup> and there may be others. If the study's findings demonstrate that these methane emission contributions from low production well sites do not contribute in any significant manner, it is imperative that EPA consider these findings and provide appropriate exemptions.

Another commenter (0464-MOPC) opposes the proposed regulations modifying NSPS OOOOa. The commenter states that the changes to the rules will have significant detrimental impacts on their operations, costs, overhead, reserve recovery, plugging costs, and employment. The commenter notes that every increase in cost directly jeopardizes their ability to produce marginal wells. They state that marginal wells are not a significant source of methane. Emissions from a well are proportionate to the volume of oil and/or gas produced. The commenter explains that marginal wells produce significantly less emissions due to the fact that they are marginal producers of oil and gas. According to the commenter, emissions from their wells are much

---

<sup>6</sup> "Quantification of Methane Emissions from Marginal (Small Producing) Oil and Gas Wells" (under review), U.S. Department of Energy, National Energy Technology Laboratory: <https://netl.doe.gov/node/9373>.

lower than those emitted from high volume wells produced by larger companies. As a responsible operator, the commenter states that they have acted to voluntarily minimize their emissions in a prudent manner that meets standards they can afford. The commenter adds that it is unfair and unwise to treat small operators with marginal wells in the same manner as larger producers. The commenter suggests that marginally producing wells (15 BOEPD/90 MCFPD or less) be exempt from EPA rules because the emissions are insignificant and the rules would be uneconomic. They further suggest that there needs to be a regulatory "off ramp" for wells such as theirs that are low producers. The commenter supports exempting marginal, low production wells from the proposed regulations.

Commenter (0464-MOPC) states that, if the EPA continues on its course to regulate emissions from marginal wells it will:

- unnecessarily increase cost of operations, cause the premature plugging of marginal wells, and significantly add to the number of orphan wells in the State of Michigan;
- bankrupt small businesses and cause irreversible economic harm to the oil and gas community;
- cause the waste of our natural resources by forever foreclosing the production of marginal wells, which is in contravention of our state laws which require the prevention of waste; and
- increase our country's reliance on foreign oil and gas.

Commenters (1341-Pennsylvania Grade Crude Oil Coalition (PGCC) *et al.*) recommend that the EPA consider the small, low-emitting nature of Pennsylvania and New York conventional oil and gas production before imposing any additional requirements in the NSPS OOOOa (and NSPS OOOOb and EG OOOOc) revisions. In summary, the commenter indicates that EPA takes a one-size-fits-all, industry-wide approach to determining whether additional, and potentially far more restrictive requirements, should be imposed on oil and gas producers. The commenter explains that their members are primarily small, family-owned businesses and individuals operating low-producing oil and gas wells. According to the commenter, profound differences exist in the scale, production, design, and layout of their members conventional operations, as compared to the large, high-volume unconventional gas wells being drilled for several miles into deep geologic formations.

Response I-2-5: In response to comments that are concerned about the requirements for small well sites, EPA points out that it believes most of these well sites would be existing sources, and therefore not subject to NSPS OOOOa standards. However, these sources would be subject to the EG OOOOc requirements, where quarterly AVO monitoring was proposed in the 2022 supplemental proposal. If the sources in question are modified, they would also be subject to quarterly AVO under the proposed NSPS OOOOb.<sup>7</sup>

EPA acknowledges comments supporting monitoring for low-production well sites, as these sites can have large leaks that could go unnoticed without regular monitoring. The DOE Study

---

<sup>7</sup> 87 FR 74718.

specifically indicated that two of the top 10 largest leaks found were located at the wellhead.<sup>8</sup> In 2021, EPA proposed to rescind the 2020 Technical Rule that exempted low-production well sites from fugitive emissions monitoring, as this exemption was not supported by the record for that rule, or by additional information reviewed since then. EPA discussed in the 2021 proposal the uncertainty around the connection between fugitive emissions and production levels, and concluded at that time that information does not show a link between production and emissions, and therefore no production level would support any exemption from fugitive monitoring.<sup>9</sup>

Therefore, in the 2021 proposal, EPA moved away from a production-based threshold and proposed instead monitoring based on site-level methane baseline emissions estimated through equipment/component count emission factors. As stated in the November 2021 proposal, EPA does remain mindful about how the fugitive emissions monitoring requirements will affect small businesses. EPA specifically sought comment on the 2021 proposed approach to determine if there were other regulatory alternatives and additional information that would warrant considering a subset of sites differently based on a potentially different emissions profile, production levels, equipment onsite, or other factors.

The EPA examined data provided through an information collection request (ICR) distributed in 2016, data provided on equipment/component counts in relation to the October 15, 2018, proposed reconsideration of NSPS OOOOa from independent producers (many of whom are small businesses), data provided through comments on the November 2021 proposal from independent producers, and data contained in the U.S. DOE marginal well study to determine if a subset of well sites with major production and processing equipment should be considered differently. Consistent with comments received on previous rulemakings, the EPA received comments on the November 2021 proposal expressing that emissions from a well are proportionate to the volume of oil and/or gas produced.<sup>10</sup> Commenters also referenced the DOE Study. However, that marginal well study (now available) concludes that the frequency and magnitude of emissions from well sites are more strongly correlated with equipment counts, not production rates.<sup>11</sup> Further, this study broke down emissions by site size and production levels and found that the smallest emissions rates were from the second production level bin (2 barrels of oil equivalent per day (boe/day) to 6 boe/day) and not the sites with production less than 2 boe/day. Another study issued in April 2022 by Omara, et al. concludes that approximately half of the methane emissions emitted from well sites in the U.S. comes from low production well

---

<sup>8</sup> Bowers, Richard L. Quantification of Methane Emissions from Marginal (Low Production Rate) Oil and Natural Gas Wells. United States. <https://doi.org/10.2172/1865859>. See Table 2 of the study for details on the top 10 emissions sources identified.

<sup>9</sup> 86 FR 63159.

<sup>10</sup> See Document ID No. EPA-HQ-OAR-2021-0317-0464.

<sup>11</sup> Section 5.2.1 of the study concludes, “The correlation between major equipment counts and site emission frequency (expressed as the number of detected emissions per piece of major equipment, i.e., not absolute count of emissions), was strong with the categorical site ‘size’ variable and moderate (positive) with the numeric equipment count. Among evaluated numeric variables, site equipment counts also exhibited the strongest associations with both frequency and magnitude of sitewide emissions, exhibiting only a moderate positive correlation with detection frequency and weak associations with whole gas and methane emission rates. Weak correlations were also consistently detected among both the frequency and magnitude of emissions, total oil and gas production, and gas production rates.” See Bowers, Richard L. Quantification of Methane Emissions from Marginal (Low Production Rate) Oil and Natural Gas Wells. United States. <https://doi.org/10.2172/1865859>. page 19.

sites (15 boe/day or less production rates).<sup>12,13</sup> However, the EPA notes that this study is not limited to fugitive emissions, and the overall impacts on emissions reductions achieved under NSPS OOOOa (and NSPS OOOOb and EG OOOOc), if these rules are finalized as proposed, would target the emissions reported in that study as a whole. Therefore, the EPA does not have compelling information that suggests production levels should provide the basis for consideration of different fugitive emissions requirements for well sites.

The EPA is therefore finalizing the proposed (86 FR 63158-63159) removal of the exemption of low production well sites from fugitive VOC emissions monitoring, thereby restoring the semiannual monitoring requirement established in the 2016 NSPS OOOOa.

#### ***2.4.2 Gathering and Boosting Station/Compressor Station Monitoring***

Comment: Commenter (0755-Texas Pipeline Association (TPA)) recommends that fugitive emissions monitoring at compressor stations only be required on a semi-annual basis. The commenter does not support or concur with EPA's proposal to increase the frequency of required fugitive emissions monitoring in this proposal to quarterly at compressor stations, including gathering and boosting compressor stations.<sup>14</sup> They contend that a requirement for more frequent monitoring would be unduly burdensome, given that one pipeline system could have numerous compressor stations that are often located in remote areas. In addition, they state that the resources (both personnel and equipment) to comply with survey requirements may be limited, a concern that they say that the EPA itself acknowledged in the preamble for the initial NSPS OOOOa proposal.<sup>15</sup> Moreover, the commenter states that the leak rate in the gathering and boosting industry segment is particularly low.<sup>16</sup> The commenter adds that, as recently as September 2020, EPA concluded that semiannual monitoring was sufficient. According to the commenter, they do not believe that, little more than a year later, EPA has uncovered a sufficient basis to reject that conclusion and to cut in half the required monitoring interval. The commenter urges EPA to retain the current requirement of semiannual monitoring for fugitive emissions at compressor stations, including gathering and boosting compressor stations.

Similarly, commenter (0923-Lambda Energy Resources LLC (Lambda)) believes it is overly burdensome to require quarterly compressor monitoring in respect to surveys and record keeping. The commenter notes that the value of increased monitoring to reduce small amounts of methane and VOCs does not offset the associated expense and manpower required to fulfill the proposed regulations. The commenter suggests that perhaps a baseline for compressor stations could be undertaken as a similar proposal for less than 3 tpy well sites to determine future requirements of a particular site.

---

<sup>12</sup> Omara, M., Zavala-Araiza, D., Lyon, D.R. et al. Methane emissions from US low production oil and natural gas well sites. Nat Commun 13, 2085 (2022). <https://doi.org/10.1038/s41467-022-29709-3>.

<sup>13</sup> The EPA notes that Omara et al. analyzed data from offsite measurements of methane emissions from well sites. These measurements would include methane from any leak, venting, flaring, or other source onsite and, therefore, conclusions from this study cannot be directly applied to the specific fugitive sources covered by this action.

<sup>14</sup> See 86 FR 63158-59, 63169, 63174 (Nov. 15, 2021).

<sup>15</sup> See 80 FR 56643 (Sept. 18, 2015) (noting possible logistical challenges in securing the services of qualified monitoring personnel and possible shortages of monitoring equipment).

<sup>16</sup> See data collected at Docket ID No. EPA-HQ-OAR-2017-0483-0027.

Commenter (0763-TCEQ and RRC) suggests that changing monitoring frequency for the transmission and storage segments from semiannual to quarterly creates confusion with the other actions taken in 2021 regarding NSPS OOOOa as these facilities have transferred back and forth between affected facility status due to policy changes within the existing NSPS OOOOa. Proposed subclassification of compressor stations within the NSPS will create the same confusion.

Response I-2-6: As stated in the December 2022 supplemental proposal, the analyses EPA conducted for NSPS OOOOb and EG OOOOc confirms that quarterly monitoring remains both achievable and cost-effective for compressor stations, and several state agencies have rules that require quarterly monitoring at compressor stations.

The cost analysis conducted for the 2021 proposal was a comprehensive evaluation of emissions, reductions, and costs associated with various leak detection and repair programs, which firmly established that the cost effectiveness of quarterly monitoring for compressor stations is reasonable.<sup>17</sup> The 2021 proposal established that BSER for reducing methane and VOC emissions from all compressor stations, including gathering and boosting stations, transmission stations, and storage stations was quarterly monitoring. In the 2022 supplemental proposal, EPA retained the proposed quarterly OGI (or EPA Method 21) monitoring requirement for fugitive emissions components affected facilities located at compressor stations, based on finding no reasons to change this frequency.

Therefore, based on the reasoning provided in the November 2021 proposal that the EPA lacked justification and erred in revising the VOC monitoring frequency for gathering and boosting compressor stations from quarterly to semiannual and the cost-effectiveness of control for quarterly monitoring, the EPA is finalizing the restoration of the quarterly monitoring requirement for gathering and boosting compressor stations, as established in the 2016 NSPS OOOOa.

### ***2.4.3 Well Site Definition***

Comment: Commenter (0817-GPA) strongly supports EPA's proposal to maintain the definition of "well site" that EPA adopted in the 2020 Technical Rule, which excludes third-party equipment from the flange immediately upstream of the custody meter assembly and equipment.<sup>18</sup> The commenter states that they outlined previously for EPA that including ancillary midstream equipment, such as meters, within the definition of a "well site," is not feasible and creates significant problems for midstream operators.<sup>19</sup>

The commenter (0817-GPA) explains that the principal reason is simple: most wellhead gathering metering systems are located near or on the producer's well pad but are owned and

---

<sup>17</sup> 86 FR 63196 (Nov. 15, 2021).

<sup>18</sup> See 86 FR 63165 (Nov. 15, 2021).

<sup>19</sup> See, e.g., GPA Comments, Docket No. EPA-HQ-OAR-2010-0505-6881 (Dec. 4, 2015) at 8-12; GPA Supplemental Comments, Docket No. EPA-HQ-OAR-2010-0505-7552 at 1-3 (Apr. 15, 2016); GPA Comments, Docket No. EPA-HQ-OAR-2010-0505-6881 (Dec. 4, 2015) at 8-12; GPA Comments, Docket No. EPA-HQ-OAR-2017-0346-0406 (Dec. 8, 2017) at 4-9.

operated separately by a midstream company, not the producer. The commenter adds that a single midstream company could have hundreds of meters on the property of third-party producers. Each company lacks operational control over the other's equipment for purposes of monitoring, repair, and replacement. According to the commenter, midstream operators cannot allow producers to access or repair a gas gathering meter due to its crucial role in calculating the gas accepted by the gathering company and the related revenue accounting.

Commenter (0539-Alaska Oil and Gas Conservation Commission (AOGCC)) notes that EPA states in the proposal that an operator's responsibility ends at the flange upstream of the custody transfer meter.<sup>20</sup> In Alaska, production must be metered prior to leaving the lease/unit and that the operator is responsible for the custody transfer metering system.

The commenter (0817-GPA) further states that before the changes made in the 2020 Technical Rule, the "well site" definition included co-located midstream equipment with the upstream producer's equipment. With respect to midstream operators, the commenter notes that their co-located equipment would have been subject to new NSPS OOOOa LDAR requirements whenever a third-party producer constructed a new well, re-fractured an existing well, or took any other action that increased emissions at the well site. The commenter adds that the EPA recognized these practicalities in redefining "well site" in the 2020 Technical Rule—and the commenter supports the proposal to use the 2020 Technical Rule's definition of "well site" for methane regulations.

Response I-2-7: EPA acknowledges the commenter's support and has finalized the definition of well site as proposed. Specifically, well site is defined at 40 CFR 60.5430a:

*Well site* means one or more surface sites that are constructed for the drilling and subsequent operation of any oil well, natural gas well, or injection well. For purposes of the fugitive emissions standards at §60.5397a, well site also means a separate tank battery surface site collecting crude oil, condensate, intermediate hydrocarbon liquids, or produced water from wells not located the well site (e.g. centralized tank batteries). Also, for the purposes of the fugitive emissions standards at §60.5397a, a well site does not include:

- (1) UIC Class II oilfield disposal wells and disposal facilities;
- (2) UIC Class I oilfield disposal wells; and
- (3) The flange immediately upstream of the custody meter assembly and equipment, including fugitive emissions components, located downstream of this flange.

Comment: Commenter (0539-AOGCC) states that it is unclear if a well test separator at a well site would qualify as major production and processing equipment. The definition of major production and processing equipment does include separators, but the commenter asked whether the intent is to cover all separators, including well test separators that only accommodate a well or two at a time and the streams are recombined before production leaves the well site to head to

---

<sup>20</sup> See 86 FR 63165 (Nov. 15, 2021).

a central processing facility, or whether it is supposed to only apply to larger process related separators.

Commenter (0539-AOGCC) states drilling a new well or fracking or refracking a well on a well site appears to trigger the entire well site, and any and all processing facilities located downstream of the well site, instead of just the impacted well(s), becoming subjected to the new regulations. This could lead to operators not conducting such work on a marginal well due to the fact that doing so would appear to dramatically increase their regulatory burden for the entire field. Also, it is not clear if the new well trigger only applies if it is a new grassroots well or if it applies if an existing well is sidetracked or a lateral is added.

Response I-2-8: The definition of major production and processing equipment in NSPS OOOOa, proposed NSPS OOOOb, and proposed EG OOOOc is not limited to a particular type of separator. The definition of major production and processing equipment covers all types of separators. An existing well site would become subject to NSPS OOOOb if it meets the modification criteria in 40 CFR §60.14, or an existing well is hydraulically fractured, or when an existing well is hydraulically refractured.

Comment: Commenter (0425-Darrah Oil, 0539-AOGCC) believes that Class II enhanced oil recovery (EOR) wells should have the same exemption considerations as Class II disposal wells.

Commenter (0539-AOGCC) refers to the proposal where EPA states that UIC Class I wells and UIC Class II disposal wells are excluded due to negligible fugitive VOC and methane emissions. (86 FR 62125). By the same logic, the commenter believes that UIC Class II EOR water injection wells should also be excluded.

Commenter (0425-Darrah Oil Company, LLC (Darrah)) adds that, as a company that is studying Class VI wells for carbon dioxide sequestration, the commenter would encourage all disposal wells to be exempt to further the EPA's goal that disposal wells help achieve.

Response I-2-9: As described in the 2021 proposal<sup>21</sup> (and consistent with the 2020 Technical Rule for NSPS OOOOa where EPA amended the definition of a well site), EPA made it clear that for purposes of the fugitive emissions standards, a well site does not include: (1) UIC Class II oilfield disposal wells and disposal facilities; (2) UIC Class I oilfield disposal wells; and (3) the flange immediately upstream of the custody meter assembly and equipment, including fugitive emissions components, located downstream of this flange. These proposed exclusions were not changed in the 2022 Supplemental Proposal, as EPA continues to believe that fugitive emissions from UIC Class I oilfield disposal wells and UIC Class II oilfield wastewater disposal wells are negligible, as previously stated.<sup>22</sup>

As far as the concerns regarding UIC Class II EOR water injection wells, EPA agrees with the commenter that fugitive emissions are low. As currently defined in 40 CFR §144.6, EOR water injection wells are already included, specifically named under 40 CFR §144.6(b)(2):

---

<sup>21</sup> 86 FR 63165 (November 15, 2021).

<sup>22</sup> 85 FR 57407 (September 15, 2020).

(b) Class II. Wells which inject fluids:

(1) Which are brought to the surface in connection with natural gas storage operations, or conventional oil or natural gas production and may be commingled with waste waters from gas plants which are an integral part of production operations, unless those waters are classified as a hazardous waste at the time of injection.

(2) For enhanced recovery of oil or natural gas; and

(3) For storage of hydrocarbons which are liquid at standard temperature and pressure.

#### ***2.4.4 Wellhead Only Well Sites***

Comment: Commenter (0810-PAO) states that the EPA is proposing to exclude from fugitive emissions monitoring a well site that is or later becomes a “wellhead only well site,” which the 2020 Technical Rule defines as “a well site that contains one or more wellheads and no major production and processing equipment.” The 2020 Technical Rule defined “major production and processing equipment” as including reciprocating or centrifugal compressors, glycol dehydrators, heater/treaters, separators, and storage vessels collecting crude oil, condensate, intermediate hydrocarbon liquids, or produced water. The commenter supports the EPA’s November 2021 Proposal that follows the 2020 Technical Rule.

Similarly, commenter (0797-North Dakota Department of Environmental Quality (NDDEQ) and North Dakota Industrial Commission (NDIC)) agrees with EPA’s proposal that “wellhead only” well sites be excluded from fugitive emissions monitoring based on considerable research and rationale already established in the 2016 NSPS OOOOa rulemaking as well as the 2020 Technical Rule. The commenter also agrees with the November 2021 Proposal to exclude well sites from fugitive emissions monitoring upon those sites becoming wellhead only well sites as provided in the 2020 Technical Rule. According to the commenter, their own experience supports EPA’s conclusion that emissions from these sources are “extremely low.”<sup>23</sup> The commenter notes that North Dakota (which they have knowledge of) has only observed a handful of wellhead only well sites with fugitive emissions, and it appears that in those rare cases that the emissions were more a result of operator error. They add that they believe that the safety risk alone precludes any widespread issue of fugitive emissions from these sites.

Response I-2-10: EPA acknowledges the commenter’s support and has finalized this provision as proposed.

#### ***2.4.5 Initial Monitoring for Well Sites***

Comment: Commenter (0810-PAO) states that the EPA is proposing to further amend the 2016 NSPS OOOOa to extend the deadline for conducting initial monitoring from 60 to 90 days for monitoring both VOC and methane fugitive emissions at all well sites and compressor stations

---

<sup>23</sup> See 80 FR 56611 (Sept. 18, 2015).

(except those on the Alaska North Slope provided elsewhere in the November 2021 Proposal). The commenter supports the November 2021 Proposal that follows the 2020 Technical Rule.

Response I-2-11: EPA acknowledges the commenter's support and has finalized this requirement as proposed.

#### **2.4.6 Repair Provisions**

Comment: One commenter (0782-Berkshire Hathaway Energy Company (BHE)) supports reconciling NSPS OOOOa delay of repair regulatory text consistent with the 2020 Technical Rule. The commenter recommends delay of repair text be amended to address the delay necessary when parts are unavailable, an issue that will be especially important for existing sources. Commenter (0782-BHE) supports updates to delay of repair provisions in the 2020 Technical Rule to NSPS OOOOa and reconciling that regulatory text for transmission and storage and upstream operations.

For NSPS OOOOa (and NSPS OOOOb and EG OOOOc), the commenter (0782-BHE) notes that the EPA requested feedback on whether to allow delay of repair due to parts availability. The commenter recommends that EPA include delay of repair provisions for infrequent circumstances when parts availability extends the timeline for repair. The commenter explains that, although such delays will still be infrequent, allowing delay of repair for parts availability is even more imperative for existing sources, because longer lead times, special fabrication, *etc.* are more likely for legacy parts from existing equipment than new sources. Without this delay of repair provision, if part delivery exceeds current delay of repair allowances, the commenter states that operators may be placed in an untenable conflict with federal requirements – *i.e.*, shutting down compressors or entire compressor stations (and compromising reliable natural gas delivery and thus conflicting with the operator's Federal Energy Regulatory Commission (FERC) Certificate), or meeting the FERC obligation (*i.e.*, equipment not shut down to await the part and repair) and thus not meeting EPA compliance requirements.

Commenter (0782-BHE) provides that previous comments submitted to EPA by INGAA<sup>24</sup> and others provide examples of parts availability issues. The commenter notes that, in their experience, the likely parts are large, unique valves used for compressor isolation or isolating sections of a facility or pipeline. These valves are not standard items and come in many configurations. The commenter explains that, given the size and unique specifications of each valve, they contend that it is not practical or economical to maintain a significant inventory of such items. They add that such items may require special fabrication with lead times of many months, and thus may not conform to the current delay of repair provisions. According to the commenter, recent supply chain issues provide another example of an unforeseen circumstance that may arise that affects parts availability and the need for a related delay of repair provision.

---

<sup>24</sup> EPA Docket ID No. EPA-HQ-OAR-2010-0505-4104 (Nov. 22, 2011) (INGAA's comments on proposed Subpart OOOO).

The commenter reports that there are EPA<sup>25</sup> and state examples<sup>26</sup> where such provisions have been included in LDAR programs. The commenter expresses support for a similar provision in the EPA methane regulations. As an example, the commenter describes a recently identified a leak on a 16-inch valve. Upon investigation, they determined that repair (*e.g.*, replacing sub-components of the large valve) was not possible and an exact replacement valve could not be ordered because the valve was obsolete. Investigation into a new replacement indicated a lead time on the order of at least 18 weeks. Without delay of repair provisions, the commenter states that a maintenance shutdown would occur in the interim. To maintain safety and reliability, delay due to “parts availability” is needed for this situation. Upon receipt of the part, if the process is operating, the repair will need to be completed when the process is next blown down for maintenance.

Commenter (0782-BHE) states that the EPA requested feedback on documentation required for a parts-based delay of repair. The commenter recommends that the required recordkeeping follow current NSPS OOOOa criteria, where the operator documents the delay basis and repair schedule. For example, purchase orders and other documentation (as needed) on order and delivery dates would support delay due to parts availability. These records would be maintained by the operator and made available to the applicable regulatory agency upon request.

Commenter (0782-BHE) adds that the EPA also requested feedback on the repair schedule when parts are received. The commenter suggests that no special regulatory text is needed because the repair schedule could follow the current NSPS OOOOa criteria. Under such criteria, a repair is completed within 30 days of receiving the part if feasible, but may be delayed if warranted by circumstances, *e.g.*, repair can be delayed until the next scheduled blowdown for maintenance if a blowdown is required to complete the repair.

Similarly, commenter (0815-AGA) states that the EPA must allow for the lead times needed to obtain certain types of parts (supports INGAA comments on this issue). They add that operators should not be penalized for circumstances they do not control, and state that imposing penalties will not reduce emissions where a repair simply cannot be performed until a part is received.<sup>27</sup> The commenter requests that EPA provide in the regulatory text for revised NSPS OOOOa and new NSPS OOOOb that where no shutdown or blowdown is needed, the operator should repair the leak within 30 days after receiving the parts. The commenter supports that where a repair requires a shut down or blowdown, the regulatory text should allow the repair to be performed during the next scheduled shutdown for maintenance after receipt of the requisite parts, not to exceed two years. Again, the commenter states that this will avoid unnecessary blowdown emissions.

**Response I-2-12:** Consistent with the delay of repair provisions related to fugitive emissions from equipment located at well sites and compressor stations, EPA is amending 40 CFR

---

<sup>25</sup> 40 CFR, §60.482-9a(e)

<sup>26</sup> CCR 1001-9, Colorado Department of Public Health and Environment, Regulation Number 7, Part D, Section I.L.5 (Repair and Monitoring) (which allows a repair to be delayed if parts are unavailable or for other good cause); Md. Code Regs. 26.11.41.03.A(9)(c)(i) (allowing delay of repair if parts or equipment need to be ordered and delivered).

<sup>27</sup> INGAA Comments, section IV.C.

60.5397a(h)(3) to allow the delay of repairs due to the lack of availability of parts in some circumstances. NSPS OOOOa has been revised to allow for delay of repair due to unavailability of parts if replacement parts are necessary and cannot be acquired within the repair timeline if either replacement part supplies have been depleted and replacement part supplies had been sufficiently stocked before the supplies were depleted or a replacement part requires custom fabrication. Replacement parts must be ordered within 10 calendar days after the first attempt at repair. The repair must be completed within 30 calendar days of receipt of the replacement parts or during the next scheduled shutdown for maintenance after the parts are received (if the repair requires a shutdown). As the EPA was considering provisions allowing for delay of repair due to parts unavailability for sources regulated under NSPS OOOOb and EG OOOOc, the EPA found that the supplemental information submitted and reasoning for allowing delay of repair due to parts unavailability under NSPS OOOOb and EG OOOOc is equally applicable to sources regulated under NSPS OOOOa and, for that reason, is also including the provision in 40 CFR 60.5397a(h)(3).

Comment: Commenters (0817-GPA, 0815-AGA, 1391-INGAA, 0810-PAO, 0755-TPA) specifically support the November 2021 Proposal to allow delays of repair until the next scheduled maintenance shutdown.

Commenter (1391-INGAA) states that, as EPA notes, these maintenance shutdowns occur on a regular schedule, and it makes sense to do the repairs during these shutdowns to avoid unnecessary methane venting and disrupting the reliability of gas transmission.

Comment (0817-GPA) supports EPA's November 2021 Proposal to extend the 2020 Technical Rule "delay of repair" provision, which provides that where repairs are technically infeasible, they should be made during the next scheduled compressor station shut down for maintenance.<sup>28</sup> Previously, the commenter explained that NSPS OOOOa had required repairs to be made during the next scheduled compressor shutdown or after a planned vent blowdown.<sup>29</sup> As the commenter notes that they previously explained in comments and a March 2017 white paper, requiring the repair or replacement of components during a planned vent blowdown can prolong natural gas supply disruptions, jeopardize safety, and potentially release more methane emissions than would be avoided by repairing or replacing a leaking component.<sup>30</sup>

Commenter (0755-TPA) supports EPA's proposal to make clear that completion of delayed repairs at compressor stations under NSPS OOOOa need only be completed during a scheduled maintenance shutdown, not the next shutdown of any kind. The commenter explains that shutdowns can occur for many different reasons, and a shutdown that is not scheduled for maintenance purposes can be a highly inappropriate occasion for conducting or completing repairs. They add that some planned shutdowns do not occur for maintenance reasons, last for a very short time, and are made on short notice. The commenter states that it would be unreasonable, and unworkable in practice, to require that repair personnel be mustered, and

---

<sup>28</sup> See 86 FR 63164 (Nov. 15, 2021).

<sup>29</sup> See 83 FR 10628, 10638 (Mar. 12, 2018).

<sup>30</sup> See, e.g., GPA Comments, Docket No. EPA-HQ-OAR-2017-0346-0406 (Dec. 8, 2017) at 9-11; GPA & INGAA, The Delay of Repair Obligations in 40 C.F.R. § 60.5397a(h)(2) Create Compliance Issues that Need to be Addressed Through Regulatory Revisions (Mar. 2017).

repairs be made during these events. In addition, they note that requiring complicated repairs to be made in these circumstances would disrupt normal operations more than would otherwise be the case and thus would disrupt production and transmission activities by delaying the unit's return to normal service. Similarly, they contend that it would be unreasonable to require repairs to be made where a leak was detected shortly before a scheduled shutdown, as it might not always be possible or feasible to locate appropriate repair personnel and/or parts in a timely manner given the short notice that would be involved. Again, the commenter states that requiring repairs to be completed during such a shutdown could greatly lengthen the shutdown, causing unnecessary disruption to natural gas supply. Accordingly, the commenter concludes that it is appropriate for EPA to clarify that completion of delayed repairs at a compressor station is required only during a scheduled compressor station shutdown where maintenance activities have been scheduled. According to the commenter, this represents a reasonable accommodation of the issues expressed above and would align the oil and natural gas NSPS more closely to the delay-of-repair provisions in other NSPS (*e.g.*, Subpart VVa).<sup>31</sup>

Response I-2-13: EPA acknowledges the commenters' support for the provisions to allow delay of repair (where applicable) until the next compressor station shutdown for maintenance. The final rule includes this provision as proposed.

## **2.5 Alternative Means of Emissions Limitation (AMEL)**

Comment: Commenter (0938-TXOGA) states that the AMEL process is critical to promoting innovation in the sector and should be further improved and streamlined. The commenter notes that the EPA highlights that a key theme from the roundtables that it held in preparation for this rulemaking was “improving and streamlining the EPA’s AMEL [alternate means of emissions limitation] process, such as by structuring it so it could apply broadly rather than on a site-by-site basis.”<sup>32</sup> The commenter adds that they agree with EPA’s statements that the AMEL provisions were and continue to be available for the aspects of the rule that were affected by the CRA resolution. In addition to other legal bases that apply to all of the CRA-affected provisions, the commenter states that the AMEL provisions are akin to a “general provision” and apply without regard to any particular pollutant or segment of the source category, and thus, there should be no question that they continue to be available for companies to utilize and for EPA to approve through the established process. Thus, the commenter agrees with EPA’s decision to clarify the continued applicability and availability of the AMEL provisions for methane emissions, including the amendments made in the 2020 Technical Rule.

On a forward-looking basis and given that: (1) EPA recognizes that it is the “technical innovations [that] have produced a range of technologies and best practices to monitor, eliminate[,], or minimize these emissions, which in many cases have the benefit of reducing multiple pollutants at once and recovering saleable products;”<sup>33</sup> and (2) such “technologies and best practices have been deployed by individual oil and natural gas companies,”<sup>34</sup> the commenter (0938-TXOGA) states that the AMEL process provides one of the most promising opportunities

---

<sup>31</sup> 40 CFR § 60.482-9.

<sup>32</sup> 86 FR 63146.

<sup>33</sup> *Id.* at 63114.

<sup>34</sup> *Id.*

to create step changes in emissions reduction and improvement. The commenter states that they appreciate EPA's efforts to standardize the process and encourages EPA to ensure that the process is streamlined enough that the burden on both the regulators and those who seek to deploy innovative technologies is not overly burdensome—as that will ultimately be counterproductive to the goal of achieving technological advancements.<sup>35</sup> Specifically, the commenter suggests the following as examples of improvements to EPA's AMEL standards:

1. EPA could publish a list of available technologies for all operators, not just for specific operators seeking AMEL. In addition, EPA can enhance transparency and further drive innovation throughout the sector by making available information on how it evaluates alternate technologies, including the flexibility available.
2. EPA should allow companies to replace OGI surveys with an alternate technology with equivalent effectiveness (subject to (3), below).
3. EPA should avoid a point-by-point "equivalency" requirement for alternate technologies. We do not consider that to be required by the regulations, and such a requirement would be counterproductive to fostering innovation and step-changes in technology. For example, some alternative technologies may provide benefits in identifying large leak events sooner than an OGI schedule would dictate, and this could and should be allowed. The equivalence evaluation in such a case would be based on the emissions reduction capability rather than a leak-by-leak evaluation.
4. When a method is approved for a specific technology, all companies should be allowed to use the same method without the need to pursue a formal process for a new AMEL. In other words, if an AMEL is approved for a particular affected facility, streamlining of process should be available for other companies. This is consistent with the original AMEL approach, which allowed technology companies to apply for nationwide AMEL.

Commenter (0740-Utah Petroleum Association (UPA)) states the November 2021 Proposal discusses state fugitive emission standards that EPA previously approved including standards for Utah, "EPA is now proposing that all well sites and compressor stations located in and subject to the specified State regulations in 40 CFR 60.5399a may utilize these alternative fugitive emissions standards for both methane and VOC fugitive emissions."<sup>36</sup> The commenter supports retaining this approval.

Commenter (0755-TPA) supports the proposal to extend the rules regarding AMEL applications to all applicants seeking an AMEL for methane and VOC work practice standards in NSPS OOOOa. The commenter notes that in the 2020 Technical Rule, EPA recognized the benefits of streamlining the requirements pertaining to applications to use AMEL for VOC emissions from, inter alia, reciprocating compressors and gathering and boosting compressor stations. The commenter notes that the EPA now proposes to apply those provisions to work practice

---

<sup>35</sup> According to the commenter: "We highlight as an example of success in this area EPA's Plantwide Applicability Limit (PAL) regulations under 40 CFR § 52.21(aa). EPA undertook an innovative permit initiative in the 1990s and ultimately issued regulations intended to standardize and streamline the process in 2002. Since that time, numerous PAL permits have been issued and significant emissions reductions have occurred that would not otherwise have happened. The key to the success of that program was that the regulations standardized the process but also provided EPA and states the flexibility to adapt as long as core criteria were met."

<sup>36</sup> See Proposal p. 63167 and 40 CFR §60.5399a(n).

standards for methane emissions as well. The commenter states that they support this proposal because it is appropriate not to unduly limit the category of those who can submit AMEL use applications, whether the pollutant at issue is VOC or methane. If applicable information requirements and reduction demonstrations are met, as provided by the rules, then it is beneficial to increase flexibility by allowing submission of applications by “any person,” including but not limited to states and political subdivisions (included in the definition of “person” by the CAA at 42 USC §7602(e)), owners and operators of covered sites, manufacturers, vendors, and trade associations.

Commenter (0756-Baker Hughes) specifically supports the EPA proposal to retain 2020 Technical Rule amendments to the AMEL application requirements aimed at streamlining the process for evaluation and possible approval of advanced measurement technologies. The commenter notes that the amendments expand the pool of applicants for AMEL to include manufacturers and vendors, that allow applicants to supplement field data with modeling analyses, test data and other documentation, and that allow the application of approved AMEL to multiple sites will speed the development and deployment of innovative methane detection and control technology. The commenter adds that the speed and clarity of the AMEL process is critical to meeting the methane emission objectives shared by this Administration and the oil and gas industry.

Commenter (0820-Pioneer) supports the multiple reforms that EPA included to enhance the AMEL process to allow for emerging technologies in NSPS OOOOa. The commenter states they also support the application of approved emerging technologies by EPA to other sources within the oil and natural gas industry. Specifically, the commenter states that the EPA should allow for basin-wide equivalency determinations or basin-wide approvals, once equivalency has been demonstrated, and incorporation by reference of emerging technologies to other sites.

Commenter (0820-Pioneer) expresses additional support for the allowance for modeling and testing at a controlled test environment to demonstrate performance of a new technologies. They add that they also appreciate the EPA allowing for vendors and manufacturers as applicants for approval of emerging technology and not limiting the submissions to oil and natural gas companies with sites. The commenter explains that artificially limiting submissions to oil and natural gas companies prohibits the experts that are developing these new and emerging technologies from working with EPA and other stakeholders to implement the technologies as broadly as possible to reduce emissions at a lower cost.

Commenters (0820-Pioneer Natural Resources USA, Inc. (Pioneer), 0831-AXPC) support EPA’s recognition of approved state programs that are equivalent to EPA’s LDAR requirements and recommends that EPA continue with that allowance. It prevents redundancy of recordkeeping and reporting and allows for those state programs that are more stringent than EPA’s to continue. The commenters believe that state equivalency becomes even more important with EPA proposing emission guidelines that will require state plans. Without allowing for state equivalency, it will make developing and approving state plans more difficult in the future.

Response I-2-14: EPA acknowledges the various commenters support for the application of the AMEL provisions to work practices that apply to methane and VOC emissions. Many of the

points raised by commenters related to AMEL in the context of NSPS OOOOa and the associated AMEL process were discussed in the Response to Public Comments Document for the 2020 Technical Rule.<sup>37</sup> Since this rulemaking did not propose to alter that AMEL process for NSPS OOOOa, EPA directs commenters to that 2020 response to comment document and incorporates those comment responses here.

More specifically, in response to comments on the AMEL provisions in NSPS OOOOa related to permitting a broader application of AMEL technology alternatives, “point by point” equivalency, and basin-wide equivalency see EPA’s discussion in Sections V.C.1 and VI.C.1 of the preamble to the 2020 Technical Rule.<sup>38</sup> That discussion within those sections responds to all of these commenter’s suggestions regarding AMELs in the context of OOOOa.

Furthermore, in the context of NSPS OOOOb, EPA has taken a different approach that addresses many, if not all, aspects of these comments. While the AMEL provisions finalized in NSPS OOOOb are the same as in NSPS OOOOa, the final rule for OOOOb also includes separate provisions concerning alternative methane detection technologies. Please see section XI.A.1 of the November 2021 Proposal preamble for specific solicitations for comment regarding advanced measurement technologies. See also section IV.B (Advanced Methane Detection Technologies) of the December 2022 Supplemental Proposal on this topic, and section X.B (Advanced Methane Detection Technology Work Practices) of the final rule preamble. See also Volume II Chapter 5 (Advanced Methane Detection Technologies of the RTC for EPA’s responses to comments on alternative methane detection technology.

The comments summarized above regarding AMEL were provided prior to EPA having fully articulated an alternative methane detection and quantification program. EPA believes that many, if not all, concerns expressed by commenters above can be addressed via this new program that exists outside of the AMEL context. EPA believes the new alternative technology component of the rule should limit the number of AMEL applications and streamline alternative methane detection technologies that can be used under the rules. Once an alternative test method for an alternative technology has been approved, if it is broadly applicable, the EPA will post it to the Emission Measurement Center website.<sup>39</sup> Any owner or operator who meets the specific applicability for the alternative test method, as outlined in the alternative test method, may use the alternative test method to comply with the alternative periodic screening approach or alternative continuous monitoring approach.

Comment: Commenter (0938-TXOGA) notes that the EPA states that it is continuing approval of the Texas regulations that have been previously approved as alternatives for fugitive emissions components located at well sites and compressor stations in Texas. The commenter states that this will avoid the need for duplicative activities by companies.

Commenter (0755-TPA) also supports rule provisions that allow owners and operators of

---

<sup>37</sup> Oil and Natural Gas Sector: Emission Standards for New, Reconstructed, and Modified Sources Reconsideration 40 CFR Part 60, subpart OOOOa Response to Public Comments on Proposed Rule [83 FR 52056, October 15, 2018] Comments. EPA-HQ-OAR-2017-0483-2291.

<sup>38</sup> 85 FR 57398 (September 15, 2020).

<sup>39</sup> <https://www.epa.gov/emc/oil-and-gas-approved-alternative-test-methods>.

compressor stations in Texas to comply with fugitive emissions standards promulgated by TCEQ in lieu of complying with equivalent standards in the federal NSPS, and the current proposal to extend those provisions to methane emissions for gathering and boosting stations as well as methane and VOC emissions for compressor stations in the transmission and storage industry segment. The commenter states that this increases flexibility for regulated companies, eliminates duplication at the state level, and eases compliance burdens, while still maintaining environmental protections.

Commenter (0820-Pioneer) supports EPA's recognition of approved state programs, specifically the Texas Standard Permit program, that are equivalent to EPA's leak detection and repair requirements and recommends that EPA continue with that allowance. The commenter states that it prevents redundancy of recordkeeping and reporting and allows for those state programs that are more stringent than the NSPS to continue.

Response I-2-15: EPA acknowledges the support of the specified alternative fugitive emissions standards that facilities may opt to utilize to demonstrate compliance with the fugitive emissions standards in §60.5397a. These alternative fugitive emissions standards have been finalized as proposed.

## **2.6 Pneumatic Pumps**

Comment: Commenter (0755-TPA) states that owners and operators of pneumatic pump facilities should have additional options to demonstrate no detectable methane emissions from CVS. The commenter notes that the EPA is proposing to amend current NSPS OOOOa requirements to allow pneumatic pump affected facilities to demonstrate no detectable methane emissions from CVS either by using annual Method 21 monitoring, as currently required, or by using one of two additional options: monthly audio, visual, olfactory (AVO) monitoring or OGI monitoring at the fugitive monitoring frequency. The commenter agrees that operators should have the ability to choose from all of these options with respect to demonstrations for methane emissions, just as they are currently allowed to choose from these options for VOC emissions demonstrations pursuant to amendments finalized in the 2020 Technical Rule.

The commenter (0755-TPA) suggests that the current proposal has the benefit of giving operators additional options beyond the use of Method 21. Method 21 is acceptable as an option but should never be required as the only acceptable monitoring method. In the experience of some of the commenters' members, Method 21 can be slow and cumbersome, while OGI can often be performed much more quickly and efficiently, as can AVO monitoring. Method 21 can also be relatively labor intensive and, as EPA itself has noted, "is not as cost-effective as OGI."<sup>40</sup> The proposal would also create efficiencies by allowing for the same monitoring method (OGI) to be used for pneumatic pumps located at the same site as controlled storage vessels. Moreover, as EPA points out, the commenter notes that OGI is already being used for sites that are subject to fugitive emissions monitoring and the CVS can readily be monitored during the fugitive emissions survey at little or no additional cost.<sup>41</sup> According to the commenter, providing an

---

<sup>40</sup> See EPA-452/R-15-002, August 2015, "Regulatory Impact Analysis of the Proposed Emission Standards for New and Modified Sources in the Oil and Gas Sector," at 7-29.

<sup>41</sup> See 86 FR 63 L62 (Nov. 15, 2021).

AVO option is a beneficial option, inter alia, because requiring either Method 21 or OGI for the sole purpose of monitoring CVS associated with a pneumatic pump would be unduly burdensome and would create substantial additional expense with little countervailing environmental benefit.

Response I-2-16: EPA acknowledges the support from the commenter and has finalized this provision as proposed.

## **2.7 Professional Engineer (PE) Certification**

Comment: Commenter (0755-TPA) states that in-house engineers should be allowed to make required certifications and determinations, as should non-PE outside personnel with appropriate expertise. The commenter notes that the EPA is proposing changes in NSPS OOOOa to the certification requirements regarding a determination that it is technically infeasible to route emissions from a pneumatic pump to a control device or process and regarding certification that design and operation of CVS will meet applicable requirements. The commenter adds that, specifically, the EPA is proposing to allow certification of technical infeasibility by either a PE or an in-house engineer with expertise on the design and operation of the pneumatic pump, and further to allow either a PE or an in-house engineer with expertise on the design and operation of the CVS to certify the design and operation will meet the requirement to route all vapors to the control device or back to the process.

The commenter (0755-TPA) supports the proposal to allow in-house engineers to make such certifications. The commenter adds that, as they have stated in prior comments, it is inappropriate to eliminate the ability of otherwise-qualified personnel to review and assess operations at regulated sources. The commenter explains that the fact is that in-house engineers are often the most experienced and knowledgeable personnel with respect to site design and control as well as specific design and feasibility questions, and as such they are often the most qualified personnel to make the assessments for which certifications are required.

Commenter (0755-TPA) also expresses that they believe that EPA should expand the universe of persons who could make required certifications and determinations to include non-PE outside personnel. According to the commenter, companies on occasion can experience shortages or temporary unavailability of personnel and in those instances rely on outside personnel. The commenter notes that such outside personnel can be as knowledgeable of and familiar with design and operations as in-house employees. They believe that company-hired contractors or consultants should also be allowed to sign off on certifications if they have appropriate expertise, *e.g.*, if they have designed the system in question. The commenter contends that this would provide additional flexibility without sacrificing any environmental protections because such third parties would have to have appropriate expertise on design and operation of the system in order to complete a certification or to make a required technical determination.

Similarly, commenter (0787-Atmos Energy Corporation (Atmos)) supports aligning NSPS OOOOa certification requirements for natural gas pneumatic pumps so that an in-house engineer can determine whether it is technically infeasible to route emissions from a natural gas

pneumatic pump to a control device or process. According to the commenter, in-house engineers are likely to have more knowledge about the site and can therefore apply a higher level of scrutiny to such determinations. Additionally, the commenter notes that in-house engineers have training comparable to PEs.

Commenter (0831-American Exploration and Production Council (AXPC)) supports EPA allowing for in-house engineers to be used for certification as the commenter agrees with EPA assessment that in-house engineers may be more knowledgeable about site design and control than a third-party PE.<sup>42</sup>

Commenter (0831-AXPC) adds that not only are in-house engineers likely to be more knowledgeable about site design but requiring PE certification can unnecessarily raise costs and delays, as there are not enough PEs certified in the required oil and natural gas requirements to support the rulemaking. Thus, if EPA wanted to require PE certification, it would need to provide significantly longer compliance timeframes to support the need to hire and train PEs.

Commenter (0585-Kentucky Oil and Gas Association (KOGA)) also supports EPA's proposal to maintain the change from the 2020 Technical Rule to permit a PE or an in-house engineer with experience in the design and operation of a CVS to perform certification. This will provide relief to the companies that have an engineering staff that is capable of performing this determination.

Response I-2-17: EPA acknowledges the support of the commenters regarding the allowance of certifications by either a PE or an in-house engineer with expertise related to the technical infeasibility to route pneumatic pumps to control and the certification of the design and operation of CVS that route vapors to control. The final rule allows certifications for these purposes by either a PE or an in-house engineer with expertise. EPA is not expanding this certification to include outside engineers that are not licensed PEs because the commenter did not provide information that demonstrates these outside engineers would have the same level of expertise required to make such evaluations for certification.

## **2.8 Natural Gas Processing Plant Initial Compliance Timeline for Leak Detection and Repair**

Comment: Commenter (0755-TPA) supports the extension of the 180-day initial compliance deadline regarding methane standards for leaks at processing plants. The commenter explains that, in rule amendments made in the 2020 Technical Rule, EPA clarified that the initial compliance deadline for VOC equipment leak standards at natural gas processing plants was 180 days. They state that this was a beneficial clarification for two reasons: first, it brought NSPS OOOOa in line with existing requirements in NSPS KKK, and second, it gave owners and operators a reasonable and workable period within which to bring affected equipment into proper operation and to conduct a thorough and accurate check on whether the equipment is in conformance with applicable leak standards.

Response I-2-18: EPA acknowledges the commenter's support for the proposed initial

---

<sup>42</sup> 86 FR 63162 (Nov. 15, 2021).

compliance deadline for the leak detection and repair requirements at onshore natural gas processing plants. The final amendments to NSPS OOOOa include this initial compliance deadline as proposed.

## **Chapter 3. Significant Contribution Finding and the Congressional Review Act**

### **3.1 Regulation of Transmission and Storage Sources and Regulation of Methane**

#### ***3.1.1 Regulation of Transmission and Storage Sources***

Comment: Several commenters (0763-Texas Commission on Environmental Quality (TCEQ) and Railroad Commission (RRC), 0790-West Virginia Office of the Attorney General *et al.* (WV AG *et al.*), 0793-Permian Basin Petroleum Association (PBPA), 0921-U.S. Chamber of Commerce, 0819-State of West Virginia *et al.* (WV *et al.*)) assert that the November 2021 Proposal’s regulation of transmission and storage sources and regulation of methane violate Clean Air Act (CAA) section 111 because EPA has failed to make the threshold findings such regulation and, instead, reintroduced the 2016 NSPS OOOOa’s mistakes.

Commenter (0819-WV *et al.*) contends that the November 2021 Proposal reintroduced many of the 2016 rule’s mistakes. According to the commenter, the November 2021 Proposal once again tries to regulate the transportation and storage segments of oil and natural gas production sources without making the endangerment findings Congress required.

According to commenters (0790-WV AG *et al.*, 0819-WV *et al.*), to establish new source emission limits, EPA must list the category of stationary sources that “cause, or contribute significantly to, air pollution which may reasonably be anticipated to endanger public health or welfare.” CAA section 111(b)(1)(A). The commenters state that the EPA failed to make the requisite finding for transmission and storage sources. According to commenters, the agency neglects to acknowledge that it is creating a new source category for transmission and storage of oil and natural gas. This new category incorporates many types of stationary sources of oil and natural gas that were never included in the 1979 endangerment finding’s oil and natural gas production category—at least before the short-lived 2016 rule. Rather than make a SCF for this new category, EPA impermissibly relies on prior findings about different source categories emitting different pollutants. *Id.* at 63,134-35.

According to commenters (0790-WV AG *et al.*), the Proposed Rule tries to expand EPA’s authority to regulate sources of methane relating to oil and gas transmission and storage that EPA had never regulated before. But the Proposed Rule goes even further than the 2016 Rule. *Id.* at 63,116 (specifying that the Proposed Rule addresses “emissions sources previously not regulated under the 2016 NSPS”). Newly regulated sources include well liquid unloading operations and oil wells with associated natural-gas emissions. See *id.* at 63,117. EPA was wrong to add transmission and storage sources in 2016, and it appropriately reversed that decision in 2020. In the Proposed Rule, EPA misreads its own 1979 source category designation of oil and natural gas production sources to say that the category also reaches transportation and storage.

Commenters (0790-WV AG *et al.*) continue:

The circumstances surrounding EPA's 1979 rulemaking for production sources casts significant doubt on the Proposed Rule's reinterpretation of that category. EPA issued the 1979 Rule in response to Congress's directive to publish a list of "major stationary sources of air pollution." Priority List and Additions to the List of Categories of Stationary Sources, 44 Fed. Reg. 49,222 (Aug. 21, 1979). Congress knew that this rulemaking was a momentous change in environmental regulation. Thus, it required EPA not only to institute ordinary notice-and-comment proceedings when fashioning the rule, but also to consult "Governors and State air pollution control agencies" before issuing the list of new major sources categories. *Id.*

EPA did just that. The Agency collaborated with the Governors of all 50 States in a series of working group meetings and revised its initial proposal as a result of significant public input. 44 Fed. Reg. 49,222. The final list of major source categories came out of much deliberation and compromise, and accordingly, the source categories in the 1979 rule were worded carefully. For example, the initial set of major sources states that "petroleum transportation and marketing" could be a major source of pollution, but it did not reach the same conclusion for natural gas transportation. *Id.* at 49,226. Instead, the 1979 rule consciously decided to exclude both transportation sources, and found instead that "crude oil and natural gas production" met the statutory parameters. *Id.* (emphasis added).

The public debate that went into the 1979 rule makes it particularly difficult to reinterpret the major source categories EPA initially listed. After all, "regulatory drafting is often an exercise in political compromise," one that involves "the President, Congress, interest groups, and the courts." Jennifer Nou, *Regulatory Textualism*, 65 DUKE L. J. 81, 83 (2015). The parties involved carefully bargained over the meaning and scope of the 1979 rule, and it was the focus of intense public scrutiny. In reviewing the initial list of the major source categories, all parties studied the "provision-by-provision analyses in preambles" to interpret the public meaning of the regulation. *Id.* at 119. The "provision-by-provision" analysis for the 1979 rule reveals no intent to regulate natural gas storage or transportation, despite showing such intent for other categories like petroleum. 44 Fed. Reg. at 49,222. Under the rule, no then-regulated party, and no part of the group responsible for the drafting, would have believed that EPA had any authority to regulate oil and natural gas sources outside the production context.

The Proposed Rule's attempt to expand the 1979 rule is an impermissible shortcut around a regulatory compromise. The rule improperly shoehorns the transportation and storage segments into the existing category of oil and natural gas. Perhaps the Proposed Rule could make oil and natural gas transportation and storage a regulated source category—assuming EPA first makes a proper endangerment finding. But these areas are not currently within a listed category. Because of this conscious omission, EPA lacks authority to regulate here unless it does the legwork and finds that the transmission and storage segments of the industry contribute significantly to air pollution that may reasonably be anticipated to endanger public health or welfare.

Commenter (0921-U.S. Chamber of Commerce) states that, gradually expanding the universe of sources within the transmission and storage segment as EPA proposes to do without making the requisite findings exacerbates the legal concerns they have with the rulemaking. The commenter contends that this approach could have the net effect of expanding an existing source category incrementally in an end run around the CAA's requirements to undertake an endangerment finding and a SCF. The commenter adds that, to the extent that additional emission sources are included in the supplemental proposal or any proposal thereafter within the oil and gas NSPS, EPA must comply with the process requirements of the statute for a source category expansion. The commenter concludes that the EPA should, therefore, take this opportunity to help ensure the legal durability of these important regulations by making all requisite findings for the transmission and storage segment.

Response I-3-1: The EPA disagrees with the adverse commenters' statements that the 1979 listing did not include the transmission and storage segment. The 2016 NSPS OOOOa stated that the Crude Oil and Natural Gas Production source category, as the EPA listed it for regulation under CAA section 111(b)(1)(A) in 1979, included the transmission and storage segment. The 2016 rule was correct – the EPA's 1979 listing of the source category should be considered to have included the transmission and storage segment. This is evident because the EPA's 1979 listing of the source category was part of a broader process in which the EPA comprehensively identified all of the nation's industrial source categories. The EPA did not specifically identify the transmission and storage segment as part of that process, and therefore it is logical that the EPA considered that segment to be part of the oil and gas source category.

In the 1977 CAA Amendments, Congress added CAA section 111(f)(1)-(2), which required the EPA to list additional source categories and promulgate standards of performance within certain periods of time, and established criteria for the EPA to determine priorities for promulgating those standards. 42 U.S.C. § 7411(f)(1)-(2) (1977). To implement these requirements, the EPA conducted a study that identified all the source categories it had not yet listed for regulation under CAA section 111(b)(1)(A) and that prioritized them for listing and regulation: *Priorities for New Source Performance Standards Under the Clean Air Act Amendments of 1977*, EPA-450/3-78-019 (April 1978) ("1978 Priority List"). Subsequently, the EPA revised the prioritization for some of the source categories, "Revised Prioritized List of Source Categories for New Source Performance Standards," EPA-450/3-79-023 ("1979 Priorities List"). The EPA then promulgated a final rule that, as required by CAA section 111(f), listed additional source categories for regulation under CAA section 111(b)(1)(A), consistent with the 1979 Priorities List. *See* 44 FR 49222 (Aug. 21, 1979) (1979 Listing Rule).

The 1978 Priorities List identified 203 source categories. This included 47 that it characterized as "minor" and therefore did not prioritize for regulation. Of the remaining 156, the report stated that a number could not be evaluated at that time due to lack of information, and therefore would not be prioritized for regulation. The report characterized the remaining source categories as "major," and prioritized them for regulation. *Id.* at 9. Thus, the report comprehensively identified all the nation's source categories. *Id.* at A-2, Table A-1 (listing "Source Categories Not Evaluated"); A-3 to A-6, Table A-2 (list of "Minor Sources"). The EPA confirmed the comprehensiveness of the 1978 Priorities List when it promulgated the 1979 Listing Rule. *See* 44

FR 49223 (noting that the 1978 Priorities List identified the source categories being listed for regulation, other source categories not evaluated, and minor source categories).

The 1978 Priorities List included, as one of the major source categories, “Crude Oil and Natural Gas Production Plants.” *See, e.g.*, 1978 Priorities List at 115, Table 3-12. The 1979 Priorities list included the same source category, 1979 Priorities List at 9, Table 3-2, and this source category was listed for regulation under CAA section 111(b)(1)(A) in the 1979 Listing Rule, under the name, Crude Oil and Natural Gas Production. 44 FR 49226. The EPA initially proposed NSPS for this source category in 1984. *See, e.g.*, 49 FR 2636, 2637 (Jan. 20, 1984). The EPA promulgated the initial NSPS for this source category in two 1985 rules. 50 FR 26122 (June 24, 1985) (VOC emissions from equipment leaks), 50 FR 40158 (Oct. 1, 1985) (SO<sub>2</sub> emissions). Both rules concerned onshore natural gas processing plants.

Although the 1979 listing identified the oil and gas industry as “Crude Oil and Natural Gas Production,” the above-described history of the 1979 listing and initial regulation of the oil and gas source category makes evident that from its inception the source category included the transmission and storage segment. The 1978 Priorities List, which, as noted above, was the report that formed the foundation for the EPA’s 1979 listing of the oil and gas source category, along with numerous other source categories, did not specifically identify the transmission and storage segment of the gas industry. However, the report was designed to comprehensively identify the nation’s industrial source categories. It included “major” source categories, which it indicated should be prioritized for regulation; “minor” source categories, which it indicated should not be prioritized for regulation; and ones that could not be evaluated because of a lack of information. 44 FR 49223. It is not plausible that this comprehensive listing would have overlooked the transmission and storage segment of the oil and gas industry, particularly when it included numerous “minor” source categories that did not merit regulation.

Commenters (0790-WV AG *et al.*) assert that the 1979 list was drafted by a team of stakeholders who negotiated its content, imply that the stakeholders negotiated over the scope of the oil and gas source category, and conclude that the result of that negotiation was that they gave the source category a narrow scope, as reflected in its title, “Crude Oil and Natural Gas Production.” Their assertion is not persuasive, for many reasons. That the 1979 listing would have been drafted by a team of stakeholders is not consonant with the EPA’s obligation to promulgate the listing through a notice-and-comment rulemaking process that must meet the requirements of CAA section 111 and withstand judicial review under CAA section 307(d)(9). Moreover, aside from the fact that CAA section 111(f) generally required EPA to consult with states before making listing decisions and promulgating standards, commenters do not cite any evidence of such negotiation in the record over the scope of any of the source categories and, in particular, they do not cite anything concerning the scope of the oil and gas source category. In any event, any consultation by the states would not have affected the fact that the background documents that formed the basis of the listing sought to comprehensively identify the source categories across the nation, as described above.

The initial regulation of the source category in 1985 concerned natural gas processing plants, which made clear that the scope of the source category was not limited to the production segment of the oil and gas industry, and instead was broader. This fact further undermines commenters

(0790-WV AG *et al.*) argument. They state, referring to their allegations that the 1979 listing was drafted by a negotiating team of stakeholders, “Under the rule, no then-regulated party, and no part of the group responsible for the drafting, would have believed that EPA had any authority to regulate oil and natural gas sources *outside the production context*” (emphasis added). However, in fact, the first standards promulgated for the source category were outside the production context – they were for the processing segment. Thus, it was clear from the outset that the source category was broader than just production sources.<sup>1</sup>

The EPA explicitly recognized that the source category included the transmission and storage segment in the 2012 NSPS OOOO, 77 FR 49496, when it first promulgated NSPS for sources in that segment; and again in the 2016 NSPS OOOOa, when it promulgated NSPS for additional sources in that segment.

In any event, the 2016 NSPS OOOOa further addressed the concerns commenters raised by re-listing the oil and gas source category to include the transmission and storage segment. That is, the 2016 rule went on to assume that the oil and gas source category as listed in 1979 did not include the transmission and storage segment, and then the rule revised the source category to include that segment and determined that the revised source category causes, or contributes significantly to, air pollution which may reasonably be anticipated to endanger public health or welfare, in accordance with CAA section 111(b)(1)(A).

The 2016 rule explained that it was appropriate to include the transmission and storage segment in the revised source category because that segment was interrelated with the production and processing segments. The 2016 rule’s basis for this determination is described in the preamble for this action.

The preamble also describes the major reasons why the transmission and storage segment is interrelated with the production and processing segments. In addition, across all the segments, the gas predominantly consists of methane. The natural gas enters the production and processing segments as field gas, and the processing changes its composition by removing most of the contaminants, those contaminants are a relatively small part of the gas. Moreover, some amounts of VOCs and HAPs remain in the gas; thus, the physical change in the composition of the gas simply means changes in the ratio of the methane, VOCs, and HAPs. For example, according to the 2020 Policy Rule, the average methane content of (i) produced gas ranges from 69-83%, (ii) gas in the processing segment is 78%; and (iii) gas in the transmission and storage segment ranges from 94-95%. 85 FR at 57029. This change in composition of the gas confirms that the segments are reasonably understood as comprising a sequence of functions leading to a single outcome, which is to convey methane, in as pure a form as possible, for distribution: the function of the production segment is to recover the gas, which is primarily methane, but with

---

<sup>1</sup> The 2020 Policy Rule argued that in proposing the first standards of performance in 1984, 49 FR 2637 (1984), and promulgating them in 1985, 50 FR 26124 (June 23, 1985), the EPA’s description of the source category was limited to the production and processing segments. 85 FR 57025-26 (discussing the 1984 proposal). However, the 2016 NSPS OOOOa interpreted the 1984 proposal to be consistent with the scope of the source category including the transmission and storage segment, 81 FR 35832, but in any event, the 1985 rule’s standards were limited to the processing segment, and so the rule had no occasion to consider whether the source category extended to the transmission and storage segment. When the EPA turned to the transmission and storage segment in the 2012 rule, it recognized that the source category included that segment. 77 FR 49496.

contaminants; the purpose of the processing segment is to remove contaminants and thereby purify the methane; and the purpose of the transmission and storage segment is to convey the methane for distribution.<sup>2</sup>

Moreover, the same control requirements apply to all the segments. As described in the preamble, methods of monitoring for fugitive emissions using OGI to find leaks to prompt equipment repair or replacement and capturing emissions and routing to a control device such as a flare or routing to a process through a CVS and the requirements for process controllers, pumps, storage vessels, centrifugal and reciprocating compressors in production and processing are the same as for that same equipment in transmission and storage. The 2016 NSPS OOOOa pointed this similarity out as well. 2016 RTC at 1-16.

Further indication that the segments are interrelated is found in the effects that the segments have on each other. As the EPA stated in the 2016 NSPS OOOOa:

Because they are interrelated, segments that follow others are faced with increases in throughput caused by growth in throughput of the segments preceding (*i.e.*, feeding) them. For example, the relatively recent substantial increases in natural gas production brought about by hydraulic fracturing and horizontal drilling result in increases in the amount of natural gas needing to be processed and moved to market or stored. These increases in production and throughput can cause increases in emissions across the entire natural gas industry.

81 FR 35832. Similarly, regulatory requirements for the production and processing segments that reduce fugitive emissions or other forms of waste have the effect of increasing throughput for the transmission and storage segment.

While it is true that the production and processing segments use some different equipment than the transmission and storage segment, that is simply a result of the fact that the two sets of segments have different functions, and does not provide evidence that they are not interrelated. The production segment has some different equipment (such as equipment for a well completion) than the processing segment but those segments are well-recognized as interrelated. What is more relevant is that, as the EPA also explained in the 2016 NSPS OOOOa, “some equipment (*e.g.*, storage vessels, pumps, compressors) are used across the oil and natural gas industry, which further supports considering the industry as one source category.” 81 FR 35832. In fact, virtually all of the equipment used in the transmission and storage segment is also used in the production and processing segments. This includes methods of monitoring for fugitive emissions and storage vessels, pumps, process controllers, and compressors. While some equipment, such as dehydrators are used differently in the production and processing segments than in the transmission and storage segment, the key functions of the equipment, such as removal of water

---

<sup>2</sup> It should also be noted that field gas produced in different basins in the U.S. varies widely in its amounts of VOCs and HAPs. Field gas produced in the Appalachian region has, on average, a higher percentage of methane (95.6%) and fewer contaminants than gas in the transmission and storage segment, on average, in the U.S. (94-95%, as noted above). See Memorandum to U.S. EPA from Eastern Research Group, “Natural Gas Composition,” Dkt. No. EPA-HQ-OAR-2017-0757 (November 13, 2018) (Table 2). The 2020 Policy Rule acknowledged that “[t]he composition of field gas varies across basins,” and notes that “the Appalachian region is predominantly dry gas and northern mid-continent (North Dakota) is primarily wet gas.” 84 FR 50248.

and impurities in the case for dehydrators and compressing fluids in the case of a compressor, remains the same regardless of segment.

In any event, the fact that there are differences among the sources in a source category does not indicate that the source category should be divided into smaller and more uniform source categories. In general, Congress recognized that a source category may include different sources, under CAA section 111(b)(2), which provides that “[t]he Administrator may distinguish among classes, types, and sizes within categories of new sources for the purpose of establishing such standards.” In the extreme case, if source categories were limited to sources that were identical, there would be no need for this authorization to subcategorize.

The scope of the source category as defined in 2016, and affirmed in this rule, is well within the reasonable bounds of the EPA’s past practice in defining source categories, which sometimes even contain sources that are located in multiple distinct industries. *See* 40 CFR part 60, subpart Db (industrial-commercial-institutional steam generating units), 40 CFR part 60, subpart IIII (stationary compression ignition internal combustion engines). In this regard, the House Report that accompanied the 2021 CRA joint resolution correctly noted that “even the presence of large distinctions in equipment type and emissions profile across two segments would not necessarily preclude EPA from regulating those segments as a single source category, so long as the EPA could identify some meaningful relationship between them,” House Report at 7, as the EPA did in the 2016 Rule. The EPA has included production, processing, transfer and storage sources in the same source category for the coal industry. Specifically, the coal preparation and processing plants source category includes thermal dryers, pneumatic coal-cleaning equipment, coal processing and conveying equipment (including breakers and crushers), coal storage systems, transfer and loading systems, and open storage piles. 40 CFR 60.250(d).

With respect to the Crude Oil and Natural Gas source category, the oil production segment differs from the natural gas production segment, and each of those segments differs from the natural gas processing segment, but those segments were placed in the source category in the 1979 listing. The natural gas transmission and storage segment does not differ more from the natural gas processing segment than oil production does.

That EPA has discretion in determining the scope of a source category, based, in some cases, on unique factors of the source category, is further illustrated by its treatment of petroleum refineries as a separate source category. The EPA appropriately identified petroleum refining as a separate source category in light of the enormous complexity of the petroleum industry. A refinery converts crude oil into a large number of different products and feedstocks for still more products, ranging from gasoline and fuel oils to asphalt and naphtha. It has extensive infrastructure for raw material intake and complex large-scale operations. Moreover, refineries tend to adapt their operations frequently to optimize production based on product specification (for example, type of gasoline) and market conditions. By contrast, produced natural gas is primarily intended to become a single product, sales gas, and requires much more simplified processing than petroleum does refining. The production, processing, transmission and storage segments provide a sequence of operations designed to produce this single product, and those operations seldom change. These differences between petroleum refining and the natural gas industry highlight the interrelatedness of the production, processing, transportation, and storage

functions for the natural gas industry. As the EPA stated in the 2016 NSPS OOOOa, “The process of producing natural gas for distribution involves operations in the various segments of the natural gas industry.... In contrast, oil production involves drilling/extracting oil, which is immediately followed by distribution offsite to be made into different products.” 81 FR 35832 n.26.

The EPA’s 1986 expansion of the source category of industrial fossil fuel-fired steam generators to include non-fossil fuel-fired steam generators as well as commercial and institutional steam generators, 51 FR 42794 (Nov. 25, 1986), provides a precedent for the EPA’s actions in the 2016 NSPS OOOOa. In 1979, the EPA added “Industrial Fossil Fuel-Fired Steam Generators: Industrial Boilers” to the list of source categories under CAA section 111(b)(1)(B). 44 FR 49222. After it began to develop new source performance standards for this source category, the EPA became aware of substantial similarities between the affected sources and other types of sources. 49 FR 25156 (June 19, 1984) (proposed expansion of the source category). Accordingly, in 1986, the EPA “amend[ed] the ... list for regulation under [CAA] section 111 ... by expanding the source category of industrial fossil fuel-fired steam generators to cover all steam generators, including both fossil and nonfossil fuel-fired steam generators, as well as steam generators used in industrial, commercial, and institutional applications.” 51 FR 42794. The EPA justified this expansion on the grounds that “[a]ll of these types of steam generators exhibit emission characteristics which are similar in quantity and type. Furthermore, the emission control devices which have been found to be effective on steam generating units are also effective in reducing emissions from other types of steam generators.” *Id.* at 42794-95. That is, “the emission control techniques which are applicable to fossil fuel-fired boilers are generally applicable to nonfossil fuel-fired boilers as well.” 49 FR 25156. The EPA went on to determine that this expanded source category of “industrial-commercial-institutional steam generating units contribute[s] significantly to air pollution which may reasonably be anticipated to endanger public health or welfare.” 51 FR 42794.<sup>3</sup> Thus, in the 1986 steam generator rule, as in the 2016 NSPS OOOOa, the EPA revised the CAA section 111(b)(1)(A) list by expanding a source category to include more sources that had commonalities with the initially listed sources, including the same equipment, control technology, and types of emissions, and by making a new significant contribution and endangerment finding for the expanded source category.

The above discussion is sufficient to support the EPA’s view that in the 2016 NSPS OOOOa, the agency reasonably exercised its discretion to expand the source category to include the transmission and storage segment. While not essential to support that view, it should also be noted that some new sources in the transmission and storage segment have been subject to NSPS since the 2012 rule, and others since the 2016 rule. Numerous sources have complied with the NSPS, including making capital investments to install the requisite controls. See 2016 TSD. Commenters who argue that that the transmission and storage segment should be removed from the source category, and therefore that the NSPS for the affected sources should be rescinded, do not argue that the NSPS are unduly burdensome, and the EPA is aware of no evidence that the NSPS are unduly burdensome. The fact that the NSPS for the transmission and storage segment have been on the books and complied with by the affected sources, provides another reason to maintain them.

---

<sup>3</sup> The EPA did not alter the treatment of utility steam generators as a separate source category. 51 FR 42794.

The legislative history of the joint resolution disapproving the 2020 Policy Rule makes clear that part of Congress' reason for that action was its intention that the EPA should include the transmission and storage segment as part of the oil and gas source category and promulgate GHG requirements for the sources in that segment.<sup>4</sup>

The objection of commenters (0921-U.S. Chamber of Commerce) to including the transmission and storage segment because, in its view, doing so incrementally expands the source category without making the requisite endangerment finding, is not valid. As noted, on the assumption that the source category as determined in the 1979 listing did not include the transmission and storage segment, in the 2016 NSPS OOOOa, the EPA revised the source category to include that segment and made an endangerment finding for the revised source category. Just as the EPA could have determined the source category to include the transmission and storage segment in 1979 (again, assuming that in 1979, the EPA did not determine the source category to include that segment), it could do so in the 2016 rule. The fact that it did not determine the source category to include the segment in 1979 (again, assuming that the EPA did not do so then) does not preclude it from revising the source category to include the segment later, as long as the EPA makes an endangerment finding for the revised source category. The EPA's discretion to determine the scope of a source category, subject to the constraints of CAA section 307(d)(9), extends to defining a source category to include the interrelated components of an industry. There is no basis under CAA section 111 to preclude the EPA from revising a source category to expand it simply because the EPA defined the source category more narrowly at an earlier point in time, as long as, again, the EPA makes an endangerment finding for the revised source category.

### ***3.1.2 Redundancy of Methane Regulation***

Comment: Commenter (0819-WV *et al.*) adds that the EPA also expands methane regulations through redundant and costly requirements.

In contrast, Commenter (0807-BP) notes that the regulation of methane emissions is not redundant with the regulation of VOC emissions because, among other reasons, regulation of methane established the predicate to regulate existing sources which emit the vast majority of methane.

Response I-3-2: The EPA responded in the preamble to the argument that under the 2016 NSPS OOOOa, the NSPS for GHG were redundant to the NSPS for VOC, and therefore unnecessary.

---

<sup>4</sup> A commenter, -0921 (Chamber of Commerce), stated that pigging operations and related blowdown activities are not integrated with any of the segments. We explain in RTC vol. 1, chapter 18, that in the November 2021 Proposal, EPA solicited comment and data to assist the Agency in evaluating the potential for developing emissions standards for additional emission sources, including pigging operations and related blowdown activities. EPA did not propose emissions standards for pigging operations and related blowdown activities in the December 2022 Supplemental Proposal; therefore, this final action does not include emissions standards for these emission sources. We may consider regulation through a future action, including in the next 8-year review of the NSPS. Accordingly, it is not necessary to address this comment further at present.

## 3.2 Rational Basis Finding or Pollutant-Specific Significant Contribution Finding

### 3.2.1 General

Commenter (0763-TCEQ/RRC) questions EPA's authority to promulgate a NSPS for methane without first conducting a methane or greenhouse gas (GHG)-specific significant contribution finding (SCF) under CAA §111(b)(1)(A). The commenter stated that because the challenge to the 2020 Technical Rule remains pending, the petitions on the 2016 Rule continue to be stayed. As a result, the commenter asserts that the legal basis for the NSPS OOOO and NSPS OOOOa rules and EPA's interpretation of its authority under section 111 remain in question. The commenter adds that they believe a SCF is necessary prior to EPA regulating under CAA §111 and states that the EPA has not made a SCF here.

According to commenters (0790-WV AG *et al.*, 0819-WV *et al.*), to establish new source emission limits, EPA must list the category of stationary sources that "cause, or contribute significantly to, air pollution which may reasonably be anticipated to endanger public health or welfare." CAA section 111(b)(1)(A). The commenters state that the EPA must make two separate findings: (1) that a given form of air pollution "may reasonably be anticipated to endanger the public health or welfare," and (2) that a given category of stationary sources "causes, or contributes significantly to" that air pollution. The commenters argue that the EPA refused to make either finding before issuing the November 2021 Proposal. Arguments include:

- From the outset, the agency has not even tried to make a timely endangerment finding. Instead, it impermissibly relies on prior endangerment findings, including its 2009 Finding that GHG emissions from automobile exhausts may, taken together, "reasonably be anticipated to endanger public health or welfare." 86 Fed. Reg. at 63,124. Beyond offering generalities about harms from methane emissions, EPA does not credibly attempt to make a similar finding for the specific pollutant at issue here. Unsurprisingly, EPA also fails to explain how emissions from mobile sources like cars can justify regulation at stationary facilities.

Commenter (0793-PBPA) states that, roughly a year before EPA's November 2021 Proposal, EPA acknowledged that two statutorily-mandated threshold questions must be answered before issuance of CAA section 111 standards. One of the questions involves the question related to making a methane-specific endangerment finding. As a predicate to promulgating new source performance standards, the commenter states that the EPA must determine that methane emissions from the oil and gas sector contribute significantly to endangerment. That is, determining a pollutant-specific endangerment finding for the source category requires EPA to determine that methane emissions from the oil and gas sector have a significant effect on global surface temperatures. After all, the commenter notes that Congress unambiguously applied the SCF requirement not only to the source category (here, the oil and gas sector), but also to the "air pollution" (here, methane) that actually causes the endangerment. According to the commenter, as EPA previously (and rightly) reasoned, "because Congress limited EPA to regulating only stationary sources in a category that the Administrator must first determine to cause or contribute

significantly to dangerous pollution, it is not reasonable to read ‘air pollutants’ to refer to any of the source category’s air pollutants for which EPA has not made a [SCF].”

Commenter (0763-TCEQ/RRC) questions EPA’s authority to promulgate a NSPS for methane without first conducting a methane or GHG-specific SCF under CAA section 111(b)(1)(A). The commenter asserts that a SCF is necessary prior to EPA regulating under CAA §111 and that EPA’s proposal has not yet made a SCF.

Commenters (0819- WV *et al.*, 0790-WV AG *et al.*) assert that the proposed rule cannot justify its failure to make pollutant- and source-specific finding by creating a new “rational basis” test. The commenters state that, in the November 2021 Proposal preamble, EPA claims authority to promulgate regulations for particular pollutants “as long as it has a rational basis for doing so.” 86 Fed. Reg. at 63,150. The commenters add that the agency explains that it need only satisfy the requirement to determine a source category “causes, or contributes significantly to, air pollution which may reasonably be anticipated to endanger the public health or welfare” when it first lists a category. Afterward, the commenters note that the EPA claims power to regulate any other pollutants “emitted from the source category” if it has “a rational basis to do so.” *Id.* The commenter contends that this interpretation cannot be squared with the plain text of the CAA. The commenters state that the EPA must make the SCF each time it regulates a pollutant from the source category. The commenters provide the following arguments:

...[t]he pollutant-specific reading flows naturally from the statutory text and structure. As a textual matter, the endangerment finding modifies and relates back to “air pollution,” not “sources.” 42 U.S.C §7411(b)(1)(A). The provision requires EPA to determine whether a source causes or contributes significantly to “air pollution which may reasonably be anticipated to endanger public health or welfare.” *Id.*... Only after the endangerment determination of a particular air pollutant may EPA look at whether the particular category of sources “contributes significantly” to that pollution. *Id.*

This text does not support EPA’s novel idea that a single endangerment finding at the source level can justify regulating any pollution the source may produce. Section 111(b)(1)(B) says EPA may issue performance standards after it lists a source category under Section 111(b)(1)(A). 42 U.S.C. §7411(b)(1)(B). Yet the definition of “standard of performance” is tied to the specific pollutants EPA concludes endanger health and welfare, not a generic cap on all potential pollutants the source might emit. *Id.* §7411(a)(1) (defining a “standard of performance” as “a standard for emissions of air pollutants”). Similarly, [s]ection 111(b)(3) commands the Administrator to “issue information on pollution control techniques for categories of new sources and air pollutants subject to the provisions of this section.” *Id.* §7411(b)(3) (emphasis added)

So the statute contemplates that the processes for adding new source categories and new air pollutants are the same: EPA must make the required findings to tie specific sources to specific pollutants. Yet EPA’s “rational-basis” approach creates inconsistency between how new source categories and new pollutants are added to the stationary source program. While new source categories must be added the traditional (and statutorily required) way, EPA can bootstrap jurisdiction over any new pollutants it chooses,

provided they come from existing source categories. The text does not support treating source categories and pollutants differently at all, let alone so dramatically.

Second, the CAA's text does not support EPA's rational-basis standard. The Proposed Rule cites no language from the statute saying the agency needs only a rational basis to regulate a new pollutant from an existing source category. Instead, the agency cites only a nonbinding House Report, a source that does not describe the actual legal standard nor have any power to change it. 86 Fed. Reg. at 63,150. This test is foreign to the CAA, and EPA's insistence on crafting a standard out of whole cloth is troubling.

Of course, it is easy to guess why EPA prefers the rational-basis standard. This low bar would allow EPA to bypass the endangerment finding altogether and ignore the reason Congress required it—confirming that a particular pollutant causes significant harm to health or welfare before greenlighting costly regulation. See *Coal. For Responsible Regul., Inc. v. EPA*, 684 F.3d 102, 117-18 (D.C. Cir. 2012) (per curiam), rev'd in part on other grounds sub. nom., *UARG*, 573 U.S. 302. The statute allows setting standards of performance only where the air pollutant “may reasonably be anticipated to endanger public health or welfare” and where emission of the pollutant from a particular source “causes, or contributes significantly” to that pollution. 42 U.S.C. § 7411(b)(1)(A).

These statutory terms matter. For one thing, they ensure that EPA cannot evade the requirement to consider costs when regulating new pollutants. The “upshot of inserting the adjective ‘significant’ was a consideration of which risks are worth the cost of elimination.” *Michigan v. EPA*, 213 F.3d 663, 677 (D.C. Cir. 2000) (per curiam). Congress also designed the pollutant-specific endangerment finding to make sure affected parties could hold EPA accountable for its decisions. By contrast, a rational-basis classification is almost impossible to challenge successfully in court. In the constitutional realm, for instance, a rational-basis classification will be upheld if there “is any reasonably conceivable state of facts that could provide a rational basis for the classification.” *FCC v. Beach Commc'ns, Inc.*, 508 U.S. 307, 313 (1993). Congress has deliberately chosen language that does not fit a standard where the actual costs of regulation are such weak backstops to new-claimed agency powers.

Perhaps EPA believes that there is room for a rational basis-approach because the statute is ambiguous. After all, the Supreme Court has held that “if the statute is silent or ambiguous with respect to the specific issue, the question for the court is whether the agency's answer is based on a permissible construction of the statute.” *Chevron, USA, Inc. v. Nat. Res. Def. Council, Inc.*, 467 U.S. 837, 843 (1984). But to find that ambiguity, an agency must use the “traditional tools of statutory construction.” *Epic Sys. Corp. v. Lewis*, 138 S. Ct. 1612, 1630 (2018) (quotation omitted). Nothing here suggests EPA has undertaken that effort. In fact, for the reasons explained, the traditional tools point toward an unambiguous, more rigorous standard—one that requires an endangerment finding for specific air pollutants before justifying nationwide regulation. Imagined ambiguity provides only superficial shelter.

Third, the rational-basis approach undermines the values of cooperative federalism embedded in the CAA. Congress intended the Act to address air pollution while also maintaining the traditional division of authority between federal and state regulators. When Congress delegated authority to EPA to enact clean air rules, it also emphasized that “air pollution prevention . . . is the primary responsibility of States and local governments.” 42 U.S.C. § 7401(a)(3). This respect for state sovereignty is reflected in other parts of the statute, too. Congress assigned the critical ability to develop implementation plans for existing sources to the States—plans “which, after EPA approval, are published as regulations in the Federal Register.” *People of State of Cal. ex rel. State Air Res. Bd. v. Dep’t of Navy*, 431 F. Supp. 1271, 1274 (N.D. Cal. 1977), *aff’d*, 624 F.2d 885 (9th Cir. 1980). The CAA repeatedly calls out the supremacy of States and local communities in controlling pollution. See, e.g., 42 U.S.C. § 7416 (“[N]othing in this chapter shall preclude or deny the right of any State or political subdivision thereof to adopt or enforce (1) any standard or limitation respecting emissions of air pollutants or (2) any requirement respecting control or abatement of air pollution.”); *id.* § 7431 (“[N]othing in this chapter constitutes an infringement on the existing authority of counties and cities to plan or control land use, and nothing in this chapter provides or transfers authority over such land use.”).

Grafting rational basis onto the statute defies these principles of federalism. Of course, the CAA imbues EPA with significant authority to set national performance standards, but it is not boundless. The demand to make and justify an endangerment finding for pollutants from a source category gives EPA meaningful guidelines—and preserves the States’ roles while keeping the agency within its own. In short, a rational-basis standard gives EPA a blank check that Congress never wrote.

Conversely, commenters (0458-Maryland Department of the Environment (MDE), 0807-BP America, Inc. (BP), 0926-Austin Energy (Austin) *et al.*) support EPA’s November 2021 Proposal to regulate methane in the oil and natural gas industry as a measure to meet its obligation under section 111(b) of the CAA.

Commenter (0926-Austin *et al.*) states that Congress’ disapproval of the 2020 Policy Rule under the CRA has reaffirmed EPA’s historical interpretation of CAA section 111 (which they support). The commenter adds that they agree that Congress has made clear that EPA does not have the authority to pursue actions that deregulate methane emissions from the source category or deregulate the transmission and storage segment. According to the commenter, in this case, it would be arbitrary and capricious for EPA to decline to regulate GHG emissions from the Crude Oil and Natural Gas source category given it is the largest source of anthropogenic methane emissions in the U.S., methane emissions are the second most significant GHG emissions in the U.S., and the impacts of greenhouse gas emissions from both new and existing sources. Thus, the commenter concludes that the EPA has a rational basis to regulate GHG emissions from the oil and natural gas source category.

Commenter (0807-BP) notes that the 2016 NSPS Rule established an appropriate basis for promulgating regulations to control methane emissions, in addition to volatile organic compound (VOC) emissions, from all of these segments. The commenter contends that, because EPA

previously determined the crude oil and natural gas source category causes or contributes significantly to air pollution, EPA is authorized to promulgate a NSPS for methane without requiring a new, pollutant-specific “endangerment” finding. Furthermore, the commenter states that the large amount of methane emissions from oil and gas sources and impact of methane emissions on climate change, plus the availability of cost-effective control options, provides EPA with a rational basis to regulate those emissions under CAA section 111.

Commenter (0844-Environmental Defense Fund *et al.* (EDF *et al.*)) asserts that there is no question that EPA is authorized to regulate GHG emissions under section 111 of the CAA. In *Massachusetts v. EPA*,<sup>5</sup> the Supreme Court held that the statute’s general definition of “air pollutant” appearing at 42 U.S.C § 7602(g) includes greenhouse gases, a finding it reaffirmed in *Utility Air Regulatory Group v. EPA* (UARG).<sup>6</sup> The commenter provides that the Court further ruled unanimously in *American Electric Power Company v. Connecticut* that section 111 of the CAA in particular “speaks directly” to GHG regulation, and that in enacting this provision, “Congress designated . . . EPA . . . as best suited to serve as primary regulator of greenhouse gas emissions.”<sup>7</sup>

In fact, in *Massachusetts*, the commenter (0844-EDF *et al.*) notes that the Court made clear that EPA must regulate sources’ GHG emissions—new motor vehicles, in that case—unless “it determines that greenhouse gases do not contribute to climate change or if it provides some reasonable explanation as to why it cannot or will not exercise its discretion to determine whether they do.”<sup>8</sup> Following the Court’s instructions, in 2009, the commenter states that the EPA concluded that emissions of six well-mixed GHG emissions from mobile sources—including methane—do, indeed, “cause or contribute to, air pollution which may reasonably be anticipated to endanger public health or welfare.”<sup>9</sup> The commenter contends that the Endangerment Finding was made after an extraordinarily thorough scientific review and careful consideration of public comments. It was reaffirmed after full consideration of petitions for reconsideration and was upheld in its entirety by the D.C. Circuit in the face of a vigorous industry challenge.<sup>10</sup> The commenter added that the Court found that the Endangerment Finding was procedurally sound, consistent with Supreme Court case law, and amply supported by the administrative record, observing that “[t]he body of scientific evidence marshaled by EPA in support of the Endangerment Finding is substantial.”<sup>11</sup> And while it granted certiorari on one component of the D.C. Circuit’s holding in *CRR I*, the Supreme Court declined to review any aspect of the lower court’s holding on the Endangerment Finding.<sup>12</sup>

<sup>6</sup> 573 U.S. 302, 316 (2014).

<sup>7</sup> 564 U.S. 410, 424, 428 (2011).

<sup>8</sup> *Massachusetts*, 549 U.S. at 533.

<sup>9</sup> Endangerment and Cause or Contribute Findings for Greenhouse Gases Under Section 202(a) of the Clean Air Act, 74 Fed. Reg. 66,496 (Dec. 15, 2009) (“the Endangerment Finding”).

<sup>10</sup> *Coal. for Responsible Regulation, Inc. v. EPA* (*CRR I*), 684 F.3d 102, 116-27 (D.C. Cir. 2012), *aff’d in part, rev’d in part sub nom. Util. Air Regulatory Grp. v. EPA*, 134 S. Ct. 2427 (2014) and amended sub nom. *Coal. for Responsible Regulation, Inc. v. EPA* (*CRR II*), 606 F. App’x 6 (D.C. Cir. 2015).

<sup>11</sup> *Id.* at 120.

<sup>12</sup> See *Util. Air Regulatory Grp. v. EPA*, 134 S. Ct. 418, 2013 U.S. LEXIS 7380 (Oct. 15, 2013).

The commenter (0844-EDF *et al.*) contends that the 2009 Finding fully satisfies any requirement for an endangerment determination under CAA section 111, not only for the NSPS OOOOa rule and the NSPS OOOOb and EG OOOOc proposals, but for any other listed source category for which EPA may set GHG standards going forward. The commenter states that the EPA made very clear in 2009 that the endangerment component of its finding rule applied generally to the sum total of all anthropogenic GHG “air pollution,” irrespective of the sources from which the individual “air pollutants” were emitted.<sup>13</sup> This distinction originates in the CAA itself. Section 202(a)(1) provides that

[t]he Administrator shall by regulation prescribe (and from time to time revise) in accordance with the provisions of this section, standards applicable to the emission of any *air pollutant* from any class or classes of new motor vehicles or new motor vehicle engines, which in [her] judgment cause, or contribute to, *air pollution* which may reasonably be anticipated to endanger public health or welfare.<sup>14</sup>

Thus, the commenter (0844-EDF *et al.*) concludes that the statutory provision applied in the 2009 Endangerment Finding required EPA to consider whether “air pollution” may reasonably be anticipated to endanger, not the “pollutant” itself.

Furthermore, the commenter (0844-EDF *et al.*) adds that the scientific research conducted in the 12 years since the Endangerment Finding was issued has not merely reaffirmed the Finding’s fundamental conclusion but has made clear that climate change is much more dire—and that deep and immediate cuts to anthropogenic GHG emissions are much more urgently needed—than was understood even a decade ago. The commenter provides that the research conducted after EPA issued the NSPS OOOOa rule in 2016 demonstrates that methane emissions, in particular from the oil and gas sector, are not only enormous, but are markedly higher than previous estimates (including EPA’s) suggested. According to the commenter, while EPA need only articulate a rational basis for issuing methane regulations from this source category under CAA section 111, it would be justified in issuing such regulations even if it *were* required (which it is not) to formally determine that an individual pollutant emitted by a source category significantly contributes to dangerous pollution.<sup>15</sup> The commenter concludes that there can thus be no legitimate dispute that, consistent with *Massachusetts*, *UARG*, and *American Electric Power*, EPA not only *may* regulate oil and gas methane emissions under section 111, but *must* do so.

Furthermore, the commenter (0844-EDF *et al.*) asserts that the EPA correctly determined in the NSPS OOOOa rulemaking that the quantity of methane emitted by the oil and gas source category easily qualifies as “significant” under any reasonable definition. The commenter reports that, although the agency asserted in NSPS OOOOa that it need not make such a pollutant-specific significant finding in order to issue CAA section 111 standards, and the House Report

---

<sup>13</sup>See, e.g., 74 Fed. Reg. 66,496, 66,506 (Dec. 15, 2009) (“[T]he Administrator is to consider the cumulative impact of sources of a pollutant in assessing the risks from air pollution, and is not to look only at the risks attributable to a single source or class of sources.”).

<sup>14</sup> 42 U.S.C. § 7521(a)(1) (emphasis added).

<sup>15</sup> For more discussion of this question, see Part III.D.2 of the commenter’s letter (NSPS OOOOa’s “Significance” Finding for Oil and Gas Methane Emissions Is Neither Flawed Nor Required To Justify the Rule’s Methane Standards.”).

accompanying the 2021 CRA resolution affirmed that position, the record leaves no doubt that oil and gas sector methane emissions are “significant” in any event. Thus, the commenter states that under any feasible interpretation of CAA section 111, EPA may thus issue GHG regulations for the oil and gas sector in the form of methane standards.

Commenter (0914-Class of ’85 Regulatory Response Group (Class of ’85)) states that, for decades, EPA has interpreted section 111(b)(1) of the CAA as requiring an SCF only for the initial listing of the source category and then authorizing the Agency to regulate any pollutant emitted by that source category—provided that EPA has a rational basis for doing so. However, the commenter notes that the EPA reinterpreted CAA section 111(b)(1) in its 2020 Policy Rule, finding that the statute “requires the Administrator to make—or, at least, authorizes the Administrator to require—a pollutant-specific SCF” each time EPA proposes to regulate a pollutant emitted by a listed source category.<sup>16</sup> In its comments on the proposed 2020 Policy Rule, the commenter states that they urged EPA to refrain from adopting the new interpretation of CAA section 111(b)(1) because it would interfere with the regulatory certainty and consistency on which electric generators and other regulated industries depend when making business decisions. The commenter reaffirms those comments here in support of EPA’s November 2021 Proposal to reaffirm the longstanding interpretation of CAA section 111(b)(1). The commenter provides that CAA section 111(b)(1) does not compel EPA to make a pollutant-specific SCF.

Commenter (0914-Class of ’85) notes that, while the statute sets out criteria for listing source categories (*i.e.*, whether a source category “causes, or contributes significantly to, air pollution which may reasonably be anticipated to endanger public health or welfare”), it does not expressly establish criteria for the regulation of specific pollutants. CAA section 111(b)(1)(B) instructs EPA to promulgate standards of performance and revise them as the Administrator deems appropriate, signaling that the decision of which pollutants should be regulated under CAA section 111(b) is left to the discretion of the Agency. In exercising this discretion, the commenter states that the EPA must demonstrate that it has a rational basis for setting standards for listed source categories (*i.e.*, that the Agency is not acting arbitrarily or capriciously in promulgating such regulations).<sup>17</sup> The commenter states that, as the Agency explained in its response to comments on the 2016 NSPS for the oil and natural gas sector—which preceded the 2020 Policy Rule—“the EPA’s use of the phrase ‘rational basis’ . . . explains how the agency’s actions are supported by the record and is a reasonable exercise of the EPA’s broad authority

---

<sup>16</sup> See, e.g., 80 Fed. Reg. 64,510 (Oct. 23, 2015) (NSPS for fossil fuel-fired EGUs); 77 Fed. Reg. 9304 (Feb. 16, 2012) (NSPS for fossil-fuel-fired electric utility, industrial-commercial-institutional, and small industrial-commercial institutional steam generating units); 75 Fed. Reg. 54,970 (Sept. 9, 2010) (NSPS for Portland cement plants); 74 Fed. Reg. 51,950 (Oct. 8, 2009) (NSPS for coal preparation and processing plants); 73 Fed. Reg. 35,838 (June 24, 2008) (NSPS for petroleum refineries); 70 Fed. Reg. 28,606 (May 18, 2005) (NSPS for coal-fired electric utility steam generating units); 54 Fed. Reg. 34,008 (Aug. 17, 1989) (NSPS for fluid catalytic cracking unit regenerators); 52 Fed. Reg. 47,826 (Dec. 16, 1987) (NSPS for industrial-commercial-institutional steam generating units); 50 Fed. Reg. 36,956 (Sept. 10, 1985) (NSPS for Portland cement plants); 41 Fed. Reg. 3826 (Jan. 26, 1976) (NSPS for primary aluminum reduction plants).

<sup>17</sup> The commenter states that, when the CAA does not provide specific criteria for EPA’s actions under a particular provision, as under section 111(b)(1)(B), the Agency is held to the “arbitrary or capricious” standard under Section 307(d)(9) of the Clean Air Act, 42 U.S.C. § 7607(d)(9) (providing that a court may reverse an EPA action that is “arbitrary, capricious, an abuse of discretion, or otherwise not in accordance with law”), and section 706(2) of the Administrative Procedure Act, 5 U.S.C. § 706(2) (same).

under section 111.” The commenter adds that, except for the nine-and-a-half months during which EPA required a pollutant-specific SCF, throughout the life of the NSPS program EPA has reasonably interpreted CAA section 111(b)(1) to require an SCF as a prerequisite only for the initial listing of a source category. The commenter concludes that the EPA should not revert to the short-lived requirement to establish a pollutant-specific SCF.

Response I-3-3: The EPA disagrees with the commenters who assert that CAA section 111 requires, or authorizes the EPA to require, a pollutant-specific SCF as a predicate to regulation of air pollutants under CAA section 111. We agree with the commenters who say that CAA section 111 imposes a rational basis test as the predicate. We explain our interpretation of CAA section 111 and respond to the main adverse comments in the preamble.

In addition, we note the following:

Interpreting these provisions of CAA section 111 to entail a rational basis standard for standards of performance is consistent with the purpose of CAA section 111, which Congress explained when it adopted the section in the 1970 CAA Amendments.

According to the report of the Senate Committee on Public Works: “The provisions for new source performance standards are designed to ensure that new stationary sources are designed, built, equipped, operated, and maintained so as to reduce emissions to minimum. ... The overriding purpose of this section would be to prevent new air pollution problems....” S. Rep. 91-1196 at 15-16 (Sept. 17, 1970). The report explained that to achieve this purpose, the standards would (i) apply to “[m]ajor new facilities such as electric generating plants ... petroleum refineries ... and various other commercial and industrial operations;” and (ii) be based on “application of the latest available emission control technology or through other means of preventing or controlling air pollution.” *Id.*

This purpose is reflected in the requirements of CAA section 111 that the EPA identify categories of stationary sources that contribute significantly to dangerous air pollution, and then, on a specified timetable, promulgate standards, based on the “best system of emission reduction ... adequately demonstrated,” for emissions of the air pollutants.

This purpose can be achieved by applying a standard of rationality to the EPA’s promulgation of standards for the air pollutants emitted from the source category, consistent with CAA section 307(d)(9)(A). There is no need for an additional requirement that the EPA also determine that an individual air pollutant contributes significantly to dangerous air pollution, as a predicate to promulgating a standard for that air pollutant. In fact, such a requirement would undermine the purposes of CAA section 111. To see this, assume that the EPA lists a source category under CAA section 111 because it emits numerous air pollutants that, taken together, contribute significantly to dangerous air pollution. Consistent with the “overriding purpose of [CAA section 111] ... to prevent new air pollution problems,” S. Rep. 91-1196 at 15-16 (Sept. 17, 1970), the EPA must address each air pollutant that could lead to a “new air pollution problem[]” by promulgating standards of performance that “reduce emissions to a minimum.” These standards should apply to all of the air pollutants that the source category emits, except for any emitted in minor amounts or any that do not have adverse impacts on health or welfare. Interposing an

additional limitation, that the EPA may promulgate standards only for particular air pollutants that it determines contribute significantly to dangerous air pollution, may prevent the EPA from addressing some of the source category's emissions, in this example, and thus may undermine the purpose of CAA section 111.

The commenters asserting that CAA section 111 requires, or authorized the EPA to require, a pollutant-specific SCF, do not offer an interpretation of CAA section 111 that supports their assertions. They point to the reference in CAA section 111(a)(1) to “air pollutants” as part of the definition of “standard of performance” and the requirement in CAA section 111(b)(3) that the EPA issue information on pollution control techniques for “air pollutants,” but those provisions are consistent with the CAA section 111 requirements that the EPA promulgate standards for emissions of air pollutants and offer no support for the commenters' assertions that a pollutant-specific SCF is necessary as a predicate for such standards. More specifically, CAA section 111(b)(1)(B) requires the EPA, once it has listed a source category, to promulgate “standards of performance,” and CAA section 111(a)(1) defines a “standard of performance” as a “standard for emissions of air pollutants” that must be based on systems of emission reduction for those pollutants. The requirement in CAA section 111(b)(3) for the EPA to issue information on pollution control techniques is consistent with those requirements because such information could inform those standards. But the reference in CAA section 111(a)(1) and (b)(3) to “air pollutants” does not somehow point towards a requirement for a significant contribution finding determination for a particular air pollutant as a predicate for promulgating the standards. Most importantly, as discussed in the preamble, CAA section 111(b)(1)(A), by its terms, requires the EPA to determine the effect of a “category of sources” on “air pollution,” and contains no such requirement for “air pollutants.”

The 2020 Policy rule offered an interpretation of CAA section 111 to support its view that the provision requires, or at least authorizes the EPA to require, a pollutant-specific significant contribution finding as a predicate to promulgating an NSPS for a new pollutant, but commenters did not endorse this interpretation and the EPA considers it strained and rejects it.<sup>18</sup> The 2020 rule stated that the source categories that the EPA is required to list under CAA section 111(b)(1)(A) typically emit multiple air pollutants, and that although CAA section 111(b)(1)(B), read together with CAA section 111(a)(1), requires that the EPA promulgate standards for “emissions of air pollutants,” it does not specify which air pollutants. The 2020 rule drew a comparison to the provisions for the new source review prevention of significant deterioration (PSD) program under CAA section 165(a)(1) and 169(1), as interpreted by the Supreme Court in *Utility Air Regulatory Group v. EPA*, 573 U.S. 302 (2014) (*UARG*).<sup>19</sup> Those provisions apply the PSD requirements to stationary sources that emit specified amounts of “any air pollutant.” The Court held that the phrase “any air pollutant” in CAA section 169(1) does not include GHG, even though they are air pollutants. The Court explained that the statutory context made clear

---

<sup>18</sup> Note that the 2019 proposal for the 2020 Policy rule offered a somewhat different legal interpretation than in the 2020 rule. Because the 2020 rule did not finalize that proposed interpretation, we do not think it merits further discussion here. 84 Fed. Reg. 50260.

<sup>19</sup> In *UARG*, the Court interpreted the similar provisions of the Title V permit program, CAA sections 501(2)(B) and 302(j), the same way. 573 U.S. at 323-24.

that the PSD program could not reasonably be applied to sources on account of their GHG emissions.

This is because the program’s applicability limits, which are based on specified tons of pollutants emitted, and its substantive and procedural requirements, which the Court found created “heavy ... burdens,” were intended by Congress to apply to “a relative handful of large sources.” However, according to the Court, because GHG are emitted in much higher quantities than other air pollutants, applying the PSD requirements to sources on account of their GHG emissions would create anomalous results by expanding the program to large numbers of small sources that were not equipped to carry those burdens. 573 U.S. at 322-23.

The 2020 Policy Rule sought to apply the reasoning of *UARG* to argue that CAA section 111(b)(1)(B)’s requirement that the EPA promulgate standards for “emissions of air pollutants” should not apply to all air pollutants, but only those for which the EPA made a pollutant-specific significant contribution finding. The 2020 Policy Rule reasoned that this limitation is necessary to avoid “the risk that the EPA may regulate air pollutants emitted in small quantities or otherwise having little adverse effect.” 85 FR 57037.

The 2020 Policy Rule’s on *UARG* is misplaced. In *UARG*, the Court’s holding that the term “any air pollutant” in CAA section 169(1) does not include GHG, and therefore that the PSD program does not cover sources on account of their GHG emissions, was informed by other of the CAA provisions for the PSD program, including applicability limits and substantive and procedural requirements, that the Court found would create anomalous results if the PSD program applied to those sources. CAA section 111 includes no comparable provisions. That is, there are no other provisions in CAA section 111 that would create anomalous results unless the EPA is limited to promulgating standards for “emissions of air pollutants” only for air pollutants that the EPA makes a significant contribution finding for. On the contrary, the 2020 Policy Rule’s concern that limits are necessary to ensure that the EPA does not attempt to promulgate standards for air pollutants emitted in minor amounts or that are innocuous can be addressed through the rational basis test. In fact, as discussed above, other relevant provisions support the rational basis test; in particular, CAA section 307(d)(9)(A) applies the arbitrary or capricious standard for judicial review, which is consistent with the rational basis test.

Other CAA provisions that do explicitly require a pollutant-specific finding – for the most part, a cause-or-contribute finding – highlight that CAA section 111 does not do so. When Congress adopted CAA section 111(b)(1)(A)-(B) and 111(a)(1) in the 1970 CAA Amendments, and revised them in the 1977 CAA Amendments, Congress also adopted or revised several other provisions that by their terms required the EPA to make a pollutant-specific finding, although Congress used somewhat different phrasing in some of those provisions. These provisions include CAA sections 108, 112, 115, 202, 211, and 231.<sup>20</sup> The inclusion of clear requirements

---

<sup>20</sup> See CAA section 108(a)(1)(A)-(B), 42 U.S.C. 1857c-3(a)(1)(A)-(B) (1970) (Administrator is required to publish a list “which includes each air pollutant which in his judgment has an adverse effect on public health or welfare” and “the presence of which in the ambient air results from numerous or diverse mobile or stationary sources”); CAA section 112 (added in 1970 CAA Amendments and revised in 1977 CAA Amendments; “hazardous air pollutant” is defined as, in relevant part, “an air pollutant . . . which in the judgment of the Administrator causes, or contributes

for pollutant-specific findings in other CAA provisions confirms that the absence of such a requirement in section 111 indicates Congress' intention not to include such a requirement there. *See United States v. Gonzales*, 520 U.S. 1, 5 (1997) ("Where Congress includes particular language in one section of a statute but omits it in another section of the same Act, it is generally presumed that Congress acts intentionally and purposely in the disparate inclusion or exclusion.") (internal quotations omitted).<sup>21</sup>

---

to, air pollution which may reasonably be anticipated to result in an increase in mortality or an increase in serious irreversible, or incapacitating reversible, illness;" this definition was substantially revised in the 1990 CAA Amendments); CAA section 115(a), 42 U.S.C. 1857d(a) (1970) (Administrator is authorized to take action to address "pollution of the air in any State or States which endangers the health or welfare of any persons"); CAA section 202(a)(1), 42 U.S.C. 1857f-1(a)(1) (1970) (Administrator is required to regulate "the emission of any air pollutant from any class or classes of new motor vehicles or new motor vehicle engines, which in his judgment causes or contributes to, or is likely to cause or to contribute to, air pollution which endangers the public health or welfare"); CAA section 202(a)(1), as revised by the 1977 CAA Amendments, 42 U.S.C. 7521(a)(1) (1977), ("The Administrator shall by regulation prescribe . . . standards applicable to the emission of any air pollutant from any class or classes of new motor vehicles or new motor vehicle engines, which in his judgment cause, or contribute to, air pollution which may reasonably be anticipated to endanger public health or welfare"); CAA section 211(c)(1), 42 U.S.C. 1857f-6(c)(1) (1970) (Administrator is authorized to regulate "any fuel or fuel additive for use in a motor vehicle or motor vehicle engine if any emission products of such fuel or fuel additive will endanger the public health or welfare"); CAA section 211(c)(1)(A) (as revised in 1977 CAA Amendments; the Administrator is authorized to regulate any fuel or fuel additive "if in the judgment of the Administrator any emission product of such fuel or fuel additive causes, or contributes, to air pollution which may reasonably be anticipated to endanger the public health or welfare"); CAA section 231(a)(2), 42 U.S.C. 1857f-9(a)(2) (1970) (Administrator is required to regulate "emissions of any air pollutant from any class or classes of aircraft or aircraft engines which in his judgment cause or contribute to or are likely to cause or contribute to air pollution which endangers the public health or welfare"). In addition, in the 1990 CAA Amendments, Congress adopted several additional provisions that require findings that bear some similarity to the findings discussed above. These include (1) CAA section 129(e) (Administrator or state is required to require the owner or operator of any unit to comply with emission limitations or implement any other measures, if the Administrator or the state determines that emissions in the absence of such limitations or measures may reasonably be anticipated to endanger public health or the environment"); (2) CAA section 183(f)(1)(A) (Administrator is required to promulgate standards for VOC and any other air pollutant from loading and unloading of tank vessels "which the Administrator finds causes, or contributes to, air pollution that may be reasonably anticipated to endanger public health or welfare"); (3) CAA section 213(a)(1)–(3) (Administrator is required to (i) conduct a study to determine if emissions from nonroad engines and nonroad vehicles "cause, or significantly contribute to, air pollution which may reasonably be anticipated to endanger public health or welfare;" (ii) determine whether emissions of certain pollutants from new and existing nonroad engines and vehicles "are significant contributors to ozone or carbon monoxide concentrations in more than 1 area which has failed to attain the national ambient air quality standards (NAAQS) for ozone or carbon monoxide;" and if so, (iii) promulgate regulations containing standards applicable to such emissions from those classes or categories of new nonroad engines and new nonroad vehicles "which in the Administrator's judgment cause, or contribute to, such air pollution") (CAA section 213(a)(4), which concerns different pollutants than under CAA section 213(a)(2)–(3), has requirements similar to the requirements of those provisions); (4) CAA section 615 (Administrator is required to regulate "[i]f, in the Administrator's judgment, any substance, practice, process, or activity may reasonably be anticipated to affect the stratosphere, especially ozone in the stratosphere, and such effect may reasonably be anticipated to endanger public health or welfare").

<sup>21</sup> The 2019 proposal for the 2020 Policy rule stated that although Congress included a significant contribution finding for the source category, and not for individual pollutants, it may have conflated the two, and the proposal pointed to these other provisions to support that view. 84 FR 50264. The 2020 rule did not pursue this argument, and the EPA rejects it. CAA section 111(b)(1)(A)–(B) and 111(a)(1) are clear by their terms in requiring a source category finding and not a pollutant-specific one, in contrast to several other CAA provisions; the proper interpretation is that Congress meant what it said in CAA section 111, and that is highlighted by the contrast with

A closer look at the provisions adopted or revised in the 1970 and 1977 CAA Amendments shows differences between them and CAA section 111, which further highlight that CAA section 111 does not include a requirement for a pollutant-specific finding. As discussed above, in CAA section 111, Congress directed the EPA to identify the source category for regulation, including making a significant contribution and endangerment finding for it, and then promulgate standards for the air pollutants emitted from it on the basis of technological or other systems of emission reduction. In contrast, in several of the other 1970 or 1977 provisions, Congress identified the source category for the EPA to regulate, and then directed the EPA to regulate air pollutants from it that cause or contribute to dangerous air pollution. *See* CAA section 202(a) (classes of new motor vehicles or new motor vehicle engines); section 231(a)(2) (classes of aircraft or aircraft engines).<sup>22</sup> In several other provisions, Congress directed the EPA to regulate air pollutants that the EPA determines cause or contribute to dangerous air pollution, without reference to source categories. *See* CAA sections 108(a)(1)(A)-(B) (pollutants that adversely affect public health or welfare and result from numerous or diverse sources), 112 (hazardous air pollutants), 115(a) (pollutants that originate in the U.S. and cross into, and endanger public health or welfare in, a foreign country).<sup>23</sup> In other provisions, Congress directed the EPA to regulate products if emissions from them cause or contribute to dangerous air pollution. *See* CAA 211(c)(1) (fuels).

In all of these provisions, Congress directed the EPA to identify air pollutants that contribute to an air pollution problem, as a predicate for regulation. In contrast, under CAA section 111, Congress directed the EPA to identify source categories that significantly contribute to dangerous air pollution, as a predicate for regulation, and then to control air pollutants from the listed source categories through application of control technology or other system of emission reduction, without any requirement to further identify particular air pollutants.

In the preamble, the EPA explains that the rational basis test is consistent with the EPA's lengthy regulatory history under CAA section. On the other hand, in several previous rules, the EPA rejected comments that it was required to make a pollutant-specific significant contribution finding. In the 2009 rule for the coal preparation and processing plant source category, the EPA rejected comments that it was required to make pollutant-specific significant contribution findings for the pollutants it was regulating for the first time from that source category as a predicate for regulation. 74 FR 51957. In the 2015 rule for electric utility generating plants, the EPA rejected similar comments for GHG, and explained that the sole predicate was that the EPA have a rational basis for regulating GHG. 80 Fed. Reg. 64510, 64530 (Oct. 23, 2015).<sup>24</sup>

---

what Congress said in the other CAA provisions, not that Congress meant something it did not say in CAA section 111. Furthermore, CAA section 213(a)(4) explicitly requires the EPA to make two findings -- (1) emissions from new nonroad engines or vehicles contribute significantly to an air pollution problem, and (2) emissions from classes or categories of new nonroad engines or vehicles cause or contribute to the air pollution problem -- which indicates that Congress knows how to provide such a two-finding requirement and chose not to do so in CAA section 111.

<sup>22</sup> Provisions added in the 1990 CAA Amendments follow a similar pattern. *See* CAA section 129(e) (solid waste incineration units), 183(f)(1)(A) (loading and unloading of tank vessels), 213(a) (nonroad engines).

<sup>23</sup> A provision added in the 1990 CAA Amendments follows a similar pattern. *See* CAA section 615 (regulation of any substance, practice, process, or activity that affects the stratosphere and endangers public health or welfare).

<sup>24</sup> In the technical support documents for several of the first section 111(d) emission guidelines for existing sources

In addition, interpreting CAA section 111 to require a pollutant-specific SCF is inconsistent with CAA section 111(f). Congress added CAA section 111(f) in the 1977 CAA Amendments, and revised it in the 1990 CAA Amendments, for the purpose of requiring the EPA to promulgate CAA section 111 standards on a faster pace. The 1977 CAA Amendments adopted CAA section 111(f)(1), which required the EPA to list under CAA section 111(b)(1)(A), within one year, major stationary source categories not already listed, and to promulgate standards of performance for them within three to five years. 42 U.S.C. § 7411(f)(1) (1977). The 1977 CAA Amendments also adopted CAA Section 111(f)(2), which included criteria for the EPA to determine priorities for promulgating those standards. 42 U.S.C. § 7411(f)(2) (1977). By 1990, the EPA still had not made what Congress considered to be satisfactory progress in promulgating standards of performance for the listed source categories. Accordingly, the 1990 CAA Amendments revised CAA section 111(f)(1) to update the schedule for the EPA to promulgate the remaining standards.

As noted above, by the time of the 1977 and 1990 CAA Amendments, the EPA had promulgated numerous rulemakings under CAA section 111, and had never interpreted the provision to require a pollutant-specific significant contribution finding. The Courts have held that Congress is considered to be aware of an administrative interpretation under certain circumstances. *See Lorillard v. Pons*, 434 U.S. 575, 580 (1978) (“Congress is presumed to be aware of an administrative or judicial interpretation of a statute and to adopt that interpretation when it re-enacts a statute without change”).

In the 1977 and 1990 CAA Amendments, Congress left in place the essential requirements of CAA section 111(b)(1)(A) that the EPA list source categories that contribute significantly to dangerous air pollution, of CAA section 111(b)(1)(B) that the EPA conduct rulemaking to promulgate standards of performance, and of CAA section 111(a)(1) defining standards of

---

that the EPA promulgated, the EPA included statements that CAA section 111 required the EPA to determine that the pollutant subject to regulation contributed significantly to dangerous air pollution. 84 FR 50266 (citing the emission guidelines that accompanied the technical support documents); *see, e.g.*, EPA, “Final Document: Control of Fluoride Emissions from Existing Phosphate Fertilizer Plants,” EPA-450/2-77-005, at 2-1 (Mar. 1977)) (“Before [section 111(b)] standards may be established, the Administrator must find that the pollutant in question ‘may contribute significantly to air pollution which causes or contributes to the endangerment of public health or welfare’ [see section 111(b)(1)(A)]. Because this finding is, in effect, a prerequisite to the same pollutant being identified as a designated pollutant under section 111(d), all designated pollutants will have been found to have potential adverse effects on public health, public welfare, or both.”) Contrary to assertions in the 2019 proposal, 84 FR 50266, these statements do not indicate that the EPA previously interpreted CAA section 111 to require a pollutant-specific significant contribution finding as a predicate for promulgated standards of performance for any air pollutant. The statements are in the background section of technical support documents for emission guidelines under CAA section 111(d), and are intended to make clear that the EPA has established the necessary predicate for regulating emissions from existing sources. Any such pollutant-specific significant contribution finding itself is not relevant for emission guidelines. If EPA had taken the position that such pollutant-specific significant contribution findings were necessary, it would have made them in either the rulemakings that listed the source categories or the rulemakings that promulgated standards of performance for new sources. In fact, the EPA did not make any such findings in those actions. For example, in the rulemaking that promulgated standards of performance for fluoride emissions from phosphate fertilizer plants, the EPA correctly noted that it had listed the source category by determining that “these categories of sources contribute significantly to air pollution which causes or contributes to the endangerment of public health or welfare....” 39 FR 37603 (Oc. 22, 1974). Those statements in the emission guidelines technical support documents should be viewed as erroneous, overly simplified summaries of the CAA section 111 rulemaking process intended only to provide background information.

performance as standards for emissions of air pollutants determined in a specified manner.<sup>25</sup> In addition, Congress added and then amended requirements in CAA section 111(f) to accelerate that rulemaking to promulgate standards of performance. Under these circumstances, Congress should be presumed (i) to have been aware that the EPA interpreted CAA section 111(b)(1)(B) to apply a standard of rationality in determining which pollutants to regulate, and not to require, or authorize the EPA to require, a pollutant-specific significant contribution finding; and (ii) to have adopted that interpretation.

Moreover, nothing in CAA section 111(f) or its legislative history indicates that Congress intended the EPA to promulgate a pollutant-specific significant contribution finding. CAA section 111(f)(2)(A)-(B) requires the EPA to consider “the quantity of air pollutant emissions” from each source category and “the extent to which each such pollutant may reasonably be anticipated to endanger public health or welfare” in prioritizing rulemaking. Those provisions, by their terms bear some similarity to the terms that Congress has used in other CAA provisions that require pollutant-specific cause-or-contribute findings, noted above, and thus highlight that Congress knew how to require pollutant-specific contribution findings, and did not do so in CAA section 111.

On the contrary, interpreting CAA section 111 to require a pollutant-specific SCF would unavoidably slow down EPA promulgation of standards of performance and could lead to fewer standards, which is inconsistent with Congress’ intention in adopting CAA section 111(f) to require the EPA to adopt standard for quickly. *See* House Committee on Interstate and Foreign Commerce, *Clean Air Act Amendments of 1977*, at 194–195, 95th Cong. (May 12, 1977) (H. Rept. 95–294).<sup>26</sup>

---

<sup>25</sup> Congress amended some of the provisions of CAA section 111(b)(1)(A) in the 1977 CAA Amendments, and amended some of the provisions of CAA section 111(a)(1) in both the 1977 and 1990 CAA Amendments, *compare* 42 U.S.C. 7411(a)(1) (1970) *with* 42 U.S.C. 7411(a)(1) (1977) *and* 42 U.S.C. 7411(a)(1) (1990), but those amendments did not change the essential requirements noted above.

<sup>26</sup> In the 1977 CAA Amendments, Congress amended the terms of six CAA provisions, CAA sections 111(b)(1)(A), 108, 112, 202, 211, and 231, that each established cause-or-contribute, significant contribution, endangerment or similar findings, to make their provisions more uniform and more preventive or precautionary in nature. The House-Senate Conference Report described the amendments to these six provisions, as a group, with the following statement: “In all future rulemaking in these areas, the Administrator could regulate any air pollutant from those sources, the emissions of which ‘in his judgment cause or contribute to air pollution which may reasonably be anticipated to endanger public health or welfare.’” H.R. Rep. No. 95–564, at 183–84 (1977). Contrary to statements in the 2019 proposed rule, 84 FR 50264–65, this statement in the Conference Report cannot be read to support interpreting CAA section 111 as requiring a pollutant-specific significant contribution finding. This statement was a paraphrase of all the six provisions, taken together. Most of them – all but CAA section 111 – do require by their terms, a pollutant-specific cause-or-contribute or similar finding, and so the statement reflects that approach. But none of the six provisions uses the precise wording set off by quotation marks in the statement: “in his judgment cause or contribute to air pollution which may reasonably be anticipated to endanger public health or welfare.” That the statement is designed to be a general paraphrase is clear by the fact that it is not accurate with respect to CAA section 108. That provision does not authorize the EPA to regulate emissions directly, rather, it authorizes the EPA to list pollutants, which sets in motion a process that results in the states regulating air pollutants. In any event, even if the statement could be read to interpret CAA section 111 to require a pollutant-specific finding – and it should not be read in that way, but if it is – that finding would be only a cause-or-contribute finding, and not a significant contribution finding. Similarly, the Report of the House Committee on Interstate and Foreign Commerce also

The 2020 Policy Rule asserted that rational basis test is vague, so that under it, the EPA could promulgate standards of performance for sources that emit minimal quantities of air pollutants, or air pollutants with no adverse effects on public health or welfare. The EPA disagrees with this view. As noted above, what the EPA has termed the rational basis test is fully consistent with the arbitrary or capricious standard of review under CAA section 307(d)(9)(A), and that standard of review is well established. In the seminal case of *Motor Vehicle Mfrs. Ass'n of U.S., Inc. v. State Farm Mut. Auto. Ins. Co.*, 463 U.S. 29, 42-43 (1983), the Supreme Court explained that under this standard of review, “the agency must examine the relevant data and articulate a satisfactory explanation for its action including a rational connection between the facts found and the choice made,” and the court will uphold the rule if it is “rational, based on consideration of the relevant factors and within the scope of the authority delegated to the agency by the statute.” In making rational basis determinations under CAA section 111, the EPA has considered the amount of the air pollutant emitted by the source category, both in absolute terms and by drawing comparisons, as well as the availability of control technologies. See *National Lime Assoc. v. EPA*, 627 F.2d 416, 426 & n.27 (D.C. Cir. 1980) (discussing the EPA’s reasons for not promulgating standards for NO<sub>x</sub>, SO<sub>2</sub> and CO from lime plants); 80 FR 64510, 64530 (October 23, 2015) (rational basis determination for GHGs from fossil fuel-fired electricity generating power plants); 73 FR 35838, 35859–60 (June 24, 2008) (providing reasons why the EPA was not promulgating GHG standards for petroleum refineries). Courts routinely review rules under the “arbitrary and capricious” standard, as noted in the House Report, at 11.

Beyond general assertions that the rational basis test is vague, the 2020 rule did not identify any instances in the more than 50 years of EPA rulemaking under CAA section 111 in which its use led, or could have led, to the poor outcomes they postulate – *i.e.*, EPA regulation of air pollutants that have no adverse impacts due to their small quantities or innocuous effects. On the contrary, as noted in the preamble, in a 1980 rulemaking to promulgate standards of performance for lime manufacturing sources, the EPA declined to regulate NO<sub>x</sub> emissions on grounds that the source category emitted only small amounts of that pollutant. This regulatory history is consistent with the incentives that drive EPA action, which are to devote its limited resources to complying with its statutory obligations and promulgating regulation that improves public health and welfare. In any event, if the EPA did promulgate standards of performance for air pollutants emitted in minimal amounts or innocuous air pollutants, the Courts could invalidate them as arbitrary or capricious under CAA section 307(d)(9)(A).

In any event, it is clear that the 2020 rule’s concerns have no validity in this rulemaking--the methane emissions from the Crude Oil Natural Gas source category cannot be considered few in quantity or innocuous in their effects. As discussed in the preamble, this source category is by far

---

included a statement summarizing the amendments to the various provisions, which was that the amendments “provide the same standard of proof for regulation of any air pollutant.” H.R. Rep. No. 94-1175, at 33 (1976). The 2019 proposal cited this statement as well to support its interpretation that CAA section 111 requires or authorizes the EPA to require a pollutant-specific significant contribution finding. 84 Fed. Reg. at 50,265. Like the above-discussed statement from the Conference Report, the one from the House Committee was a general summary designed to apply to all the amended provisions, most of which concerned pollutant-specific findings, and cannot be read as an indication of congressional intent that CAA section 111 require a pollutant-specific finding. In any event, and again as with the Conference Report statement, if the House Committee statement is interpreted to support a pollutant-specific finding – and it should not be so interpreted, but if it is – that finding would be only a cause-or-contribute finding, and not a significant contribution finding.

the largest emitter of methane emissions in the U.S., and methane emissions are responsible for a large portion of the climate impacts of GHG.

The EPA also agrees with the comments by industry stakeholders (0914-Class of '85 Regulatory Response Group (Class of '85)) that revising the EPA's long-standing interpretation of CAA section 111 to require an SCF only for the initial listing of the source category and then to authorize the Agency to regulate any pollutant emitted by that source category—provided that EPA has a rational basis for doing so – with a requirement, or authorization for the EPA to require a pollutant-specific SCF each time the EPA proposes to regulate a pollutant emitted by a listed source category, would interfere with the regulatory certainty and consistency on which electric generators and other regulated industries depend when making business decisions.

In addition, we also note that, as explained in the preamble, the 2016 NSPS OOOOa made, in the alternative, a pollutant-specific SCF for GHG from the Crude Oil and Natural Gas source category, as well as an endangerment finding for GHG air pollution, which addresses the concerns of adverse commenters on this rule.

### ***3.2.2 Methane-specific Endangerment Finding, including Significant Contribution Finding***

Comment: Commenter (0793-PBPA) states that as a predicate to promulgating new source performance standards, the EPA must determine that methane emissions from the oil and gas sector contribute significantly to endangerment. That is, determining a pollutant-specific endangerment finding for the source category requires EPA to determine that methane emissions from the oil and gas sector have a significant effect on global surface temperatures. After all, the commenter notes that Congress unambiguously applied the SCF requirement not only to the source category (here, the oil and gas sector), but also to the “air pollution” (here, methane) that actually causes the endangerment.

In contrast, Commenter (0844-EDF *et al.*) states that, although the Endangerment Finding technically addresses a pollutant it defines as “the mix of six long-lived and directly-emitted greenhouse gases”—carbon dioxide, methane, nitrous oxide, hydrofluorocarbons, perfluorocarbons, and sulfur hexafluorides<sup>27</sup>—EPA is well within its authority to regulate methane in particular as the designated pollutant. In *American Electric Power*, the commenter provides that the Supreme Court left no doubt that EPA may, under CAA section 111, regulate specific GHGs (carbon dioxide, in that case) among the six well-mixed pollutants that were the subject of the 2009 Endangerment Finding.<sup>28</sup>

Response I-3-4: The EPA disagrees with the comment stating that a methane-specific significant contribution is required. If CAA section 111 requires the EPA to make a pollutant-specific endangerment finding, it is appropriate for that finding to be for GHG, not methane, for the reasons explained in the preamble.

---

<sup>27</sup> See 74 Fed. Reg. at 66,497.

<sup>28</sup> See generally *Am. Elec. Power Co.*, 564 U.S. at 401.

### ***3.2.3 Whether to Base Endangerment Findings on A Predetermined Threshold***

Comment: Commenter (0793-PBPA) states that, another question is related to meeting articulated criteria for judging significance of contribution. The commenter suggests that the EPA articulate criteria for distinguishing between a “contribution” and a “significant contribution” to dangerous pollution and, before regulating under CAA section 111, must conclude that the pollutant and source category being assessed meet the test for the latter. The commenter contends that the EPA has sensibly pronounced that without articulated criteria, “it is impossible to evaluate whether [a SCF] is well reasoned.” In the absence of articulated criteria, the commenter states that any prior or present-day determination of significant contribution or “rational basis” EPA may claim is arbitrary.

Commenter (0914-Class of '85) notes that the EPA proposes to reaffirm that when the Agency makes an endangerment finding for a source category under section 111(b)(1)(A) of the CAA, “that finding should be made in consideration of the particular facts and circumstances, not a predetermined threshold.” The commenter supports the Agency’s November 2021 Proposal to maintain the long-accepted interpretation and practice for how the Administrator makes an endangerment finding. Specifically, the commenter supports EPA’s November 2021 Proposal to reaffirm that endangerment findings be made “in consideration of the particular facts and circumstances” and to reject the establishment of a predetermined threshold for what constitutes a “significant contribution” to air pollution under section 111(b)(1)(A). The commenter asserts that the concept of a predetermined SCF threshold was a departure from the longstanding approach EPA has taken in determining significant contribution and endangerment on a case-by-case basis.<sup>29</sup> As the Agency explains in the November 2021 Proposal, “[d]uring the 50 years that it has made listing decisions, the EPA has always relied on the individual facts and circumstances.” The commenter states that industrial sectors and local air agencies have come to rely on EPA’s established interpretation of CAA section 111(b)(1)(A). The commenter concludes that the EPA should continue to evaluate significant contribution and endangerment on a case-by-case basis, which will allow the Agency to consider the wide range of information available about source categories and their emissions. The commenter states that this will ensure that regulated entities are treated fairly based on all of the particular facts and circumstances that may be relevant to EPA’s listing of new source categories under CAA section 111.

Response I-3-5: The EPA disagrees with the comment stating that a significant contribution must be made on the basis of an established standard or criteria. Any significant contribution finding required under CAA section 111 may be made on the basis of the facts and circumstances, for the reasons explained in the preamble.

### ***3.2.4 Other Aspects of Endangerment Finding***

Comment: Commenter (0793-PBPA) states that, although Congress disapproved the 2020 Policy Rule under the Congressional Review Act (CRA), EPA is still obliged to follow the express

---

<sup>29</sup> See *Coal. for Responsible Regulation*, 684 F.3d at 122–23 (the inquiry “necessarily entails a case-by-case, sliding-scale approach to endangerment because ‘[d]anger . . . is not set by a fixed probability of harm, but rather is composed of reciprocal elements of risk and harm, or probability and severity.’ EPA need not establish a minimum threshold of risk or harm before determining whether an air pollutant endangers.”) (internal citation omitted).

terms of the statute. In articulating its methane-specific endangerment finding and the significant contribution criteria, the commenter suggests that the EPA:

- (1) compare methane emissions from the U.S. oil and gas industry[11] to worldwide methane emissions in order to adjudge whether the former significantly contributes to global climate change; and
- (2) demonstrate how the proposal will not lead to an increase in global methane emissions if declines in domestic oil and gas production due to these standards is counteracted by increased production in countries with relatively less stringent emission control requirements.

Response I-3-6: In the 2016 NSPS OOOOa, the EPA made an alternative significant contribution finding for GHG from the Crude Oil and Natural Gas source category, in part on the basis of comparing the methane emissions from that source category to world-wide methane emissions. *See* 81 FR 35839-40 and Tables 6-7 (“As illustrated by the domestic and global GHG comparison data summarized above, the collective GHG emissions from the oil and natural gas source category are significant, whether the comparison is domestic (where this sector is the largest source of methane emissions, accounting for 32 percent of United States methane and 3.4 percent of total United States emissions of all GHG), global (where this sector, while accounting for 0.5 percent of all global GHG emissions, emits more than the total national emissions of over 150 countries, and combined emissions of over 50 countries), or when both the domestic and global GHG emissions comparisons are viewed in combination.”).

The EPA disagrees with commenters’ assertion that the EPA should demonstrate how the proposal will not lead to an increase in global methane emissions if declines in domestic oil and gas production due to these standards is counteracted by increased production in countries with relatively less stringent emission control requirements. That assertion is irrelevant to the question of whether emissions from the U.S. oil and gas source category contribute significantly to dangerous air pollution. *See Massachusetts v. EPA*, 549 U.S. 497, 533-34 (2007) (assertions that regulating GHG might impair President’s ability to negotiate with foreign nations to reduce emissions are irrelevant to the question of whether GHG from U.S. motor vehicles contribute to climate change). In any event, that assertion is also speculative with respect to the impact of standards of performance on U.S. production, the impact of U.S. production changes on foreign production, and the emission controls on foreign production.

### **3.3 2020 Policy Rule**

Comment: Commenter (0793-PBPA) states that, although Congress disapproved the 2020 Policy Rule under the CRA, EPA is still obliged to follow the express terms of the statute and, at the very least, should better explain its disregard of threshold questions as part of this process. The commenter provides that the EPA’s proposal “broaden[s] the types of sources” subject to regulation and requires, “for the first time[,] regulation of hundreds of thousands of existing sources across the country.” And EPA projects that the rule as proposed would result in an annual domestic oil production decline of 12.2 million barrels, which will inevitably cause another country—undoubtedly with relatively less stringent emission control requirements—to

seize the opportunity to increase production (and methane emissions) accordingly.<sup>30</sup> The commenter contends that, while EPA has a role to play with respect to regulating methane emissions, the commenter contends that, under these circumstances it is incumbent on EPA to comply with unambiguous statutory predicates and its prior, well-reasoned interpretations of them.

Response I-3-7: In explaining the rationale for this action in the preamble and in responding to comments in the preamble and this response-to-comments document, the EPA has explained why it rejects the statutory interpretations in the 2020 Policy Rule.

### **3.4. Oil and Gas Methane CRA Joint Resolution**

Comment: Commenter (0808-American Petroleum Institute (API)) argues that the CRA rescission of the 2020 Policy Rule does not extend to the legal rationale and policy positions used to justify the 2020 Policy Rule and does not endorse the legal and policy interpretations in the preceding 2012 and 2016 rules.

Commenter (0808-American Petroleum Institute (API)) adds that “EPA’s suggested approach would indiscriminately and inappropriately sweep away legal and policy positions stated in the record of the Policy Rule that are necessary for proper implementation of CAA § 111. For example, EPA explains in the preamble to the final Policy Rule that VOC ‘are not the type of air pollutant that, if subjected to a standard of performance for new sources, would trigger the application of CAA section 111(d).’ 85 Fed. Reg. at 57040. Reversal of this uncontroversial interpretation would cause CAA § 111(d) to have a far broader scope than is reasonable or warranted under the plain text of the statute. Such an outcome is not required or supported by the CRA action.”

Commenter (0808-API) states that the CRA applies to “rules.” The commenter notes that when EPA promulgates a final rule, the “rule” is the regulatory text (which imposes legal obligations or creates legal rights) and not the explanation and justification provided in the preamble to the rule. Thus, according to the commenter, a rescission under CRA section 801(b)(1) and the prohibition under CRA section 801(b)(2) on issuing a rule in substantially the same form apply only to the relevant regulatory text and do not apply to EPA’s explanation in the administrative record that accompanies the regulatory text. Contrary to EPA’s suggestion, the commenter asserts that the legislative history of this particular CRA action cannot and does not change the plain meaning of the CRA statute. See *INS v. Cardoza-Fonseca*, 480 U.S. 421, 452-3 (1987) (J. Scalia, concurring in the judgment) (“Judges interpret laws rather than reconstruct legislators’ intentions. Where the language of those laws is clear, we are not free to replace it with an unenacted legislative intent.”).

Similarly, commenter (0819-WV *et al.*) contends that the CRA resolution has no legal effect beyond undoing the 2020 Policy Rule. The commenter states that it does not authorize the 2016 Rule’s deviations from CAA section 111’s limits on EPA’s authority. The commenter adds that the resolutions of disapproval passed under the CRA cannot expand an agency’s statutory

---

<sup>30</sup> As just one example, if the proposed rule is finalized PBPA projects a 9% increase in global methane emissions were Turkmenistan to incrementally replace our lost domestic oil production.

powers. The CRA provides only that a rule disapproved by joint resolution “shall not take effect or continue,” and that “a new rule that is substantially the same as such a rule may not be issued, unless the reissued or new rule is specifically authorized” by subsequent congressional act. 5 U.S.C. §801(b). In other words, the commenter states that the limits that empowering statutes place on agencies do not change after Congress enacts a CRA resolution. The commenter notes that resolutions can only further restrict agency power—they preclude regulatory actions “substantially similar” to actions taken under the disapproved rule. *Id.* According to the commenter, the CRA’s silence about the statute underlying the disapproved rule does not implicitly repeal existing statutory constraints. Indeed, “repeals by implication are not favored” and will not be “infer[red] . . . unless such a construction is absolutely necessary . . . in order that the words of the later statute shall have any meaning at all.” *Nat’l Ass’n of Home Builders v. Defs. of Wildlife*, 551 U.S. 644, 662 (2007) (quotations and alterations omitted). The commenter states that no such inference is needed here. The CRA’s meaning is plain without resorting to reading it to repeal separate limits on agency authority.

As to the 2021 CRA resolution specifically, the commenter (0819-WV *et al.*) notes that the November 2021 Proposal claims that “[i]n disapproving the 2020 Policy Rule under the CRA, Congress explicitly rejected the 2020 Policy Rule interpretations and embraced EPA’s rationales for the 2016 . . . [R]ule.” 86 Fed. Reg. at 63,147-48. The commenter states that the EPA relies for support on legislative history and statements of individual members of Congress who supported the Resolution, see *id.* at 63,149, rather than grounding its conclusion in the CRA Resolution’s purportedly “express” text.

According to the commenter (0819-WV *et al.*) a CRA resolution, like any act of Congress, operates through its enacted language. “[O]nly the words on the page constitute the law adopted by Congress and approved by the President.” *ACA Connects - Am.’s Comme’ns Assn. v. Frey*, 471 F. Supp. 3d 318, 325 (D. Me. 2020) (quoting *Bostock v. Clayton Cnty.*, 140 S. Ct. 1731, 1738 (2020)). CRA resolutions are not interpreted by reference to “[c]ongressional debates and public statements,” but by “the ordinary public meaning of its terms at the time of its enactment.” *Id.* Faced with a CRA resolution like this one, the commenter states that the court in *ACA Connects* concluded that the resolution “nullifi[ed]” the prior rule, but “create[d] no overarching federal policy, and enact[ed] no scheme” directing future regulation. *Id.*

Commenter (0819-WV *et al.*) contends that because the 2021 CRA resolution contains no language that so much as hints at CAA section 111’s limits—much less amends them—it cannot support the November 2021 Proposal’s attempts to bypass them. The commenter adds that while it is true, EPA may not choose a new rule substantially similar to the rule Congress disapproved, but the rule it does choose must satisfy CAA section 111.

Commenter (0790-WV AG *et al.*) states that, by nullifying the 2020 Policy Rule, the CRA resolution effectively re-imposed the 2016 Rule. But it did not enact that rule’s reading of the CAA into law. Many of the November 2021 Proposal’s statutory failings are outgrowths of those that underscored the 2016 Rule. The November 2021 Proposal does not shy away from this overlap but embraces it—and casts the CRA resolution as legal support for its reading. This interpretation puts more weight on the resolution than it can bear. According to the commenter,

the CRA resolution has no legal effect beyond undoing the 2020 Policy Rule. It does not authorize the 2016 Rule's deviations from CAA section 111's limits on EPA's authority.

Response I-3-8: The EPA responds to these comments in the preamble. In addition, commenters cite *ACA Connects - Am. 's Commc 'ns Assn. v. Frey*, 471 F. Supp. 3d 318 (D. Me. 2020) (*ACA Connects*) to support their argument that the legislative history of the joint resolution is not relevant, but that case is distinguishable and does not provide support. In that case, plaintiffs, which were trade associations whose members included internet service providers (ISPs) in the state of Maine, sought declaratory and injunctive relief against a Maine state statute that protected the privacy of online customer information (the Maine statute). As relevant here, the plaintiffs/ISPs argued that the Maine statute was preempted on grounds that it was in conflict with a CRA joint resolution that Congress had adopted.<sup>31</sup> That joint resolution had disapproved a 2016 Federal Communications Commission (FCC) internet service provider (ISP) privacy order (the FCC Order), which, in turn, had repealed earlier FCC action.<sup>32</sup>

The plaintiffs/ISPs argued that the legislative history of that joint resolution included statements from Congressmen that they sought to prevent the imposition of rules that affected only ISPs, and further sought to facilitate the creation of a single, uniform set of privacy rules. The plaintiffs/ISPs asserted that those statements amounted to a federal scheme that the Maine statute conflicted with, and therefore that the Maine statute was preempted.

The District Court rejected this argument. It noted that the one sentence joint resolution stated that “Congress disapproves the [FCC Order]... [which] shall have no force or effect.” *Id.* at 325 (quoting the joint resolution). The court went on to state that “only the words on the page constitute the law adopted by Congress and approved by the President,” and that those “words on the page” were simply the text of the joint resolution, not the congressional debates. *Id.* (quoting *Bostock v. Clayton Cty., Georgia*, 140 S.Ct. 1731, 1738 (2020) (emphasis omitted)). Accordingly, the District Court concluded that Congress's disapproval of the FCC Order “creates no overarching federal policy, and enacts no scheme with which the Maine ... [s]tatute can conflict.” *Id.*

Contrary to the commenters, the EPA considers the legislative history of the CRA joint resolution disapproving the 2020 Policy rule to be important because it clarifies Congress's purposes for disapproving the rule and its intentions for how the EPA should respond. We do not read *ACA Connects* to call our view into question. As discussed above, when Congress enacted the CRA, it stipulated that the legislative language of a joint resolution would be a one-sentence disapproval of the agency action, and its sponsors recognized the importance of using the legislative history to express congressional intention for how the agency could or should proceed with further rulemaking.

Congress followed this approach in disapproving the 2020 Policy Rule. The language of the joint resolution was a one-sentence disapproval, in accord with the requirements of the CRA, and both the Senate sponsors and the House Committee explained the flaws in the 2020 rule and their

---

<sup>31</sup> S.J. Res. 34, Pub. L. No. 115-22, 131 Stat 88 (Apr. 3, 2017).

<sup>32</sup> “Protecting the Privacy of Customers of Broadband and Other Telecommunications Services,” 81 FR 87274 (December 2, 2016).

intention for further EPA action. In *ACA Connects*, the plaintiffs/ISPs argued that the legislative history of the joint resolution disapproving the FCC Order constituted a federal scheme of a single, uniform set of privacy rules, with respect to which the Maine statute was in actual conflict. But that argument was clearly incorrect. The legislative history could not, and did not purport to, create federal requirements in-and-of-itself. On the contrary, some of the statements in the legislative history -- consistent with the purposes of the CRA as expressed by its sponsors, noted above -- recommended further action that the FCC could take. *See* 163 Cong. Rec. H2497 (2017) (statement of Rep. Capuano) (stating that the FCC should take case-by-case action instead of comprehensive regulation); *id.* at S1928 (Sen. Thune) (same). Therefore, the legislative history of the joint resolution disapproving the FCC Order was irrelevant for the purposes asserted by plaintiffs/ISPs, as the District Court held, but that has no bearing on the importance of the legislative history of the joint resolution disapproving the 2020 Policy Rule for the present rulemaking.

Comment: Conversely, commenter (0844-EDF *et al.*) states that, as a result of the CRA resolution, the 2020 Policy Rule was “made of no force or effect” and must “be treated as though [it] had never taken effect.” The commenter adds that, moreover, EPA is now prohibited from issuing “a new rule that is substantially the same as” the 2020 Policy Rule unless Congress passes new legislation permitting it. The commenter contends that any attempt by EPA either to remove the transmission and storage sector from the oil and gas source category as regulated under CAA section 111 or to rescind methane standards for this source category would directly violate a congressional dictate and would be “arbitrary, capricious, an abuse of discretion, or otherwise not in accordance with law.”<sup>33</sup> The commenter adds that, even if Congress had not enacted (and the President had not signed) the CRA resolution, EPA would still have been compelled to reverse the 2020 Policy Rule and reinstate the NSPS OOOOa rule’s standards and source category definition. According to the commenter, this is because the 2020 Policy Rule was based on patently incorrect legal foundations and was plainly arbitrary and capricious, as the commenters stated they explained in detail in their comments submitted to EPA on the 2020 Policy Rule.<sup>34</sup> The commenter provides a brief summary of reasons in their comment letter [see pages 49 through 57 of the commenter’s letter], including:

- Removing transmission and storage equipment from the source category definition was arbitrary and capricious. The commenter asserts that the EPA properly determined in the NSPS OOOOa rulemaking that the 1979 source category listing was broad enough to encompass transmission and storage equipment in addition to production and processing equipment. plant. Even in the absence of the CRA resolution, the commenter states that the EPA would have been obligated to rectify the Policy Rule’s flaws and revert to the source category definition that appeared in the NSPS OOOOa rule. Congress clearly agreed, explaining in the House Report accompanying the CRA resolution that in NSPS OOOOa, EPA had “correctly” judged that the interrelated nature of the upstream and

---

<sup>33</sup> 42 U.S.C. § 7607(9)(a).

<sup>34</sup> Env. Def. Fund, et al., Comments on Oil and Natural Gas Sector: Emission Standards for New, Reconstructed, and Modified Sources Review, Dkt. No. EPA-HQ-OAR-2017-0757-2134, at 18-43 (discussing exclusion of downstream sources from source category), 43-90 (discussing withdrawal of methane standards) (Nov. 25, 2019).

downstream segments and the general similarity of equipment across the segments justified a single source category.<sup>35</sup>

- Withdrawing methane standards for the oil and gas sector was arbitrary and capricious.
  - NSPS OOOOa's methane standards are not redundant. When confronted with the fact that, by its own logic, the oil and gas VOC standards were no less redundant than methane standards and could be rescinded without affecting EPA's obligation to issue existing source guidelines for the sector, EPA demurred that VOC standards should remain on the books because they were in place first and that "the decision of which NSPS to retain should not turn on the impact on existing sources," once again ignoring the massive environmental consequences of its decision. As described in the House report accompanying the CRA resolution, "the [Policy] Rule's misinterpretation of section 111 was glaring and enormously consequential" for ignoring the impacts on existing source emissions,<sup>36</sup> and was thus arbitrary and capricious.
  - NSPS OOOOa's "significance" finding for oil and gas methane emissions is neither flawed nor required to justify the rule's methane standards. The Policy Rule's interpretation of section 111 as additional pollutant-specific SCFs in order for EPA to regulate new pollutants from a previously-listed source category thus contravenes the basic language of the statute. The House Report accompanying the CRA resolution asserts that [t]he plain language of section 111 does not support this interpretation. The EPA's statutory interpretation prior to the [Policy Rule] is correct and would be reinstated by this resolution of disapproval. This action reaffirms that once a source category is listed, regulation of any pollutant is reasonable provided that the EPA has a rational basis for concluding that regulation is appropriate to address dangerous air pollution."<sup>37</sup>
  - No reliance interests on the deregulatory effects arose as a result of the Methane Policy Rule. Apart from the brief interlude between the time that EPA finalized the Policy Rule and the new administration took office and issued Executive Order 13,390, oil and gas operators have either had to comply with NSPS OOOOa in its entirety or have been on clear notice not only that NSPS OOOOa would likely be reinstated, but that stronger emissions standards—including requirements for existing sources—would likely be established by EPA. Any reliance interests that oil and gas operators may have had on the deregulatory effects of the Policy Rule are thus misplaced and should play no role in EPA's regulatory design of the NSPS OOOOb and c rules.

Similarly, commenter (0458-MDE) further supports the joint resolution under the CRA that disapproved the relaxations in the 2020 Policy Rule. The commenter states that they understand that much of the requirements from the 2016 Standard have been reinstated and are back into effect upon the enactment of the joint resolution. Any new, modified, or reconstructed facility

---

<sup>35</sup> H. Rep. No. 117-64 at 24.

<sup>36</sup> H. Rep. No. 117-64 at 26.

<sup>37</sup> H. Rep. No. 117-64 at 28.

that would have been subject to the 2016 Standard, but for the 2020 Policy Rule, will immediately become subject to the 2016 Standard.

Commenter (1294-Ohio Clinicians for Climate Action (OCCA)) notes that it is appropriate for the EPA to heed the joint resolution of Congress adopted on June 30, 2021, under the CRA, and to disapprove the EPA's final rule titled, "Oil and Natural Gas Sector: Emission Standards for New, Reconstructed, and Modified Sources Review," Sept. 14, 2020 ("2020 Policy Rule"). The commenter states that this is responsive to the President's January 20, 2021, Executive Order titled "Protecting Public Health and the Environment and Restoring Science to Tackle the Climate Crisis."

Commenter (0610-Occidental (Oxy)) supports regulation of methane emissions from new and existing oil and gas operations and notes that their President and CEO Vicki Hollub testified in April 2021 before the Senate Energy and Natural Resources Committee in support of invoking the CRA to recognize EPA's authority to regulate methane. The commenter provides that they work with external stakeholders at the state and federal level to advocate for environmentally sound methane regulations that achieve methane emission reductions, incentivize early action, and support flexibility and innovation.

Commenter (0926-Austin *et al.*) provides that their companies agree with EPA's interpretation of Congressional action under the CRA that it must regulate methane emissions across the oil and gas sector, including emissions from the transmission and storage segment, and support EPA's development of EG for states to implement existing source regulations. The commenter states that their companies see methane emission reductions as a critical component to addressing climate change and meeting the emission reduction goals established by the Biden-Harris Administration.

Commenter (1423-Congressman Donald S. Beyer (Beyer) *et al.*, 1434-Senator Martin Heinrich (Heinrich) *et al.*) states that the EPA's November 2021 Proposal strengthens and modernizes rules adopted in 2016 for new and modified oil and gas facilities and builds upon the bipartisan CRA resolution (H.J.Res.34, S.J.Res.14), enacted by Congress and signed by the President, with support from the oil and gas industry and electric utilities, to restore federal methane protections and regulation of oil and gas operations.

Response I-3-9: These comments are generally consistent with the positions the EPA has adopted in the preamble. No further response is needed.

### **3.5 Regulatory Certainty**

Comment: Commenter (0921-U.S. Chamber of Commerce) asserts that, in the development of regulations for new and existing sources, it is critical that EPA create regulatory standards that are well grounded in the authority of the statute to minimize the possibility that either a court would set aside aspects of the regulations or a future presidential administration would be inclined to revisit them. The commenter suggests that the EPA can achieve this kind of durability only by staying within the clear statutory authority conferred under the CAA and by avoiding

overreach – abstaining from attempting novel or untested legal approaches and from overreading the mandate of the CRA resolution that disapproved the prior 2020 Policy Rule.<sup>38</sup>

Commenter (0820-Pioneer Natural Resources USA, Inc. (Pioneer)) supports EPA’s November 2021 Proposal to rescind the 2020 Policy Rule and states that a clear regulatory program would provide operators with certainty and predictability in their capital spending, strategic planning and operations. The commenter adds that sensible methane regulation that balances the benefits of domestic oil and gas production with environmental protection is necessary to elevate natural gas as a clean energy solution, thereby strategically positioning this valuable resource for growth and viability in the future. The commenter suggests that the optimum result would be reasonable regulations that will incentivize early action, drive performance improvements, facilitate proper enforcement, support operational flexibility, and encourage technological innovation, particularly in the rapidly evolving area of methane leak detection, now and in the future.

Response I-3-10: The EPA believes that the legal interpretations, policy positions, and determinations made in this action achieve the goals of certainty and predictability that the commenters recommend.

### **3.6 Outdated Text in the CFR**

Comment: Commenter (0727-Oklahoma Secretary of Energy and Environment (OSEE) and Oklahoma Department of Environmental Quality (ODEQ)) states that the EPA outlines the legislative history of the CRA joint resolution to disapprove the 2020 Policy Rule on page 63149 of the November 2021 Proposal. The CRA joint resolution was signed into law by President Biden on June 30, 2021. The CRA joint resolution disapproved the 2020 Policy Rule, and therefore the 2020 Policy Rule is treated as though it had never taken effect. 86 Fed. Reg. 63149 (citing 5 U.S.C. 801(f)). However, the commenter notes that the rule text of the 2020 Policy Rule remains in the CFR, even though its provisions are no longer in effect due to the CRA joint resolution. According to the commenter, this disparity between the rules currently in effect after passage of the CRA joint resolution and the outdated rule language that remains in the text of the CFR creates confusion for both the regulated community and regulatory agencies, and especially members of the public who may be unaware of the CRA joint resolution. The commenter asserts that regulatory clarity is needed immediately to reduce confusion and potential for error in compliance with and enforcement of the correct rule text.

Response I-3-11: The EPA is finalizing amendments to the CFR necessary to reflect the CRA joint resolution of disapproval of the 2020 Policy Rule.

---

<sup>38</sup> See Joint Resolution, Pub. L. No. 117–23, 135 Stat. 295 (2021); see also H.R. Rep No. 117-64 (2021); and EPA’s “Legal Basis for Proposal Scope”, 86 Fed. Reg. at 63,147-53.

## Chapter 4. Overview of BSER, Control and Control Costs

### 4.1 Control of Methane and VOC Emissions in the Crude Oil and Natural Gas Source Category

#### 4.1.1 *Best System of Emission Reduction (BSER)*

##### 4.1.1.1 Periodic Revisions to BSER

Comment: Commenter (0746-Methane Action) requests that EPA provide a process for annually revising the list of “best systems of emission reduction” for each source to expedite the use of rapidly developing methods of removing methane from both near the source and further from sources. By way of example, the commenter provides a summary of descriptions of methods, based on recent articles coauthored by Methane Action Board Member Professor Rob Jackson of Stanford and consulting scientist Dr. Renaud de Richter, that they suggest warrant further research and development and cost effectiveness estimates for their implementation.

Response I-4-1: CAA section 111(b)(1)(B) requires the EPA to “at least every 8 years review and, if appropriate, revise” performance standards. As indicated by the “at least,” this provision does not prohibit the EPA from conducting such reviews more frequently than every 8 years. However, while the EPA recognizes that methods to reduce (or eliminate) methane emissions continue to emerge, the suggested annual reviews of BSER is impractical.

The EPA points out that there are aspects of the final rule that recognize and accommodate emerging technologies. For example, for those associated gas wells that are allowed to routinely flare emission due to a demonstration of technical infeasibility, owners and operators are required to re-evaluate the situation each year to determine if options have become available that would allow the gas to be used in a beneficial manner (i.e. not flared). Also, the rule includes provisions to allow the use of emerging technologies to identify fugitive methane leaks if owners and operators follow the prescribed approval processes.

##### 4.1.1.2 Use of Non-Combustion Devices and Innovative Technologies

Comment: Commenter (0601-Connecticut Department of Energy and Environmental Protection (CT DEEP)) suggests that EPA give priority to non-emitting controls or means for recovering emissions as an alternative to combustion controls. The commenter explains that while combustion control of natural gas, such as thermal oxidizers and flares, results in reduction of VOC and methane, they usually create emissions of nitrogen oxides and carbon dioxide, which are inconsistent with ozone attainment and climate change goals for many states, including Connecticut [their state].

Response I-4-2: In evaluating BSER for the various sources of emissions in the oil and natural gas industry, EPA included numerous types of non-combustion technologies, many of which totally eliminate methane emissions. The EPA must abide by the requirements in CAA section 111 to select BSER as systems that are adequately demonstrated, taking into account the costs

and any nonair quality health and environmental impact and energy requirements. For numerous emission sources covered by NSPS OOOOb and EG OOOOc, the BSER was determined to be systems that do not include combustion. Examples include programs to identify and repair fugitive leaks, zero-emitting process controllers and pumps, and routing associated gas to a sales line or using it for another beneficial purpose.

Comment: Commenter (0594-Huntsman Corporation) requests that EPA consider structuring the rule such that methane pyrolysis expressly qualifies for “useful purpose.” The commenter explains that doing so would achieve the agency’s goal of reducing flaring and beneficially using the gas while achieving additional benefits beyond reducing methane emissions. The commenter offered to work with EPA to craft a definition that facilitates the use of methane pyrolysis to generate an environmentally friendly material and significantly reduce methane emissions.

Response I-4-3: In the December 2022 Supplemental Proposal, methane pyrolysis was specifically included in the rule as one example of “another useful purpose” for which associated gas would be allowed to be used. While EPA still considers it to be an acceptable option, the final rule removed all specific examples. See section XI.2.g of the final rule preamble for more discussion of this topic.

Comment: Commenter (0594-Huntsman Corporation) requests that the EPA tailor the November 2021 Proposal to encourage the use of innovative technologies, such that EPA can ensure that participants not only meet the proposed standards for emission reduction but may have opportunities to generate advanced materials that leverages further greenhouse gas (GHG) emission reductions. By way of example, the commenter describes their Miralon® advanced carbon materials which are produced from methane gas using a form of methane pyrolysis to break down the carbon in methane into a carbon nanomaterial, while also creating a clean hydrogen fuel. The commenter states that to date, the process has achieved 80-90 percent single-pass efficiencies converting methane into carbon and can achieve far higher conversion (greater than 99 percent) with multiple passes. The commenter believes that their methane conversion technology is uniquely positioned to advance efforts to address the increasing rates of methane emissions and harmful resulting impacts, including CO<sub>2</sub> emissions from flaring. Regarding innovative technologies, the commenter explains that section 111(j) of the Clean Air Act (CAA) provides a direct route for use of advanced technologies by creating a pathway for persons to request an EPA waiver from the requirements of a standard of performance in order to “encourage the use of an innovative technological system or systems of continuous emission reduction” and believes their methane pyrolysis technology fits within four factors<sup>1</sup> the Administrator should consider when determining if the waiver is appropriate.

The commenter (0594-Huntsman Corporation) encourages EPA to provide an opportunity for entities to apply for such waivers. Further, the commenter explains that CAA 111(j) is not the only avenue which EPA can use to consider innovation, especially since the waiver process involves more lead-time given the requirements for a notice and comment period and occurs after the standard of performance is established. The commenter references the D.C. Circuit Court of Appeals conclusion that “[w]e do not believe that EPA is precluded from encouraging

---

<sup>1</sup> 42 USC § 7411(j)(1)(A)(i) through (iv); 40 USC § 7411(j)(1)(A); *Sierra Club v. Costle*, 657 F.2d 298 (D.C. Cir., 1981).

technological innovation through [new source performance standards] NSPS either because section 111(a) prohibits the agency from doing so or because section 111(j) is meant to be the exclusive statutory mechanism for promoting new methods of pollution control.” To the contrary, the commenter explains, Congress was concerned “that the NSPS should not stymie technological innovation.” The commenter provides examples of pathways which were used by EPA in the past (*e.g.*, a commercial demonstration permit in the context of coal and oil-fired electric utility steam generating units) and requests that the final rule open the door for more flexible standards for entities that seek permits for commercial demonstration of innovative technologies.

Commenter (0921-U.S. Chamber of Commerce) states that the November 2021 proposed emissions standards must allow for innovation and not limit compliance to certain technologies. Commenter (0831-American Exploration and Production Council (AXPC)) suggests that the regulation of methane should encourage innovation and flexibility, instead of command-and-control regulations that hinder the goal of reducing methane emissions; allow and incentivize the development and deployment of technologies to monitor and mitigate methane emissions for compliance purposes; appropriately quantify and assess the feasibility, costs and benefits of implementing new requirements for existing facilities; avoid creating duplicative and overlapping regulatory regimes at the federal and state levels; and properly interpret and follow the relevant provisions of the CAA.

Response I-4-4: NSPS OOOOb and EG OOOOc provide clear and enforceable requirements, while also balancing the consideration of innovation and flexibility. Many of the final standards and presumptive standards are structured in a manner that provides owners and operators numerous options for compliance. They also are structured in a manner that will allow for the use of emerging technologies and solutions that are developed in the future. For example, the process controller standards in NSPS OOOOb and EG OOOOc require “zero emissions.” Owners and operators can utilize a variety of types of currently available controllers to meet the specific needs of the site, ranging from electric controllers to controllers powered by compressed air.

## **4.2 Control Costs of Standards**

### ***4.2.1 Natural Gas Savings***

Comment: Commenters (0755-Texas Pipeline Association (TPA), 0817-GPA Midstream Association (GPA)) state that EPA’s assumptions that certain sectors will recover revenue based on natural gas saved through methane reductions is incorrect. Commenter (0755-TPA) states that in EPA’s consideration of the costs and benefits of the November 2021 Proposal, EPA takes the position that costs of increased emission controls on regulated parties will be offset by increased revenue due to reduced leakage and reduced venting - *i.e.*, less product will escape so more product can be sold, resulting in increased revenue. The commenter states that this calculus is inappropriate, however, where the company in question does not own the gas, because a company that does not own a product receives no increase in revenue when that product is sold. The commenter urges EPA to ensure that any such revenue increase projections are not attributed to operations where the company in question does not own the gas being handled or

transported. The commenter offers to work with EPA to help precisely identify the types of operations that should be excluded in EPA's projections of increased revenue. Similarly, commenter (0817-GPA) states that in several sections of the preamble, Regulatory Impacts Analysis (RIA), and Technical Support Document (TSD), EPA asserts that facilities in the gathering and boosting (G&B) and natural gas processing segments own the natural gas in their systems and that reducing gas leakage will offset emission control costs, but the commenter states that this assumption is incorrect. Instead, the commenter states that owners and operators in the G&B and processing segments are paid a transportation fee to move and prepare the natural gas for delivery into an interstate pipeline system. The commenter further explains that this transportation fee is assessed even in larger integrated companies that own the upstream production facilities and midstream G&B and processing facilities as they are typically set up as separate business units. The commenter urges EPA to correct its cost estimates to note that the regulated entities will receive no monetary benefit from any natural gas saved because of the November 2021 Proposal. Further, the commenter requests that EPA understand that the costs of new regulation may be passed through to upstream entities via increased transportation fees, depending upon contract terms and the parties' respective business interests. For these reasons, the commenter recommends that EPA reassess its cost-benefit analyses to omit cost savings from recovered gas for the G&B and processing segments.

Response I-4-5: The commenter contends that because some companies in the gathering and boosting segment do not own the gas that they are transporting, the revenues from natural gas recovery should not be included as an offset to compliance costs in this segment. EPA agrees that affected sources may not own recovered product, but disagrees regarding the treatment of product recovery for estimating national costs. From a social perspective, the increased financial returns from natural gas recovery accrues to entities somewhere along the natural gas supply chain and thus, should be accounted for in the national impacts analysis. From an economic perspective, in the long run, no single entity is going to bear the entire burden of the compliance costs or fully receive the financial gain of the additional revenues associated with natural gas recovery. The change in economic surplus resulting from natural gas recovery is going to be spread out amongst different agents via price mechanisms. Therefore, the most simple and transparent option for allocating these revenues would be to keep the compliance costs and associated revenues together in a given source category and not add assumptions regarding the allocation of these revenues across agents.

In addition, while the EPA's analyses calculated the volume of natural gas savings and their impacts on the annual costs, all the final BSERs were determined to be cost effective without consideration of those natural gas savings. In other words, BSER determinations were not impacted by assumptions regarding natural gas savings.

#### ***4.2.2 Cumulative Impact of All Oil and Natural Gas Sector Regulatory and Policy Actions***

Comment: Commenter (0821-Xcel Energy, Inc. (Xcel)) cautions the EPA that the cumulative impact of all regulatory and policy actions taken to reduce emissions from the oil and natural gas sector be considered and that actions taken should be complementary and avoid unnecessary increases in cost while reducing emissions. The commenter states that it would be contrary to the objective of significantly reducing the nation's GHG emissions if overregulation inadvertently advantaged coal over natural gas for electric generation.

Response I-4-6: The standards included in the final NSPS OOOOb and the presumptive standards in EG OOOOc were developed in accordance with the statutory requirements in Section 111 of the CAA. Consistent with Executive Order 12866, RIAs accompanying the November 2021 Proposed Rule, December 2022 Supplemental Rule, and the Final Rule all appropriately evaluate the regulatory impacts of the NSPS OOOOb and EG OOOOc regulatory actions.

Comments on the impacts of the other regulatory actions mentioned by the commenter are out of scope for this response to comments document. However, the EPA notes that we are developing emissions standards for GHG emissions from coal-fired electric utilities in a separate action under Section 111 of the CAA. (see 88 FR 33240, May 23, 2023).

#### ***4.2.3 Cost Effectiveness Threshold for Methane***

Comment: Commenters (0834-Air Advocacy Coalition (A2C), 0808-American Petroleum Institute (API)) request that EPA better explain the rationale and provide factual support for the November 2021 proposed \$1,800/ton cost effectiveness threshold for methane. Commenter (0834-A2C) states that EPA is required, in proposed and final CAA rules, to prepare a statement of basis and purpose that includes, among other things, the “factual data” on which the rule is based.<sup>2</sup> The commenter states that this is consistent with EPA’s more fundamental obligation in conducting rulemaking to “examine the relevant data and articulate a satisfactory explanation for its action including a rational connection between the facts found and the choice made.”<sup>3</sup>

Commenter (0808-API) states that the only justification that the EPA presents for using a methane cost effectiveness threshold of \$1,800/ton is that the Agency used a similar methane cost effectiveness threshold in the 2016 NSPS OOOOa rule; this commenter contends that a “because we did it before” justification is inadequate. Instead, the commenter argues, CAA section 111 requires that EPA develop a record to support its determination that the NSPS standards “represent[] the best balance of economic, environmental, and energy considerations.” Further, the commenter states that an agency action is arbitrary and capricious if it does not “examine the relevant data and articulate a satisfactory explanation for its action including a rational connection between the facts found and the choice made.” Instead, the commenter asserts, in the November 2021 Proposal EPA fails to meet these standards because it presents essentially no “relevant data” to support its proposed cost effectiveness threshold and, because of that, EPA cannot and does not explain how the “relevant data” inform the choice of \$1,800/ton. The commenter surmises, for example, that perhaps EPA believes that using values up to \$2,185/ton in the 2016 rule provides evidence that values in this range are acceptable in the November 2021 Proposal because the 2016 rule has been widely implemented across the affected industry. If this is what EPA believes, it should have said so, but they do not believe that EPA explained this. Moreover, the commenter states that EPA has made no effort in the current rule to show why \$2,185/ton is an appropriate touchstone, beyond simply asserting it to be true. The commenter believes that failure to present “relevant data” and to explain how those data inform the November 2021 Proposal fundamentally undermines the proposed value of \$1,800/ton. Lastly, the commenter explains that EPA’s factual determinations must be

---

<sup>2</sup> CAA § 307(d)(3)(A).

<sup>3</sup> *Motor Vehicle Mfrs. Ass’n v. State Farm*, 463 U.S. 29, 43 (1983).

“supported by substantial evidence when considered on the record as a whole,” but contends that the \$1,800/ton threshold is supported by no evidence at all, much less substantial evidence.<sup>4</sup>

Response I-4-7: Section VIII.B of the Final Rule presents a detailed discussion of how EPA considered control costs in this action. It includes a description of the information that the EPA relied upon in formulating its cost effectiveness analyses, an explanation of the methodology of, and rationale behind, the analyses, and a discussion of why the final BSER for each emission source is reasonable through the lens of a cost effectiveness analysis.

EPA disagrees with the contention by Commenter (0808-API) that the record for this rulemaking does not include factual support, relevant data, and rationale. The EPA provided technical support documents for the November 2021 Proposed Rule and the December 2022 Supplemental Proposal, and they were further updated for the Final Rule. In each instance, the EPA has provided not only the technical support documents, but also Excel workbooks detailing the underlying data and analyses. In the three Federal Register preambles, EPA has also explained its analyses of control options and the selected BSER in great detail.

The EPA also notes that cost effectiveness, and the reasonableness of any particular cost effectiveness value, is only one piece of EPA’s consideration of BSER. Specifically, as explained in detail in Section VIII.B of the Final Rule, the EPA conducted additional cost analyses that each separately reinforce the reasonableness of the final standards.

#### ***4.2.4 Existing State Programs as a Basis for National Standards***

Comment: Commenters (0935-Colorado Oil and Gas Association (COGA), 0797-North Dakota Department of Environmental Quality (NDDEQ) and North Dakota Industrial Commission (NDIC)) have concerns with using existing state programs as the basis for national standards. Commenter (0935-COGA) states that EPA must provide evidence supporting the anticipated standards, specifically when citing state regulations as reasonable for national standards. The commenter states that CAA section 111 has its own criteria which the Administrator must evaluate before establishing federal NSPS or requiring states to submit plans establishing standards of performance for existing sources.<sup>5</sup> The commenter explains that a state regulation may not be constrained in the same manner as CAA section 111, and the state may be willing to impose costs that are not reasonable elsewhere. Therefore, the commenter argues, statements from EPA that assume that if a state agency found a particular regulation to be appropriate for its own state, the costs must be reasonable for nationwide application and the degree of emission limitation under consideration must be achievable through application of the BSER, are unwarranted. The commenter states that Colorado is an example of this, where the state’s extremely stringent oil and gas regulations were promulgated in response to unique local conditions and state statutes; the commenter argues that the EPA should analyze the anticipated

---

<sup>4</sup> *Sierra Club v. Costle*, 657 F.2d 298, 330 (D.C. Cir. 1981); *Motor Vehicle Mfrs. Assn. v. State Farm*, 463 U.S. 29, 43 (1983); *New Jersey v. EPA*, 517 F. 3d 574, 583; *Coalition for Responsible Regulation v. EPA*, 684 F. 3d 102, 122 (D.C. Cir. 2012).

<sup>5</sup> 42 U.S.C. §§ 7411(b)(1)(B) and (d)(1).

standards' costs and benefits through a national lens and determine whether the national costs are reasonable.

Commenter (0797-NDDEQ/NDIC) contends that the conclusion that California (CA) and Colorado (CO) are good and representative models for the costs of the November 2021 Proposal and as the baseline to evaluate other state programs is arbitrary and fails to consider the actual oil and gas production sector in the United States. By way of example, the commenter notes that ND is ranked third in the U.S. among all states in the production of oil and gas, just behind Texas (TX) and New Mexico (NM). The commenter states that those three states account for over 60 percent of the oil and gas production nationwide, whereas CO and CA are ranked fifth and seventh respectively, accounting for just 8 percent of total production volumes in the U.S.<sup>6</sup> and for this reason, ND, TX, and NM are better and more representative baselines for evaluating the November 2021 Proposal. The commenter also points out that CA and CO have air quality issues which have forced these states to implement increasingly stringent air emission requirements that have still failed to achieve attainment with air quality standards. These circumstances, the commenter says, along with their much higher populations, do not make them representative of other states or relevant for determining the costs other states might incur in implementing EPA's proposal. The commenter believes that EPA cannot fairly characterize the costs in the absence of an actual proposed rule, and in any event has underestimated the compliance costs that states will incur in developing the required emissions guidelines (EG) plans for OOOOc. Further, the commenter states that the RIA does not appear to have sufficient data to accurately calculate these costs and that the baseline data is biased. The commenter contends that, overall, in both the November 2021 Proposal and related RIA, the EPA downplays the burden of developing the EG OOOOc state plans.

Response I-4-8: The EPA did review and consult a number of state regulations and programs during the development of NSPS OOOOb and EG OOOOc. These included not only Colorado and California, but also North Dakota, Texas, New Mexico, Pennsylvania, Ohio, Wyoming, and other states. While EPA looked to these state regulations and programs to identify strategies and control options that have been successfully implemented, EPA did not presume that a measure appropriate for a given state was necessarily suitable for nationwide implementation.

With regard to the argument by Commenter (0797-NDDEQ/NDIC) that the EPA should "analyze the anticipated standards' costs and benefits through a national lens and determine whether the national costs are reasonable," the EPA is not required to undertake a formal cost-benefit analysis, as explained in further detail in Section VIII.B of the Final Rule. EPA performed independent and comprehensive cost analyses in accordance with the requirements of section 111 of the CAA, as explained in detail in Section VIII.B. In a few very limited instances EPA used cost information from a state's technical support analyses, but relied upon a number of different sources, including substantial information provided by the regulated industry, in its BSER analyses of the capital and annual costs of control measures considered.

Regarding statements by Commenter (0797-NDDEQ/NDIC) that the EPA has downplayed or underestimated the burdens on states of developing EG OOOOc state plans, the EPA notes that the Information Collection Request (ICR) and supporting statement for the November 2021

---

<sup>6</sup> U.S. Energy Information Administration, at <https://www.eia.gov/state/rankings/?sid=US#/series/46>.

Proposed Rule included estimates of the time and resources necessary for state agencies to develop EG OOOOc state plans, but the commenter did not provide any specific comments on that analysis. These cost impacts on state agencies are also contained in the ICR and supporting statements for the December 2022 supplemental proposal and the final rule. With regard to EPA's estimated burden for states to develop EG OOOOc state plans, see the ICR Supporting Statements located at Document ID Item Nos. EPA-HQ-OAR-2021-0317-0144 (NSPS OOOO and NSPS OOOOa), EPA-HQ-OAR-2021-0317-1556 (NSPS OOOOb), EPA-HQ-OAR-2021-0317-1553 (EG OOOOc), for this action located at Docket ID No. EPA-HQ-OAR-2021-0317.

#### ***4.2.5 Collaboration with States***

Comment: Commenter (0797-NDDEQ/NDIC) suggests that EPA is missing opportunities to decrease burden, such as focusing on ways to collaborate with states to invest in cost-effective improvements to emissions control program implementation and enforcement to achieve performance improvements. By way of example, the commenter cited the first optical gas imaging camera used by ND, which was obtained with the assistance of an EPA grant and has dramatically changed how ND conducts its inspections of the oil and natural gas sector.

Response I-4-9: As noted in response I-4-8, the EPA considered the elements of numerous state programs during the development of NSPS OOOOb and EG OOOOc. Regarding the specific instance cited by the commenter, the use of optical gas imaging is a fundamental aspect of the final rule.

Comment: Commenter (0957-Wyoming Coalition of Local Governments (WCLG)) states that many states, including Wyoming, have made extensive efforts to regulate emission sources within their respective borders, and asserts that oil and gas companies should not be subject to duplicative state and federal regulatory requirements due to the adoption of the EPA's November 2021 Proposal. The commenter adds that there is little recognition of the state regulatory measures that link air quality standards to operational regulation, which the commenter believes to be a major omission in the November 2021 Proposal.

Response I-4-10: EPA acknowledges the efforts undertaken by states such as Wyoming to regulate emissions from the oil and natural gas industry and, as discussed in Response I-4-8, considered the advancements in these state regulations in the development of NSPS OOOOb and EG OOOOc. The EG OOOOc were developed pursuant to CAA section 111(d) and EPA's implementing regulations at 40 CFR Part 60 Subpart Ba, which includes specific requirements for emission guidelines. When states develop their state plans in accordance with EG OOOOc, they have the ability to do so in a manner that reduces regulatory duplication. For further detail, see Section V.A of the 2022 Supplemental Proposal preamble and Section VI.A of the Final Rule preamble. When developing these emission guidelines, the EPA gave specific consideration to the fact that some states already have existing regulations in place for the oil and natural gas industry. See Section XIII.C.2 within the final rule preamble. This section titled "state flexibilities" discusses issues relevant to this comment such as leveraging an existing program for state plan submittal purposes and averaging.

#### ***4.2.6 Unquantified and Ancillary Benefits***

Comment: Commenter (0761-Exelon Corporation (Exelon)) recommends that EPA consider unquantified and ancillary benefits in the rulemaking. According to the commenter, economic principles and best practices for agency rulemaking dictate that consideration of costs and benefits of any CAA section 111 rule include all quantifiable and unquantifiable, direct and indirect costs and benefits. The commenter states that Executive Order (E.O.) 12866 governing agency rulemaking provides that “agencies should assess all costs and benefits” of proposed regulatory actions, and, for “significant regulatory actions,” must assess “benefits anticipated from the regulatory action (such as, but not limited to, the promotion of the efficient functioning of the economy and private markets, the enhancement of health and safety, the protection of the natural environment, and the elimination or reduction of discrimination or bias).” Similarly, the commenter references guidance from the Office of Management and Budget (OMB) which directs agencies to “look beyond the direct benefits and direct costs of your rulemaking and consider any important ancillary benefits and countervailing risks. An ancillary benefit is a favorable impact of the rule that is typically unrelated or secondary to the statutory purpose of the rulemaking...” Further, the commenter argues, EPA’s long-standing practice is to include in a cost-benefit analysis benefits that are not directly intended by the rulemaking.<sup>7</sup>

Response I-4-11: The EPA has met the requirements of CAA section 111 and EO 12866. The commenter did not provide specific examples of the unquantified and ancillary benefits that it believes are missing from the EPA’s analyses. For more information, see Section XVI of the Final Rule preamble and the RIA for the Final Rule.

#### ***4.2.7 Other Cost Benefit Analysis Methodology Comments***

Comment: Commenter (0326-Driss Lonqueux (Lonqueux)) recommends that EPA determine the kinds of controls that are technologically and economically viable for producers by providing a transparent cost-benefit analysis and setting technology-based standards. The commenter states that the first step to mitigate uncertainties is to publish a microeconomic cost-benefit analysis to provide the unit economics of flaring versus capture and sales. Commenter (0326-Lonqueux) states that the November 2021 Proposal fails to promote emerging technologies that have already met EPA screening criteria (compressed natural gas (CNG) trucking, natural gas liquid (NGL) recovery, gas-to-power). The profitability of each technology depends on identifiable factors such as production volumes, gas composition, and distance between wells, and processing plants.

Response I-4-12: The EPA developed the technology-based emission standards in NSPS OOOOb and EG OOOOc using a transparent cost analysis in accordance with the requirements of CAA section 111. The EPA established standards that represent BSER based on the currently available emission reduction techniques, but that are flexible enough to allow the use of emerging technologies. The EPA did not specifically evaluate costs for the emerging technologies mentioned by the commenter. However, these are specifically options that are allowed to be used to comply with the final standards and presumptive standards. For example,

---

<sup>7</sup> U.S. White House Office of Management and Budget, Circular A-4 (Sept. 17, 2003), [https://obamawhitehouse.archives.gov/omb/circulars\\_a004\\_a-4/](https://obamawhitehouse.archives.gov/omb/circulars_a004_a-4/); U.S. Environmental Protection Agency, EPA’s Guidelines for Preparing Economic Analyses (Dec. 17, 2010)), <https://www.epa.gov/environmental-economics/guidelines-preparing-economic-analyses>.

for associated gas wells, the final NSPS OOOOb requires that the associated gas be either (1) routed into a gas gathering flow line or collection system to a sales line, (2) used as an onsite fuel source, (3) used for another useful purpose that a purchased fuel or raw material would serve, or (4) injected or reinjected. Under the third option, CNG trucking, NGL recovery, and gas-to-power are all acceptable compliance methods.

Comment: Commenter (1388-Private Citizen) states that the rule does not go far enough in reducing methane and pollutant emissions and recommends more stringent controls with a goal of zero (prohibited) emissions in the future. The commenter states that these more robust restrictions are needed because the 2023–2035 time frame for comparing cost versus benefits is too short. The commenter states that the cost of mitigating climate change will be much greater in the future, well beyond 2035, when the negative impacts of climate change will be much more devastating and cost us much more in our attempts for mitigation, whereas the cost to the facility is mostly upfront and immediate with some minor costs from testing extending for the life of the facility. The commenter further states that health care costs from industry pollutant emissions and associated loss of productivity for diseases that are instigated now but don't progress to critical stage until many years later, support a longer time frame for determining the cost benefit analysis. The commenter recommends that the cost-benefit analysis be computed for at least the next 100 years.

Response I-4-13: The EPA extended the analysis horizon beyond 2035 to 2038 but declined to extend the analysis further due to the significant uncertainties in projected long-run sectoral trends. In addition, the EPA notes that the monetized climate benefits associated with the 2023–2038 CH<sub>4</sub> emission reductions reflects the discounted stream of benefits resulting from those emission reductions over a much longer time horizon (out to 2300). The commenter did not provide data to substantiate the assertion health care costs and loss of productivity support a longer time frame for the cost benefit analysis.

### **4.3 Compliance Costs**

Comment: Commenter (0600-Pacific Investment Management Company LLC (PIMCO)) states that acknowledging that the relative costs of compliance will vary given the size of the company, they overall view the costs as negligible. EPA estimates that the net cost of compliance would range from \$0.9 to \$1.5 billion on an annualized basis from 2026–2035 for the entire sector to address both new and existing sources. This accounts to 0.3 percent of annual sector capex estimates and about 0.2 percent of annual industry revenues.<sup>8</sup> For some companies, methane emissions abatement may be cost-neutral or lead to a long-term benefit as emissions which are captured can be sold.

Several commenters (0577-Kansas Independent Oil & Gas Association (KIOGA), 0824-Wyoming Department of Environmental Quality (WDEQ)) express concern that the November 2021 Proposal would impose requirements with potentially exorbitant costs for new and existing sources, but particularly for existing sources.

---

<sup>8</sup> Standards of Performance for New, Reconstructed, and Modified Sources and Emissions Guidelines for Existing Sources: Oil and Natural Gas Sector Climate Review, 86 Fed. Reg. 63,110, 63,157 (Proposed Nov. 15, 2021).

Commenter (0824-WDEQ) states that the new requirements in EG OOOOc (which establishes EG for existing sources) mirror many of the requirements in NSPS OOOOb. Put simply, the commenter contends that there are exorbitant and even infeasible costs associated with retrofitting certain control requirements on all existing sources considered affected facilities under the rule - and the definitions of such affected facilities have also been expanded for many different types of equipment. According to the commenter, the number of existing facilities in Wyoming that would have to undergo costly retrofitting procedures in addition to the increased monitoring and compliance burdens would be massive. At this time, it is impossible to know exactly what the economic impacts would be to operators and the feasibility of continuing their operations and retaining employees, but it is reasonable to assume that they would be significant.

Response I-4-14: As evidenced by this series of comments, the opinions of the public vary considerably regarding the impacts that the compliance costs will have on the industry. EPA maintains that the costs associated with the final NSPS OOOOb and EG OOOOc are reasonable taking into account emission reductions and any nonair quality health and environmental impact and energy requirements. See the discussions in section VII.C. of the December 2022 Supplemental Proposal and Section VIII.B of the Final Rule preamble related to how EPA considered control costs in this action.<sup>9</sup>

Comment: One commenter (0577-KIOGA) provided quotes for 95 percent combustion devices to meet compliance with this regulation. Certified combustion devices are more expensive than devices that do not carry the certification, which is contrary to the EPA's expectation that certified devices may be economically favorable. A certified combustion device that will meet gas flow rate requirements and gas quality will cost owners/operators \$12,000 – \$22,000 to purchase and an additional \$8,000 to install, for a total installed cost of \$20,000 – \$30,000 per well. A conventional oil well may cost \$300,000 to \$600,000 to drill and complete. Installation of a combustion system could add 5 percent to 10 percent to the total cost of the project. The additional compliance cost will eliminate projects from being implemented.

The commenter (0577-KIOGA) contends that compliance costs will be considerably greater than the estimates that have been provided by the EPA. The commenter states that the installation of a certified combustor will cost \$20,000 – \$30,000 and does not include the cost to purchase and install a separator, install piping, complete the required surveys, and complete the required reporting for each well that is drilled. The commenter estimates that the compliance costs could exceed 10 percent of the capital cost to drill a well. According to the commenter, these costs are significant and could drive many small operators out of business. The commenter disagrees with the EPA's assessment that the industry can bear the cost and survive.

In addition, the commenter (0577-KIOGA) adds that over the past several years, many small oil and gas companies in Kansas have been working to develop compliance programs to meet the requirements of NSPS OOOOa. The commenter provides a table [see below] of a sample of some of the compliance costs. According to the commenter, it is not a complete list of costs, but an example of some of the additional required activities and the costs associated with each

---

<sup>9</sup> 87 FR 74842 (Dec. 6, 2022).

activity. According to the commenter, as the list of costs demonstrates, the cost of compliance negatively impacts small business.

| Activity                                                  | Cost                 | Frequency                     |
|-----------------------------------------------------------|----------------------|-------------------------------|
| VOC inspection of tank facility                           | \$500 - \$2,000      | 2x per year per facility/well |
| Documentation and record keeping                          | \$20,000 - \$100,000 | Annually                      |
| Green Completion (only for non-delineation wells)         | \$10,000 - \$15,000  | Every new exploration well    |
| Install sample fittings (parts and labor) for gas samples | \$500 - \$1,000      | Every new facility            |
| Laboratory analysis                                       | \$500 - \$1,000      | Every new facility            |
| Engineering evaluation of lab data analysis               | \$250 - \$500        | Every new facility            |
| PE Certification of combustion system                     | \$2,500 - \$3,000    | Every new facility            |
| Installation of combustion system                         | \$20,000 - \$40,000  | Every new facility            |
| Monthly inspection of combustion system                   | \$250 - \$500        | Monthly                       |
| Monthly inspection after removal of combustion system     | \$2,500 - 4,000      | Monthly                       |
| Design of combustion system                               | \$10,000 - \$15,000  | One time cost                 |
| Develop record keeping system                             | \$40,000 - \$50,000  | One time cost                 |
| Develop site specific monitoring plans                    | \$30,000 - \$50,000  | One time cost                 |
| Purchase FLIR camera                                      | \$95,000 - \$100,000 | One time cost                 |
| FLIR camera training                                      | \$3,000 - \$5,000    | One time cost                 |
| Purchase sample collection equipment                      | \$2,000 - \$5,000    | One time cost                 |

*Table 2. Compliance Activities and Costs Required by NSPS OOOOa*

**Response I-4-15:** The commenter appears to assume that a combustion device will be required to comply with NSPS OOOOb standards and EG OOOOc presumptive standards. This is not the case. In fact, for several emission sources the use of a combustion device that achieves 95 percent reduction is not allowed (e.g., process controllers) or allowed only in very limited circumstances (e.g., associated gas wells, pumps).

For the most part, the costs provided by the commenter are less than the estimates that EPA used in the BSER analyses. For example, for associated gas, the capital cost estimate used by EPA was just over \$100,000 and annual costs were \$36,000 per year. See the Final Rule TSD, Chapter 4.

**Comment:** Commenter (0577-KIOGA) states that they believe that EPA has underestimated the annual burden for recordkeeping and reporting requirements in NSPS OOOOa. The commenter provides information on compliance costs that are significantly higher than the estimates used by EPA in the November 2021 Proposal. The commenter suggests that the documentation required by the proposed regulation creates ample opportunities for any operator to be cited by EPA for missing information.

Commenter (0577-KIOGA) notes that EPA estimated that the average owner or operator will spend approximately 38 hours per year (98,438 labor hours/2,554 owners and operators), in the first three years, on compliance reporting activities. This time estimate is expected to cost the average owner \$1,316 per year (\$3,361,074 per year/2,554 owners and operators). The commenter estimates that a one-time cost to develop a management and reporting system to be \$40,000 - \$50,000 and an ongoing cost of compliance of \$20,000 - \$100,000 per year (one-part time employee early in the program and potentially two full time people within a few years). The commenter contends that the required information will be a substantial burden on small organizations to collect, manage, store, and report to the Agency on an annual basis. According to the commenter, this does not include the increase in operating costs that will come from Leak

Detection and Repair (LDAR) survey costs, reporting costs, and additional capital investment to meet emissions reductions.

The commenter (0577-KIOGA) adds that the documentation will necessitate many more hours than the EPA's estimated 38 hours per year. Companies are evaluating the need to hire another one to two people solely to meet the reporting requirements of this new regulation. The commenter believes that a full-time position(s) may be required to meet all of the annual reporting and data management requirements to maintain compliance. They estimate that the fully loaded cost (salary and benefits) to fill this position will be an additional \$50,000 – \$60,000 per year per person to current operations. These requirements are not trivial.

Commenter (0577-KIOGA) reports that some operators in Kansas may drill 200 oil wells and perform work that would meet the EPA's definition of a "modification" for more than 250 existing wells in a five-year period. This is an average of 90 wells being drilled or modified each year, not including associated tanks or other Fugitive Emissions Components. The commenter expects this level of activity to resume as oil prices increase for some of the active owners/operators in Kansas. The commenter adds that they believe that smaller owners/operators will reduce their drilling and maintenance programs until the oil price increases again. The reporting work will continue to grow each year as we continue to drill and modify wells because the current year work is added to all work from prior years. This growing workload will require the hiring of additional employees in the future.

Response I-4-16: The recordkeeping and reporting requirements for NSPS OOOOb are comparable to those in NSPS OOOOa, as are EPA's estimates of the associated burden. While this commenter has speculated about projected costs, it is notable that industry representatives that have been complying with NSPS OOOOa did not provide comments or information to indicate that their actual costs are significantly higher than EPA's estimates. See discussion in section VIII.B. of the December 2022 Supplemental Proposal related to information collection activities in the proposed amendments<sup>10</sup> and section XVII.B of the Final Rule preamble. Also see the ICR document that the EPA prepared, which has been assigned OMB Control No. 2060–0721 and EPA ICR number 2523.05.

Comment: Several commenters (0929-National Stripper Well Association (NSWA), 0585-Kentucky Oil and Gas Association (KOGA), 0425-Darrah Oil Company, LLC (Darrah)) state that the November 2021 Proposal as currently described will place an extreme financial burden on their members.

Commenter (0929-NSWA) asserts that this is especially troubling in a time when many of their members are beginning to recover, and adjust, from the economic impacts of the COVID pandemic and market turns. For example, the commenter notes that optical gas imaging (OGI) cameras required under the November 2021 Proposal can cost producers over \$100,000. These added costs are simply not feasible for smaller operations. In addition, the expensive one-time investments required by the proposed regulation and the additional documentation costs cannot be overlooked. Building new reporting systems is expensive and will come with additional increases in payroll costs as new employees will be needed to process all of the required

---

<sup>10</sup> 87 FR 74844 (Dec. 6, 2022).

documentation. According to the commenter, smaller producers do not have the same economies of scale as larger producers and cannot spread increases in fixed compliance costs over as many projects. They contend that this will result in many of their members likely going out of business as they are unable to maintain profitability. The commenter states that the potential full costs of the rule are particularly disconcerting because the EPA often underestimates costs. Considering the cost estimates for monitoring tanks and wells the EPA has provided for low production wells, the monitoring cost alone will add an estimated 10 percent to 50 percent additional cost to the operating expenses (depending on the final monitoring frequency that is required). This, the commenter states, does not include all of the other costs associated with implementing the rule.

Commenter (0929-NSWA) notes that the November 2021 Proposal preamble does include a cost per inspection reported. The EPA estimated annual costs of the fugitive emissions program at well sites is estimated to range from \$2,490 for biennial monitoring to \$8,140 for monthly monitoring. To appreciate the impact, the commenter provides the following example: the typical marginal well produces approximately 1 barrel of oil per day. Using the EPA's cost estimates, biennial inspections required for the typical marginal well equates to \$6.82 / barrel of additional operating cost ( $\$2,490 \text{ for biennial inspections} / (1 \text{ barrel per day} \times 365 \text{ days per year}) = \$6.82/\text{barrel}$ ). Monthly monitoring cost is estimated to be \$22.30/barrel of additional operating cost ( $\$8,140 \text{ for monthly inspections} / (1 \text{ barrel per day} \times 365 \text{ days per year}) = \$22.30 / \text{barrel}$ ). When the typical operating cost for a marginal well is \$20 / barrel to \$40 / barrel, this is a significant increase to the operating cost just for the fugitive emissions monitoring program.

As an example, the commenter (0929-NSWA) provides that implementing a \$3,000/year program on a well that produces one barrel per day (below that is considered extremely low, the commenter assures us small operators produce a lot of wells at or near that level. The average per well output in Kansas was close to 1.6 billion barrels (Bbls) per day last year.) would cost that well \$8.22 per Bbl produced and likely condemn its ability to operate at a profit. The additional compliance cost will result in many of the marginal wells being permanently abandoned. The commenter states that the loss of production will result in higher energy costs for all Americans, job loss for oil and gas employees, and lost revenue for mineral owners.

Response I-4-17: See EPA responses in Volume I, Chapter 20, subsection 20.2.7 of this volume for responses to comments related to the impacts on small businesses and marginal producers.

Comment: Several commenters (0929-NSWA, 0585-KOGA, 0425-Darrah) state that the EPA provides several cost metrics in the preamble, based on the cost of emissions reductions (*i.e.*, dollars per ton). While this metric may be meaningful to the EPA staff, it is not meaningful to industry. They suggest that the EPA consider implementation costs of the rule in metrics that the industry uses, specifically cost per unit of production (*i.e.*, \$/million cubic feet (MCF) of gas or \$/barrel of oil). The commenters explain that these are the metrics that industry uses to make decisions, not dollars per ton of emissions reduced. According to one of the commenters (0929-NSWA), industry does not have a way to translate the EPA's cost estimates to validate their assumptions or understand how it will impact our businesses. The commenter suggests that the EPA also provide cost metrics based on the cost per inspection and cost per unit of production.

Response I-4-18: Section 111 of the CAA specifies that EPA must establish "the best system of emission reduction which (taking into account the cost of achieving such reduction and any

nonair quality health and environmental impact and energy requirements) the Administrator determines has been adequately demonstrated.” Calculating a dollar per ton of reduction is a direct method of accounting for the cost of an emission reduction.

In some cases, the emissions, and thus the emission reductions, are directly related to a metric commonly used by the industry. For example, the amount of associated gas produced is directly proportional to the emissions and thus the emission reductions. Therefore, for a particular well it would be straightforward to calculate dollars per MCF of production. However, given the numerous differences from well to well, notably the amount of methane in the associated gas, the dollars per MCF of production would vary from well to well. In other instances, such as fugitive component leaks, correlations exist between the cost and the number of components to be monitored.

Comment: Commenter (0957-Wyoming Coalition of Local Governments (WYCLG)) notes that the EPA included a cost analysis for the technical and monitoring requirements in the November 2021 Proposal, but that the analyses addressed each individual requirement separately without a discussion as to the cumulative costs per well site to comply with all the new proposed requirements. For example, the November 2021 Proposal estimates the cost of implementing the proposed fugitive emissions monitoring guidelines at well sites and concludes that is cost effective. It also makes similar cost-effective conclusions on other proposed requirements to control emissions from equipment not previously regulated, such as tank batteries, which would require retrofitting of the necessary emission control equipment at existing well sites. The commenter states that individually the cost to comply with each proposed monitoring or technical requirement may be reasonable but it is no longer a reasonable cost when you consider the total costs of complying with all of the proposed monitoring requirements and emissions standards. The commenter emphasizes that this is especially true for smaller businesses and those that operate lower producing wells.

Response I-4-19: As has been stressed by the industry throughout the development of NSPS OOOOb and EG OOOOc, and prior to that during the development of NSPS OOOO and OOOOa, there is considerable variation in the equipment and processes at oil and natural gas production sites. Therefore, the overall site-wide cost will vary substantially from site to site, which would make it difficult to evaluate site-wide costs for representative facilities.

However, a key metric that the EPA used in determining BSER for the covered emissions sources is the cost per unit of emission reduction, or cost effectiveness (e.g., dollars per ton of methane or VOC emissions reduced or eliminated). If the cost effectiveness of the requirements for every individual emission source (affected facility or designated facility) is reasonable, then the collective cost effectiveness must also be reasonable.

While the BSER analyses and decisions were on an emission source basis, the regulatory impact analysis does consider the collective costs of all measures and the impacts on businesses. See the RIA for the Final Rule for more information. In addition, the EPA considered costs of compliance on industry as a whole, as explained in further detail in Section VIII of the Final Rule preamble.

Comment: Commenter (1301-Northern Arapaho Tribe Business Council (NATBC)) requests that the EPA provide additional detail about the costs of complying with new measures under the November 2021 Proposal at a useful scale, including the likely range of costs for:

- Quarterly monitoring of major well sites and compressor stations
- Surveying of smaller well sites
- Routing associated gas to flare or control devices that meet 95 percent reduction Rule requirement
- Reducing tank and tank battery emissions to meet 95 percent reduction Rule requirement
- Replacement of pneumatic pumps and pneumatic controllers to meet 95 percent to 100 percent reduction Rule requirements, respectively

The commenter (1301-NATBC) states that the November 2021 Proposal currently provides only a very brief, two-paragraph summary regarding compliance costs, offering merely an estimated aggregate present value compliance cost of “\$13 billion” between 2023-2035. That projected overall estimate is not helpful to the commenter in assessing the likely cost burden of bringing individual petroleum and natural gas operations into compliance with the numerous distinct requirements of the November 2021 Proposal.

The commenter (1301-NATBC) asserts that more granular examples and information would be helpful. For example, our understanding is that a single industry-grade handheld Forward Looking InfraRed (FLIR) thermal imaging camera used for gas leak detection costs \$13,000-\$55,000 depending on the model. Under the November 2021 Proposal, operators will have to purchase or rent such equipment to conduct mandatory monitoring and surveying of well sites. Because thermal imaging is likely to detect leaks not typically detected by visual inspections, maintenance costs are also likely to increase. The commenter notes that there will also be additional costs associated with recordkeeping for the required new monitoring.

The commenter (1301-NATBC) states that the November 2021 Proposal, as presented, does not adequately address the expenses necessitated by the Rule to be borne by operators. During Northern Arapaho’s January 24, 2022, consultation with the EPA regarding the proposed rule, the commenter notes that EPA representatives indicated that: (1) they possess and would provide additional information regarding estimated costs of bringing individual wells into compliance with the proposal regarding fugitive emissions; and (2) EPA will be issuing supporting statements regarding expenses associated with the anticipated record-keeping burden and implementation plan development. The commenter states that they look forward to disclosure of that information. The commenter concludes that EPA should account for and report on all such implementation-scale compliance costs.

Response I-4-20: The detailed information requested by the commenter is provided in the technical support documents. These include the TSD for the November 2021 proposal,<sup>11</sup> the TSD for the December 2022 supplemental proposal,<sup>12</sup> and the TSD for the final rule.<sup>13</sup> All three

---

<sup>11</sup> November 2021 TSD.

<sup>12</sup> December 2022 TSD.

<sup>13</sup> Final Rule TSD.

of these TSDs, as well as Microsoft Excel workbooks that provide more details on the calculations, are available in the docket.

## Chapter 5. Control Devices

### 5.1 Flares

#### *5.1.1 Emergency Flares Applicability Clarification*

Comment: Commenter (0843-Environmental Integrity Project (EIP)) states that the November 2021 Proposal fails to define critical terms needed for implementation, including the terms that describe flare operating scenarios considered to be permissible and/or covered by the proposed rule. The commenter urges EPA to carefully define what constitutes an unforeseeable startup, shutdown, or malfunction (upset) versus foreseeable operating scenarios. In particular, the commenter contends that EPA must explain the difference between and define an “emergency” flare and a “process” flare (if “process flares” are allowed). The commenter requests that if EPA means to exclude emergency flares from the requirements generally applicable to flares, the rule should state so explicitly, as well as state precisely what constitutes emergency versus routine flaring. Otherwise, they recommend that EPA clarify that emergency flares are subject to the flaring requirements.

The commenter (0843-EIP) notes that in Texas, most flares are authorized to release only nominal, pilot flame, emissions, and some flares are authorized to release large amounts of pollution during “planned maintenance, startups, and shutdowns.” Texas has acknowledged that oil and gas operators, specifically, need additional guidance to comply with NSPS OOOOa given the state’s emission events rules.<sup>1</sup> However, despite efforts at guidance, the commenter notes that the Texas data clearly shows that operators claim and report “upsets” (defined in Texas as “emission events”) for all manner of weather-related, emergency/non-emergency, third-party-caused, and routine business practices. For example, operators have filed upset/emission event reports in Texas “to conduct maintenance,” when third parties (*i.e.*, gas processing plants) “shutdown to perform maintenance,” “since the gas could not be sold....,” “for planned maintenance,” and other routine or easily foreseeable events.<sup>2</sup>

The commenter (0843-EIP) contends that recent initial enforcement actions illustrate the need for EPA to clearly define flare operating scenarios covered by the November 2021 Proposal. Texas operators throughout the Permian Basin claim normal and routine events as upsets. For example, in one recent investigation, Texas regulators explained:

It has been determined by the TCEQ that emissions caused by routine downstream actions are not emission events and must be permitted. Downstream conditions which are reasonably routine activities should be anticipated and the upstream facility should consider these activities as part of their permitted emissions. Since many of the reported

---

<sup>1</sup> See TCEQ, Oil and Gas Industry Emissions Events (EE) Workshop, (Nov. 5, 2020). Accessible at: <https://www.tceq.texas.gov/downloads/assistance/industry/oil-gas/og-emissions-events-presentation.pdf>.

<sup>2</sup> Submission Attachment B, TCEQ STEERS Incident Reports, Incident Tracking Numbers 334964, 335023, 337490, 338078, 344345 TCEQ Search Air Emission Event Reports (texas.gov).

events were caused by conditions downstream of this site and were reasonably routine, the emissions are considered to require a permit.<sup>3</sup>

See Attachment C of commenter's (0843-EIP) public submission, TCEQ Johnson Unit Compliance Investigation, Occidental Permian (June 22, 2021); see also Attachments D & E of commenter's public submission (two other recent TCEQ investigation reports for facilities in the Permian Basin).

The commenter (0843-EIP) adds that there is no definition or clarity for operators as to what constitutes "reasonably routine" and, therefore, the line between permitted activities and upsets remains blurred.

Response I-5-1: EPA disagrees that it is necessary to define startup, shutdown, and malfunction because the rule requires that owners and operators always operate each control device in compliance with the control device requirements when gases, vapors, and fumes are vented from the affected facility through the closed vent system to the control device. The provisions for exemption from compliance during periods of startup, shutdown and malfunctions provided for in 40 CFR 60.8(c) do not apply to NSPS OOOOb and EG OOOOc.

### ***5.1.2 Support Increased Regulation of Flaring***

Comment: Commenter (0807-BP America, Inc. (BP)) supports EPA exploring ways to enhance regulatory oversight through standards that incorporate assurances to reduce flaring. The commenter welcomes the opportunity to provide additional comments on flares in the supplemental rulemaking.

Commenter (0770-Northern Plains Resource Council (NPRC)) believes that EPA has an obligation to strengthen its November 2021 Proposal and advance rules that leave no loopholes nor future opportunities for methane pollution from oil and gas infrastructure.

Commenter (0729-Energy Workforce & Technology Council (EWTC)) believes that the regulation of flaring is an additional component that will be paramount to the efforts of decreasing overall emissions. The commenter states that traditionally, flaring has been a means for producers and operators to combust uneconomic or unusable natural gas that is produced as part of the extraction process at the well site. The commenter notes that while the majority of harmful components in the field gas are neutralized through flaring, incomplete combustion by inefficient flares can result in significant quantities of methane emitted to the atmosphere, so called "methane slip."

Commenter (0828-Union of Concerned Scientists (UCS)) states that EPA must strengthen its position regarding routine flaring. The commenter asserts that the costs of routine flaring are staggering and despite operators flagrantly wasting saleable product, many of flaring's true costs are borne on the backs of the public in the form of health-harming and climate-forcing

---

<sup>3</sup> See Attachment C, TCEQ Investigation Report, Customer: Occidental Permian Ltd., June 22, 2021  
See also Attachments D&E (two other recent TCEQ investigation reports for facilities in the Permian Basin; Docket online access restricted-copyrighted materials).

pollutants.<sup>4</sup> However, the commenter notes that the November 2021 Proposal continues to defer to the immediate interests of producers over the health and wellbeing of the public. The commenter states that EPA must eliminate its too permissive allowance for operators to fail to meet what should be a baseline requirement for production: planning and investing in sufficient gas offtakes.

Commenters (0444-Damascus Citizens for Sustainability (DCS), 0715-Dayenu Circle of Jewish Silicon Valley (DCJSV)) note that the rule does not regulate flaring, a large source of emissions. The commenter notes that New Mexico and Colorado regulate flaring, and they request that EPA follow their examples.

Response I-5-2: See discussion in section IV.H.2 of the December 2022 Supplemental Proposal related to combustion control devices and sections IV.F.2.a.ii and IV.F.2.a.iii. of the December 2022 Supplemental Proposal related to flaring of associated gas.<sup>5</sup> Also, see Chapter 17 of this Response to Comments document (Volume I) for more information related to flaring of associated gas.

Comment: Several commenters (0201-Sierra Club-Lone Star Chapter (Sierra Club-LSC), 0559-TX State Senator Eckhardt, 0941-350Silicon Valley, 1297-Texas State House) support federal regulation of flaring because they contend that several states fail to enforce regulation and because several state rules are insufficient.

Commenter (0201-Sierra Club-LSC) provides examples of Texas's inaction. The commenter notes that Railroad Commission of Texas (Texas RRC) through Rule 32 has specific rules on flaring and venting, but other than some modest improvements on reporting and data, has continued to allow oil producers to flare off large volumes of gas. While the Texas Commission on Environmental Quality (TCEQ) does have well established regimes on oil and gas air permitting, there is a confusing array of different kinds of permits depending on the size and location of oil and gas wells and associated equipment. Texas does not have specific standards on methane and has rejected suggestions to develop state standards. In leasing state lands, neither the General Land Office nor the university systems that benefit from leasing these lands have imposed specific standards on oil and gas producers. Indeed, state leadership – both the TCEQ and RRC – have opposed previous federal efforts to implement strong methane standards, often joining in lawsuits to prevent regulations designed to lower emissions.

Moreover, the commenter (0201-Sierra Club-LSC) contends that state legislature and the Governor have failed to take any action to reduce flaring, venting or fugitive emissions, other than through the creation of incentives like the Texas Emissions Reduction Plan. Indeed, in some cases, the legislature has stepped in and made it harder to increase regulation of oil and gas air emissions in Texas.

---

<sup>4</sup> The proposed rule estimates product recovery—across all intervention measures—to be on the order of \$5.5 billion through 2035, or \$520 million each year (Fed. Reg. 63123).

<sup>5</sup> 87 FR 74779, 74780, and 74792 (December 6, 2022).

Commenters (0559-TX State Senator Eckhardt, 1297-Texas State House) report that in the last seven years, the Texas RRC has granted operators more than 27,000 permits to flare,<sup>6</sup> resulting in the burning of nearly 1 trillion cubic feet of natural gas.<sup>7</sup> In 2020, the Texas RRC granted about 4,500 exceptions to flaring regulations.<sup>8</sup> Commenter (0559-TX State Senator Eckhardt) states that according to ExxonMobil, their “experience in the Permian Basin demonstrates that zero routine flaring is within everyone’s reach.”<sup>9</sup> and the Texas Methane and Flaring Coalition “agrees we should strive to end routine flaring.”<sup>10</sup> The commenter reports that despite all of these benefits, methane leaks and flaring are common. The commenter states that industry needs clear guidance and nationally established minimum standards, instead of an unproductive (and sometimes counterproductive) piecemeal state approach.

Response I-5-3: See discussion in section IV.H.2 of the December 2022 Supplemental Proposal related to combustion control devices and sections IV.F.2.a.ii and IV.F.2.a.iii. of the December 2022 Supplemental Proposal related to flaring of associated gas.<sup>11</sup> Also, see Chapter 17 of this Response to Comments document (Volume I) for more information related to flaring of associated gas.

Comment: Commenter (0807-BP) is pleased that EPA is soliciting comment on operation of flares as flaring is a significant source of methane for their sector. The commenter provides details of their efforts to reduce and intention to eliminate flaring. In April 2021, the commenter announced their intention to eliminate routine flaring in their U.S. onshore operations by 2025 or sooner. To achieve this goal, all newly constructed well sites are tied into gas delivery pipelines from start-up, and new wells are not brought online unless the wells have access to a gas pipeline. The commenter reports that it is also building centralized production facilities and converting legacy wells from high pressure systems to low pressure gas gathering systems to tie in more of their existing production into centralized facilities. Notably, since taking operational control over BHP’s oil and gas assets in Texas’s Permian Basin in 2019, the commenter reports that they have reduced flaring intensity in the basin from 16 percent in the fourth quarter of 2019 to less than 1 percent today.

The commenter (0807-BP) provides that actions to address the efficiency and operations of flares include installing air assist to improve the flare combustion efficiency and thermocouple sensors on all flare stacks to notify operations teams of unlit flares. They add that all flares have auto-ignitors to attempt to remotely reignite flames that have extinguished.

<sup>11</sup> 87 FR 74779, 74780, and 74792 (December 6, 2022).

Another commenter (0729-EWTC) states that flaring alternatives and on-site innovations that have emerged from within the energy sector have already addressed concerns regarding traditional flaring and companies are developing new ways to reduce and decrease flaring efforts altogether. The commenter notes that chief among these efforts has been the repurposing of collected field gas to power wellsite operations. The commenter states that gases that would have traditionally been flared are now being used on-site in a closed-loop process with minimal methane emissions.

Response I-5-4: We acknowledge the information provided by the commenters.

Comment: Commenter (0757-Private Equity Stakeholder Project (PESP)) notes that private equity-backed operators have a track record of releasing problematic levels of methane into the atmosphere. In EDF's analysis of 2018 flaring data, private equity firm NGP Capital's Steward Energy II<sup>12</sup> was the 60<sup>th</sup> largest Permian natural gas producer, but it was the fourth largest flarer by volume. The commenter reports that Steward flared more natural gas than XTO Energy, despite XTO having produced more than 10 times the amount of natural gas as Steward. The commenter adds that Steward was found to flare approximately 65 percent of all the gas it produces – meaning that about two-thirds of the natural gas Steward extracts from the ground is flared – further damaging the environment and nearby communities.<sup>13</sup>

Response I-5-5: See discussion in section IV.H.2 of the December 2022 Supplemental Proposal related to combustion control devices and sections IV.F.2.a.ii and IV.F.2.a.iii. of the December 2022 Supplemental Proposal related to flaring of associated gas.<sup>14</sup> Also, see Chapter 17 of this Response to Comments document (Volume I) for more information related to flaring of associated gas.

### ***5.1.3 Oppose Increased Regulation of Flaring***

Comment: Commenters (0808-American Petroleum Institute (API), 0831-American Exploration and Production Council (AXPC)) state that the refining sector is vastly different than oil and gas well sites, centralized production facilities, and compressor stations. The commenters state that the oil and natural gas production sector does not operate at steady state conditions. Equipment design must be tailored to the conditions and fluid compositions supplied by the reservoir.

Commenter (0808-API) reports that oil and natural gas are located thousands of feet below the surface and must flow in two or three phases to the surface. The mixture is then separated in the two or three-phase separator with steady pulses of produced water sent from the bottom of the separator to its storage vessel, hydrocarbon liquids off the middle to its storage vessel, and natural gas off the top of the separator to the gathering system.

---

<sup>12</sup> Steward Energy, "History," January 6, 2022, <https://stewardenergy.net/about-steward/>.

<sup>13</sup> Colin Leyden, "New Permian Data Show How Worst Offenders Prevent Progress on Flaring," Texas Clean Air Matters - EDF, August 14, 2019, <https://blogs.edf.org/texascleanairmatters/2019/08/14/new-permian-data-show-how-worst-offenders-preventprogress-on-flaring/>.

<sup>14</sup> 87 FR 74779, 74780, and 74792 (December 6, 2022).

The commenter (0808-API) states that as production declines in a gas well, management of wellbore liquids can mean that flow to the control device can vary from essentially zero to high flow rates and quickly back to zero rapidly and often. The commenter explains that this highly variable, non-steady state flow mandates equipment to be sized much larger than ideal steady state conditions would dictate and makes flow measurement infeasible in these conditions.

The commenter (0808-API) believes it is not appropriate nor cost effective to apply refinery-oriented requirements to upstream flares. Costs for Subpart CC controls at refineries are \$1 million plus, with major ongoing costs. Costs would be much greater at upstream facilities without the necessary utilities and instrumentation resources. The commenter contends that it is not clear that there is instrumentation available that would work reliably under the varying operating conditions. Additionally, the commenter notes that adding natural gas to a flare to control the BTU content incurs capital costs as well as ongoing costs and generates considerable greenhouse gases that would not otherwise be emitted.

The commenter (0808-API) notes that many states have moved to include some type of flare monitoring requirement within their local regulations or permitting processes. For example, Texas<sup>15</sup> requires that flares meet 40 CFR 60.18 requirements for minimum heating value and maximum tip velocity and have a continuous pilot flame (monitored by thermocouple or equivalent device) or an automatic ignition system.

Response I-5-6: See discussion in section IV.H.2 of the December 2022 Supplemental Proposal related to requirements for combustion control devices.<sup>16</sup> See additional responses related to comments on combustion control devices in Volume II, Chapter 17.

Comment: Commenter (0585-Kentucky Oil and Gas Association (KOGA)) notes that many environmental groups advocating for EPA to eliminate oil and gas companies' ability to burn gas at well sites through a flare are the same environmental organizations that oppose new pipelines to move gas into markets. The commenter states that without the ability to transport gas to market via pipeline, burning the gas with a flare is one of the last options available.

Commenter (0585-KOGA) requests that EPA allow small volumes of gas to be flared, without incurring the expense of delivering a flare that has a 95 percent certification to the wellsite because that small volume of gas that is burned through the low-cost maintenance event should not be burdened with the significant expense of delivering a flare to the wellsite. The commenter contends that a typical maintenance cost for many of our operators is \$3,500 to \$5,000 to service an oil or gas well. The commenter reports that the additional cost to deliver and set up a 95 percent certified flare system is estimated to be an additional \$1,000 to \$2,000 per maintenance event. This requirement will add 30 percent to 40 percent to the cost of servicing the well with little additional environmental benefit.

<sup>15</sup> Texas Commission on Environmental Quality, Control Device Requirements Charts for Oil and Gas Handling and Production Facilities (February 2012).

<https://www.tceq.texas.gov/assets/public/permitting/air/NewSourceReview/oilgas/control-dev-reqch.pdf>.

<sup>16</sup> 87 FR 74792 (December 6, 2022).

Response I-5-7: See discussion in section IV.H.2 of the December 2022 Supplemental Proposal related to combustion control devices and sections IV.F.2.a.ii and IV.F.2.a.iii. of the December 2022 Supplemental Proposal related to flaring of associated gas.<sup>17</sup> Also, see Chapter 17 of this Response to Comments document (Volume I) for more information related to flaring of associated gas.

Comment: Commenter (0817-GPA Midstream Association (GPA)) states that “additional measures” for flares are not required, cost efficient, or appropriate for control device performance. The commenter believes that the manufacturer’s design guarantee should be allowed for compliance purposes to ensure good combustion. The commenter provides that, in assessing whether additional measures add value in the midstream sector, it is important to consider that flaring at midstream facilities is very different than those at large industrial facilities, such as chemical plants or refineries, and provide a basis for EPA to distinguish regulation among flares in different sectors. Flares for gathering and boosting compressors and at natural gas processing plants do not have streams with the types of complex gases found in chemical plants and oil refineries. The commenter notes that there is no significant concentration of inert gases in the flare systems and no ethylene or propylene to increase combustion zone net heating values. Moreover, the commenter contends that midstream operations have substantially lower flow rates than chemical plants or refineries. They add that there is simply a lower volume of continuous waste streams. The commenter states that this is especially true at compressor stations, where flares and combustors are used to control specific equipment, not multiple sets of process units.

Moreover, the commenter (0817-GPA) informs that the accurate flow measurement for low flow streams is costly. The commenter estimates that these flow meters are approximately \$100,000.<sup>18</sup> Requiring the industry to obtain these flow meters for each site within a short compliance timeframe would only increase costs. Adding low flow meters would not be cost effective given the low waste stream flow and the number of flow meters<sup>19</sup> that would need to be installed. Thermocouples (or equivalent devices) currently ensure that a pilot is lit continuously and an alarm sounds when the pilot is lost. The commenter believes that is sufficient to track and verify operation. If EPA were to consider further verification, the commenter recommends that EPA consider using minimum flows or hours (*e.g.*, X volume per year) as monitoring threshold while excluding temporary flares. Moreover, commenter (0817-GPA) adds that, particularly in the case of the midstream sector, compressor stations are often remotely located, numerous, and not manned continuously and would, therefore, require expensive equipment and/or extensive and

---

<sup>17</sup> 87 FR 74779, 74780, and 74792 (December 6, 2022).

<sup>18</sup> EPA expects costs of ultrasonic meter installation to be \$50,000. See EPA, Replace Bi-Directional Orifice Metering with Ultrasonic Meters (available at [https://urldefense.com/v3/\\_\\_https://www.epa.gov/sites/default/files/2016-06/documents/replacebidirectional.pdf\\_\\_;!!Omh0IfYXnA!hIdkI7nB\\_2pNpsUacEKDs4Uy5JCX7ksNZfTcw7\\_hvr56P8eeLVOJLU-kfuR925nG\\$](https://urldefense.com/v3/__https://www.epa.gov/sites/default/files/2016-06/documents/replacebidirectional.pdf__;!!Omh0IfYXnA!hIdkI7nB_2pNpsUacEKDs4Uy5JCX7ksNZfTcw7_hvr56P8eeLVOJLU-kfuR925nG$)) (*last accessed* January 14, 2022).

<sup>19</sup> EPA estimates 1484 compressor stations in the justification for this rule. Proposed Rule TSD, EPA-HQ-OAR2021-0317-0166. Assuming 1 flare for a dehydrator, 1 flare for tanks, and 1 flare for the facility blowdowns, this would total 4,452 flow meters for gathering and boosting alone. There were 462 gas plants reported under GHGRP. See EPA, GHGRP Data Sets (available at <https://www.epa.gov/ghgreporting/data-sets>). (*last accessed* January 14, 2022). Assuming 2 flares per facility for equipment blowdowns and 1 flare for loading for each facility, this would be another 1,386 flares in the processing segment.

unrealistic operational changes to conduct continuous monitoring with no expected real benefit. Maintenance would be a significant burden for the midstream industry. Unlike with manned facilities with on-site maintenance staff and fabrication shops, it may take days before staff could get to an unmanned site to make repairs. According to the commenter, this could mean that a site may have to shut down until repairs are completed or be in violation.

Response I-5-8: See discussion in section IV.H.2 of the December 2022 Supplemental Proposal related to combustion control devices.<sup>20</sup> Additional responses on the final requirements for monitoring flow to combustion control devices are located in Volume II, Chapter 17.

Comment: Commenter (0911-North Dakota Petroleum Council (NDPC)) states that if EPA requires flares that meet 40 CFR 60.18 with no exceptions, additional gas needs to be brought onsite to make up the minimum flowrate, likely increasing greenhouse gas emissions. The commenter notes that North Dakota, as well as some other states, allow for combustion devices other than those that meet 40 CFR 60.18. Some wells and storage tanks do not produce enough gas to support the minimum flow rate as specified in 40 CFR 60.18. In these cases, the best practice is to use a flare that has a lower destruction efficiency with an auto-ignitor that sparks every few seconds.

Response I-5-9: EPA notes that it is not mandating the use of flares in NSPS OOOOb or EG OOOOc. Flares are a control option for various affected facilities within the rule, but other control options such as carbon beds or condensers can also be used in low flow situations where a flare may not be viable, as long as the control device is capable of achieving the level of control specified in the rule. Pressure valves can also be used to prevent flow to the flare until there is enough flow to ensure adequate combustion efficiency.

#### ***5.1.4 Support Banning of Flaring/Non-Emergency Flaring***

Comment: Commenters (0357-National Parks Conservation Association (NPCA), 0435-Wespath Benefits and Investments, 0437-New York Office of the State Comptroller (NYOSC), 0578-Grand Canyon Trust (GCT), 0589-NEI Investments (NEI), 0720-Miller/Howard Investments, 0723-Ceres, 0724-Boston Trust Walden, 0728-Calvert Research and Management, 0734-American Thoracic Society (ATS), 0757-PESP, 0770-NPRC, 0783-CA Assemblymember Bloom *et al.*, 0788-350 Seattle, 0795-American Lung Association *et al.* (ALN *et al.*), 0796-Asthma and Allergy Foundation of America – Michigan Chapter *et al.* (AAFA-MI *et al.*), 0812-Ohio Farmers Union *et al.* (OFU *et al.*), 0837-Clean Water Action *et al.* (CWA *et al.*), 0840-Navajo Nation, Counselor Chapter House, 0841-Red Mesa Chapter Governance-Navajo Nation (RMCG-Navajo), 0920-WE ACT for Environmental Justice (WAEJ), 0927-Interfaith Center on Corporate Responsibility (ICCR), 0937-Fort Berthold Protectors of Water and Earth Rights (Fort Berthold POWER), 0941-350Silicon Valley, 0942-CleanEarth4Kids, 0947-Alliance of Nurses for Healthy Environments-Colorado *et al.* (ANHE-CO *et al.*), 0948-Quirk, 0949-Liveable Arlington, 0958-Climate Code Blue (CCB), 1270- League of Women Voters of the United States (LWVUS), 1282-Earthworks, 1297-Lopez *et al.*, 1302-Wyoming Outdoor Council (WYOC) and the Powder River Basin Resource Council (PRBRC), 1330-Catskill Mountainkeeper, 1338-Lexington Climate Action Network, 1339-Waterway Advocates, 1372-Generate Capital PBC,

---

<sup>20</sup> 87 FR 74792 (December 6, 2022).

1389-VERIS Wealth Partners, 1423-Beyer *et al.*, 1434-Heinrich *et al.*) urge EPA to prohibit the practice of routine flaring. Many of these commenters express concern regarding flaring emissions of VOCs, carbon monoxide, sulfur dioxide, polycyclic aromatic hydrocarbons, nitrogen oxides, black carbon, and other pollutants which they state have significant adverse human health impacts and flaring carbon dioxide emissions' contribution to climate change. Representative specific comments are provided in the following paragraphs.

Commenter (0783-CA Assemblymember Bloom *et al.*) states that many California communities also suffer from the impacts of flaring. According to the commenter, news reports of plumes of black smoke and related health threats are common in Richmond<sup>21</sup> and Los Angeles<sup>22</sup> because of this practice of burning gas as a waste product, instead of capturing and selling it as part of oil extraction. The commenter states that the consequence is the release of toxic pollutants that contribute to public health crises and climate change. According to a joint USC-UCLA study, living within "3 miles of flaring is associated with increased risk of preterm birth"<sup>23</sup> and the practice is also linked to higher rates of asthma, as well as negative cardiopulmonary and cardiovascular impacts. As one of the authors of the study stated, "Our findings show that flaring is an environmental justice issue... We found that a significant number of Black, Indigenous and Latinx people live near flaring. High rates of poverty and other barriers to health in rural areas — such as a lack of access to health care — could worsen the health effects of flaring-related exposures."<sup>24</sup> The commenter asserts that, given that leading operators and some states have successfully ended routine flaring, there is no justifiable reason to continue allowing the practice and EPA should use this regulatory process to end it in non-emergency situations.

Commenters (0942-CleanEarth4Kids, 0937-Fort Berthold POWER, 0947-ANHE-CO *et al.*, 1339-Waterway Advocates) suggest ending all routine flaring along with setting monitoring, enforcement, and fines to ensure unlit flares are not venting methane.

Commenter (0357-NPCA) requests that the supplemental proposal eliminate the wasteful and dangerous practice of routine flaring at oil and gas facilities, except in emergency situations. The commenter notes that routine flaring burns natural gas as a waste product, emitting a host of climate and health-harming pollutants. They add that flaring also wastes money, companies operating on federal and tribal lands waste approximately \$330 million each year through leaks, venting and flaring.

Commenter (0920-WAEJ) urges EPA to end venting and routine flaring and ensure there is proper enforcement to guarantee unlit flares are not venting methane. The commenter supports EPA's intention to regulate this significant source of methane under the CAA for the first time because doing so will prevent fugitive methane emissions and dangerous co-pollutants such as polycyclic aromatic hydrocarbons, carbon monoxide, nitrogen oxides, heavy metals, and black

---

<sup>21</sup> See for instance, multiple stories over just a few months in 2021, such as <https://www.youtube.com/watch?v=JgK7O4UgoEI>, <https://abc7news.com/richmond-chevron-flaring-black-smoke-refinery/10943396/>, <https://richmondconfidential.org/2021/10/29/richmond-chevron-refinery-flaring/>.

<sup>23</sup> Lara J Cushing et al 2021. Up in smoke: characterizing the population exposed to flaring from unconventional oil and gas development in the contiguous US. *Environ. Res. Lett.* 16 034032. <https://iopscience.iop.org/article/10.1088/1748-9326/abd3d4>.

<sup>24</sup> <https://news.usc.edu/183286/americans-oil-gas-flaring-health-risks-usc-research/>.

carbon. The commenter notes that these pollutants lead to adverse health impacts that unduly burden environmental justice communities.

The commenter (0920-WAEJ) urges EPA to reconsider their November 2021 Proposal on how to utilize gas that would otherwise be vented as it could lead to added environmental and health burdens for frontline communities. The commenter recommends weighing the benefits of requiring producers to capture gas for on-site power or other useful purposes or routing it to a flare or control devices with the potential climate and environmental justice impacts of these mitigation measures.

Commenter (0958-CCB) recommends that EPA ban routine flaring at all oil and gas sites. The commenter notes that in addition to contributing to methane emissions, flaring exposes worker and surrounding communities to VOCs, polycyclic aromatic hydrocarbons, carbon monoxide, toxic heavy metals, soot, benzene and formaldehyde, posing serious health harms.

Commenter (0437-NYOSC) notes that in prior outreach to EPA on this matter, the New York State Common Retirement Fund and other investors have called for the elimination of venting and minimization of flaring. The commenter believes that the proposed rule only partially meets expectations for a robust rule that fully addresses methane emissions. The commenter urges EPA to end the practice of routine natural gas flaring. Natural gas flaring produces GHG emissions and waste a potentially saleable product which could otherwise be captured. The commenter notes that a growing number of companies have voluntarily committed to ending routine flaring and recommends that EPA require an end to this harmful and wasteful practice.<sup>25</sup>

Commenter (0435-Wespath Benefits and Investments) urges the EPA to set a near-term end date for operators to cease routine flaring of natural gas at oil and gas facilities, as states like Colorado and New Mexico have already done.

Commenter (0757-PESP, 1282-Earthworks) believes that EPA's November 2021 Proposal does not go far enough to address pollution from flaring. The commenters assert that EPA's final rule must prohibit the practice of routine flaring at oil and gas sites. The commenters state that when companies rush to extract oil, some forgo investments necessary to capture and sell gas and instead burn it as a waste product, emitting a host of climate and health-harming pollutants. Flaring is a wasteful practice and a large source of methane, carbon dioxide, nitrogen oxides, VOCs, and HAPs. Capturing natural gas that would otherwise be vented or flared reduces significant amounts of pollution and even generates revenue for operators. The commenters assert that EPA must eliminate flaring except in emergency situations.

Commenter (0578-GCT, 0812-OFU *et al.*, 0948-Quirk, 1423-Beyer *et al.*, 1434-Heinrich *et al.*) urges EPA to adopt final federal rules to cut methane by prohibiting routine venting and flaring, following the example of Alaska, Colorado, and New Mexico. Commenters (0723-Ceres, 0788-350Seattle, 0841-RMCG-Navajo, 0937-Fort Berthold POWER, 0941-350Silicon Valley, 1330-Catskill Mountainkeeper) recommend that EPA end routine flaring at oil and gas facilities, as

---

<sup>25</sup> Hampton, Liz, "U.S. Shale Producer APA ends Flaring, Captures More Gas as Prices Soar," Reuters, October 11, 2021. Available at: <https://www.reuters.com/business/energy/us-shale-producer-apa-ends-flaring-captures-more-gas-prices-soar-2021-10-11/>.

states like Colorado and New Mexico have done. Commenter (0723-Ceres) states that EPA must ensure that flaring only occurs in emergency situations. The commenter notes that capturing gas that would otherwise be flared or vented would generate revenue for operators. Commenter (0841-RMCG-Navajo) reports that flares commonly malfunction and spew methane directly into the atmosphere.

Similarly, commenter (1302-WYOC/PRBRC) recommends that in future rules EPA ban routine flaring at oil and gas sites, following the lead of states like Colorado and New Mexico. The commenter asserts that when companies develop oil and gas resources, they often forgo investments necessary to capture and sell gas and instead vent or flare it as a waste product. Companies may also choose to flare gas when prices are low, as it may be more economically expedient to simply flare the gas than to pay for transport. The commenter states that gas flares emit a host of climate and health-harming pollutants, and many have been found to malfunction or fail entirely, spewing methane directly into the atmosphere. The commenter notes that the practice of routine flaring represents a significant loss of revenue as well as operators are not required to pay royalties on the valuable natural resource, meaning that states and land managers lose out on important revenues. According to the commenter, this is particularly damaging for Wyoming, which relies heavily on fossil fuel royalties to fund the budget. The commenter recognizes that there are emergency situations where flaring is needed, however, oil and gas operators should not be allowed to flare simply when it is economically convenient for them.

Commenter (0941-350 Silicon Valley) asserts that EPA must ban routine flaring at oil and gas facilities, as states like Colorado and New Mexico have done already, and as the European Union recently proposed to do. The commenter states that the wasteful and dangerous practice of routine gas flaring in the industry must be halted. Frequently flaring is incomplete, resulting in substantial amounts of methane emissions, sometimes in combination with gases having even greater global warming potentials, such as black carbon and nitrous oxide, and frequently with harmful amounts of criteria pollutants such as benzene and SO<sub>2</sub>. Even when routine flaring combustion is complete it is still undesirable because it is a significant source of carbon dioxide emissions.

The commenter states that banning routine flaring is crucial for eliminating the methane emissions that often accompany excessive flaring.<sup>26</sup>

Commenter (1270-LWVUS) recommends that EPA prohibit all non-emergency flaring. The commenter states that there is an urgent need for detailed consideration of problems related to the extensive use of flaring, both at well sites and downstream. The commenter explains that while flaring is preferable to emissions of methane, it is currently overused, and the flaring process is inadequately controlled. The commenter notes that this will likely necessitate financial support for a significant portion of smaller oil and gas producers.

Commenter (1270-LWVUS) provides the following information on flaring. Drilling, extraction, storage and processing of gas and oil all may be accompanied by bursts of natural gas being released to the air. Such venting operations result in large emissions of methane. Flaring these vented streams can reduce methane emissions but is not a generally acceptable approach. At its

---

<sup>26</sup> Permian Methane Analysis Project, EDF.

best it wastes a valuable resource, generates CO<sub>2</sub> without producing anything of value, and generates soot, which contains large amounts of polyaromatic hydrocarbons that are toxic, carcinogenic and also potent global warming agents.

The commenter (1270-LWVUS) explains that flares operating at optimum efficiency should completely burn more than 99 percent of natural gas emissions according to a report from the International Energy Agency (IEA).<sup>27</sup> However, as wells start to operate at less than maximum flow, the flare performance is more strongly affected by environmental conditions such as windspeed. With very high winds the flares may even be blown out. Failure to maintain the flares in proper working condition can also decrease combustion levels and contribute to the likelihood of the flame being extinguished.

The commenter (1270-LWVUS) adds that the IEA study estimates the average worldwide efficiency for flares to be about 92 percent. Most flaring in the U.S. occurs at oil and gas basins that do not have options to export natural gas. According to the commenter, it would be better to capture the gas and transport it to markets, use it on site to supply heat or electrical generation, or convert it to products such as methane or LNG that can be shipped out in trucks. For large scale producers of gas and oil, these efforts to monetize this now-wasted gas should result in a significant net benefit. The commenter notes that some major companies have, in fact, begun to take such steps on a voluntary basis.<sup>28</sup>

For small companies, the commenter (1270-LWVUS) informs that the monetization of the lost gas will not offset the cost of implementing appropriate ways to market it. The commenter suggests that if these companies are required to pay for the methane they are emitting, it seems likely they will turn to flaring. At smaller companies, which often have older equipment and lower throughput to the flare, the commenter suggests it seems likely that the problems associated with all flaring equipment will be exacerbated.

The commenter (1270-LWVUS) states that the IEA has suggested that all but emergency flaring be prohibited at all wellsite facilities (as well as at the downstream facilities that will be covered in future regulations). They suggest that funding be supplied as appropriate to help smaller facilities make the necessary investments. Unless all non-emergency flaring is ended worldwide by 2030, the IEA says, the U.S. will be unable to meet the goals laid out in its Net Zero by 2050 road map. The commenter notes that it seems likely that many countries will fail to meet this goal, but the U.S. can and should meet it.

Commenter (0578-GCT) states that flares are prone to malfunctioning, or being left unlit, and as a result using flaring to dispose of associated gas produces significant flaring emissions. The commenter reports that a recent study by EDF estimates 75,000 metric tons of methane emissions were released from properly functioning flares, 30,000 metric tons from malfunctioning flares, and 200,000 metric tons from unlit flares in the Permian Basin.<sup>29</sup> The commenter informs that the study is limited in that it was only conducted in the Permian Basin. But the commenter asserts that, given the equipment used in the Permian Basin is not unique

---

<sup>27</sup> <https://www.iea.org/reports/flaring-emissions>.

<sup>28</sup> <https://www.whitehouse.gov/briefing-room/statements-releases/2021/03/31/fact-sheet-the-american-jobs-plan/>.

<sup>29</sup> EDF. Flaring Aerial Survey Results. Available at: <https://www.permianmap.org/flaringemissions/>.

across the oil and gas industry and oil and gas operations are found across the U.S., including the Colorado Plateau, there is grounds to assume that hundreds of thousands of metric tons of methane are likely emitted on the Colorado Plateau and across other areas of the U.S. each year without knowledge of surrounding communities.

The commenter (0578-GCT) notes that EPA estimates that functioning flares have 98 percent flaring efficiency rate based on a study conducted by EDF,<sup>30</sup> but the commenter states that the EDF's study found that flare malfunctions ranged from 3.3 percent to 11.5 percent at a random survey of routine flaring sites in the Permian Basin.<sup>31</sup> The study also found that 5 percent of flares were not fully lit and were failing to properly combust methane, and an additional 5 percent were unlit and directly venting methane.<sup>32</sup> Nearly 57 percent of these flares had multiple malfunctions.<sup>33</sup> The study goes on to state that "At this rate, flaring can now be considered one of the largest sources of methane emissions in the Permian Basin."<sup>34</sup>

Commenter (1267-CA AG *et al.*) contends that the EPA has underestimated HAP emissions from the oil and natural gas sector by relying on the National Emissions Inventory (NEI) to estimate emissions for rulemakings generally.<sup>35</sup> The 2017 Emission Inventory is based on emissions data reported to EPA by state and local agencies. However, the commenter suggests that this emissions data is often underreported for various reasons. For example, they explain that emissions from flares are commonly reported based on an assumption that flares operate at 98 percent destruction efficiency. The commenter explains that this means that operators reporting emissions from flares assume that 98 percent of the VOCs, methane, and HAPs being routed to the flare are combusted and converted into carbon dioxide. However, the commenter states that, in many instances, flares are operating at much lower destruction efficiencies or are unlit and are not operating at all. The commenter reports that seven random studies of routine flaring oil and natural gas sites found flare malfunctions ranged from 3.3 percent to 11.5 percent.<sup>36</sup> When expanded to all wells—the sites including lower-production, "marginal wells" – flare malfunctions jumped from 29 percent to 36 percent.<sup>37</sup> The commenter adds that a repeat study covering 200 square kilometers found that many malfunctioning flares failed more than once during a week; about one quarter of malfunctioning flares had problems on all three days of the study and over half of malfunctioning flares had problems on two days of the study.<sup>38</sup> In those situations, assuming a 98 percent destruction efficiency underestimates the actual emissions. The

<sup>38</sup> Id. at 8.

commenter states that a reduced destruction efficiency from 98 percent to 97 percent results in a 50 percent increase in emissions. A reduced destruction efficiency from 98 percent to 90 percent results in a 500 percent increase in emissions. The commenter adds that, if the flare is completely unlit, the resulting increase in emissions is 5000 percent. Based on the prevalence of malfunction and unlit flares, the commenter reports that the study concludes that actual emissions from flares are 3.5 times higher than reported.<sup>39</sup>

Commenter (0795-ALN *et al.*) provides that a ban on flaring is feasible and viable. The commenter notes that flaring of associated gas is a widely used practice for disposing of methane that comes to the surface where infrastructure is not in place to capture and transport it, resulting in the gas being burned off as waste. The commenter states that the practice is particularly common at oil wells, which may not bother to build infrastructure to capture gas. The commenter notes that the boom in domestic oil production enabled by fracking caused natural gas flaring to proliferate; in the Eagle Ford Shale region of south Texas, for example, from 2012 to 2016, 82 percent of flares were linked to oil wells, and nine out of ten were fracking wells.<sup>40</sup>

The commenter (0795-ALN *et al.*) notes that gas flaring contributes to climate change. A 2017 study of emissions from gas flares in North Dakota found that incomplete combustion from flaring was responsible for 20 percent of the total emissions of methane and ethane from the Bakken shale fields.<sup>41</sup> (Ethane is a very short-lived greenhouse gas, staying in the atmosphere only a matter of months.) The commenter asserts that these emissions are a significant problem, given that a 2020 study ranked the U.S. as one of the world's top nations for flaring.<sup>42</sup> The commenter states that while gas flaring across major U.S. oil basins dipped to a multi-year low during 2020 perhaps as a result of the Covid-19 pandemic,<sup>43</sup> it may be expected to pick up as the industry rebounds.

Besides contributing to climate change, the commenter (0795-ALN *et al.*) asserts that flaring also generates pollution that can have direct effects on the health of those working in or living near oil and gas operations. The commenter reports that air pollutants from flaring operations include VOCs, polycyclic aromatic hydrocarbons, carbon monoxide, toxic heavy metals and soot and include several carcinogens, notably benzene and formaldehyde. They add that a study of flaring in the Eagle Ford Shale showed flaring to be the dominant source of exposure to nitrogen oxide air pollutants in an otherwise rural area, thus creating respiratory health risks.

The commenter (0795-ALN *et al.*) reports other health impacts associated with gas flaring include greater risk of preterm birth and problems associated with sleep disruption. A 2020 study

<sup>42</sup> Roest, G. S., & Schade, G. W. (2020). Air quality measurements in the western Eagle Ford Shale. *Elementa Science of the Anthropocene*, 8(1), 18. doi: <http://doi.org/10.1525/elementa.414>.

<sup>43</sup> Rystad Energy. (December 2020) Permian, Bakken gas flaring falls to multi-year lows, satellite data shows. <https://www.rystadenergy.com/newsevents/news/newsletters/UsArchive/shale-newsletter-december-2020/>.

of pregnant women living in the Eagle Ford Shale area of Texas found that exposure to oil and gas flaring was associated with a 50 percent increase in the risk of preterm birth.<sup>44</sup> Preterm birth is a leading contributor in the United States to infant death. Gas flaring, along with the intense artificial lighting used during round the-clock drilling and fracking operations, contributes to increased light pollution in rural areas. A 2021 study found that residents exposed to light pollution from oil and gas operations experienced increased levels of insufficient sleep.<sup>45</sup> Light pollution has long been linked to disruptions in melatonin levels and circadian rhythm, associated with depression, sleeping disorders, metabolic disease and cancer.<sup>46</sup>

However, the commenter (0795-ALN *et al.*) states that the experience of three oil- and gas-producing states indicates that the industry can drastically curtail flaring. The Alaska Oil and Gas Conservation Act prohibits waste of oil and natural gas, including the burning of from an oil or gas well, unless authorized by the Alaska Oil and Gas Conservation Commission or in the case of emergency or system testing.<sup>47</sup> Colorado adopted a ban on routine flaring of gas in November 2020, authorizing only a limited option to flare under special conditions, with the approval of the Colorado Oil and Gas Conservation Commission and not for longer than 24 hours.<sup>48</sup> And just months later, in March 2021, the New Mexico Oil Conservation Commission finalized rules to eliminate venting and flaring at new and existing wells by April 2022<sup>49</sup>.

Commenter (0589-NEI) states that eliminating the practice of routine flaring is a low hanging fruit that has significant potential to reduce emissions. The commenter notes that leading companies have already committed to ending the practice of routine flaring (*e.g.*, Apache, EOG and others) and several states and competing jurisdictions (*e.g.*, Alberta) are working towards the same goal. The commenter adds that the World Bank's Zero Routine Flaring by 2030 initiative, and the support it has from industry, shows the appetite this measure already has in the marketplace.

Commenter (1423-Beyer *et al.*) refers to EPA's reporting that flaring frequently occurs in routine, nonemergency situations or is used to bypass pollution control equipment, producing unacceptably high releases of sulfur dioxide and other pollutants including uncombusted

methane.<sup>50</sup> The commenter notes the World Bank’s Zero Routine Flaring by 2030 Initiative has estimated that flaring results in more than 400 million tons of CO<sub>2e</sub> emissions every year and wastes a valuable resource.<sup>51</sup>

Commenter (0927-ICCR) urges EPA to develop a rule to end routine flaring by 2025. The commenter notes that flaring reduction has been a priority ask from investors in dialogues as well as in resolutions filed with companies in recent years.<sup>52</sup> The commenter states that well-managed companies with whom investors have engaged have adopted commitments to ensure gathering operations are in place before they start drilling, obviating the need for routine flaring. With a wide range of operators – including from historically high-flaring basins such as the Bakken<sup>53</sup> and the Permian<sup>54</sup> – committing to eliminate routine flaring by 2025 or sooner, is clear that this goal is achievable for all. However, the commenter believes that a regulatory floor is needed to manage routine flaring, given its prevalence in basins like the Permian and the unacceptable level of methane emissions from unlit or malfunctioning flares revealed by studies.<sup>55</sup>

Commenter (1297-Lopez *et al.*) calls on EPA to end routine flaring by 2025 either as part of this proposal or as part of a future supplemental rule. The commenter notes that many leading oil and gas companies have announced plans to end routine flaring by 2025 and believes this is a reasonable timeline.

Commenter (0326-Lonqueux) urges EPA to phase out flaring if, as asserted by the November 2021 Proposal, the sustainable solution to GHG emissions is to “incentivize or require the sale or productive use instead of flaring.” The commenter notes that by prohibiting venting, operators must decide whether to invest in flaring equipment or to sell the unwanted gas that was captured from oil wells. The installation of a sales line presents significant uncertainties and costs for producers—access to pipelines, cost of capital, unstable natural gas prices, and cost of operations. The commenter notes that there is a risk that operators without a gas flare will be more inclined to install one if this proposal is passed and those already equipped will continue

<sup>56</sup> Permian Map Analysis, <https://data.permianmap.org/pages/flaring>.

business as usual. Increased routine flaring is a problem because it is inefficient in fulfilling the proposed rule's goals.

Commenter (0734-ATS) notes that shale fracking has become a primary production method of oil and natural gas, and along with it, flaring of associated gas has proliferated.<sup>56</sup> The commenter reports recent findings that indicate that flaring contributes to 0.12 percent of global total disability-adjusted life years (DALYs) attributable to PM2.5 air pollution and 6.51 percent of total DALYs attributable to climate change.<sup>57</sup>

Response I-5-10: See discussion in section IV.H.2 of the December 2022 Supplemental Proposal and section X.H of the preamble to the final rule related to combustion control devices. See discussion in sections IV.F.2.a.ii and IV.F.2.a.iii. of the December 2022 Supplemental Proposal and section X.F.2 of the preamble to the final rule related to flaring of associated gas.<sup>58</sup> Also, see Volume I, Chapter 17, and Volume II, Chapter 6, for more information related to flaring of associated gas.

EPA notes that owners and operators are allowed to use flares as a control device to meet the emission standard for affected facilities in NSPS OOOOb and EG OOOOc. However, owners and operators must meet the monitoring, recordkeeping, and reporting requirements for flares in NSPS OOOOb and EG OOOOc.

Comments on the Nation Emissions Inventory are outside the scope of this rulemaking. However, EPA is finalizing requirements in NSPS OOOOb and EG OOOOc to ensure that owners and operators who use a flare as a control device on an affected facility monitor the flare to ensure the flare continuously achieves the required emission standard.

### ***5.1.5 Propane Fuel Fed Pilot Flares***

Comment: Commenter (0431-NuEnergy) states that if EPA's goal is to reduce the amount of hydrocarbons that are burned it doesn't make sense to use a propane fed flare with a thermo coupler to burn a very small amount of residual methane from such sources as an oil tank. The commenter asserts that is counterintuitive because in many cases more propane than residual methane would burn. The commenter suggests there needs to be a limit for residual methane in a propane fed flare. The commenter states that aggregate emissions would likely be greater than simply venting or sending emissions to a flare without the extra propane that feeds to a flare.

Commenter (0598-Countrymark) notes that they have provided feedback to EPA multiple times that the requirement to fuel a continuous pilot with supplemental propane increases operating costs and emissions. The commenter states that the wells in the Illinois Basin produce such a low

<sup>58</sup> 87 FR 74779, 74780, and 74792 (December 6, 2022).

volume of gas that the propane used for the pilot light generates more emissions than might be possible without the continuous pilot light.

Response I-5-11: EPA notes that it is not mandating the use of flares in NSPS OOOOb or EG OOOOc. Flares are a control option for various affected facilities within the rule, but other control options such as carbon beds or condensers can also be used in low flow situations where a flare may not be viable, as long as the control device is capable of achieving the level of control specified in the rule.

See Volume II, Chapter 17, Section 17.1.1, for responses to comments on the requirement for a continuous burning pilot flame. See Volume I, Chapter 9, and Volume II, Chapter 13, for responses related to comments on storage vessels.

### ***5.1.6 Flare Design, Operation and Monitoring Requirements***

Comment: Commenter (0742-ADEC) does not see a need for any additional flare monitoring, recordkeeping or reporting that may conflict with already existing requirements. The commenter notes that all flares already operate with a design destruction efficiency of 95 percent or greater. The commenter explains that flares at oil and gas production facilities are primarily safety devices and are regulated by the Alaska Oil and Gas Conservation Commission (AOGCC), who permits and authorizes routine or non-routine flaring for other than safety reasons. AOGCC rules (20 AAC 25.235) already require strict monitoring and accounting of flaring activity to minimize waste of the resource. The commenter provides that improved efficiency and flare performance is provided by flare thermal pilot safety devices and/or flare monitoring cameras maintained by the production center operator.

The commenter (0742-ADEC) supports the continued use of 40 CFR §60.18 requirements and monitoring to demonstrate 98 percent destruction efficiency for flares and vendor information for other control devices. The commenter's authorization mechanisms for flares closely match 40 CFR §60.18 requirements and changing the representable destruction efficiencies of flares used in this NSPS will create a disconnect between the new NSPS, existing NSPS, and state authorization mechanisms. For other control devices, the commenter has the same concern about overlap. The commenter points to the 2016 EPA-453/B-16 publication "Control Techniques Guidelines for the Oil and Natural Gas Industry", which discusses the use of flares and other control devices.

Response I-5-12: See discussion in section IV.H.2 of the December 2022 Supplemental Proposal related to combustion control devices.<sup>59</sup>

Comment: Several commenters (0326-Lonqueux, 0723-Ceres, 0757-PESP, 0828-UCS, 0843-EIP, 1282-Earthworks) recommend that EPA ensure the proper operation of flares by frequent inspections and other monitoring requirements (with required repair provisions to return flares to proper operation when issues discovered). Some of the specific comments provided are included in the following paragraphs.

---

<sup>59</sup> 87 FR 74792 (December 6, 2022).

Commenters (0757-PESP, 1282-Earthworks) assert that EPA must ensure flares are operating properly and are frequently inspected to ensure they are lit and operating at a maximum efficiency.

Similarly, commenter (0723-Ceres) urges EPA to ensure strong methane emission performance standards by ensuring that flares are operating properly and frequently inspected.

Commenter (0828-UCS) asserts that because flares frequently malfunction, resulting in significant methane emissions due to either becoming unlit or operating at reduced efficiency, EPA must require that in the rare instances where flaring is permitted, monitoring is frequent, and repairs are rapid.

Commenter (0326-Lonqueux) recommends that EPA define an industry standard for the design, operation, and monitoring of flaring devices to limit malfunction, because the presence of undetected dysfunctional flares results in a failure to prevent the release of uncombusted methane into the atmosphere.

Commenter (0843-EIP) requests that EPA establish continuous monitoring requirements for flares. The commenter states that the EPA notes that numerous stakeholders raised concerns that control efficiency of flaring achieved in practice falls below required thresholds. In part to address these concerns, EPA clarifies that the Proposed Rule “would require that when using a flare, the flare must meet the requirements in 40 CFR 60.18 and that monitoring, recordkeeping, and reporting be conducted to ensure that the flare is constantly achieving the required 95 percent reduction.” However, the commenter notes that Subpart A does not actually contain any monitoring requirements that would assure flares are achieving a 95 percent reduction efficiency, and that it is EPA’s obligation to establish these monitoring requirements in Subpart OOOO itself.

Response I-5-13: See discussion in section IV.H.2 of the December 2022 Supplemental Proposal and section X.H of the preamble to the final rule related to requirements for combustion control devices.<sup>60</sup>

Comment: Commenter (0558- Center for Climate and Energy Solutions (C2ES)) suggests that EPA require operators to conduct regular flare combustion efficiency training. The commenter states that if flaring cannot be avoided, operators need to maintain efficient flaring operations to minimize methane emissions. The commenter notes that in the case of flares that combust large volumes of gas, they are often designed with air- or steam-assisted devices that can be optimized to achieve near complete (greater than 98 percent) combustion. This optimization requires increasing the flow of air or steam into the combustion zone of the flare to provide extra oxygen and reduce smoke formation. The commenter contends that although maintaining the efficiency of flare combustion might be challenging if the waste gases have relatively low heating value, monitored and skilled operation can achieve optimum rates that maximize combustion and minimize smoke.

Response I-5-14: EPA is not requiring operators to attend regular flare combustion efficiency training. However, we have added requirements for flares that will ensure they are operated

---

<sup>60</sup> 87 FR 74792 (December 6, 2022).

properly and maintain a minimum combustion efficiency. See discussion in section IV.H.2 of the December 2022 Supplemental Proposal<sup>61</sup> and section X.H of the preamble to the final rule related to requirements for combustion control devices.

Comment: Commenter (0843-EIP) contends that EPA is obligated, pursuant to these regulations, to establish continuous monitoring requirements to ensure control devices are operated and maintained in conformance with their designs to ensure compliance. The commenter states that the proposed current approach of leaving it to the permitting authorities to establish monitoring requirements on a piecemeal, permit-by-permit basis makes little sense. They add that leaving it up to state permitting authorities has not worked. For example, in Texas, the commenter reports that the EPA has determined that the most commonly used permits at oil and gas facilities – minor new source review “Permits-by-Rule” – fail to contain adequate monitoring. These permits are available, and widely used, to authorize emissions even at major Title V and New Source Review (NSR) sources.

The commenter (0843-EIP) notes that, and EPA acknowledges, the Agency’s Office of the Inspector General (OIG) found similar issues in its review of numerous permits issued in Colorado and Oklahoma, and its July 8, 2021, report found that “State permitting authorities had difficulty verifying continuous compliance with combustion efficiency requirements for flares and enclosed combustors” and “recommended that the EPA explore additional means to verify continuous compliance in NSPS OOOO and NSPS OOOOa that would provide additional tools for State agencies to properly permit and enforce combustion efficiency.” The OIG Report noted that in the 16 natural gas extraction industry synthetic-minor-source permits it reviewed, 26 permit limits “did not specify a method for determining compliance” while another 55 limits “lacked sufficient direct testing or parametric monitoring to assure that the assumed control efficiency of control devices was being met.” OIG Report at 12-13. The OIG Report also noted that EPA “conducts minimal oversight” of synthetic-minor-source permits and “does not assess whether state and local agencies have developed permit limits in accordance” with EPA’s issued guidance regarding practical enforceability. *Id.* at 6; see also *id.* At 8 (“Neither EPA headquarters nor regional offices conduct regular or routine evaluations or review synthetic-minor-source permits and the limitations adopted by facilities to avoid major source status.”).

The commenter (0843-EIP) provides that the EPA notes that the current standards “require owners and operators to perform an initial demonstration of compliance for all control devices used to meet the standards in the rule and require monthly EPA Method 22 observations to demonstrate continuous compliance with visible emission requirements, in addition to monitoring for the presence of a pilot light.” However, the commenter notes that visible emissions requirement in 40 C.F.R. § 60.18, which prohibits visible emissions from flares for periods longer than five minutes in any consecutive two-hour period, is intended in large part to prevent flares from smoking (which releases soot and black carbon) and does not constitute an adequate means of continuously assuring that flares are meeting their required destruction efficiency. This is especially the case since Method 22 (and Method 9, which Method 22 is based upon) is limited to the observation of “visible” emissions during daylight hours and even then,

---

<sup>61</sup> 87 FR 74792 (December 6, 2022).

only under certain weather conditions.<sup>62</sup> The OIG’s Report itself noted that most of the applicable permits it reviewed also “included requirements to periodically verify that a pilot light was operating and to check for visible emissions,” OIG Report at 14, as currently required by 40 C.F.R. § 60.18 and Subpart OOOO. As the Report states, however, “these are not parametric measures that accurately show what control efficiency the device is actually achieving” and “do not assure that the device is continuously meeting its assumed control efficiency of 95 percent.” Id. At 14.<sup>63</sup>

Response I-5-15: See discussion in section IV.H.2 of the December 2022 Supplemental Proposal related to requirements for combustion control devices.<sup>64</sup>

Comment: Commenter (0843-EIP) recommends that, in the final rule, EPA first determine whether Subpart A performance standards are appropriate for NSPS OOOO flares, or whether more specific standards are needed to assure that NSPS OOOO flares achieve at least 98 percent destruction efficiency. If EPA determines that Subpart A should continue to apply, the commenter asserts that EPA must identify the appropriate monitoring methods intended to ensure compliance as discussed above. If EPA selects different performance standards needed to achieve 98 percent efficiency, the commenter asserts that EPA must identify the monitoring needed to assure compliance with those performance standards. The commenter recommends that the final rule clarify whether EPA has evaluated methods (including operating parameters) that can be used to determine whether flare smoking can be identified after nightfall, when it rains, or under other adverse conditions. For example, the commenter notes that the Proposed Rule states that one OGI expert “noted seeing many flares that were not operating the way they were intended to and that were not adequately designed” and suggested EPA consider using a combination of OGI in conjunction with fugitive emissions monitoring to make sure controls are working. The commenters agree that EPA should consider this route, as well as require video surveillance of flares, which would capture and record any smoking incidents and be a more effective way to identify violations and motivate compliance.<sup>65</sup>

Commenter (0843-EIP) agrees that a 98 percent control efficiency for flares is achievable by design and supports EPA’s November 2021 Proposal to set this higher standard. However, the commenter reiterates that an increased standard of performance is meaningless without the monitoring measures necessary to ensure a 98 percent standard is being met on a continuous basis (let alone the current 95 percent standard). As discussed, the commenter states that EPA is

---

<sup>62</sup> See generally EPA Method 22, [https://www.epa.gov/sites/default/files/2019-08/documents/method\\_22\\_0.pdf](https://www.epa.gov/sites/default/files/2019-08/documents/method_22_0.pdf); EPA Method 9, [https://www.epa.gov/sites/default/files/2017-08/documents/method\\_9.pdf](https://www.epa.gov/sites/default/files/2017-08/documents/method_9.pdf).

<sup>63</sup> See also id. at 19 (“EPA has not presented adequate technical information to assure that permitting authorities can continuously verify compliance with ECD-related emission limitations. As noted in our report, verifying that the pilot light is operating and checking ECDs periodically for visible emissions are not compliance actions that accurately demonstrate the assumed control efficiency is being met on a continuous basis. In addition, monitoring the flow rate does not guarantee the assumed control efficiency is being met.”)

<sup>64</sup> 87 FR 74792 (December 6, 2022).

<sup>65</sup> This issue is of particular importance because studies on the effects of visible emissions from flares have shown that they disproportionate impact on historically socioeconomically disadvantaged and vulnerable populations. See, e.g., Lara J. Cushing et al., “Up in smoke: characterizing the population exposed to flaring from unconventional oil and gas development in the contiguous US.” 2021 Environ. Res. Lett. 16 034032. Accessible at: <https://iopscience.iop.org/article/10.1088/1748-9326/abd3d4>.

obligated to establish monitoring requirements by its own regulations, and evidence from the field demonstrates that leaving it up to state permitting authorities has not been effective.

Response I-5-16: See discussion in section IV.H.2 of the December 2022 Supplemental Proposal related to requirements for combustion control devices.<sup>66</sup> Additionally, see discussion in section XI.H.2 of the preamble to the final rule related to requirements for monitoring combustion control devices with OGI cameras. See discussion in Volume II, Chapter 17, Section 17.1.3 on use of video cameras for visible emissions monitoring.

Comment: Commenter (0843-EIP) provides details on the level of performance being achieved in practice by flares in the field.

The commenter (0843-EIP) points to ambient monitoring data from the Texas portion of the Permian Basin, which indicate that flares claiming 98 percent destruction efficiency are not achieving that level of performance. Much of the Permian Basin contains very sour gas high in hydrogen sulfide, one of the main reasons that flares are supposed to achieve a 98 percent destruction efficiency. Hydrogen sulfide and sulfur dioxide emissions data are informative and indicate that flares fail to perform as claimed. Texas Permian Basin operators reported more upsets (or “Emission Events” as defined in the Texas State Implementation Plan) than any other TCEQ region, with reported values based largely on oil and gas sources’ assumed 98 percent flare destruction. Flares convert hydrogen sulfide to sulfur dioxide, and so properly functioning Permian Basin flares are expected to release significant SO<sub>2</sub>. Newly installed ambient monitors near Odessa (Ector County) Texas reveal substantially more ambient hydrogen sulfide (and less ambient SO<sub>2</sub>) than expected, indicating that these flares are not performing as claimed.

The commenter (0843-EIP) provides tables that summarize publicly available monitoring data from TCEQ showing ambient hourly hydrogen sulfide (H<sub>2</sub>S) levels in Ector County, Texas. [Table: Goldsmith Monitor Data – 20 Highest Hourly, and Table: West Odessa H<sub>2</sub>S Monitor Data – 20 Highest Hourly presents Date, Time and H<sub>2</sub>S (ppb) data] The hydrogen sulfide levels are higher than the levels that would be expected based on all reported emissions. The commenter suggests that this is likely due in part to un-combusted gas. If flares in this region were performing as claimed, the commenter believes there would be higher recorded ambient SO<sub>2</sub> and lower recorded ambient H<sub>2</sub>S. Instead, the commenter states that the TCEQ’s monitors show dangerously high H<sub>2</sub>S levels, well above the state’s nuisance-based clean air standard of 80 parts per billion.

Response I-5-17: EPA acknowledges the information provided by the commenter.

Comment: Commenter (0843-EIP) supports EPA imposing a 98 percent standard for flares regulated under NSPS OOOO, as well as monitoring requirements to ensure that such flares actually meet the 98 percent standard on a continuous basis, similar to petroleum refinery sector standards. The commenter asserts that if EPA finalizes the rule to include heat pump and velocity as key monitoring parameters, continuous British thermal unit (Btu) meters and continuous velocity meters should also be required. The commenter notes that EPA recognizes technologies such as “digital pilot light monitors, combustion temperature, gas flow meters, gas

---

<sup>66</sup> 87 FR 74792 (December 6, 2022).

chromatography (GC) units, and passive remote monitoring of combustion efficiencies at the flare tip” have been used for flares controlling landfill gas.

Response I-5-18: See discussion in section IV.H.2 of the December 2022 Supplemental Proposal related to combustion control devices.<sup>67</sup>

Comment: Commenter (0756-Baker Hughes) believes that setting a minimum threshold is not feasible for unassisted flares because it is not possible to control combustion efficiency for unassisted flares. The commenter recommends that EPA require continuous monitoring, reporting and verification. Rather than basing reported emissions on assumptions (e.g., stack is designed to meet xx percent CE), the commenter recommends that reports should be based on real time monitoring. Also, with real time monitoring in place, the commenter believes that operators may find levers to improve the combustion efficiency – effective control depends on accurate measurement.

Response I-5-19: EPA received a similar comment on the December 2022 Supplemental Proposal. EPA’s response to this comment is provided in Volume II, Chapter 17.

#### ***5.1.7 Flare Technology Requirement Recommendations (Including Monitoring Technologies)***

Comment: Commenter (0558-C2ES) suggests that EPA require operators to use technologies that can help maintain the combustion of the flare and provide a back-up ignition in case of failure of a pilot light. The commenter notes that in the case of flares that handle small volumes of gas, they are often equipped with a pilot light that is used to maintain ignition of the flare flame. Most of the pilot lights currently used (e.g., thermocouples) suffer from weather-dependent malfunctions and intermittency problems.

Response I-5-20: See Volume II, Chapter 17, Section 17.1.1, for responses to comments on the requirement for a continuous burning pilot flame. At this time, EPA is not requiring the use of a backup ignition system for combustion control devices. However, it is prudent that operators be alerted promptly when flares are unlit, as unlit flares can be very large emission sources. As such, EPA has added language to the final rule to require an alert to the nearest control room whenever the pilot flame is extinguished.

Comment: Commenter (0756-Baker Hughes) provides that one of the key requirements for flare operation is to maintain net heating value of flare combustion zone gas (NHVcz) of approximately 270 Btu/scf minimum, typically measured by using a gas analyzer or calorimeter. The commenter’s experience is that those instruments are difficult to maintain. The commenter states that field data acquired using flare.IQ (discussed below) indicate that the NHV calculation coming from the sound speed computation method is a suitable alternative for flare gas NHV measurement. NHV from sound speed is within 3 percent when compared to measurements using a GC or a mass spectrometer.

---

<sup>67</sup> 87 FR 74792 (December 6, 2022).

Response I-5-21: EPA received a similar comment on the December 2022 Supplemental Proposal. EPA's response to this comment is provided in Volume II, Chapter 17.

Comment: Commenter (0570-Konica Minolta Sensing Americas, Inc.) provides technology information to improve performance and minimize malfunction of flares. The commenter states that there is a big difference in the images obtained by OGI cameras between efficient and inefficient combustion. The commenter points to images in their comment letter (images contained in comment letter include three efficient combustion images, and three incomplete combustion images). With efficient combustion, the commenter explains that the signal from the tip of the equipment stays around the equipment and does not travel far, indicating that the signal is primarily caused by heat or steam. With incomplete combustion, the commenter explains that the signal from the left combustor trails off the image due to the plume of unburned hydrocarbon gas extends downwind. The commenter notes that checking a flaring condition with an OGI camera can provide important clues to understanding the combustion state.

Response I-5-22: EPA agrees that OGI cameras can provide important information regarding the emissions from combustion control devices. See discussion in section XI.H.2 of the preamble to the final rule related to requirements for monitoring combustion control devices with OGI cameras.

Comment: Commenter (0756-Baker Hughes) recommends that EPA set the degree of emissions limitation achievable at 98 percent for assisted flares. The commenter notes that there are commercially available technologies, such as flare.IQ, that achieve a combustion efficiency of 98 percent, and has been installed by operators worldwide. The commenter recommends that EPA require continuous monitoring of combustion efficiency. The commenter notes that technology is currently available to cost-effectively monitor flare performance, such as flare.IQ. (The commenter references Attachment B of their comment letter: Appendix B: Specifications for Baker Hughes flareIQ. This Appendix includes additional information on Baker Hughes flareIQ regarding combustion efficiency and control). The commenter provides the following details on their technology in the body of their comment letter:

Flare.IQ provides the live molecular weight and heating value measurement for flare gas from an ultrasonic flowmeter, without any additional hardware. The technology also provides automatic monitoring of combustion efficiency and flare combustion control for assisted flares and has been used to reduce methane emissions at 130 upstream sites.

Commenters (0729-EWTC, 0756-Baker Hughes) state that flare.IQ was launched in 2017 with an emphasis on the North American market and regulatory compliance with the EPA Refinery Sector Rule 63.670. The commenters note that the technology is now available in all regions and covers oil and gas production facilities. Currently, there are approximately 51 installations worldwide and several pilots are underway in Brazil, Egypt, Russia, United Arab Emirates and Europe. For example, as noted above, significant field validation occurred in 2020 and 2021 when customers started to deploy flare.IQ technology to help better understand, measure and ultimately reduce methane emissions at 130 upstream sites.

Further, the commenters (0729-EWTC, 0756-Baker Hughes) note that it is critical to verify combustion efficiency in real-time because it can deviate for different flares and different plant operating conditions. The flare.IQ technology has a response time of six seconds for assisted flares and has been proven to achieve real-time control for assisted flares.

Response I-5-23: See discussion in section IV.H.2 of the December 2022 Supplemental Proposal related to combustion control devices.<sup>68</sup> See discussion in section XI.H.5 and XI.H.6 of the preamble to the final rule related to monitoring assisted combustion control devices and alternative monitoring of combustion control devices.

Comment: Commenter (1371-Frost Methane Labs (Frost)) thinks the cheapest way to reduce emissions from unlit or malfunctioning flares is via continuous visual and/or thermal monitoring. Since most oil and gas flares are open – a no-retrofit solution is to install an internet connected webcam directed towards the flare. Such a device would report data to a server, which would run a machine vision algorithm to determine whether the flare is lit, and to detect obvious malfunctions often indicated by black smoke. This system would automatically alert the operator to any major changes in flare conditions via email or text. To reduce false positive rates, a thermal camera could be attached to this in addition or instead of a visual camera. While less accurate, such a device is significantly lower cost than a camera that detects methane directly – whose costs start at \$50K per unit for just the hardware. The commenter estimates the cost of the full service of visual and thermal imaging, image detection and notification to the operator to be \$1k - \$5k per flare per year – depending on the volume of units in the area, specific characteristics required, length of time to store the data generated and other inspection features that might be useful. Such a service could alert an operator within 20 minutes of a flare issue and provide data on the malfunction from the images preceding the event. The commenter provides that their company can provide this hardware, software and service.

Statistics on flare malfunctions or blows out frequency are not available, nor are statistics on the duration of these outages. The commenter (1371-Frost) provides the following is a conservative estimate: there are daily site inspections, so a flare that blows out will take on average 12 hours to detect, and another 2 to relight. The flow of unlit methane vented over this time is assumed to be roughly constant. The proposed solution reduces detection time from 12 hours to 20 minutes, and the overall venting time from 14 hours to 2:20; this would reduce emissions from unlit flares by 83 percent. If inspections happen every 2 days, and a flare that is extinguished takes an average of 24 hours to be detected, the results are more dramatic with a 91 percent reduction in unlit flare emissions.

The commenter (1371-Frost) provides the following five alternatives for consideration.

Satellite imagery – Flares are visible from a variety of visual and mid wave infrared (MWIR) sources. A publicly available data source which can theoretically detect flare outages is VIIRS. The commenter believes (but are not experts in this field) that it can produce an image at most once a day, assuming there are no clouds. Since this monitoring would not require any onsite hardware, the cost of the system would only consist of software and could therefore be < \$500 / year/flare. In a hypothetical cloudless

---

<sup>68</sup> 87 FR 74792 (December 6, 2022).

environment, the average detection time of an unlit flare would be 12 hours. Assuming physical inspections by the operator occur once a day, if they were scheduled 12 hours offset from the satellite flyovers, the average detection time could be reduced to 6 hours. Given our previous assumptions of 2 hours relight time from detection, this would reduce emissions by 43 percent. If the area has frequent clouds, it could be many days between observations and the utility of this method is greatly diminished. There are also private satellites that can capture these images more frequently. However, the costs of tasking a satellite for this purpose are high. Most private satellite constellations are visual, and so would need higher resolution than the VIIRS dataset to be able to detect flare malfunctions. The commenter states that this is only financially feasible if a solution provider could show multiple flares in the same image, and the area is relatively cloud free.

**Methane camera** – The commenter states that a MWIR methane camera is the technically best solution to detect methane from unlit flares and other sources, as it observes the methane directly. However, Methane cameras hardware range from \$50-100K, and additional connectivity and software would be required. A question is whether these systems could come down in price if there was significant adoption, as bearing that cost per site may be very high. If a MWIR camera was shared between sites – a dedicated operator could drive the camera to multiple sites for inspection – the visit frequency would still likely not be more than twice a day and the cost of a dedicated operator is assumed to be an additional \$100k/year.

**Onsite methane ‘sniffer’ detector** – Methane detectors that work by detecting methane molecules that drift by them can be very good for detecting large onsite leaks. These devices are very low cost and can detect leaks from sources other than flares. However, since methane molecules generally rise, and flare tips are mounted relatively high, it is likely that ground-level sniffers will not detect flare outages. The commenter contends that this may be a good solution for some non-flare leak detection.

**Flare Mounted Internet Connected Thermocouple** – For new flares another option is an internet connected device with a thermocouple instead of a camera to measure flare temperature. Unlike the camera method, the device would need to be mounted near the flame itself. The device itself would be marginally cheaper but will not be able to catch incomplete combustion problems, only full flare outages and would not be able to provide imagery leading up to the outage.

**Increase frequency of human inspection of the flares** – Assume that an inspection will happen every 12 hours instead of 24, and that an operator can visit 3 flares in an hour, and costs 100K / year + 30K / year in fuel and vehicle expenses. The operator would visit 24 flares in an 8 hour shift. This would cost 180K / 24 sites = \$4.3k / site / year for a 43 percent reduction in unlit flare emissions. The commenter notes that this is a somewhat more expensive option than the proposed onsite solution of continuous visual and thermal camera monitoring for lower emission reduction results.

Response I-5-24: EPA acknowledges the different methodologies the commenter has submitted. EPA agrees that unlit flares are an issue in this sector. As such, EPA is finalizing a requirement that operators be alerted promptly when flares are unlit, as unlit flares can be very large emission sources, by requiring an alert to the nearest control room whenever the pilot flame is extinguished.

EPA agrees with the commenter that because flare tips are mounted relatively highly, it is unlikely that a handheld methane analyzer will be able to detect emissions from a flare.

See discussion in section XI.H.2 of the preamble to the final rule related to requirements for monitoring combustion control devices with OGI cameras and during audio, visual, and olfactory inspections. See discussion in Volume II, Chapter 17, Section 17.1.3 on use of video cameras for visible emissions monitoring.

EPA is not finalizing a requirement for owners and operators to review flare operation using satellite data, as we are finalizing more localized, site-level controls for these devices. See discussion in section IV.H.2 of the December 2022 Supplemental Proposal and section X.H of the preamble to the final rule related to combustion control devices.<sup>69</sup>

Comment: Commenter (0604-Providence Photonics, LLC (Providence)) provides the following comments on multiple aspects regarding control device efficiency and operation.

The commenter (0604-Providence) notes that, unlike most industrial processes, flares represent a process that occurs in the open atmosphere. As a result, flare control efficiency can be impacted by both process changes and environmental factors. Considering the potential methane emissions attributed to flaring, ensuring sufficient control efficiency across a wide range of process and environmental conditions is essential. Flare manufacturers and operators both have a role to play in ensuring that flares have a high control efficiency. A critical part of ensuring proper flaring is an accurate and affordable measurement technology that can provide both inspection and continuous monitoring. Although there are technical challenges related to flare measurement, there are cost effective technologies available to address these challenges. Some of these technologies are presented below.

Commenter (0604-Providence) provides details on available methods to demonstrate compliance with control efficiency standards. The commenter reports that in recent years there have been some breakthrough technological advancements in the field of measuring flare performance. These advancements provide options that were not available for previous regulatory cycles. Available methods to demonstrate compliance with control efficiency standards are listed in Exhibit 3 of their comment letter and discussed below. [Exhibit 3 of the commenter's letter is a Table, *Available Measures to Ensure that Flares Meet Control Efficiency Standard* includes the 4 Methods and their Implementation, Frequency/Mode of operation, Compliance Criteria, Cost, Maturity of Method, Additional Benefits, Incentives that EPA should provide, and Limitations.] Some of the methods discussed below are suitable for continuous monitoring, some are more suited to periodic inspection, and some can do both.

---

<sup>69</sup> 87 FR 74792 (December 6, 2022).

#### Method 1: Indirect monitoring.

The first method listed in Exhibit 3 is the same method EPA promulgated for refineries and ethylene plants. This method established a surrogate parameter (NHVcz/NHVdil) which can be continuously monitored to ensure proper control efficiency. It requires 7 inline instruments to be installed (4 for vent gas line and 3 for assist media line). In the upstream, the vent gas composition tends to be more consistent than those found in refineries and ethylene plants, so perhaps periodic gas composition analysis data could be used in lieu of an online GC, calorimeter, or MS. This would reduce the number of instruments required from 7 to 6. This method is the costliest due to the number of instruments required. The equipment must be installed in line with the process stream, so this method is only suited to continuous monitoring.

#### Method 2: Direct monitoring with VISR.

The second method listed in Exhibit 3 is the VISR method to directly monitor flare combustion efficiency (CE). In December 2019, the commenter submitted a comprehensive information package on the VISR method to another rulemaking docket, Docket EPA-HQ-OAR-2017-0357-0039. That submittal is also applicable to this rule, and the commenter is submitting the same package by reference.<sup>70</sup> The package includes background information on the VISR method, its validation, characterization of its accuracy and precision, and example applications in the field. This direct CE monitoring method is achieved with a single remote sensing device and has numerous benefits (as shown in Exhibit 1 of the commenter's submission [Exhibit 1 is an excel file graphing the OGI Operating Envelope equation for Methane and Butane]), including a lower cost than Method 1 (the method specified in 40 CFR 63 subparts CC and YY). Although it is cheaper than Method 1, the commenter states that it may still be too expensive for continuous monitoring on a single flare to be regulated by this proposed rule. The portability and ease of operation of this method makes it suitable for periodic compliance testing. Although not as effective as continuous compliance monitoring, periodic compliance testing is not uncommon in NSPS subparts for other source categories and in state/federal permits. Periodic compliance testing can be effective if the testing protocols are prescribed such that the testing conditions represent the worst-case operating conditions of the flare in question. It certainly can be used to establish a site-specific operating envelope for a flare – see more discussion on the fourth method later in this section. This can be a low-cost option for this source category when applied to periodic inspections.

#### Method 3: Direct monitoring with simplified VISR.

The third method in Exhibit 3 utilizes a simplified VISR instrument to monitor flare NHVcz/NHVdil, *i.e.*, the same surrogate as monitored by the first method already codified in 40 CFR 63 subpart CC and YY for refinery and ethylene production plants. Method 3 can be considered an alternative test method to measure NHVcz/NHVdil which will be an order of magnitude less expensive than the method specified in 40 CFR 63

---

<sup>70</sup> <https://www.regulations.gov/comment/EPA-HQ-OAR2017-0357-0039>.

(*i.e.*, Method 1). The remote device used in this method is a multi-spectral infrared imager, radiometrically calibrated and capable of measuring spectral radiances from the flame, which can be used to derive a signal (called Combustion Index) that is correlated to NHVcz/NHVdil. The multi-spectral imager used in this method is less sophisticated than the one used in the original VISR device for Method 2, therefore the cost is much lower. The cost of this simplified VISR device is comparable to an OGI camera used (and required by this rule) for leak detection. The tradeoff is that it cannot measure flare CE as accurately as the full version VISR, but it can accurately measure NHVcz/NHVdil as demonstrated through validation testing. More information about this new method can be found in Exhibits 4 & 5. [Exhibit 4 includes a paper (Yousheng Zeng and Jon Morris, Remotely Monitoring Flare Combustion Zone Net Heating Value) and a presentation (Yousheng Zeng and Jon Morris, Remotely Monitoring Flare Combustion Zone Net Heating Value (NHVcz) on simplified VISR given at the American Flame Research Committee (AFRC) 2021 Industrial Combustion Symposium. The flare monitoring system presented in the paper and the presentation was referred to as “Mantis Lite,” a brand name for the system that implement the Method 3 in Exhibit 3] [Exhibit 5 of the commenter’s submission, Updated information on simplified VISR method, contains a chart from slide 14 from Exhibit 4 presentation and an updated chart that was updated by adding one more method.] As shown in Exhibits 4 & 5, the commenter notes that the results generated by the prototype of this method agree with the results from the more complex and more expensive Method 1 instrumentation.

This method is suited to continuous monitoring (and closed loop control). Due to its portability and ease of operation, it can also be used for a periodic compliance testing or to establish an operating envelope for a flare. The commercial version of this simplified VISR device for Method 3 has been manufactured. Final tests will be conducted in early 2022 and it is the commenter’s intention to provide additional test results for this method during the comment period for EPA planned supplemental proposal for this rulemaking.

#### Method 4: Establish operating envelope.

The fourth method in Exhibit 3 is to set an operating envelope (OE) for a flare. The OE will be established by varying flare operating parameters, such as vent gas flow rate, vent gas/assist ratio, etc. under different environmental conditions (such as wind speed), while monitoring the flare CE or NHVcz/NHVdil. Lower and upper limits will be established for each flare operating parameter that ensure that flare control efficiency indicated by CE, NHVcz, or NHVdil is higher than the regulatory threshold of 96.5%, 270 Btu/scf, or 22 Btu/ft<sup>2</sup>, respectively. If CE is used as the criteria to establish OE, one of the following methods can be used during the test for establishing the OE: 1) the VISR method (*i.e.*, Method 2 in Exhibit 3), 2) Passive FTIR, or 3) extractive sampling method. If NHVcz or NHVdil is used as the criteria to establish OE, one of the following methods can be used during the test for OE: 1) the method specified in 40 CFR 63 subpart CC, or 2) the simplified VISR method (*i.e.*, Method 3 in Exhibit 3).

Although Method 4 is discussed here as a continuous monitoring method in the context of large assisted flares, Method 4 can also be used by manufacturers of small flares to certify a specific flare model as discussed in the small flare section above.

The commenter (0604-Providence) concludes that the proposed rule will cover a wide range of flares from a primitive well site to a sophisticated gas processing plant. The commenter advocates for flexibility in this rule that allows operator to choose a suitable method from the available methods listed in Exhibit 3 for each flare based on its circumstances (technical feasibility, practicability, cost-effectiveness, and other environmental and economic factors).

Response I-5-25: EPA agrees that it is important to ensure sufficient control efficiency across the range of conditions under which a control device will operate. See discussion in section IV.H.2 of the December 2022 Supplemental Proposal and section X.H of the preamble to the final rule related to combustion control devices.<sup>71</sup>

EPA is finalizing requirements for monitoring the pilot flame, the vent gas flow rate, the vent gas heating value, and the visible emissions from combustion control devices, as well as monitoring assist gas for assisted flares. We are also finalizing a pathway that will let owners and operators seek approval for other methods to monitor the control efficiency of flares and enclosed combustion devices, potentially including the methods described in this comment. See discussion in section XI.H.6 of the preamble to the final rule related to alternative monitoring of combustion control devices.

Comment: Commenter (0604-Providence) asserts that the requirement for monthly Method 22 observations to demonstrate continuous compliance with visible emission (VE) requirements is as ineffective and meaningless as using a one-time initial compliance demonstration for flare control efficiency to represent an emission source whose performance can vary with process and environmental changes. To truly enforce the visible emission standard, the commenter contends that a continuous monitoring method is needed because the visible emissions can occur anytime. Continuous monitoring systems based on visible cameras (*i.e.*, cameras operating in the visible light spectrum) can be an option and has been previously allowed in VE compliance assurance situations such as other NSPS subparts and state/federal permits. There are at least two severe shortcomings of using visible cameras:

1. Visible spectrum cameras can only detect visible emissions during daylight hours.
2. Compliance is based on inspection of visible images (either by an operator or by algorithm), which introduces data management and recordkeeping challenges. Storing and indexing a large number of visible images for audit and compliance determination creates a practical challenge – how frequently should images be captured, stored and indexed, how should images be reviewed and retrieved for compliance determination, especially when the standard is expressed as “no visible emissions, except for periods not to exceed a total of 5 minutes during any 2 consecutive hours” as in current refinery rule for flare [40 CFR 63.670 I]. It is extremely difficult, if not impossible, to make a

---

<sup>71</sup> 87 FR 74792 (December 6, 2022).

determination of compliance with this standard based on either a few or a large number of visible spectrum photos captured by the visible camera-based monitoring system.

The commenter (0604-Providence) states that there is now a much more effective and practical solution available which addresses this technical challenge and the shortcomings of visual camera-based compliance methods. The VISR based flare monitoring instruments (both the original VISR device and the simplified VISR device) can continuously monitor visible emissions from the flare as it simultaneously monitors flare CE (in the case of original VISR device) or flare NHVcz/NHVDil (in the case of simplified VISR device). The VISR based flare visible emission monitoring is based on the distinctive infrared radiance emitted by soot (in contrast with radiance from gases) in the flame. This soot-emitted radiance is measured by a metric called Smoke Index (SI). The scale of SI is 0-10. When there is no soot, the SI will be very low, generally below 1 on a scale from 0 to 10. The SI will increase monotonically as the level of soot (and thus level of visible emissions) increases. With the current 0-10 scale, visible emissions are observed when SI is in a range from 1.5-2. Because SI is an unitless index, it could be rescaled to a different range if desired. More importantly, it can be correlated to opacity readings by recording the SI and making opacity readings simultaneously in a calibration test. Because the SI is based on the Infrared radiance from soot, it works in both daytime and nighttime. Therefore, the problem of the visible camera-based smoke monitoring system not being able to work in nighttime is solved.

The commenter (0604-Providence) reports that unlike a visible camera-based system, the results of the VE monitoring by the SI method are not images. The result for each 1-second data cycle in the SI method is resolved to a single numeric value, which can be recorded in the same fashion as any process data such as temperature, flow rate, etc. The SI results can be plotted for easy understanding on how the flare is performing in terms of its visible emissions (see multiple examples of SI time series plots in Exhibits 6). A monitoring method which provides a continuous numeric value makes it a trivial task to determine compliance against a standard such as “no more than a total of 5 minutes during any 2 consecutive hours”. For example, simply averaging the 1-second SI values into 1-minute values would allow the operator to determine if there are a total of five minutes above the threshold in any 2 consecutive hours. If so, a deviation or potential violation of the standard may have occurred. Otherwise, the flare is in compliance with the visible emission standard.

In summary, the commenter (0604-Providence) believes that the current flare visible emission requirements (40 CFR 60.18 general provision, 40 CFR 63 subpart CC for refinery, and 40 CFR 63 subpart YY for ethylene production plants) are inadequate. The visual emissions standard is used to control emission of particulate matter, a criteria pollutant. As these emissions can occur any time during the day or night, regulations should ensure that the standard is met on a continuous basis without regard to the time of day. There are historical reasons why previous regulations have not required continuous visual emissions monitoring, but with the advent of new technologies, the regulations for flare visible emissions should be changed and the new regulations should enforce the flare visible emission standards on a continuous basis, day and night.

Commenter (0604-Providence) questions whether flare monitoring requirements for refineries and ethylene plants are appropriate, practical and/or economically feasible, for this rule. The commenter notes that technology in this field has advanced to provide new cost-effective monitoring methods. Consider that a single device (simplified VISR device described as Method 3 in Exhibit 3) can continuously monitor NHVcz/NHVdil, visible emissions and the presence of a pilot at a cost no more than the OGI camera required for leak detection. The commenter asserts that this allows for simple and cost-effective monitoring and inspections to ensure that flaring in this sector is efficient, and emissions are minimized. The commenter recommends that EPA establish the performance standards and provide multiple compliance demonstration options, such as the ones the commenter identified in Exhibit 3 of their comment letter (see previous comment provided by this commenter) and allow operators to choose what is appropriate for their flares. The commenter requests that small flares covered by these regulations (CO<sub>2</sub> emission rate less than 25,000 tn/yr) be required to demonstrate that the flare meets the performance standard (across the expected operating envelope) with an initial demonstration of compliance and periodic inspections. The commenter request that large flares covered by these regulations be required to demonstrate continuous compliance with the performance standard as required in other sectors. The commenter notes that the difference here is that new technologies offer the ability to achieve these performance standards at a much lower cost.

Response I-5-26: Regarding different requirements for different size control devices, see Response I-5-31. See discussion in section XI.H.6 of the preamble to the final rule related to alternative monitoring of combustion control devices. See discussion in Volume II, Chapter 17, Section 17.1.3 on use of video cameras for visible emissions monitoring.

EPA disagrees that monthly EPA Method 22 visible emissions observations are ineffective. However, EPA acknowledges that is important for owners and operators to be aware of issues with control devices as quickly as possible. The largest issue with combustion control devices is the incidence of unlit control devices. As such, in addition to the requirement to have a continuously lit pilot flame, EPA has added a requirement for an alert to the nearest control room whenever the pilot flame is extinguished.

Comment: Commenter (0604-Providence) states (and provides supporting figures) that the VISR methods (both the original VISR method and the simplified VISR method) described in Exhibit 3 of their comment letter (see previous comment provided by this commenter) are viable methods of monitoring flare pilot flame. The commenter recommends that this new rule be structured to allow for adoption of this new method for monitoring flare pilot presence.

[Comment letter submissions includes a Figure (Figure 3) of 3 flare images side-by-side. The Figure shows a lit flare with a small purge rate and the same flare when there was no vent gas and only the flare pilot was on. On the left of the figure is an image of the test flare in visible light spectrum. In the middle of the figure is a VISR image of the same flare when it was idling at a purge rate. On the right of the figure is a VISR image of the same flare when there was no vent gas and only the pilot was lit.]

The commenter notes (0604-Providence) that the VISR image shown in Figure 3 of their comment letter submission is for illustration purpose. The presence or absence of the pilot flame

will be reflected in the VISR data stream, and no images will be stored. There is no additional data management needed for this feature. When the pilot detection feature is enabled, the VISR system will flag the data and raise alarm when no pilot flame is detected. Additionally, the commenter reports that VISR instruments can distinguish the combustion gases of the pilot flame from the hot metal pilot hood. Another example of flare pilot captured by the VISR instrument is shown in Figure 4 of their comment letter submission. [Figure 4 of the commenter's submission includes a single image of a flare captured by VISR instrument.] In this case, the commenter notes that the flare main flame was lifted, and the two pilots were visible by the VISR instrument. In this VISR image, the metal pilot hood is shown in blue color and the pilot flame in red color. The distinction between the two is based on the different IR spectral characteristics between solid material (the metal hood) and the gaseous material (the pilot combustion products).

Commenter (0604-Providence) informs that pilot monitoring based solely on the temperature of the pilot hood (either thermocouple-based or single spectral IR based) will have a delayed response when the pilot flame goes out because it will not alarm until the metal hood cools down. Detection of pilot combustion gases, such as the VISR method, will be instantaneous. When the pilot flame goes out, there will be no pilot combustion gases and the VISR device will detect this without any latency. It should be noted that if the flare is operating properly and the pilot flame is engulfed by the main flame, the VISR device will not be able to distinguish the pilot flame from the main flame. However, this will be a moot point because the purpose of monitoring the presence of the pilot flame is to ensure the flare is lit. If the main flame is present, this purpose has been accomplished. This new rule should be structured to allow for adoption of this new method for monitoring flare pilot presence.

Response I-5-27: See discussion in section XI.H.6 of the preamble to the final rule related to alternative monitoring of combustion control devices.

Comment: Commenter (0604-Providence) provides comments on “how OGI may be used to identify poor combustion efficiency” and “how OGI has been used to evaluate the heat signature of gases exiting the top of the stack and/or presence of any unburned hydrocarbon trailing or advective plumes.” The commenter recommends OGI cameras not be used to determine the efficiency of a flare but could be used to evaluate whether a flare is lit.

The commenter (0604-Providence) understands that the term “OGI” in these questions refers to the typical single spectral Infrared (IR) cameras used for detection of fugitive gas plumes and referenced in other parts of this proposed rule. Although in some special circumstances OGI can hint at poor combustion (further discussions on this subject later), its use for evaluating flare performance is unreliable in most cases and can be misleading. OGI cameras utilize a single narrow bandpass filter to image gas plumes. OGI will be able to image a plume against the background if 1) the plume contains gas (or gases) that has IR spectral bands which overlap with the transmission curve of the bandpass filter in the OGI camera (*e.g.*, spectral bands in the wavelength of 3.2-3.4 micrometer); 2) the temperature of the plume is different from the temperature of the background (ref. to as delta-Temperature or  $\Delta T$  in the OGI field); and 3) there is sufficient amount of such gas(es) in the plume that can create sufficient contrast in the OGI imager against the background. The commenter has used the term “OGI triangle” to describe

these three prerequisite conditions for gas imaging. The plume from a flare or enclosed combustor can contain aerosols, *e.g.*, small amounts of carbon soot, particles of trace amounts of inorganic substances in the feed and carried over to the plume, or even liquid droplets. Although these aerosols may have very low concentrations, the IR radiance from them can be quite high relative to the sensitivity of the OGI camera due to the high temperature of the post-combustion gas plume (*i.e.*, extremely high  $\Delta T$ ). Even though the IR spectrum of the radiance emitted by these aerosols does not have “peaks” overlapping with the OGI camera bandpass filter as hydrocarbon gases do (*i.e.*, the IR spectrum of the aerosol will be broad, resembling that of a blackbody or graybody), the radiance in the spectral region of an OGI can still be comparable to that of gases due to the fact that aerosols are much more dense than gases and the temperature can be much higher than the background (high  $\Delta T$ ). As a result, the hot post-combustion gas plume is usually visible by OGI cameras even when they are not visible by naked eyes. This is often misinterpreted as evidence of hydrocarbon in the post combustion plume when it is more typically evidence of aerosols which do not necessarily indicate good or poor combustion.

Even if the contribution from aerosol radiance is negligible and the radiance emitted from the flame and received by the OGI camera is predominately from combustion gases, the commenter (0604-Providence) explains that the images captured by a single spectral OGI camera cannot be used to assess the combustion efficiency of the flare, not even qualitatively. The radiance from the combustion gases will be a function of the temperature of the gases and the size of the plume. Both variables can change from flare to flare and from one condition to another within the same flare. An image with a single infrared spectrum will not provide sufficient information to assess the performance of the flare. Only multi-spectral or hyper-spectral imaging with a sophisticated and quantitative algorithm can be used to assess and measure the flare performance.

The commenter (0604-Providence) adds that an operator of the OGI camera will see the post-combustion gas plume but cannot tell if it contains unburned hydrocarbon or the normal presence of aerosols at a high temperature. Therefore, they suggest that the mere presence of a trailing gas plume from a combustion device in the OGI imager is generally inconclusive in terms of judging the combustion efficiency of the combustion device. The public comment submission includes a Figure (Figure 5). Figure 5 includes example images in a single spectral band comparable to the common OGI cameras. By examining these images, the commenter states that one would not be able to tell the difference. However, the commenter states that they were taken from the same flare operating under drastically different conditions and they represent different flare combustion efficiencies as indicated in the caption of Figure 5.

[Figure 5 of the public submission include 3 images side-by-side of a single spectral image of the same flare under different conditions and having different combustion efficiencies. Left: CE = 97.2 percent. Middle: CE = 88.3 percent. Right: CE = 98.5 percent]

The commenter (0604-Providence) continues by stating that there may be a few exceptions. For example, if there are split trailing plumes in the OGI imager following a combustion device, it could indicate a poor combustion. In this scenario, the gases and aerosols are separated at some distance downwind from the flare tip due to their density differences, and each of the split plumes still maintains some cohesive shape with sufficient concentration and temperature difference against the background (*e.g.*, sky background). Although the OGI camera cannot

differentiate the gas and aerosols as discussed above, the fact that gravity has separated the plume into two segments is a strong indication of poor combustion. To observe this phenomenon and conclude poor combustion, some prerequisite conditions must simultaneously exist: there must be sufficient masses in both the unburned hydrocarbon plume and the aerosols plume that have survived the atmospheric dispersion and dilution of the atmospheric air mass before and after they are separated by gravity, and they must separately maintain high enough optical density and temperature differential against background far enough downwind from the release point. If these conditions are not met, this phenomenon will not be observed even if the combustion device has a poor combustion efficiency. On the other hand, the commenter notes that the absence of such a phenomenon does not prove a high combustion efficiency.

If a flare is unlit due to pilot malfunction, the commenter (0604-Providence) informs that an OGI camera will be able identify such a condition. The plume leaving the flare tip could be a dark plume (absorptive plume) or white plume (emissive plume) depending on the temperature of the vent gas(es) relative to the background (usually the sky) temperature, and there should be no combustion at the tip (as indicated by a very bright plume, usually saturating the associated pixels) in the OGI camera. For a lit flare, it is not possible to assess its combustion efficiency with an OGI camera except under some special conditions as discussed above. For this reason, the commenter recommends that OGI cameras not be used to determine the efficiency of a flare but could be used to evaluate whether a flare is lit.

Response I-5-28: In the final rulemaking, EPA is not requiring owners and operators to continuously monitor the flare efficiency with an OGI camera, as we agree that an OGI camera can provide a qualitative assessment of the flare operation but cannot provide the control efficiency being achieved. See discussion in section XI.H.2 of the preamble to the final rule related to requirements for monitoring combustion control devices with OGI cameras.

Comment: Commenter (0604-Providence) provides comments on OGI continuous flame imaging systems. The commenter states that new technologies that provide real-time measurement of control efficiency do exist, and they are listed in Exhibit 3 of their public comment submission (see earlier comment from this commenter and cited Exhibit 3), particularly Method 2 and Method 3 in Exhibit 3. However, using the flame size and temperature captured by an OGI or an IR imager as a surrogate for flare efficiency is not scientifically sound. First, the flame size captured by the IR imager is simply a function of flaring rate and the orientation of the flame relative to the imager. These variables have no definitive relationship with flare combustion efficiency. A flare may have similar size but significantly different efficiency, or vice versa. Figure 5 discussed above gives examples to demonstrate this point. Secondly, the temperature captured by these imagers are a measurement of “apparent temperature” even if the imagers are radiometrically calibrated. Because the flame consists primarily of combustion gases (which can be drastically different from the blackbody that is used to radiometrically calibrate the IR imager), the apparent temperature measured by the IR imager may be significantly different from the actual combustion temperature depending on variables such as optical density (related to flame depth along the camera’s line of sight) and the amount of aerosols in the flame, and they will be significantly different from pixel to pixel (representing different parts of the flame). If the maximum apparent temperature is used based on a single pixel (or several pixels), it may represent a small parcel of the combustion gases near the center of the flame and may not be

representative of the combustion temperature of the flame (as a whole). This maximum, localized apparent temperature tends to be the same regardless of combustion conditions. Through the commenter's testing, the commenter has observed such a stable apparent flame maximum apparent temperatures while the flare combustion efficiency varied significantly – as shown in Table 1. [Comment included Table 1: Flare combustion efficiency (% - percent) verses maximum apparent temperature(C), comparing 8 separate cases of flares]

As a result, the commenter (0604-Providence) recommends that EPA not consider flame size or flame temperature as surrogate parameters for flare efficiency as there is no scientific merit to this approach. Instead, the commenter requests that the EPA consider technologies which directly measure efficiency (such as Method 2 in Exhibit 3) or those which measure a parameter which is proven to be correlated to flare efficiency (such as Method 3 in Exhibit 3 of the commenter's public comment submission).

Response I-5-29: EPA is not approving the use of continuous OGI or infrared imaging as techniques for monitoring control efficiency in the final rule. See discussion in section XI.H.6 of the preamble to the final rule related to alternative monitoring of combustion control devices.

Comment: Commenter (0604-Providence) provides comments on methane emission rate from flares. The commenter strongly recommends that EPA structure this rule with allowance for operators to utilize new, cost-effective, easy-to-install and operate, and environmentally beneficial technologies such as the simplified VISR device described here.

For quantifying methane emissions from flaring, the commenter (0604-Providence) reports that the most common method currently used is to apply a presumed control efficiency (typically 98%) to the flowrate of the flare. This method is highly inaccurate. By definition, using this method will produce a methane emission rate which is proportional to the flow rate. The higher the flowrate, the higher the methane emission rate, *e.g.*,  $\text{emission rate} = (100\% - 98\%) \times \text{flowrate}$ . In practice, when the flare gas flowrate is low, the chance for over-assist is higher and the risk for lower control efficiency is higher, which can lead to a higher emission rate than the emission rate based on the presumed control efficiency. On the other hand, the commenter adds that when the flare gas flowrate is high, the flare tends to operate at a higher combustion efficiency and the emission rate is likely lower than the emission rate calculated based on the presumed control efficiency.

The commenter (0604-Providence) refers to Figure 6 of their comment letter. [Note: Figure 6 of the commenter's public comment submission is entitled "Methane Emission Rate (Measured vs. Estimated)."] The Figure compares methane emission rate to estimated and measured methane by various methods.] They note that the Figure is based on testing conducted by the commenter at John Zink's flare testing facility in Tulsa, OK. The flare tip was the same flare tip used for the 2010 TCEQ flare study. The grey line represents the natural gas flaring rate in lb/hr (plotted on the secondary y-axis). This flaring rate is measured by flowmeter with temperature and pressure compensation (referred to as the Ref. method for flowrate). In this dataset, the commenter explains that the vent gas was natural gas with a methane concentration of 90 percent. The orange line [illustrated in the figure] represents the calculated methane emission rate (lb/hr) using the common method of assuming 98 percent control efficiency. Note that the orange line

parallels the grey line because the emission rate is exactly proportional to the flaring rate (by 2 percent) when a presumed 98 percent control efficiency is applied.

The commenter (0604-Providence) continues that the green line [illustrated in Figure 6 of the commenter's public comment submission] represents the actual methane emission rate based on the flowrate measured by flowmeter (with temperature and pressure compensation) and flare combustion efficiency measured by the VISR method (*i.e.*, Method 2 in Exhibit 3 of the commenter's public comment submission). The commenter considers this to be the reference method for the methane emission rate as it is the most accurate method available. During this study, the level of assist was changed for each flaring condition to produce a range of control efficiencies. The commenter states that the data shows that the actual methane emission rate as measured by the reference method (the green line in the figure) is significantly different than the estimated 98% control efficiency (orange line). As shown Figure 6 of the commenter's public comment submission, the green line is significantly higher than the orange line when the flare was over-assisted (*e.g.*, Test ID T07a-e near the middle section of the chart) indicating that actual methane emissions are much higher than the 98 percent control efficiency estimate. Inversely, when the flaring rate is high and it was not over-assisted (*e.g.*, Test ID T10b-T11k), the orange line is significantly higher than the green line indicating that actual methane emissions are much lower than the 98% control efficiency estimate.

The commenter (0604-Providence) informs that the purple line in Figure 6 of the commenter's public comment submission is the methane emission rate as measured by the low cost simplified VISR method (Method 3 in Exhibit 3 of the commenter's public comment submission) using flow data provided by the test facility. The commenter also used the simplified VISR device to measure the flowrate. The use of the VISR method for flare flow rate measurement is explained in Exhibit 7 of the commenter's public comment submission. The blue line in the Figure 6 of the commenter's public comment submission is the methane emission rate measured solely by the simplified VISR method (Method 3 in Exhibit 3) without the flow measurement provided by the test facility. In Figure 6 it is labeled as "Measured Solely by Mantis Lite" (Mantis Lite is brand name for a device using Method 3). As stated in a previous section and in Exhibit 3, Method 3 of the commenter's public comment submission directly measures NHVcz. For the purpose of measuring methane emissions, the commenter developed a non-linear equation between NHVcz and the flare CE based on test data. Although the CE measured by this method is not as accurate as the CE measured directly by Method 2 in Exhibit 3, it has a significant benefit of utilizing a low-cost device. The results of this method (the blue line in Figure 6 of the commenter's public comment submission) are close to the most accurate method (the green line in Figure 6 of the commenter's public comment submission) and much more accurate than the current 98% control estimate (the orange line in Figure 6 of the commenter's public comment submission). Comparing the blue line and purple line in Figure 6 of the commenter's public comment submission), it is seen that the simplified VISR method provides the same accuracy with and without a flow measurement. The commenter states that the combination of the CE and flowrate measured by this simplified VISR method allows us to measure the methane emission rate using a single, low-cost remote sensing device.

The commenter (0604-Providence) explains that this data shows that this method will be applicable even when the flare is not equipped with a flowmeter to measure the flare gas flow

rate. If the flare already has a flowmeter installed, the flowrate measured by the flow meter and the CE measured by the simplified VISR method can be used to calculate the methane emission rate. This result is represented by the purple line in Figure 6 of the commenter's public comment submission.

The commenter (0604-Providence) refers to a table in their comment letter that presents a summary of methane emission rates measured by the four different methods in Figure 6 of their public comment submission. They explain that the results are presented in both emission rate (lb/hr) and the bias with respect to the Reference method. The data has been segmented into two groups: "Proper Operation" and "Over-assisting." The commenter states that the most accurate method is the Reference method, which is also an expensive method. The 98 percent control method is the least expensive method (the cost will be the flowmeter and temperature and pressure instruments). However, it overestimates methane emissions by 304 percent when the flare is operated properly and underestimates methane emissions by 69 percent when the flare is over-assisted. In comparison, the simplified VISR method (Method 3 in Exhibit 3) drastically reduces the bias at a cost comparable to an OGI camera for leak detection. The benefit of using Method 3 (with or without a flowmeter) is clearly demonstrated in Table 2 (of the commenter's public comment submission. [Note: Table 2 of the commenter's submission is titled "Flare methane emission rate measured by four different methods." Table 2 compares flared methane emissions rates by 4 different references: Reference Method, 98 Percent Control, Method 3 w/Flowmeter and Method 3 w/o Flowmeter.] The commenter states that the same device can simultaneously monitor visible emissions and presence of the pilot flame at no additional cost. The commenter strongly recommends that EPA structure this rule with allowance for operators to utilize new, cost-effective, easy-to-install and operate, and environmentally beneficial technologies such as the simplified VISR device (Method 3) described here.

Response I-5-30: EPA acknowledges the information provided by the commenter. See discussion in section XI.H.5 and XI.H.6 of the preamble to the final rule related to monitoring assisted combustion control devices and alternative monitoring of combustion control devices.

### ***5.1.8 Flare Recordkeeping and Reporting Requirements***

Comment: Commenter (0604-Providence) recommends that EPA promulgate separate reporting requirements (or standards) for flares based on the flare size or flaring rate.

Response I-5-31: EPA disagrees with the commenter. It is important to ensure that any control device used to achieve the emission standard for an affected facility is capable of continuously meeting the standard. All control devices must meet the same standard (the emission standard for the affected facility), and as such, separate standards cannot be applied to different sizes of control devices. EPA also disagrees that separate reporting requirements should apply to different control devices, as the goal of using any control device is to ensure that the emission standard for the affected facility is achieved. Recordkeeping and reporting are necessary components of compliance used to document that the control device is working properly, and the affected facility is in compliance with the emission standard.

### 5.1.9 Standard Recommendations Based on Flare Size

Comment: Commenter (0604-Providence) provides specific recommendations for regulatory requirements for both small and large flares.

Commenter (0604-Providence) states that flares that will be regulated under the proposed rule can be segregated into two categories: large and small. The distinction between these categories can be debated, but for the purpose of these comments the commenter will refer to large flares as those with a CO<sub>2</sub> emission rate exceeding 25,000 tpy. NETL collected and published data on flare size distribution which suggests that large flares account for about 10 percent of all flares.<sup>72</sup> The commenter provides a figure (Figure 2 of their comment letter) that shows the distribution of flares in the Permian, Bakken and Eagle Ford basins. [Figure 2 of the commenter's submission shows the distribution of flare sizes in Permian, Bakken and Eagle Ford. Source: NETL, 2020. The figure is a line graph that illustrates as the feed flow rate (mscfd) increases the number of flares decrease.]

The commenter (0604-Providence) asserts that methane emission inventories to date have been compiled by assuming that all flares have the same efficiency (typically a value of 98 percent is used) under all process and environmental conditions. The commenter believes that applying this assumed control efficiency to all flares without regard to actual performance is not prudent as it will lead to regulations and expenditure of resources in areas that do not deliver the desired control of methane emissions. For example, the commenter notes that if you apply a 98 percent control efficiency to the NETL flare distribution without regard to actual performance, you will reach the conclusion that most of the methane emissions come from small flares and regulations should focus on that category. However, when the actual efficiency is considered, the conclusion may be different. The commenter has measured hundreds of flares in these basins and found that the small flares tend to have highest efficiency while large flares can demonstrate lower efficiencies and more opportunity for optimization. For this reason, the commenter recommends that EPA consider the inaccuracy in current methane emission inventories when proposing flaring rules for this sector.

Commenter (0604-Providence) states that small flares tend to be simple in design without significant control methods to adjust the flare performance based on process or environmental conditions. Because of the relatively simple design and lack of control mechanism, the performance of these flares is often more reliant on the flare design (*i.e.*, manufacturer) rather than the flare operator. For these types of flares, the commenter recommends that measures employed to ensure the control efficiency standards have the following elements:

1. *Flare manufacturer's performance certification.* The commenter recommends a regulatory process for flare manufacturers to certify the performance of a specific flare model across the operating range (analogous to the way mobile source emissions are controlled – auto manufacturers are responsible for meeting emission standards). The commenter recommends that flare manufacturers complete performance testing to establish an operating envelope for each flare model which guarantees the desired control

---

<sup>72</sup> Submission Figure 2: Distribution of flare sizes in Permian, Bakken and Eagle Ford. Source: NETL, 2020. The figure is a line graph that shows as feed flow rate increases the number of flares decreases.

efficiency across the expected range of process and environmental conditions. This range of conditions should include, at a minimum, the range in flaring rates (*i.e.*, turn down ratio), gas composition and wind speed. The commenter suggests there should be an option for the operator to do this performance testing, but it will be far more efficient for the flare manufacturer to certify the flare design and prescribe the operating envelope to the operator. In addition to efficiency, the commenter believes this approach will produce more consistent results across the sector because establishing flare performance and operating envelope is not a trivial task and doing so for such a large number of flares in the field will likely yield less consistent (and less accurate) results, especially considering many of these flares are operated by small businesses with limited resources and technical expertise.

2. *Performance testing on installation.* The commenter recommends an initial compliance test to confirm that the control efficiency is achieved, similar to the compliance demonstration requirements in the 40 CFR 60.18. The operator should have some flexibility when demonstrating initial compliance with two options proposed here:
  - a. The operator can demonstrate that they are operating within the manufacturer's established operating envelope and reference the manufacturer's performance data to demonstrate initial compliance.
  - b. The operator can perform a direct measurement of efficiency to demonstrate initial compliance.
3. *Periodic inspection.* After initial compliance demonstration, the commenter recommends that the flare be inspected at a fixed interval to ensure that it is meeting the control efficiency. Like the initial demonstration of compliance, this periodic inspection could be a direct measurement of control efficiency or a demonstration that the flare is operating within the flare manufacture's established operating envelope. When establishing the interval for the periodic inspection, the commenter recommends that EPA factor in the life cycle of these small flares. The requirement for periodic inspections should be waived if the flare is equipped with a continuous monitor which ensures that the flare is meeting the desired control efficiency.

The commenter (0604-Providence) asserts that large flares tend to be more complex and typically use assist media (*e.g.*, air, steam, or additional combustible gas) to influence the flame dynamics and achieve better combustion efficiency with smokeless operation. When the assist media is not properly administered (*e.g.*, over-assist), the effect could be the opposite of the intended outcome resulting in low combustion efficiency. With the exception of flares regulated under the Petroleum Refinery Sector Standards (40 CFR 63, subpart CC) and NESHAP for ethylene production facilities (40 CFR 63, subpart YY) where continuous monitoring of flare performance is required, the commenter believes that the current measures to ensure that these large flares meet the control efficiency standards (*e.g.*, the heat content in the vent gas and exit velocity in 40 CFR 60.18) are either non-existent or ineffective. These large flares can be over-assisted for long periods of time without the operator having any knowledge of the problem, resulting in emissions much higher than assumed efficiencies. This problem was observed in the refinery and ethylene sectors, prompting regulations to require continuous monitoring of flare efficiency. The commenter recommends that large flares regulated under this proposed rule be

required to continuously demonstrate compliance with the applicable control efficiency standards.

Previous standards have only considered exit velocity and the heat content of the vent gas. This may be sufficient for unassisted flares, but for assisted flares, the commenter states that calculating the heat content based solely on the vent gas and not accounting for the diluting effect of assist media (*e.g.*, air for air-assisted flares) is not an adequate measure of flare control efficiency. The effect of the assist media can cause a very low combustion efficiency if it is not adjusted properly to the changing vent gas flowrate. This is the premise of the more recent requirements in 40 CFR 63 subparts CC and YY where a surrogate parameter is established to account for the effect of assist media. For steam assisted flares, Combustion Zone Net Heating Value (NHVcz) is the surrogate parameter which is continuously monitored to demonstrate compliance with the established performance standards. For air assisted flares, Net Heating Value Dilution Parameter (NHVdil) is the surrogate parameter. NHVcz/NHVdil has been codified in 40 CFR subpart CC and YY for flares at petroleum refineries and ethylene plants, respectively, and should be applied to the large flares in this regulation. While NHVcz/NHVdil monitoring is a good way to ensure proper control efficiency for assisted flares, it is an indirect method using a surrogate parameter to demonstrate compliance with control efficiency standards. EPA should also consider recent technology advancements which provide a direct measurement of control efficiency, such as the Video Imaging Spectral Radiometry (VISR) method (Zeng, *et. Al.*, 2016; Morris, *et. Al.*, 2019a, Morris, *et. Al.*, 2019b) which has been validated through extensive testing. These direct measurement technologies can provide an environmental benefit beyond the indirect methods by allowing for closed loop control and continuous and autonomous optimization of the flare performance.

Commenter (0604-Providence) believes that current regulations are also inadequate with respect to the frequency of determining compliance with performance standards. The commenter notes that the current NSPS OOOO and OOOOa requirements require only an initial demonstration of compliance. According to the commenter, considering the wide variability of performance from flare operations, an initial one-time demonstration of compliance is nearly meaningless. For small flares, the commenter proposed periodic inspections to ensure compliance, but for large flares in this sector continuous monitoring should be required. The continuous method should directly monitor the control efficiency or monitor a surrogate parameter, such as NHVcz, to ensure that the required control efficiency is achieved under all process and environmental conditions. Large flares can have high flaring rates, so even a relatively short period of low efficiency can produce methane emission rates that are an order of magnitude higher than current emission inventory estimates. The commenter contends that continuous monitoring for these flares presents the best opportunity for control of methane emissions from flaring.

Response I-5-32: Regarding different requirements for different size control devices, see Response I-5-31. See discussion in section IV.H.2 of the December 2022 Supplemental Proposal related to combustion control devices.<sup>73</sup> See discussion in section XI.H.5 and XI.H.6 of the preamble to the final rule related to monitoring assisted combustion control devices and alternative monitoring of combustion control devices.

---

<sup>73</sup> 87 FR 74792 (December 6, 2022).

Comment: Commenter (0809-Earthjustice) highlights specific examples of gaps or shortcomings in the NSPS proposal that they note are also relevant to the NESHAP rulemaking. The commenter recommends that EPA seek to address these areas in the NSPS rulemaking and the NESHAP reconsideration and section 112(d)(6) review to directly address these areas with respect to air toxics emissions and their effects on human health.

The commenter (0809-Earthjustice) recommends that EPA update the NSPS flare standards application to the oil and gas sector given that the NSPS general flare standards under 40 C.F.R. § 60.18 are nearly identical to the NESHAP general flare standards under 40 C.F.R. § 63.11, which are overdue for review. In doing so, the commenter suggests that the EPA follow the improved flare operational and monitoring requirements of the 2015 Refinery Rule and recent NESHAP rulemakings for chemical and petrochemical source categories. However, the commenter states that EPA should not add the malfunction loopholes included in some of these rules.<sup>74</sup>

Response I-5-33: This comment on NESHAP is outside the scope of this rulemaking under CAA section 111.

## **5.2 Other/All Combustion Devices**

### ***5.2.1 Combustion Efficiency***

Comment: Several commenters do not support mandating the requirement for combustion control devices to attain a 98 percent control efficiency. Some of the specific comments provided are included in the following paragraphs.

Commenter (0808-API) does not support the proposed change in the standards for wet seal centrifugal compressors, storage vessels, and pneumatic pumps that would require 98 percent reduction of methane and VOC emissions from those affected facilities.

Commenter (0810-Petroleum Alliance of Oklahoma (Petroleum Alliance-OK)) contends that EPA should not mandate the requirement for combustion control devices at oil and gas well sites to attain 98 percent destruction efficiency but allow it as an option in situations where it is cost effective and feasible. The commenter recommends that EPA provide incentives to operators where use of this equipment is feasible. The commenter recommends EPA avoid burdensome monitoring requirements that dissuade operators from using combustion control devices that can attain 98 percent destruction efficiency.

The commenter (0810- Petroleum Alliance-OK) states that combustion control devices are engineered and operated under certain conditions (*e.g.*, consistent flows and appropriate gas

---

<sup>74</sup> See, *e.g.*, RISE St. James et al., Petition for Reconsideration of the National Emission Standards for Hazardous Air Pollutants (NESHAP): Miscellaneous Organic Chemical Manufacturing (MON) Risk and Technology Review 31-43 (Oct. 13, 2020) (discussing loopholes), <https://www.regulations.gov/comment/EPA-HQ-OAR-2018-0746-0242>; RISE St. James et al., Petition for Reconsideration of Generic Maximum Achievable Control Technology Standards Residual Risk and Technology Review for Ethylene Production 8-21 (Sep. 4, 2020) (discussing loopholes), <https://www.regulations.gov/comment/EPA-HQ-OAR-2017-0357-0075>.

quality) to attain a 98 percent destruction efficiency. The commenter notes that this may be appropriate in certain situations (*e.g.*, newer wells). However, as wells decline, gas flows and pressures decrease or become variable, and it becomes increasingly difficult to ensure complete combustion to achieve the 98 percent DE. The commenter believes that the use of complex control devices and monitoring/automation systems are possible to implement for very small vapor streams, but they are significantly more costly, especially for marginal/low production wells, and may make the well uneconomical. Also, the commenter adds that the gas quality may also be a factor preventing the use of combustion control devices with higher destruction efficiencies.

Commenter (0817-GPA) supports the continued use of a 95 percent control efficiency requirement, particularly for midstream activities, due to cost and operational flexibility. The commenter notes that the November 2021 Proposal provides a logical rationale for retaining the 95 percent control efficiency and the Technical Support Document (TSD) discusses the real difficulties of continuously maintaining a 98 percent control efficiency. The commenter notes that one of the biggest barriers identified in the TSD is that, in order to reach such a high destruction efficiency, “monitoring systems require electricity.”<sup>75</sup> The commenter contends that, as is well-documented, many midstream sites are remote, unmanned locations that lack consistent access to electricity. The commenter notes that the cost of running electricity to sites—which is difficult to estimate on an industry-wide basis—was not included in the TSD cost estimate. Even without the added cost of electricity, the TSD estimated that “capital costs increased greatly” for a 98 percent destruction efficiency, “going from \$80,000 to \$430,000” while also increasing annualized costs.<sup>76</sup> The commenter agrees that these amounts are not cost-effective at oil and gas facilities for VOC or methane control.

Further, the commenter (0817-GPA) contends that requiring 98 percent destruction efficiency would greatly limit operational flexibility. Whereas 98 percent efficiency can only be reached with additional equipment to maximize flare combustion, the 95 percent efficiency standard is technology neutral. The commenter notes, for example, this allows for necessary maintenance downtime for VRUs.

Commenter (0817-GPA) recommends a new rulemaking proposal if EPA reconsiders its position on combustion efficiency. If, based on public comments, EPA elects to require a higher standard (such as a 98 percent efficiency), the commenter recommends a new proposed rulemaking be issued to provide stakeholders with sufficient new information and the opportunity to comment. The commenter asserts that the November 2021 Proposal has included little to no information that would support a change in EPA’s position, such as proposed regulatory language, the costs and benefits associated with such a change, and whether certification to a 98 percent combustion efficiency is even possible for affected devices. Moreover, the commenter contends that significant capital investments have been made and business structured based on the well-established 95 percent efficiency standard and with the substantial new demands that may result

---

<sup>75</sup> Oil and Natural Gas Sector: Emission Standards for New, Reconstructed, and Modified Sources and Emissions Guidelines for Existing Sources: Oil and Natural Gas Sector Climate Review, Background Technical Support Document (Oct. 2021) (“TSD”) at 6-23.

<sup>76</sup> *Id.*

from the November 2021 Proposal as is, any increase in required efficiency to 98 percent even for only select control devices, should be considered in light of the overall burdens imposed.

Response I-5-34: See discussion in section IV.H.2 of the December 2022 Supplemental Proposal related to combustion control devices.<sup>77</sup>

Comment: Commenter (0604-Providence) recommends that EPA set the control efficiency standard at 98 percent. The commenter notes that the most common control devices in this sector are combustion devices. The commenter contends that a wide range of studies have demonstrated that properly designed and operated combustion devices can easily achieve 98 percent control efficiency. For properly designed combustion devices, the commenter states that there is virtually no additional cost to move the control efficiency from 95 percent to 98 percent, yet the environmental benefit will be substantial. A 95 percent control efficiency will produce a 5 percent methane slip rate, more than double the slip rate for a 98 percent control efficiency. If EPA is concerned about the feasibility of requiring a 98 percent control efficiency for non-combustion control devices, the commenter recommends a separate efficiency standard be promulgated with a 98 percent control efficiency for combustion devices and a 95 percent control efficiency for non-combustion devices. The commenter suggests that a combustion device used for control of methane emissions should meet a minimum standard of 98 percent control efficiency.

Response I-5-35: See discussion in section IV.H.2 of the December 2022 Supplemental Proposal related to combustion control devices.<sup>78</sup>

### ***5.2.2 Control Technology Alternatives to Flaring***

Comment: Commenter (0594-Huntsman) views the use of methane pyrolysis as an effective flaring replacement in the long term. The commenter provides the following technology details.

Commenter (0594-Huntsman) informs that MIRALON® advanced carbon materials are produced from methane gas and potentially other hydrocarbons. The commenter's floating catalyst chemical vapor deposition (CVD) process, a form of methane pyrolysis, uses a reactor to break down the carbon in methane into a carbon nanomaterial while also creating a clean hydrogen fuel. During the pyrolysis, methane (for example, from flare gas), is pre-heated and introduced into a reactor where it is mixed with a combination of gases and a metal catalyst at high temperatures to isolate pure, solid carbon. To date, the process has achieved 80-90 percent single-pass efficiency converting methane into carbon and can achieve far higher conversion (99 percent +) with multiple passes. Projections show that transforming one small flare of 20 tons per day of natural gas into feedstock for this process over a ten-year period could avoid 230,000 tons of CO<sub>2e</sub> over a decade while only requiring 550 tons of CO<sub>2e</sub> to build based on construction materials. Assuming the energy comes from a portion of the hydrogen co-product, the commenter states that this delivers a 420x return on invested carbon.

---

<sup>77</sup> 87 FR 74792 (December 6, 2022).

<sup>78</sup> 87 FR 74792 (December 6, 2022).

The commenter (0594-Huntsman) notes that reducing dependence on flares also reduces the potential for related performance problems and malfunctions. But methane pyrolysis also provides a practical means to improve performance and reduce the effect of malfunctions. The commenter contends that once methane pyrolysis is scaled and readily available, a well could switch between pyrolysis and flaring as needed – giving critical time to a facility to repair and/or improve flaring and eliminating any period where no controls are in place. The commenter’s eventual goal would be to take this one step further and for methane pyrolysis to be the dominant form of methane destruction, with flaring relegated to an emergency backup option.

Response I-5-36: EPA acknowledges the information provided by the commenter on an alternative technology to flaring. EPA does not specify a specific control technology that must be used to meet the requirements of the rule, but instead specifies a control standard. Owners/operators have the flexibility to choose the control device that would best meet their needs and meet the requirements of the rule, which is 95 percent reduction of VOC and methane emissions, for applicable affected facilities.

### ***5.2.3 Monitoring Requirements***

Comment: Commenter (0810- Petroleum Alliance-OK) recommends that EPA avoid burdensome or onerous monitoring requirements that dissuade operators from using combustion control devices that can attain a 95 percent destruction efficiency.

Commenter (0763-TCEQ) believes that existing monitoring and recordkeeping programs are sufficient to demonstrate compliance with destruction efficiency representation for control devices, and additional requirements will create regulatory and monitoring overlap and may also overlap or conflict with existing requirements.

Response I-5-37: See discussion in section IV.H.2 of the December 2022 Supplemental Proposal related to combustion control devices.<sup>79</sup>

---

<sup>79</sup> 87 FR 74792 (December 6, 2022).

## **Chapter 6. Environmental Justice (EJ) Implications and Stakeholder Outreach**

### **6.1 Environmental Justice and Impacts of Climate Change**

#### ***6.1.1 General Comments of Concern***

Comment: Several commenters (0276-Greater Boston Physicians for Social Responsibility (GBPSR), 0340-Mothers & Others for Clean Air (Mothers & Others), 0351-Department of Environmental Health Sciences, Mailman School of Public Health, Columbia University (Columbia), 0347-Columban Center for Advocacy and Outreach, Missionary Society of St. Columban (Columban), 0385-Silent Spring Institute (Silent Spring), 0402-Cancer Free Economy Network (Cancer Free), 0585-Kentucky Oil and Gas Association (KOGA), 0733-Conservation Voters New Mexico (CVNM), 0734-American Thoracic Society (ATS), 0781-National Tribal Air Association (NTAA), 0783-CA Assemblymember Bloom *et al.*, 0800-State of Utah, Public Lands Policy Coordinating Office (Utah), 0833-Environmental Programs Department, Ute Mountain Ute Tribe (Ute Tribe), 0837-Clean Water Action (CWA) *et al.*, 0844-Environmental Defense Fund (EDF) *et al.*, 0920-WE ACT for Environmental Justice (WAEJ), 0941-350Silicon Valley, 0943-Sault Ste. Marie Tribe of Chippewa Indians, Sault Tribe Environmental Department (Sault Tribe), 0949-Liveable Arlington, 1271-National Religious Partnership For The Environment (NRPE), 1282-Earthworks, 1330-Catskill Mountainkeeper, 1337-Boston Catholic Climate Movement (BCCM), 1350-EOS at Federated Hermes (EOS), 1383-New Mexico Interfaith Power and Light (NMIPL), 1384-Louisiana Environmental Action Network (LEAN) and Lower Mississippi Riverkeeper (LMRK), 1388-Private Citizen) express concern regarding the health of populations living near oil and natural gas development. A sample of some of their specific comments follows.

Commenters (0605-Muscogee (Creek) Nation, 0781-NTAA) supports EPA's efforts at evaluating and achieving EJ. The commenter states that, not only is an EJ review required, but it is also a part of good government. The commenter reports that studies have shown that residents of EJ communities are more vulnerable to the impacts of pollution due to pre-existing health conditions that often are higher in these communities due to lack of access to adequate nutrition and health care. The commenter suggests that doing the work of reaching out to these communities and taking a hard look at how environmental policies will impact their health is a much smarter approach than trying to address adverse health outcomes later on, along with the distrust that will have built up in the community as they have watched their health decline even further.

Commenter (1388-Private Citizen) states that existing facilities negatively impact our climate and our health. The commenter emphasizes that persons, many of them in low income and EJ communities, living near industry facilities have suffered negative health impacts, and reduced property values as a result of continuing, and sometimes life-long exposure to industry pollutants.

Commenter (1383-NMIPL) states that frontline communities currently suffer from the health effects of pollution which in their region (NM and TX) are experienced disproportionately by the

most vulnerable and the young who are part of Native American, Latinx and lower income communities.

Commenter (1271-NRPE) states that the African American community is disproportionately impacted by air pollution because of historical and ongoing systemic racism, which has placed our communities adjacent to polluting industries. With more than 1 million African Americans living within a half-mile of an existing natural gas facility, methane pollution leaves these communities exposed to toxic air pollution, with negative health impacts including cancer, reproductive and respiratory problems.

Commenter (0943-Sault Tribe) supports EPA's efforts at evaluating and achieving EJ. According to the commenter, studies have shown that residents of EJ communities are more vulnerable to the impacts of pollution due to pre-existing health conditions that often are higher in these communities due to lack of access to adequate nutrition and health care.

Commenter (0800-Utah) appreciates the acknowledgement of EJ, community involvement, and small business impacts because many of the oil and gas sources in Utah are in rural areas where the oil and gas industry has a large economic impact.

Commenter (0783-CA Assemblymember Bloom *et al.*) notes that California is the seventh-largest producer of crude oil in the nation and ranks third in oil refining capacity<sup>1</sup>, much of which occurs next to or within communities that are low income and inhabited primarily by people of color. As a result, the commenter states that oil extraction, refinement, and natural gas storage pose serious health threats to millions of Californians, including but not limited to those living in the predominantly black, indigenous, and people of color (BIPOC) communities of East Los Angeles, Richmond, and the Central Valley. Consequently, the commenter asserts that methane emissions represent not only environmental and health threats; they are an EJ crisis. The commenter also provides information on the adverse health effects from methane and volatile organic compound (VOC) emissions [see pages 1 and 2 of the commenters' letter].

Commenter (0920-WAEJ) contends that low-income communities, communities of color and tribal nations, especially in energy producing states, have been treated as sacrifice zones by this sector. The commenter suggests that frontline communities not only bear the brunt of the impacts of the climate crisis but they are disproportionately exposed to the harmful pollution and health and safety risks of oil and gas development as a result of decades of discriminatory zoning practices. The commenter adds that the industry is also a significant source of smog-causing VOCs and air toxics like benzene, formaldehyde, and ethylbenzene, which are emitted alongside methane. Numerous studies show that low-income, Indigenous, Black, and Hispanic people who live in close proximity to oil and gas development and operations are adversely affected by a

---

<sup>1</sup> U.S. Energy Information Administration: California State Energy Profile, <https://www.eia.gov/state/print.php?sid=CA>.

range of negative health impacts, from migraines, depression, asthma attacks, irreversible lung damage, cardiovascular disease to cancer, preterm births, and premature deaths.<sup>2,3,4,5,6</sup>

Commenter (0734-ATS) states that a disproportionate amount of methane emissions come from a relatively small number of facilities, sometimes termed “super-emitters.” The commenter notes that, in California, each 10 percent increase in census block group proportion of Black residents is associated with a 10 percent increased odds of exposure to methane “super-emitter” facilities. The commenter adds that, across Colorado, Oklahoma, Pennsylvania, and Texas, minoritized communities, especially those with predominately Black residents, are much more likely to be close to oil and natural gas fracking wells. Furthermore, the commenter reports that low-income residents in Pennsylvania are disproportionately exposed to harmful air toxins and pollutants released from fracking operations.

Commenter (0402-Cancer Free) expresses specific concern with rising cancer rates—and a growing body of research points to chemicals in our environment as important, and preventable, risk factors for cancer.<sup>7</sup> The commenter notes that a legacy of oppression and systemic racism have led to a pattern of BIPOC populations disproportionately exposed to hazardous pollution,<sup>8</sup> including air pollution,<sup>9</sup> in tandem with a propensity to be more affected by climate change impacts.<sup>10</sup>

Commenters (0351-Columbia) assert that reducing methane and co-pollutant emissions from oil and gas wells could immediately improve public health and environmental justice concerns nearby and also slow long-term climate change that threatens our species.

<sup>10</sup> NAACP. (2021). Environmental and Climate Justice. Accessed December 15th. <https://naacp.org/knowissues/environmental-climate-justice>.

Commenter (1282-Earthworks) states that the Oil and Gas Threat Map shows 12.6 million people living within a half mile radius of oil and gas extraction, processing or compressor stations. That includes 2.9 million at risk students in 9,000 schools suffering 750,000 asthma attacks and 500,000 lost school days per year. The commenter adds that numerous peer-reviewed scientific studies have documented elevated levels of harmful air pollutants in and around areas with oil and gas production activity and have shown that oil and gas facilities are the source of the excess pollution. Research that specifically deals with health indicates correlations between risks and/or prevalence of disease and proximity to facilities. The commenter notes that the half mile “threat radius” was chosen because it is a very conservative estimate of the area within which elevated levels of toxic pollution are seen, and the distance within which health impacts have most clearly been correlated with the presence of oil and gas facilities. The commenter states that the T Variables include total population, race and ethnicity, number of children, number of schools, and student enrollment.

Commenters (0837-CWA *et al.*, 1330-Catskill Mountainkeeper) state that over 12.5 million Americans live within half a mile of oil and gas operations. In California, commenter (0837-CWA *et al.*) notes that the number is over two million. According to the commenter, that is two million predominantly low-income people of color that have an elevated risk of cancer, asthma, respiratory, pulmonary and cardiovascular diseases, and an increased risk of negative birth outcomes like low-birth weight pregnancies, preterm birth and other birth related problems.

Similarly, commenter (0941-350 Silicon Valley) states that over 12.4 million Americans live within a half mile of an oil or gas well, gas compressor or gas processor.<sup>11</sup> Minorities are disproportionately represented in this group which has experienced an elevated incidence of cancer, asthma, pulmonary and cardiovascular diseases.<sup>12</sup> Also, pregnant women living in oil and gas producing regions face an increased risk of premature birth.<sup>13</sup>

Commenter (0788-350 Seattle) reports that over 12.4 million Americans live within half a mile of oil and gas operations, are disproportionately of color, and are likely to experience serious health effects from fossil fuel pollution. These health effects include an elevated risk of cancer, asthma, respiratory, pulmonary and cardiovascular diseases. In addition, the commenter notes that pregnant women living in oil and gas producing regions face an increased risk of premature birth, according to this study from 2020. The commenter adds that the EPA’s own research has estimated nearly 2,000 extra deaths each year will be caused by air pollution exposures from the oil and gas sector in 2025 and each year thereafter.

Several commenters (0557-Union for Reform Judaism (URJ), 0789-Pennsylvania Department of Environmental Protection (PA DEP), 0941-350 Silicon Valley) express specific concerns regarding climate change and impacts on vulnerable communities.

---

<sup>11</sup> Alan Septoff, “Over 12 Million Americans Live in the Oil and Gas Threat Zone”, Earthworks, June 17, 2016.

<sup>12</sup> Lara J. Cushing et al., “Up in Smoke: characterizing the population exposed to flaring from unconventional oil and gas development in the contiguous US”, Environmental Research Letters, vol 16, n0 3, 2021.

<sup>13</sup> Lara J. Cushing et al., “Flaring from unconventional oil and gas development and birth outcomes in the Eagle Ford Shale in South Texas”, Environmental Health Perspectives, July 15, 2020.

Commenters (0557-URJ) express specific concern regarding the climate crisis as an ever-worsening tragedy, causing rising sea levels, global temperature extremes, and increases in severe weather, wildfires, and droughts. The commenter notes that climate impacts are detrimental to human health and wellbeing, particularly and disproportionately felt by vulnerable Communities of Color.

Commenter (0789-PA DEP) states that one of the most notable findings from their 2021 Pennsylvania Climate Impacts Assessment is that climate change will not affect all Pennsylvanians equally. The commenter reports that some may be more at risk because of their location, income, housing, health, or other factors.

Commenter (0941-350 Silicon Valley) suggests that, in addition to methane's effects on climate, EPA must also address the climate justice aspects of methane pollution.

Response I-6-1: EPA acknowledges the commenters' support for EPA's efforts to evaluate and address environmental justice in the November 2021 Proposal. Additionally, EPA has considered the information provided by the commenters regarding the impact of methane, VOC, and other air pollutant emissions from the oil and natural gas industry on the health of nearby populations, as well as other vulnerable communities, and finds that it is consistent with the approach that EPA has taken in the final rule.

### ***6.1.2 Native American Environmental Justice Impacts***

Comment: Commenters (0391-Keweenaw Bay Indian Community (KBIC), 0833-Ute Tribe) express concern regarding the carve out of regulatory exceptions for Alaska. The commenters note that, although they recognize that the winter conditions in Alaska provide additional challenges, they are concerned that Alaska Native Villagers are not being protected equally or sufficiently. The commenters encourage the EPA to explore or research options that can be used in cold conditions that could provide more consistent protections for the fragile ecosystems and public health in Alaska.

Response I-6-2: The conditions in the Alaskan North Slope provide unique challenges for owners and operators in the oil and natural gas industry. As a result, EPA has determined that the best system of emission reduction (BSER) for certain affected and designated facilities in the oil and natural gas source category is different for sources located in the Alaskan North Slope and the rest of country. For example, EPA is finalizing the fugitive emissions standards at well sites and compressor stations on the Alaska North Slope to be annual OGI monitoring with the first attempt at repair within 30 days of finding fugitive emissions and the final repair within 30 days of first attempt. There would also be an option to use annual EPA Method 21 monitoring with 500 ppm defined as a leak instead of OGI monitoring. Owners and operators on the Alaska North Slope would also have the option to use the alternative period screening with advance measurement technology approach or monitoring and repair based on using a continuous monitoring system instead of OGI monitoring. EPA explained the rationale in the November 2021 Proposal<sup>14</sup> and additional explanation in the December 2022 Supplemental Proposal.<sup>15</sup> See

---

<sup>14</sup> 86 FR 63163 and 86 FR 63174-63175.

<sup>15</sup> 87 FR 74740.

40 CFR 60.5397b and 40 CFR 60.5397c for final requirements for fugitive emissions components. Another example, EPA is finalizing a standard of 6 scfm for continuous bleed pneumatic controllers in Alaska at sites where onsite power is not available and a standard of OGI monitoring and repair of emissions from intermittent natural gas driven pneumatic controllers. EPA explained the rationale in the November 2021 Proposal<sup>16</sup> and did not propose any changes in the December 2022 Supplemental Proposal. See 40 CFR 60.5390b and 40 CFR 60.5394c for final requirements for process controllers. Where possible, EPA is finalizing the same BSEER for affected sources located in the Alaskan North Slope as the rest of the country. Some examples of this include the requirements for well completions, storage vessels, and associated gas. Additionally, see the final rule, Adoption and Submittal of State Plans for Designated Facilities: Implementing Regulations Under Clean Air Act Section 111(d) at 88 FR 80480, November 17, 2023, and its corresponding Summary of Public Comments and Responses on Proposed Rule Adoption and Submittal of State Plans for Designated Facilities: Implementing Regulations Under Clean Air Act Section 111(d) (Subpart Ba) Docket ID No. EPA-HQ-OAR-2021-052.

Comment: Commenters (0578-Grand Canyon Trust (GCT), 0781-NTAA) express that climate change and oil and natural gas operations disproportionately impact near source low wealth, minority communities, particularly Tribal communities.

Commenters (0605-Muscogee (Creek) Nation, 0781-NTAA, 0833-Ute Tribe, 0943-Sault Tribe) states that, while EJ concerns may apply to many Tribal communities, there also needs to be recognition that Tribes are very distinct entities that preexist establishment of the United States. The commenters assert that Tribes possess authority that predates the U.S. Constitution regarding the governance of their own internal affairs. For these reasons, the commenters state that EJ is an important issue, but must never usurp Tribal sovereignty and self-determination. Further, the commenters argue that EJ must never replace government-to-government consultation directly with Tribes. They add that, any EJ actions must treat Tribes as sovereign nations with self-determination first and part of the EJ community second. The commenters suggest that the EPA's baseline assessment to determine if EJ concerns exist is not sufficient analysis with respect to considering and addressing Tribal impacts.

Commenter (0788-350 Seattle) states that the EPA's baseline assessment to determine if EJ concerns exist is not sufficient analysis with respect to considering and addressing Tribal impacts.

Commenter (0578-GCT) reports that a report by the Clean Air Task Force states that residents of the Navajo Nation are two times more likely to live within a half mile of an oil and gas facility compared to Utah and New Mexico.<sup>17</sup> The commenter adds that it also highlights that residents of Northern Ute Lands in the Uinta Basin, Utah are 42 times more likely to live within a half mile of an oil and gas facility. Proximity to oil and gas facilities also indicates exposure to methane pollution, hazardous air pollutants (HAPs), and VOCs. Historically, the commenter

---

<sup>16</sup> 86 FR 63207- 63209.

<sup>17</sup> Clean Air Task Force. Tribal Communities at Risk: The Disproportionate Impacts of Oil and Gas Air Pollution on Tribal Air Quality. Available at: [https://cdn.catf.us/wpcontent/uploads/2018/05/21094517/Tribal\\_Communities\\_At\\_Risk.pdf](https://cdn.catf.us/wpcontent/uploads/2018/05/21094517/Tribal_Communities_At_Risk.pdf). At 3.

states Tribes have a complex history in relation to oil and gas development in that they depend on coal and gas for revenue and jobs but have also supported conservation, public health and cultural preservation measures. According to the commenter, however, the relationship between the federal government, industry and Tribes has been fraught with exploitation and injustice<sup>18</sup> with Tribal communities not being fully compensated for their investment and shouldering the environmental costs and public health burden.<sup>19</sup>

Commenter (0794-Mandan, Hidatsa and Arikara Nation (MHA Nation)) asserts that, in upholding its trust responsibility EPA must consider the viewpoints of Tribes committed to pursuing responsible oil and gas development. The commenter is concerned that the Oil and Gas Methane Regulations as proposed would unreasonably burden development of tribal energy resources. The commenters state that the EPA has committed to upholding its trust responsibility by "protect[ing] the environmental interests of Indian Tribes when carrying out its responsibilities that may affect the reservations."<sup>20</sup> The commenter adds that EPA's trust responsibility also requires it to protect the right of tribes to develop their trust resources. Indeed, the commenter states that the federal government's "trust responsibility consists of the highest moral obligations that the United States must meet to ensure the protection of tribal and individual Indian lands, assets, resources, and treaty and similarly recognized rights."<sup>21</sup>

Commenter (0794-MHA Nation) notes that, in reaffirming the agency's Indian Policy in September 2021, EPA Administrator Michael S. Regan expressly "recognize[d] the right of tribes as sovereign governments to self-determination and acknowledge[d] the federal government's trust responsibility to tribes."<sup>22</sup> The commenters recommend that EPA engage with tribes on a government-to-government basis and consider the interests of tribes, like the MHA Nation, that are committed to implementing policies that both adequately protect the environment and allow for continued oil and gas development. According to the commenter, this is especially true in cases such as this when a proposed EPA regulation threatens the development of the MHA Nation's tribal trust assets. The commenter suggests that, in managing tribal trust assets, the federal government has an obligation to "[p]romote tribal control and self-determination over tribal trust lands and resources."<sup>23</sup> Lastly, the commenters assert that, in

Regan, to all EPA Employees, regarding "Reaffirmation of the U.S. Environmental Protection Agency's Indian Policy" (Sept. 30, 2021), <https://www.epa.gov/system/files/documents/2021-09/oita-21-000-6427.pdf>.

<sup>23</sup> U.S. Department of the Interior, Departmental Manual, part 303, ch. 2: Principles for Managing Indian Trust Assets (Oct. 31, 2000), <https://www.doi.gov/sites/doi.gov/files/elips/documents/303-dm-2.pdf>; see also U.S. Department of the Interior, Bureau of Trust Fund Administration, Trust Principles, <https://www.doi.gov/ost/about-us/Trust> (last visited Jan. 28, 2022).

developing its proposed Oil and Gas Methane Regulations EPA did not adequately consider how tribes that have embraced oil and gas development would be impacted.

Commenter (0844-EDF *et al.*) states that, as EPA notes in its environmental justice analysis, Native American populations on average may be exposed to a higher concentration of ozone from oil and natural gas VOC emissions than white populations.<sup>24</sup> The commenter reports that Native Americans who are part of the Navajo Nation in Utah and New Mexico and the Fort Berthold Indian Reservation are two times more likely to live within a half mile of an oil and gas facility compared to individuals in encompassing states, and those in Uintah-Ouray (Northern Ute) are 42 times more likely to be within a half mile than individuals in encompassing states.<sup>25</sup>

Response I-6-3: EPA recognizes the status and rights of Tribal Nations, as sovereign governments, to self-determination and acknowledges the federal government's trust responsibility to Tribes. EPA provides programs, resources, financial assistance, technical assistance and training, consultation opportunities and dedicated engagement to help identify and mitigate perceived and tangible implications to Tribes.

On November 16, 2021, EPA sent a letter to all 574 Federally Recognized Tribes inviting Tribes to participate in Tribal Consultation on the November 2021 Proposal. Three Tribes (MHA Nation, the Northern Arapaho Tribe, and the Eastern Shoshone Tribe) requested consultation and those consultations were held on January 24, 2022, January 24, 2022, and January 25, 2022, respectively. On November 14, 2022, EPA sent an additional letter to all 574 Federally Recognized Tribes inviting Tribes to participate in a Tribal Consultation on the December 2022 Supplemental Proposal. EPA held Tribal Consultation with MHA Nation on January 24, 2023. On February 24, 2023, EPA held an informational meeting with the Ute Tribe.

EPA recognizes that some implications may be felt disproportionately across Indian country as well as in communities. EPA's EJ analyses focused on a baseline distribution of emissions from oil and natural gas sources, enabling the Agency to characterize risks due to oil and natural gas emissions prior to implementation of the rule. While the EPA agrees that baseline assessment alone is not the optimal approach for determining if EJ concerns exist with respect to considering and addressing Tribal impacts, it was the only analytic approach feasible when preparing the November 2021 Proposal and December 2022 Supplemental Proposal RIAs.

With respect to considering how the rule would impact tribal trust assets, EPA considered how tribes that have embraced oil and gas development would be impacted by this rulemaking through consideration of the impacts of potential regulation on employment among overburdened or marginalized communities. The RIA notes that a reduction in employment in the oil and natural gas sector may be associated with loss of income for workers in the oil and gas industry, and for oil and gas communities.

---

<sup>24</sup> RIA 4-18.

<sup>25</sup> Clean Air Task Force, Tribal Communities at Risk: The Disproportionate Impacts of Oil and Gas Air Pollution on Tribal Air Quality (2018) 3.

### 6.1.3 Conducted EJ Analyses

Comment: Several commenters (0351-Columbia, 0385-Silent Spring, 0573-Kansas Department of Health and Environment (KDHE), 0727-Oklahoma Secretary of Energy and Environment (OSEE) and Oklahoma Department of Environmental Quality (ODEQ), 0844-EDF *et al.*, 0949-Liveable Arlington) cite several EJ analyses conducted that specifically looked at EJ in the context of oil and natural gas operations. Examples of some of these comments are provided below.

Commenter (0351-Columbia) reports that their studies have used spatial methods and electronic health record data on thousands of individuals where they could control for both individual and area-level factors (Casey *et al.* 2016, Casey *et al.* 2018, Casey *et al.* 2019, Tustin *et al.* 2017, Rasmussen *et al.* 2016). As a result of these studies, they report that they have found relationships between living closer to more wells and more actively producing wells and increased risk of preterm birth, migraine headache, depression, and cardiovascular disease in Pennsylvania. In studies in California with Dr. Rachel Morello-Frosch they have also used statewide birth certificate data and found that living within 1 km of an oil or gas well was associated with increased odds of low birth weight, small for gestational age birth, and decreased term birth weight among individuals living in rural areas (Tran *et al.* 2020). The commenter also notes that a study in Texas found an increased risk of preterm birth among women exposed to gas flaring (Cushing *et al.* 2020). The commenter adds that, in California, there have been recent studies that found evidence that people of color are more likely to live closer to methane super-emitters, suggesting that reducing emissions from oil and gas wells is also an issue of environmental justice (Casey *et al.* 2021).

Commenter (0844-EDF *et al.*) reports that, in Texas there are over 800,000 Latinos living within half a mile of an oil or gas well, in Colorado nearly 3 out of 10 people living near a well are Latino, and in California 2 out of 5 people living near a well are Latino.<sup>26</sup> In the U.S. overall, more than 1.81 million Latinos live within a half mile of existing oil and gas facilities and more than 1 million African Americans live within a half mile of existing natural gas facilities.<sup>27</sup> The commenter notes that a recent study of almost 61 million Medicare patients conducted nationwide indicates a strong association between exposure to harmful pollutants associated with oil and gas facilities and mortality for minorities.<sup>28</sup> The commenter provides specific disproportionate air pollution exposure burdens for differing minority populations (*e.g.*, African Americans, Latinos, Native Americans).

---

<sup>26</sup> Latino Communities at Risk: The Impact of Air Pollution from the Oil and Gas Industry, Clean Air Task Force (CATF), League of United Latin American Citizens (LULAC), National Hispanic Medical Association (NHMA) 2016.

<sup>27</sup> Clean Air Task Force, Latino Communities at Risk: The Impact of Air Pollution from the Oil and Gas Industry (2016) (“CATF Latino Communities”) at 2; Clean Air Task Force, Fumes Across the Fence-Line: The Health Impacts of Air Pollution from Oil & Gas Facilities on African American Communities (2017) (“CATF African American Communities”) at 4.

<sup>28</sup> Di *et al.*, Air Pollution and Mortality in the Medicare Population, NEW ENGLAND J. OF MEDICINE (June 29, 2017); Di Q, Dai L, Wang Y, Zanobetti A, Choirat C, Schwartz JD, Dominici F, Association of short-term exposure to air pollution with mortality in older adults, JAMA (Dec. 26, 2017); 318(24):2446-56.

Commenter (0385-Silent Spring) notes that it is well-documented that oil and gas wells and other operations are disproportionately located in communities of color. In EPA's own criteria air pollutant (CAP) EJ analysis, the commenter notes that it was demonstrated that both Native American and Hispanic populations experience higher exposure of ozone as a result of VOC emissions from oil and gas sources when compared to the general population.<sup>29</sup> Meanwhile, in California, the commenter reports that there are 5.4 million people who live within 1 mile of an existing oil and gas well, and 1.8 million of this 5.4 million (33 percent) also live in, as identified by California EPA's tool CalEnviroscreen 2.0, areas most burdened by environmental pollution.<sup>30</sup> Most notably, the commenter notes that 92 percent of the 1.8 million people living in these areas most disparately exposed to pollution are people of color.<sup>31</sup> The commenter adds that research has also displayed that census tracts in Pennsylvania exposed to pollution from gas wells have a significantly higher percent of residents below the poverty line when compared to census tracts not exposed to gas well pollution.<sup>32</sup> Meanwhile, the commenter states that an analysis of the Eagle Ford shale in Texas displays that even though white, non-Hispanic residents are more likely to live in the vicinity of oil and gas wells, primarily (80 percent) Hispanic census blocks are exposed to twice as many gas flares within 5 km as compared to primarily white, non-Hispanic census blocks.<sup>33</sup>

Commenter (0949-Liveable Arlington) reports that "[m]ore than 30,000 Arlington children go to public school within half a mile of wells, according to an analysis by Reveal from The Center for Investigative Reporting, and up to 7,600 infants and young children attend private daycares within that radius. Eighty-five percent of the public school students are children of color, and more than two-thirds live in poverty. Altogether, more than half of Arlington's public schools and day care facilities are within a half-mile of active gas production. Eight day care centers are within 600 feet, the standard setback in Arlington."<sup>34</sup>

Commenter (0573-KDHE) conducted an analysis (using EJSCREEN tool) of Kansas county populations impacted at an environmental justice index of greater or equal to 90th percentile for the air toxics cancer and air toxics respiratory fields. Using the option of comparing Kansas counties with U.S. counties as a whole, the commenter found that five Kansas counties had cancer or respiratory impacts. The commenter then ranked oil and gas production on a county basis for 2020 and compared rankings with the five greater or equal to 90th percentile

<sup>34</sup> Investigation by Reveal for Public Radio International.

counties found in EJSCREEN. Results for oil-producing counties turned up three counties, with the highest ranking of these counties ranking 76th among 90 oil producing counties in the state, with 26,800 bbl annual production. The commenter notes that average Kansas county oil production is 314,000 bbl. Results for natural gas-producing counties showed one impacted county with any gas production, with this county ranking 47th among 49 natural gas-producing counties in the state, with 0.016 MMcf annual production. The commenter notes that average Kansas county natural gas production is 3,351 MMcf. According to the commenter, their analysis did not find a significant correlation between oil or gas production and negative health outcomes on a county basis.

Commenter (0727-OSEE/ODEQ) reports that a study by Price Waterhouse for the American Petroleum Institute determined that the oil and gas sector was responsible (including direct and indirect employment) for 16.7 percent of the Oklahoma workforce.<sup>35</sup> The commenter adds that many oil and gas jobs employ residents of rural communities.<sup>36</sup> To assess the possible impacts of job losses in those communities, work performed by the U.S. Department of Agriculture's (USDA's) Economic Research Service investigated economic, social, and demographic factors that affect the poverty status of residents of rural communities. For 2019, the commenter reports that the USDA estimated Oklahoma's statewide poverty rate at 15.1 percent with 19.7 percent of Oklahoma's children living in poverty.<sup>37</sup> The commenter states that rural counties, especially in the southeastern part of the state are particularly impacted by poverty. The availability of middle class oil and gas jobs in rural Oklahoma mitigates the poverty experienced in many of these communities. The commenter requests that, to ensure that just policies are adopted, EPA weigh the economic impacts on vulnerable communities, especially rural communities, as carefully as the environmental benefits are evaluated.

Response I-6-4: EPA acknowledges the information provided by commenters to support EPA's efforts to evaluate and address environmental justice in the November 2021 Proposal. As described in the 2021 RIA, EPA is aware of all studies identified in the bibliography of peer-reviewed studies published since 2015 provided by the Health Effects Institute that evaluate populations that may be disproportionately impacted by the oil and natural gas industry. However, there is considerable discordance among study results. For example, studies differ with regards to geographic area, population of interest, and health outcome. For those reasons, EPA instead relies on associations between exposure and health effects from standardized documents, such as integrated science assessments.

In response to comments regarding the percent of Oklahoma's workforce that is directly or indirectly employed by the oil and gas sector, EPA notes impacts of the proposed regulation on employment among overburdened or marginalized communities was considered in section 4.2.5

<sup>35</sup> "Impacts of the Oil and Natural Gas Industry on the US Economy in 2019," prepared by PricewaterhouseCoopers LLP, prepared for the American Petroleum Institute, July 2021, available on-line: <https://www.api.org/-/media/Files/Policy/American-Energy/PwC/API-PWC-Economic-Impact-Report.pdf>.

<sup>36</sup> See, for example, the article "Feeling the Pain: In Rural Oklahoma, Oilfield Communities See the Ups and Downs of Oil and Gas Industry Firsthand," by Heidi Brandes, February 11, 2021, available on-line on the web page of The Petroleum Alliance: <https://www.thepetroleumalliance.com/feeling-the-pain-in-rural-oklahoma-oilfield-communities-see-the-ups-and-downs-of-oil-and-gas-industry-first-hand/>.

<sup>37</sup> U.S. Department of Agriculture, Economic Research Service, Rural Poverty & Well-Being, state poverty rate data available on-line: <https://data.ers.usda.gov/reports.aspx?ID=17826>.

of the RIA. The RIA notes that a reduction in employment in the oil and natural gas sector may be associated with loss of income for workers in the oil and gas industry, and for oil and gas communities. EPA disagrees it did not weigh the economic impacts on vulnerable communities, especially rural communities, as carefully as the environmental benefits.

## 6.2 Environmental Justice Implications

### 6.2.1 Control of Emissions is Needed to Reduce EJ and Climate Impacts

Comment: Several commenters (0340-Mothers & Others, 0347-Columban, 0398-Representative Barragan *et al.*, 0402-Cancer Free, 0605-Muscogee (Creek) Nation, 0761-Exelon Corporation (Exelon), 0788-350Seattle, 0791-Airdar Inc. (Airdar), 0800-Utah, 0807-BP America, Inc. (BP), 0941-350 Silicon Valley, 1337-BCCM) support control of emissions from oil and gas operation to reduce EJ and climate impacts. Below are examples of these comments.

Commenter (0347-Columban) strongly supports the November 2021 Proposal; however, the commenter urges EPA to set stronger standards. The commenter contends that, in the United States, strict methane rules are urgently needed to protect the health of many communities, especially minority communities, Latino, African American and Indigenous communities. The commenter states that the United States and EPA must ensure we meet our international commitments and obligations. The commenter requests that EPA strengthen the November 2021 Proposal to address climate change and protect the public health of vulnerable communities through supplemental rulemaking or other action, in order to:

1. End the wasteful and dangerous practice of routine flaring at oil and gas facilities, as states like Colorado and New Mexico have done already.
2. Require regular monitoring at all smaller, high-polluting, and leak-prone wells,
3. Work to incorporate emission monitoring results generated by community groups and other third parties into its standards.
4. Continuously engage with front-line community workers and other community-based organization as we believe community participation is critical to address gaps and measure success.
5. Lastly, the commenter urges EPA to finalize this rulemaking as quickly as possible. Our planet is in a climate crisis. The lives of many in the United States and abroad are already in danger.

Commenter (0398-Representative Barragan *et al.*) suggests that there is a need to expand the rule to address the control of emissions from smaller leak prone wells and the wasteful practice of flaring to ensure the protection of frontline communities that are often communities of color and low-income communities from pollution. The commenter added that flaring studies have shown that Latino, Black, and indigenous communities are disproportionately exposed to flaring and its associated health risks,<sup>38</sup> including the development and exacerbation of asthma, cardiopulmonary problems, and cardiovascular mortality. The commenter emphasized the need

---

<sup>38</sup> <https://news.usc.edu/183286/americans-oil-gas-flaring-health-risks-usc-research/>.

to control methane and health harming co-pollutants, including VOCs and toxic and hazardous chemicals like benzene.

Commenter (0340-Mothers & Others) expresses that the proposed methane rule will help address climate change by reducing one of the most potent greenhouse gases that exists. However, the commenters suggest that it needs to be stronger. The commenter states that we have the tools and technology to meet stronger standards, because some states already have strong standards. The commenter recommends that EPA eliminate venting and flaring, close loopholes, and inspect ALL wells for leaks. The commenter reports that children living near gas wells are just as vulnerable to the health effects of methane and associated VOCs no matter who or how large the company is that owns the well. According to the commenter, the EPA needs to respond to the scientists and health experts urging stronger standards and set standards without loopholes that are fully protective of human health.

Commenter (0807-BP) agrees that the steps EPA proposes to reduce methane emissions are not only important to addressing climate change, but they also have the potential to improve air quality and public health for communities that have experienced a cumulative exposure to pollution impacts over time, including communities with environmental justice concerns. See 86 Fed. Reg. 63,110, 63, 122 (Nov. 15, 2021) (“Under the proposed rule, the EPA expects that VOC emission reductions will improve air quality and are likely to improve health and welfare associated with exposure to ozone, [fine particles that have a diameter less than 2.5 micrometers] PM2.5, and [hazardous air pollutants] HAP.”).

Commenter (1337-BCCM) states that, by taking decisive action we can curb harmful emissions and cut health-harming local air pollution for over 9 million people who live near oil and gas operations across the U.S.

Commenter (0941-350 Silicon Valley) states that reducing methane emissions would have many co-benefits of the improved health of residents and workers in neighboring communities.

Commenter (0800-Utah) encourages EPA to continue to support flexibility with these rules to ensure balance with economics and protection of human health and the environment.

Commenter (0402-Cancer Free) states that air pollutants, as well as greenhouse gases emitted from oil and gas sources only serve to exacerbate climate and health inequities in parallel, and the proposed rules, if accepted, have great potential to mitigate both inequities.

Commenter (0761-Exelon) suggests that any final rule should include strong measures to protect disadvantaged and overburdened communities from disproportionate adverse public health and environmental effects of air pollution emitted from the new and existing sources that are addressed in the November 2021 Proposal.

Commenter (0605-Muscogee (Creek) Nation) encourages EPA to consider and compare the costs of the controls to the full range of negative costs experienced from the oil and natural gas industry's high methane, VOC, and HAP emissions.

Commenter (0791-Airdar) adds with issues around social justice and environmental, social, and governance (ESG) standards becoming increasingly important to society, allowing industry to use more advanced monitoring technologies will allow companies to better address these issues, be proactive, and reduce costs related to the consequences of not addressing these issues sooner.

Response I-6-5: EPA acknowledges the commenter's support for EPA's efforts to evaluate and address environmental justice concerns and climate impacts in the November 2021 Proposal. Additionally, EPA has considered the information provided by the commenters regarding the impact of methane, VOC, and other air pollutant emissions from the oil and natural gas industry on the health of nearby populations, as well as other vulnerable communities, and finds that it is consistent with the approach that EPA has taken in the final rule. See sections X and XI of the final preamble for a full discussion of the final standards.

Comment: Commenter (0808-American Petroleum Institute (API)) supports appropriate consideration and adequate protection of disadvantaged groups and that the EPA has made EJ a priority in developing the November 2021 Proposal. For example, the commenter notes that the EPA made extensive outreach to disadvantaged and potentially overburdened populations and proactively sought to address their concerns in the proposal. EPA also included provisions in the November 2021 Proposal that are at least partially designed to address EJ issues. For example, the commenter states that the EPA explains that it provided for the use of "cutting edge" technologies in the rule, "alongside a rigorous fugitive emissions monitoring program that is based on traditional OGI technology." 86 Fed. Reg. at 63139. To address the concern of "addressing large emission sources faster," the commenter states that the EPA proposes "more frequent monitoring at sites with more emissions." *Id.* And in response to concerns about health impacts, "EPA is proposing rigorous guidelines for pollution sources at existing facilities, methane standards for storage vessels, strengthened and expanded standards for pneumatic controllers, and standards for liquids unloading events that will further reduce emissions." *Id.*

Commenter (0808-API) supports EPA's attention to potential EJ issues and agrees that the measures described above will significantly reduce emissions from this sector and should result in corresponding risk reductions for all potentially affected individuals. The commenter asserts that the natural gas and oil industry's top priorities are protecting the public health and safety – regardless of race, color, national origin or income – and the environment. The commenter notes that they strive to understand, discuss and appropriately address community concerns with our operations. The commenter added that they are committed to supporting constructive interactions between industry, regulators, and surrounding communities/populations that may be disproportionately impacted.

Response I-6-6: EPA acknowledges the commenter's support for EPA's efforts to evaluate and address environmental justice concerns in the November 2021 Proposal. EPA takes a consistent approach to this issue in the final rule.

Comment: Commenter (0783-CA Assemblymember Bloom *et al.*) asserts that, because methane emissions represent an environmental justice crisis, they recommend that EPA expand the proposed methane rule to ensure that smaller leak prone wells are covered with regular inspections under the rule, and it eliminates routine flaring. While the commenter states that the

EPA's proposed regulatory changes are promising, they do not believe they go far enough to curb the overall threats of methane and its co-pollutants, or address the unjust level of exposure experienced by communities of color. The commenter explains that, while it is easy to ignore smaller, leak-prone wells because they generate such a small proportion of usable product, the huge number of these facilities and their leakage makes them large emitters of methane, with particular concern in earthquake prone regions such as California.<sup>39</sup> Yet under EPA's November 2021 Proposal, the commenter notes that operators that calculate less than 3 tons of methane/year may avoid regular monitoring, resulting in significant environmental pollution. For this reason, they urge EPA to enact comprehensive requirements for frequent leak inspections, regardless of the size of the wells involved.

Response I-6-7: In response to comments received on the November 2021 Proposal, EPA proposed a different regulatory approach for fugitive emissions at well sites in the December 2022 Supplemental Proposal. For details, please see discussion in section IV.A.1.a.ii of the December 2022 Supplemental Proposal.<sup>40</sup> Please also see section X.A.1 of the preamble to the final rule which details EPA's final standards related to fugitive emissions at well sites.

### ***6.2.2 Title VI of the Civil Rights Act***

Comment: Commenter (0920-WAEJ) suggests that the EPA strengthen enforcement and interpret the methane standards through the lens of Title VI of the Civil Rights Act. The commenter states that the EPA's historical failure to effectively enforce Title VI perpetuates the troublesome trend of concentrating oil and gas facilities in environmental justice communities already overburdened by pollution and has led to chronic diseases or comorbidities in addition to increasing vulnerabilities to climate change impacts. The commenter adds that the Clean Air Act (CAA) standards are based on industrial standards of pollution and suggests that the EPA shift away from enforcement of the CAA as a stand-alone regulation but rather in conjunction with racially disproportionate burden. The commenter states that section 111(d) and Title VI should be viewed together and enforced in harmony to address existing and prevent future environmental harms to frontline communities by the fossil fuel industry, which we see as human and civil rights violations. The commenter contends that Title VI should not be subordinate to environmental laws.

Response I-6-8: The commenters appear to be advocating that the EPA improve enforcement of Title VI of the Civil Rights Act with respect to oil and gas facilities. This is not a comment on the proposed CAA section 111(d) standards themselves, and is therefore outside the scope of the rulemaking. EPA will take the commenters suggestions regarding enforcement under advisement.

### ***6.2.3 EPA's EJ Analysis***

Comment: Commenter (0727-OSEE/ODEQ) states that the RIA uses Public Use Microdata Area (PUMA) data to identify oil and gas communities. The commenter asserts that this level of

---

<sup>39</sup> Mary Kang et al, 2019. Potential increase in oil and gas well leakage due to earthquakes, Environ. Res. Commun. 1 121004, <https://iopscience.iop.org/article/10.1088/2515-7620/ab576e>.

<sup>40</sup> 87 FR 74705; December 6, 2022.

analysis is insufficiently specific in identifying impacts on rural areas. This assertion, according to the commenter, is demonstrated by the map (Figure 4-9 on p. 4-36 of the RIA) which shows the relatively large size of each PUMA. In addition, the oil and gas PUMAs shown in the map cover more than half the state of Oklahoma. In contrast, the commenter notes that the environmental justice communities in EJScreen<sup>41</sup> are identified with much finer granularity. The commenter states that this raises the question: to what degree does this analysis inherently bias the evaluation of costs and benefits, possibly privileging certain communities compared to others?

Commenter (0727-OSEE/ODEQ) states that Table 4-9 in the RIA document provides demographic data for the entire group of PUMAs with high oil and gas intensity. This analysis is used to draw various conclusions concerning the ethnic make-up, educational attainment, and income of residents in these areas compared with other areas with lower oil and gas intensity. According to the commenter, by aggregating the high oil and gas PUMAs for these analyses, EPA fails to give a sufficiently granular analysis of the impacts of the types of rural communities found in Oklahoma. The commenter contends that this contrasts with EPA's approach in evaluating impacts on environmental justice communities. The commenter notes that, while the analysis in the RIA that follows (see Table 4-10 and Figure 4-10 of the RIA) provides some greater specificity, it is still insufficient and still fails to meet the standards EPA uses for evaluating EJ communities.

Response I-6-9: The commenters note that PUMAs cover large spatial area in rural settings, contrast that with the finer spatial scale used for distributional exposure analysis and suggest that EPA should use a finer spatial scale to analyze impacts on oil and gas communities. EPA believes that PUMAs are an appropriate scale to analyze impacts on oil and gas communities. Performing such an analysis at a small spatial unit such as the tract or 12 km grid cell would face data limitations and would limit EPA's ability to analyze economically important spillover effects on nearby tracts or grid cells.

Comment: Commenter (1267-California Office of the Attorney General (CA AG) *et al.*) suggests that EPA has significantly underestimated the EJ impacts associated with HAP emissions from the oil and natural gas sector, including the cumulative and long-term impacts on communities and workers exposed to the emissions from a disproportionate number of facilities continuously sited in already overburdened neighborhoods. First, the commenter states that the EPA has only considered the cancer-related risks on EJ communities;<sup>42</sup> however, according to EPA's own data, four of the eight most significant HAP pollutants from the oil and natural gas sector are not classified by EPA as carcinogenic.<sup>43</sup> These include toluene, ethylbenzene, mixed xylenes, and n-hexane. The commenter notes that exposure to these pollutants has other deleterious effects on human health. For example, the commenter states that chronic exposure to toluene can cause irritation of the upper respiratory tract, eye irritation, dizziness, headaches, and difficulty with

---

<sup>41</sup> See <https://www.epa.gov/ejscreen>.

<sup>42</sup> RIA at 4-25 ("To evaluate the potential EJ impacts associated with baseline HAP emissions from the oil and gas sector, the EPA has assessed the cancer risks and estimated the demographic breakdown of people living in areas with potentially elevated risk levels.").

<sup>43</sup> Id. at 3-21.

sleep.<sup>44</sup> Similarly, the commenter notes that long-term inhalation exposure to xylenes in humans has been associated with a number of effects in the nervous system including headaches, fatigue, tremors, and impaired motor coordination.<sup>45</sup> The commenter adds that chronic exposure to n-hexane causes numbness in the extremities, muscular weakness, blurred vision, headache, and fatigue.<sup>46</sup> According to the commenter, EPA's omission of these impacts from HAP exposure in its consideration of the EJ impacts of the oil and natural gas sector results in an analysis that does not reflect the full toxic burden imposed. The commenter recommends that EPA revise its analysis to account for and recognize these non-cancer impacts.

Response I-6-10: EPA did not assess noncancer hazards for toluene, ethylbenzene, mixed xylenes, and hexane for this RIA. Based on the air toxics concentrations modeled in the cancer risk assessment, the non-cancer hazard from these HAP would be expected to be well below health-protective values.

Comment: Commenter (0842-Institute for Policy Integrity at NYU School of Law (NYU)) requests that EPA expand its distributional analysis beyond baseline conditions to evaluate the impacts of the November 2021 Proposal and alternatives. The commenter explains that the EPA conducts an extensive distributional analysis in the November 2021 Proposal's accompanying RIA that qualitatively and quantitatively identifies disparities in the populations exposed to emissions from the oil and gas source category.<sup>47</sup> However, the commenter suggest that this analysis fails to capture the distributional impacts of the November 2021 Proposal. Instead, they state that the analysis evaluates only the current baseline emissions emitted from the source category and concludes without support that communities experiencing disproportionate impacts in the baseline scenario "may realize disproportionate improvements in air quality resulting from emissions reductions."<sup>48</sup> The commenter argues that the EPA cannot reasonably conclude that disadvantaged communities will see disproportionate improvements without analyzing the impacts of the November 2021 Proposal on baseline conditions.

According to the commenter (0842-NYU), the EPA's analysis, while thorough, fails to evaluate the distributional impact of the November 2021 Proposal itself. They suggest that a baseline understanding of disproportionate burdens created by the source category is helpful but must be accompanied by an analysis that evaluates the distribution of impacts resulting from the November 2021 Proposal and any marginal differences from adopting EPA's proposed alternatives. Indeed, they state that President Biden's Memorandum on Modernizing Regulatory Review calls for analysis that reveals rules' "distributional consequences . . . to ensure that regulatory initiatives appropriately benefit and do not inappropriately burden disadvantaged, vulnerable, or marginalized communities."<sup>49</sup> And evaluation of alternatives is crucial to a meaningful analysis to avoid an agency merely concluding the distributional impacts of its regulatory approach are acceptable without knowing whether the distributional impacts of an

---

<sup>44</sup> Id. at 3-23 – 3-24.

<sup>45</sup> Id. at 3-25.

<sup>46</sup> Id. at 3-26.

<sup>47</sup> 2021 PRIA, *supra* note 3, at 4-43.

<sup>48</sup> Id. at 4-43.

<sup>49</sup> Memorandum on Modernizing Regulatory Review § 2(b)(ii), 86 Fed. Reg. 7223, 7223 (Jan. 25, 2021)).

available regulatory alternative are significantly more desirable.<sup>50</sup> Thus, the commenter asserts that the EPA should conduct a distributional analysis of the November 2021 Proposal and its alternatives to determine whether another approach may be more advantageous to disadvantaged communities.

Response I-6-11: EPA's EJ analyses focused on a baseline distribution of emissions from oil and natural gas sources, enabling the Agency to characterize risks due to oil and natural gas emissions prior to implementation of the rule. While the EPA agrees that baseline assessment alone is not the optimal approach for determining if EJ concerns exist, it was the only analytic approach feasible when preparing the November 2021 Proposal and December 2022 Supplemental Proposal RIAs.

## 6.3 EJ Outreach and Engagement

### *6.3.1 Need for Additional Communication and Outreach to Disadvantaged Communities*

Comment: Commenter (0911-North Dakota Petroleum Council (NDPC)) supports additional communication with and outreach to disadvantaged communities but does not understand by what authority under the CAA the EPA plans to regulate or enforce EJ considerations or negative externalities in a NSPS.

Response I-6-12: EPA finalized requirements regarding meaningful engagement associated with state plan development in the final rule, Adoption and Submittal of State Plans for Designated Facilities: Implementing Regulations Under Clean Air Act Section 111(d) at 88 FR 80480, November 17, 2023, and its corresponding Summary of Public Comments and Responses on Proposed Rule Adoption and Submittal of State Plans for Designated Facilities: Implementing Regulations Under Clean Air Act Section 111(d) (Subpart Ba) Docket ID No. EPA-HQ-OAR-2021-052.

### *6.3.2 Community-Based Initiatives*

Comment: Commenter (0734-ATS) suggests that community-based participatory research (CBPR) initiatives can help to engage communities affected by nearby oil and natural gas production facilities.<sup>51</sup> The commenter reports that such work from Los Angeles has demonstrated that individuals living nearby such sites, which have a higher proportion of low-income and minoritized residents, experience increases in asthmatic symptoms and lower lung function.<sup>52,53</sup> The commenter adds that historical practices of redlining and housing segregation in California contributed substantially to minoritized individuals only securing nearby housing

oil and natural gas extractive areas.<sup>54</sup> The commenter recommends that EPA outlines clear recommendations to ensure that oil and natural gas producers engage local communities to participate in decisions regarding new extraction and refining operations and to participate in local monitoring strategies. Furthermore, the commenter suggests that funds be allocated to ensure that CBPR initiatives can monitor the community health and environmental impacts of nearby oil and natural gas facilities.

Response I-6-13: EPA finalized requirements regarding meaningful engagement associated with state plan development in the final rule, Adoption and Submittal of State Plans for Designated Facilities: Implementing Regulations Under Clean Air Act Section 111(d) at 88 FR 80480, November 17, 2023, and its corresponding Summary of Public Comments and Responses on Proposed Rule Adoption and Submittal of State Plans for Designated Facilities: Implementing Regulations Under Clean Air Act Section 111(d) (Subpart Ba) Docket ID No. EPA-HQ-OAR-2021-052.

## **6.4 Proposed Rule Will Result in Adverse Economic Impacts/Environmental Justice Economic Impacts**

Comment: Commenter (0803-Ohio Oil and Gas Association (OOGA)) contends that the November 2021 Proposal will stifle oil and gas development in Ohio which will result in inverse EJ and significant negative impacts to Ohio's economy. While U.S. EPA's intentions are seemingly well intentioned, the commenter states that the U.S. EPA's analysis and considerations in this regard are, at best, one sided. According to the commenter, the additional and more stringent controls required under the November 2021 Proposal impose substantial burdens on the industry that will inevitably render many operations, particularly low production wells, economically infeasible. The commenter adds that the U.S. EPA fails to recognize that the oil and gas industry provides necessary and critical services to overburdened and underserved communities and that the impact of November 2021 Proposal on the industry effectively results in "inverse" environmental justice in these communities. Notably, for example, there are approximately 61,000 active wells in Ohio. The commenter notes that about 60 percent of the wells in Ohio involve private contractual relationships between the producer and the landowner to take a limited amount of natural gas for the Lessor's private domestic use (*e.g.*, heat a farmhouse, supply fuel for cooking, etc.). The commenter states that this means that there are approximately 36,700 rural Ohioans who have direct access to natural gas because of oil and gas facilities. The commenter concludes that compliance with U.S. EPA's November 2021 Proposal will challenge the future viability of well operations in rural Ohio which will have a significant negative impact on the people in those communities.

Commenter (0911-NDPC) fears that potentially extraneous and overly burdensome new requirements would have the reverse impact on economically and socially disadvantaged communities by steering oil and gas investment away from communities of need.

---

<sup>54</sup> Cumming, DG. Black Gold, White Power: Mapping Oil, Real Estate, and Racial Segregation in the Los Angeles Basin, 1900-1939. *Engag Sci Technol Soc* 4, 85–110 (2018).

Commenter (1301-Northern Arapaho Tribe Business Council) suggests that EPA recognize the challenges for relatively small owners and operators such as the Tribe and help mitigate economic impacts to small operators by providing for streamlined or phased-in compliance. Given the noted EJ implications of the Rule, the commenter suggests prioritizing measures that improve local air quality and health impacts.

Response I-6-14: EPA's NSPS OOOOb and EG OOOOc are projected to cause small changes in oil and natural gas production and prices. Pursuant to section 603 of the RFA, EPA prepared an FRFA that examined the impact of the rule on small entities along with regulatory alternatives that could minimize that impact. The complete FRFA is available for review in the Regulatory Impact Analysis (RIA) (see section 4.4).

Comment: Commenters (0814-Independent Petroleum Association of America (IPAA) *et al.*, 0836-Domestic Energy Producers Alliance (DEPA)) express that the EPA should take into consideration that many rural areas of this country rely on oil and gas industry for their livelihood.

Commenter (0814-IPAA *et al.*) states that the EPA's November 2021 Proposal dedicates extensive discussion to ensure "robust and meaningful public engagement" with "underserved or overburdened communities." The commenter adds that the EPA focuses on the "particularly vulnerable to the climate and health impacts of pollution from this source category." The commenter supports such efforts. The commenter reminds EPA that in many rural areas of this country that "this source category" is not simply something defined by the CAA but it is their livelihood – it allows them to heat their homes and hopefully stay above the poverty level. The commenter adds that workers in this source category and their families live and breathe in close proximity to these emissions sources – they care what is being emitted. EPA's November 2021 Proposal represents a real threat to these rural communities. Homeowners and farms often rely on the gas from wells located on their property or pipelines that transverse their property to heat their homes and/or provide critically important income.

Commenters (0814-IPAA *et al.*, 0836-DEPA) note that, beyond the homeowners and farmers that directly rely on gas from wells on their property and/or pipelines that transverse their property, there are many communities that rely exclusively on gas supplied by low production/marginal wells located geographically close to their homes and would not be served if certain low production wells are shut-in because the small, local oil and natural gas company cannot afford to comply with the regulations in the November 2021 Proposal. While the citizens of these rural parts of the country are certainly concerned with the "climate and health impacts of pollution from this source category" – they are also concerned with their livelihood and putting food on the table. The potential impacts of the November 2021 Proposal extend well beyond the operators in this "source category." According to the commenters, consideration of the impact to the numerous "mom and pop" companies selling gas, food, lodging, etc. that rely on this source category needs to be factored into the "environmental justice implications" of the November 2021 Proposal in order to constitute "meaningful engagement" of "underserved and overburdened communities." The commenters state that the November 2021 Proposal crunches numbers to support "cost-effective" controls. They add that EPA also engages in an interesting discussion of what constitutes the "best system of emission reduction" (BSER) and the "cost" of

achieving such reduction. The commenters suggest that describing or defining what is "reasonable" as something not "exorbitant" and not something "greater than the industry could bear and survive," by individuals that in most cases have never been to these rural areas of the country is not comforting to the members and their dependent families of employees. The commenters supports EPA's efforts to go beyond the numbers and to better understand the real impact of the November 2021 Proposal on rural populations of this country.

Commenter (0946-Michigan Oil and Gas Association (MOGA)) reminds the EPA that many "underserved or overburdened communities" are often located in rural areas where oil and gas drilling and production provides jobs and sustains local economies. The commenter is concerned that the proposed future new source performance standards (NSPS) OOOOb and emission guidelines (EG) OOOOc will likely result in the early plugging of marginal wells that cannot absorb the initial implementation and ongoing costs of the proposed regulations. The commenter states that plugging of wells will have a direct impact on associated small businesses, including hotels, restaurants, service, retail and other "mom and pop" stores that rely on the oil and gas industry to survive. The commenter recommends that EPA consider the economic impacts on these small rural "underserved or overburdened communities" when determining the cost benefit analysis for the minimal reduction of methane from marginal wells.

Commenter (0727-OSEE/ODEQ) expresses concern that the proposed rule's focus on environmental justice may not take into consideration its potential economic effects on EJ communities within oil and gas dependent economies and that the proposal does not provide fair consideration of the economic impacts in distressed rural communities that may not meet EPA's definition of "environmental justice community." The commenter encourages EPA to broaden its evaluation of the costs and benefits of the proposed rule to incorporate economic effects with the same level of granularity that was used in targeting communities living in proximity to facilities that would be subject to this rulemaking. In particular, how will these policies affect employment in economically-distressed rural communities in states like Oklahoma?

Commenter (0727-OSEE/ODEQ) is concerned that EPA's analysis is just too vague and too broad-brush. The commenter suggests that important questions need to be addressed. How many marginal wells are expected to close as a result of the proposed rules? How many jobs are expected to be lost and which communities are likely to experience those losses? The commenter notes that it may be challenging to attempt to address these issues with sufficient rigor, but an attempt is certainly warranted to justify policies that will have disproportionate impacts on some communities to benefit the entire public. To conclude, the commenter states that they do not object to the evaluation of environmental impacts on environmental justice communities, but respectfully request EPA perform a similarly detailed and rigorous analysis of economic impacts, especially in rural communities.

Response I-6-15: EPA disagrees it did not weigh the economic impacts on vulnerable communities, especially rural communities, as carefully as the environmental benefits. Employment impacts of environmental regulations are generally composed of a mix of potential declines and gains in different areas of the economy over time. NSPS OOOOb and EG OOOOc are projected to cause small changes in oil and natural gas production and prices. As a result, demand for labor employed in oil and natural gas related activities and associated industries

might experience adjustments as there may be increases in compliance-related labor requirements as well as changes in employment due to quantity effects in directly regulated sectors and sectors that consume oil and natural gas products. However, regulatory employment impacts can vary across occupations, regions, and industries; by labor and product demand and supply elasticities; and in response to other labor market conditions. Isolating such impacts is a challenge, as they are difficult to disentangle from employment impacts caused by a wide variety of ongoing, concurrent economic changes. At this time, EPA is unable to quantify well shut-in or employment shifts, either jobs losses in the oil and gas sector and oil and gas communities, or subsequent jobs gains in other sectors or locations. For more information, see EPA's final RIA.

## Chapter 7. Fugitive Emissions from Well Sites

### 7.1 Fugitive Emissions from Well Sites

#### 7.1.1 General Support

Comment: Several commenters (0196-Evangelical Environmental Network (EEN), 0443-Seventh Generation Interfaith Inc. (SGI), 0455-Radio Drama Network, Inc. (RDN), 0460-Trinity Health, 0538-Change Finance, PBC (Change Finance), 0559-TX State Senator Eckhardt, 0737-Clarke Valve, 0766-Cheniere Energy, Inc. (Cheniere), 0782-Berkshire Hathaway Energy Company (BHE), 0789-Pennsylvania Department of Environmental Protection (PA DEP), 0932-GHGSat, Inc., 1382-National Grid, 1389-VERIS Wealth Partners, 1372-Generate Capital, PBC (Generate), 0728-Calvert Research and Management (Calvert), 0724-Boston Trust Walden, 0720-Miller/Howard Investments, Inc. (MHI)) express general support for EPA's November 2021 Proposal to reduce methane emissions from the oil and gas segment. Several of the commenters urge the EPA to ensure strong methane emission performance standards by crafting a regulation that maintains or expands strong leak monitoring and repair standards, including through expanded use of advance leak detection technologies.

Commenter (0782-BHE) argues even without broad federal mandates for existing sources, LDAR programs have been “built out” within natural gas operations in response to NSPS OOOOa, voluntary programs, and state mandates. The November 2021 Proposal explores alternatives to current LDAR programs, such as tiered programs where leak mitigation schedules, reporting and other requirements are dependent on leak size. While leak mitigation program flexibility is a worthy goal, in general it may be premature to adopt LDAR replacement programs because technology such as component-level leak quantification is not yet available to quickly and cost effectively measure leak rates. Even as technology barriers are addressed, any “new” program elements should be added as optional alternatives rather than supplant established LDAR programs. For future scenarios that add alternative options, commenter (0782-BHE) recommends that EPA retain these standard LDAR programs and avoid adding complications or replacing current LDAR with alternatives. The current programs have been established across the asset base and have proven effective at eliminating most leaks and reducing leak emissions. Prescribed replacement of the current LDAR programs would inappropriately impugn existing and successful programs and introduce significant burden to build out new replacement programs without justification for such an outcome. Similarly, EPA requested feedback on programmatic approaches for LDAR such as subcategorization. The commenter recommends not adding such approaches to the existing, established LDAR approach because of potential complications. Commenter (0782-BHE) recommends that EPA explore development of alternative optional leak mitigation approaches through systematic development and demonstration of the alternatives.

Commenter (0789-PA DEP) notes that in Pennsylvania's experience, implementing quarterly leak detection and repair (LDAR) provisions has proven to be a cost-effective method to reduce methane emissions for new or modified natural gas production at unconventional wellsite, compression, processing, and transmission facilities. Accordingly, the commenter encourages EPA to include quarterly LDAR inspection requirements for all new or modified natural gas

production, compression, processing, and transmission facilities in the proposed rule. If an exemption is included in the rule, the commenter encourages EPA to consider limiting the exception to facilities which do not include equipment that is highly prone to failure.

Commenters (1389-VERIS Wealth Partners, 1372-Generate Capital, 0728-Calvert, 0724-Boston Trust Walden, 0720-MHI) urge EPA to ensure strong methane emission performance standards by crafting a regulation that includes all potentially significant sources of methane emissions, including smaller leak-prone wells, under emission standards.

Response I-7-1: EPA acknowledges the commenters support for the November 2021 Proposal's requirements for fugitive emissions components located at well sites. See discussion in section IV.A.1 of the December 2022 Supplemental Proposal for additional response to comments requesting strengthening of these standards.<sup>1</sup> Please also see section X.A.1 of the preamble to the final rule which details EPA's final standards related to fugitive emissions components located at well sites.

Comment: Commenter (0752-American Forest & Paper Association (AF&PA) and The Process Gas Consumers Group (PGC)) states that the pulp and paper industry and certain members spent approximately \$2.56 billion to purchase natural gas in 2018. Making a conservative assumption that leakage comprises a small percentage of the total gas purchased, it is estimated that the PGC spent at least \$50 million in 2018 for natural gas they did not receive due to leakage. Importantly, this estimation does not consider the costs of pipeline service disruptions from natural gas leakage. The commenter asserts that LDAR requirements in the proposed regulations could increase the safe and reliable operation of natural gas pipelines and reduce losses and these types of incidents.

Response I-7-2: EPA acknowledges the commenter's support for the November 2021 Proposal's standards for fugitive emissions components at well sites.

Comment: Commenters (0920-We Act for Environmental Justice (WAEJ); 1338-Lexington Climate Action Network (Lexington-CAN)) urge EPA to consider additional measures in order to reach the ambitious goal of reducing methane emissions 65 percent by 2025 (only 3 years from now) by making sure that all wells are subject to regular and frequent LDAR. Commenter (0920-WAEJ) urges the EPA to require companies to address leaks from ALL wells, including smaller wells as well as compressor stations and storage vessels, regardless of their potential to emit (PTE), ensuring they are subject to continuous LDAR as frequently as possible. EPA should work with the Department of Interior, which is responsible for distributing funds from the bipartisan infrastructure law, to identify and plug highly polluting orphan oil and gas wells across the country.<sup>2</sup>

Response I-7-3: EPA acknowledges the commenters support for the November 2021 Proposal's requirements for fugitive emissions components located at well sites. See discussion in section IV.A.1 of the December 2022 Supplemental Proposal for additional response to comments

---

<sup>1</sup> 87 FR 74722-74736 (December 6, 2022).

<sup>2</sup> Grist, Abandoned oil well counts are exploding — now that there's money on the table (2022), <https://grist.org/energy/abandoned-oil-wells-cleanup-infrastructure-law/>.

requesting strengthening of these standards.<sup>3</sup> Please also see section X.A.1 of the preamble to the final rule which details EPA's final standards related to fugitive emissions from well sites.

Comment: Commenter (0949-Liveable Arlington) requests that EPA require 24-hour air monitoring for new and existing wells within half a mile of homes, schools, preschools, daycares, and medical centers. Automatic LDAR inspections should be required when air monitors show elevated levels of hazardous air pollutants (HAP). The commenter asks that EPA immediately deploy the best available emissions control technology. The commenter recommends monthly LDAR for all new and existing wells.

Commenters (0942-CleanEarth4Kids.org, 0937-Fort Berthold Protectors of Water and Earth Rights (Fort Berthold POWER), 0947-Alliance of Nurses for Healthy Environments-Colorado (ANHE-CO) *et al.*, 1339-Waterway Advocates) suggest the administration take immediate action to cut methane pollution by at least 65 percent for 2025 by requiring all wells, regardless of their size or PTE, to be monitored for monthly LDAR. The commenters assert that these reports must be publicly available.

Commenter (0841-Red Mesa Chapter Governance-Navajo Nation (RMCG-Navajo), 0840-Counselor Chapter House-Navajo Nation (Counselor-Navajo)) urge EPA to strengthen its final rule by eliminating loopholes that allow certain wells to forgo regular inspections and require regular monitoring at smaller, leak prone wells.

Response I-7-4: See discussion in section IV.A.1 of the December 2022 Supplemental Proposal for response to comments requesting strengthening of these standards.<sup>4</sup> See discussion in section IV.B.2 for response to comments related to the use of continuous monitoring systems.<sup>5</sup> Please also see section X.B.2 of the preamble to the final rule which details EPA's final standards related to continuous monitoring under the advanced methane detection technology program.

Comment: Commenter (0786-Enerplus Resources (USA) Corporation (Enerplus)) has concentrated on technology and engineering to eliminate potential leak points through improved facility design and operation. The commenter specifically discusses a lock-down thief hatch system, which, according to the commenter, is a significant technological advancement to address leaks. More details on the technology are provided in the commenter's letter. The commenter requests reduced inspection frequencies for facilities engineered to eliminate and prevent leaks. Provisions for this allowance will encourage technological innovation across the industry.

Response I-7-5: In response to comments received on the November 2021 Proposal, EPA proposed a different regulatory approach for this particular affected/designated facility in the December 2022 Supplemental Proposal. For details, please see discussion in section IV.A of the

---

<sup>3</sup> 87 FR 74722-74736 (December 6, 2022).

<sup>4</sup> 87 FR 74722-74736 (December 6, 2022).

<sup>5</sup> 87 FR 74744 (December 6, 2022).

December 2022 Supplemental.<sup>6</sup> Please also see section X.A.1 of the preamble to the final rule which details EPA’s final standards related to fugitive emissions from well sites.

Comment: Commenter (0570-Konica Minolta Sensing Americas, Inc. (Konica)) states large leaks can be easily found even at long distances such as at the entrance to a facility. Therefore, the commenter considers periodic screening with an OGI as a practical solution. Many oil and gas operators and service companies already have or are considering OGI cameras, and they would utilize their own assets as much as possible. Therefore, the commenter believes it is possible to give operators flexibility in their choices while achieving emission reduction goals.

Response I-7-6: EPA agrees that providing owners and operators flexibility in achieving emission standards is appropriate. EPA proposed specific provisions for the use of advanced methane measurement technologies for both periodic screening and continuous monitoring as an alternative to OGI in the 2022 Supplemental Proposal (see Section IV.B.) The final NSPS OOOOb and EG OOOOc include provisions for the use of alternative test methods using advanced methane detection technologies that allow for periodic screening or continuous monitoring for fugitive emissions.

### ***7.1.2 Definitions Related to Fugitive Emissions Components***

Comment: Commenter (0737-Clarke Valve) encourages EPA to change the definition of a “leak” from 500 parts per million (ppm) to 50 ppm. It has been known for decades that methane is far more potent than carbon dioxide, as is reflected in the November 2021 Proposal.<sup>7</sup> Therefore, allowing emissions up to 500 ppm to continue accommodates aging seal technology, while significant scientific and material advances have been available for the last few decades that easily allow manufacturers to meet a more stringent standard. In fact, several valve manufacturers already are using widely available mature seal technology, such that their valves are achieving emissions below 50 ppm, the commenter notes. On the other hand, some of the largest valve manufacturers will only adhere to the minimum requirements in law, which is why the new requirements must be as stringent as possible to achieve maximum emissions reductions.

The commenter (0737-Clarke Valve) also encourages EPA to continue to further explore all options to reduce fugitive emissions, with a particular emphasis on control valves, where an immediate and significant impact can be achieved in the reduction of fugitive emissions. Currently, when analyzing types of equipment, although unintended, fugitive emissions from control valves are estimated to account for approximately 60 percent of total fugitive emissions.<sup>8</sup>

Response I-7-7: The BSER for fugitive emissions components is a fugitive emissions monitoring and repair program that includes audio, visual, and olfactory (AVO) monitoring with or without OGI monitoring, depending on the equipment at the well site or centralized production facility.

<sup>6</sup> 87 FR 74722 (December 6, 2022).

<sup>7</sup> Standards of Performance for New, Reconstructed, and Modified Sources and Emissions Guidelines for Existing Sources: Oil and Natural Gas Sector Climate Review (Proposed Rule), 86 Fed. Reg. 63110 (Nov. 15, 2021).

<sup>8</sup> Mackay, James E., and Kevin J. Smith. Monitoring and Containment of Fugitive Emissions from Valve Stems – Electrical Conductivity and Gas Adsorption Measurements on Metal Oxides. Department of Chemical and Biological Engineering, University of British Columbia.

EPA Method 21 is an allowed alternative to the OGI monitoring, where a leak is defined as an instrument reading of 500 ppm above background or greater.

Comment: Commenter (0793-Permian Basin Petroleum Association (PBPA)) states that EPA has proposed that emissions resulting from control devices operating in a manner that are not in full compliance with any federal rule, state rule, or permit “are also considered fugitive emissions.” See 86 Fed. Reg. at 63,170 & 63,247. Fugitive emissions components have traditionally been those associated with process equipment. See, e.g., 40 C.F.R. §60.5430a (defining “fugitive emissions component” to include those components associated with process equipment, such as “valves, connectors, pressure relief devices, open-ended lines, flanges, covers and [certain] closed vent systems.”). While malfunction-type emissions from control devices would be unauthorized emissions potentially subject to permit-driven reporting requirements, there is no reasoned basis for characterizing those as fugitive emissions.

Response I-7-8: In response to comments received on the November 2021 Proposal, EPA revised the fugitive emissions components definition to not include control devices in the December 2022 Supplemental Proposal. For details, please see discussion in section IV.A.1.a.ii. of the December 2022 Supplemental Proposal.<sup>9</sup> Please also see section X.A of the preamble to the final rule which details EPA’s final standards related to fugitive emissions from well sites and section XI.A.1.a of the preamble to the final rule which discusses responses to significant comments related to the definition of fugitive emissions components.

Comment: Commenter (0573-Kansas Department of Health and Environment (KDHE)) states that in anticipation of the potentially very large number of emission surveys that will need to be performed under this rule at its outset, particularly at low-emitting well sites, keeping the option of EPA Method 21 would help mitigate bottlenecks for owners/operators being able to carry out survey requirements.

Response I-7-9: Consistent with the November 2021 Proposal and the December 2022 Supplemental Proposal, the final NSPS OOOOb and EG OOOOc retain EPA Method 21 as an allowed alternative to OGI monitoring.

Comment: Commenter (0844-Environmental Defense Fund (EDF) *et al.*) notes that as EPA has recognized that “[a] key factor in evaluating how to target fugitive emissions is clearly identifying the emissions of concern and the sources of those emissions.”<sup>10</sup> According to the commenter, EPA has also correctly recognized that “data shows that the universe of components with potential for fugitive emissions is broader than the illustrative list included in the 2016 NSPS OOOOa, and that the majority of the largest emissions events occur from a subset of components that may not have been clearly included in the definition.”<sup>11</sup> The commenter supports EPA’s November 2021 Proposal to expand the definition of fugitive emission components to more broadly encompass significant emissions sources and offer a few

---

<sup>9</sup> 87 FR 74705; December 6, 2022.

<sup>10</sup> 86 Fed. Reg. 63,169.

<sup>11</sup> *Id.*

recommendations on how EPA can further strengthen this definition to achieve the aims articulated in the November 2021 Proposal.

The commenter (0844-EDF *et al.*) recommends amending the proposed definition as follows (additions underlined and deletions struck out):

any component or piece of equipment with components that has the potential to emit fugitive emissions of methane and VOC at a well site (including a centralized production facility or tank battery) or compressor station, including but not limited to all valves, connectors, PRDs, open-ended lines, flanges, ~~all~~ covers and closed vent systems, ~~all~~ thief hatches ~~or~~ and other openings on ~~a controlled~~ any storage vessel, compressors, instruments, meters, natural gas-driven pneumatic controllers, ~~or~~ natural gas-driven pumps, agitator seals, distance pieces, crankcase vents, blowdown vents, pump seals and diaphragms, separators, pressure vessels, dehydrators, heaters, flares, and other control devices. ~~However, natural gas discharged from natural gas-driven pneumatic controllers or natural gas-driven pumps are not considered fugitive emissions if the device is operating properly and in accordance with manufacturers specifications. Control devices, including flares, with emissions resulting from Emissions detected during fugitive monitoring from natural gas-driven pneumatic controllers, natural-gas driven pneumatic pumps, flares, and other control devices are not considered fugitive emissions only if the device is operating in a manner that is not in full compliance with any all applicable Federal rules, State rules, or and permits. are also considered fugitive emissions components.~~

The commenter (0844-EDF *et al.*) believes these recommended changes would reduce ambiguity about fugitive monitoring and what is considered a fugitive emission. The commenter recommends including equipment types in the definition to avoid ambiguity that might cause certain sources of fugitive emissions to not be surveyed (*e.g.*, separators are not included in the proposed definition even though separator dump valves are a known significant source of large fugitive emission events.) Under a proper reading of the proposed definition, separator dump valves should be included within the term “valve.” But to avoid ambiguity, the commenter believes EPA should include certain equipment types like separators in the definition so it is clear that monitoring of separator dump valves and components on all other equipment is required.

The commenter (0844-EDF *et al.*) also recommends including “centralized production facility” and tank batteries as affected facilities where fugitive monitoring is required. Again, under a proper reading of the proposed definition, the commenter thinks monitoring would be required at these sites. But including a specific reference or a cross-reference to the affected facility definition is important to avoid ambiguity and ensure fugitive monitoring occurs at tank batteries and other centralized production facilities, which are known large sources of fugitive emissions.

The commenter (0844-EDF *et al.*) thinks that EPA should include a non-exhaustive but more comprehensive list of fugitive emission components and equipment. Including a greater variety of components will help ensure they are not overlooked during fugitive monitoring and will reduce the potential for interpretations that might incorrectly narrow the scope of fugitive

monitoring. In Colorado, for example, fugitive monitoring is required at “well production facilities.”<sup>12</sup> Well production facility means:

*all equipment* at a single stationary source directly associated with one or more oil wells or natural gas wells upstream of the natural gas processing plant. This equipment includes, but is not limited to, equipment used for storage, separation, treating, dehydration, artificial lift, combustion, compression, pumping, metering, monitoring, and flowline.<sup>13</sup>

In the commenter’s opinion (0844-EDF *et al.*), it is critical that EPA must avoid circularity in the definition that could be interpreted as not requiring fugitive monitoring for venting components and control devices if the operator believes the components are operating as intended. Fugitive monitoring must be required at venting components (like pneumatics) and control devices (like flares) *for the purpose of determining* if the device is operating properly or not.<sup>14</sup> The commenter believes that as currently written, an operator might believe that a flare or venting pneumatic is operating as intended and decide that it does not need to be surveyed for fugitive emissions. However, monitoring is the only way to ensure such a device is operating correctly and not malfunctioning and emitting at greater levels than intended. The commenter suggests that EPA make clear that all gas-driven pneumatics, flares, and other control devices are subject to fugitive monitoring no matter whether they are operating correctly or not.<sup>15</sup> A clear regulatory definition explaining that fugitive emissions include impermissible vented emissions (*i.e.*, those exceeding permissible levels or due to malfunctions) is also important for the structure and follow-up requirements of advanced monitoring.<sup>16</sup>

Response I-7-10: In response to comments received on the November 2021 Proposal, EPA proposed a different regulatory approach for this particular affected/designated facility in the December 2022 Supplemental Proposal. For details, please see discussion in section IV.A.1.a.ii. of the December 2022 Supplemental Proposal related to the definition of fugitive emissions components.<sup>17</sup> Please also see section X.A of the preamble to the final rule which details EPA’s

---

<sup>12</sup>Colo. Code Regs. § 1001-9, Pt. F, § N, p. 287 (“‘Well production facilities’ are also subject to LDAR requirements and storage tank maintenance requirements. This definition is meant to include all of the emission points, as well as any other equipment and associated piping and components, owned, operated, or leased by the producer located at the same stationary source[.]”).

<sup>13</sup>Id. at Pt. D, § I.B.30 (emphasis added).

<sup>14</sup>See, e.g., Cal. Code Regs. Tit. 17, § 95667, <https://ww2.arb.ca.gov/sites/default/files/2020-03/2017%20Final%20Reg%20Orders%20GHG%20Emission%20Standards.pdf> (requiring leak monitoring at natural gas driven pneumatic controllers and pumps).

<sup>15</sup>According to the International Energy Agency, flare efficiency and methane slip is “an area often overlooked by regulators.” IEA analysis shows “in 2020, flares leaked on average around 8% of the natural gas and natural gas liquids that should have been combusted – more than double previous estimates. Incomplete combustion from flares accounted for about 10% of total oil and gas methane emissions, 95% of which was avoidable.” The best way to prevent emissions from flares is eliminating flaring entirely, as discussed in Part IV.I (flaring). IEA, Curtailing Methane Emissions from Fossil Fuel Operations: Pathways to a 75% Cut by 2030 (October 2021), <https://www.iea.org/reports/curtailing-methane-emissions-from-fossil-fuel-operations>.

<sup>16</sup> See Part IV.A.3 (advanced monitoring) of the commenter’s letter; see also Fox et al., A review of close-range and screening technologies for mitigating fugitive methane emissions in upstream oil and gas, 14 Env. Res. Lett. 053002 (2019), <https://iopscience.iop.org/article/10.1088/1748-9326/ab0cc3/pdf> (discussing regulatory equivalence issues stemming from advanced methods’ inability to distinguish between fugitive and vented emissions).

<sup>17</sup> 87 FR 74723 (December 6, 2022).

final standards related to fugitive emissions from well sites and section XI.A.1.a of the preamble to the final rule which discusses responses to significant comments related to the definition of fugitive emissions components.

Comment: Commenters (0755-Texas Pipeline Association (TPA), 0803-Ohio Oil & Gas Association (OOGA), 0817-GPA Midstream Association (GPA), 0911-North Dakota Petroleum Council (NDPC), 0938-Texas Oil & Gas Association (TXOGA)) believe EPA's proposed definition of "fugitive emission component" is too broad and covers too many potential emission sources. Some commenters specifically object to the inclusion of emissions from non-regulated sources and malfunctioning controllers and control devices.

The commenter (0755-TPA) questions the November 2021 Proposal because the line between "operating properly" and not "operating properly" with this type of equipment is, in many cases, far from clear and the determination is often highly subjective in nature. In particular, the criteria for determining a malfunctioning device from an OGI survey is subjective, not objective. Finalization of this sort of definition would leave owners and operators with continuing questions and uncertainty as to whether, in a given circumstance at a given facility, a particular piece of equipment was included in the definition of "fugitive emissions component" such that the NSPS applied. This sort of uncertainty adds undue regulatory burden and makes compliance difficult, and in many cases a subjective guessing game. The emissions requirements related to control devices and pneumatic controllers should be handled under the rules governing each specific affected source type, not under rules applicable to fugitive emissions generally.

The commenter (0755-TPA) thinks it is important that EPA limit the list of fugitive emission components to equipment that is not designed to vent as part of its intended operations, so as to keep the rules' focus on equipment that creates emissions as the result of an abnormal, unintended condition that needs to be repaired. Removing equipment such as thief hatches and crankcase vents, which are intended to release emissions as part of normal operations, would bring the definition more in line with the traditional concept of what constitutes a fugitive emissions component, *i.e.*, a piece of equipment that is emitting fugitive emissions due to unintended malfunction, not intended operations. Narrowing the list in this manner would also have the benefit of reducing the number of individual components that would be subject to the extensive survey, repair, replacement, and recordkeeping/reporting requirements that would apply to components covered by the fugitive emissions rules. The application of such onerous requirements should be as limited as possible, and in no event should such requirements be applied to equipment that is allowing emissions as an integral part of its design and operations. The commenter notes that EPA did not include an unrealistically expansive list of fugitive emissions components in other rules, *e.g.*, LDAR regulations in subpart VVa, lists only the following covered equipment: "pump, compressor, pressure relief device, sampling connection system, open-ended valve or line, valve, and flange or other connector in VOC service and any devices or systems required by this subpart."<sup>18</sup> Notably, this list does not include equipment types that are designed to vent as part of intended operations. The commenter argues in finalizing the list of fugitive components in this rulemaking, EPA should compose a list that is similarly reasonable and realistic.

---

<sup>18</sup> 40 CFR § 60.481 a.

The commenter (0803-OOGA) requests that EPA exclude safety equipment (*e.g.*, pressure relief valves), which only emit out of necessity in an emergency situation, from the definition of “fugitive emissions component.” It is unclear whether such emissions are treated as “malfunctioning controllers” under the November 2021 Proposal. Regardless, safety equipment are integral and necessary components and the activation of such equipment resulting in emissions should not be treated as a malfunction nor otherwise regulated and included in the baseline methane emission estimate.

Commenter (0817-GPA) states that the November 2021 Proposal provides no basis for assuming OGI cameras can detect control device malfunctions. The commenter does not understand why EPA believes OGI cameras could detect malfunctioning control devices or how/if EPA evaluated a recent EPA Region 8 study examining OGI observations of enclosed combustion devices and their correlation to analyzer sampling.<sup>19</sup> The study does not reach a conclusion on the effectiveness of OGI to detect a malfunctioning control device and indicates there is no obvious comparison between stack test data and OGI observations. The study demonstrates the difficulty in distinguishing between control device heat signatures and emissions and identifies the challenges of using an OGI camera to determine if enclosed combustion devices are meeting desired combustion efficiencies. The commenter suggests EPA should address this study.

If EPA requires the use of OGI cameras to identify control device malfunctions, the commenter (0817-GPA) requests that it allow operators to take additional confirmatory steps prior to effectuating any repairs. After an OGI camera operator believes they have detected a malfunctioning control device, EPA should require the operator to first confirm the malfunction through other information, such as reviewing operating conditions at the facility based on thermocouple readings, flow rates, level indicators, gas analyses, and physical inspection of equipment. If this information fails to show a control device malfunction, then the operator should not be required to take any further action.

Response I-7-11: In the December 2022 Supplemental Proposal made significant revisions to the definition of fugitive emissions components that was proposed in November 2021. For details, please see discussion in section IV.A.1.a.ii. of the December 2022 Supplemental Proposal related to the definition of fugitive emissions components.<sup>20</sup> Please also see section X.A of the preamble to the final rule which details EPA’s final standards related to fugitive emissions from well sites, including the final definition of fugitive emissions components, which does not include control devices or controllers. Please also see section XI.A.1.a of the preamble to the final rule which discusses responses to significant comments related to the definition of fugitive emissions components.

Comment: Commenters (0727-Oklahoma Secretary of Energy and Environment (OSEE) and Oklahoma Department of Environmental Quality (ODEQ), 0817-GPA, 0911-NDPC, 0938-TXOGA) state that EPA seems to be using a different definition for fugitive emissions in the

---

<sup>19</sup> EPA, Region 8, Wyoming Department of Environmental Quality, Measuring Enclosed Combustion Device Emissions Using Portable Analyzers (May 14, 2020).

<sup>20</sup> 87 FR 74723-74724 (December 6, 2022).

November 2021 Proposal than has been historically used in New Source Review (NSR) and Title V. In 40 CFR 70.2, fugitive emissions are defined as:

“those emissions which could not reasonably pass through a stack, chimney, vent, or other functionally equivalent opening.”

The commenter (0727-OSEE/ODEQ) indicates that in the November 2021 Proposal it is stated that:

“...fugitive emissions are unintended...” and “... not considered fugitive emissions if the device is operating properly and in accordance with manufacturers specification.”

The commenters (0727-OSEE/ODEQ, 0911-NDPC) feel these statements are inconsistent and inaccurate. The EPA should consider that not all emissions can reasonably be routed to a control device or back into the process. Technical feasibility should be a consideration and option for any natural gas-driven pneumatic device standard.

The commenters (0727-OSEE/ODEQ, 0938-TXOGA) note that the November 2021 Proposal states that it would change and expand the definition of “fugitive emissions component” for the purpose of regulating the group of all fugitive emissions components at well sites and compressor stations<sup>21</sup>, providing:

[D]ata shows that the universe of components with potential for fugitive emissions is broader than the illustrative list included in the 2016 NSPS OOOOa, and that the majority of the largest emissions events occur from a subset of components that may not have been clearly included in the definition.<sup>22</sup>

The commenters (0817-GPA, 0938-TXOGA) indicate that it seems that the November 2021 Proposal anticipates including equipment that is already regulated and controlled in other sections of the subpart and should be removed from the definition to avoid ambiguity. For example, the commenter (0938-TXOGA) states that the current definition of “fugitive emissions component” under NSPS OOOOa specifically does not include covers and closed vent systems regulated under 40 CFR §§60.5411 or 60.5411a and thief hatches or other openings on a controlled storage vessel subject to §60.5395 or §60.5395a.<sup>23</sup> In the November 2021 Proposal, the commenter (0938-TXOGA) says that EPA seems to be reversing, without adequate explanation and conduct of reasoned decision making, equipment EPA previously considered and decided not to include in the definition in response to comments on the 2016 NSPS OOOOa

---

<sup>21</sup> 86 Fed. Reg. at 63,169-170.

<sup>22</sup> Id. at 63,169.

<sup>23</sup> See 40 C.F.R. § 60.5430a (“Fugitive emissions component means any component that has the potential to emit fugitive emissions of VOC at a well site or compressor station, including valves, connectors, pressure relief devices, open-ended lines, flanges, covers and closed vent systems not subject to § 60.5411 or § 60.5411a, thief hatches or other openings on a controlled storage vessel not subject to § 60.5395 or § 60.5395a, compressors, instruments, and meters. Devices that vent as part of normal operations, such as natural gas-driven pneumatic controllers or natural gas-driven pumps, are not fugitive emissions components, insofar as the natural gas discharged from the device's vent is not considered a fugitive emission. Emissions originating from other than the device's vent, such as the thief hatch on a controlled storage vessel, would be considered fugitive emissions.”) (emphasis added).

proposed rule.<sup>24</sup> The commenters (0817-GPA, 0938-TXOGA) argue the November 2021 Proposal does not establish a basis for expanding this definition, and EPA needs to complete the required procedural steps if it wishes to do so.

The commenter (0817-GPA) indicates the November 2021 Proposal never discusses these aspects of the definition of “fugitive emission component” under 40 CFR §60.5430a or any of the exemptions to it. Nor does it acknowledge that covers, thief hatches, and closed vent system are already regulated by the Section 60.5411a work practice standards. Given the absence of either proposed regulatory language or discussion in the November 2021 Proposal preamble, the commenter does not know whether EPA intends to eliminate these work practice standards in lieu of fugitive emission monitoring or require adherence to both monitoring and work practice standards, much less why EPA is changing its position.

The commenter (0727-OSEE/ODEQ) notes that fugitive emissions components have not included sources of emissions that are vented to the atmosphere through a stack or something similar. If EPA intends for these additional sources to be included in an OGI survey, they should not be included within the fugitive source definition. If EPA insists on adding true point sources to the definition of “fugitive emissions component,” then EPA may need to provide additional clarification regarding the requirement to use the actual stack height for a flare subject to reporting requirements for emissions inventory purposes, since fugitive components have different parameters for characterizing the release.

Response I-7-12: In response to comments received on the November 2021 Proposal, EPA proposed a different regulatory approach for this particular affected/designated facility in the December 2022 Supplemental Proposal. For details, please see discussion in section IV.A.1.a.ii. of the December 2022 Supplemental Proposal related to the definition of fugitive emissions components.<sup>25</sup> Please also see section X.A of the preamble to the final rule which details EPA’s final standards related to fugitive emissions from well sites and section XI.A.1.a of the preamble to the final rule which discusses responses to significant comments related to the definition of fugitive emissions components.

Comment: Commenter (0785-John Crane Inc.) recommends that EPA adopt the proposed definition of “fugitive emissions component” based on its increased inclusion of component types as compared to the prior definition. Prescriptive policies that target a subset of specific infrastructure could disincentivize emissions reduction for several large emitters previously left out of scope, in the commenter’s opinion.

Response I-7-13: In response to comments received on the November 2021 Proposal, EPA proposed a different regulatory approach for this particular affected/designated facility in the December 2022 Supplemental Proposal. For details, please see discussion in section IV.A.1.a.ii. of the December 2022 Supplemental Proposal related to the definition of fugitive emissions components.<sup>26</sup> Please also see section X.A of the preamble to the final rule which details EPA’s final standards related to fugitive emissions from well sites and section XI.A.1.a of the preamble

---

<sup>24</sup> See 81 Fed. Reg. at 35,858.

<sup>25</sup> 87 FR 74723 (December 6, 2022).

<sup>26</sup> Id.

to the final rule which discusses responses to significant comments related to the definition of fugitive emissions components.

Comment: Commenter (0737-Clarke Valve) states control valves also leak through the stem of the valve. These emissions have a major impact, in terms of the emissions footprint of any facility or production unit. Thus, the commenter requests that EPA consider including in its rules going forward fugitive emissions from the stem of the control valve.

Response I-7-14: The definition of fugitive emissions component already includes valves, which include emissions from any part of the valve, including the stem. Therefore, no change to the definition is necessary for this purpose.

Comment: Commenters (0802-Kraken Oil & Gas LLC (Kraken), 0831-American Exploration and Production Council (AXPC)) ask that EPA maintain the definitions for fugitive emissions and fugitive emission components as defined in the 2016 NSPS OOOOa rule.

The commenters (0802-Kraken, 0831-AXPC) note that EPA's proposed definition conflicts with the current definition of fugitive emissions used in EPA's NSR and Title V permitting programs. Therefore, the commenters recommend that EPA revise the definition to be consistent with the current definitions used by EPA.

The commenter (0802-Kraken) provides two definitions of fugitive emissions:

The Montana Administrative Code, Chapter 17.8 – Air Quality, Section 17.8.101 – Definitions include the following definition of fugitive emissions:

(20) "Fugitive emissions" means those emissions which could not reasonably pass through a stack, chimney, vent, or other functionally equivalent opening.

(41) "Stack, vent, or roof monitor" means any flue, conduit, chimney, vent, or duct arranged to conduct emissions.

The North Dakota Administrative Code, Article 33.1-15 Air Pollution Control, 33.1-15-01-04. Definitions include the following definition of fugitive emissions:

14. "Fugitive emissions" means solid airborne particulate matter, fumes, gases, mist, smoke, odorous matter, vapors, or any combination thereof generated incidental to an operation process procedure or emitted from any source other than through a well defined stack or chimney. 47. "Stack or chimney" means any flue, conduit, or duct arranged to conduct emissions.

The commenter (0831-AXPC) adds, 40 CFR 70.2 defines fugitive emissions as "those emissions which could not reasonably pass through a stack, chimney, vent, or other functionally-equivalent opening." EPA's NSR and Title V regulations do not consider whether a source is operating properly to determine if their emissions are fugitive. Instead, for the new source rule, it should be determining if it could reasonably (or is it technically feasible) to pass through a stack, chimney, vent, or other functionally equivalent opening.

The commenter (0831-AXPC) states with respect to pneumatic devices, not all pneumatic devices are able to connect piping to route vented gas back into a lower pressure process or to a control device. The commenter provides a figure showing a vent that can be unscrewed and has standard pipe threads that can be adapted to piping on the left and a pneumatic device that does not have that capability on the right.

Response I-7-15: In response to comments received on the November 2021 Proposal, EPA proposed a different regulatory approach for this particular affected/designated facility in the December 2022 Supplemental Proposal. For details, please see discussion in section IV.A.1.a.ii. of the December 2022 Supplemental Proposal related to the definition of fugitive emissions components.<sup>27</sup> Please also see section X.A of the preamble to the final rule which details EPA's final standards related to fugitive emissions from well sites and section XI.A.1.a of the preamble to the final rule which discusses responses to significant comments related to the definition of fugitive emissions components.

Comment: Commenters (0831-AXPC, 0808-American Petroleum Institute (API)) express various concerns related to the November 2021 Proposal's expansion of the definition of fugitive emissions component, including the proposal to classify a malfunction or operational upset as fugitive emissions.

The commenter (0831-AXPC) believes that the inclusion of control devices, including flares, with emissions resulting from the device operating in a manner that is not in full compliance with any federal rule, state rule, or permit as a fugitive emission is wholly inappropriate for multiple reasons. It does not meet the long-standing and widely accepted definition of fugitive emissions and there is not a generally accepted methodology to inspecting a control device using current fugitive emission monitoring practices, AVO and OGI. The commenter (0808-API) similarly states that OGI and EPA Method 21 are not even feasible for flares and requests that EPA explain how these methods would apply or, conversely, prescribe acceptable and workable alternative methods under the LDAR program.

The commenter (0808-API) asks that the proposed definition be clarified. All other equipment included in the definition is not expected to leak (at least in any significant amount). As a result, when periodic leak monitoring is conducted, the goal is to discern the presence of a leak. In contrast, even well operating emissions control devices and flares will have a permissible level of emissions. Thus, a periodic LDAR-type emissions survey should be expected to detect some amount of methane or VOC emissions. This raises the question of what amount of emissions triggers the need for further action under the LDAR work practices, such as investigation and corrective action. The conceptual answer is an amount that represents noncompliance with applicable emissions or work practice standards. But the commenter indicates that the November 2021 Proposal does not describe a mechanism for determining what level of emissions corresponds to compliant conditions and how to determine the increased amount that represents actionable noncompliance. In other words, the rule does not define what constitutes a "leak" for purposes of emissions control devices or flares. To be workable, EPA must include such details in the final rule, the commenter recommends.

---

<sup>27</sup> 87 FR 74723 (December 6, 2022).

Commenter (0808-API) believes that when work practice standards are fully implemented, emissions addressed by those standards cannot constitute a “violation.” The “no detectable emissions standard” is a work practice standard. As with all other fugitive emissions components, detection of a leak (in this case, defined as detectable emissions) through routine LDAR monitoring triggers the obligation to repair the leak. If that repair is accomplished according to the specific requirements in the rule, then there is no violation because the work practice has been fully implemented.

Commenter (0808-API) points out that long ago, EPA rejected the idea that numeric emissions limitations can or should be applied to fugitive emissions components. EPA has presented no reason in the November 2021 Proposal to depart from its historical approach with regard to fugitive emissions from closed vent systems. EPA must make it clear that a closed vent system remains in compliance when a leak is detected, as long as the associated work practices requiring investigation and repair are followed.

According to the commenters (0831-AXPC, 0808-API), neither AVO nor OGI would be able to determine if the flare is not operating in compliance with federal, state or permit requirements; only a determination whether the flare is lit or unlit is possible with these methods. There is no published protocol that outlines how a control device should be observed with an OGI camera and what determines a malfunction. For example, a 95 percent control efficiency is allowed, so theoretically 5 percent of waste stream emissions are allowed to be emitted into the atmosphere.

The commenter (0831-AXPC) explains that malfunctions occur from mechanical equipment, but every malfunction may not be a potential violation of the underlying standards. There are some circumstances where EPA’s requirement to “take corrective action to complete all necessary repairs as soon as practicable and prevent reoccurrence of emissions,” could require a complete re-design of a facility. An example EPA includes is “unintentional gas carry through,” more commonly referred to as stuck dump valves (different than stuck liquid level controllers). The commenter explains that the root cause of unintentional gas carry through is typically that debris in a liquid line prevents a valve from closing. Most pressure vessel packages are not designed with a mechanism to catch debris prior to the valve, due to the infrequent occurrences when debris prevents the valve from closing. It is not cost effective in this example to implement a corrective action to prevent the emissions, but there are several options available to reduce the emissions.

The commenter (0831-AXPC) suggests the following language to better account for these situations:

In the case of a malfunction or operational upset of a control device or the equipment itself, where emissions are not expected to occur if the equipment is operating in compliance with the standards of the rule, this proposal would require the owner or operator to conduct a root cause analysis to determine why the emissions are present, take corrective action to complete all necessary repairs as soon as practicable and if reasonably feasible to prevent reoccurrence of emissions, and report the malfunction or operational upset as a potential violation of the underlying standards for the source of the emissions.

Response I-7-16: In response to comments received on the November 2021 Proposal, EPA proposed a different regulatory approach for this particular affected/designated facility in the December 2022 Supplemental Proposal. For details, please see discussion in section IV.A.1.a.ii. of the December 2022 Supplemental Proposal related to the definition of fugitive emissions components.<sup>28</sup> Please also see section X.A of the preamble to the final rule which details EPA’s final standards related to fugitive emissions from well sites and section XI.A.1.a of the preamble to the final rule which discusses responses to significant comments related to the definition of fugitive emissions components.

### ***7.1.3 Wellhead Only Well Sites***

#### **7.1.3.1 Clarification Needed**

Comment: Commenter (0831-AXPC) believes EPA needs to revise the proposed definition of “wellhead only well site.” As written, the definition of major production and processing equipment is too broad and will pull in sites that for all intents and purposes is a wellhead only well site. For example, a single storage vessel at a wellhead could meet the definition of “major production and processing equipment.” Although not routinely producing any sort of liquid, it’s common practice to see a single tank, at what is traditionally thought of at a wellhead only site, to ensure that if any liquid is ever recovered at the facility that there is proper storage and handling capacity to manage it.

The commenter (0831-AXPC) adds that natural gas-driven pneumatic controllers, natural gas-driven pneumatic pumps, and pumpjack engines should not meet the definition of “major production and processing equipment” as each of these pieces of equipment do not function as the primary equipment for production and processing purposes, but instead, commonly serve in supplementary roles for the equipment characteristically associated with “major production and processing equipment.” Further, this equipment can all be found in operation with production and processing equipment at both well sites and wellhead only well sites. If they were to be included as “major production and processing equipment” it’s possible that no facilities would even qualify as a wellhead only well site. This ancillary equipment should be considered as such because they clearly do not meet the definition of “major production and processing equipment.”

The commenter (0831-AXPC) states that the definition should also include the type of production and lack of processing associated with wells that only have a storage tank and no other equipment installed at the same location. The storage vessel in this type of configuration serves as a secondary production collection point. These types of wellheads primarily produce gas and do so directly from the wellhead to the sales line. Liquid production is minimal from these wells, as the wellbore pressures are depleted and require rod lift to artificially produce liquids. There is no separation for production from these wells as the liquids produced are extremely minimal, removing any benefit or need for processing equipment. Because the storage tank is installed only to collect liquids that are inconsistently produced from the well, it cannot be defined as major production equipment, making the wellhead the only significant piece of equipment.

---

<sup>28</sup> 87 FR 74723 (December 6, 2022).

Response I-7-17: The EPA acknowledges the concerns and requests for clarification as it relates to wellhead only well sites and major production and processing equipment.

The final rule maintains the definition of a wellhead only well site as follows:

*Wellhead only well site* means, for the purposes of the fugitive emissions standards at §60.5397b, a well site that contains one or more wellheads and no major production and processing equipment.

The EPA is finalizing a definition of major production and processing equipment that includes control devices, natural gas-driven process controllers, natural gas-driven pumps, and tank batteries, in addition to the previous equipment included in the definition in the December 2022 Supplemental Proposal. The final definition reads as follows, which EPA believes resolves the commenters concerns.

*Major production and processing equipment* means reciprocating or centrifugal compressors, glycol dehydrators, heater/treaters, separators, control devices, natural gas-driven process controllers, natural gas-driven pumps, and storage vessels or tank batteries collecting crude oil, condensate, intermediate hydrocarbon liquids, or produced water, for the purpose of determining whether a well site is a wellhead only well site.

#### 7.1.3.2 Opposed to Exemption

Comment: Commenters (0391-Keweenaw Bay Indian Community (KBIC), 0586-Navajo Nation Environmental Protection Agency (Navajo EPA), 0605-Muscogee (Creek) Nation, 0781-National Tribal Air Association (NTAA), 0833-Environmental Programs Department, Ute Mountain Ute Tribe (Ute EPD), 0844-EDF *et al.*, 0943-Sault Ste. Marie Tribe of Chippewa Indians (Sault EPD)) disagree with EPA's November 2021 Proposal to retain the wellhead only well site exemption.

The commenters (0391-KBIC, 0586-Navajo EPA, 0605-Muscogee (Creek) Nation, 0781-NTAA, 0833-Ute EPD, 0943-Sault EPD) say that even if these sites do not contain major production and processing equipment, they can contain smaller equipment that can leak or malfunction and are still capable of releasing, and still do release, fugitive emissions. Alternatively, EPA should narrow the definition of "wellhead only well sites" subject to this exemption so that sites that contain equipment with the potential to release fugitive emissions of methane and VOC are subject to the monitoring requirements. Given that wellhead only well sites connect to gathering facilities where fugitive emissions monitoring is required, the commenters do not believe requiring monitoring at these sites is infeasible or particularly costly.

The commenter (0844-EDF *et al.*) points out that emissions, including large emission events, have been observed at wellhead only well sites.<sup>29</sup> If EPA retains this exemption it should expand the definition of major production and processing equipment to ensure no equipment with potentially significant emissions is located at a site excluded from regular monitoring as a wellhead-only well site. The current definition does not include certain pieces of failure-prone

---

<sup>29</sup>Attachment B to the commenter's letter (PermianMAP November 2021 Flyover Results).

equipment that could cause large emission events, like natural-gas driven pneumatic controllers and pumps, gas-driven pumpjack engines, and flares.<sup>30</sup> Flares can be located at or near wellhead-only sites and must be clearly encompassed in the definition of major production or processing equipment.<sup>31</sup> The commenter suggests EPA also make clear that the proximity of the major production and processing equipment to the wellhead is not relevant for determining whether a site qualifies for the exemption. The commenter feels that EPA should clarify that major production or processing equipment is at the site if it is associated with the site (*i.e.*, if gas is routed from the wellhead to a nearby flare, that flare is part of the site (unless already part of another affected facility, like a centralized production facility)). Otherwise, the commenter believes the regulations will create incentives to simply locate this equipment farther away from the site.

The commenter (0844-EDF *et al.*) supports EPA's November 2021 Proposal to include a definition of "centralized production facility," which would be subject to fugitive monitoring requirements, and believes this may help eliminate incentives to strategically place equipment to avoid fugitive monitoring requirements. If EPA retains the wellhead-only well site exemption, it should narrow it to apply only to single wellhead sites. Well sites that contain more than one wellhead must not be exempt, since there is no limit to the number of components (and therefore sources of fugitive emissions) that could exist at such sites, even if no associated equipment is present. Even without the addition of associated equipment, a well site with multiple single wellheads could be a significant source of emissions, if there is a very large leak coming from one of the wellheads.<sup>32</sup>

Response I-7-18: In response to comments received on the November 2021 Proposal, EPA proposed a different regulatory approach for this particular affected/designated facility in the December 2022 Supplemental Proposal. For details, please see discussion in section IV.A.1.a.ii. of the December 2022 Supplemental Proposal related to wellhead only well sites.<sup>33</sup> Please also see section X.A.1 of the preamble to the final rule which details EPA's final standards related to fugitive emissions from well sites.

#### 7.1.3.3 Support of Exemption

Comment: Commenters (0797-North Dakota Department of Environmental Quality (NDDEQ) and North Dakota Industrial Commission (NDIC), 0810-The Petroleum Alliance of Oklahoma (Petroleum Alliance-OK)) agree with EPA's November 2021 Proposal that wellhead only well sites be excluded from fugitive emissions monitoring based on considerable research and rationale already established in the 2016 NSPS OOOOa rulemaking as well as the 2020 Technical Rule.

---

<sup>30</sup>See Part IV.A.2 of the commenter's letter for a full summary of scientific evidence on failure-prone equipment types.

<sup>31</sup> See Attachment B (PermianMAP November 2021 Flyover Results) (finding that low-producing sites had a higher rate of flare malfunctions (31.3%) when compared to higher production sites (9.4%), and that malfunctioning flares at low-producing sites are often completely unlit and venting methane).

<sup>32</sup> Zavala-Araiza (2015), at 8176-8174; Attachment B (PermianMAP November 2021 Flyover Results).

<sup>33</sup> 87 FR 74729-74736 (December 6, 2022).

The commenter's (0797-NDDEQ and NDIC) own experience supports EPA's conclusion that emissions from these sources are "extremely low." The commenters (0797-NDDEQ and NDIC) have only observed a handful of wellhead only well sites with fugitive emissions, and it appears that in those rare cases that the emissions were more a result of operator error. The commenters (0797-NDDEQ and NDIC) believe that the safety risk alone precludes any widespread issue of fugitive emissions from these sites.

Response I-7-19: In response to comments received on the November 2021 Proposal, EPA proposed a different regulatory approach for this particular affected/designated facility in the December 2022 Supplemental Proposal. For details, please see discussion in section IV.A.1.a.ii. of the December 2022 Supplemental Proposal related to wellhead only well sites.<sup>34</sup> Please also see section X.A.1 of the preamble to the final rule which details EPA's final standards related to fugitive emissions from well sites.

Comment: Commenter (0577-Kansas Independent Oil & Gas Association (KIOGA)) does not support the November 2021 Proposal that "wellhead only sites" must calculate fugitive emissions. The EPA stated it does not believe these emissions would exceed 3 tpy threshold to require routine monitoring; therefore, it should not impose substantial requirements. Additionally, the small businesses that make up the independent oil and gas industry should not be burdened with purchasing and learning how to operate an OGI device costing approximately \$90,000 to comply with the fugitive emissions requirements at wellhead only sites. The EPA did not evaluate the cost for these small entities to comply with the proposed EG OOOOc; therefore, they should be excluded from applicability.

Response I-7-20: In response to comments received on the November 2021 Proposal, EPA proposed a different regulatory approach for this particular affected/designated facility in the December 2022 Supplemental Proposal. For details, please see discussion in section IV.A.1.a.ii. of the December 2022 Supplemental Proposal related to wellhead only well sites.<sup>35</sup> Please also see section X.A.1 of the preamble to the final rule which details EPA's final standards related to fugitive emissions from well sites.

#### ***7.1.4 Baseline Methane Emissions Calculations***

##### ***7.1.4.1 Request for Clarification***

Comment: Commenter (0749-Petroleum Association of Wyoming (PAW)) claims there are inconsistencies in the method of calculating emissions at the well site. The commenter asks that EPA provide clarification on what methods would be considered acceptable.

Response I-7-21: In response to the comments received on the November 2021 Proposal, EPA proposed a different regulatory approach for this particular affected/designated facility in the December 2022 Supplemental Proposal. For details, please see discussion in section IV.A.1.a.ii. of the December 2022 Supplemental Proposal related to fugitive emissions from well sites.<sup>36</sup>

---

<sup>34</sup> 87 FR 74729-74736 (December 6, 2022).

<sup>35</sup> 87 FR 74729-74736 (December 6, 2022).

<sup>36</sup> 87 FR 74724-74736 (December 6, 2022).

Please also see section X.A.1 of the preamble to the final rule which details EPA's final standards related to fugitive emissions from well sites.

Comment: Commenters (0446-Artex Oil Company (Artex), 0739-Citation Oil & Gas Corp. (Citation), 0847-Mull Drilling Company, Inc. (Mull), 1085-Small Operator Society LLC (SOS)) requests clarification on the baseline emissions calculation.

The commenter (1085-SOS) states that EPA needs to define the emission production threshold that require inspection (*i.e.*, 3 tpy and above) and make explicit what operations are exempt from routine inspections as well as from what sources count toward that total (*i.e.*, only fugitives, tank battery, both, and/or other equipment).

The commenter (0739-Citation) also asks whether the site level baseline emissions should be based on post-control emissions, post-legally and practicably enforceable limits, actual emissions, pre-control emissions, *etc.*

The commenters (0847-Mull, 1085-SOS) understand that when estimating emissions, the tanks and well are considered a single site. However, the commenters are unsure how to estimate emissions from the tanks and ask for clear and consistent methodology to estimate the emissions from tanks.

Commenter (0446-Artex) states the proposed regulations are duplicative. For example, EPA proposes that the calculation of the baseline methane emission rate should include “each natural gas-driven pneumatic pump, continuous bleed natural gas-driven pneumatic controller...intermittent bleed natural gas driven pneumatic controller...major equipment found in Table W-1B and Table W-1C of Greenhouse Gas Reporting Program (GHGRP) Subpart W [which includes compressors]...[and] each storage vessel tank battery located at the well site.”<sup>37</sup> Each of these identified sources will already be regulated under the proposed NSPS OOOOb; therefore, including these sources artificially inflates the operator's calculation of the baseline emission rate as well as EPA's own estimated emissions reductions used to calculate the cost effectiveness of the November 2021 Proposal.

Response I-7-22: In response to the comments received on the November 2021 Proposal, EPA proposed a different regulatory approach for this particular affected/designated facility in the December 2022 Supplemental Proposal. For details, please see discussion in section IV.A.1.a.ii of the December 2022 Supplemental Proposal related to fugitive emissions from well sites.<sup>38</sup> Please also see section X.A.1 of the preamble to the final rule which details EPA's final standards related to fugitive emissions from well sites.

Comment: Commenter (0727-OSEE/ODEQ) believes that the proposal that well sites with site-level baseline methane emissions below 3 tpy are not required to conduct OGI monitoring, but are required to perform a survey to confirm if the well site actual emissions are less than 3 tpy appears to be a contradiction within the rule, making it unclear what EPA is proposing. The

---

<sup>37</sup> 86 FR 63170 through 63171.

<sup>38</sup> 87 FR 74724-74736 (December 6, 2022).

commenter requests that EPA ensure that the rule text clarifies how facilities should demonstrate the actual emissions are accounted for in the calculation.

The commenter (0727-OSEE/ODEQ) note the ambiguity in EPA's November 2021 Proposal could be read to lead to two possible scenarios, and requests that EPA clarify its intent with respect to the requirements for well sites with site-level baseline methane emissions below 3 tpy. In these scenarios they use OGI as an example but recognize another approved leak detection method could be used.

*Scenario 1:* It can be inferred that the purpose of this demonstration is to require each well site with baseline methane emissions below 3 tpy to conduct an initial survey to find and fix any leaking fugitive emissions components, then no additional OGI monitoring would be required thereafter. If this is EPA's intent, EPA should clearly require an initial survey to be conducted at each well site requesting the exemption for methane emissions below 3 tpy and an additional requirement to fix any fugitive emission leaks within a 90-day timeframe with possible re-monitoring to verify repair of the leaking fugitive emission.

*Scenario 2:* It can be inferred that the purpose of this demonstration is to require each well site with baseline methane emissions below 3 tpy to quantify the emissions from each well site. Additionally, it is unclear whether, if a certain number of leaks are found, the well site would not qualify for this exemption. The tools to quantify emissions using OGI are expensive and time consuming for such a marginal well site, and it is questionable whether this is cost effective compared to any environmental benefit gained. If the purpose of the potential requirement in scenario 2 is EPA's intent, that requirement is unclear and OSEE and the commenter respectfully request EPA clarify the intent behind this requirement.

Response I-7-23: In response to the comments received on the November 2021 Proposal, EPA proposed a different regulatory approach for this particular affected/designated facility in the December 2022 Supplemental Proposal. For details, please see discussion in section IV.A.1.a.ii of the December 2022 Supplemental Proposal related to fugitive emissions from well sites.<sup>39</sup> Please also see section X.A.1 of the preamble to the final rule which details EPA's final standards related to fugitive emissions from well sites.

Comment: Commenter (0810-Petroleum Alliance-OK) urges EPA to use terminology small oil and gas operators are familiar with without the help of consultants. The lack of plain language and complicated compliance mandates has left many small businesses confused and overwhelmed. The proposal does not use common oil field measurement terminology that operators understand. The EPA's proposed thresholds in tpy do not equate to something understandable or useable by smaller operators without the assistance of hired consultants to conduct emission calculations for each well to make that determination. The commenter requests that EPA propose a rule using terminology that is transparent, understandable, and useable by small oil and gas businesses (preferably production info) so they can easily comply, avoiding the need to hire consultants which will increase the cost of compliance. As an alternative, EPA could

---

<sup>39</sup> 87 FR 74724-74736 (December 6, 2022).

develop a matrix or framework that provides smaller operators the option to use in lieu of conducting detailed calculations to determine if the methane emission at their site exceed the proposed thresholds.

Response I-7-24: In response to the comments received on the November 2021 Proposal, EPA proposed a different regulatory approach for this particular affected/designated facility in the December 2022 Supplemental Proposal. For details, please see discussion in section IV.A.1.a.ii of the December 2022 Supplemental Proposal related to fugitive emissions from well sites.<sup>40</sup> Please also see section X.A.1 of the preamble to the final rule which details EPA's final standards related to fugitive emissions from well sites.

Comment: Commenter (0775-Air Pollution Control Division, Colorado Department of Public Health and Environment (CDPHE), 1267-California Office of the Attorney General (CA AG) *et al.*) state that EPA's approach does not account for equipment failures, which means more sites will fall below the 3 tpy methane emission threshold and will not be required to conduct any monitoring. EPA acknowledges that its approach "assumes all equipment is operating as designed."<sup>41</sup> Also, sites should be required to use the uncontrolled PTE calculation for their storage vessels in their site-level baseline estimate to account for times when these vessels are not operating as designed, which is a known cause of large emission events.

Response I-7-25: In response to the comments received on the November 2021 Proposal, EPA proposed a different regulatory approach for this particular affected/designated facility in the December 2022 Supplemental Proposal. For details, please see discussion in section IV.A.1.a.ii of the December 2022 Supplemental Proposal related to fugitive emissions from well sites.<sup>42</sup> Please also see section X.A.1 of the preamble to the final rule which details EPA's final standards related to fugitive emissions from well sites.

Comment: Commenter (0573-KDHE) believes that site-specific emissions estimates are the only means to achieve fair and accurate estimates. EPA's staff working on the (triennial) National Emissions Inventory for nonpoint sources has already developed a Microsoft Access-based Oil & Gas Tool, which would be capable of adapting current county-based estimates to well site-based estimates of methane emissions. The commenter strongly recommends that EPA staff developing this rule communicate with EPA Emissions Inventory System staff to see and understand the capabilities of their Oil & Gas Tool.

Response I-7-26: In response to the comments received on the November 2021 Proposal, EPA proposed a different regulatory approach for this particular affected/designated facility in the December 2022 Supplemental Proposal. For details, please see discussion in section IV.A.1.a.ii of the December 2022 Supplemental Proposal related to fugitive emissions from well sites.<sup>43</sup> Please also see section X.A.1 of the preamble to the final rule which details EPA's final standards related to fugitive emissions from well sites.

---

<sup>40</sup> 87 FR 74724-74736 (December 6, 2022).

<sup>41</sup> 86 Fed. Reg. at 63,171.

<sup>42</sup> 87 FR 74724-74736 (December 6, 2022).

<sup>43</sup> 87 FR 74724-74736 (December 6, 2022).

Comment: Commenter (0938-TXOGA) notes that the time frames in the proposal for calculating methane emissions per site are insufficient to allow operators time to generate accurate calculations. The commenter also requests that EPA specify in any supplemental proposal or final rule that operators who default to performing quarterly OGI at all locations are not subject to recordkeeping requirements related to methane site calculations.

Response I-7-27: In response to the comments received on the November 2021 Proposal, EPA proposed a different regulatory approach for this particular affected/designated facility in the December 2022 Supplemental Proposal. For details, please see discussion in section IV.A.1.a.ii of the December 2022 Supplemental Proposal related to fugitive emissions from well sites.<sup>44</sup> Please also see section X.A.1 of the preamble to the final rule which details EPA’s final standards related to fugitive emissions from well sites.

Comment: Commenter (0938-TXOGA) notes EPA states that it may create a “sliding scale” requirement for OGI monitoring at well sites, which would correlate to PTE for fugitive emissions of the well site.<sup>45</sup> In discussing how to calculate baseline fugitive emissions, EPA notes that the calculation assumes (and has always assumed) that the equipment is operating as designed. This makes sense, of course, because a fundamental principal of determining potential emissions is the “physical and operational design” of equipment.<sup>46</sup> EPA asks whether it should require sites to “use the uncontrolled PTE calculation for their storage vessels in their site-level baseline estimate to account for times when these vessels are not operating as designed, which is a known cause of large emission events of concern.”<sup>47</sup>

Response I-7-28: In response to the comments received on the November 2021 Proposal, EPA proposed a different regulatory approach for this particular affected/designated facility in the December 2022 Supplemental Proposal. For details, please see discussion in section IV.A.1.a.ii of the December 2022 Supplemental Proposal related to fugitive emissions from well sites.<sup>48</sup> Please also see section X.A.1 of the preamble to the final rule which details EPA’s final standards related to fugitive emissions from well sites.

Comment: Commenter (0938-TXOGA) argues treating large emission events as part of the baseline estimate is not appropriate and should not be included in any proposed or final rule. Reducing the incidence and magnitude of large emission events is best accomplished through other means, not by distorting the baseline emissions calculation to sweep into the requirements sources and emissions events that are not appropriately included. This would be similar to assuming that controls are malfunctioning and operating with upsets in determining PTE. The commenter believes that such an approach would distort the baseline calculation in a manner that would make the cost-effectiveness of the rule inconsistent with historic EPA actions and with the facts, in that it would assume very large emissions in the calculation—which are not occurring and may not ever occur—and then take credit for reducing them by sweeping into the

---

<sup>44</sup> 87 FR 74724-74736 (December 6, 2022).

<sup>45</sup> See 86 Fed. Reg. at 63,172, tbl. 13, Proposed Well Site Monitoring Frequencies Based on Site-Level Baseline Methane Emissions.

<sup>46</sup> See 40 C.F.R. § 52.21(b)(4) (potential to emit means “the maximum capacity of a stationary source to emit a pollutant under its physical and operational design”) (emphases added).

<sup>47</sup> 86 Fed. Reg. at 63,171.

<sup>48</sup> 87 FR 74724-74736 (December 6, 2022).

requirements sources that otherwise would not be appropriately regulated. While the November 2021 Proposal suggests that altering the baseline calculation methodology would lead to more precise baseline emission calculations, in fact, it would distort the calculation to be less accurate. Other approaches are available to address large emission events and those should be considered and proposed when EPA issues its upcoming proposed action.<sup>49</sup>

Commenter (0938-TXOGA) concludes EPA should not add to the definition of fugitive emission components equipment that is otherwise regulated or controlled by other portions of the subpart.

Response I-7-29: In response to the comments received on the November 2021 Proposal, EPA proposed a different regulatory approach for this particular affected/designated facility in the December 2022 Supplemental Proposal. For details, please see discussion in section IV.A.1.a.ii of the December 2022 Supplemental Proposal related to fugitive emissions from well sites.<sup>50</sup> Please also see section X.A.1 of the preamble to the final rule which details EPA's final standards related to fugitive emissions from well sites.

#### 7.1.4.2 Subpart W Emission Factors

Comment: Commenter (0727-OSEE/ODEQ) suggests that instead of owners/operators using default average component counts found in GHGRP to calculate their site-level baseline methane emissions, owners/operators should be allowed to use actual component counts if that data is available. For example, in Oklahoma's point source inventories, facilities provide their actual component counts, which in turn provides better emissions estimates.

Response I-7-30: In response to the comments received on the November 2021 Proposal, EPA proposed a different regulatory approach in the December 2022 Supplemental Proposal that does not require owners/operators to calculate their site-level baseline methane emissions. For details, please see discussion in section IV.A.1.a.ii of the December 2022 Supplemental Proposal related to fugitive emissions from well sites.<sup>51</sup> Please also see section X.A.1 of the preamble to the final rule which details EPA's final standards related to fugitive emissions from well sites.

Comment: Commenter (0814-Independent Petroleum Association of America *et al.* (IPAA)) states that, unlike other elements of the EPA proposal, the LDAR provisions are based on equipment within the well site. While this concept is appropriate, several key issues need to be understood:

1. The basis for the thresholds,
2. The scope of components that comprise the fugitive emissions baseline, and,
3. The validity of the emissions estimates for the fugitive emissions components.

The commenter (0814-IPAA *et al.*) states EPA's basis for selecting its thresholds is thinly based on assumptions related to the cost effectiveness of its OGI LDAR requirements that are

---

<sup>49</sup> In the one instance of which TXOGA is aware in which EPA used uncontrolled emissions as a basis for applicability, the circumstances were narrow.

<sup>50</sup> 87 FR 74724-74736 (December 6, 2022).

<sup>51</sup> 87 FR 74724-74736 (December 6, 2022).

debatable. EPA's scope of components for the fugitive emissions program must be consistent with its other requirements and reflective of the validity of its emissions estimating tools. The commenter believes EPA is correct in excluding individual wells from the well site definition for the LDAR program. EPA should similarly exclude individual wells from its other regulatory requirements. EPA is creating specific requirements for numerous components of the well site. These components should not be included in the fugitive emissions calculations, in part because Subpart W emissions factors would not reflect their emissions. These include pneumatic controllers, pneumatic pumps, and storage tanks.

The commenter (0814-IPAA *et al.*) suggests that before EPA implements these new requirements, particularly for low production existing wells, it must validate its subpart W emissions estimating factors. The subpart W emissions factors were not developed for the purposes for which they are now being used and are based on a limited number of facilities using technology that may be well out of date. It is also structured to reflect both normal and failed equipment operations and thereby includes factors to reflect the fat tail aspect of oil and natural gas production operations.

The commenter (0814-IPAA *et al.*) adds that the emissions factor for intermittent pneumatic control valves is a case in point. EPA is expanding its scope of pneumatic controller regulation in this proposal to include intermittent controllers. Part of EPA's justification for this action is the high Subpart W emissions factor for these controllers. This emissions factor resulted from work by the Gas Technology Institute (GTI). The factor is 13.5 standard cubic feet per hour (scfh). It is based on 19 intermittent controllers most of which were in Canada. Subsequent studies by Oklahoma Independent Petroleum Association (OIPA) (not the Petroleum Association of Oklahoma) and EPA of intermittent controllers, many of which were on low production wells have produced emissions factors far lower than the Subpart W factor – 0.4 scfh (OIPA) and 0.32 scfh (EPA). Yet, EPA still uses the GTI factor for the subpart W GHG reporting and presumably for its proposed emissions calculations justifying its new proposal.

The commenter (0814-IPAA *et al.*) adds that millions of dollars will be spent on compliance with these LDAR requirements (and on replacement of intermittent pneumatic controllers). The requirements should not impose these costs when the environmental benefits are specious. Among the most vulnerable operations to be burdened by these regulations will be low production wells – the primary target of the environmental groups determined to “keep it in the ground.” Recent work for a DOE Report shows that the low production wells that it measured and evaluated would overwhelmingly fall below the EPA proposed 3 tpy threshold. It is imperative that EPA's subpart W emissions factors are as accurate as these field tests.

The commenter (0814-IPAA *et al.*) notes that EPA offers no explanation or justification that the total site-wide calculations be re-calculated every time “equipment” is added or removed from the site. The commenter believes this calculation is unjustified with no environmental benefit.

Commenter (0577-KIOGA) requests clarification on how to calculate the emission factors to determine the level of methane emissions for leak monitoring frequency and to determine the GHG standards for well sites shown in Table 3 at 86 Fed. Reg. 63121. The EPA has stated that

the GHG emission factors in 40 CFR 98, Subpart W were to be used and not the emission factors in EPA-453/R-95-017 [Protocol for Equipment Leak Emission Estimates].

Response I-7-31: In response to the comments received on the November 2021 Proposal, EPA proposed a different regulatory approach for this particular affected/designated facility in the December 2022 Supplemental Proposal. For details, please see discussion in section IV.A.1.a.ii of the December 2022 Supplemental Proposal related to fugitive emissions from well sites.<sup>52</sup> Please also see section X.A.1 of the preamble to the final rule which details EPA’s final standards related to fugitive emissions from well sites.

#### 7.1.4.3 Repeating Calculation When Equipment is Added/Removed

Comment: Commenter (0446-Artex) states EPA has not provided clear mechanisms for revising the required LDAR monitoring frequency based on changes to the baseline methane emission rate. EPA proposes that “this calculation would be repeated every time equipment is added to or removed from the site”<sup>53</sup> but does not explicitly explain how this repeated calculation would be used to revise the site’s applicable LDAR monitoring frequency. Without explicit “off-ramp” provisions for performing this analysis, state and local agencies implementing EPA’s proposed rule could invoke “anti-backsliding” principles to require that a site continue implementing LDAR monitoring at the frequency established based on the initial calculation of the baseline methane emission rate. In this case, EPA’s proposed requirement that the calculation be “repeated every time equipment is added to or removed from the site”<sup>54</sup> would constitute a meaningless paperwork exercise ostensibly occurring ad infinitum for even the smallest of routine maintenance and replacement activities at a given site.

Response I-7-32: In response to the comments received on the November 2021 Proposal, EPA proposed a different regulatory approach for this particular affected/designated facility in the December 2022 Supplemental Proposal. For details, please see discussion in section IV.A.1.a.ii of the December 2022 Supplemental Proposal related to fugitive emissions from well sites.<sup>55</sup> Please also see section X.A.1 of the preamble to the final rule which details EPA’s final standards related to fugitive emissions from well sites.

#### 7.1.4.4 Large Events/Malfunctions/Abnormal Process Emissions

Comment: Commenter (0844-EDF *et al.*) supports EPA using site-specific baseline emission calculation to categorize sites. However, as proposed, the site-level estimates still fail to fully characterize site-level emissions because they do not account for super-emitter and abnormal process emissions. These categories of emissions are particularly prevalent and problematic in the production segment, representing more than 70 percent of total emissions.<sup>56</sup> Adopting the

---

<sup>52</sup> 87 FR 74724-74736 (December 6, 2022).

<sup>53</sup> 86 FR 63170.

<sup>54</sup> *Ibid.*

<sup>55</sup> 87 FR 74724-74736 (December 6, 2022).

<sup>56</sup> Alvarez 2018.

following recommendations will help ensure sites fall into representative emission tiers and are subject to the appropriate frequency of monitoring:

1. Use emission factors that account for malfunctions,
2. Use uncontrolled emissions for tanks, and
3. Estimate emissions from all potentially emitting onsite equipment such as flares in the calculation.

The commenter (0844-EDF *et al.*) agrees with EPA that its previous model plant approach, which divided well sites into production-based categories and then assigned average estimated component and equipment counts to derive emissions, did not capture actual well site component and equipment counts, particularly at more complex facilities.<sup>57</sup> It was also not representative of well site emissions because it relied on emission factors that do not account for large emission events and because it tended to underestimate average onsite equipment counts.<sup>58</sup> The commenter believes EPA has correctly recognized the flaws in this approach, as well as in those that assume leak rates are well correlated with production levels.<sup>59</sup>

The commenter (0844-EDF *et al.*) notes however, EPA's proposed approach, suffers from flaws that will cause underestimating of actual emissions, shortcomings that are especially problematic when operators rely on the calculation to determine the required frequency of inspections for a particular site. The commenter recommends that EPA revise the site-level calculation methodology to account for super-emitters and equipment failures, rather than using the proposed PTE calculation described in the proposal preamble.<sup>60</sup>

The commenter (0844-EDF *et al.*) adds that another issue with the proposed approach is that it allows operators to estimate site-level emissions on the assumption that any control equipment will be 100 percent effective 100 percent of the time. This assumption does not reflect reality and ignores countless field observations of the repeated failure of control equipment that leads to large emission events, especially those associated with tanks.<sup>61</sup>

The commenter (0844-EDF *et al.*) notes that the proposed approach does not require operators to calculate potential emissions from all of the emitting equipment onsite, only a subset. Flares are an example of a commonly malfunctioning piece of equipment that can cause major emission events is totally left out of consideration in EPA's proposed site-level emission calculation. A representative site-level emission calculation cannot exclude potential emissions from any equipment located at the site.

---

<sup>57</sup> Attachment F (ICR analysis).

<sup>58</sup> *Id.*

<sup>59</sup> 86 Fed. Reg. 63187; see also Lin et al., Declining methane emissions and steady, high leakage rates observed over multiple years in a western US oil/gas production basin, 11 *Sci. Reports* 22291 (2021), <https://www.nature.com/articles/s41598-021-01721-5> (finding a steady leak rate of 6-8% over six years in the Uinta Basin even as production declined and attributing high leak rate in part to the abundance of low producing wells in the basin).

<sup>60</sup> 86 Fed. Reg. 63171.

<sup>61</sup> See Attachment B (PermianMAP November 2021 Flyover Results); see also Part IV.A.1.

The commenter (0844-EDF *et al.*) states if PTE is supposed to represent the theoretical PTE, then in most cases, a well site's PTE is equivalent to its entire methane production (*i.e.*, natural gas production adjusted by methane content). For example, if there is a malfunction that causes 100 percent of the gas production to vent, such as a stuck separator dump valve, then the site's emissions are equivalent to its methane production. In rare cases, a site's emissions may even exceed production, such as an over-pressurized gathering system venting at an upstream tank. EPA's proposed calculation using subpart W methods and assuming controls are working does not, in fact, calculate PTE, but rather the possible baseline emissions of a site that is operating without any malfunctions whatsoever on a continuous basis. Numerous research studies have shown that this approach underestimates average emissions due to malfunctions.

Response I-7-33: In response to the comments received on the November 2021 Proposal, EPA proposed a different regulatory approach for this particular affected/designated facility in the December 2022 Supplemental Proposal. For details, please see discussion in section IV.A.1.a.ii of the December 2022 Supplemental Proposal related to fugitive emissions from well sites.<sup>62</sup> Please also see section X.A.1 of the preamble to the final rule which details EPA's final standards related to fugitive emissions from well sites.

Comment: Commenter (0814-IPAA *et al.*) asserts that baseline emissions calculations should be representative of normal operations, not large emissions events. The EPA seems to allow for sites with calculated baseline emission less than 3 tpy be exempt from surveying obligations and then makes every effort to make it such no sources will be able to demonstrate baseline emission below 3 tpy. To the extent low production wells are required to calculate baseline emission, the calculation should be a calculation of fugitive emissions, *i.e.*, leaks.

Response I-7-34: In response to the comments received on the November 2021 Proposal, EPA proposed a different regulatory approach for this particular affected/designated facility in the December 2022 Supplemental Proposal. For details, please see discussion in section IV.A.1.a.ii of the December 2022 Supplemental Proposal related to fugitive emissions from well sites.<sup>63</sup> Please also see section X.A.1 of the preamble to the final rule which details EPA's final standards related to fugitive emissions from well sites.

#### 7.1.4.5 Alternatives to Baseline Emissions Calculation

Comment: Commenter (0564-Arkansas Independent Producers & Royalty Owners (AIPRO)) believe baseline emissions for triggering LDAR survey frequency should be based on fugitive emissions only as defined by the fugitive emissions in 40 CFR 60, subpart OOOOa rather than the November 2021 proposal which includes all emissions sources/types in the baseline determination.

The commenter (0564-AIPRO) proposes that operators should be allowed to utilize the results of historical LDAR surveys to determine its baseline fugitive emissions PTE, rather than being required to use the component count methodology established in subpart W. Many operators have well sites already enrolled in an LDAR program that have established a low leak rate. Forcing these sites to utilize the component count methodology to calculate fugitive PTE while

---

<sup>62</sup> 87 FR 74724-74736 (December 6, 2022).

<sup>63</sup> 87 FR 74724-74736 (December 6, 2022).

possessing real world data is not practical. Utilizing site-wide methane emissions from all sources (process emissions, manual tank venting, process emissions, *etc.*) not just fugitive emissions, is not practical, overly burdensome, not cost-effective and, most importantly, will not accomplish meaningful fugitive emissions reductions, in the commenter's opinion.

The commenter (0564-AIPRO) states that 40 CFR subpart W, EPA's GHGRP, allows for adjusted emission factors based on the most recent LDAR survey conducted at the location, when done either voluntarily or as required by federal, state, tribal, or municipal regulation. In many instances this emission total is less than the calculated numbers based on emissions factors. Given that the LDAR survey calculation is more representative of the actual emissions at the location, it would only make sense to be able to have the option to use those numbers in determining the baseline fugitive emissions for a location.

Response I-7-35: In response to the comments received on the November 2021 Proposal, EPA proposed a different regulatory approach for this particular affected/designated facility in the December 2022 Supplemental Proposal. For details, please see discussion in section IV.A.1.a.ii of the December 2022 Supplemental Proposal related to fugitive emissions from well sites.<sup>64</sup> Please also see section X.A.1 of the preamble to the final rule which details EPA's final standards related to fugitive emissions from well sites.

Comment: Commenter (0938-TXOGA) believes that it is not necessary for EPA to propose a new methodology for determining site-specific emissions estimates. Rather, EPA should incorporate the emission calculation methodologies used for 40 CFR part 98, subpart W compliance into its proposed and final rules, to promote consistency between the NSPS and the current GHG reporting requirements under subpart W and greater accuracy in generating emissions estimates. For owners/operators that are already subject to mandatory GHG reporting under subpart W, any new approach to developing site-specific emissions estimates would create additional burden without commensurate benefit and, perhaps more importantly, confusion for sources calculating site-specific emissions under both programs.

Response I-7-36: In response to the comments received on the November 2021 Proposal, EPA proposed a different regulatory approach for this particular affected/designated facility in the December 2022 Supplemental Proposal. For details, please see discussion in section IV.A.1.a.ii of the December 2022 Supplemental Proposal related to fugitive emissions from well sites.<sup>65</sup> Please also see section X.A.1 of the preamble to the final rule which details EPA's final standards related to fugitive emissions from well sites.

Comment: Commenters (0739-Citation, 0777-Ascent Resources, LLC (Ascent)) argue that fugitive monitoring requirements based on emissions calculations is improper.

The commenter (0777-Ascent) argues the EPA should base the frequency of fugitive monitoring requirements under the NSPS and existing source guidelines on the level of methane emissions from sources and equipment that will be subject to the fugitive monitoring program. The commenter requests that EPA not use "site level methane baseline emissions" but rather site-level baseline fugitive emissions, based on the calculated emissions rates from the fugitive

---

<sup>64</sup> 87 FR 74724-74736 (December 6, 2022).

<sup>65</sup> 87 FR 74724-74736 (December 6, 2022).

components that will be subject to the fugitive monitoring program. It would be arbitrary to base the intensity of fugitive monitoring requirements on emissions calculations that do not reflect the number and type of fugitive components at a site, when those fugitive-specific emissions calculations are readily available.

The commenter (0739-Citation) similarly states fugitive monitoring requirements should be based on a facility's potential for fugitive emissions, not from emissions associated with engines, dehydrators, venting, storage tanks, *etc.* Fugitive emission monitoring will have no effect on emission rates other than on fugitive emissions.

Response I-7-37: In response to the comments received on the November 2021 Proposal, EPA proposed a different regulatory approach for this particular affected/designated facility in the December 2022 Supplemental Proposal. For details, please see discussion in section IV.A.1.a.ii of the December 2022 Supplemental Proposal related to fugitive emissions from well sites.<sup>66</sup> Please also see section X.A.1 of the preamble to the final rule which details EPA's final standards related to fugitive emissions from well sites.

Comment: Commenter (0844-EDF *et al.*) believes EPA should require operators to calculate site-level baseline emissions using more accurate emission factors, like the averaged emission factors from Rutherford *et al.* The Rutherford tool provides equipment-level emission factors that are calculated by summing component-level emission factors according to estimated component counts per piece of equipment using methods described in Section 3.3 of the study and Section 5.2 for the GHG Inventory (GHGI).<sup>67</sup> These emission factors, derived from numerous recent peer-reviewed studies, will estimate site-level emissions more accurately than EPA's subpart W factors.

Response I-7-38: In response to the comments received on the November 2021 Proposal, EPA proposed a different regulatory approach for this particular affected/designated facility in the December 2022 Supplemental Proposal. For details, please see discussion in section IV.A.1.a.ii of the December 2022 Supplemental Proposal related to fugitive emissions from well sites.<sup>68</sup> Please also see section X.A.1 of the preamble to the final rule which details EPA's final standards related to fugitive emissions from well sites.

Comment: Commenters (0775-CDPHE, 0844-EDF *et al.*) question EPA's claims that the proposed quarterly monitoring at sites from 3 tpy to 8 tpy is more stringent than Colorado regulations.<sup>69</sup> EPA fails to account for the significant differences in actual coverage that result

---

<sup>66</sup> 87 FR 74724-74736 (December 6, 2022).

<sup>67</sup> *Id.* at 11-12.

<sup>68</sup> 87 FR 74724-74736 (December 6, 2022).

<sup>69</sup> 86 Fed. Reg. 63,192. EPA's comparison uses a site-level VOC-to-methane ratio of 0.28 to compare the 3 tpy methane threshold to the Colorado's VOC tiers, but tanks typically have a much higher VOC-to-methane ratio, which EPA's analysis does not take into account. This is particularly important since Colorado regulations are based on tank emissions when tanks are present.

from using a different site-level emission calculation. Furthermore, Colorado recently updated its regulations, increasing monitoring frequencies and requiring regular monitoring at all tiers.<sup>70</sup>

Commenter (0844-EDF *et al.*) notes Colorado uses an uncontrolled tank emission calculation that is more representative of real site conditions.<sup>71</sup> This calculation still does not account for issues like unlit flares and stuck separator dump valves, but it is more representative of a site's actual potential emissions. The commenter states this approach still greatly underestimates actual site-level emissions because it does not account for most equipment failures and relies on outdated emission factors. However, it is directionally an improvement from EPA's proposed PTE calculation because it uses uncontrolled tank emissions, and tanks are the largest source of fugitive and abnormal process emissions by most estimates.

Commenter (0775-CDPHE) states EPA's calculations and claims that the proposed thresholds are much more stringent than Colorado's are based on the inappropriate assumption of 0.28 VOC: methane (by weight) in tank emissions. The commenter provides further information in their comment letter on why this assumption is inaccurate. In the commenter's estimation, the VOC emissions associated with a methane emission rate of 3 tpy from storage tanks equates to 32.7 tpy VOC, not 0.83 tpy VOC. At the threshold of 32.7 tpy VOC, Colorado is already requiring at least quarterly monitoring.

Commenter (0844-EDF *et al.*) replicated EPA's PTE analysis based on the Enverus 2019 well pads, using average component emissions per site, GHGRP tank emission factors, and a Monte Carlo simulation for pneumatic pump and pneumatic controller emissions.<sup>72,73</sup> The commenter was able to predict the number of sites above and below the proposed 3 tpy threshold. From this analysis, they were able to assign each site to an inspection frequency under the new Colorado regulations (annual for >0 and =2 and ≤50 tpy VOC, and monthly for >50 tpy VOC).<sup>74</sup> Under Colorado regulations, emissions are calculated using actual uncontrolled tank emissions (based on state-specified emission factors). If a site does not have a tank, the calculation is based on the site-wide actual controlled VOC emissions. Another commenter (0775-CDPHE) believes that

[https://drive.google.com/file/d/1JXzWUuPedxqHVCqiU6BdK3GJn\\_Z0x50X/view](https://drive.google.com/file/d/1JXzWUuPedxqHVCqiU6BdK3GJn_Z0x50X/view).

<sup>71</sup> 5 Colo. Code Regs. § 1001-9, Pt. D, § II.E.4.e,  
<https://drive.google.com/file/d/1ZwPwoAHVWEoRmPhoa11UNEiP-RC9ZpI7/view>.

<sup>72</sup> In order to recreate the site level dataset used by the EPA in their analyses, we first downloaded well level characteristic and production data for all wells with production in 2019 from Enverus Prism. We removed offshore wells by excluding Enverus Basin "GOM Offshore", Enverus State "CAO" and a series of counties designated as offshore (see API State and County Codes). After speaking with Enverus regarding their methods for creating their pad identifier, we identified an issue of exceptionally large pads (>25,000 active wells) created through their spatial model. Enverus is currently working to resolve this issue, and is open to feedback on a more accurate model. As a preliminary step, EDF decided to disaggregate sites by operator in order to split identified pads with more than one operator. This led to the creation of ~4,000 more pads from the original dataset (~.5%). To determine low-producing sites we calculated site level BOE produced per day and selected those below 15 BOEpd.

<sup>73</sup> Attachment G (Lyon PTE Analysis).

<sup>74</sup> For simplicity, we ignored differences for sites in proximity to occupied areas or in disproportionately impacted (DI) communities. This is a conservative comparison because many sites in Colorado are subject to more frequent inspections than in our simplified analysis.

EPA should permit states to use VOC emissions as a proxy for comparing the stringency of a state program with EPA's proposed thresholds.

Commenter (0844-EDF *et al.*) states Colorado's site-level calculation more accurately predicts actual emissions and therefore places sites in more accurate monitoring tiers. Because EPA's proposed calculation will underestimate actual emissions in the vast majority of cases and fails to account for the well-documented problem of abnormal emission events caused by equipment failures, the commenter recommends EPA revise the calculation by 1) employing emission factors that account for malfunctions, 2) using uncontrolled tank emissions, and 3) ensuring that every piece of equipment at the site, including flares, is included in the calculation.

Response I-7-39: In response to the comments received on the November 2021 Proposal, EPA proposed a different regulatory approach for this particular affected/designated facility in the December 2022 Supplemental Proposal. For details, please see discussion in section IV.A.1.a.ii of the December 2022 Supplemental Proposal related to fugitive emissions from well sites.<sup>75</sup> Please also see section X.A.1 of the preamble to the final rule which details EPA's final standards related to fugitive emissions from well sites.

Comment: Commenters (0437-New York Office of the State Comptroller (NYOSC), 0756-Baker Hughes, 0788-350 Seattle) believes that the total site-wide emission baseline should be measured, rather than calculated.

The commenter (0756-Baker Hughes) is of the opinion that emissions factors are often inaccurate as applied to a given site and cannot capture the normal variation between different sites. Nor does this approach account for the age of equipment, variation in gas quality (wet, dry, sweet, sour, *etc.*), or provide a means of assessing the likelihood and impact of large emission events. Only by direct measurement can an appropriate and effective baseline be determined.

The commenter (0437-NYOSC) urges EPA to take measures to ensure accurate assessment of methane emissions using empirical data rather than factor-based estimates.

The commenter (0788-350-Seattle) believes that a rule based on a PTE calculation may allow thousands of wells to avoid regular monitoring. The commenter agrees with the testimony of Natural Resources Defense Council's Lissa Lynch in calling for the removal of this loophole for smaller wells.

Response I-7-40: In response to the comments received on the November 2021 Proposal, EPA proposed a different regulatory approach for this particular affected/designated facility in the December 2022 Supplemental Proposal. For details, please see discussion in section IV.A.1.a.ii of the December 2022 Supplemental Proposal related to fugitive emissions from well sites.<sup>76</sup> Please also see section X.A.1 of the preamble to the final rule which details EPA's final standards related to fugitive emissions from well sites.

---

<sup>75</sup> 87 FR 74724-74736 (December 6, 2022).

<sup>76</sup> 87 FR 74724-74736 (December 6, 2022).

Comment: Commenter (0785-John Crane Inc.) recommends that the site-level methane baseline emissions are open to be derived from population-based emission factors or from surveys, based on the owner or operator's preference. The sites will require some frequency of surveys regardless of the baseline calculation; therefore, some operators may choose to perform the survey at once (and instead of a calculation) and consider it a part or whole of their annual survey requirements. The commenter recommends that the EPA foster the exploration and use of a variety of measurement and monitoring system technologies appropriate for the region and conditions for which they are being deployed to ensure optimal efficiency and accuracy of results.

Response I-7-41: In response to the comments received on the November 2021 Proposal, EPA proposed a different regulatory approach for this particular affected/designated facility in the December 2022 Supplemental Proposal. For details, please see discussion in section IV.A.1.a.ii of the December 2022 Supplemental Proposal related to fugitive emissions from well sites.<sup>77</sup> Please also see section X.A.1 of the preamble to the final rule which details EPA's final standards related to fugitive emissions from well sites.

Comment: Commenter (0737-Clarke Valve) believes that valves that are part of such production and processing equipment should continue to be included in a site's baseline emissions. More specifically, stem fugitive emissions from control valves should be part of a site's baseline emissions. The commenter encourages EPA to continue allowing EPA Method 21 to be used to calculate baseline emissions at oil and gas sites.

Response I-7-42: In response to the comments received on the November 2021 Proposal, EPA proposed a different regulatory approach for this particular affected/designated facility in the December 2022 Supplemental Proposal. For details, please see discussion in section IV.A.1.a.ii of the December 2022 Supplemental Proposal related to fugitive emissions from well sites.<sup>78</sup> Please also see section X.A.1 of the preamble to the final rule which details EPA's final standards related to fugitive emissions from well sites.

Comment: Commenter (0446-Artex) states EPA is proposing "site-specific emissions estimates based on the number and type of equipment located at the individual site to determine the monitoring frequency." EPA acknowledges that these types of equipment include pressure relief valves (PRVs) and pneumatic controllers which are both integral to the safe design and operation of a well site. Establishing LDAR applicability on the basis of the number of these critical safety components effectively encourages owners and operators to forego the installation of PRVs and pneumatic controllers in an attempt to achieve baseline methane emission rates below the 3 tpy threshold. The possibility of catastrophic equipment failure motivated by these attempts to avoid LDAR applicability would pose a far greater risk to human health and environmental protection than the risks mitigated by EPA's November 2021 Proposal.

Response I-7-43: In response to the comments received on the November 2021 Proposal, EPA proposed a different regulatory approach for this particular affected/designated facility in the December 2022 Supplemental Proposal. This approach proposed that the equipment located at

---

<sup>77</sup> 87 FR 74724-74736 (December 6, 2022).

<sup>78</sup> 87 FR 74724-74736 (December 6, 2022).

the site would be the basis for determining the fugitive emissions monitoring requirements, in lieu of using the self-reported baseline emissions as a threshold proposed in November 2021. For details, please see discussion in section IV.A.1.a.ii of the December 2022 Supplemental Proposal related to fugitive emissions from well sites.<sup>79</sup> Please also see section X.A.1 of the preamble to the final rule which details EPA's final standards related to fugitive emissions from well sites.

#### **7.1.5 Well Sites with Baseline Emissions <3 tpy**

Comment: Commenters (0195-Evangelical Environmental Network (EEN), 0201-Sierra Club, Lone Star Chapter (Sierra Club-LSC), 0391-KBIC, 0401-Mercy Investment Services, Inc. (Mercy), 0421-Big Thicket Biosphere Reserve (BTBR), 0434-Impax Asset Management, LLC (Impax), 0448-As You Sow (AYS), 0435-Wespath Benefits and Investments (Wespath), 0455-RDN, 0460-Trinity Health, 0560-Legal & General Investment Management America, Inc. (LGIM America), 0586-Navajo EPA, 0589-NEI Investments (NEI), 0753-Institute of Governance & Sustainable Development (IGSD) and Center for Human Rights and the Environment (CHRE), 0757-Private Equity Stakeholder Project (PESP), 0781-NTAA, 0807-BP America Inc. (BP), 0812-Ohio Farmers Union (OFU) *et al.*, 0844-EDF *et al.*, 0931-Essential Information, Inc. (Essential), 0937-Fort Berthold POWER) agree that well sites with baseline emissions below 3 tpy should be required to report emissions. Some commenters believe EPA's proposed reporting requirements suffice while others argue for more stringent requirements.

Commenters (0195-EEN, 0201-Sierra Club-LSC, 0391-KBIC, 0586-Navajo EPA, 0753-IGSD/CHRE, 0757-Private Equity Stakeholder Project, 0775-CDPHE, 0781-NTAA, 0844-EDF *et al.*) believe well sites less than 3 tpy should be required to conduct quarterly or at least regular monitoring for leaks, particularly where leak prone equipment is present on the site. The commenter (0201-Sierra Club-LSC) requests that EPA should go further and require monthly LDAR for wells and compressor stations.

Commenter (0837-Clean Water Action (CWA) *et al.*) requests that EPA increase monitoring and inspection for smaller, high polluting wells.

Commenters (0753-IGSD/CHRE, 0775-CDPHE) argue the EPA should follow Colorado's lead and require monitoring of all wells.<sup>80</sup> Further, Colorado's program, which has formed the basis

---

<sup>79</sup> 87 FR 74724-74736 (December 6, 2022).

<sup>80</sup> CDPHE, Air Quality Control Commission Regulation Number 7: CONTROL OF OZONE VIA OZONE PRECURSORS AND CONTROL OF HYDROCARBONS VIA OIL AND GAS EMISSIONS (EMISSIONS OF VOLATILE ORGANIC COMPOUNDS AND NITROGEN OXIDES), (2021), 1-404, 287 ("Well production facilities' are also subject to LDAR requirements and storage tank maintenance requirements. This definition is meant to include all of the emission points, as well as any other equipment and associated piping and components, owned, operated, or leased by the producer located at the same stationary source (a defined term specific to permitting). The 'owned, operated, or leased' qualifier in the definition is not meant to reduce the stringency of LDAR requirements in situations where there are multiple owners or operators of the well production facility. This definition is meant to exclude natural gas compressor stations from 'well production facility' and avoid overlapping LDAR requirements. This definition is also meant to exclude natural gas storage wells."); See also Environmental Defense Fund (17 Dec. 2021) With Powerful New Oil and Gas Rules, Colorado Sets Bar for Nation-leading Protections, Press Release ("Today the Colorado Air Quality Control Commission voted unanimously to adopt landmark rules limiting oil and gas methane and air pollution. The rules will require frequent inspections for all

for many other LDAR programs around the country, including EPA's, should continue to be found equivalent to EPA's LDAR program, without the need for an overly complicated and technical comparison of the proposed thresholds. Grouping small, potentially leak-prone wells into LDAR requirements sets Colorado closer to achieving the state's environmental justice law (HB21 – 1266), which calls for a 60 percent reduction in greenhouse gas emissions by 2030.<sup>81</sup>

The commenter (0753-IGSD and CHRE) notes that exempting sources below 3 tpy from monitoring would ignore the risks these wells represent and the threat that these sources could become large emitters, or that collectively, they might nonetheless represent significant emissions.

The commenters (0605-Muscogee (Creek) Nation, 0833-Ute EPD, 0943-Sault EPD) argue that simply because a well site has lower estimated emissions does not mean that the equipment will not malfunction or fail resulting in significant emissions. These leaks and malfunctions must be identified and addressed as soon as possible to avoid emission of VOC, methane, and HAP. A single inspection after the rule is finalized will not address this problem, in the commenters' opinion.

The commenter (0201-Sierra Club-LSC) states EPA must remove the LDAR exemption for well sites that have a calculated PTE below 3 tpy of methane. Under the proposal, these wells need only conduct one LDAR inspection to fulfill their obligations; the commenter wants them to be subject to no less stringent LDAR requirements than all other wells. At a minimum, if EPA insists on including some form of relaxed LDAR standards for less complex wells, it must limit that exemption more than it has done in the proposal. For instance, EPA could require regular LDAR at all well sites that have certain kinds of malfunction-prone equipment (like storage vessels and separators), even if they otherwise fall below the 3 tpy threshold. Other possibilities also exist as well to limit this exemption.

The commenter (0195-EEN) indicates that the proposed standards in the rule would be strengthened by incorporating quarterly LDAR inspection of all wells with 2 tpy or more. This recommendation is based on the EPA's own conclusion in the November 2021 Proposal, which states: "...sites with total baseline methane emissions of 2 tpy, the commenter concludes that regular monitoring at semiannual or quarterly frequencies would be cost-effective." Based on this conclusion that quarterly inspection of well sites with 2 tpy is cost-effective, the commenter recommends that the 3 tpy emissions threshold in the November 2021 Proposal be reduced to 2

---

wells, including smaller, leak-prone ones which have been shown to be responsible for an outsized share of emissions. In addition, the rules will prohibit venting of methane during maintenance activities.").

<sup>81</sup> Boulder County (17 Dec. 2021) Air Commission strengthens oil and gas leak repair requirements, but fails to ensure Colorado will meet its climate goals (last visited 5 Jan. 2022) ("The new regulations will move Colorado towards the targets set by a 2021 environmental justice law (HB21-1266), but the state will fall short of the goal of 60 percent reductions by 2030. Additional emissions reductions will still be needed to meet that goal. HB21-1266 also requires these regulations to provide extra protections for communities that are disproportionately impacted by oil and gas pollution, as well as by climate change. The rules adopted today do require more frequent inspections and repairs at sites near where people live, work and play. But some provisions do not extend to disproportionately impacted communities statewide — only in the ozone-impacted Front Range.").

tpy emissions and that the frequency of inspections be increased to quarterly. The commenter recommends that sites below 2 tpy be inspected at least annually.

The commenter (0937-Fort Berthold POWER) states all wells, regardless of their PTE should have monthly LDAR inspections. The commenter's community is directly impacted by the toxic pollutants that are emitted alongside methane and the commenter is also facing the terrible consequences of these greenhouse gases being emitted by the effects of global warming.

Commenter (1330-Catskill Mountainkeeper) suggests requiring monthly leak inspections at all wells and compressor stations and eliminate exemptions for smaller, high polluting and leak-prone wells, including for wells that produce less than 3 tpy of emissions (or, alternatively, consider mandating continuous monitoring with real-time reporting, which may be cost-effective at many sites and allow earlier detection and enforcement).

Response I-7-44: In response to the comments received on the November 2021 Proposal, EPA proposed a different regulatory approach for this particular affected/designated facility in the December 2022 Supplemental Proposal. For details, please see discussion in section IV.A.1.a.ii of the December 2022 Supplemental Proposal related to fugitive emissions from well sites.<sup>82</sup> Please also see section X.A.1 of the preamble to the final rule which details EPA's final standards related to fugitive emissions from well sites.

Comment: Commenters (0401-Mercy, 0434-Impax, 0435-Wespath, 0448-AYS, 0455-RDN, 0460-Trinity Health; 0589-NEI; 0757-PESP; 0812-OFU *et al.*, 0931-Essential) believe that the EPA's November 2021 Proposal standards for oil and natural gas methane emissions are an important step in the right direction, and urge the EPA to ensure strong methane emission performance standards by crafting a regulation that includes all potentially significant sources of methane emissions, including smaller leak-prone wells, under emission standards.

The commenter (0757-PESP) believes that rigorous monitoring requirements that reduce emissions by 80 to 90 percent must apply comprehensively across all facilities, including wells below 3 tpy. These PTE calculations are based on emission factors that very likely underrepresent the true extent of fugitives originating from these wells, and do not account for equipment failures or malfunctions that can lead to super-emitting events. Furthermore, marginal wells are mostly owned by larger companies that have the capacity to ensure compliance. Thus, EPA should not provide special and more lenient requirements for these wells, but should mandate regular monitoring at all wells, regardless of their calculated PTE.

The commenter (0931-Essential) strongly opposes the lack of emissions monitoring at small oil and gas wells under the proposed rules. The commenter states if equipment breaks or is not functioning as intended, significantly greater amounts of methane emissions could be leaking from these small wells for years. It would fall on state air control agencies to catch problems. However, air control agencies are only required under federal guidelines to conduct regular Full Compliance Evaluations, Partial Compliance Evaluations, and Investigations for Title V major emitter sources, and for synthetic minor sources with potentials to emit 80 percent of Title V

---

<sup>82</sup> 87 FR 74724-74736 (December 6, 2022).

major emitter thresholds.<sup>83</sup> Thus, the commenter says that smaller well sites have no federally-mandated inspection schedule and fugitive emissions problems may be ongoing for years with no plan for government intervention. Even if a state inspector happened to visit a small well, he/she would not be likely to do OGI monitoring and so could miss the fugitive emissions problems, unintentionally allowing methane leaking to be chronic.

The commenters (0589-NEI, 0931-Essential) argue if owners have the resources to invest in the building and operating of these small wells, they surely have the resources to conduct a site visit twice a year to check for fugitive methane and VOC emissions. Furthermore, it is presumably in their interest to visit wells occasionally to ensure that they are operating at maximum efficiency to obtain good returns on investments. Thus, the commenters do not think it can be convincingly argued that bi-annual inspections for fugitive emissions is an undue burden on an owner. The commenter (0931-Essential) recommends a minimum of semiannual OGI monitoring for all well sites with total site-level baseline methane emissions less than 3 tpy.

Response I-7-45: In response to the comments received on the November 2021 Proposal, EPA proposed a different regulatory approach for this particular affected/designated facility in the December 2022 Supplemental Proposal. For details, please see discussion in section IV.A.1.a.ii of the December 2022 Supplemental Proposal related to fugitive emissions from well sites.<sup>84</sup> Please also see section X.A.1 of the preamble to the final rule which details EPA's final standards related to fugitive emissions from well sites.

Comment: Commenter (0421-BTBR)) says that currently the EPA monitors methane emissions from industries in the Beaumont/Port Arthur area including a number of high polluting facilities, such as Valero and Oxbow Calcining. Under the current rule, the EPA allows operators to calculate lower potential polluting emissions (less than 3 tpy) that can escape regular leak detection. The Texas Commission of Environmental Quality (TCEQ) Emissions Event database indicates that tons more sour gas is released annually through flaring. Moreover, flaring releases sulfur dioxide, which likely contribute to exceedances of the EPA's health-based sulfur dioxide National Ambient Air Quality Standard (1-hour standard) for Jefferson County, Texas.

Response I-7-46: In response to the comments received on the November 2021 Proposal, EPA proposed a different regulatory approach for this particular affected/designated facility in the December 2022 Supplemental Proposal. For details, please see discussion in section IV.A.1.a.ii of the December 2022 Supplemental Proposal related to fugitive emissions from well sites.<sup>85</sup> Please also see section X.A.1 of the preamble to the final rule which details EPA's final standards related to fugitive emissions from well sites.

Comment: Commenter (0844-EDF *et al.*) supports the November 2021 Proposal's requirements for quarterly OGI monitoring at well sites and tanks batteries, but the commenter urges the Agency to finalize stronger standards that require quarterly monitoring at all sites with potentially significant emissions including smaller sites below 3 tpy. If EPA retains the tiered

---

<sup>83</sup> EPA Office of Enforcement and Compliance Assurance, Oct 4, 2016. Clean Air Act Stationary Source Compliance Monitoring Strategy of October 2016. EPA Online. Accessed Jan 20, 2022: <https://www.epa.gov/sites/default/files/2013-09/documents/cmsspolicy.pdf>, pp. 6-12.

<sup>84</sup> 87 FR 74724-74736 (December 6, 2022).

<sup>85</sup> 87 FR 74724-74736 (December 6, 2022).

structure, it should categorically exclude sites with failure-prone equipment from any tier subject to less frequent monitoring. The commenter also urges EPA to increase monitoring frequencies at the largest sites where potential emissions are very high and monitoring is highly cost-effective.

The commenter (0844-EDF *et al.*) states to remedy the numerous problems inherent in allowing smaller sites to forgo regular monitoring, EPA should eliminate the 3 tpy tier and require quarterly monitoring at these sites, particularly if it retains the wellhead only exemption.<sup>86</sup> Quarterly monitoring is effective at reducing emissions and can be conducted at low cost at all sites. If EPA retains the tiering structure, it should exclude sites with known high-emitting equipment from any low-PTE category because of the potential for failure that could lead to major emission events. Numerous studies show that tanks, separators, flares, and gas-driven pneumatics commonly fail and lead to significant emissions.<sup>87</sup> EPA should categorically exclude any site with this type of equipment from qualifying for an exemption from routine monitoring through a low-PTE calculation. This would also streamline the rule's compliance and enforcement process because operators and inspectors could automatically eliminate certain well sites from qualifying for the exemption from regular monitoring simply by observing that certain kinds of equipment were present at the site, rather than having to calculate and verify PTE for those sites. Under their first approach, the commenter replicated EPA's PTE analysis. Following EPA's methods using 2019 Enverus Prism data and subpart W methods, the commenter estimates that the 3 tpy threshold would exempt 20 percent of well sites (48 percent of oil wells and 19 percent of gas wells) from regular monitoring, forgoing up to 330,000 tons of methane reductions.<sup>88</sup> These 20 percent of wells comprise 14 percent of fugitive emissions, in line with what EPA estimates in the rule.

<sup>87</sup> See Part X, Subsection A *infra*; Zavala-Araiza et al., Toward a Function Definition of Methane Super-Emitters: Application to Natural Gas Production Sites, 49 *Env. Sci. Tech.* 8167 (2015), <https://pubs.acs.org/doi/pdf/10.1021/acs.est.5b00133>; Lyon, D. R. et al. Aerial surveys of elevated hydrocarbon emissions from oil and gas production sites, 50 *Env. Sci. Tech.* 4877–4886 (2016) (finding that emissions from tank vents and hatches accounted for roughly 90% of all detected hydrocarbon sources emitting >3–10 kg per hour. Other sources observed included separator pressure relief valves, dehydrators and flares.); Rutherford et al., Closing the methane gap in US oil and natural gas production emissions inventories, 12 *Nature Comms.* 4715 (2021), <https://www.nature.com/articles/s41467-021-25017-4#citeas> (Figure 3 shows tanks as the largest emission source and biggest reason for disagreement with GHGI data. It also shows that flare methane emissions are underestimated in the GHGI and shows pneumatics and separators as large sources.); Zavala-Araiza et al., Super-emitters in natural gas infrastructure are caused by abnormal process conditions, 8 *Nature Comms.* 14012 (2017), <https://www.nature.com/articles/ncomms14012>; Tyner & Johnson, Where the Methane Is—Insights from Novel Airborne LiDAR Measurements Combined with Ground Survey Data, 55 *Env. Sci. Tech.* 9773 (2021) <https://pubs.acs.org/doi/pdf/10.1021/acs.est.1c01572> (“More than half of emissions were attributed to three main sources: tanks (24%), reciprocating compressors (15%), and unlit flares (13%).”); Lyman et al., Aerial and ground-based optical gas imaging survey of Uinta Basin oil and gas wells, 7 *Elementa. Sci. of the Anthropocene* 43 (2019), <https://doi.org/10.1525/elementa.381> (“The majority of observed emission plumes were from liquid storage tanks (75.9% of all observed plumes), including emissions from pressure relief valves and thief hatches on the tank or from piping that connects to the tank. Well pads with control devices to reduce emissions from tanks (combustors or vapor recovery units) were more likely to have detected emissions.”).

<sup>88</sup> Attachment G (Lyon PTE analysis).

As a second approach to estimating the 3 tpy threshold, commenter (0844-EDF *et al.*) used GHGRP data, extrapolated nationwide and disaggregated to the site level. First, GHGRP data were analyzed with a statistical model that uses production data and reported basin-level emissions to estimate county-level emissions from both reporters and non-reporters. Then, facility-level emission estimates were disaggregated down to an individual site level based on that site's percentage of the whole facility's production. This method of disaggregation likely overestimates emissions at lower production sites, which may not have all of the equipment found at larger sites. This method predicts that close to 70 percent of sites will be below the 3 tpy threshold, comprising 21 percent emissions. These first two methods likely approximate ways in which operators will estimate their own PTE. However, measurement studies have shown that these "bottom-up" approaches can significantly underestimate emissions at a site. Therefore, the commenter also performed the analysis using measured site-level emission factors.

For the third approach, commenter (0844-EDF *et al.*) used the site-level emissions factors (weakly correlated with production) from Alvarez *et al.* to predict site-level emissions.<sup>89</sup> Comparing these site-level emissions estimates to the 3 tpy threshold, the commenter estimates that about 14 percent of sites are actually under a 3 tpy threshold, but that these sites only comprise around 1 percent of fugitive emissions. This method may overestimate emissions at some of the smaller, low-equipment site since emission factors aren't able to distinguish between sites with significant equipment and sites with very little equipment.

The commenter (0844-EDF *et al.*) continues, the fourth approach represents a hybrid: calculating whether a site is above or below the 3 tpy threshold using the GHGRP emissions approach, but then calculating the percentage of site and fugitive emissions under that threshold using the Alvarez site-level emissions. This column approximates the potential impacts of operators using a PTE approach but having site-wide emissions in line with what Alvarez *et al.* found. This approach finds that the roughly 70 percent of sites below the 3 tpy threshold comprise about 40 percent of fugitive emissions.

The commenter (0844-EDF *et al.*) finds these methods demonstrate that it is difficult to predict exactly what percentage of emissions are left unmitigated by the 3 tpy threshold, but that it is likely to be substantial. Uncertainty around the number of sites that could be allowed to forgo regular monitoring and the magnitude of emissions potentially forgone strongly weigh against EPA finalizing the November 2021 Proposal's approach to sites below 3 tpy. The commenter argues EPA should not finalize a loophole for sites below 3 tpy because doing so could leave sites responsible for up to 43 percent of fugitive emissions inadequately monitored. To look at this another way, if EPA finalizes its LDAR program as proposed and includes a one-time only inspection frequency for well sites under 3 tpy, their analysis shows this could reduce the overall effectiveness of its LDAR program by as much as half and leave millions of tons of pollution unaddressed. This one-time monitoring loophole thus significantly undermines the effectiveness of not just the fugitive monitoring program, but the entire November 2021 Proposal.

The commenter (0844-EDF *et al.*) goes further, the November 2021 Proposal's loophole is not supported by cost considerations, scientific evidence of emissions from smaller sites, or any

---

<sup>89</sup> Alvarez 2018.

small business concerns. Leaving such a significant portion of easily achievable emission reductions on the table that could be cost-effectively cut is illogical and goes against EPA's directives under the CAA, the Congressional Review Act Resolution (which, in practice, effectively nullified the low-production well exemption), and Executive Order 13,990. Forgoing these emission reductions will make it much more difficult for the Administration to meet its climate commitments made in Glasgow at the 26th United Nations Climate Change Conference of the Parties and under the Global Methane Pledge. It will also cause serious enforceability and compliance issues, setting up gamesmanship and creating room for inaccurate interpretations of regulatory obligations. Further, the November 2021 Proposal's loophole raises serious environmental justice concerns that undercut the Administration's commitment to protecting frontline communities from the disproportionate burdens of pollution. Last, exemptions for low-utility sites allow operators to neglect maintenance and disincentivize proper closure, potentially exacerbating the orphan well problem.

The commenter (0844-EDF *et al.*) states while the November 2021 Proposal's one-time monitoring requirement differs from the low-production or marginal well exemption for new sources finalized under the last Administration, the commenter expects the universe of sites falling into each category to be very similar.<sup>90</sup> The 3 tpy category does not include all low-producing or marginal sites (*i.e.*, those producing an average of less than 15 BOE/d), but it will likely exempt hundreds of thousands of sites from regular monitoring. Marginal sites tend to have less equipment onsite, and therefore will calculate low potential emissions using EPA's proposed PTE calculation.

Related to the flaws in EPA's November 2021 Proposal's PTE calculation for operators (discussed above), commenter (0844-EDF *et al.*) thinks EPA's analysis estimating the number of sites and amount of emissions potentially falling below 3 tpy is flawed. The commenter's attempt to recreate this analysis, which is outlined in EPA's Appendix A, revealed multiple problems, and the commenter believes it is unsuitable for estimating sites' PTE.<sup>91</sup> First, well site equipment counts, which are key inputs to the fugitive emission calculations, are applied randomly and do not account for likely relationships between production and equipment counts. Similarly, pneumatic controller and pump counts are assigned randomly even though higher production sites are expected to have higher equipment counts. In the likely case that low-production sites tend to have lower equipment counts, then this method of estimating site-level PTE over-assigns pneumatic pumps and controllers to these sites, which means EPA projects that less sites are below 3 tpy than would be expected. Second, these methods do not account for regional differences in emission factors or natural gas composition. Finally, and most critically, these approaches do not account for anomalous emission rates that can occur due to malfunctions. For example, a high production natural gas site with low equipment counts and little condensate production may have a low PTE based on these calculations, but if the separator dump valve is left open, then the site's emissions may be several orders of magnitude higher.

Using the Rutherford model, commenter (0844-EDF *et al.*) separately evaluated the sites and emissions from sites that EPA would classify as below 3 tpy. The commenter estimates that of all the sites EPA's analysis would place below 3 tpy, 22 percent actually have emissions above

---

<sup>90</sup> Attachment G (Lyon PTE Analysis).

<sup>91</sup> *Id.*

that threshold. Those 22 percent of sites account for 90 percent of total emissions from all sites that would qualify for the exemption under EPA's analysis. In other words, 90 percent of the unabated emissions that EPA estimates would result from the 3 tpy exemption originate from sites that should not, in fact, qualify for that exemption based on their actual emissions. Further, their analysis indicates that emissions from sites EPA would deem below 3 tpy PTE are underestimated by a factor of four.<sup>92</sup>

Response I-7-47: In response to the comments received on the November 2021 Proposal, EPA proposed a different regulatory approach for this particular affected/designated facility in the December 2022 Supplemental Proposal. For details, please see discussion in section IV.A.1.a.ii of the December 2022 Supplemental Proposal related to fugitive emissions from well sites.<sup>93</sup> Please also see section X.A.1 of the preamble to the final rule which details EPA's final standards related to fugitive emissions from well sites.

Comment: Commenter (0844-EDF *et al.*) states EPA's November 2021 Proposal to require a one-time inspection at smaller sites is an inadequate approach for dealing with fugitive emissions from oil and gas sources, which are known to be intermittent, varying in size, and difficult to predict. For instance, operators may choose to conduct one-time monitoring during favorable conditions that do not accurately reflect the true extent of emissions from the site in question. And even if a one-time survey is conducted properly, it only represents a snapshot in time, and an equipment failure (particularly for sites with failure-prone equipment like tanks and flares) could cause the same site to begin experiencing large emissions any time after the survey. The commenter argues under the proposed approach, super-emitters at these sites could go permanently undetected. Many of the smaller sites that would be allowed to conduct a one-time survey are older and declining in production and are therefore more likely to be poorly maintained. Most of them have also never been subject to federal air-pollution regulation and have likely never upgraded any of their equipment. These older, declining sites are less valuable to operators who have little financial incentive to maintain them properly, resulting in components that may be rusted and in poor condition. All of these factors make sites below 3 tpy highly prone to leaks and equipment failures, and a one-time inspection does not resolve that problem.

The commenter (0844-EDF *et al.*) continues, results from recent surveys conducted in the Permian Basin confirm that emissions from low production sites are recurrent and would not be mitigated by a one-time inspection and repair standard.<sup>94</sup> From November 12-21, 2021, the commenter contracted Leak Survey Inc. (LSI) to survey emissions across the Permian Basin using helicopter-based OGI. With an infrared camera mounted to an R44 helicopter with a gimbal for image stabilization, LSI visited 519 different upstream production sites. LSI then returned to 154 of these sites to collect repeat observations within a week's time. At each site, LSI noted any source of detectable methane emissions and recorded video, which are publicly available along with a complete methodology on Permianmap.org. Over 80 percent of

---

<sup>92</sup> Id.

<sup>93</sup> 87 FR 74724-74736 (December 6, 2022).

<sup>94</sup> Attachment B (PermianMAP November 2021 Flyover Results); see also EDF, Methodology for EDF's Permian Methane Analysis Project (PermianMAP) (Nov. 17, 2021), [https://www.edf.org/sites/default/files/documents/PermianMapMethodology\\_1.pdf](https://www.edf.org/sites/default/files/documents/PermianMapMethodology_1.pdf).

observations were linked to production data from Enverus Prism by totaling the amounts of oil and gas produced within a 175m radius buffer from the latitude and longitude reported by LSI. Roughly 60 percent of observations were from low-producing sites generating less than 15 BOED.

The commenter (0844-EDF *et al.*) finds these low-producing sites had a higher rate of flare malfunctions (31.3 percent) when compared to higher production sites (9.4 percent). Additionally, the malfunctioning flares found at low-producing sites were almost all (90.5 percent) completely unlit and venting methane.<sup>95</sup> Even if only active for a short period of time, unlit flares release large amounts of methane into the atmosphere. For example, a flare with 98 percent combustion efficiency would have nearly fifty times higher emissions than normal when unlit. Possible causes of this high rate of malfunction include the intermittency of flares at these sites, due to low production levels, as well as likely less-frequent site visits by operators. The fact that low-producing sites more often exhibit one of the most consequential equipment malfunctions stresses the importance of surveying those sites frequently.

The commenter (0844-EDF *et al.*) states when comparing repeat observations from low-producing sites within a week, 56.3 percent of sites (54/96) had detectable emissions at some point. This includes emissions from all equipment types, such as flares, tanks, separators, and compressors. About one-third of sites had emissions during one site visit and not the other, while about one-quarter had detectable emissions during both visits. Of the sites with emissions observed during both visits, more than half of the sites had different pieces of equipment emitting on each day.

Although the analysis is segregated based on production, commenter (0844-EDF *et al.*) expects similar emission trends between the low-producing sites surveyed and Permian sites classified as less than 3 tpy PTE, given the low production and relatively low equipment counts of the surveyed sites. Based on EPA's PTE methodology in RIA Appendix A, the commenter estimates these sites would have a maximum emission rate of ~10 tpy for tank and fugitive emissions. One-time monitoring is inadequate because these sites often have highly intermittent emissions and emissions that emanate from variable pieces of equipment. At the low-producing sites where LSI collected repeat observations, a site visit on only one day would fail to mitigate emissions from 52.8 percent of sites that had multiple emission sources over two days.<sup>96</sup>

Response I-7-48: In response to the comments received on the November 2021 Proposal, EPA proposed a different regulatory approach for this particular affected/designated facility in the December 2022 Supplemental Proposal. For details, please see discussion in section IV.A.1.a.ii of the December 2022 Supplemental Proposal related to fugitive emissions from well sites.<sup>97</sup> Please also see section X.A.1 of the preamble to the final rule which details EPA's final standards related to fugitive emissions from well sites.

---

<sup>95</sup> See Attachment I (Warren Permian Slides 2021) ("Insights from Repeated Helicopter OGI on Methane Emissions and Flaring Performance across Industry Segments in the Permian Basin.").

<sup>96</sup> On average, the sites that would still have emissions after one day of survey and repairs include one half of the sites that had emissions on one survey day and not the other, along with the sites that had emissions on both days but from different sources each day. These sites total 28.5 out of the 54 sites seen to have emissions across both days.

<sup>97</sup> 87 FR 74724-74736 (December 6, 2022).

Comment: Commenter (0844-EDF *et al.*) states several recent studies demonstrate that smaller wells emit a significant percentage of their gas production—some venting all of their reported produced gas to the atmosphere, or even losing more gas through leaks than they produce for sale.<sup>98</sup> A recent study involving site-level measurements of over seventy well pads in the Permian Basin found that methane emissions are higher than in most other measured basins. This study also found no relationship between production and emissions, and that marginal wells had similar emissions to non-marginal wells.<sup>99</sup> Other recent observations in the Permian Basin have confirmed that marginal sites and even wellhead-only sites can be sources of the largest methane plumes.<sup>100</sup>

The commenter (0844-EDF *et al.*) adds another 2018 study investigated methane emissions characteristics to develop a new national methane emission estimate for the natural gas production sector. The study used site-level methane emissions data from over 1,000 natural gas production sites in eight basins, including 92 new site-level methane measurements in the Uinta, northeastern Marcellus, and Denver-Julesburg basins.<sup>101</sup> It examined natural gas production sites and categorized them as low (sites producing 1,000 Mcfd). The study found that low natural gas production sites “emit a larger fraction of their CH<sub>4</sub> production” than the intermediate and high production sites.

The commenter (0844-EDF *et al.*) states a 2020 study involving direct measurements of methane and VOC emissions from marginal oil and gas wells in the Appalachian Basin of southeastern Ohio, all producing <1 BOE/d, found similar results.<sup>102</sup> The study found that marginal wells are a disproportionate source of methane and VOC emissions relative to production. It estimated that oil and gas wells in this lowest production category emit approximately 11 percent of total annual methane from oil and gas production reported in EPA’s GHGI, even though they produce only about 0.2 percent of oil and 0.4 percent of gas in the U.S. per year.

The commenter (0844-EDF *et al.*) states despite this wealth of data examining emissions from marginal sites, some industry stakeholders have claimed that EPA does not have enough information to regulate marginal sites and should wait for a pending study conducted by GSI Services with funding from the Department of Energy.<sup>103</sup> Yet this study looks only at emissions from sites that operators volunteered for the study and primarily utilizes component-level measurements that have been demonstrated to underestimate site-level emissions. Even so, drafts of the study show general agreement with skewed emission distributions but find lower average

<sup>102</sup> Deighton et al., Measurements show that marginal wells are a disproportionate source of methane relative to production (2020).

<sup>103</sup> See, e.g., IPAA, SER Comments (Aug. 12, 2021), [https://www.ipaa.org/wp-content/uploads/2021/08/SER103Comments-GO-WV.IPAA\\_.TIPRO-color.pdf](https://www.ipaa.org/wp-content/uploads/2021/08/SER103Comments-GO-WV.IPAA_.TIPRO-color.pdf).

emission rates than other literature. Nothing contained in the draft study significantly changes what is already known about emissions from marginal sites.

The commenter (0844-EDF *et al.*) adds that the most comprehensive study of marginal well site (<15 BOED) emissions to date finds that these sites have production-normalized methane loss rates six to twelve times higher than other sites and represent roughly half (37-75 percent) of all U.S. production site methane emissions.<sup>104</sup> While 80 percent of production sites nationwide contain these marginal wells, they only produce 6 percent of the nation's oil and gas output. Nationally, about 60 percent of marginal sites are ultra low-production sites, producing less than 2 BOED. These wells generate just a trickle of usable product despite disproportionately harming human health and the environment.

The commenter (0844-EDF *et al.*) states the Omara *et al.* study uses available production data from Enverus to assess marginal sites' regional distribution, production characteristics, and operator profiles. Using this data in combination with data on marginal well site emissions previously collected from a diversity of regions across the U.S., the study generates a new national estimate of the total methane emissions from marginal well sites and assesses the significance of these emissions in comparison to emissions from all U.S. production sites. Omara *et al.*'s assessment carries significant policy implications for effective mitigation of U.S. oil and gas methane emissions. It finds that marginal well sites are abundant and that their methane losses occur at high rates exceeding 10 percent of site-level methane production.<sup>105</sup> Field-based observations point to avoidable maintenance-related issues as a key driver of emissions at marginal well sites, particularly at older, lower-producing sites that tend to suffer from prolonged lack of attention from their owners or operators<sup>106</sup>—the precise problem that would be rectified by regular monitoring requirements. Even as their production declines over time, marginal sites' emissions continue from both routine and nonroutine, but avoidable, sources. Marginal sites also display the fat-tailed emission distribution commonly observed in the oil and gas sector.<sup>107</sup> Identifying high-emitting sites and uncovering the root causes of excessive emissions is key to mitigation.

The commenter (0844-EDF *et al.*) argues recognizing the disproportionately large role that low-producing sites play in contributing to total emissions in the U.S. is critical to developing appropriate regulations and achieving targeted reductions.<sup>108</sup> Exemptions for marginal sites risk leaving half of production site emissions unabated without adequate justification. Given that marginal sites generate less than 6 percent of domestic oil and gas production, there are no legitimate concerns that requiring their owners to regularly monitor them and repair equipment leaks would significantly harm domestic energy production. The commenter argues these studies underscore the critical importance of regular LDAR at the smallest of sites—many of which

<sup>108</sup> Id.

would be exempt under EPA’s proposed 3 tpy threshold. These wells—which number in the hundreds of thousands—produce very little usable product, yet they are large and disproportionate polluters. EPA must ensure emissions from these wells are minimized by requiring regular monitoring and repairs.

Response I-7-49: In response to the comments received on the November 2021 Proposal, EPA proposed a different regulatory approach for this particular affected/designated facility in the December 2022 Supplemental Proposal. For details, please see discussion in section IV.A.1.a.ii of the December 2022 Supplemental Proposal related to fugitive emissions from well sites.<sup>109</sup> Please also see section X.A.1 of the preamble to the final rule which details EPA’s final standards related to fugitive emissions from well sites.

Comment: Commenter (0844-EDF et al.) states EPA partially justifies the 3 tpy exemption on a finding that “given the diversity of ownership, while their cost assumption that distributes the costs of recordkeeping evenly across 22 sites within a company-defined area is a reasonable estimate for the population as a whole, it may underestimate the costs and therefore overestimate the cost-effectiveness for owners with fewer than 22 well sites (and conversely, underestimate cost-effectiveness for owners with more than 22 well sites).”<sup>110</sup> Again, this consideration is incorrectly applied to smaller sites: any different treatment on the basis of production (or potential emissions) will likely disproportionately benefit larger operators who own many sites. The vast majority of marginal sites are owned by companies operating 50 or more sites—and this is without considering those companies’ additional ownership of non-marginal sites.<sup>111</sup>

The commenter (0844-EDF *et al.*) finds throughout the November 2021 Proposal, EPA seems to believe that smaller sites are owned by smaller companies that operate fewer wells. EPA provides no justification for this assumption, and the commenter’s analyses of Enverus Prism data shows that it is incorrect. Ninety-two percent of marginal well sites are actually owned by larger companies, defined as those that operate 25 or more sites.<sup>112</sup> The commenter’s analysis also shows that more than three-quarters of marginal wells are owned by companies that operate more than one hundred well sites and generate hundreds of millions in gross revenue each year.<sup>113</sup>

Response I-7-50: In response to the comments received on the November 2021 Proposal, EPA proposed a different regulatory approach for this particular affected/designated facility in the December 2022 Supplemental Proposal. For details, please see discussion in section IV.A.1.a.ii of the December 2022 Supplemental Proposal related to fugitive emissions from well sites.<sup>114</sup> Please also see section X.A.1 of the preamble to the final rule which details EPA’s final standards related to fugitive emissions from well sites.

---

<sup>109</sup> 87 FR 74724-74736 (December 6, 2022).

<sup>110</sup> 86 Fed Reg 63190.

<sup>111</sup> Attachment A (Omara AGU Slides 2021).

<sup>112</sup> Attachment J (Wolfe & Lackner Operatorship Analysis).

<sup>113</sup> As noted above, although marginal production does not directly correlate to PTE, many marginal sites will fall below 3 tpy using EPA’s proposed calculation.

<sup>114</sup> 87 FR 74724-74736 (December 6, 2022).

Comment: Commenter (0844-EDF *et al.*) states a tiering system that is based on self-determined PTE calculated via a complex mathematical formula is prone to human error and gamesmanship. It will also be more difficult to enforce because determining the applicable regulatory standard for a site requires a regulator to conduct the same complex mathematical calculation. A site's PTE is likely to change over time, as equipment is added and removed and as production levels vary. EPA has proposed that operators would have to recalculate PTE every time equipment is added or removed from the site, creating further potential for error and confusion.<sup>115</sup> If EPA retains a tiered approach, categorically excluding sites with failure-prone equipment from tiers subject to less frequent monitoring is a solution that would ease some enforcement concerns.

The commenter (0844-EDF *et al.*) continues, in the article *Next Generation Compliance: Preventing Widespread Violations that Threaten Climate Goals*, Cynthia Giles highlights methane regulations for oil and gas production as “the classic situation in which compliance is likely to be bad.”<sup>116</sup> The oil and gas sector has many characteristics that make it prone to poor compliance, including: “millions of widely dispersed sources; emissions that are hard to observe or measure; industries that know government’s chances of figuring out they are in violation are low; and many states that are unwilling to hold operators accountable.”<sup>117</sup> The article also points out that the “widespread and faulty assumptions that most companies comply, and that enforcement can take care of the rest, are obviously incorrect here,” arguing that more stringent standards will lead to even greater noncompliance as operators—many of whom have never been subject to federal methane regulation—are faced with new costs.<sup>118</sup> Giles’ topline recommendations for federal oil and gas regulations are to 1) aim for clarity and simplicity, 2) minimize exemptions, and 3) require frequent monitoring.<sup>119</sup> The commenter includes Giles’ recommendations in detail.<sup>120</sup>

The commenter (0844-EDF *et al.*) argues Giles’s concerns are directly applicable to the November 2021 Proposal’s exemption from regular monitoring for sites below 3 tpy, and to the co-proposed middle tier. In the November 2021 Proposal, EPA proposed to draw lines between categories of sites for differential treatment and plans to let operators themselves calculate where their sites fall. EPA has thus built in pathways to noncompliance and created incentives for operators to find ways to qualify for less frequent monitoring. And once an operator has decided its site is below 3 tpy and conducted a one-time inspection, that site will no longer be monitored or subject to recordkeeping and reporting standardse.

The commenter (0844-EDF *et al.*) argues enforcement is likewise complicated and made less effective by the tiering structure. Inspectors will be unable to simply visit a site and determine its compliance obligations. Rather, they will have to conduct a PTE calculation, which they will

<sup>118</sup> Giles, *Next Generation Compliance* at 47.

<sup>119</sup> *Id.* at 48-49.

<sup>120</sup> *Id.* at 48-49.

then compare to the operator's own calculation, and will have to resolve any resulting discrepancies before determining the source's compliance obligations. Nor can inspectors determine a site's compliance obligations through by monitoring, since PTE is not reflective of the site's actual emissions. These concerns are exacerbated by the resource limitations that EPA and states will face when enforcing these rules at hundreds of thousands of sources nationwide. For these reasons alone, EPA should eliminate the PTE-based tiered monitoring system and require quarterly monitoring at all sites. At a minimum, EPA should include equipment-based categorical exclusions so it is visibly apparent upon a site inspection what frequency of monitoring is required.

Response I-7-51: In response to the comments received on the November 2021 Proposal, EPA proposed a different regulatory approach for this particular affected/designated facility in the December 2022 Supplemental Proposal. For details, please see discussion in section IV.A.1.a.ii of the December 2022 Supplemental Proposal related to fugitive emissions from well sites, which included an equipment-based approach for determining the fugitive emissions monitoring requirements.<sup>121</sup> Please also see section X.A.1 of the preamble to the final rule which details EPA's final standards related to fugitive emissions from well sites.

Comment: Commenter (0844-EDF *et al.*) states a problem with the 3 tpy threshold is that by exempting these frequently older sites from regular inspections and federal requirements, operators will have no reason or incentive to take care of them and ensure they are properly shut down. In fact, the exemption creates the opposite incentive: because an operator would not have to spend any money or take any steps to comply with the regulations, they would be incentivized to leave the site as-is rather than properly shut it down. The commenter believes EPA should structure regulatory requirements to ensure proper maintenance and closure as well sites reach the end of their productive and economically viable lives. By failing to require regular inspections at smaller wells, EPA is enabling poor maintenance and disincentivizing proper plugging and closure.

The commenter (0844-EDF *et al.*) continues, as regulations become more stringent and leading operators endeavor to reduce their emissions, operators increasingly offload underperforming assets to smaller companies that lack shareholder and other external pressure to reduce emissions.<sup>122</sup> A lack of stringent regulatory requirements for these under-performing assets makes them more attractive to prospective buyers who lack both internal emission reduction goals and would not face regulatory pressure to cut emissions.<sup>123</sup> And to larger companies seeking to reduce their overall emissions, these are "assets with disproportionately high

---

<sup>121</sup> 87 FR 74724-74736 (December 6, 2022).

<sup>122</sup> Hiroko Tabuchi, Here Are America's Top Methane Emitters. Some Will Surprise You., New York Times (Oct. 2021) <https://www.nytimes.com/2021/06/02/climate/biggest-methane-emitters.html> ("As the world's oil and gas giants face increasing pressure to reduce their fossil fuel emissions, small, privately held drilling companies are becoming the country's biggest emitters of greenhouse gases, often by buying up the industry's high-polluting assets.").

<sup>123</sup> See, e.g., Zachary Mider and Rachel Adams-Heard, Diversified Energy Said Emissions Fell. Now It Says They Didn't: U.S. gas producer told investors one thing, regulators another, Bloomberg Green (Oct. 20, 2021), <https://www.bloomberg.com/news/articles/2021-10-20/gas-producer-diversified-energy-said-emissions-fell-now-it123says-they-didn-t>.

emissions primed for disinvestment.”<sup>124</sup> This problem is borne out in emissions data for companies, which shows that “five of the industry’s top ten emitters of methane . . . are little-known oil and gas producers, some backed by obscure investment firms, whose environmental footprints are wildly large relative to their production.”<sup>125</sup>

The commenter (0844-EDF *et al.*) states a lack of federal requirements to detect and fix leaks may make these assets more attractive to buyers and allow the high-polluting practice of extending the lives of aging, underperforming sites, even while they often lack the funds to pay for plugging.<sup>126</sup> Exempting smaller sites from regular inspections could thus encourage companies to buy up these underperforming and high-polluting sites and keep them operating longer before potentially going bankrupt, leaving taxpayers holding the bag.<sup>127</sup> Among many other reasons described herein, EPA should subject these sites to similar requirements as other well sites to avoid inadvertently incentivizing and subsidizing irresponsible business models.<sup>128</sup>

Response I-7-52: In response to the comments received on the November 2021 Proposal, EPA proposed a different regulatory approach for this particular affected/designated facility in the December 2022 Supplemental Proposal. For details, please see discussion in section IV.A.1.a.ii of the December 2022 Supplemental Proposal related to fugitive emissions from well sites.<sup>129</sup> Please also see section X.A.1 of the preamble to the final rule which details EPA’s final standards related to fugitive emissions from well sites.

Comment: Commenter (0844-EDF *et al.*) reiterates utilization of the Rutherford model indicated that 22 percent of sites that could be placed in the less than 3 tpy PTE tier are actually likely to emit more than 3 tpy.<sup>130</sup> This analysis required matching the commenter’s 2019 wellsite dataset to 2019 GHGRP facilities and wells. The commenters were then able to determine which facilities had average emissions per site below 3 tpy. Of the approximately 530,000 wells in EF\_W\_ONSHORE\_WELLS\_2019 from the 2019 GHGRP Subpart W dataset<sup>131</sup> they were able to match ~460,000 wells with production in 2019 (330,000 sites) from Enverus Prism. Of the sites matched to GHGRP facilities, more than 50 percent of sites were determined to be at facilities with average site level emissions below 3 tpy and 25 percent of sites between 3 and 8

tpy. Average site level emissions were calculated using reported 2019 emission data and the number of matched sites at each facility. While the sites below 3 tpy emitted about 11 percent of reported 2019 facility emissions, they produced almost 30 percent of matched 2019 production. Comparatively, sites between 3-8 tpy emit almost 25 percent of reported emissions but produce the lowest fraction of production, 24 percent. While the commenter would need to run the Rutherford Model for these sites specifically, it is reasonable to assume that with a more accurate prediction method, the commenter would also find that sites originally placed in the 3-8 tpy tier have higher emissions in reality.

Response I-7-53: In response to the comments received on the November 2021 Proposal, EPA proposed a different regulatory approach for this particular affected/designated facility in the December 2022 Supplemental Proposal. For details, please see discussion in section IV.A.1.a.ii of the December 2022 Supplemental Proposal related to fugitive emissions from well sites.<sup>132</sup> Please also see section X.A.1 of the preamble to the final rule which details EPA's final standards related to fugitive emissions from well sites.

Comment: Commenter (0844-EDF *et al.*) states EPA should require quarterly or more frequent OGI at all sites regardless of the site-level emission estimate, particularly if EPA retains its well-head only exemption. If EPA retains the tiered approach, it should exclude sites with failure-prone equipment from tiers subject to less frequent monitoring and should revise the PTE calculation to account for the well-documented existence of super-emitters. Covering smaller, leak-prone wells with frequent inspections is critical as the commenter's analysis here shows that EPA's currently proposed one time only inspections at these well sites could reduce the overall effectiveness of its LDAR program by as much as half.

Response I-7-54: In response to the comments received on the November 2021 Proposal, EPA proposed a different regulatory approach for this particular affected/designated facility in the December 2022 Supplemental Proposal. For details, please see discussion in section IV.A.1.a.ii of the December 2022 Supplemental Proposal related to fugitive emissions from well sites.<sup>133</sup> Please also see section X.A.1 of the preamble to the final rule which details EPA's final standards related to fugitive emissions from well sites.

Comment: Commenter (0844-EDF *et al.*) argues the November 2021 Proposal's PTE calculation is less likely to accurately capture potential emissions when considering its application to smaller sites that may calculate less than 3 tpy, allowing those sites to avoid regular monitoring and repair. These sites, many of which are declining marginal or stripper wells, are even less likely than other sites to be operating correctly in the way the proposed PTE calculation assumes.<sup>134</sup> Most of these declining sites have never been subject to federal air pollution regulations, will have older and more-leak prone equipment and components, and are likely lowest on operators' priority lists for regular inspections and equipment upgrades.<sup>135</sup> All of these factors suggest that

---

<sup>132</sup> 87 FR 74724-74736 (December 6, 2022).

<sup>133</sup> 87 FR 74724-74736 (December 6, 2022).

many sites calculating less than 3 tpy are among the most likely to emit above the level otherwise determined by EPA's calculation under the November 2021 Proposal.

Response I-7-55: In response to the comments received on the November 2021 Proposal, EPA proposed a different regulatory approach for this particular affected/designated facility in the December 2022 Supplemental Proposal. For details, please see discussion in section IV.A.1.a.ii of the December 2022 Supplemental Proposal related to fugitive emissions from well sites.<sup>136</sup> Please also see section X.A.1 of the preamble to the final rule which details EPA's final standards related to fugitive emissions from well sites.

Comment: Commenters (0326-Driss A. Lonqueux (Private Citizen), 0357-National Parks Conservation Association (NPCA), 0398- Representative Barragan *et al.*, 0437-NYOSC, 0560-LGIM America, 0605-Muscogee (Creek) Nation, 0715-Dayenu Circle of Jewish Silicon Valley (DCJSV), 0744-New York State Department of Environmental Conservation (NYSDEC); 0753-IGSD/CHRE, 0803-OOGA, 0822-Texas Alliance of Energy Producers (TAEP), 0833-Ute EPD, 0943-Sault EPD, 1267-CA AG *et al.*, 1270-League of Women Voters of the United States (LWVUS), 1387-350 Bay Area Action, 1388-Private Citizen, 1423-Representative Beyer *et al.*, 1434-Senator Heinrich *et al.*) encourage the EPA to issue the strongest regulations possible in oil and gas monitoring, regardless of source-size, to ensure that leaks and plumes are included. It is commonly understood that oil and gas sites currently emit more methane (often many times more) than is generally estimated, due to the existence of unaccounted-for methane plumes and leaks.

The commenter (0560-LGIM America) adds research has shown that these wells can often be a significant source of methane emissions and the lack of ongoing monitoring may allow them to continue the outsized rate of pollution. Ownership data has also shown that such wells are often owned by large companies, who likely have the financial wherewithal to perform more robust maintenance.<sup>137</sup>

Response I-7-56: In response to the comments received on the November 2021 Proposal, EPA proposed a different regulatory approach for this particular affected/designated facility in the December 2022 Supplemental Proposal. For details, please see discussion in section IV.A.1.a.ii of the December 2022 Supplemental Proposal related to fugitive emissions from well sites.<sup>138</sup> Please also see section X.A.1 of the preamble to the final rule which details EPA's final standards related to fugitive emissions from well sites.

Comment: Commenter (0326-Private Citizen) states the November 2021 Proposal shows unprecedented intention to expand requirements to existing sources. Identifying and repairing leaks is essential and quarterly inspections are a good start. The use of a production level threshold to determine the exemption of well sites is flawed because low-production sites account for disproportionately high levels of methane emission. While the November 2021 Proposal seeks to focus monitoring efforts on sites with larger likelihood of leakage, low-production wells are generally older and therefore more prone to fugitive emissions. They must be submitted to the same rigor of monitoring. The monitoring and reporting of wells cannot be

---

<sup>136</sup> 87 FR 74724-74736 (December 6, 2022).

<sup>137</sup> [https://www.edf.org/sites/default/files/documents/MarginalWellFactsheet2021\\_0.pdf](https://www.edf.org/sites/default/files/documents/MarginalWellFactsheet2021_0.pdf).

<sup>138</sup> 87 FR 74724-74736 (December 6, 2022).

conditioned on output. With over 75 percent of marginal well sites owned by large companies with over 100 active wells, there is no reason for these companies, which already monitor their high-production wells—not to bear the cost of monitoring and reporting performance standards on low-production wells. The commenter recommends that the EPA removes the inspection exemption on low-production wells to ensure that (1) well-resourced companies are not given a free pass to pollute and (2) the improvements due to increased monitoring efforts are not offset by exemption loopholes.

Response I-7-57: In response to the comments received on the November 2021 Proposal, EPA proposed a different regulatory approach for this particular affected/designated facility in the December 2022 Supplemental Proposal. For details, please see discussion in section IV.A.1.a.ii of the December 2022 Supplemental Proposal related to fugitive emissions from well sites.<sup>139</sup> Please also see section X.A.1 of the preamble to the final rule which details EPA’s final standards related to fugitive emissions from well sites.

Comment: Commenter (1270-LWVUS) states small producers are less likely to take these actions voluntarily because they are often using old equipment on wells that have long since passed peak production, meaning that their ratio of leaked gas to marketed gas is much higher than that of major producers. The November 2021 Proposal appears to emphasize self-reporting. The commenter believes that this needs to be augmented by oversight and independent measurements of leakage at the well sites.

Response I-7-58: In response to the comments received on the November 2021 Proposal, EPA proposed a different regulatory approach for this particular affected/designated facility in the December 2022 Supplemental Proposal. For details, please see discussion in section IV.A.1.a.ii of the December 2022 Supplemental Proposal related to fugitive emissions from well sites.<sup>140</sup> Please also see section X.A.1 of the preamble to the final rule which details EPA’s final standards related to fugitive emissions from well sites.

Comment: Commenter (0803-OOGA) objects to EPA’s November 2021 Proposal to remove the exemption (from the requirement to monitor fugitive emissions) for low production wells from Subpart OOOOa. 286 FR 63170 and urges EPA to retain the exemption for low-production wells. A significant portion of the more than 61,000 wells in Ohio meet the definition of a low production well (*i.e.*, produce at or below 15 barrels of oil equivalent per day (BOED) and, in fact, produce on average far less than 15 BOED. Notwithstanding the Association’s objection to removing the exemption for low production wells, the November 2021 Proposal’s site-level baseline methane estimate methodology to determine whether a well site is subject to the fugitive emissions monitoring requirement is flawed for several reasons.

Commenter (0431-NuEnergy Operating, Inc. (NuEnergy)) states that the lower limit for exempt wells is too low and could easily be tripled with negligible effect on the environment.

Response I-7-59: In response to the comments received on the November 2021 Proposal, EPA proposed a different regulatory approach for this particular affected/designated facility in the December 2022 Supplemental Proposal. For details, please see discussion in section IV.A.1.a.ii

---

<sup>139</sup> 87 FR 74724-74736 (December 6, 2022).

<sup>140</sup> 87 FR 74724-74736 (December 6, 2022).

of the December 2022 Supplemental Proposal related to fugitive emissions from well sites.<sup>141</sup> Please also see section X.A.1 of the preamble to the final rule which details EPA's final standards related to fugitive emissions from well sites.

Comment: Commenters (1423-Representative Beyer *et al.*; 1434-Senator Heinrich *et al.*) argue EPA should finalize a comprehensive rule that includes pollution reduction requirements for smaller wells. There are thousands of these wells scattered across the country and while they produce very little usable product, they can be a significant and disproportionate source of methane emissions. Under the November 2021 Proposal, operators that calculate lower potential emissions could escape regular leak monitoring. This gap needs to be addressed before the EPA rules are finalized to ensure that smaller wells are also regularly monitored.

The commenter (1423-Representative Beyer *et al.*) adds that such wells comprise a majority of the nation's fleet of oil and gas wells, produce a small fraction of the nation's petroleum, and are responsible for an outsize share of methane emissions from the industry.<sup>142</sup> In order to protect public health, particularly in frontline communities, EPA must ensure these wells receive frequent inspections to find and fix pollution leaks. Furthermore, the fact that the vast majority of these wells are owned by large operators and the availability of technology for cost-effective leak monitoring and detection means any carve-outs or exemptions are simply unnecessary. Reducing methane emissions can create good, high-quality jobs. The methane mitigation service sector in the U.S. has nearly doubled in size since 2017 and would have further opportunity to grow.<sup>143</sup>

Response I-7-60: In response to the comments received on the November 2021 Proposal, EPA proposed a different regulatory approach for this particular affected/designated facility in the December 2022 Supplemental Proposal. For details, please see discussion in section IV.A.1.a.ii of the December 2022 Supplemental Proposal related to fugitive emissions from well sites.<sup>144</sup> Please also see section X.A.1 of the preamble to the final rule which details EPA's final standards related to fugitive emissions from well sites.

Comment: Commenters (0605-Muscogee (Creek) Nation, 0833-Ute EPD, 0943-Sault EPD) support the November 2021 Proposal's increased frequency of fugitive emissions monitoring for new and existing sources. The commenters believe that the shortest duration of time between monitoring should be used in the final rule. Because many large emission events occur because of leaking equipment, longer monitoring periods would allow leaks to continue to emit unchecked for longer periods of time.

<sup>144</sup> 87 FR 74724-74736 (December 6, 2022).

The commenters (0605-Muscogee (Creek) Nation, 0833-UTE EPD, 0943-Sault EPD) support the use of advanced technologies, but for them to be used as a complement to the required monitoring until the technologies are more proven. Once the advanced technologies are proven, the owner/operator can submit them for approval as an equivalent alternative method. The commenters feel this is important to protect fenceline communities from the HAP associated with oil and natural gas emissions.

The commenter (0833-UTE EPD) believes that the use of OGI should be emphasized over EPA Method 21 for monitoring and that Method 21 should not be used for follow-up surveys after emissions were detected. The commenter (0833-UTE EPD) believes OGI is more efficient and effective at identifying leaks and fugitive emissions.

The commenters (0605-Muscogee (Creek) Nation, 0833-UTE EPD, 0943-Sault EPD) believe well sites with estimated emissions of less than 3 tpy should be required to conduct quarterly or at least regular monitoring for leaks, particularly where leak-prone equipment is present on the site. Again, leaks and malfunctions are the largest source of emissions. Just because a well site has lower estimated emissions, does not mean that the equipment will not malfunction or fail resulting in significant emissions. These leaks and malfunctions must be identified and addressed as soon as possible to avoid emission of VOC, methane, and HAP. A single inspection after the rule is finalized will not address this problem.

Response I-7-61: In response to the comments received on the November 2021 Proposal, EPA proposed a different regulatory approach for this particular affected/designated facility in the December 2022 Supplemental Proposal. For details, please see discussion in section IV.A.1.a.ii of the December 2022 Supplemental Proposal related to fugitive emissions from well sites.<sup>145</sup> Please also see section X.A.1 of the preamble to the final rule which details EPA's final standards related to fugitive emissions from well sites.

Comment: Commenter (1267-CA AG *et al.*) states EPA's November 2021 Proposal of a one-time survey for sites with PTE of 3 tpy or less to "ensure that they are operating in a well-controlled manner and not experiencing leaks or malfunctions that would cause their emissions to exceed 3 tpy,"<sup>146</sup> does not address the problem of future leaks or malfunctions. Malfunctions are known to account for a large amount of methane emissions. The commenter (1267-CA AG *et al.*) urges EPA at a minimum to require a resurvey or monitoring on at least an annual basis to account for such situations.

The commenter (1267-CA AG *et al.*) recommends, based on the experience of some leading states, that EPA consider requiring regular fugitive emissions monitoring and repair for all well sites regardless of their PTE or production level. Large leaks can happen at any time, even at well sites with low PTE, and regular monitoring is necessary to detect and mitigate those fugitive emissions. EPA's exemption of well sites with a PTE of less than 3 tpy also leaves a significant source of methane emissions on the table. According to EPA's 2021 GHGI, fugitive methane emissions for 2019 in the oil and natural gas source category were 96,000 metric tons methane for petroleum systems and 351,500 metric tons for natural gas systems, for a total of 447,500

---

<sup>145</sup> 87 FR 74724-74736 (December 6, 2022).

<sup>146</sup> *Id.* at 63,190.

metric tons.<sup>147</sup> And scientific evidence shows that EPA inventories dramatically underestimate the amount of methane emitted by the oil and natural gas sector. A synthesis of site-level emissions studies in 2018 found that the U.S. oil and natural gas sector methane emissions are approximately 60 percent higher than EPA estimates.<sup>148</sup> By EPA's estimate, approximately 86 percent of fugitive emissions can be attributed to wells with site-wide baseline emissions of 3 tpy or greater.<sup>149</sup> Thus, EPA's proposed exemption for well sites with PTE of less than 3 tpy would leave approximately 14 percent of fugitive emissions—as much as 100,000 metric tons of methane by some estimates—unregulated.

Response I-7-62: In response to the comments received on the November 2021 Proposal, EPA proposed a different regulatory approach for this particular affected/designated facility in the December 2022 Supplemental Proposal. For details, please see discussion in section IV.A.1.a.ii of the December 2022 Supplemental Proposal related to fugitive emissions from well sites.<sup>150</sup> Please also see section X.A.1 of the preamble to the final rule which details EPA's final standards related to fugitive emissions from well sites.

Comment: Commenter (0744-NYSDEC) adds, if adopted, New York's Part 203 rulemaking will cover lower producing wells, based on the finding that exempting such wells would decrease emissions reductions in this subsector around 95 percent. The commenter strongly urges EPA to consider the contribution of methane from these wells, including their potential to be super-emitters, to determine if future action is warranted. 1, the commenter recommended that EPA work with small-business sources to identify areas where they may gain experience and other resources in meeting the requirements to ensure critical emission reductions. EPA has not yet addressed this, and the commenter suggests that this be considered for future work.

Response I-7-63: In response to the comments received on the November 2021 Proposal, EPA proposed a different regulatory approach for this particular affected/designated facility in the December 2022 Supplemental Proposal. For details, please see discussion in section IV.A.1.a.ii of the December 2022 Supplemental Proposal related to fugitive emissions from well sites.<sup>151</sup> Please also see section X.A.1 of the preamble to the final rule which details EPA's final standards related to fugitive emissions from well sites.

Comment: Commenter (0795-American Lung Association (ALN) *et al.*) provides studies and data that conclude fugitive emissions are underestimated and smaller wells are a major contributor.

The commenter (0795-ALN *et al.*) states considerable amounts of methane leak from oil and gas wells, driving up atmospheric methane levels and exacerbating climate change. Quantifying that leakage has proven difficult, with academic studies estimating average leaks from active gas

Sci. Tech. 12915 (2018), <https://pubs.acs.org/doi/10.1021/acs.est.8b03535>; Cusworth *et al.*, Intermittency of Large.

<sup>149</sup> 86 Fed. Reg. at 63,190.

<sup>150</sup> 87 FR 74724-74736 (December 6, 2022).

<sup>151</sup> 87 FR 74724-74736 (December 6, 2022).

wellsites (encompassing production, gathering, and processing) at rates ranging from 1.9 percent<sup>152</sup> to nearly 10 percent.<sup>153</sup> Regardless of the uncertainty over the precise amount, the problem of methane leakage from oil and gas wells is significant, and EPA is right in calling for meaningful steps to identify those leaks and repair them.

Commenter (0795-ALN *et al.*) argues not all wells contribute equally to methane leakage. Marginal wells near the end of their lifespans—so-called stripper wells—appear to represent a disproportionately large source of methane emissions relative to their production, according to a study published in 2020.<sup>154</sup> The study found that stripper wells typically are not profitable to operate but because the cost of decommissioning them can be greater than the cost of keeping them running they are kept online or at the ready, sometimes leaking more gas than what is intentionally extracted, captured, and used. An estimated 700,000 of these low-producing, marginal wells exist in the United States. The commenter continues, while many stripper wells have low emissions, a few emit at much higher levels. On the face of it, this would seem to make high-emitting stripper wells an ideal target for regulation. However, researchers have found it difficult to predict which wells are going to be “super-emitters.” Furthermore, where emissions are intermittent, accurate measurement would require continuous, site-specific monitoring, which is not a realistic prospect given the number of possible leak sites and the time and cost required to deploy enough inspectors and equipment. Thus, a broadly applicable regimen of monitoring and repair is necessary, with small wells and large ones subject to regular leak inspection and requirements for repair. Any proposal that would exempt wells whose operators calculate low levels of emissions would be misguided.

Commenter (0753-IGSD/CHRE) cites a study that found including leaks in methane emission estimates would result in emissions estimates 48–76 percent greater than the EPA’s current estimates.<sup>155</sup> In places where oil and gas production has decreased, methane leaks may still

<sup>155</sup> Barkley Z. R., et al., (2021) Analysis of Oil and Gas Ethane and Methane Emissions in the Southcentral and Eastern United States Using Four Seasons of Continuous Aircraft Ethane Measurements. *GEOPHYS RES ATMOS* 126, (“In this study, we perform an inverse analysis on 200 h of atmospheric boundary layer C2H6 measurements to estimate C2H6 emissions from the US O&G sector. Measurements were collected from 2017 to 2019 as part of the Atmospheric Carbon and Transport (ACT) America aircraft campaign and encompass much of the central and eastern United States. We find that for the fall, winter, and spring campaigns, C2H6 data consistently exceeds values that would be expected based on EPA O&G leak rate estimates by more than 50%. C2H6 observations from the summer 2019 data set show significantly lower C2H6 enhancements in the southcentral region that cannot be reconciled with data from the other three seasons, either due to complex meteorological conditions or a temporal shift in the emissions. Combining the fall, winter, and spring C2H6 posterior emissions estimate to an inventory of O&G CH4 emissions, we estimate that O&G CH4 emissions are larger than EPA inventory values by 48%–76%.”).

significantly contribute to greenhouse gas emissions.<sup>156</sup> Random and persistent methane plumes that would classify a site as super-emitting may escape accountability under current estimates. The EDF detected 900 methane plumes from over 500 sites in the Permian Basin over an 11-day period, demonstrating that super-emitting sites are still prevalent in the basin.<sup>157</sup>

Commenter (0578-Grand Canyon Trust (GCT)) states recent research estimates that some marginal oil and gas wells emit as much or more gas than they are reported producing.<sup>158</sup> It is also estimated that wells in this lowest production category emit approximately 11 percent of total annual methane emissions in the from oil and gas production, despite that they produce about 0.2 percent of oil and 0.4 percent of gas in the United States each year.<sup>159</sup> Another study from 2018 found that “On average, low NG [natural gas] producing sites emit a larger fraction of their CH<sub>4</sub> production than high NG producing sites.”<sup>160</sup> In their comments, EDF estimates that the 3 tpy threshold would exempt 20 percent of well sites total, 40 percent of which are oil wells and 19 percent of which are gas wells, from regular monitoring, forgoing up to 330,000 tons of methane reductions.<sup>161</sup> As these wells are a significant source of methane pollution, and are found across the country including on the Colorado Plateau, the commenter urges the EPA to strengthen its monitoring requirements to require at a minimum quarterly monitoring at wells including those with baseline emissions less than 3 tpy.

Commenter (0822-TAEP) states while EPA has chosen to reverse its position on the use of production rates to define a threshold to recognize lower regulatory requirements, it should recognize that the DOE funded study of the emissions profile of marginal wells (low production wells) provides data showing that these well sites overwhelmingly fall below the 3 tpy of methane emissions based on actual sampling. However, the framework that the DOE study created in defining the factors that can influence emissions – *e.g.*, production rate, oil or natural gas

---

<sup>156</sup> Lin J. C, Bares R., Fasoli B., Garcia M., Crosman E., Lyman S., (2021) Declining methane emissions and steady, high leakage rates observed over multiple years in a western US oil/gas production basin. SCI REP 11, 22291, 1-12, 1 (“Here we present a unique analysis of one of the longest-running datasets of in-situ methane observations from an oil/gas production region in Utah’s Uinta Basin. The observations indicate Uinta methane emissions approximately halved between 2015 and 2020, along with declining gas production. As a percentage of gas production, however, emissions remained steady over the same years, at ~6–8%, among the highest in the U.S. Addressing methane leaks and recovering more of the economically valuable natural gas is critical, as the U.S. seeks to address climate change through aggressive greenhouse emission reductions.”).

<sup>157</sup> McGee M., (23 Sept. 2021) New Aircraft Measurements Once Again Detect High Levels of Methane in Permian Basin, Environmental Defense Fund (last visited 5 Jan 2022) (“The new data was collected during an 11-day period in August by Carbon Mapper as part of EDF’s PermianMAP initiative. The aircraft detected over 900 plumes of methane from more than 500 sources. As with previous surveys of the area, this new data again confirm that super emitting sites continue to be a problem across the Permian.”).

Methane Emissions from Natural Gas Production Sites in the United States: Data Synthesis and National Estimate. Environmental Science & Technology. 2018 52 (21), 12915-12925 DOI: 10.1021/acs.est.8b03535. Available at: <https://pubs.acs.org/action/showCitFormats?doi=10.1021%2Facs.est.8b03535&href=/doi/10.1021%2Facs.est.8b03535>.

<sup>161</sup> Based on EDF’s approach, a single pneumatic controller causes emissions to exceed 3 tpy. EPA assumes that approximately 20% of well pads have no pneumatic controllers.

production, number of pieces of equipment at the site – could provide EPA with a framework for the development of an emissions calculation guideline for small businesses and low production well sites.

Commenter (0948-CA Assemblymember Quirk) adds studies by researchers at Carnegie Mellon University and others have shown that these wells have disproportionately high emissions and generate relatively low contributions to national oil and gas production. Subjecting even small, low-production wells and facilities to regular inspections is necessary for mitigating climate impacts.

Commenter (0918-Colorado Local Government Coalition (Colorado LGC)) states low-producing wells are the most abundant type of oil and gas well in the United States, and a surprising number of them are venting all or more than their reported produced gas into the atmosphere.<sup>162</sup> This makes low-producing wells a disproportionate source of VOC and methane emissions compared to their energy production and underscores the need for robust control requirements.

The commenter (0918-Colorado LGC) states a 2020 study involving direct measurements of methane and VOC emissions from marginal oil and gas wells (wells producing less than 1 BOE/d) in the Appalachian Basin of southeastern Ohio found that marginal wells are a disproportionate source of methane and VOCs relative to oil and gas production. The study estimated that oil and gas wells in this lowest production category emit approximately 11 percent of total annual methane production from upstream oil and gas sources in the EPA greenhouse gas inventory, although they produce about 0.2 percent of oil and 0.4 percent of all gas produced in the US per year.<sup>163</sup>

The commenter (0918-Colorado LGC) adds in another recent study involving site-level measurements of over 70 Permian Basin well pads found no relationship between emissions and production. Per the study, wells with production below 10 BOE/d had similar emissions as non-marginal wells, based on a comparison of absolute methane emissions and gas production by site.<sup>164</sup>

The commenter (0918-Colorado LGC) states a 2018 study of sites in eight basins across the US is in accord. Researchers obtained site-level methane emissions data from over 1000 natural gas production sites, including 92 new site-level methane measurements in the Uinta, northeastern Marcellus, and Denver-Julesburg Basins, to investigate methane emissions characteristics and develop a new national methane emission estimate for the natural gas production segment. The study looked at natural gas production sites and categorized them as low (sites producing 1000

<sup>163</sup> Id.

<sup>164</sup> Robertson et al., New Mexico Permian Basin Measured Well Pad Methane Emissions Are a Factor of 5–9 Times Higher Than U.S. EPA Estimates, 54:21 ENVTL. SCI. TECHNOL. 13926-13934 (2020), <https://pubs.acs.org/doi/10.1021/acs.est.0c02927>.

Mcfd). Low natural gas production sites accounted for 85 percent of the total number of sites in the study and nearly two-thirds (63 percent) of the total methane emissions.<sup>165</sup>

The commenter (0918-Colorado LGC) states several past studies have reported measurement-based results for methane leakage from low production oil and gas wells. These studies varied in geography and scope; while some focused on low-production wells, others measured low production wells as part of a larger measurement campaign that also included non-low production wells. The commenter (0918-Colorado LGC) has identified seven of these studies based on the criteria that they reported both the measured site-level methane emissions and the O&G production data.

The commenter (0918-Colorado LGC) states the studies reveal wide variability in methane leakage rate at the site-level, ranging from 0 to 22 kg/h/site (median = 0.32 kg/h/site = 2.8 metric tpy; average = 1.2 kg/h/site = 10.5 metric tpy). Similarly, as a fraction of their methane production, the data show that methane loss rates from these sites ranged from 0 to >100 percent. More than one-quarter (28 percent) of the measured sites emitted >1 kg/h/site (or > 8.8 metric tpy) and nearly one-third (31 percent) emitted more than 10 percent of their production. The top 5 percent of high emitting sites accounted for approximately 50 percent of the total measured methane emissions, indicating that the phenomenon of “super-emitting” sites that has been observed throughout the O&G supply chain is also prevalent among these low-producing sites.

The commenter (0918-Colorado LGC) notes these studies identified poor maintenance as one of the primary drivers of observed methane leakage at these sites. For example, Deighton *et al.* (2020) observed that the “state of maintenance at these wells was poor;” some sites were in a state of disrepair (*e.g.*, rusty well shafts, broken valves, *etc.*), while others were found to be venting as a result of fallen trees on the wellheads.<sup>166</sup> Similarly, Omara *et al.* (2016) reported “rusted or corroded well casings, field piping, regulators, valves and meters,” and identified a few of these decrepit components as “substantial sources of leaks” at the low-production well sites.<sup>167</sup> These avoidable methane emissions are not well represented in traditional emission factor calculations and contribute to the significant differences that have often been observed between inventory-based estimates and measurement studies.

The commenter (0918-Colorado LGC) states the studies assessed here indicate that low-production wells are likely a disproportionately large source of O&G methane emissions nationally. For example, for the very low production category of 0-1 boe per day wells, Deighton *et al.* (2020) estimate that these wells account for 11 percent of the production-related methane emissions in the EPA’s GHGI. Similarly, Omara *et al.* (2018) estimated that 63 percent of production-related methane emissions come from well sites that produce <100 Mcfd. Therefore,

mitigating the methane emitted from these sites could reduce a significant proportion of oil and gas methane emissions nationally.

The commenter (0918-Colorado LGC) argues these studies demonstrate that controlling low-producing wells is essential to curbing emissions from oil and gas facilities.

Commenter (0918-Colorado LGC) states an analysis conducted through the Boulder County Public Health's oil and gas inspection program concluded that low-producing facilities (*i.e.*, those with tank VOC emissions less than 6 tpy) leak at similar frequencies as larger facilities, supporting proposals to increase LDAR inspection frequencies at these well sites. The commenter cited results from the Boulder County oil and gas inspection program in place since 2014.<sup>168</sup>

The commenter (0918-Colorado LGC) provides a table showing the sites for each of the five years of the program where leaks were detected as well as the cumulative data for all five years of the program.<sup>169</sup> The commenter (0918-Colorado LGC) provides a figure showing the number of sites in Boulder County that experienced one or more leak(s) from 2014 through 2018.<sup>170</sup>

The commenter (0918-Colorado LGC) states in the 2019 AQCC Regulation 7 rulemaking, the Local Government Coalition, which was a party to the hearing, analyzed the frequency of leak occurrence at low producing facilities from the Boulder County LDAR program. The LGC obtained the Division's Air Pollutant Emission Notice (APEN) database containing potential storage tank VOC emissions estimates used during the permitting process. These estimates can classify a well production facility into the corresponding Regulation 7 well production facility LDAR requirements for inspection frequency. A comparison of these estimates with leak frequency over a 5-year inspection period in Boulder County showed little correlation. That is, well production facilities experienced roughly the same rate of leaks across the range of leak inspection frequencies. The commenter provides a table showing Boulder County Voluntary Inspection Program Leak Frequency by Regulation 7 Denver Metro/North Front Range (DMNFR) Ozone Nonattainment Area Storage Tank VOC Threshold.<sup>171</sup> Facilities with greater than one leak did not differ significantly based on production level. In short, low producing facilities leak at similar frequencies as larger facilities.

Response I-7-64: In response to the comments received on the November 2021 Proposal, EPA proposed a different regulatory approach for this particular affected/designated facility in the December 2022 Supplemental Proposal. For details, please see discussion in section IV.A.1.a.ii of the December 2022 Supplemental Proposal related to fugitive emissions from well sites.<sup>172</sup>

---

<sup>168</sup> Id. at p. 6.

<sup>169</sup> Between 2014 and 2018, more than 600 oil and gas facility site visits were conducted with an infrared camera for leak detection. Cumulatively, gas leaks were detected at 86% of inspected sites, with the percentage each year ranging from 38% to 49%. 64% of the sites with leaks experienced them in multiple calendar years.

<sup>170</sup> Id. at p. 7.

<sup>171</sup> Rebuttal Statement of the Local Government Coalition, Proposed Amendments to Regulation Number 7 and Regulation Number 22, p. 4-5 (Nov. 23, 2021).

Please also see section X.A.1 of the preamble to the final rule which details EPA's final standards related to fugitive emissions from well sites.

Comment: The commenters (0437-NYOSC, 0918-Colorado LGC, 1388-Private Citizen) believe small wells less than 3 tpy emissions should be monitored often like larger wells. Altogether (or individually) small wells can be massive methane emitters. Requiring only an annual inspection is not sufficient and will result in months of undetected fugitive emissions.

Commenter (0437-NYOSC) believes the November 2021 Proposal only partially meets investors' expectations for a robust rule that fully addresses methane emissions. The commenter urges the EPA to expand monitoring requirements to require regular inspection and repair of leaks from wells with low production rates (those with estimated annual emissions of 3 tpy or less). These smaller wells can be a significant source of methane emissions and regular inspections are needed to ensure that leaks at these sources are detected and stopped.<sup>173</sup>

Response I-7-65: In response to the comments received on the November 2021 Proposal, EPA proposed a different regulatory approach for this particular affected/designated facility in the December 2022 Supplemental Proposal. For details, please see discussion in section IV.A.1.a.ii of the December 2022 Supplemental Proposal related to fugitive emissions from well sites.<sup>174</sup> Please also see section X.A.1 of the preamble to the final rule which details EPA's final standards related to fugitive emissions from well sites.

Comment: Commenter (0424-Division of Air Quality, West Virginia Department of Environmental Protection (WVDEP)) opposes the November 2021 Proposal's baseline requirements for fugitive emissions at well sites with fugitive emissions between 0 and 3 tpy. Establishing a substantive requirement would require an air quality permit in West Virginia and would impose a burden on the state and the sources it regulates without providing any air quality benefit because there is not any proposed control following the baseline measurement. This is a bureaucratic overreach.

Commenter (0424-WVDEP) believes in the final EG OOOOc low production well sites should be exempt from the rule along with individual homeowners, farmers, and very small businesses. The designated facility category for fugitive emissions at well sites between 0 and 3 tpy should be eliminated in the final rule because low production wells should be exempt. Additionally, the commenter objects to the November 2021 Proposal to repeal the amendments in the 2020 Technical Rule that exempted low production well sites from monitoring fugitive emissions under the NSPS.

Response I-7-66: In response to the comments received on the November 2021 Proposal, EPA proposed a different regulatory approach for this particular affected/designated facility in the December 2022 Supplemental Proposal. For details, please see discussion in section IV.A.1.a.ii of the December 2022 Supplemental Proposal related to fugitive emissions from well sites.<sup>175</sup>

---

<sup>173</sup> Zavala-Araiza, Daniel, et.al. "Toward a Functional Definition of Methane Super-Emitters: Application to Natural Gas Production Sites," Environmental Science and Technology, 49, 13, 8167-8174, 2015/.

<sup>174</sup> 87 FR 74724-74736 (December 6, 2022).

<sup>175</sup> 87 FR 74724-74736 (December 6, 2022).

Please also see section X.A.1 of the preamble to the final rule which details EPA's final standards related to fugitive emissions from well sites.

Comment: Commenter (0446-Artex) states EPA relied on potentially suspect data to conclude that “fugitive emissions at any given site is impacted more by the number and type of equipment at the site and maintenance practices, which can vary widely among well sites with low production.”<sup>176</sup> To support this claim, EPA cites an October 2020 study<sup>177</sup> in which 29 of the 71 “successful” measurements were actually below the detection limit (BDL). A study in which over 40 percent of the measurements are BDL does not meet minimum data quality standards for a rulemaking of this magnitude. The only other study cited in support of EPA's claim actually arrives at the opposite conclusion, “finding a reduced but still significant prevalence of OGI-detectable emissions at complex marginal wellpads”<sup>178</sup> where “Classification of marginal vs non-marginal wells followed the criterion of 15 barrels-of-oil equivalent (BOEd) production...”<sup>179</sup> Since EPA's own sources establish a correlation between production and emission rate, the commenter requests that EPA retain the exemption for low-production well sites currently codified at 40 CFR 60.5397a(1)(i) and (ii) in NSPS OOOOa and that EPA include this same exemption in NSPS OOOOb.

Response I-7-67: In response to the comments received on the November 2021 Proposal, EPA proposed a different regulatory approach for this particular affected/designated facility in the December 2022 Supplemental Proposal. For details, please see discussion in section IV.A.1.a.ii of the December 2022 Supplemental Proposal related to fugitive emissions from well sites.<sup>180</sup> Please also see section X.A.1 of the preamble to the final rule which details EPA's final standards related to fugitive emissions from well sites.

Comment: Commenter (0598-Countrymark Energy Resources, LLC (CER)) states the first way to relieve the compliance burden on Small Entity Representatives (SER) is to provide a path to remove affected facilities (well sites, tank batteries, and/or compressors) from monitoring when the PTE is low. As EPA has noted in the preamble, there is a point where the environmental benefits do not exceed the cost of completing the inspections and reporting requirements. To remain consistent with EPA's proposed structure, the commenter recommends when wellsite emissions fall below 3 tpy, monitoring and reporting requirements may be eliminated (eliminated for both the well site and associated tanks). The commenter further recommends that any tank battery that falls below 7.2 tpy (6 tpy VOC and 1.2 tpy methane) have monitoring and reporting requirements be eliminated. Monitoring and reporting requirements will not be required for the affected facilities until the facility meets EPA's definition of a “modification,” whereby monitoring and reporting activities will begin again.

<sup>179</sup> Ibid.

<sup>180</sup> 87 FR 74724-74736 (December 6, 2022).

Response I-7-68: In response to the comments received on the November 2021 Proposal, EPA proposed a different regulatory approach for this particular affected/designated facility in the December 2022 Supplemental Proposal. For details, please see discussion in section IV.A.1.a.ii of the December 2022 Supplemental Proposal related to fugitive emissions from well sites.<sup>181</sup> Please also see section X.A.1 of the preamble to the final rule which details EPA’s final standards related to fugitive emissions from well sites.

Comment: Commenter (0573-KDHE) opposes the proposed baseline requirements for fugitive emissions at well sites with fugitive emissions between 0 and 3 tpy. Establishing a substantive requirement would require an air quality permit in Kansas and would impose a burden on the state and the sources it regulates without providing any air quality benefit because there are not any proposed controls following the baseline measurement.

Response I-7-69: In response to the comments received on the November 2021 Proposal, EPA proposed a different regulatory approach for this particular affected/designated facility in the December 2022 Supplemental Proposal. For details, please see discussion in section IV.A.1.a.ii of the December 2022 Supplemental Proposal related to fugitive emissions from well sites.<sup>182</sup> Please also see section X.A.1 of the preamble to the final rule which details EPA’s final standards related to fugitive emissions from well sites.

Comment: Commenter (0763-Texas Commission on Environmental Quality (TCEQ) and Railroad Commission (RRC)) states requiring an initial OGI survey to demonstrate non-leaking status for well sites with baseline PTE emissions less than 3 tpy of methane assumes that the newly constructed or modified facilities are out of compliance, which is not typical in the commenter’s NSR authorization mechanisms. The EPA has not indicated how this reporting will be accomplished and how an enforceable limit can be implemented at an affected facility. Commenter (0763-TCEQ/RRC) requests that EPA confirm the recordkeeping, monitoring, and reporting requirements under these rules are sufficient to meet the periodic and sufficiency monitoring requirements of Title V.

Response I-7-70: In response to the comments received on the November 2021 Proposal, EPA proposed a different regulatory approach for this particular affected/designated facility in the December 2022 Supplemental Proposal. For details, please see discussion in section IV.A.1.a.ii of the December 2022 Supplemental Proposal related to fugitive emissions from well sites.<sup>183</sup> Please also see section X.A.1 of the preamble to the final rule which details EPA’s final standards related to fugitive emissions from well sites.

Comment: Commenter (0577-KIOGA) states in January 2021, the International Energy Agency (IEA) released a regulatory roadmap and toolkit focused on “Driving Down Methane Leaks from the Oil and Gas Industry.” The roadmap details that, “understanding the nature and magnitude of your emissions will be critical to designing sound regulations.” This is a primary tenet of what the commenter seeks to convey with the Biden Administration. One key aspect of the independent component of the oil and natural gas production industry is its breadth – spanning

---

<sup>181</sup> 87 FR 74724-74736 (December 6, 2022).

<sup>182</sup> 87 FR 74724-74736 (December 6, 2022).

<sup>183</sup> 87 FR 74724-74736 (December 6, 2022).

from large, high production wells to low production wells. These wells do not all have the same emissions profiles, and those different profiles should be considered in regulations.

The commenter (0577-KIOGA) states low production wells are those that produce 15 barrels/day (or 90 mcf/d) or less. The national average low production oil well is about 2.5 barrels/day and the low production natural gas well is about 24 mcf/d. Of the roughly one million active oil and natural gas wells in the United States, about 750,000 are low production wells, typically operated by small businesses. The regulatory structure applied to low production wells is significant because their viability is so dependent on their cost of operation.

The commenter (0577-KIOGA) notes the 2016 EPA NSPS fugitive emissions regulations created a specific problem for low production wells. When EPA developed its fugitive emissions requirements, it generated its BSER technology based on large, hydraulically fractured well sites and its initial proposal applied only to these sites. However, in finalizing the fugitive emissions regulations, EPA expanded their scope to include low production wells, but it never revised the BSER requirements to reflect this broader application. The high production well LDAR program is economically infeasible for low production wells and provides minimal environmental benefits. EPA agreed to reconsider the low production well impact of its fugitive emissions program. In its 2020 revisions to the NSPS, the fugitive emissions program now provided an off-ramp when well sites fall below 15 barrels/day. The implications for low production wells are further compounded by the decision to base the EPA regulatory program on managing methane. Under the CAA, the choice of regulating methane can trigger a nationwide existing facility regulation that would apply EPA BSER technology to the 750,000 low production wells currently in operation.

The commenter (0577-KIOGA) adds industry does not question the need to cost effectively manage its emissions. Many independent producers participate in voluntary actions to reduce emissions — including fugitive emissions.

The commenter (0577-KIOGA) argues industry seeks to find a regulatory pathway designed for the sources it regulates. The 2016 NSPS fugitive emissions program that was designed for large facilities should not be applied to low production well sites. The 2020 NSPS reconsideration moved to correct that error. EPA followed the path it used in its October 2016 Control Techniques Guidelines for low production wells when it excluded them from its model fugitive emissions program. There may be an appropriate low production well program. When EPA developed its NSPS regulations, it had no emissions profile for low production wells. The U.S. DOE initiated a study of low production well air emissions that was completed at the end of 2021. Results from the DOE third-party methane emission study of low production wells and facilities indicate no quantifiable or measurable emissions from wells or tank facilities. If EPA needs to design a low production well program, it should utilize the emissions profile information developed by the DOE and then focus on the most cost-effective options to address the key sources.

Response I-7-71: In response to the comments received on the November 2021 Proposal, EPA proposed a different regulatory approach for this particular affected/designated facility in the December 2022 Supplemental Proposal. For details, please see discussion in section IV.A.1.a.ii

of the December 2022 Supplemental Proposal related to fugitive emissions from well sites.<sup>184</sup> Please also see section X.A.1 of the preamble to the final rule which details EPA’s final standards related to fugitive emissions from well sites.

Comment: Commenter (0577-KIOGA) opposes the proposed baseline requirements for fugitive emissions at well sites with fugitive emissions between zero and 3 tpy. This action would impose significant burdens and costs without providing any air quality benefit.

Response I-7-72: In response to the comments received on the November 2021 Proposal, EPA proposed a different regulatory approach for this particular affected/designated facility in the December 2022 Supplemental Proposal. For details, please see discussion in section IV.A.1.a.ii of the December 2022 Supplemental Proposal related to fugitive emissions from well sites.<sup>185</sup> Please also see section X.A.1 of the preamble to the final rule which details EPA’s final standards related to fugitive emissions from well sites.

Comment: Commenter (0431-NuEnergy) states the best way to keep stripper wells producing is for the EPA to continue to exempt wells that produce less than 15 barrels per day from complying with methane emissions. Otherwise, those wells would likely be plugged rather than spend the capital to comply.

Response I-7-73: In response to the comments received on the November 2021 Proposal, EPA proposed a different regulatory approach for this particular affected/designated facility in the December 2022 Supplemental Proposal. For details, please see discussion in section IV.A.1.a.ii of the December 2022 Supplemental Proposal related to fugitive emissions from well sites.<sup>186</sup> Please also see section X.A.1 of the preamble to the final rule which details EPA’s final standards related to fugitive emissions from well sites.

Comment: Commenter (0425-Darrah Oil Company, LLC (Darrah)) states wells that are low producers of the hydrocarbon products are also low producers of methane. The information that suggested that they are disproportionately large emitters has been proven to be wrong by the DOE among others, but the ghost of this idea lives on. These are the wells that can least afford monitoring and are the lessor of the sources. Most states already have definitions of “stripper wells” that allow them to extend the last few years of a well’s economic life. It would benefit the EPA not to waste resources on these margins and it should adopt exemptions for wells that states define as stripper wells. An outright exemption would eliminate confusion for state regulations that are expected to regulate them.

Response I-7-74: In response to the comments received on the November 2021 Proposal, EPA proposed a different regulatory approach for this particular affected/designated facility in the December 2022 Supplemental Proposal. For details, please see discussion in section IV.A.1.a.ii of the December 2022 Supplemental Proposal related to fugitive emissions from well sites.<sup>187</sup> Please also see section X.A.1 of the preamble to the final rule which details EPA’s final standards related to fugitive emissions from well sites.

<sup>184</sup> 87 FR 74724-74736 (December 6, 2022).

<sup>185</sup> 87 FR 74724-74736 (December 6, 2022).

<sup>186</sup> 87 FR 74724-74736 (December 6, 2022).

<sup>187</sup> 87 FR 74724-74736 (December 6, 2022).

Comment: Commenter (0822-TAEP) supports the concept of using a 3 tpy low production facility exclusion from the quarterly LDAR program but recommends an annual AVO (audio, visual, olfactory) review rather than the OGI EPA program. However, it is essential that EPA recognize that most of the well sites falling below 3 tpy will be operated by small businesses and small businesses that are currently below the 25,000 tpy of CO<sub>2</sub>eq reporting threshold (1,000 tpy of methane) for the GHGI. Consequently, EPA needs to develop, in concert with the Small Business Administration, a straightforward guideline document for use in determining whether a site is below 3 tpy of methane. This guideline document should be developed prior to the planned supplemental proposal for subparts NSPS OOOOb and EG OOOOc and subject to comments during that proposal.

Response I-7-75: In response to the comments received on the November 2021 Proposal, EPA proposed a different regulatory approach for this particular affected/designated facility in the December 2022 Supplemental Proposal. For details, please see discussion in section IV.A.1.a.ii of the December 2022 Supplemental Proposal related to fugitive emissions from well sites.<sup>188</sup> Please also see section X.A.1 of the preamble to the final rule which details EPA's final standards related to fugitive emissions from well sites.

Comment: Commenters (0444-Damascus Citizens for Sustainability (DCS), 0538-Change Finance, 0770-Northern Plains Resource Council (NPRC)) urge EPA to craft a regulation that includes all potentially significant sources of methane emissions, including smaller or low-emitting wells.

The commenter (0444-DCS) is concerned about the November 2021 Proposal to only monitor air pollution at so-called "low-emitting wells" once a year. Special attention must be given to sites where air pollution is assumed to be low. Penn State University concluded that the EPA underestimates methane pollution from the gas industry by 48 to 76 percent. The commenter believes EPA should establish accurate, real-time air pollution monitoring systems at new and existing well sites. EPA must continue to conduct this air monitoring as wells age because EPA correctly states in the proposed rulemaking that the majority of avoidable air pollution at gas wells is caused by aging, unmaintained equipment.

The commenter (0444-DCS) urges the EPA to go further to ensure public health is prioritized, frontline communities are protected, climate emissions are addressed, and oil and gas companies are held accountable. The new rule will also go a long way to meeting US obligations under the Global Methane Pledge, which requires a reduction of methane emissions by 30 percent by 2030.

Response I-7-76: In response to the comments received on the November 2021 Proposal, EPA proposed a different regulatory approach for this particular affected/designated facility in the December 2022 Supplemental Proposal. For details, please see discussion in section IV.A.1.a.ii of the December 2022 Supplemental Proposal related to fugitive emissions from well sites.<sup>189</sup> Please also see section X.A.1 of the preamble to the final rule which details EPA's final standards related to fugitive emissions from well sites.

---

<sup>188</sup> 87 FR 74724-74736 (December 6, 2022).

<sup>189</sup> 87 FR 74724-74736 (December 6, 2022).

Comment: Commenter (0785-John Crane Inc.) notes that in cases where the advanced measurement technology has been field-proven and has demonstrated commercially and academically the ability to provide accurate emissions quantification (and not just detection) at a level below the 3 tpy threshold, it should be acceptable to use it as an appropriate alternative to OGI for all emissions rates. Given that OGI and EPA Method 21 may not find all leak sources, and therefore would not be appropriate for detection when large leaks have been found, the commenter proposes that EPA Method 21 is no longer appropriate alternative to routine OGI surveys.

Response I-7-77: See discussion in section IV.B.3 of the December 2022 Supplemental Proposal.<sup>190</sup> For the final rule, EPA maintains that EPA Method 21 is a valid alternative to OGI surveys. See section X.B.1 of the preamble to the final rule for description of the final rule requirements. The EPA disagrees with the commenter that OGI and EPA Method 21 are not appropriate for detection when large leaks have been found. Both methods have routinely been used to find small and large leaks.

#### ***7.1.6 Well Sites with Baseline Emissions $\geq 3$ tpy***

Comment: Commenters (0605-Muscogee (Creek) Nation, 0781-NTAA, 0833-UTE EPD, 0943-Sault EPD, 0391-KBIC) support quarterly monitoring versus semiannual monitoring for well sites between 3 and 8 tpy.

Response I-7-78: In response to the comments received on the November 2021 Proposal, EPA proposed a different regulatory approach for this particular affected/designated facility in the December 2022 Supplemental Proposal. For details, please see discussion in section IV.A.1.a.ii of the December 2022 Supplemental Proposal related to fugitive emissions from well sites.<sup>191</sup> Please also see section X.A.1 of the preamble to the final rule which details EPA's final standards related to fugitive emissions from well sites.

Comment: Commenter (0777-Ascent) believes that semiannual monitoring is appropriate for well sites with baseline methane emissions below 8 tpy and represents a reasonable balance of the cost and burden associated with conducting fugitive monitoring surveys and the potential emissions reductions from these smaller sites with lower fugitive component counts.

Response I-7-79: In response to the comments received on the November 2021 Proposal, EPA proposed a different regulatory approach for this particular affected/designated facility in the December 2022 Supplemental Proposal. For details, please see discussion in section IV.A.1.a.ii of the December 2022 Supplemental Proposal related to fugitive emissions from well sites.<sup>192</sup> Please also see section X.A.1 of the preamble to the final rule which details EPA's final standards related to fugitive emissions from well sites.

Comment: Commenter (0795-Allergy & Asthma Network) states EPA must strengthen the rule to ensure that small wells are included in frequent regular inspection and repair requirements. At

---

<sup>190</sup> 87 FR 74747 (December 6, 2022).

<sup>191</sup> 87 FR 74724-74736 (December 6, 2022).

<sup>192</sup> 87 FR 74724-74736 (December 6, 2022).

a minimum EPA must ensure that sites with estimated emissions between 3 and 8 tpy are subject to the same frequency of inspection as those with estimated emissions above 8 tpy.

Response I-7-80: In response to the comments received on the November 2021 Proposal, EPA proposed a different regulatory approach for this particular affected/designated facility in the December 2022 Supplemental Proposal. For details, please see discussion in section IV.A.1.a.ii of the December 2022 Supplemental Proposal related to fugitive emissions from well sites.<sup>193</sup> Please also see section X.A.1 of the preamble to the final rule which details EPA's final standards related to fugitive emissions from well sites.

Comment: Commenter (0844-EDF *et al.*) states EPA should at minimum finalize quarterly monitoring at all sites above 3 tpy, but should also require more frequent monitoring, especially at the largest sites.

Commenter (0844-EDF *et al.*) supports EPA's November 2021 Proposal to require quarterly monitoring at sites above 8 tpy. Quarterly monitoring, and in many cases more frequent monitoring, is in the commenter's opinion well-justified, cost-effective, and necessary to achieve substantial emission reductions. The commenter believes EPA should require at minimum quarterly monitoring at all sites where it is cost-effective, including those from 3 to 8 tpy and all or at least some sites below 3 tpy.

The commenter (0844-EDF *et al.*) believes at large sites, where an abnormal process event could emit even more massive amounts of pollution into the air, quarterly monitoring may not be sufficient, and EPA should therefore require monthly monitoring where it is cost-effective to do so.<sup>194</sup> Leaving such events undetected and unrepaired for multiple months at a time could have devastating climate and health impacts.<sup>195</sup> By EPA's own analysis, monthly monitoring at these sites is extremely cost-effective, even resulting in cost savings for the largest sites.<sup>196</sup> It is arbitrary for EPA to so closely scrutinize cost-effectiveness at the smallest of sites on grounds that those sites have lower potential emissions but not require more frequent monitoring at the sites with the highest potential emissions—especially where increased monitoring could be achieved at low or zero net cost.

The commenter (0844-EDF *et al.*) states it is also incrementally cost-effective to increase monitoring from quarterly to monthly at sites above 20 tpy.<sup>197</sup> EPA should more granularly evaluate whether it might be incrementally cost-effective to increase to monthly monitoring at sites between 15 and 20 tpy. EPA should also evaluate the incremental cost-effectiveness of increasing to bi-monthly (six times per year) monitoring.

---

<sup>193</sup> 87 FR 74724-74736 (December 6, 2022).

<sup>194</sup> Our modeling with FEAST, discussed more below, shows that monthly monitoring is highly effective at reducing super-emitter events. See Attachment L (FEAST National Slides).

<sup>195</sup> See, e.g., Conley et al., Methane emissions from the 2015 Aliso Canyon blowout in Los Angeles, CA, 351 Science 1317 (2016), <https://www.science.org/doi/10.1126/science.aaf2348>.

<sup>196</sup> TSD at Table 12-13a, 12-13b.

<sup>197</sup> TSD at Table 12-13c.

The commenter (0844-EDF *et al.*) notes the D.C. Circuit has repeatedly held that section 111 requires the “maximum practicable degree” of control.<sup>198</sup> The CAA does not necessarily require EPA to set a standard at a level that reflects the maximum level of control that is technologically possible, but it does require the agency to maximize the level of emission reductions that can be achieved while giving reasonable consideration to the other statutory factors.<sup>199</sup>

The commenter (0844-EDF *et al.*) continues, with regard to costs, this means that the standard must achieve the maximum degree of emission reductions without becoming exorbitantly costly or ruinous for the regulated industry.<sup>200</sup> Monthly monitoring at the highest tpy sites is well within the range EPA has deemed reasonable; in some cases, it even results in negative costs, while achieving at least 10 percent more emission reductions than quarterly monitoring and even better results if super-emitter reductions are considered. EPA should thus require monthly monitoring at any site where it is cost-effective.

Response I-7-81: In response to the comments received on the November 2021 Proposal, EPA proposed a different regulatory approach for this particular affected/designated facility in the December 2022 Supplemental Proposal. For details, please see discussion in section IV.A.1.a.ii of the December 2022 Supplemental Proposal related to fugitive emissions from well sites.<sup>201</sup> Please also see section X.A.1 of the preamble to the final rule which details EPA’s final standards related to fugitive emissions from well sites.

Comment: Commenter (0564-AIPRO) proposes that the agency delay further proposed rulemaking until the DOE concludes its study on marginal well emissions and the EPA is able to consider the DOE conclusions in its proposed rule. If based solely on fugitive emissions PTE or actuals, the commenter supports the November 2021 Proposal for well sites with baseline emissions between 3 and 8 tpy of semiannual OGI surveys, as well as quarterly OGI surveys for sites above 8 tpy.

The commenter (0564-AIPRO) believes that a 3 tpy site-wide baseline methane emissions triggering quarterly LDAR survey frequency is not practical, overly burdensome, not cost-effective and, most importantly, will not accomplish meaningful fugitive emissions reductions.

Response I-7-82: In response to the comments received on the November 2021 Proposal, EPA proposed a different regulatory approach for this particular affected/designated facility in the December 2022 Supplemental Proposal. For details, please see discussion in section IV.A.1.a.ii of the December 2022 Supplemental Proposal related to fugitive emissions from well sites.<sup>202</sup> Please also see section X.A.1 of the preamble to the final rule which details EPA’s final standards related to fugitive emissions from well sites.

<sup>202</sup> 87 FR 74724-74736 (December 6, 2022).

Commenter (0573-KDHE) believes quarterly OGI monitoring for site-level methane thresholds of  $\geq 3$  and  $< 8$  tpy is too burdensome for smaller producers. The commenter recommends the frequency be lowered to semiannual, as in the November 2021 Co-Proposal.

Response I-7-83: In response to the comments received on the November 2021 Proposal, EPA proposed a different regulatory approach for this particular affected/designated facility in the December 2022 Supplemental Proposal. For details, please see discussion in section IV.A.1.a.ii of the December 2022 Supplemental Proposal related to fugitive emissions from well sites.<sup>203</sup> Please also see section X.A.1 of the preamble to the final rule which details EPA's final standards related to fugitive emissions from well sites.

### **7.1.7 Monitoring Costs**

Comment: Commenter (0844-EDF *et al.*) indicates that fugitive monitoring is generally very low cost, and in many cases may lead to cost savings from captured gas. Recent reports have identified oil and gas methane mitigation as a crucial near-term opportunity to limit climate warming that can be accomplished at low cost with available technologies and practices, making it the low-hanging fruit of climate action. For fugitive monitoring specifically, costs are extremely low, particularly in comparison to control techniques required in other sectors.<sup>204</sup> The commenter provides extensive input on fugitive monitoring costs and cost-effectiveness.

The commenter (0844-EDF *et al.*) cites to the IEA who recently found that “more than 70 percent of [global oil and gas methane] emissions can be abated with existing technologies” and “the cost of mitigation is often lower than the market value of the gas that is captured.”<sup>205</sup> The IEA estimates that “almost 45 percent of oil and gas methane emissions can be avoided with measures that would come at no net cost,” and identifies LDAR standards as one of the most important measures.<sup>206</sup> The IEA's analysis assumes quarterly monitoring occurs at all sites, but it also finds that “new and emerging technologies—including continuous monitoring sensors, aircraft, drones and satellites—can significantly reduce the cost of detecting fugitive sources when combined with on-site surveys.”<sup>207</sup>

The commenter (0844-EDF *et al.*) also cites to the United Nations Environment Program (UNEP) has similarly found that 60–80 percent of total oil and gas methane emissions can be cut at low cost and that the sector has “the greatest potential for negative cost abatement” because “captured methane adds to revenue instead of being released to the atmosphere.”<sup>208</sup> According to the commenter, A recent UNEP report examines analyses of per-ton abatement costs in the oil and gas sector and finds averages “around US \$1,000 per tonne of methane in the Harmsen

---

<sup>203</sup> 87 FR 74724-74736 (December 6, 2022).

<sup>204</sup> 86 Fed. Reg. 63,157 (EPA estimated that total capital costs due to compliance with the proposal would only represent a 0.3% increase for the sector. EPA regulations for EGUs increasing capital expenditures by 15.8% have been upheld as reasonable by the D.C. Circuit. This underscores how minimal any compliance costs are for an industry that spends hundreds of billions annually.).

<sup>205</sup> IEA, *Curtailling Methane Emissions from Fossil Fuel Operations: Pathways to a 75% cut by 2030* (October 2021), <https://www.iea.org/reports/curtailling-methane-emissions-from-fossil-fuel-operations>.

<sup>206</sup> *Id.*

<sup>207</sup> *Id.* at 25.

<sup>208</sup> UNEP, *Global Methane Assessment 96* (May 2021), <https://www.unep.org/resources/report/global-methane> [hereinafter “UNEP Global Methane”].

analyses, near zero in the IEA analysis, and having a net negative cost of roughly US \$700 per tonne methane in the IIASA analysis.”<sup>209</sup> Even the highest of these figures—\$1,000 per ton—is less than half of the cost reported by EPA for the vast majority of the industry.<sup>210</sup> The report further points out that “[IEA] analysis shows that the category with the largest mitigation potential, upstream LDAR, is also the cheapest.”<sup>211</sup>

According to the commenter (0844-EDF *et al.*), numerous studies have shown that over time and with repeated inspections, OGI programs reduce emissions and also help to prevent large emission events.<sup>212</sup> Studies have indicated that repair programs are highly effective where some are finding that more than 90 percent of leaks remained fixed a year later.<sup>213</sup> However, the same study also found that each individual survey reduced a site’s overall fugitive emissions by only 22 percent on average because of new leaks that occurred afterwards, indicating the need for “frequent, effective, and low-cost LDAR surveys to target new leaks” and a “more definitive classification of leaks and vents.”<sup>214</sup>

The commenter (0844-EDF *et al.*) believes that EPA’s methodology for calculating costs of the OGI program generally overestimates costs, thereby underestimating cost-effectiveness. When coupled with the failure to account for large emission events, the LDAR requirements appear much less cost-effective than would actually be true in most situations. The commenter urges EPA to revisit its repair cost assumptions, especially given the changes to the definition of “fugitive emission component” and the updated work practice standards for other sources to ensure they are not overestimates. The commenter is of the opinion that repairs of certain components and equipment that are required to be functioning properly under other work practice standards, *e.g.*, pneumatics, tank control systems, and flares, and cannot be attributed to the costs of fugitive monitoring and repair. The operator is already required to ensure certain components and equipment function properly, so counting those costs in the costs of the LDAR program would be double counting.

The commenter (0844-EDF *et al.*) conducted an in-depth analysis of EPA’s cost analysis. The commenter indicates that if EPA relies on API cost data for reporting, recordkeeping and data management then it should not also include recordkeeping and reporting costs elsewhere in its analysis. Specifically, EPA should remove the \$15,000 per year recordkeeping and reporting costs that are factored into the \$142/hour labor rate for OGI camera surveys. The commenter notes that EPA should adjust its annual report cost to account for the fact that the API cost data includes preparation of the report for submittal to EPA. The three hours of additional labor EPA includes for preparing the annual report and storing/filing records likely double counts API’s costs to review and submit the annual report to EPA.

<sup>213</sup> See Ravikumar 2020.

<sup>214</sup> Id.

The commenter (0844-EDF *et al.*) adds there are additional reasons to think that API's costs do not accurately reflect current costs associated with the OGI program. The costs provided by API were submitted in 2019, before EPA's 2020 amendments to NSPS OOOOa that streamlined the rule's recordkeeping and reporting requirements. In the 2020 rulemaking, EPA eliminated the requirement to keep various records, including those related to interim repairs and annual reports, and estimated the revisions would save \$1,100 per site annually. The EPA has not explained how the costs submitted by API in 2019 accurately reflect the costs that would be expected to occur under the revised and retained 2020 recordkeeping standards. EPA simply assumed in certain instances that the 2020 revisions would reduce costs by 25 percent.

The commenter (0844-EDF *et al.*) specifically also says that if EPA accounts for travel in the total hours used to calculate OGI camera survey costs, per well site, then it should not also include travel time costs in the labor costs. Two hours per well site for travel time is likely an overestimate, based on survey times in annual compliance reports submitted to EPA. In 2018, MJB concluded that the average time to conduct an LDAR survey is approximately 1.25-1.6 hours per well, including travel time between sites.<sup>215</sup> Specifically, MJB reported an average time between ending a survey at one site and starting a survey at the next site from less than five minutes to more than 2 hours, with an average of 30 minutes.

The commenter (0844-EDF *et al.*) also believes that survey times are also likely overestimated. Based on a review of annual compliance reports submitted to EPA in early 2021, for the approximately 300 upstream LDAR surveys with reported start-and end-time data reviewed, over half took less than 30 minutes to complete and 82 percent took an hour or less. Less than five percent of the LDAR surveys in the reports reviewed took more than 1.5 hours per well site. The average reported time to conduct the LDAR surveys was just over 30 minutes per well site across the data set.

The commenter (0844-EDF *et al.*) highlights that one company submitted 71 reports in the first quarter of 2021 and reported that it completed each of its surveys in exactly one hour. This survey time covered upstream sources, including tank batteries and well pads with up to 30 wells, and is presumably a time period that adequately captures the time spent at these sites. One hour therefore likely overestimates many surveys for well pads with fewer wells. For this company, a one hour survey is reportedly sufficient for all of its first quarter 2021 surveys.

In the commenter's (0844-EDF *et al.*) opinion, annual recordkeeping database maintenance and license fee costs are overestimated. The commenter notes that EPA's OGI costs include a category for annual recordkeeping database maintenance and license fee costs based on the average cost provided to EPA by API.<sup>216</sup> In its memo to EPA, API reports data for two data systems: (1) in-house database and/or spreadsheets; and (2) customized commercial software systems. API reports, and EPA uses, the average of the cost per facility for 29 in-house and 308 customized commercial software systems. The fact that over 90 percent of the facilities in the dataset are using the customized commercial software system should be reflected in the average cost per facility in order to account for the fact that most facilities are using this type of system. The commenter believes EPA should use the weighted average of the data points across all 337

---

<sup>215</sup> Attachment C (Memo from MJB to EDF 2018).

<sup>216</sup> EPA- EPA-HQ-OAR-2017-0483-2248\_attachment\_1 (May 22, 2019).

facilities, or \$544/year per facility, instead of the \$868/year per facility cost presented by API, which is the average of the two costs.<sup>217</sup>

The commenter (0844-EDF *et al.*) states that EPA used an average ongoing annual fee of \$470 for its model plant. Applying this same method but using API's weighted average of \$544/year results in an even lower estimate for annual recordkeeping and data management costs, closer to \$300/year.

The commenter (0844-EDF *et al.*) also believes the initial costs to set up a data management program are overestimated. The fact that over 90 percent of the facilities in the dataset are using the customized commercial software system should be reflected in the average setup cost per facility in order to account for the fact that most facilities are using this type of system. EPA should consider the weighted average of the data points across all 337 facilities, or \$1,622 per facility, instead of the \$2,839 per facility cost presented by API.<sup>218</sup> In fact, this cost is more in line with the \$1,500 per facility setup cost assumed by CARB in its 2017 rulemaking for GHG emission standards for oil and gas facilities.<sup>219</sup>

The commenter (0844-EDF *et al.*) indicates that it revised EPA's cost analysis to include:

1. Revised labor rate for OGI camera surveys that removes the recordkeeping, reporting, and travel time costs,
2. Revised annual recordkeeping database maintenance and license fee costs to reflect the weighted average API data, and
3. Revised one-time initial setup costs to reflect CARB's setup cost estimate.

According to the commenter (0844-EDF *et al.*), these changes result in a roughly 20 percent decrease in annual costs per well site. Note, these revised costs likely still overestimate costs as annual reporting costs are included in both additional recordkeeping/data management costs and annual report costs, and the revised costs also likely overestimate both the travel time and survey time assumed for OGI camera surveys. If the time for survey and travel were revised from 3.4 hours to 1.25 hours the well site costs for monthly OGI monitoring (including all of the other revisions described above) would be \$2,493, or roughly 40 percent less than EPA's estimates. The commenter provides Figure 5: Comparison of OGI Cost of Control & Revised Cost of Control.<sup>220</sup>

Using these revised cost assumptions, the commenter (0844-EDF *et al.*) recalculated the cost-effectiveness of OGI monitoring frequencies across the same tiers used by EPA.<sup>221</sup> Specific

---

<sup>217</sup>Costs are calculated using API data, as follows:  $\$36,500/29 \text{ facilities} = \$1,259/\text{facility}$  for in-house systems  $\$147,000/308 \text{ facilities} = \$477/\text{facility}$  for customized commercial systems Weighted average:  $(\$1,259/\text{facility} * 29 \text{ facilities}) + (\$477/\text{facility} * 308 \text{ facilities}) / (29 + 308) = \$544/\text{facility}$ .

<sup>218</sup> Costs are calculated using API data, as follows:  $\$125,000/29 \text{ facilities} = \$4,310/\text{facility}$  for in-house systems  $\$421,500/308 \text{ facilities} = \$1,369/\text{facility}$  for customized commercial systems Weighted average:  $(\$4,310/\text{facility} * 29 \text{ facilities}) + (\$1,369/\text{facility} * 308 \text{ facilities}) / (29 + 308) = \$1,622/\text{facility}$ .

<sup>219</sup> CARB, Cost Estimates (2017), <https://www.arb.ca.gov/regact/2016/oilandgas2016/oilandgas2016.htm>; CARB, Attachment 2, (2016), <https://ww2.arb.ca.gov/sites/default/files/barcu/regact/2016/oilandgas2016/oilgasatt2.pdf>

<sup>220</sup> Attachment E (EPA OGI Cost Analysis - well sites).

<sup>221</sup> See Attachment E (EPA OGI Cost Analysis - well sites).

details can be found in the commenter's letter and attachments. As noted above, these are conservative estimates based on reduced costs per well site of 20 percent. If EPA revised travel time and time for the survey, the cost per well site would be reduced by about 40 percent, which results in an even greater cost-effectiveness. The commenter provides tables with additional information in their commenter letter.

The commenter (0844-EDF *et al.*) believes that EPA should consistently apply its cost-effectiveness calculations and questions why EPA does not explain why it evaluated cost at granular level for smaller sites, but not at larger sites. With very small calculated baseline emissions such as 1 tpy, control measures appear less cost-effective. The commenter believes this methodology is inappropriate and places undue emphasis on cost-effectiveness at the smallest sites. Nevertheless, EPA found quarterly monitoring at 2 and 3 tpy sites to be within its accepted cost-effectiveness range.<sup>222</sup>

The commenter (0844-EDF *et al.*) believes the granularity skews the analysis to disfavor monitoring at lower tpy sites, yet there is no guarantee that these sites will remain below a given tpy threshold. If EPA retains this granularity at lower tpy sites, it should evaluate higher tpy sites the same way and examine whether more frequent monitoring is justified at those sites, including by evaluating bi-monthly monitoring. If the majority of sites within a given tier (*i.e.*, 1-3 tpy) can be monitored cost-effectively, then EPA should require monitoring at all the sites within that tier or otherwise adjust its parameters. The commenter asserts that it is arbitrary for EPA to exclude an entire tier of sites consisting of 3 tpy increments from regular monitoring because it found that monitoring at only one tpy increment within the tier would not be cost-effective.

The commenter (0844-EDF *et al.*) emphasizes that cost, which must only be "reasonable" under section 111 of the CAA is only one factor EPA must examine when setting BSER, and EPA may not elevate costs over other statutory factors, such as the quantity of emission reductions achieved by a particular system. Nor does section 111 require EPA to use any particular approach to evaluate whether costs are reasonable. Thus, in this case EPA could evaluate LDAR costs by simply averaging cost-effectiveness across tpy tiers and setting BSER applied to all sites within a given range. It would be reasonable for EPA to assume that the average operator owns a diverse array of sites, spanning the different tpy tiers, and that the average 22-site area consists of sites spanning the tpy tiers. The commenter thinks that EPA could therefore assume that costs would be spread across those sites, allowing for higher costs at certain sites that would be offset by lower costs at others. Finally, EPA should not elevate its incremental cost-effectiveness analysis over more important considerations, such as emission reductions.

---

<sup>222</sup>86 Fed. Reg. 63189 ("[F]or sites with total baseline methane emissions of 2 tpy, we conclude that regular monitoring at semiannual or quarterly frequencies would be cost-effective."); see also *id.* at 63,155 ("EPA finds the cost-effectiveness values up to \$1,800/ton of methane reduction to be reasonable").

The commenter (0844-EDF *et al.*) adds that cost-effectiveness estimates from leading states are much lower than EPA's, *e.g.*, Colorado.<sup>223,224</sup> Colorado's 2021 rulemaking used hourly inspection rates of \$105 for in-house and \$137 for contractors, as well as an hourly repair cost of \$82.06 to generate cost-effectiveness estimates.<sup>225</sup> The commenter relied on these assumptions (with a slightly shorter repair timeline) and the EDF Methane Policy Analyzer to generate adjusted cost-effectiveness estimates based on the 2021 Colorado rulemaking.<sup>226</sup> These estimates generally employ the Colorado Air Pollution Control Division's methodology but reflect the commenter's alternative proposal as part of the Colorado rulemaking to require monthly screening at all well sites and all compressor stations in Colorado (as opposed to the tiered structure that was ultimately adopted). Under the alternative proposal operators would choose between monthly advanced screening (paired with annual or semiannual Approved Instrument Monitoring Method (AIMM) or monthly AIMM). The commenter includes *Figure 7: EDF-Adjusted Cost-Effectiveness Estimates Based on CO 2021 Methodology*.<sup>227</sup>

The commenter (0844-EDF *et al.*) notes that CARB cost estimates are also lower than EPA's. In 2016, CARB estimated that quarterly monitoring cost \$23-\$75 per ton of CO<sub>2</sub>e reduced using 20-and 100-year GWP, with and without gas savings.<sup>228</sup> CARB used \$60/hr for labor, based on the average of contractor data points it gathered (\$55, \$70, \$62, \$55, \$50).<sup>229</sup> CARB also assumed \$1,500 per facility to account for setup costs.<sup>230</sup>

The commenter (0844-EDF *et al.*) states that publicly available cost estimates are much lower than EPA's and are around \$500-600 per well site.<sup>231</sup> Data from oil and gas producing companies and methane mitigation companies consistently confirm the cost of LDAR surveys are even lower. One company, Jonah Energy, documented a 75 percent reduction in leak

<sup>231</sup>Kemp & Ravikumar, New Technologies Can Cost Effectively Reduce Oil and Gas Methane Emissions, but Policies Will Require Careful Design to Establish Mitigation Equivalence, 55 *Env. Sci. Tech* 9140 (2021) <https://pubs.acs.org/doi/10.1021/acs.est.1c03071>; EPA Methane Detection Technology Workshops (Presentations of Arvind Ravikumar and Erin Tullos), available at, <https://www.regulations.gov/document/EPA-HQ-OAR-2021-0317-0181>; Ravikumar & Lyon, Impact of survey frequency on emissions mitigation at oil and gas sites, Appendix D (December 2018), [https://www.edf.org/sites/default/files/content/Appendix\\_D\\_Ravikumar\\_and\\_Lyon\\_Impact\\_of\\_Survey\\_Frequency\\_on\\_Emissions.pdf](https://www.edf.org/sites/default/files/content/Appendix_D_Ravikumar_and_Lyon_Impact_of_Survey_Frequency_on_Emissions.pdf).

detection over five years in Wyoming.<sup>232</sup> Jonah Energy also found that total LDAR program costs decreased from \$99 per inspection in the first year to \$29 per inspection in the fifth year.<sup>233</sup> Further, in each year, the total value of the captured gas across Jonah Energy's operations offset LDAR survey costs by at least \$10,000, including one year where the captured gas resulted in more than \$90,000 net in savings.<sup>234</sup>

Lastly, the commenter (0844-EDF *et al.*) points out that Texas-based Rebellion Photonics has stated that its own leak detections services cost \$250 per site.<sup>235</sup> FLIR Systems reports that LDAR inspections conducted by third-party service providers may cost as little as \$141 per site, which is far lower than EPA's estimate.<sup>236</sup> Based on its own data, Target Emission Services found that LDAR monitoring costs for compressor stations are \$1,220, inclusive of onsite monitoring, travel expenses, and reporting, per survey.<sup>237</sup>

Response I-7-84: In response to the comments received on the November 2021 Proposal, EPA proposed a different regulatory approach for this particular affected/designated facility in the December 2022 Supplemental Proposal. For details, please see discussion in section IV.A.1.a.ii of the December 2022 Supplemental Proposal related to fugitive emissions from well sites.<sup>238</sup> Please also see section X.A.1 of the preamble to the final rule which details EPA's final standards related to fugitive emissions from well sites.

Comment: Commenter (0597-Indiana Oil & Gas Association (INOGA)) advocates that EPA perform a cost effectiveness analysis at multiple points during the life of a well to determine when the additional regulatory requirements can no longer be economically justified. While EPA may consider this analysis to be burdensome, the proposed regulations will be far more burdensome for the commenter's members as they are required to implement new requirements that substantially increases their operating costs for the entire life of each asset.

Response I-7-85: In response to the comments received on the November 2021 Proposal, EPA proposed a different regulatory approach for this particular affected/designated facility in the December 2022 Supplemental Proposal. For details, please see discussion in section IV.A.1.a.ii

of the December 2022 Supplemental Proposal related to fugitive emissions from well sites.<sup>239</sup> Please also see section X.A.1 of the preamble to the final rule which details EPA’s final standards related to fugitive emissions from well sites.

Comment: Commenter (0955-Vaquero Energy Inc. (Vaquero)) requests that for wells that do not meet the November 2021 Proposal’s categorical exemption, EPA revise the cost effectiveness data. EPA has used a linear model to predict the reduction in emissions from increasing the inspection frequency. However, EPA estimates that the costs will not increase linearly. The commenter states that if inspection frequency doubles, inspection cost will at least double. The commenter believes EPA has also significantly underestimated the cost for inspection. Hiring an out-of-state contractor with an OGI camera to perform inspections will be twice the cost if inspections are performed twice as many times per year, not 7 percent greater (\$3,200 Semiannual inspection cost / \$3,000 Annual inspection cost = 7 percent).

Response I-7-86: In response to the comments received on the November 2021 Proposal, EPA proposed a different regulatory approach for this particular affected/designated facility in the December 2022 Supplemental Proposal. For details, please see discussion in section IV.A.1.a.ii of the December 2022 Supplemental Proposal related to fugitive emissions from well sites.<sup>240</sup> Please also see section X.A.1 of the preamble to the final rule which details EPA’s final standards related to fugitive emissions from well sites.

Comment: Commenter (0835-Center for Methane Emissions Solutions (CMES)) believes EPA has miscalculated LDAR costs. As the leading organization of methane mitigation companies in the United States, the commenter claims it is uniquely suited to convey to the Administration an accurate accounting of the true costs associated with implementing an OGI LDAR program.

For example, the commenter (0835-CMES) believes EPA has significantly increased cost estimates of “annual recordkeeping database maintenance and license fee” and “additional recordkeeping/data management costs.” According to assumptions provided to the Agency, EPA suggests that costs associated with recordkeeping is responsible for an increase of \$700 in monitoring costs since 2020. The commenter notes that these assumptions are inaccurate. For example, one nationally recognized member of the commenter’s organization provides recordkeeping to its customers as part of their standard agreement and estimates the cost at about \$50. The commenter encourages EPA to revise this estimate because recordkeeping is likely already included in service contracts, and that readily available technology makes such a task cost-effective.

Response I-7-87: In response to the comments received on the November 2021 Proposal, EPA proposed a different regulatory approach for this particular affected/designated facility in the December 2022 Supplemental Proposal. For details, please see discussion in section IV.A.1.a.ii of the December 2022 Supplemental Proposal related to fugitive emissions from well sites.<sup>241</sup>

---

<sup>239</sup> 87 FR 74727-74729 (December 6, 2022).

<sup>240</sup> 87 FR 74727-74729 (December 6, 2022).

<sup>241</sup> 87 FR 74727-74729 (December 6, 2022).

Please also see section X.A.1 of the preamble to the final rule which details EPA’s final standards related to fugitive emissions from well sites.

Comment: Commenter (0959-Colt Midstream LLC (Colt)) states the November 2021 Proposal would make it difficult for small and midsize operators to have in-house individuals trained to perform the surveys as well. The number surveys, approximately 100, where a trainer and trainee are required to perform together creates a burden for operators who may not have the quantity of facilities or personnel to meet the 100 surveys required prior to field testing. The additional requirement for the senior survey personnel to require having 500 documented surveys to act as trainer is a burden. Most companies just starting a program may have a difficult time acquiring this person.

Response I-7-88: In response to the comments received on the November 2021 Proposal, EPA proposed a different regulatory approach for this particular affected/designated facility in the December 2022 Supplemental Proposal. For details, please see discussion in section IV.A.1.a.ii of the December 2022 Supplemental Proposal related to fugitive emissions from well sites.<sup>242</sup> Please also see section X.A.1 of the preamble to the final rule which details EPA’s final standards related to fugitive emissions from well sites.

Comment: Commenter (0844-EDF *et al.*) states because EPA found quarterly monitoring at sites as low as 2 tpy cost-effective,<sup>243</sup> it should at least extend quarterly monitoring requirements to those sites. EPA acknowledges that regular monitoring at certain sites below 3 tpy would be cost-effective, but states that “[c]ost-effectiveness, however, is not the only relevant factor in setting the BSER, particularly for a source as numerous and diverse as well sites.”<sup>244</sup> But EPA’s stated rationales under the other BSER considerations are not supported by the record. EPA states that “[v]arious studies demonstrate that the vast majority of emissions come from a relatively small subset of wells,” and because of this, “EPA would like to ensure that resources and effort are focused on those wells that emit the most methane and VOC.”<sup>245</sup> While focusing resources on mitigating the greatest sources of emissions makes sense, that is no justification to categorically exempt other important sources from regular monitoring requirements.

The commenter (0844-EDF *et al.*) states there is no evidence of a shortage of resources. Most information available suggests that there are ample resources and that methane mitigation services are widely available and rapidly growing.<sup>246</sup> A recent report from Datu Research provides a comprehensive survey of the U.S. methane mitigation industry.<sup>247</sup> This report shows that this is a rapidly growing industry—finding a 90-percent increase in services firms over the

<sup>247</sup> Datu 2021 at 8.

2017 report<sup>248</sup>, and deeming these numbers “almost certainly an undercount in all manufacturing and service categories.”<sup>249</sup> The commenter notes the following key findings:

- The industry comprises dozens of job types, with annual salaries ranging from \$37,150 to \$140,960.
- Most of the firms (70 percent) are small businesses.
- Nearly 25 percent of the manufacturing firms and over 40 percent of the services firms were founded in the past 12 years.
- Firms are adding new U.S. employee locations. In 2021, Datu identified a total of 748 employee locations for manufacturing and service firms, an increase of 26 percent over the number previously identified.
- Firms anticipate growing jobs. Of 57 firms that responded to Datu’s survey, 75 percent of the manufacturing firms and 88 percent of the service firms reported that if future state or federal methane emission rules were put in place, they would anticipate hiring more employees.
- These jobs appear poised to grow soon, in light of EPA’s November 2021 Proposal and at least eight states preparing to either introduce new methane rules or expand the scope of existing ones.<sup>250</sup>

The commenter (0844-EDF et al.) adds monitoring at smaller sites can also be done cost-effectively. In assessing cost-effectiveness, EPA should recognize that most operators own multiple wells, and EPA should group sites accordingly. In fact, for consistency with its analyses of higher-tpy wells, EPA could simply group all sites below 5 tpy together for cost-effectiveness considerations. But if EPA retains its current approach for lower-emitting sites, it should evaluate cost-effectiveness consistently at the same granularity across lower and higher tpy sites. In particular, EPA should seek to identify the point at which more frequent monitoring—six to twelve times per year—would be cost-effective and designate a separate category for those sites.

The commenter (0844-EDF *et al.*) argues EPA has greatly overestimated the costs of OGI monitoring primarily due to an overestimate of recordkeeping and database management costs, an overestimate in the time necessary to conduct an OGI survey, and double counting of certain cost components. The overestimation of costs makes monitoring at these sites appear less cost-effective than is actually the case. Additionally, many sites below 3 tpy have not been subject to federal air pollution regulation before and will likely have old and failure-prone equipment. Because of this, the commenter expects that many of the sites will contain large leaks when inspected, so monitoring would be more cost-effective than assumed by EPA.

The commenter (0844-EDF *et al.*) states many operators that lack experience complying with federal regulations will simply hire contractors to conduct fugitive monitoring rather than creating an entire in-house program. The same is true for smaller operators who may lack the staff and expertise to conduct fugitive monitoring. In this situation, some of the costs EPA has analyzed are inapplicable or should be reduced. For example, an operator that contracted with an

---

<sup>248</sup> Datu Research, Find and Fix: Job Creation in the Emerging Methane LDAR Industry (March 2017), <https://www.edf.org/sites/default/files/find-and-fix-datu-research.pdf>.

<sup>249</sup> See Datu 2021 at Appendix A (full list of firms and offerings).

<sup>250</sup> Datu 2021 at 3.

OGI provider is unlikely to spend any time reading Appendix K or developing a fugitive monitoring plan. They may also contract for recordkeeping and data management services, further reducing costs. EPA should consider these possibilities and analyze costs appropriately.<sup>251</sup>

Response I-7-89: In response to the comments received on the November 2021 Proposal, EPA proposed a different regulatory approach for this particular affected/designated facility in the December 2022 Supplemental Proposal. For details, please see discussion in section IV.A.1.a.ii of the December 2022 Supplemental Proposal.<sup>252</sup> Please also see section X.A.1 of the preamble to the final rule which details EPA's final standards related to fugitive emissions from well sites.

Comment: Commenter (0835-CMES) states that as the leading organization of methane mitigation companies in the United States, the commenter is uniquely suited to convey an accurate accounting of the true costs associated with implementing an OGI LDAR program. In reviewing the November 2021 Proposal, the commenter believes that EPA has miscalculated. For example, EPA has significantly increased cost estimates of "annual recordkeeping database maintenance and license fee" and "additional recordkeeping/data management costs." According to assumptions provided to the Agency, EPA suggests that costs associated with record keeping is responsible for an increase of \$700 in monitoring costs since 2020. The commenter (0835-CMES) is pleased to convey that these assumptions are inaccurate. Many methane mitigation service providers offer such services as part of their contract. Separate contracts for such services are highly unusual. Further, one nationally recognized member of the commenter's organization provides recordkeeping to its customers as part of their standard agreement and estimates the cost at about \$50. The commenter encourages EPA to revise this estimate because record keeping is likely already included in service contracts, and that readily available technology makes such a task cost-effective.

Response I-7-90: In response to the comments received on the November 2021 Proposal, EPA proposed a different regulatory approach for this particular affected/designated facility in the December 2022 Supplemental Proposal. For details, please see discussion in section IV.A.1.a.ii of the December 2022 Supplemental Proposal.<sup>253</sup> Please also see section X.A.1 of the preamble to the final rule which details EPA's final standards related to fugitive emissions from well sites.

Comment: The commenter (0824-Wyoming Department of Environmental Quality (WDEQ)) disagrees with EPA's assessment that the cost of semiannual monitoring at low production well sites is cost effective for all well site operations in Wyoming. In the commenter's opinion, EPA's assessment ignores other significant such as the cost of OGI equipment needed for monitoring, personnel and contractor costs, and the new proposed Appendix K requirements. New and modified oil and gas sources in Wyoming require sources to utilize Best Available Control Technology (BACT). In 2018, the commenter's analysis found that at a 6 tpy control threshold for VOC, the cost to control VOC using semiannual fugitive emissions monitoring was

---

<sup>251</sup> See, e.g., Colorado Air Quality Control Commission, Regulatory Analysis (Dec. 5, 2019), <https://www.edf.org/sites/default/files/content/Attachment%20B%20-%20Regulatory%20Analysis%2C%20Colorado%20Dep%E2%80%99t%20of%20Public%20Health%20and%20the%20Environment%20%28Dec.%205%2C%202019%29.pdf>.

<sup>252</sup> 87 FR 74727-74729 (December 6, 2022).

<sup>253</sup> 87 FR 74727-74729 (December 6, 2022).

\$12,591/ton, and for quarterly fugitive emissions monitoring, the cost ranged from \$27,855/ton to \$53,076/ton. Based on the cost to control VOC, it was determined semiannual fugitive emissions monitoring was BACT. The commenter recommends that EPA re-evaluate its emission control thresholds and cost-of-controls to fully account for all factors.

Response I-7-91: In response to the comments received on the November 2021 Proposal, EPA proposed a different regulatory approach for this particular affected/designated facility in the December 2022 Supplemental Proposal. For details, please see discussion in section IV.A.1.a.ii of the December 2022 Supplemental Proposal.<sup>254</sup> Please also see section X.A.1 of the preamble to the final rule which details EPA's final standards related to fugitive emissions from well sites.

Comment: Commenter (0808-API) states that EPA's cost analysis erroneously assumes operators would not purchase an OGI camera. As API pointed out in the commenter's December 4, 2015, comment letter on proposed NSPS OOOOa,<sup>255</sup> EPA continues to exclude the cost of an OGI camera within the cost benefit analysis and assumes operators will only rely on third-party contractors to perform OGI monitoring, which is incorrect. The commenter indicates that API survey responses collected by a third-party ranged from \$90,000-\$100,000 for an OGI camera. A conservative assumption would be to include the costs for at least a single OGI camera. Most companies own and operate numerous cameras because it takes a team of LDAR technicians to implement and manage an OGI monitoring program across hundreds to thousands of sites.

Response I-7-92: In response to the comments received on the November 2021 Proposal, EPA proposed a different regulatory approach for this particular affected/designated facility in the December 2022 Supplemental Proposal. For details, please see discussion in section IV.A.1.a.ii of the December 2022 Supplemental Proposal.<sup>256</sup> Please also see section X.A.1 of the preamble to the final rule which details EPA's final standards related to fugitive emissions from well sites.

### ***7.1.8 Audio, visual, and olfactory (AVO)***

Comment: Commenters (0585-Kentucky Oil and Gas Association (KOGA), 0598-CER) support the use of AVO. These commenters suggest this is a low-cost way for small and large businesses to monitor for emissions. Most of the large emission sources may be identified through AVO inspections, without the need to utilize an OGI camera. The OGI cameras are very expensive to purchase and maintain or to hire a qualified contractor to perform the inspections. The commenter (0585-KOGA) recommends that EPA does not include burdensome recordkeeping and reporting for AVO inspections. This is an unnecessary use of employee time and not valuable to EPA. At most, the commenter recommends that operators only need to report on leaks that are identified and repaired through AVO inspections.

Response I-7-93: In response to the comments received on the November 2021 Proposal, EPA proposed a different regulatory approach for this particular affected/designated facility in the

---

<sup>254</sup> 87 FR 74727-74729 (December 6, 2022).

<sup>255</sup> API comments filed December 4, 2015 (EPA-HQ-OAR-2010-0505-4776).

<sup>256</sup> 87 FR 74727-74729 (December 6, 2022).

December 2022 Supplemental Proposal. See discussion in section IV.A.1.a.ii of the December 2022 Supplemental Proposal related.<sup>257</sup>

Please also see section X.A.1 of the preamble to the final rule which details EPA's final standards related to fugitive emissions from well sites. The EPA is finalizing the work practice standards for monitoring with AVO inspections only for single wellhead only well sites and small well sites and a combination of AVO inspections with OGI (or EPA Method 21) for multi-wellhead only well sites and well sites with major production and processing equipment and centralized production facilities.

### **7.1.9 Small/Marginal Wells**

Comment: Commenters (0727-OSEE/ODEQ, 0810-Petroleum Alliance-OK, 1341-Pennsylvania Grade Crude Oil Coalition (PGCC) *et al.*) ask that EPA defer regulating marginal/low production wells until the DOE report on small/marginal wells is published.

Commenter (1422-Senator Marshall *et al.*) states that the DOE will soon release an in-depth analysis on methane emissions produced by marginal wells and the results of that study will be extremely valuable to this rulemaking process. The commenter explains that this federally funded report on the "Quantification of Methane Emissions from Marginal (Small Producing) Oil and Gas Wells" will provide actionable data on how small production operations contribute to global emissions, and preliminary information from the DOE indicate no quantifiable or measurable emissions. The commenter suggests that, with the report due to be released any day now, they believe that there is no justifiable reason to not wait so that the results can be fully considered as part of the rulemaking process.

Comment: Commenter (0603-Representative Arrington *et al.*) urges the EPA to suspend publication of any related proposal until the DOE completes their study titled, "Quantification of Methane Emissions from Marginal Oil and Gas Wells."

Commenter (0603-Representative Arrington *et al.*) states that the objective of this federally funded study is to quantify methane emissions from marginal oil and gas well-sites at various basins across the U.S., including the Permian Basin. Scheduled for public release in December 2021, the report will provide critical data on emissions from low producing wells, which must be considered in any forthcoming EPA Emissions Rule. The commenter states that there is an ongoing debate regarding the efficacy of regulating emissions from low production wells, and it is important to acknowledge key information this study will provide regarding where in the production chain emissions are detectable.

Commenter (0603-Representative Arrington *et al.*) points out that approximately 75 percent of the existing oil and natural gas wells in the U.S. are low producing wells. The commenter notes that any regulatory change will affect the business of thousands of operators, their dependents, as well as state and local revenues that rely on robust energy production. To ensure the EPA promulgates a rule relating to emissions in good faith, publication must be postponed until the ongoing study is finalized, and the study's findings must be taken into consideration during the

---

<sup>257</sup> 87 FR 74728-74736 (December 6, 2022).

drafting process. According to the commenter, not only would it be irresponsible to do otherwise, but it would needlessly jeopardize our nation's small and independent oil and gas producers.

Commenter (0603-Representative Arrington *et al.*) states that it is vital that NSPS and EG for the oil and gas sector be cost-effective, reasonable, and based on the best available information.

The commenter (0727-OSEE/ODEQ) believes EPA disregards important forthcoming information on marginal and low-producing wells by proposing to subject said wells to frequent OGI monitoring. EPA should wait to publish any final rule until the report, “Quantification of Methane Emissions from Marginal (Low Production Rate) Oil and Natural Gas Wells,” conducted by the National Energy Technology Laboratory (NETL) has been completed.<sup>258</sup> The final report can help inform EPA on this most recent rulemaking and, specifically, to understand at what point are small and marginal producing wells no longer cost effective to require fugitive monitoring using OGI.

The commenter (0810-Petroleum Alliance-OK) states when EPA developed its NSPS OOOOa regulation for oil and gas, it had no emissions profile for marginal/low production wells; however, EPA proceeded to regulate them with a limited data set. Currently, EPA still has a limited data set that fully characterizes these types of wells. The DOE is conducting a study to better characterize emissions from these types of wells (expected to be publicly available in early 2022). EO 13990 requires the Federal Government, “...be guided by the best science and be protected by processes that ensure the integrity of Federal decision-making.”

The commenters (1341-PGCC *et al.*) state that EPA’s justification for abruptly abandoning the model plant approach for determining whether low-producing well sites are exempt from LDAR requirements is flawed.

The commenters (1341-PGCC *et al.*) refer to sections of the preamble to the November 2021 Proposal discussing EPA’s prior use of model plants to estimate emissions across different well sites. The commenters say that notably, EPA’s historical model plant approach in developing new source performance standards for the oil and natural gas sector led to the low-production well site” exemption to LDAR requirements embodied in the 2020 Technical Rule. After years of using a low production model plant approach, EPA proposes to abruptly pivot to a site-level baseline methane emissions approach to determining whether a well site (even an extremely low-producing stripper well site) is subject to LDAR requirements, the commenters remark.

The commenters (1341-PGCC *et al.*) observe that a close look at EPA’s justification for abandoning the low-production well site approach shows it falls far short of a reasonable and fair analysis. EPA has failed to acknowledge, much less obtain and analyze, the pending final draft DOE study designed to provide a “robust, “apples-to-apples” assessment of methane emissions from marginal vs. non-marginal well sites. EPA also does not reference or analyze the OGI monitoring results from the Independent Oil and Gas Association of New York (IOGANY) study and the results of PADEP’s monitoring, both of which are explained in detail and provided with PGCC’s August 12, 2021, letter that was sent to EPA. Rather than review and evaluate a study

---

<sup>258</sup>The following link shows the current status of the project: <https://netl.doe.gov/node/9373>.

performed by a sister Agency and other information provided to it, the commenters state that EPA's proposed pivot to a "site-level baseline methane emissions" approach appears to be based solely on data and information provided by an environmental group, without independently and objectively evaluating and analyzing that data. Further, the commenter says that EPA acknowledges that this data and information does not unequivocally prove that low-producing well sites emit more than other well sites, and instead, EPA states that it is "quite possible" that low-producing well sites "could have higher emissions."

The commenters (1341-PGCC *et al.*) do not believe EPA has provided adequate justification for moving away from the model plant approach. The commenters request that EPA release and consider the NETL's final draft report on methane emissions from marginal well sites and re-open its hasty decision to abandon the model plant approach for determining projected costs and emission reductions for potentially requiring LDAR at the extremely low-producing oil and gas wells. A meaningful and objective analysis of all available information will show that the small operations of members of the commenter's group should be exempt from any LDAR requirement in the November 2021 Proposal, both because the cost-effectiveness for any such requirements are prohibitive and because any emissions do not warrant potentially costly requirements.

Response I-7-94: In response to the comments received on the November 2021 Proposal, EPA proposed a different regulatory approach for this particular affected/designated facility in the December 2022 Supplemental Proposal. For details, please see discussion in section IV.A.1.a.ii of the December 2022 Supplemental Proposal related to establishing an equipment-based approach for determining the fugitive emissions monitoring and repair requirements.<sup>259</sup> Please also see section X.A.1.a.ii of the preamble to the final rule which details EPA's final standards related to the four subcategories of well sites, including single wellhead only well sites and small well sites.

Comment: Commenter (0814-IPAA *et al.*) states the predominant impact of EG OOOOc will be on low production well sites and their associated facilities. EPA has identified its view of low production well sites in the LDAR proposal as facilities emitting 3 tpy or less of methane. In other facilities, EPA has used different thresholds, such as 4 tpy of VOC for storage tanks or 6 tpy of VOC for storage tanks or 20 tpy of methane for storage tanks. These thresholds reflect various cost effectiveness assessments. Key to the analysis of emissions is the quality of emissions estimates – an issue where EPA's materials are suspect.

The commenter (0814-IPAA *et al.*) notes EPA's November 2021 Proposal to eliminate the low production well exemption and require all sources to calculate baseline emissions is extremely problematic for many small businesses and operators.

The commenter (0814-IPAA *et al.*) states EPA's continued emphasis on component counts over throughput and operating pressure in determining the amount of fugitive emissions fails to recognize basic physics. Almost all emissions calculations are based on throughput but to then discount throughput when evaluating fugitive emissions simply does not make sense. The Producer Associations are not disputing that component count does have an impact on emissions

---

<sup>259</sup> 87 FR 74724-74736 (December 6, 2022).

– the more pieces of equipment connected together increases the chances for leaks – but the Producer Associations continue to argue that production rates and pressure play a significantly more important role in fugitive emissions.

The commenter (0814-IPAA *et al.*) notes the DOE Report has shown that most low production well sites (15 boe/d and less) emit less than 3 tpy of methane based on actual measurements. At issue is whether these measurement results would compare with the subpart W calculation in EPA proposal for the same facilities. The well site definition should be based on the common facilities at a well site that are not separately regulated under NSPS OOOO, OOOOa, or OOOOb. For example, tanks/tank batteries and liquid unloading operations should not be part of the well site emissions determination.

The commenter (0814-IPAA *et al.*) states while they believe that a low production well definition is a far simpler method that produces comparable results, on the basis of the above well site definition and the use of accurate emissions factors, the commenter notes that they can accept the concept of using a 3 tpy low production facility exclusion from the quarterly LDAR program but recommends an annual AVO (audio, visual, olfactory) review rather than the OGI EPA program.

The commenter (0814-IPAA *et al.*) states it is essential that EPA recognize that most of the well sites falling below 3 tpy will be operated by small businesses and small businesses that are unaccustomed to calculating methane emissions. Consequently, EPA needs to develop, in concert with the Small Business Administration, a straightforward guideline document that operators could use in determining whether a site is below 3 tpy of methane. This guideline document should be developed prior to the planned supplemental proposal for NSPS OOOOb and EG OOOOc and subject to comments during that proposal.

The commenter (0814-IPAA *et al.*) states to elaborate on this issue, while EPA lays out a conceptual approach to determine site emissions using available subpart W emissions factors and other estimating tools, small production operations have no familiarity with these tools and the subtleties of their application. If EPA continues to reverse its position on the use of production rates to define a threshold to recognize lower regulatory requirements, it should recognize that the DOE Report provides data showing that these well sites overwhelmingly fall below the 3 tpy of methane emissions based on actual sampling. Moreover, the framework that the DOE Report created in defining the factors that can influence emissions, *e.g.*, production rate, oil or natural gas production, number of pieces of equipment at the site, could provide EPA with a framework for the development of an emissions calculation guideline for small businesses and low production well sites.

Commenter (0585-KOGA) believes that the 2020 Technical Rule exemption for wells producing less than 15 barrels per day (or equivalent gas flow) was appropriate and easily understood by industry and regulating entities alike. If EPA is going to continue using an emission rate, the commenter recommends that EPA utilize the same emission rate as NSPS OOOO that sources emitting less than 4 tons per year are exempt from monitoring and reporting requirements. The sources do not produce enough of emissions to justify the high cost of monitoring and reporting requirements set forth by EPA.

Response I-7-95: In response to the comments received on the November 2021 Proposal, EPA proposed a different regulatory approach for this particular affected/designated facility in the December 2022 Supplemental Proposal. For details, please see discussion in section IV.A.1.a.ii of the December 2022 Supplemental Proposal related to establishing an equipment-based approach for determining the fugitive emissions monitoring and repair requirements.<sup>260</sup> The EPA is finalizing the equipment-based program using model plants each with various equipment types located at the site. In the final rule, well sites with specific leak-prone equipment have one set of requirements, while well sites with other equipment (or that lack leak-prone equipment, e.g., small well sites) have a different set of requirements. Section X.A.1.a.ii of the preamble to the final rule details EPA's final standards related to four subcategories of well sites.

Comment: Commenter (0810-Petroleum Alliance-OK) states marginal wells are defined in federal law as oil wells producing 15 barrels per day or less and natural gas wells producing 90 thousand cubic feet (Mcf) per day or less. The Interstate Oil and Gas Compact Commission (IOGCC) defines a marginal well as a well that produces 10 barrels of oil or 60 Mcf of natural gas per day or less. However, according to the IOGCC's 2016 report regarding marginal wells in Oklahoma, the average crude oil and natural gas production for a marginal well is approximately 1.43 barrels per day of crude oil and 18 Mcf of natural gas per day. Oklahoma has approximately 28,000 marginal crude oil wells and 45,000 marginal natural gas wells. Approximately 9.5 percent of Oklahoma's total crude oil production and approximately 12.0 percent of Oklahoma's total natural gas production comes from marginal wells. These wells provide an important revenue resource for the State. In addition, small businesses in the Mining, Quarrying, and Oil and Gas Extraction industry in Oklahoma employ over 20,000 people, or over 50.5 percent of the private workforce employed in that sector in 2017. Many small oil and gas businesses may be negatively impacted if the November 2021 Proposal is implemented.

The commenter (0810-Petroleum Alliance-OK) adds that marginal wells provide a significant share of the U.S. domestic oil and natural gas output and economic contributions. The commenter states that since approximately 2006, marginal wells have produced oil and natural gas valued at nearly \$30 billion annually, or approximately 10 percent of the total value of oil and natural gas produced domestically. It is important that EPA understand the importance and benefits of marginal wells and small business impacts to the U.S., the State of Oklahoma, and small businesses, and consider this information in its rulemaking process.

Commenter (0824-WDEQ) adds that there would be significant costs associated with meeting the requirements of proposed Appendix K, which are entirely inhibitive for many stripper well operators who would be subject to these requirements. As such, the commenter disagrees with EPA's assessment that it "no longer believes that production levels provide an appropriate threshold for any exemption from fugitive monitoring." Small operators are already voicing concerns that they will have to shut down operations demonstrating that EPA's assessment is inaccurate, the commenter concludes.

Commenter (0929-National Stripper Well Association (NSWA)) states that an important reason that EPA should pursue the traditional process is that the DOE is poised to release a study – many weeks overdue – on emissions from low production wells that needs to be reviewed and

---

<sup>260</sup> 87 FR 74724-74736 (December 6, 2022).

considered by EPA as it intends to withdraw certain exemptions for low production wells. The study will provide in depth analysis on methane emissions produced by marginal wells and the results of that study will be extremely valuable to this rulemaking process.

Commenter (0929-NSWA) states that this federally-funded report on the “Quantification of Methane Emissions from Marginal (Small Producing) Oil and Gas Wells” will provide actionable data on how small production operations contribute to global emissions, and preliminary information from the DOE indicate no quantifiable or measurable emissions. With the report due to be released any day now, there is no justifiable reason to not wait so that the results can be fully considered as part of the rulemaking process prior to the DOE study being released to the public, fully analyzed by EPA, and incorporated into the agency’s decision making process on a final methane rule, which should also be subject to a 90 day comment period.

Commenter (0946-Michigan Oil and Gas Association (MOGA)) notes that during their Small Business Advocacy Review (SBAR) meetings, many small-entity oil and gas companies from all over the U.S. expressed their concerns regarding the expansion of NSPS OOOOa regulations to marginal and low production wells. The commenter did not receive an answer to whether EPA had evaluated the long-term environmental costs regarding early plugging of producing wells and the correlated ripple effect on the environment resulting from the drilling of new wells. The exploration, site preparation and drilling of new wells will likely be expedited as marginal and low production wells are forced to be plugged and abandoned early by burdensome regulations. The commenter states that the responsible long-term management of existing oil wells would offset the tremendous costs and environmental impacts related to drilling new wells to replace the lost oil production from already drilled and constructed wells and facilities. The commenter was unable to voice questions and concerns regarding proposed actions to include low and marginal wells into regulations originally designed for high volume production operations. These proposed actions would create conflicting regulations to the State of Michigan’s Natural Resources and Environmental Protection Act 451 of 1994, Section 324, Part 61504 law to prevent the waste of resources. The genesis of the State of Michigan’s regulations was to prevent over production of well early in a well’s lifespan, which can damage the producing formation and create isolated and un-recoverable pockets of oil and gas. Instead, Michigan’s regulations require operators to throttle production to enhance the longevity of production and protect against un-recoverable and wasted resources.

Response I-7-96: In response to the comments received on the November 2021 Proposal, EPA proposed a different regulatory approach for this particular affected/designated facility in the December 2022 Supplemental Proposal. For details, please see discussion in section IV.A.1.a.ii of the December 2022 Supplemental Proposal related to establishing an equipment-based approach for determining the fugitive emissions monitoring and repair requirements.<sup>261</sup> This approach does not require the owner/operator to calculate the site baseline emissions, but rather requires an identification of equipment located at the site in order to determine which of four subcategories the well site falls into. Section X.A.1.a.ii of the preamble to the final rule details

---

<sup>261</sup> 87 FR 74724-74736 (December 6, 2022).

EPA's final standards related to the four subcategories of well sites, including the final requirements for small well sites.

Comment: Commenter (1341-PGCC *et al.*) suggests that the EPA consider the small, low-emitting nature of Pennsylvania and New York conventional oil and gas production before imposing any additional requirements in the NSPS OOOOa revisions, NSPS OOOOb and EG OOOOc. Commenter (0577-KIOGA) states that the potential for VOC and GHG emissions from an unconventional oil or gas well is proportionately higher than conventional oil or gas wells (and provides information on unconventional oil and gas well production to support their statement).

Commenter (1341-PGCC *et al.*) states that EPA's November 2021 Proposal generally takes a one-size-fits-all, industry-wide approach to determining whether additional, and potentially far more restrictive requirements, should be imposed on oil and gas producers. The commenter's members are comprised primarily of small, family-owned businesses and individuals operating low-producing oil and gas wells, as compared to the large, high-volume unconventional gas wells being drilled for several miles into deep geologic formations. These profound differences, in scale, production, design, and layout, must be accounted for by EPA, both in terms of understanding the adverse economic impact the November 2021 Proposal, if finalized, will have, and in terms of ascertaining whether EPA is justified in imposing requirements to regulate the small amounts of emissions from conventional oil and gas operations in Pennsylvania and New York.

Commenter (1341-PGCC *et al.*) points out that the emissions profiles associated with conventional operations are vastly different than those associated with unconventional operations. Almost all Pennsylvania and New York conventional wells are low producing "stripper" wells. By contrast, conventional well pads are 35 or more times smaller than unconventional well pads and, therefore, cause drastically less surface disturbance than unconventional pads. Significantly smaller amounts of supplies and equipment-including water and large trucks-are needed to conduct conventional operations than are required for the high-volume hydraulic fracturing performed at unconventional wells. Conventional producers generally use less than 10 percent of the pumping capacity as compared to an unconventional well, and wellhead pressures at conventional wells quickly decrease to very low pressures with many operating at less than 50 psi. New unconventional wellheads pressures are measured in the thousands of pounds. These differences in infrastructure and processes translate to small well pad emissions, and fugitive emissions are much lower at conventional wells given the extraordinarily low wellhead pressures.

Commenter (1341-PGCC *et al.*) states that the typical conventional oil well site in northwestern Pennsylvania and New York State would not normally include the following emission sources:

- Glycol dehydrators
- Amine gas sweetening units
- Line heater, heater treater, and reboilers
- Gas compressors (a gas compressor, when in use, would typically be associated with a group of wells, not a single well)
- Pneumatic controllers

- Pneumatic pumps
- Pipeline blowdowns

Commenter (1341-PGCC *et al.*) states that conventional natural gas wells in Pennsylvania and New York are similarly simple facilities. Typical conventional gas wells also involve many fewer fugitive equipment items (valves, connections, *etc.*).

Response I-7-97: In response to the comments received on the November 2021 Proposal, EPA proposed a different regulatory approach for this particular affected/designated facility in the December 2022 Supplemental Proposal. For details, please see discussion in section IV.A.1.a.ii of the December 2022 Supplemental Proposal related to single wellhead only well sites and small well sites.<sup>262</sup> Please also see section X.A.1 of the preamble to the final rule which details EPA's final standards related to single wellhead only well sites and small well sites.

As discussed in the December 2022 Supplemental Proposal, large leaks can occur from single wellhead only well sites and small well sites. These emissions can be easily identified using AVO inspections alone and would not require the use of OGI. The EPA remains mindful about how the fugitive emissions monitoring requirements will affect small businesses. For small well sites, the EPA considered many factors in finalizing monitoring requirements for these sites that have fewer pieces of equipment, many of which are owned and operated by small businesses, and the EPA is finalizing quarterly AVO inspections for these sites.

Comment: Commenter (0810-Petroleum Alliance-OK) states EPA should allow operators the ability to reduce monitoring if fugitive emissions monitoring findings are reduced or eliminated, especially for marginal/low producing wells. For example, upon completion of two successful (no findings) OGI inspections, the inspection interval requirement should be reduced to one time per year or every 2 years. In addition, EPA should consider incentives that encourages operators to anticipate sources of emissions and/or install proactive measures to effectively monitor or manage those emissions.

Response I-7-98: In response to the comments received on the November 2021 Proposal, EPA proposed a different regulatory approach for this particular affected/designated facility in the December 2022 Supplemental Proposal. For details, please see discussion in section IV.A.1.a.ii of the December 2022 Supplemental Proposal related to single wellhead only well sites and small well sites.<sup>263</sup> Please also see section X.A.1 of the preamble to the final rule which details EPA's final standards related to single wellhead only well sites and small well sites. Specifically, EPA is finalizing quarterly AVO inspections of fugitive emissions at single wellhead only well sites and small well sites. As discussed, EPA disagrees that low producing wells correlates with low emissions.<sup>264</sup> With respect to the commenter's request to reduce monitoring after not finding any fugitive emissions in two back-to-back monitoring surveys, EPA disagrees. EPA has previously considered the shifting monitoring frequency based on performance but found that a reduced monitoring schedule is inappropriate for a number of reasons, where one major reason is that this could result in fugitive emissions being undetected longer due to less frequent

---

<sup>262</sup> 87 FR 74724-74736 (December 6, 2022).

<sup>263</sup> 87 FR 74724-74736 (December 6, 2022).

<sup>264</sup> 87 FR 74731 (December 6, 2022).

monitoring.<sup>265</sup> These same reasons apply under this rule and EPA is therefore finalizing a fixed-frequency monitoring.

#### **7.1.10 Small Business/Operators**

Comment: Commenter (1341-PGCC *et al.*) suggests that EPA has ignored or failed to address several key recommendations of the small entity representatives. Regarding fugitive emissions, the Panel Report<sup>266</sup> recommended that EPA “impose fewer requirements on sources that are less likely to emit methane and/or have demonstrated a history of insignificant emissions.”<sup>267</sup> To learn more about such sources and their emissions, the Panel Report recommended EPA solicit comment on regulatory alternatives for low production well sites and for “additional data, such as the DOE study, that assess the emissions from low production well sites and subsequently use this data to evaluate how monitoring requirements can be tailored to address sources mostly likely to be the sources of largest emissions and, if warranted, subcategorize sources unlikely to emit significant amounts of methane.”<sup>268</sup>

Response I-7-99: In response to the comments received on the November 2021 Proposal, EPA proposed a different regulatory approach for this particular affected/designated facility in the December 2022 Supplemental Proposal. For details, please see discussion in section IV.A.1.a.ii of the December 2022 Supplemental Proposal related to single wellhead only well sites and small well sites.<sup>269</sup> Please also see section X.A.1 of the preamble to the final rule which details EPA’s final standards related to single wellhead only well sites and small well sites. As discussed in that section, EPA evaluated data from the DOE Study, which EPA found does not show a correlation between production and the amount of fugitive emissions. However, analysis of the data indicated a strong correlation between the major equipment count and the frequency of fugitive emissions. For that reason, EPA proposed in 2022 to distinguish among well sites based on equipment and component counts. The EPA is maintaining this approach for the final rule and is finalizing quarterly AVO inspections of fugitive emissions at single wellhead only well sites and small well sites.

Comment: Commenter (0585-KOGA) states that many of their member companies are considered to be small entities who primarily operate low production wells, which requires a low-cost structure for profitable operation. The resources available to these companies are typically limited to the small staff that they can locally employ.

The commenter (0585-KOGA) appreciates EPA’s interest in the impact that the rules will have on small business entities and considering their perspective. As the commenter’s members read

---

<sup>265</sup> 81 FR 35857 (June 3, 2016).

<sup>266</sup> Final Report of the Small Business Advocacy Review Panel on EPA’s Planned Rule Emission Standards for New, Reconstructed, and Modified Sources in the Oil and Natural Gas Sector, Document ID No. EPA-HQ-OAR-20210317-0074 (Sept. 2021) (Panel Report).

<sup>267</sup> Id at 34.

<sup>268</sup> "DOE study" refers to the National Energy Technology Laboratory (NETL) study entitled "Quantification of Methane Emissions from Marginal (Small Producing) Oil and Gas Wells," Project No. DE-FE0031702. According to NETL's website, the "draft final report [from this study] was delivered to NETL on December 6, 2021 and is currently under review by DOE for release to the public." <https://netl.doe.gov/node/9373> (last visited Jan. 29, 2022).

<sup>269</sup> 87 FR 74724-74736 (December 6, 2022).

the preamble, there is little relief from the regulation for SERs. EPA has solicited input on a few topics throughout the preamble as they relate to small business; but has not identified any specific relief from compliance requirements for those companies that meet the SER definition. As EPA develops the final regulation, the commenter asks that EPA consider opportunities to address small business impacts and provide appropriate relief from sections of the regulation that will be overly burdensome for small business. The commenter suggests the following to provide relief:

- Reduce the proposed monitoring frequency to be no more than annually.
- Extended compliance period for SERs to be a year from the effective date.
- Permit AVO inspection for SERs.
- Provide a path to remove affected facilities from monitoring requirements when the emission rate falls below 4 tpy.
- Reduce the documentation requirements.

Response I-7-100: In response to the comments received on the November 2021 Proposal, EPA proposed a different regulatory approach for this particular affected/designated facility in the December 2022 Supplemental Proposal. For details, please see discussion in section IV.A.1.a.ii of the December 2022 Supplemental Proposal related to single wellhead only well sites and small well sites.<sup>270</sup> Please also see section X.A.1 of the preamble to the final rule which details EPA's final standards related to single wellhead only well sites and small well sites.

As discussed in the December 2022 Supplemental Proposal, large leaks can occur from single wellhead only well sites and small well sites. These emissions can be easily identified using AVO inspections alone and would not require the use of OGI. The EPA remains mindful about how the fugitive emissions monitoring requirements will affect small businesses. For small well sites, the EPA considered many factors in finalizing monitoring requirements for these sites that have fewer pieces of equipment, many of which are owned and operated by small businesses, and the EPA is finalizing quarterly AVO inspections for these sites.

Comment: Commenters (0464-Muskegon Operating Company LLC (MOPC), 0824-WDEQ, 0938-TXOGA, 0946-MOGA) express concern on the impact the November 2021 Proposal with have on small operators and offer various suggestions for relief.

The commenter (0464-MOPC) argues that marginal wells are not a significant source of methane. Emissions from a well are proportionate to the volume of oil and/or gas produced. Marginal wells produce significantly less emissions due to the fact that they are marginal producers of oil and gas. Emissions from the commenter's wells are much lower than those emitted from high volume wells produced by larger companies. As a responsible operator, the commenter has taken action to voluntarily minimize their emissions in a prudent manner that meets standards they can afford.

---

<sup>270</sup> 87 FR 74724-74736 (December 6, 2022).

The commenter (0464-MOPC) states that the economic viability of their company relies on efficient and low-cost operations. The commenter opposes the proposed regulations as they will have significant detrimental impacts on their operations, costs, overhead, reserve recovery, plugging costs, and employment. The regulations will unnecessarily, unreasonably, and disproportionately raise the company's operating costs. Every increase in cost directly jeopardizes the commenter's ability to produce marginal wells. The commenter's company will not be able to absorb the additional regulatory costs.

The commenter (0464-MOPC) believes it is unfair and unwise to treat small operators with marginal wells in the same manner as larger producers. Marginally producing wells must be exempt from EPA rules because the emissions are insignificant and the rules would be uneconomic. There must be a regulatory "off ramp" for wells that are low producers. The commenter supports the exemption of marginal, low production wells from the November 2021 Proposal.

The commenter (0938-TXOGA) appreciates that EPA is concerned about underestimating the burdens potentially imposed on homeowners, farmers, and small businesses by virtue of the fugitive emissions monitoring and other requirements contemplated under the November 2021 Proposal. The commenter requests that EPA consider and incorporate into any supplemental proposal or final rule the findings of the currently ongoing DOE study on marginal wells, even if the final report has not been issued in time for the next phase of this rulemaking.<sup>271</sup>

The commenter (0946-MOGA) suggests the EPA consider past small business's documented emission reductions as a factor in their required fugitive monitoring schedule. Once again, the EPA appears to be penalizing small businesses that have adhered to requirements outlined in the current NSPS OOOOa and previous NSPS OOOO rule. These small businesses feel "targeted" for their emission reduction efforts based on past regulations and now wonder if it will end? The commenter attended several meetings with the EPA during which, the EPA admitted the bulk of emissions come from a small group of sites and companies. For these reasons, the commenter believes the EPA should avoid penalizing small businesses with documented emission reduction efforts with an "Exemption Classification" for fugitive emission monitoring.

Response I-7-101: In response to the comments received on the November 2021 Proposal, EPA proposed a different regulatory approach for this particular affected/designated facility in the December 2022 Supplemental Proposal. For details, please see discussion in section IV.A.1.a.ii of the December 2022 Supplemental Proposal related to single wellhead only well sites and small well sites.<sup>272</sup> Please also see section X.A.1 of the preamble to the final rule which details EPA's final standards related to single wellhead only well sites and small well sites.

The EPA disagrees with the commenter that marginal wells are not a significant source of methane. As discussed, EPA disagrees that low producing wells correlates with low

<sup>271</sup> See National Energy Technology Laboratory, "Quantification of Methane Emissions from Marginal (Small Producing) Oil and Gas Wells" (Project Number DE-FE0031702), <https://netl.doe.gov/node/9373> (stating that a draft final report of the study is currently under review by DOE for release to the public).

<sup>272</sup> 87 FR 74724-74736 (December 6, 2022).

emissions.<sup>273</sup> The EPA discussed in the December 2022 Supplemental Proposal, large leaks can occur from single wellhead only well sites and small well sites. These emissions can be easily identified using AVO inspections alone and would not require the use of OGI. The EPA remains mindful about how the fugitive emissions monitoring requirements will affect small businesses. For small well sites, the EPA considered many factors in finalizing monitoring requirements for these sites that have fewer pieces of equipment, many of which are owned and operated by small businesses, and the EPA is finalizing quarterly AVO inspections for these sites.

Comment: Commenter (0439-Paxton Resources, LLC (Paxton), 0822-TAEP) is concerned that OGI requirements place unique burdens on small businesses.

Commenter (0439-Paxton) believes that by going after large emitters EPA would be penalizing small businesses with no regard for the science of emissions in companies like the commenter's. The argument could be made that through existing regulations including NSPS OOOO and NSPS OOOOa, the commenter has been able to reduce methane emissions by 60 percent over 9 years. This trend will likely continue based on depletion and implementation of existing regulations on future wells, equipment and facilities. It is the commenter's opinion that the EPA should focus on large emitters rather than implementing a broad approach across varying regions that unjustly penalizes and discriminates against small businesses who are achieving success in reducing emissions by meeting the existing standards. The commenter attaches data taken directly from published Subpart W reporting on the EPA's website illustrating three Michigan companies' reductions over the last nine years averaging 45, 65, and 56 percent for CO<sub>2</sub>, methane and nitrous oxide, respectively. The commenter asks why the data for small businesses is not being considered.

The commenter (0822-TAEP) says that EPA has repeatedly heard in-house training and specialization on this is the best way to control cost, but that option is not always available to small businesses. The prospect for contract or outsourcing this requirement will place undue burden on small operators and cost estimates should reflect regional variability and rural workforce considerations that will show dramatic differences in price per service. The commenter surveyed their membership and suspect \$2,368 per facility to be low. Many of the comments from members reflect they lack the adequate staff and resources to meet this new requirement should it be implemented for all facilities. "This expense combined with other monitoring activities would make some of our leases uneconomic," said one member. Another said, "We have low volume wells. This would be cost prohibitive." For low production wells there is a significant concern that cost cannot be absorbed due to price constraints and the inability to absorb new operational requirements. This will result in a heightened negative impact to small businesses.

The commenter (0822-TAEP) asked if this contracted workforce was available across Texas to perform this new requirement and 74 percent of respondents said 'No'. There were a variety of reasons for this which included lack of workforce and training with many objections raised on the need for this at smaller operations or marginal production facilities. In many cases, operators reported that those cost may be higher because the internal operations to adapt and conduct new regulatory requirements has been limited due to the contraction of the industry in 2020. The

---

<sup>273</sup> 87 FR 74731 (December 6, 2022).

commenter created and tracks a Texas upstream oil and gas economic index, and the employment data contained within indicates the loss of about 36 percent of direct upstream jobs in Texas in the 2019-2020 industry contraction. These limitations skew the cost estimate higher due to operators being more reliant on third-party contractors to facilitate revisions to emission controls not already required by state and federal law.

Response I-7-102: In response to the comments received on the November 2021 Proposal, EPA proposed a different regulatory approach for this particular affected/designated facility in the December 2022 Supplemental Proposal. For details, please see discussion in section IV.A.1.a.ii of the December 2022 Supplemental Proposal related to establishing an equipment-based approach for determining the fugitive emissions monitoring and repair requirements.<sup>274</sup> The EPA is finalizing the equipment-based program using model plants each with various equipment types located at the site. In the final rule, well sites with specific leak-prone equipment have one set of requirements, while well sites with other equipment (or that lack leak-prone equipment, e.g., small well sites) have a different set of requirements. Section X.A.1.a.ii of the preamble to the final rule details EPA's final standards related to four subcategories of well sites.

The EPA disagrees with the commenter that marginal wells are not a significant source of methane. As discussed, EPA disagrees that low producing wells correlates with low emissions.<sup>275</sup> The EPA discussed in the December 2022 Supplemental Proposal, large leaks can occur from single wellhead only well sites and small well sites. These emissions can be easily identified using AVO inspections alone and would not require the use of OGI. AVO inspection is a low cost and simple method for identifying emissions. The EPA remains mindful about how the fugitive emissions monitoring requirements will affect small businesses. For small well sites, the EPA considered many factors in finalizing monitoring requirements for these sites that have fewer pieces of equipment, many of which are owned and operated by small businesses, and the EPA is finalizing quarterly AVO inspections for these sites.

Comment: Commenter (0573-KDHE) responds to EPA's solicitation of comment on fugitive emissions monitoring requirements burdens on small businesses. The commenter maintains an inventory of all oil and gas wells in the state, as well as annual oil and gas production by operator and cites various numbers in their comment letter indicating number of oil and natural gas operators and their 2020 production levels.<sup>276</sup> The commenter notes that numbers point to an unfair burden on small Kansas producers, and recommends alternative, less burdensome standards be proposed for small producers or that they be considered exempt from this rulemaking.

Response I-7-103: In response to the comments received on the November 2021 Proposal, EPA proposed a different regulatory approach for this particular affected/designated facility in the December 2022 Supplemental Proposal. For details, please see discussion in section IV.A.1.a.ii of the December 2022 Supplemental Proposal related to single wellhead only well sites and

---

<sup>274</sup> 87 FR 74724-74736 (December 6, 2022).

small well sites.<sup>277</sup> Please also see section X.A.1 of the preamble to the final rule which details EPA's final standards related to single wellhead only well sites and small well sites.

As discussed in the December 2022 Supplemental Proposal, large leaks can occur from single wellhead only well sites and small well sites. These emissions can be easily identified using AVO inspections alone and would not require the use of OGI. The EPA remains mindful about how the fugitive emissions monitoring requirements will affect small businesses. For small well sites, the EPA considered many factors in finalizing monitoring requirements for these sites that have fewer pieces of equipment, many of which are owned and operated by small businesses, and the EPA is finalizing quarterly AVO inspections for these sites.

Comment: Commenter (0742-Alaska Department of Environmental Conservation (AK-DEC)) states the Oil and Natural Gas development is an important economic driver for the State of Alaska providing critical domestic energy production to the United States as well as local job opportunities, resources, and other benefits to Alaska and its citizens. Alaska exercises stringent regulatory authority by numerous State agencies, this Department, the Alaska Oil and Gas Conservation Commission (AOGCC), the Department of Natural Resources, and several others, but wants to emphasize that this proposed rulemaking could punish Alaska and its oil and gas industry for less stringent regulatory oversight in other states, such as Texas and North Dakota. As an example, venting and flaring is closely regulated and monitored in Alaska through the efforts of the department and AOGCC's oversight under state regulations. An article discussing Colorado methane monitoring also proposes that EPA's one-size-fits-all approach may not be appropriate.<sup>278</sup> The commenter is concerned that EPA appears to be headed toward an approach that may not fit well for all production basins leading to detrimental impacts on Alaska's oil and gas industry for limited gains in emission reductions.

Response I-7-104: In response to the comments received on the November 2021 Proposal, EPA proposed a different regulatory approach for this particular affected/designated facility in the December 2022 Supplemental Proposal. For details, please see discussion in section IV.A of the December 2022 Supplemental Proposal related to fugitive emissions from well sites, centralized production facilities, and compressor stations.<sup>279</sup> Please also see XI.A of the preamble to the final rule which details EPA's final standards related to fugitive emissions from well sites, centralized production facilities, and compressor stations.

Comment: Commenter (0763-TCEQ/RRC) requests that a guidance document similar to the small business compliance guide for NSPS OOOOa be developed and provided as a tool to help companies understand the complex regulatory requirements that this NSPS will incorporate.

Response I-7-105: Small Entity Compliance Guides (SECGs) are prepared by EPA pursuant to section 212 of the Small Business Regulatory Enforcement Fairness Act of 1996 (SBREFA) (Title II of Public Law 104-121). EPA prepares a SECG unless the agency can certify that the final rule will not have a significant economic impact on a substantial number of small entities. As discussed in section XVII.C of the final preamble, EPA discusses the Regulatory Flexibility

---

<sup>277</sup> 87 FR 74722-74740 (December 6, 2022).

<sup>278</sup> Website at: <https://www.cpr.org/2021/11/01/colorado-oil-and-gas-methane-emissions-testing/>

<sup>279</sup> 87 FR 74724-74736 (December 6, 2022).

Act and EPA's initial and final regulatory flexibility analysis. The EPA will be preparing a SECG for NSPS OOOOb pursuant to SBREFA.

### ***7.1.12 Class II Water Disposal Wells***

Comment: Commenter (1085-SOS) states that under the rule, EPA provides an exemption for Class II water disposal wells. However, the rule has no discussion about Class II enhanced oil recovery (EOR) wells (a well that is also injecting produced water back into the ground, just into an oil-bearing-strata instead of a non-oil bearing strata for disposal). The commenter believes EPA should provide the same exemption for all Class II wells.

Response I-7-106: As currently defined in 40 CFR §144.6, EOR water injection wells are already included, specifically named under 40 CFR §144.6(b)(2):

(b) Class II. Wells which inject fluids:

(1) Which are brought to the surface in connection with natural gas storage operations, or conventional oil or natural gas production and may be commingled with waste waters from gas plants which are an integral part of production operations, unless those waters are classified as a hazardous waste at the time of injection.

(2) For enhanced recovery of oil or natural gas; and

(3) For storage of hydrocarbons which are liquid at standard temperature and pressure.

The EPA believes this resolves the commenter's concerns.

### ***7.1.13 Miscellaneous Others***

#### **7.1.13.1 Clarifications/Definitions/Units**

Comment: Commenters (0782-BHE, 0813-Black Hills Energy) request clarification on EPA's intent for production wells and underground storage wells.

Commenter (0782-BHE) argues the November 2021 Proposal does not clearly distinguish between production wells and underground storage wells, yet it appears that some requirements are intended to apply to wells in the production segment and not underground storage. The commenter recommends that EPA clearly define each well type. Further, if proposed "well" requirements are intended to include underground storage wells, then the commenter requests additional background to understand and address this requirement and opportunity to provide comment.

The commenter (0782-BHE) states the November 2021 Proposal material and context appear to indicate that LDAR requirements for compressor stations apply to wells located at underground storage facilities (*i.e.*, underground storage facility wells fall under "compressor station" rather than "well" related requirements), and that "well" requirements in the November 2021 Proposal

apply to the production segment but not storage wells. The commenter requests that this be clearly reflected in Supplemental Notice regulatory text. If EPA intends broader applicability for storage wells, then the commenter requests additional support for the rule in the TSD and RIA, because that analysis appears to focus on production wells. Justification for any new requirements for underground storage wells will allow industry to understand EPA's intent and provide feedback on technical feasibility more fully. The commenter requests EPA outreach to underground storage facility operators if new requirements are considered to ensure nomenclature, emission estimation methods, *etc.* associated with well emission estimates and categorization accurately reflect industry standards. This will also help eliminate additional confusion regarding differing requirements for production segment wells versus transmission and storage underground storage wells.

The commenter (0782-BHE) argues the lack of proposed regulatory text at times creates uncertainty around EPA's intent in the November 2021 Proposal. The transmission and storage segment includes underground storage facilities that include compression and storage wells. Regulatory text is needed to clarify what, if any, "well related" requirements discussed in the November 2021 Proposal apply to underground storage wells. The commenter suggests this could be clarified in the Supplemental Notice by including definitions for "underground natural gas storage wells" and production-related wells, and clearly indicating applicability for the different well types. For example, if a baseline emissions determination is intended to apply to transmission and storage wells, the commenter suggests emission estimates should consider segment specific characteristics and exclude non-regulated components from the emissions estimate. In addition, the commenter recommends excluding equipment co-located at the underground storage facility from the emission estimate. The commenter strongly recommends that EPA clearly state that the proposed well-related requirements are applicable to the production segment, but not the transmission and storage segment. If that is not the case, the commenter requests additional data gathering and analysis to support requirements for underground storage wells as well as opportunity to comment on such proposed applicability.

Commenter (0813-Black Hills Energy) states to date, wells (in geological formations) located in the natural gas transmission and storage segment, which are used to store natural gas, are not specifically defined in NSPS OOOO or NSPS OOOOa. NSPS OOOO defines a gas well or natural gas well as "...an onshore well drilled principally for production of natural gas." NSPS OOOOa defines a well as "...a hole drilled for the purpose of producing oil or natural gas, or a well into which fluids are injected." Both definitions only address natural gas wells which extract gas from the earth. Neither of these definitions address natural gas wells in the natural gas transmission and storage segment which serve as temporary holding places to store natural gas until it is needed to serve customer demand. The commenter requests gas natural storage wells be explicitly excluded from the definition of "well" in NSPS OOOOb and EG OOOOc to be consistent with the precedent set by NSPS OOOO and NSPS OOOOa.

Response I-7-107: As defined in §60.5430b of the December 2022 Supplemental Proposal, and consistent with 40 CFR part 60, subpart OOOOa,

“*Well site* means one or more surface sites that are constructed for the drilling and subsequent operation of any oil well, natural gas well, or injection well. For the purposes of the fugitive emissions standards at §60.5397b, a well site does not include:

- (1) UIC Class II oilfield disposal wells and disposal facilities;
- (2) UIC Class I oilfield disposal wells; and
- (3) The flange immediately upstream of the custody meter assembly and equipment, including fugitive emissions components, located downstream of this flange.”

The final rule retains the definition of a well site as proposed. As specified in the definition of a well site in §60.5430b, the only scenarios where a well site would not be subject to the fugitive emissions standards would be if the well site met any of the criteria in (1) through (3) of the definition. Therefore, the case the commenter described would be subject to fugitive emission standards for well sites under NSPS OOOOb and EG OOOOc.

Comment: Commenter (0392-C.E. Harmon Oil, Inc. (Harmon)) requests that EPA define the emission production threshold that requires inspection, what sources count, and so forth. The commenter asks if this new rule is like past GHG reporting where the American Association of Petroleum Geologists used certain groupings of counties as geologic basins, which EPA then used for areas to report GHG. Or, is the EPA going to look at each lease individually (as to tank battery which serves a group of wells), the commenter asks. If the commenter is under threshold for reporting years ago for the GHG reporting, and has since sold many leases, the commenter asks if it still would be considered under threshold.

Response I-7-108: In response to the comments received on the November 2021 Proposal, EPA proposed a different regulatory approach for this particular affected/designated facility in the December 2022 Supplemental Proposal. For details, please see discussion in section IV.A.1.a.ii of the December 2022 Supplemental Proposal related to establishing specific monitoring requirements based on the type of equipment located at the well site.<sup>280</sup> Please also see section X.A.1 of the preamble to the final rule which details EPA’s final standards related to fugitive emissions at well sites and centralized production facilities. The monitoring requirements vary depending on whether the well site is a single wellhead only well site, small well site, multi-wellhead only well site, a well site with major production and processing equipment and, or a centralized production facility. The specific fugitive emissions requirements can be found in §60.5397b of the final rule.

Comment: Commenter (1133-Gunn Oil Company (Gunn)) asks for communication in standard oil field measurements. The commenter understands gas measurements in 1,000 MSCF. All of the commenter’s instruments measure this way. The commenter also knows that anything below 1 or 2 MSCF per day rates are too small to measure and unreliable, not to mention uneconomical to try and sell. The API or some other institution that has standards for measurements should get involved to decide what is acceptable standards for measurements. The commenter sees a lot

---

<sup>280</sup> 87 FR 74736 (December 6, 2022).

about cameras and infrared images. While there is no doubt these can detect leaks, they cannot measure volumes accurately.

Response I-7-109: In response to comments received on the November 2021 Proposal, EPA proposed a different regulatory approach for subcategorizing well sites in the December 2022 Supplemental Proposal. In the December 2022 Supplemental Proposal, the EPA proposed an equipment-based program using model plants each with various equipment types located at the site. The equipment-based approach requires identification of the specific equipment located at the well site in order to determine the specific fugitive emissions monitoring requirements that apply and does not involve quantification of emissions. The EPA is finalizing the equipment-based approach, and this should resolve the commenter's concerns regarding units of measurements.

Comment: Commenter (0817-GPA) notes that the November 2021 Proposal requires operators to "take corrective action to complete all necessary repairs" of control devices "as soon as practicable." The term "as soon as practicable" should be defined. Without some specific period in which to effect repairs, and the ability to delay repairs if needed, operators are deprived of the fair notice required to comply with the law. Otherwise, the question of whether an operator failed to repair a control device "as soon as practicable" will fall to EPA inspectors and enforcement personnel who will determine whether or not a violation occurred on an *ad hoc* basis. While the commenter appreciates the flexibility implied by an "as soon as practicable" standard, a set time period to effectuate repairs, such as 60 days for control devices, with the option to delay repair for necessity (e.g., avoiding shutdowns only for the repair, weather, unavailability of parts) has worked well for the LDAR program. If EPA is intent on (improperly) viewing control devices as leaking components, the commenter suggests adding a definitive time for repairs.

Response I-7-110: In the November 2021 Proposal, EPA proposed a definition of fugitive emissions components that included control devices with emissions resulting from the device operating in a manner that is not in full compliance with any Federal rule, State rule, or permit. However, based on comments received on the November 2021 Proposal, and additional information evaluated since 2021, EPA did not include control devices in the proposed definition of fugitive emissions components in the December 2022 Supplemental Proposal. With respect to control devices, the definition was finalized as proposed in the December 2022 Supplemental Proposal and EPA believes this resolves the commenter's concerns.

Comment: Commenter (0561-TRICORD Consulting, LLC (TRICORD)) requests clarification related to the definition of "repair." The definition currently states "Repair means that a component is adjusted, or otherwise altered, to eliminate a leak." The commenter asks for clarification whether "eliminate the leak" means no emissions (which the commenter believes is usually not possible) or if it means to eliminate the image of leakage using an acceptable camera and technique.

Response I-7-111: The December 2022 Supplemental Proposal regulatory text defined "repaired" in the context of fugitive emissions as follows:

§60.5430b(1): Repaired means the following:

(1) For the purposes of fugitive emissions components affected facilities, that fugitive emissions components are adjusted, replaced, or otherwise altered, in order to eliminate fugitive emissions as defined in §60.5397b and resurveyed as specified in §60.5397b(h)(4) and it is verified that emissions from the fugitive emissions components are below the applicable fugitive emissions definition.

This definition has been retained in the final rule. According to the definition, fugitive emissions are considered eliminated when the resurvey indicates fugitive emissions are below the applicable fugitive emissions definition. This means that if EPA Method 21 is used to resurvey, the fugitive emissions component is considered repaired when the EPA Method 21 instrument indicates a concentration of less than 500 ppmv above background or when no soap bubbles are observed when the alternative screening procedures specified in section 8.3.3 of EPA Method 21 of appendix A-7 of this part are used. If the resurvey is conducted using OGI, the fugitive emissions component is considered repaired when the OGI instrument shows no indication of visible emissions.

Comment: Commenter (0807-BP) states EPA should clarify regulatory text indicating follow up actions within 14 days of “receiving the data” from the alternative screening survey. As proposed, operators have to perform the “follow-up OGI survey of all fugitive emissions components at the site within 14 days of the screening survey.” In the supplemental rule, EPA should clarify that the 14-day window for a follow-up OGI survey commences upon the operator’s receipt of the advanced screening survey results from the vendor. There are situations where operators may not receive the final survey data from third-party vendors on the day of inspection. Should the language remain as written, delays in data receipt could unintentionally consume several days afforded in the 14-day window for follow-up OGI surveys. In so doing, operators would end up with less time to execute follow-up surveys. Assuming the intent is to provide operators with a full 14 days to perform the follow-up surveys, EPA should clarify that this window begins at the time of data receipt, not the survey itself.

Response I-7-112: In the December 2022 Supplemental Proposal, EPA proposed specific frequencies for conducting periodic screenings based on the minimum detection threshold of the screening technology in the approved alternative test method(s) selected to conduct the periodic screenings. This included when regular OGI follow-up surveys would be required. Following a periodic screening, EPA proposed that the owner/operator must receive the results of the periodic screening no later than 5 calendar days after the screening occurs. The EPA is finalizing this requirement. If the results of the periodic screening indicate a confirmed detection of emissions from an affected facility, a monitoring survey of the entire fugitive emissions components affected facility must be conducted and all sources of fugitive emissions must be repaired and confirmed repaired within 30 days of receiving the results of the periodic screening. There is no specific timeframe to conduct the follow-up OGI survey or start the repairs, as long as the repairs are completed and confirmed within 30 days of receiving the results of the screening.

Comment: Commenters (0425-Darrah, 1085-SOS, 1101-Triple T Oil, LLC (Triple T)) state wells are already monitored and audited on barrel in the case of oil and thousand cubic feet (MCF) in the case of gas volumes by regulatory agencies. Changing 3 tpy to a BBL or MCF equivalent per day would provide ease of implementation and easier understanding for small producers.

The commenters (1101-Triple T, 1103-Town Oil Company (TOC)) state Eastern Kansas wells are very low-producing wells and there are many of them. There needs to be a clear definition of the amount of emissions being produced per bbl of oil that requires inspection. There also needs to be a clear definition of the source from which it is coming from, *i.e.*, well or tank battery. The regulation is extremely unclear the way it is written. The commenter (1103-TOC) adds it will be extremely expensive for a small lease owner to be able to afford the monitoring system. This more than likely will shut down production and the commenter will have to plug the wells.

Response I-7-113: In response to comments received on the November 2021 Proposal, EPA proposed a different regulatory approach for subcategorizing well sites in the December 2022 Supplemental Proposal. In the December 2022 Supplemental Proposal, the EPA proposed an equipment-based program using model plants each with various equipment types located at the site. The equipment-based approach requires identification of the specific equipment located at the well site in order to determine the specific fugitive emissions monitoring requirements that apply and does not involve quantification of emissions. The EPA is finalizing the equipment-based approach, and this should resolve the commenter's concerns regarding units of measurements. In addition, the equipment-based monitoring approach that EPA is finalizing makes it clear which monitoring requirements apply to each type of site (*i.e.*, single wellhead only well site, small well site, multi-wellhead only well site, well site with major production or processing equipment, or centralized production facility).

Comment: Commenter (0938-TXOGA) states inclusion of equipment such as natural gas-driven pneumatic controllers, natural gas-driven pneumatic pumps, and pumpjack engines in the definition of "major production and processing equipment" would unnecessarily expand the scope of the regulation to include a number of small sources that are not currently regulated and that do not have sufficient component counts to be considered a "well site" under any reasonable understanding of the term. Such an approach is not justified in light of the costs imposed on small operators with low emissions. The commenter notes that this approach would also be inconsistent with Subpart W, under which smaller equipment such as pumpjacks and pneumatic controllers would not be considered major production equipment.

Response I-7-114: In the November 2021 Proposal, EPA solicited comment on whether to expand the definition of major production and processing equipment to include natural gas-driven pneumatic controllers, natural gas-driven pneumatic pumps, and pumpjack engines.<sup>281</sup>

In the December 2022 Supplemental Proposal, based on information evaluated following the November 2021 Proposal, EPA determined that it was not appropriate to keep natural gas-driven pneumatic controllers or natural gas driven pneumatic pumps as fugitive emissions components. The EPA stated that these devices are both separate affected facilities with separate standards. identified as BSER. Therefore, in the December 2022 Supplemental Proposal, EPA proposed to maintain the definition of major production and processing equipment as follows:

*"Major production and processing equipment means reciprocating or centrifugal compressors, glycol dehydrators, heater/treaters, separators, and storage vessels*

---

<sup>281</sup> 86 FR 63173 (November 15, 2021).

collecting crude oil, condensate, intermediate hydrocarbon liquids, or produced water, for the purpose of determining whether a well site is a wellhead only well site.”

The EPA is maintaining this definition in the final rule, which does not include natural gas-driven pneumatic controllers, natural gas-driven pneumatic pumps, or pumpjack engines.

Further, the EPA is finalizing the definition of a small well site, as proposed in the December 2022 Supplemental Proposal.

*Small well site* means, for purposes of the fugitive emissions standards in §§60.5397b and 60.5398b, a well site that contains a single wellhead, no more than one piece of certain major production and processing equipment, and associated meters and yard piping. Small well sites cannot include any controlled storage vessels (or controlled tank batteries), control devices, or natural gas-driven pneumatic controllers.

#### 7.1.13.2 Extreme Weather

Comment: Commenter (0539-Alaska Oil and Gas Conservation Commission (AOGCC)) indicates that a first attempt at repair within 30 days of finding fugitive emissions and final repairs within 30 days of first attempt is not always feasible in Alaska for a couple reasons. First, there are several fields that have equipment that is literally not used anywhere else in the world so obtaining parts for a repair could be a lengthy process. Second, often times if an issue is discovered in the winter a temporary fix is completed as soon as practical but a permanent fix could require a full facility shutdown and due to the complexity of freeze protecting a facility in the winter time those shutdowns are usually performed in the summer time, so there are large chunks of the year where it would be incredibly difficult to complete a final repair within 30 days of the initial attempt at repair.

Response I-7-115: EPA has previously acknowledged the technical infeasibility issues with weather conditions for well sites and compressor stations located on the Alaska North Slope.<sup>282</sup> Consequently, reduced fugitive emissions monitoring was proposed in December 2022 at 60.5397b(g)(1)(v), which specified annual OGI monitoring for fugitive emissions monitoring of affected facilities on the Alaska North Slope. EPA disagrees that additional time is needed for sources in Alaska to conduct initial and final repair of fugitive emissions and EPA is finalizing the requirement of first attempt at repair within 30 days of finding fugitive emissions and final repair within 30 days of first attempt must be completed.

Comment: Commenters (0786-Enerplus, 0911-NDPC) note that unique weather conditions in North Dakota necessitate special provisions in locations with adverse weather conditions.

The commenter (0786-Enerplus) states increasing the frequency of LDAR inspections reduces the window of opportunity a company has to reschedule inspections delayed by adverse and dangerous weather conditions. North Dakota is one of the coldest states in the U.S. and weather can cause safety and logistical challenges. If a quarterly inspection frequency is upheld in the

---

<sup>282</sup> 86 FR 63163 (November 15, 2021).

final rule, the commenter requests allowance for inspection delays due to adverse and dangerous weather conditions.

The commenter (0911-NDPC) states North Dakota's climate poses many safety and logistical challenges that can limit inspector access to oil and gas locations for days or weeks. Ice, snow, frigid temperatures, and high winds are common occurrences. North Dakota is the coldest state in the continental U.S. during the winter and fall<sup>283</sup>, and this year has already seen temperatures below -25 °F and wind speeds greater than 30 mph. Increasing the frequency of LDAR inspections reduces the window of opportunity a company has to reschedule inspections delayed by bad weather conditions. Also, some activities at well sites may increase the safety risk to the LDAR inspector. These activities include but are not limited to well completion, maintenance, and construction activities.

Response I-7-116: The EPA is allowing in the final rule an exemption of quarterly monitoring during extreme temperatures. The final rule at §60.5397b(g)(4) specifies that fugitive emissions components affected facilities quarterly monitoring requirements are waived during a quarterly monitoring period if the affected facility is located within an area that has an average calendar month temperature below 0°Fahrenheit for two of three consecutive calendar months of a quarterly monitoring period.

#### 7.1.13.3 Worker Shortages

Comment: Commenter (0733-Conservation Voters New Mexico (CVNM)) is concerned with the extensive requirements of the November 2021 Proposal and ask the EPA to consider worker shortages, costs, extreme weather conditions, and the highly specialized nature of the instrumentation. According to the commenter, New Mexico had ten inspectors for more than 52,000 operational wells in the state at the end of 2020, and one inspector indicated at that time that she endeavored to "hit" every well at least once every three years. By contrast, the November 2021 Proposal requires that wells are to be monitored quarterly, semiannually, or annually.

Response I-7-117: In response to the comments received on the November 2021 Proposal, EPA proposed a different regulatory approach for this particular affected/designated facility in the December 2022 Supplemental Proposal. For details, please see discussion in section IV.A.1.a.ii of the December 2022 Supplemental Proposal related to fugitive emissions from well sites.<sup>284</sup> Please also see section X.A of the preamble to the final rule which details EPA's final standards related to monitoring requirements for fugitive emissions components from well sites.

#### ***7.1.14 EG 0000c***

Comment: The commenter (0739-Citation) states if existing sites are added to LDAR survey requirements as included in the November 2021 Proposal, the number of surveys will be extremely difficult to accomplish given the potential shortage of third-party LDAR contractors, which will be in high demand throughout the industry, and the remote locations of many of these

---

<sup>283</sup> Website at: [www.worldatlas.com](http://www.worldatlas.com).

<sup>284</sup> 87 FR 74724-74736 (December 6, 2022).

sites. Alternate in-house options would also be difficult based on resulting high demand for OGI cameras and associated availability. The commenter requests that the fugitive provision for existing sites be eliminated or significantly reduced.

Response I-7-118: In response to the comments received on the November 2021 Proposal, EPA proposed a different regulatory approach for this particular affected/designated facility in the December 2022 Supplemental Proposal. For details, please see discussion in section IV.A.1.a.ii of the December 2022 Supplemental Proposal related to fugitive emissions from well sites.<sup>285</sup> Specifically, single wellhead only well sites and small well sites would be subject to quarterly AVO inspections only. Please also see section X.A of the preamble to the final rule which details EPA's final standards related to fugitive emissions from well sites. The EPA expects that requiring AVO inspections only for single wellhead only well sites and small well sites will lessen the demand on OGI contractors overall. In addition, for the December 2022 Supplemental Proposal, the EPA evaluated whether to revise the November 2021 proposed two-year final compliance deadline. The EPA considered several factors that could impact the ability of a designated facility to come into compliance with the presumptive standards. The EPA described these factors in Table 31 of the 2022 Supplemental Proposal preamble.<sup>286</sup> One of those factors evaluated included the availability of specialized services (e.g., OGI contractors), which EPA acknowledged could have an impact on small businesses as the assumption is that contractors could prioritize larger businesses. The EPA also acknowledged here are a large number of designated facilities where owners or operators are dependent on the availability of equipment and services.

Comment: The commenter (0585-KOGA) believes that many marginal wells will be prematurely plugged because they will be subject to NSPS OOOOc. The wells will be covered by NSPS OOOOc because of EPA's definition of major production and processing equipment. Typical wellsite production equipment like gas/water separators, drip tanks, and water tanks (often less than 1,000 gallons in size) associated with low pressure gas wells do not have a significant potential for fugitive emissions, primarily because of the low pressures at which they are operated. But these low-pressure gas wells will require a monitoring program estimated by EPA to have an annual cost of \$4,200, 18.6 percent of the gross revenues (assuming the well produces 20 Mcf/day). The average gas well in Kentucky produces 6 Mcf/day. Using EPA's numbers, the compliance cost for the average well in Kentucky will be 62 percent of the gross revenue.

Response I-7-119: In response to the comments received on the November 2021 Proposal, EPA proposed a different regulatory approach for this particular affected/designated facility in the December 2022 Supplemental Proposal. For details, please see discussion in section IV.A.1.a.ii of the December 2022 Supplemental Proposal related to fugitive emissions from well sites.<sup>287</sup> Specifically, single wellhead only well sites and small well sites would be subject to quarterly AVO inspections only. Please also see section X.A of the preamble to the final rule which details EPA's final standards related to fugitive emissions from well sites.

---

<sup>285</sup> 87 FR 74724-74736 (December 6, 2022).

<sup>286</sup> 87 FR 74835 (December 6, 2022).

<sup>287</sup> 87 FR 74724-74736 (December 6, 2022).

Comment: Commenter (0738-Exxon Mobil Corporation (Exxon)) urges EPA to consider whether flexibilities on use of new technologies could be leveraged to address methane emissions from existing sources immediately, rather than waiting years for the State Implementation Plan process to run its course. This could perhaps be accomplished through flexibility in the base program or how new AMEL applications are reviewed. For example, detecting and addressing emissions from existing sources could perhaps factor into how EPA determines whether an AMEL application achieves “at least equivalent” emission reductions, especially under the principle of focusing efforts on finding the largest leaks.

Commenter (1382-National Grid) supports EPA’s new requirements for states to develop plans to reduce emissions from existing sources, taking into account the safety and reliability of existing operations. To avoid potential redundancies and encourage compliance, the commenter recommends collaborating with stakeholders to review the best practices of current programs and allow states the flexibility to utilize emissions data collected through emerging technologies and strategies.

Response I-7-120: EPA agrees with the commenter that it is reasonable to consider allowing for flexibilities in the use of new and alternative technologies for methane detection. In the December 2022 Supplemental Proposal, EPA included specific provisions for the use of alternative test methods using advanced methane detection technologies that would allow for periodic screening or continuous monitoring for fugitive emissions and emissions from covers and CVS used to route emissions to control devices. The EPA is finalizing these proposed alternatives that would allow for advanced screening technologies, which could be used to identify sooner than traditional detection methods such as OGI monitoring for fugitive emissions, covers on storage vessels, and CVS.

The final rule establishes a clear and streamlined pathway for technology developers and other entities to seek the EPA’s approval for the use of advanced measurement technologies under this alternative screening option. Under this pathway, entities would seek approval for alternative test methods to demonstrate the performance of alternative technologies, which would replace the use of OGI and AVO.

#### 7.1.14.1 Site-Specific Factors (Useful Life)

Comment: Commenter (1267-CA AG *et al.*) notes EPA is seeking comment on observations, any other facts that are unique to the oil and natural gas industry that could impact the remaining useful life and other factors demonstration, and whether the agency should include specific provisions regarding consideration of site-specific factors that would supplement or supersede those listed in EPA’s implementing regulations.

Commenter (1267-CA AG *et al.*) generally agrees with EPA’s observation that the design of the presumptive standards likely lessens the instances in which a performance standard in a state plan would need to be relaxed compared to the guideline to account for a facility’s remaining useful life or other site-specific factors. The control of fugitive emissions from well sites and compressor stations through use of LDAR, for example, could be done throughout the remaining useful life of these sources without the need to install any retrofit technology. In light of the fact

that CAA section 111(d)(1) requires that states be allowed to consider remaining useful life and other site-specific factors, however, the agency's observation is more relevant to the subsequent state plan process (specifically, EPA's evaluation of whether a state has demonstrated a variance for particular sources is warranted) as opposed to whether states can depart at all from EPA presumptive standards.

In the final emission guidelines, the commenter (1267-CA AG *et al.*) suggests that EPA provide guidance on how the remaining useful life criterion should be applied to the different types of designated facilities. The agency could include information on the anticipated design life of oil and natural gas wells, storage vessels, compressors, pneumatic controllers, *etc.* based on industry experience. States could then use that information in evaluating whether the remaining useful life of particular sources would justify a different numerical or non-numerical standard.

Response I-7-121: In response to the comments received on the November 2021 Proposal, EPA proposed a different regulatory approach for this particular affected/designated facility in the December 2022 Supplemental Proposal. For details, please see discussion in section IV.A.1.b of the December 2022 Supplemental Proposal related to OOOOc for fugitive emissions from well sites and section IV.A.2.b for compressor stations.<sup>288</sup> In the December 2022 Supplemental Proposal, the EPA also proposed and solicited comment on requirements for Remaining Useful Life and Other Factors (RULOF).<sup>289</sup> Please see section XIII.C.3 of the preamble to the final rule with a discussion of the requirements that EPA is finalizing as it relates to RULOF.

#### 7.1.14.2 Delay of Repair/Availability of Parts

Comment: Commenter (1391-Interstate Natural Gas Association of America (INGAA)) believes that after all of the necessary replacement parts are received, the appropriate amount of time needed to make a repair depends on whether a shutdown or blowdown is needed. If a shutdown or blowdown is needed, then NSPS OOOOc should provide that the repair may be delayed until the next scheduled shutdown for maintenance, not to exceed two years from leak discovery, as is allowed under NSPS OOOOa. This approach would also be consistent with EPA's approach to natural gas processing plants. There, EPA acknowledged the importance of making repairs during planned shutdowns and when parts are available.<sup>290</sup> This requirement was rational and safe for natural gas processing plants, and EPA should adopt a similar approach in NSPS OOOOc.

The commenter (1391-INGAA) suggests that where a shutdown or a blowdown is not needed to make the repair, then at least 30 days from receipt of all of the parts is needed to make the repair. This amount of time is needed to ensure operators have adequate time to develop a plan that ensures safety, minimizes system disruptions, and manages the necessary logistics. The commenter provides a list of requirements to ensure the safe installation of replacement parts in their comment. Some requirements include a pre-job safety analyses and accounting for extreme weather.

---

<sup>288</sup> 87 FR 74737-74740 (December 6, 2022).

<sup>289</sup> 87 FR 74816 (December 6, 2022).

<sup>290</sup> See 48 Fed. Reg. 279, 289-90 (Jan. 4, 1983); 40 C.F.R. § 60.481a; 40 C.F.R. §§ 60.481a, 60.5430.

The commenter (1391-INGAA) recommends that regarding delay of repair, an identical approach to an amendment to NSPS OOOOa be followed due to availability of parts in NSPS OOOOc. EPA is proposing to amend NSPS OOOOa to allow repairs in the transmission and storage segments that require a shut down or blowdown to be delayed until the next scheduled shutdown for maintenance, not to exceed two years from discovery of the leak. In situations when the repair in question would require a shut down or blowdown, instead of adhering exclusively to a “30-day from date of receipt” repair requirement for delays based on acquisition of replacement parts, EPA should allow for such repairs to be made during the next scheduled shutdown for maintenance, not to exceed two years from discovery of the leak. Such an approach has the benefit of avoiding unnecessary blowdown emissions.

Similarly, commenter (0815-American Gas Association (AGA)) requests that EPA allow for lead times needed to obtain certain types of parts. The commenter states that operators should not be penalized for circumstances they do not control, and imposing penalties will not reduce emissions where a repair simply cannot be performed until a part is received. The commenter requests that EPA provide in the regulatory text for revised NSPS OOOOa and new EG OOOOc that where no shutdown or blowdown is needed, the operator should repair the leak within 30 days after receiving the parts. The commenter also requests that where a repair requires a shut down or blowdown, the regulatory text should allow the repair to be performed during the next scheduled shutdown for maintenance after receipt of the requisite parts, not to exceed two years. Again, according to the commenter, this will avoid unnecessary blowdown emissions.

Commenter (1391-INGAA) suggests that limiting the availability of the delay of repair for replacement parts will not have a beneficial effect. The delay envisioned by this provision would be to account for the *unavailability* of the means by which to make a repair in the allotted timeframe. It is not intended to alleviate a burden, create efficiencies, or manage challenging logistics, all of which are themselves appropriate reasons for providing delay of repair relief.

The commenter (1391-INGAA) states that the purpose of the replacement part delay of repair provision is to ensure that companies are not penalized for circumstances they cannot control or alter. Indeed, a rule that would impose such consequences is arguably arbitrary and contrary to EPA’s authority. Including the replacement part delay of repair provision would therefore strengthen any final EPA rule. Accordingly, because a limit on the replacement part delay of repair provision, even one based on the severity of the leak, would do nothing to speed the repair or change the availability of the necessary replacement part, such limits are not appropriate or useful.

Response I-7-122: In response to these comments, and consistent with the delay of repair provisions related to equipment leaks from equipment located at onshore natural gas processing plants, as well as amendments to NSPS OOOOa that the EPA is finalizing at 40 CFR 60.5397a(h)(3), the final rule for NSPS OOOOb and NSPS OOOOc includes delay of repair provisions based on the unavailability of parts. As described by the commenter, and in previous comments on amendments to NSPS OOOOa, there are exceptional circumstances that do occur where the repair cannot be completed successfully without replacement of a part that requires custom fabrication. In the previous response to this request for the 2020 Technical Rule, the EPA stated our belief that lack of availability of parts was not sufficient justification to allow for

delayed repairs, however, the exceptional circumstances referenced by commenters and the supply chain delays experienced as a result of the pandemic have highlighted that a delay of repair may be needed for rare circumstances beyond an owner or operator's control.<sup>291</sup>

## **7.2 Alternative Screening Using Advanced Measurement Technology**

### ***7.2.1 General Comments and Support***

Comment: Several commenters (0391-KBIC, 0401-Mercy, 0434-Impax, 0435-Wespath, 0437-NYOSC, 0458-Maryland Department of the Environment (MDE), 0558-Center for Climate and Energy Solutions (C2ES), 0570-Konica, 0579-Chevron, 0592-Citizens United for Responsible Energy Development (CURED), 0610-Occidental (Oxy), 0756-Baker Hughes, 0766-Cheniere, 0770-NPRC, 0777-Ascent, 0782-BHE, 0787-Atmos Energy Corporation (Atmos), 0807-BP, 0808-API, 0820-Pioneer, 0831-AXPC, 0832-New Mexico Environmental Department (NMED), 0844-EDF *et al.*, 0926-Austin Energy *et al.*, 0932-GHGSat, Inc., 0915/1290-Bridger Photonics, 0940-Responsible Drilling Alliance (RDA), 1372-Generate Capital, 1382-National Grid) are strongly supportive of EPA's consideration to include advanced technology alternatives.

Commenter (0437-NYOSC) notes that several investors call for support for the development and deployment of innovative technologies for methane emission mitigation.

Commenter (0782-BHE) recommends that EPA initiate a program to support technology and leak mitigation program development and standardization, rather than simply adopt new approaches. The commenter recommends that EPA could address the challenges related to ensuring data integrity from leak detection and mitigation programs during the program development, such as standard methods and equivalency definitions for measurement and monitoring technologies; and standard practices and procedures (*e.g.*, training, certification) for implementation.

Commenter (0782) requests that EPA clarify how precedent established by the proposed Appendix K would relate to community-based monitoring and emerging sensor technologies. The commenter states that EPA should state how the level of rigor required by Appendix K will be reconciled against stated objectives in the proposed rule identifying and promoting advancements in leak detection including remote sensing, sensor networks, satellite measurements, methane sensors, truck based, continuous, aerial technologies and other alternatives to Method 21. The commenter recommends that EPA should apply equal rigor for all applications, however, the commenter warned the proposed Appendix K may establish an onerous precedent. The commenter urges that EPA should explicitly discuss a strategy for assessing accuracy, developing methods, and establishing rigor for future leak detection technologies and applications, such as stakeholder or community monitoring using advanced sensor technologies.

---

<sup>291</sup> See *Oil and Natural Gas Sector: Emission Standards for New, Reconstructed, and Modified Sources Reconsideration*, 40 CFR Part 60, subpart OOOOa, *Response to Public Comments on Proposed Rule* [83 FR 52056, October 15, 2018]. pgs. 8199-8200.

Commenter (0807-BP) voluntarily deploys advanced monitoring programs that monitor all operated assets. Given their deployment of multiple detection technologies, operators are able to survey the commenter's assets more frequently, and in some instances at a lower cost per wellsite than LDAR programs. For example, by leveraging these different technologies at varying frequencies, operators are able to inspect all the commenter's U.S. onshore operated assets quarterly and more frequently inspect an increasing percentage of their entire U.S. onshore portfolio.

Commenter (0592-CURED) urges the EPA to permit and even facilitate experimentation with new technologies so their development will be accelerated. Regarding leak detection for example, larger producers (such as Jonah Energy) can afford to pilot continuous monitoring that ultimately can reach better emission controls, and they should be incentivized to do so, not discouraged by overly prescriptive requirements. Smaller companies may still need to be required to have minimum monitoring.

Commenter (0820-Pioneer) believes that EPA should explicitly allow in this rulemaking for alternative means of compliance, which can also be conceptualized as alternative work-practice standards, rather than relegating all such issues to the AMEL process under CAA section 111(h)(3). If EPA allows these technologies to be used, operators will be able to identify and correct issues well before periodic site-by-site surveys may find them -resulting in significant emission reductions. The only current avenue in the CAA for operators and/or manufacturers or vendors to seek approval to use an alternative technology is in EPA's AMEL process in section 111(h) of the CAA. Although significantly improved upon in the 2020 Technical Rule, the process has historically been ambiguous and complicated with no alternative certifications being granted thus far. Therefore, the commenter suggests having a means by which to use an alternative technology outside of the statutory AMEL process, will be extremely helpful and allow operators to capitalize on these technologies to reduce emissions at competitive costs.

Commenter (0831-AXPC) believes that there is sufficient evidence to show that several screening and monitoring technologies on the market today are capable of detecting fugitive emissions from affected sources as well as, if not better than, periodic surveys using OGI or EPA Method 21. Further, some technologies have been shown to detect certain types of emissions that OGI has missed, particularly in field deployment comparisons and across larger areas.

Commenter (0832-NMED) believes EPA should consider allowing technologies that provide quantifiable, verifiable, and consistent monitoring and compliance data at a scale that can accommodate large remote regional areas consisting of hundreds or even thousands of facilities.

Commenter (0926-Austin Energy *et al.*) states companies throughout the natural gas supply chain are gaining experience with advanced methane detection technologies. The commenter recognizes the potential value many of these technologies could provide and supports EPA's efforts in the November 2021 Proposal to recognize innovative alternative methane detection technologies that are demonstrated to be as effective as existing approaches. Through compliance with the existing federal methane regulation, the industry has demonstrated that it can reduce methane emissions at a reasonable cost using available technologies and strategies.

Commenter (0458-MDE) notes that Maryland's recent regulations for controls in the natural gas sector, final effective on November 16, 2020, can provide a basis for their suggested improvements to the November 2021 Proposal. The commenter supports innovative advanced technologies to discover fugitive emissions, and Maryland regulations allow for an alternative LDAR approval, however, none of the four companies operating in Maryland have requested this alternative and meet their LDAR requirements with the use of OGI and supplemental EPA Method 21.

Commenter (0940-RDA) supports the alternative screening program and specifically requests that EPA consider the following:

- Determine the actual benefits, not simply the hypothetical benefits, of OGI, and acknowledge its limitations.
- Use rigorous benefit-cost analysis to fairly compare alternative screening methods to OGI.
- Reduce the rigidity of EPA regulations that currently inhibit the introduction of new technology into the realm of methane emission detection.
- Use the teachings of increasing abundant literature on aerial surveillance of oil and gas facilities to further tighten limits on permitted vents.

Commenter (1372-Generate Capital) suggests that the regulation ensures that emissions reporting is independently carried out and verified by third parties; and ensures that emerging technologies including aerial surveys, continuous monitoring, and satellite imaging are acknowledged as viable technologies to measure fugitive methane emissions as soon as they achieve EPA data quality thresholds. The commenter recommends EPA consider creating a task force made up of leading companies in the sector as well as monitoring technology innovators, leading academics, and other experts from civil society to identify where further improvements in technology deployment and regulation can be made. Such a task force could also facilitate the sharing of best practices such that the level of ambition can be raised continuously over time as cost-effectively as possible.

Response I-7-123: EPA acknowledges the commenters support for the use of alternative technologies.

Comment: Commenters (0756-Baker Hughes, 0811-ABB Inc. (ABB)) argue alternative technologies should be the fugitive monitoring standard above OGI and EPA Method 21 techniques.

Commenter (0811-ABB) argues the November 2021 Proposal's reliance (or emphasis) on OGI as the technology 'standard' limits the rule's overall effectiveness. OGI indirectly detects methane, in this case, through air temperature changes perceived at a specific wavelength of light. The resulting images may be dramatic for large, leaks emanating from small holes or from rapidly propagating gas plumes. Unfortunately, OGI signals can be confounded by nearby structures at temperatures different from ambient air, local weather, sunlight, or if the source is underground. Even large plumes, if moving slowly, will not be detected by OGI and since OGI is over 100 times less sensitive than current laser-based methods, OGI will miss many leaks that

otherwise would be detected. Moreover, as documented by Methane Emissions Technology Evaluation Center (METEC) scientists, reliable OGI measurements require expert training. Basing the rule on OGI is problematic both as it is used to determine which obligations apply to designated facilities as well as the supplemental technology to be used annually to ensure that smaller leaks are detected.

Response I-7-124: EPA cannot base the BSER on advanced methane detection technologies, as no such technologies have yet been approved for use by EPA.

EPA acknowledges the commenters concerns on the limitations of OGI and notes that all technologies are subject to certain limitations. OGI camera operators can have difficulty finding leaks if they do not use proper survey technique. As long as OGI camera operators are properly trained and use adequate survey techniques, which include dwelling on equipment for an appropriate amount of time, ensuring appropriate thermal backgrounds, looking at equipment from multiple angles, and accounting for interferences, EPA has no reason to believe that the operator will not find fugitive emissions that exist.

EPA has sought to propose a reasonable pathway to allow for the use of technology other than OGI for the fugitive program in the December 2022 Supplemental Proposal. See discussion in section IV.B of the December 2022 Supplemental Proposal related to advanced methane detection technologies<sup>292</sup>. Please also see section XI.B of the preamble to the final rule which details EPA's final standards related to advanced methane detection technology.

Comment: Commenter (0811-ABB) adds that advanced technology records measurements at a specific physical point. This allows minimally trained surveyors to detect and pinpoint leaks quickly, efficiently, and without the margin of error of other technologies. This saves companies time and cost and reduces the complexity inherent in the use of costly and delicate OGI cameras.

Response I-7-125: EPA acknowledges the commenters support for the use of alternative technologies. EPA has taken this comment into account as they designed the alternative technology program in the December 2022 Supplemental Proposal. See discussion in section IV.B of the December 2022 Supplemental Proposal related to advanced methane detection technologies<sup>293</sup>. Please also see section XI.B of the preamble to the final rule which details EPA's final standards related to advanced methane detection technology.

### ***7.2.2 Advanced Technologies***

Comment: Commenter (0844-EDF *et al.*) states a broad range of advanced methane monitoring technologies are available and can be utilized by operators to detect, pinpoint, and quantify fugitive emissions.<sup>294</sup> Over the past decade, rapid innovation has led to a diverse array of advanced methods: there are now at least 100 distinct methane measurement technologies that

---

<sup>292</sup> 87 FR 74740-74744 (December 6, 2022).

<sup>293</sup> 87 FR 74740-74744 (December 6, 2022).

<sup>294</sup> *Id.*

are commercially available for leak monitoring in the oil and gas industry.<sup>295</sup> Detection capabilities vary greatly and typically increase with proximity to the emission source. However, technologies that monitor from farther away, like aircraft and satellites, are usually much faster and can cover broad geographic areas frequently.<sup>296</sup>

The commenter (0844-EDF *et al.*) states a comprehensive monitoring program that utilizes both screening and close-range technologies is likely to be highly effective.<sup>297</sup> In this type of program, screening technologies are used to monitor across broad geographic areas frequently to quickly detect the largest emission sources. Close-range methods are used for both directed follow-up to pinpoint emission sources detected during screening and to routinely monitor sites for smaller leaks that would not be detected by screening methods. Typically, screening surveys cannot identify leaks at the component level nor distinguish permissible, vented emissions from fugitive and abnormal emissions. To diagnose and repair leaks, most screening methods must be paired with close-range systems. Differentiating between leaks and venting requires planning and recordkeeping to match detected emissions to planned venting events.

Commenter (0844-EDF *et al.*) states, in general, detection sensitivity declines with spatial scale of measurement, meaning those farthest from the source will be less able to detect smaller emissions. However, there is typically a trade-off between sensitivity and survey speed, and the cost of deployment tends to decline as speed increases. For example, aerial surveys with high detection limits are low cost and can quickly cover broad areas but will only detect the largest emission events, missing smaller leaks.

The commenter (0844-EDF *et al.*) states a major outstanding challenge for screening technologies is their inability to discern vented from fugitive emissions.<sup>298</sup> Under most regulations, including EPA's November 2021 Proposal, venting is authorized in certain limited circumstances, creating potential problems for screening approaches. Detection of permissible high-emission events during screening could trigger follow-up ground surveys for events like blowdowns or tank flashing. Needless searching for these events may increase the cost of screening and disincentivize use of advanced technologies. Reducing instances of permissible emissions through other regulatory standards would alleviate much of this problem, as eliminating permissible venting would enable screening techniques to become more sensitive to the presence of fugitive emissions. Moving toward zero emission standards across the full range of affected facilities could eventually eliminate this issue entirely. Another solution is to reduce detections by screening only for sources that greatly exceed venting limits, relying on ground-based monitoring to resolve smaller events. Rigorous reporting and notification of large events would also allow operators and regulators to know when a high emission event was planned and avoid sending follow-up ground crews if advanced screening detected planned emissions.

---

<sup>295</sup> Highwood Emission Management, Technical Report: Leak detection methods for natural gas gathering, transmission, and distribution pipelines (2022) <https://highwoodemissions.com/pipeline-report/> [hereinafter "Highwood 2022"].

<sup>296</sup> *Id.*

<sup>297</sup> Fox et al., A review of close-range and screening technologies for mitigating fugitive methane emissions in upstream oil and gas, 14 *Env. Res. Letters* 53002 (2019), <https://iopscience.iop.org/article/10.1088/1748-9326/ab0cc3>.

<sup>298</sup> *Id.*

The commenter (0844-EDF *et al.*) states methane detection methods differ not only in performance but also in the types of sources that can be identified and how these sources are characterized. For example, a recent study using aerial surveys identified far fewer—but much larger—sources than handheld surveys performed at the same time (39 vs 357 sources, respectively).<sup>299</sup> Many of the leaks found during the handheld survey were too small to be seen by aircraft, while many of the largest emission events occurred at a small number of sites and may have been missed during the ground inspection. This indicates that full coverage of a system is most effective with multiple technologies. Simulation studies have shown that a combination of technologies can be effective under the right circumstances.<sup>300</sup>

The commenter (0844-EDF *et al.*) states technologies include deployment platforms and sensor types, while methods include the work practices and follow up procedures. Understanding the methods in combination with a technology is critical when evaluating performance.<sup>301</sup> For example, larger emissions detected during screening must be paired with shorter repair timelines in order to achieve substantial reductions. For certain recurring or major emission events, engineering analysis might be required to diagnose and fix the underlying operational issues. Varying dispatch thresholds for follow-up is another work practice that can greatly influence the effectiveness of an approach. For example, if follow-up and repair is only required for the largest leaks, overall mitigation effectiveness will be lower than a work practice requiring follow-up on all detected leaks.

The commenter (0844-EDF *et al.*) states technologies typically consist of deployment platforms and sensors. Deployment platforms can be broadly classified into the following categories (the commenter provides additional details on each deployment platform in the commenter's letter):

- Aircraft
- Unmanned Aerial Vehicles (UAVs)/Drones
- Mobile Ground Labs (MGLs)
- Continuous Monitoring
- Satellites

The commenter (0844-EDF *et al.*) indicates that sensing modes include point measurement of ambient mixing ratios, path integrated laser-based measurements (active imaging), and column-integrated passive imaging. Sensing modes can be broadly categorized as follows (the commenter provides additional details on each sensing mode in their commenter's letter):

- Point sensing (in plume sensing)
- Active imaging (remote sensing)
- Passive imaging (remote sensing)

<sup>301</sup> See id.

- Non-methane

Response I-7-126: EPA acknowledges the commenter's support for the use of alternative technologies. See section IV.B.1 of the December 2022 Supplemental Proposal.<sup>302</sup> Please also see discussion in section IV.B of the December 2022 Supplemental Proposal related to advanced methane detection technologies<sup>303</sup>. Please also see section XI.B of the preamble to the final rule which details EPA's final standards related to advanced methane detection technology.

Comment: Commenter (0932-GHGSat, Inc.) agrees that quantification is an important step in understanding the behavior of the emissions as well as understanding their impact by quantifying the amount that is lost to the atmosphere. In turn, this can help in getting more accurate emissions inventories and having true metrics to compare against the reported progress made in the regional and national commitments on methane reduction. The commenter understands that not all available technology can quantify emissions, including the incumbent OGI technology. Some progress has been made by third-party companies in trying to provide a range of emissions rate based on the different overlays and algorithms masking the OGI reading to interpret the rate. Therefore, technology that is capable of both identifying and quantifying methane emissions, is of the utmost relevance in this regulation.

Commenter's (0932-GHGSat, Inc.) operational satellites and aircraft are capable of meeting this requirement today, as these platforms can detect and quantify methane emissions using peer-reviewed methodologies. In addition, the commenter has a machine learning/artificial intelligence analytics platform that is constantly analyzing vast amounts of data (*i.e.*, big data), with the intention of characterizing each region (in a 2 km-by-2 km grid) and provide current and forecasted data to generate actionable insights. When using the two monitoring platforms in tandem with analytics as part of a facilities' monitoring plan, a robust tiered system is created that allows for frequent monitoring of relevant leaks, while ground inspections can be used as part of maintenance plan rather than a regulatory/enforcement plan.

Response I-7-127: EPA acknowledges the commenter's support for the use of alternative technologies. See section IV.B.1 of the December 2022 Supplemental Proposal.<sup>304</sup> See discussion in section IV.B of the December 2022 Supplemental Proposal related to advanced methane detection technologies<sup>305</sup>. Please also see section XI.B of the preamble to the final rule which details EPA's final standards related to advanced methane detection technology.

#### 7.2.2.1 Drones/UAVs

Comment: Commenters (0729-Energy Workforce & Technology Council (EWTC), 0785-John Crane Inc., 0844-EDF *et al.*) discuss the capabilities of UAVs, which have been shown effective in detecting emissions in the oil and gas field.

---

<sup>302</sup> 87 FR 74740 (December 6, 2022).

<sup>303</sup> 87 FR 74740-74744 (December 6, 2022).

<sup>304</sup> 87 FR 74740 (December 6, 2022).

<sup>305</sup> 87 FR 74740-74744 (December 6, 2022).

Commenter (0844-EDF *et al.*) makes the point that like manned aircraft, UAVs/drones are not restricted to roads and can complement close-range methods by reaching dangerous or inaccessible places. Some UAV systems use point measurement technologies that directly measure methane concentrations. These point measurement UAVs are often more sensitive than aircraft techniques because of their ability to fly closer to the methane source. The primary limitations for this technology are weather, the distance from the operator, and the relatively short flight times of a few hours (at most). The minimum detection limits for UAVs are in the component-to-equipment-level range of spatial resolution. This technology is readily available and has undergone multiple controlled release tests to verify performance metrics.<sup>306</sup>

Commenter (0785-John Crane Inc.) states UAVs are well suited for proximity ground detection of leaks, quantification, and are unique in their ability to be detect emissions offshore, where aerial technologies are currently incapable. Through the commenter's partnership with SeekOps, they can monitor emissions offshore and offer highly accurate quantification in a variety of environments. When necessary, aircraft or UAV mounted emissions detection can be complemented with stationary or mobile ground technology for a variety of installations, such as gas pipelines, to validate the precise source of emissions.

Commenter (0729-EWTC) notes that since 2018, a team has been utilizing drones equipped with methane detection cameras and sensors in the Permian Basin. It has conducted over 1,000 inspections using drones and drone-mounted sensors, combined with an artificial intelligence (AI) enabled software platform. This effort is contributing to meeting an operator's goals of maintaining methane emissions intensity below 0.2 percent by 2025 and meeting the requirements of the Oil and Gas Methane Partnership (OGMP) 2.0 framework.

Response I-7-128: EPA acknowledges the commenter's support for the use of alternative technologies. See section IV.B.1 of the December 2022 Supplemental Proposal.<sup>307</sup> Please also see section X.B of the preamble to the final rule which details EPA's final standards related to alternative technologies.

#### 7.2.2.2 Aerial

Comment: Several commenters (0756-Baker Hughes, 0785-John Crane Inc., 0826-Kairos Aerospace, 0844-EDF *et al.*, 0915/1290-Bridger Photonics, 0934-Leak Surveys, Inc.) provide detailed information on their aerial technology, including capabilities, limitations and recommended methodologies to be considered under EPA's framework for alternative technologies.

Commenters (0756-Baker Hughes, 0785-John Crane Inc., 0934-Leak Surveys, Inc.) believes aerial technologies provide enough granularity with respect to site level details to distinguish emissions among different assets.

Commenter (0785-John Crane Inc.) believes aircraft mounted surveying offers greater resolution and more flexible monitoring options than satellite, although satellite technology offers high-

---

<sup>306</sup> Id.

<sup>307</sup> 87 FR 74740 (December 6, 2022).

level detection of large and super-emitters and low-cost complementary features for the ongoing monitoring of identified emissions. Aircraft mounted leak detection provides economical cover of large geographies against consistent benchmarks. Aircraft mounted surveys are lower cost on a per asset basis, safer (*i.e.*, operators do not need to stand close to the highly flammable methane) and more consistent to use than handheld devices.

The commenter (0756-Baker Hughes) adds for manned or unmanned aerial inspection, OGI or otherwise, multiple companies could share the costs of one flight that covers multiple sites. Site-specific data could then be provided to each asset owner individually.

Commenter (0826-Kairos Aerospace) reports that Kairos Aerospace LeakSurveyor™ system is a light-aircraft mounted, integrated methane gas imaging system capable of detecting medium to large-scale methane emissions. According to the company, the system consists of three integrated measurement devices:

1. An infrared spectrometer calibrated to detect methane,
2. GPS and inertial measurement unit (IMU) to record precise position; and
3. A high-resolution optical camera for visual verification of sites.

The commenter (0826-Kairos Aerospace) notes that the LeakSurveyor™ when mounted on an aircraft can survey up to 150 square miles per day with 3x3 meter methane spatial resolution, detecting emissions at the equipment group and occasionally at the individual equipment scale. Depending on the development density, this could represent thousands of oil and gas facilities per day and hundreds of miles of pipeline. In their comment letter, the commenter provides additional technical details about how the technology detects methane, how data is processed and analyzed, and how methane data is combined with precise location. The combination of data allows the operator to determine the location and likely source of the methane plume while providing important contextual information about ground activity that might be contributing to emissions, such as well maintenance.

Response I-7-129: The EPA acknowledges the commenter's remarks regarding the capabilities of aerial technologies. In response to comments received on the November 2021 Proposal, the EPA proposed an alternative fugitive emissions monitoring and repair program for new, modified, or reconstructed fugitive emissions sources (*i.e.*, collection of fugitive emissions components located at well sites, centralized production facilities, and compressor stations) in the December 2022 Supplemental Proposal (See discussion in section IV.B of the December 2022 Supplemental Proposal related to advanced methane detection technologies.<sup>308</sup>). These changes include a proposed “matrix” which would specify different screening frequencies corresponding to a range of minimum detection thresholds, in contrast to the single screening frequency and detection level proposed in the November 2021 Proposal. The final rule maintains these requirements mostly as proposed in the December 2022 Supplemental Proposal, with certain edits to the matrix based on additional conducted following the December 2022 Supplemental Proposal.

---

<sup>308</sup> 87 FR 74740-74746 (December 6, 2022).

Please also see section X.B of the preamble to the final rule which details EPA's final standards related to advanced methane detection technologies, which includes matrices of minimum detection thresholds of screening technologies and the corresponding minimum screening frequencies.

Comment: Commenter (0826-Kairos Aerospace) provides test results conducted by Stanford University using the Kairos' LeakSurveyor™ in October 2019. Specific information regarding the test itself is available in the commenter's letter. The commenter notes that the final data points and release rates were as follows:

- 35 points below 25 kg/hr-mps wind to assess minimum detection threshold.
- 21 points at 0 kg/hr to assess false positives.
- 165 points above 25 kg/hr-mps wind.

The commenter (0826-Kairos Aerospace) reports that LeakSurveyor™ detected 182 of 200 valid nonzero releases and had no false positives in the 21 negative controls, resulting in an overall detection accuracy of 91.9 percent, with 100 percent detection accuracy for releases above 15 kg/hr/mps wind.<sup>309</sup> The researchers further determined that the 50 percent probability of detection threshold likely occurred between 8.3 and 15 kg/hr/mps. In addition, Kairos' LeakSurveyor™ demonstrated a high level of quantification performance, even without on-the-ground wind measurements and low bias compared to past controlled releases for mobile methane detectors.<sup>310</sup>

The commenter (0844-EDF *et al.*) states passenger aircraft, both planes and helicopters, can be equipped with various sensor technologies and used at various elevations and frequencies. These factors, along with the survey methodologies used, affect survey speed and minimum detection limit. Some aerial technologies or methods may use remote sensing and fly higher and faster or use a technology with a lower sensitivity to cover more sites in a day. Other aerial technologies and methodologies may call for lower and slower flights or use a technology with a higher sensitivity that detects more emission events but covers fewer sites in a day.<sup>311</sup>

The commenter (0844-EDF *et al.*) states the primary limiting factors for aerial methods are weather (high winds, precipitation, cloud cover), variable reflectivity from uneven snow cover, and flight permits. Aircraft detection limits range from a few kilograms of methane per hour to tens of kilograms per hour. This technology is readily available and has undergone multiple, controlled release tests to verify performance metrics. The main advantage of aircraft technologies is the greater geographic coverage, which allows surveying of thousands of sites per day (depending on the infrastructure density). Although aircraft systems are less sensitive than other systems, some aircraft are able to cover large geographic regions rather than targeting only specific sites. This makes it possible to survey entire landscapes for large methane sources that may not otherwise be detected by targeted, site-specific inspections.

<sup>309</sup> Sherwin et al. 2021.

<sup>310</sup> Id.

<sup>311</sup> Id.

Commenter (0915/1290-Bridger Photonics)<sup>312</sup> has commercialized its aerial light detection and ranging (LiDAR) technology, Gas Mapping LiDAR™, in 2019 as a data product offering, which has been rapidly and broadly adopted by the oil and gas industry in North America over the past three years. The commenter provides a companion document representing a suggested methodology for identification of fugitive methane emissions using aerial remote sensor technology. The commenter hopes the suggested methodology can be used as a framework from which the EPA can construct a comprehensive methodology to support the November 2021 Proposal's alternative work practice using aerial scanning technology.

The commenter (0915/1290-Bridger Photonics) states this protocol is applicable to the detection of methane and, by surrogate, VOC including HAP, and hydrocarbons, such as ethane, propane, and butane. This protocol covers the responsibilities of operators under the protocol regarding aerial remote sensing scans of process equipment in oil and gas upstream and downstream sectors (from production to refining to distribution). The specific component focus for the scans is determined by the applicable subpart, and can include, but is not limited to, valves, flanges, connectors, pumps, compressors, open-ended lines, pressure relief devices, and seal systems. This protocol is applicable to all facility types from the upstream and downstream oil and gas sectors and may apply to well heads, compressor stations, boosting stations, petroleum refineries, gas processing plants, and gasoline distribution facilities when referenced by an applicable subpart. This protocol is intended to help determine the presence and location of methane and VOC leaks.

In a companion letter, the commenter (0915/1290-Bridger Photonics) provides information representing a suggested methodology for identification of fugitive methane emissions using aerial remote sensor technology.<sup>313</sup>

Commenter (0934-Leak Surveys, Inc.) states Aerial OGI (AOGI) has improved greatly over the last year and is now as effective as a ground survey on well pads and tank batteries. According to the commenter, AOGI surveys are different in that in each assessment the operator can identify each distinct component that is leaking (*e.g.*, leaking components around well sites and tank batteries and leaks from packing valves or gas emitting to the outside of a compressor building or compressor vents on blowdown.)

The commenter (0934-Leak Surveys, Inc.) provides an overview of the technology which is a new high-definition OGI camera and a stabilized gimble, which in combination provides the ability to use the digital zoom features of the camera and allows us to image individual components if needed. This concept is new to the industry and was only introduced to the industry in July of 2021. According to the commenter, AOGI is also the most inexpensive means to conduct a survey if the operator has wells that are in close proximity to each other or if operators cost-share expenses across well sites or fields. The cost associated with AOGI can run as low as \$100 per site, and because of the quality of the video recordings collected there would

---

<sup>312</sup> U.S. Department of Health and Human Services. (2010). NIOSH Pocket Guide to Chemical Hazards. NIOSH Publication No. 2010-168c. Also available from <https://www.cdc.gov/niosh/docs/2010-168c/default.html>.

<sup>313</sup> Companion to Comment Letter: Suggested Aerial Remote Sensor Methodology Pertaining to EPA Proposed Rule – Standards of Performance for New, Reconstructed, and Modified Sources and Emissions Guidelines for Existing Sources: Oil and Natural Gas Sector Climate Review (86 Fed. Reg. 63110).

be no need to perform a follow-up OGI ground survey, unless the component leaking is not visible in the video. The technology is fast and easy and has the ability to cover approximately 50,000 acres per day and (or) survey a range of 80-130 tank batteries in a single day. Because the information is acquired in real time, the camera operator can immediately notify the operator if a large emission is present or if a flare is malfunctioning; giving the operator the ability to send a field technician to the site for immediate repair. All videos are process within 24 hrs and sent back to the production superintendents for quick repair.

Response I-7-130: In response to comments received on the November 2021 Proposal, the EPA proposed an alternative fugitive emissions monitoring and repair program for new, modified, or reconstructed fugitive emissions sources (*i.e.*, collection of fugitive emissions components located at well sites, centralized production facilities, and compressor stations) in the December 2022 Supplemental Proposal (See discussion in section IV.B of the December 2022 Supplemental Proposal related to advanced methane detection technologies.<sup>314</sup>). These changes include a proposed “matrix” which would specify different screening frequencies corresponding to a range of minimum detection thresholds, in contrast to the single screening frequency and detection level proposed in the November 2021 Proposal. In addition, EPA proposed to allow owners and operators the option of using continuous monitoring technologies as an alternative to periodic screening and proposed long- and short-term emission rate thresholds that would trigger corrective action. The EPA also proposed monitoring plan requirements for owners and operators that chose to implement the alternative fugitive emissions monitoring approach and proposed to establish a clear and streamlined pathway for technology developers and other entities to seek the EPA’s approval for the use of advanced measurement technologies under this alternative option. The final rule maintains these requirements mostly as proposed in the December 2022 Supplemental Proposal, with certain edits to the matrix based on additional conducted following the December 2022 Supplemental Proposal.

For periodic screening using advanced methane detection technology, the final rule allows for the use of multiple detection technologies, instead of requiring the owner or operator to choose one technology, allowing end-users to optimize their periodic screening program by choosing the most suitable technology based on time of year and availability of technology providers. The periodic screening frequency will be based on the technology with the highest aggregate detection threshold that the owner or operator lists as a technology they plan to use in their monitoring plan.

Please also see section X.B of the preamble to the final rule which details EPA’s final standards related to advanced methane detection technologies, which includes matrices of minimum detection thresholds of screening technologies and the corresponding minimum screening frequencies.

#### 7.2.2.3 Other Technologies

Comment: Several commenters (0429-Picarro, Inc., 0748-American Fuel & Petrochemical Manufacturers (AFPM), 0844-EDF *et al.*) urge EPA to incorporate flexibility under the

---

<sup>314</sup> 87 FR 74740-74746 (December 6, 2022).

alternative technologies program and provide information on additional technologies that are capable of identifying and detecting methane emissions.

Commenter (0429-Picarro, Inc.) believes Advanced Mobile Leak Detection (AMLDD) is an important part of the solution set that operators need to identify and quantify methane emissions. A suite of technologies is needed to address the methane emission identification and quantification for the upstream and midstream sectors, for which no single tool will suffice because of several factors such as density of assets, limitations of resolution and sensitivity, and lack of proven results and accuracy for the various technologies. The commenter highlights AMLDD's comparative benefits to other measurement technologies:

- Greater accuracy and higher efficiency than traditional methods.
- Capable of more rapid deployment than alternative technologies.
- Sensor technology is less susceptible to weather-related interference than other technologies.
- Greater versatility and effectiveness than fixed-site technologies with comparable sensitivity.
- Higher resolution visualization technology for identifying and grading emission sources
- Compatible with other technologies to provide a more complete and effective solution.

The commenter (0429-Picarro, Inc.) believes it is critical for EPA to adopt a definition for AMLDD that reflects currently available technology. In their comment letter, the commenter discusses the key attributes of AMLDD technology, including a high methane sensitivity, the ability to use of the weather parameters combined with GPS technology for determining leak location, emission rate, and survey coverage areas, as well as their analytics and models used produce reliable and actionable leak survey and methane emissions data.

The commenter (0429-Picarro, Inc.) reports that their AMLDD technology solution is a proven and viable vehicle-mounted system that conducts multiple patrols through a natural gas infrastructure, collecting methane plume data and sending it to the Picarro analytics platform. The Picarro AMLDD system identifies the characteristic signatures of natural gas leaks by analyzing the methane plumes as they propagate in the atmosphere and intersect with the path of the vehicle. The system also measures atmospheric and meteorological conditions and uses algorithms to identify the origin and degree of hazard of the natural gas leak indication while virtually eliminating indications triggered by other non-natural gas sources of methane. The AMLDD technology solution should be able to accurately quantify emission rates.

According to the commenter (0429-Picarro, Inc.), more than 60 double-blind, directed field trials with 33 operators across North America, Europe, Asia, and Australia, several involving independent, third-party validation by Gas Technology Institute, NYSEARCH, Pipeline Research Council International, Inc. and others, the Picarro solution consistently found 3 times more grade 1 and grade 2 leaks than traditional survey techniques.

The commenter (0429-Picarro, Inc.) believes AMLDD is more effective than traditional leak survey at identifying gas leaks because it reduces human error, eliminates errors associated with asset record inaccuracies, and employs a more sensitive sensor.

Commenter (0748-AFPM) indicates that there are other emerging technologies being developed. One such technology is leak detection sensor network (LDSN).<sup>315</sup> The EPA should place a discussion in the preamble language encouraging such LDAR alternative technology development and the proper means of approval from the EPA for deployment. The commenter (0844-EDF *et al.*) states MGLs are defined as any stationary or mobile ground-based vehicle (car, truck, van, ATV, *etc.*) equipped with a methane sensor and a GPS. Typically, MGLs will also measure environmental conditions, especially wind speed, wind direction, temperature, and humidity. MGLs can take an active or passive approach to surveying. The active approach entails MGLs driving a predetermined route along the infrastructure to be monitored, while the passive approach entails mounting sensing equipment on vehicles performing unrelated tasks, like delivery trucks.<sup>316</sup>

Response I-7-131: EPA acknowledges the commenters support for the use of alternative technologies and recognize that there are many different technologies available. EPA has taken this comment into account as they designed the alternative technology program in the December 2022 Supplemental Proposal. See discussion in section IV.B of the December 2022 Supplemental Proposal related to advanced methane detection technologies.<sup>317</sup> Please also see section X.B of the preamble to the final rule which details EPA's final standards related to advanced methane detection technologies, which includes adoption of flexible frameworks and specific requirements that must be provided in the request for approval of alternative test methods.

### ***7.2.3 Technology-Neutral/Matrix Approach***

Comment: Commenters (0454-Kayros, 0558-C2ES, 0588-Project Canary, 0593-Our Nation's Energy Future (ONE Future), 0604-Providence Photonics, LLC (Providence), 0610-Oxy, 0747-Centre for Smart Emissions Sensing Technologies, University of Calgary (SENST), (0760-Airdar *et al.*, 0765-Institute of Clean Air Companies (ICAC), 0768-Methane Roundtable, 0781-NTAA, 0782-BHE, 0801-Carbon Mapper/RMI, 0807-BP, 0810-Petroleum Alliance-OK, 0814-IPAA *et al.*, 0826-Kairos Aerospace, 0828-Union of Concerned Scientists (UCS), 0830-Devon Energy, 0831-AXPC, 0846-Arolytics Inc., 0922-National Association of Manufacturers (NAM), 0938-TXOGA, 1375-Kinder Morgan, Inc.) believe it is important to emphasize that technologies will continue to be developed in the future to comply with leak detection standards. Some commenters add that it is critical that EPA rules are designed to ensure the standard is technology neutral, which will encourage facility operators to continuously innovate and find better solutions for emissions reduction.

The commenters (0610-Oxy, 0801-Carbon Mapper/RMI, 0807-BP, 0826-Kairos Aerospace, 0938-TXOGA) recommend that EPA adopt a screening protocol with a matrix approach that would allow operators to trade higher frequency sampling and increased spatial coverage for higher detection limits. This flexibility could reduce overall monitoring costs while expanding

---

<sup>315</sup> This technology is mentioned in the October 13, 2021, Federal Register notice, "Notice of Request for Approval of Alternative Means of Emissions Limitation."

<sup>316</sup> *Id.*

<sup>317</sup> 87 FR 74740-74746 (December 6, 2022).

the available pool of monitoring technologies, thus increasing overall detection completeness and mitigation potential.

The commenter (0454-Kayros) states given the respective and inherent limitations of all methane detection technologies, the ideal methane surveillance system must blend inputs from various types of sensors to combine their respective advantages and overcome their limitations.

The commenter (0610-Oxy) encourages a technology-neutral matrix framework that would allow for varying survey frequencies based on the resolution of the technology. This ensures that operators are not limited or restricted in their ability to identify and deploy those technologies that are best suited to their specific assets or operating conditions (*e.g.*, the ability to leverage automation and remote sensing to direct operators to highest priority sites for maintenance, repair, and response.) A technology-neutral approach also better allows for incorporation of future innovation in LDAR technologies.

The commenter (0747-SENST) believes that EPA should undertake detailed research (testing, piloting, and modeling) to develop alternative standards with screening methods. There is unlikely to be a one-size-fits-all standard given the diversity of screening methods. The commenter (0768-Methane Roundtable) recommends EPA address or seek input on the following in the supplemental rule proposal:

- How should EPA develop a compliance and enforcement framework for this rule that ensures consistency across the BSER options and any advanced technology pathways?
- How should EPA use/not use emissions data submitted as part of this rule?
- What tools should EPA use to determine source-specific compliance (*e.g.*, compliance certifications, annual emissions reports, an emissions-based performance standard (“bubble” concept))?
- Should EPA align this CAA section 111 rule with subpart W and ensure that future changes to subpart W will not require subsequent changes to this rule?
- What is the appropriate inspection and survey frequency for maintaining emission reduction progress?
- How should EPA determine whether an emissions detection requires response by an operator to repair the emissions source or whether the emission is permissible (*e.g.*, associated with a maintenance action)?
- How can EPA support the use of a combination of technologies (known by some as “tiered observations”) across regions or operations to assess overall compliance at regional scale?

The commenter (0801-Carbon Mapper/RMI) recommends that EPA adopt a system of systems (tiered observing system) approach that combines the attributes of airborne and satellite remote sensing for detection and quantification of large emission events along with surface sensor networks optimized for identifying lower emission activity across the oil and gas value chain.

Commenter (0814-IPAA *et al.*) believes that adopting a single, one-size-fits-all technology standard for alternative screening technologies is limiting not just to the success of the regulatory design, but also limiting to the development and deployment of domestic technologies aimed at

minimizing the compliance cost to the sector. In the space of alternative leak detection technologies, it is important to employ an outcomes-based regulation, rather than a prescriptive design (*i.e.*, leak detection technology thresholds). Focusing on the intended outcome of the regulation allows for multiple different technologies to be used for leak detection over large geographic areas, while minimizing cost to industry.

The commenter (0814-IPAA *et al.*) encourages the EPA to consider the growth of the technology and service sector in the design of forthcoming regulations. Consider how domestic innovation and employment are impacted by strong regulatory design that is both flexible enough to allow for multiple solutions to be deployed in the field while ensuring that the regulation is achieving its intended environmental impacts. This approach allows the EPA to have strong yet flexible standards that better suit today's technologies as well as future technologies that are being developed.

The commenter (0810-Petroleum Alliance-OK) adds the goal of emission monitoring technologies is to find and fix leaks quickly; however, a mandated, "one-size-fits-all" emission monitoring requirement may not meet that goal or work in every scenario or for every size of operator.

The commenter (0807-BP) encourages EPA to consider an integrative and flexible approach when assessing technologies for regulatory compliance purposes, as different technologies are better suited to different asset types, operations and applications. EPA can maximize the effectiveness of a more flexible monitoring approach by focusing on the desired outcome, as opposed to prescribing specific technology types. By focusing on the outcome, namely emission reductions, EPA can enable operators to leverage multiple technologies and deliver the desired emissions reduction goals in the most cost-effective, safe, and operationally efficient manner.

The commenters (0807-BP, 0831-AXPC) state that by adopting a matrix-based approach, EPA will allow operators to use a variety of technologies and work practices that will achieve a functionally equivalent or better result.

The commenter (0807-BP) adds that a matrix approach also provides EPA with a framework to evaluate future technology options that may not yet exist today, or that may not be commercially viable at scale yet. The commenter believes there are combinations of emissions detection thresholds and inspection frequencies that can achieve equivalent or greater emissions reductions than semiannual and quarterly OGI surveys. For example, LDARSim modelling by Kairos Aerospace, an aerial methane monitoring company, indicates a range of inspection frequencies and minimum detection thresholds that are estimated to be equivalent to the emissions reductions affiliated with quarterly OGI. The results indicate that a technology that monitors more frequently than the current quarterly OGI surveys can have a higher emissions detection threshold and still achieve the same emission reduction results. Therefore, the commenter supports EPA creating a matrix with additional minimum detection thresholds/inspection frequency combinations, including a higher threshold detection technology deployed more frequently.

The commenter (0826-Kairos Aerospace) states Highwood Emissions Management performed an analysis using its LDAR Simulator (LDAR-Sim) model to estimate the emissions reduction performance of a broad range of possible screening LDAR configurations.<sup>318</sup> The commenter argues LDAR-Sim is an improvement over other modeling platforms because it allows for practical considerations that vary by producer, facility, environment, and policy context, such as inspection time, snow cover, cloud cover, and low solar irradiance. It also allows the user to combine multiple inspection programs, such as periodic aerial surveys plus annual OGI inspections. Moreover, LDAR-Sim directly compares emissions under two or more monitoring programs, rather than comparing each program against a null scenario. This is preferable because a true “null scenario” rarely exists in the real world, as operations are already subject to some type of monitoring program.<sup>319</sup> The commenter finds Highwood’s analysis demonstrates that it is feasible to achieve emissions mitigation equivalent to or better than EPA’s proposed quarterly OGI-only program with a range of configurations of aerial survey frequencies and minimum detection limits.

The commenter (0830-Devon Energy) states that given the potential of technologies to effectively detect and reduce the occurrence of significant methane emission events, a matrix approach that couples screening frequency with detection sensitivity, along with appropriate analysis and follow-up, can provide the maximum amount of flexibility and will encourage broader adoption of such technologies. This approach will drive continuous improvement and potentially lead to more effective LDAR programs over time.

The commenter (0846-Arolytics Inc.) states EPA has laid out a “canned” approach to alternative LDAR that is methodology focused. The EPA approach has considered outcomes in its design by listing the required minimum detection limit required for an alternative technology, but the approach itself is not outcome-based. Producers/operators can adopt the approach, or not. For most, the canned alternative LDAR approach is probably more expensive. The commenter believes with the singular canned formula, EPA could be inadvertently selecting for one or two specific aerial technology vendors that meet the defined detection limits and selecting against many other vendors who do substantially better and relegating their businesses to investment plays where they might offer benefit to clients in different contexts.

The commenter (0846-Arolytics Inc.) suggests that based on the EPA formula for alternative LDAR, and looking out at the experience in other jurisdictions, the EPA approach may have several unintended consequences:

- Low uptake by producers who realize that the canned alternative is more expensive for their asset class.
- High uptake by producers who realize that the canned alternative is likely to result in fewer and less expensive repairs, based on their asset class.

<sup>318</sup> Fox, Thomas A., Mozhou Gao, Thomas E. Barchyn, Yorwearth L. Jamin, and Chris H. Hugenholtz, “An AgentBased Model for Estimating Emissions Reduction Equivalence Among LDAR Programs,” *Journal of Cleaner Production*, 282 (2021) 125237 (Available online December 5, 2020). <https://doi.org/10.1016/j.jclepro.2020.125237> (hereinafter, “Fox et al. 2021”).

<sup>319</sup> *Id.*

- Stagnation in the technology space where EPA in effect selects for one or two technology winners that have moderate to low detection capabilities (but high throughput).

Response I-7-132: In response to the comments received on the November 2021 Proposal, EPA proposed a different regulatory approach for alternative screening using advanced methane detection technologies in the December 2022 Supplemental Proposal. For details, please see the discussion in section IV.B.1 of the December 2022 Supplemental Proposal.<sup>320</sup>

Comment: Commenter (1299-Methane Emissions Leadership Alliance (MELA)) believes Alberta Energy Regulator (AER's) Directive 060 strikes a good balance of creating pathways for new technology while maintaining a rigorous enough process to ensure successful environmental outcomes. During the Methane Reduction Oversight Committee process, the commenter indicates that they discussed at length the merits and shortcoming of "outcome based" regulations versus "prescriptive" regulations and the AER determined that a hybrid model was the best approach. Currently, the AER regulations are prescriptive, thereby ensuring that certain facility types are inspected at certain frequencies (based on a triage defined by PTE). However, the AER left open an "outcome based" compliance option for fugitive leak detection called: The Alternative Fugitive Emissions Management Plan (alt-FEMP). The alt-FEMP option has been open to industry for the past year. The process has allowed AER to review and approve multiple new screening technologies for use in the field, with a consistent eye towards ensuring these new technologies do not inhibit the intent of the current regulatory design.

The commenter (1299-MELA) suggests the use of emission mitigation modeling to provide an effective tool to compare technologies and establish programs that will ensure new leak detection solutions are continuing to meet EPA goals and minimizing the cost to industry.

Response I-7-133: In response to the comments received on the November 2021 Proposal, EPA proposed a different regulatory approach for alternative screening using advanced methane detection technologies in the December 2022 Supplemental Proposal. For details, please see the discussion in section IV.B.1 of the December 2022 Supplemental Proposal.<sup>321</sup> Please see discussion in section IV.B of the December 2022 Supplemental Proposal related to advanced methane detection technologies.<sup>322</sup> Please also see section XI.B of the preamble to the final rule which details EPA's final standards related to advanced methane detection technology, which includes the finalization of technology-neutral matrix approach.

Comment: Commenter (0826-Kairos Aerospace) states in order to assess the performance of alternative technologies, EPA and other stakeholders need transparent, independently validated performance data on methane detection systems. This validation is a key first step before any technology should be used to ensure compliance with EPA regulations. The commenter has gone

---

<sup>320</sup> 87 FR 74740 (December 6, 2022).

<sup>321</sup> 87 FR 74740 (December 6, 2022).

<sup>322</sup> 87 FR 74740-74744 (December 6, 2022).

through independent third-party validation and the third-party has independently published the results of that work following peer review.<sup>323</sup>

Response I-7-134: In response to the comments received on the November 2021 Proposal, EPA proposed a different regulatory approach for alternative screening using advanced methane detection technologies in the December 2022 Supplemental Proposal. For details, please see the discussion in section IV.B.1 of the December 2022 Supplemental Proposal.<sup>324</sup> Please see discussion in section IV.B of the December 2022 Supplemental Proposal related to advanced methane detection technologies.<sup>325</sup> Please also see section XI.B of the preamble to the final rule which details EPA's final standards related to advanced methane detection technology, which includes the finalization of technology-neutral matrix approach.

Comment: Commenter (0801-Carbon Mapper/RMI) assessed the effectiveness of the alternative screening protocol by analyzing over 2,500 large emission oil and gas methane sources detected and quantified by multiple airborne remote sensing surveys of representative oil and gas production basins across the U.S. that are collectively responsible for about 40 percent of U.S. onshore production in 2019.<sup>326</sup> Each source in this population had instantaneous methane emission rates as low as 10 kg/hr. The commenter's analysis used previously published methods<sup>327</sup> extended to additional surveys through fall 2021, with all data sets published on the Carbon Mapper public data portal.<sup>328</sup>

The commenter (0801-Carbon Mapper/RMI) estimates the average emissions from that population of large emission sources to be  $3.4 \pm 1.1$  million metric tons of methane per year, equivalent to about 43 percent of total oil and gas production emissions reported in EPA's GHG inventory for 2019 and consistent with the commenter's estimates of the average relative contributions of strong point sources to regional scale emissions using independent top-down atmospheric estimation methods. These emissions occur in every production segment. These findings, when combined with other studies that indicate the EPA methane inventory for this sector may be under-estimated by 60 percent (Alvarez *et al.*, 2018) suggests that large emission methane sources may account for at least half of the U.S. oil and gas methane budget, underscoring the importance of screening for large emission events.

The commenter (0801-Carbon Mapper/RMI) adds the percentage of large methane emission sources that should be detectable with a given screening protocol is a function of detection limit, spatial coverage, and sampling interval (measurement frequency). The commenter provides extensive details on various concepts and calculations in their comment letter surrounding their analysis, ultimately describing and arriving at the conclusion that alternative screening methods with improved detection completeness are needed.

---

<sup>323</sup> Sherwin, Evan, Yuanlei Chen, Arvind P. Ravikumar, and Adam R. Brandt, "Single-Blind Test of Airplane-Based Hyperspectral Methane Detection Via Controlled Releases," *Elementa Science of the Anthropocene*, 2021 ("Sherwin *et al.* 2021").

<sup>324</sup> 87 FR 74740 (December 6, 2022).

<sup>325</sup> 87 FR 74740-74744 (December 6, 2022).

<sup>326</sup> EIA, 2021.

<sup>327</sup> Duren *et al.*, 2019, Cusworth *et al.*, 2021.

<sup>328</sup> <https://carbonmapper.org/data/>.

The commenter (0801-Carbon Mapper/RMI) believes that EPA's November 2021 Proposal for alternative screening is limited to well sites and compressor stations which is likely to miss at least 40 percent of large emission fugitive sources covered by this rule given the prevalence of large emissions observed for other key equipment types. Hence, the commenter recommends that the alternative screening protocol be expanded to cover all onshore production equipment including well sites, compressor stations, storage vessels, flares, and gas processing plants. The commenter also notes that while methane emissions from gathering pipelines are under the jurisdiction of the Pipeline and Hazardous Materials Safety Administration rather than EPA, much of this important production segment would automatically be sampled by many remote sensing systems given their proximity to well sites and compressor stations. The commenter believes that incentivizing operators to adopt high frequency sampling protocols could identify intermittent malfunctioning hardware, provide a quantitative performance assessment of mitigation progress, and increase overall detection completeness to nearly 90 percent. The top-down quantification capabilities of remote sensing from satellites and aircraft would offer critical additional insight beyond conventional OGI surveys that tend to be limited to providing qualitative information about leak locations. For example, such quantification could be pivotal in verifying progress against the 95 percent emission reduction targets for storage vessels, pneumatic devices, and flares. Improved quantification of large emission, high frequency anomalous sources can also be used to validate and improve process equivalency models<sup>329</sup> that can in turn be used to guide proactive emission avoidance action rather than relying solely on reactive LDAR programs.

The commenter (0801-Carbon Mapper/RMI) compared potential annual total costs and per site average costs for the three in a screening matrix for a notional monitoring program for 1000 sites in a single company defined area assumed to be confined within a 1000 km<sup>2</sup> contiguous area with roughly even spacing of production sites. The commenter's letter includes *Table 1-Proposed matrix of requirements for alternative screening methods for large emission sources*, with three options presenting a range of cost based on the commenter's assessment of average per site survey costs for current and expected near-term monitoring systems. The commenter assesses that both remote sensing (+ single annual OGIs survey) options represent substantial cost savings compared to quarterly OGI surveys but with significantly improved completeness.

The commenter (0801-Carbon Mapper/RMI) recommends a system of systems approach that combines the attributes of airborne and satellite remote sensing for detection and quantification of large emission events along with surface sensor networks optimized for identifying lower emission activity across the oil and gas value chain.

Response I-7-135: In response to the comments received on the November 2021 Proposal, EPA proposed a different regulatory approach for alternative screening using advanced methane detection technologies in the December 2022 Supplemental Proposal. For details, please see the discussion in section IV.B.1 of the December 2022 Supplemental Proposal.<sup>330</sup> Please see discussion in section IV.B of the December 2022 Supplemental Proposal related to advanced methane detection technologies.<sup>331</sup> Please also see section XI.B of the preamble to the final rule

which details EPA’s final standards related to advanced methane detection technology, which includes the finalization of technology-neutral matrix approach.

Comment: Commenter (0846-Arolytics Inc.) notes that EPA seems to have followed two assumptions in alternative LDAR regulatory design. It’s useful to clarify those assumptions and weigh them against experience in other jurisdictions.

1. Alternative programs are costly, and models are complicated. This assumption is untrue. The Alberta experience shows that cost savings from Alternative LDAR Programs can be significant. For all but the very smallest producers, the upfront costs for that design, testing, proving, will be recouped normally in the first year of program implementation. To overcome these initial hurdles, and to realize the cost incentive, a producer/operator must invest in knowledge capital to get the project started. Education is the biggest barrier. A producer/operator with knowledge, and good supports, will be better equipped to meet its methane targets.
2. One size CAN fit all. Again, this assumption is untrue. One size may fit all in a broad modelling exercise, but a model probably assumes that implementation will be even, and occurring at a certain rate. But the incentives to adopt alternative monitoring pathways are very uneven and differ by producer/operator. In general, those with the most incentive to adopt are those who will see reductions in detection “hits”, which will translate to reduction in follow-up mitigation cost. Of course, mitigation costs are generally higher than detection costs so it might be worth spending extra on monitoring to avoid mitigation expenditures.

Overall, based on the experience in other jurisdictions, the commenter (0846-Arolytics Inc.) recommends a process more like Alberta’s:

- Flexible in terms of work-practice, frequency of screening, and technology used, so as to find the best pathway for effective LDAR that is custom to a specific operator.
- Program implementation-based rather than technology based.
- Outcome-based as to let the proponents be the experts, and in charge. The EPA can determine how they define equivalency and enable a diversity of programs to be approved that meet the required outcomes.
- Knowledge based where producer/operator, and EPA, are knowledgeable about tools and programs.
- Innovative, with space for models and other advanced tools to demonstrate equivalency, and where one method or model doesn’t automatically win.
- Clearly defined criteria for acceptance to deploy an alternative program, including a clearly defined reporting framework.

Response I-7-136: EPA acknowledges the commenters support for the use of alternative technologies, including specific recommendations. EPA has taken this comment into account as they designed the alternative technology program in the December 2022 Supplemental Proposal. See discussion in section IV.B of the December 2022 Supplemental Proposal related to advanced methane detection technologies.<sup>332</sup> Please also see section X.B of the preamble to the final rule

---

<sup>332</sup> 87 FR 74740-74746 (December 6, 2022).

which details EPA's final standards related to advanced methane detection technologies, which includes adoption of flexible frameworks.

#### 7.2.3.1 Advanced Technologies Should Complement OGI/Method 21 Monitoring

Comment: Commenters (0391-KBIC, 0781-NTAA) support the use of advanced technologies, but used as a complement to the required monitoring until the technologies are more proven. Once the advanced technologies are proven, the owner/operator can submit them for approval as an equivalent alternative method. The commenter feels this is important to protect fenceline communities from the HAP associated with oil and natural gas emissions.

The commenter (0782-BHE) believes it is imperative that innovation not compromise program integrity. Innovation cannot come at the expense of methodological and programmatic development of alternative technologies and survey approaches. The commenter suggests that EPA initiate a program to support technology and leak mitigation program development and standardization, rather than adopt new approaches in this rulemaking.

The commenter (0922-NAM) states operators should be encouraged to allow sources maximum flexibility for selecting options for detection and leak repair technologies. This should also allow companies to share some of these technologies, devices or systems to identify and repair the leaks. The commenter also encourages EPA to allow the use of advanced technologies, like continuous monitoring, as an alternate to OGI.<sup>333</sup>

The commenter (0593-ONE Future) believes it is important to deploy a practical framework that does not assume that a certain technology will work in every instance and region. It is important for EPA to provide flexibility and regulatory context for operators to quickly deploy innovative technologies. As the commenter's work and experience has shown, some technologies, while promising, are not yet commercially viable. For instance, satellites can capture large methane plumes associated with known blowdown events for maintenance but aren't yet advanced enough to capture smaller leaks that operators are driven to find and fix. While commenter (0593-ONE Future) supports EPA's November 2021 Proposal to allow flexibility in the use of advanced technologies, the use of OGI cameras will continue to be a critical tool for operators to find and manage leaks. Being overly prescriptive on the use of OGI could hinder operators' ability to utilize the tool effectively, which we suggest could be a step backward.

The commenter (0828-UCS) notes in the years since EPA first expanded coverage to include methane emissions from oil and gas sources, monitoring technologies have significantly improved, affording ever-increasing identification and granular resolution on the sources of leaks throughout the sector. This expanded visibility has revealed the shocking scale of the problem and galvanized the need for robust interventions. It has also made clear the insufficiency of early data collection approaches, and the value of expanded leak-identification pathways. As EPA finalizes this rule, it must ensure that leak identification methodologies meet robust minimum operating standards while keeping the door open to a broad array of options, including independently operated leak identification efforts such as satellites and aerial surveys.

---

<sup>333</sup> For example, the NAM encourages the EPA to allow sources the option to use Method 21 as an alternate to Optical Gas Imaging.

Furthermore, for sources where equipment malfunctions can occur without ties to routine operating events, the agency should ensure that monitoring frequency enables sufficiently rapid detection for quick repairs—including, as feasible, continuous monitoring.

Response I-7-137: In response to the comments received on the November 2021 Proposal, EPA proposed a different regulatory approach for alternative screening using advanced methane detection technologies in the December 2022 Supplemental Proposal. For details, please see the discussion in section IV.B.1 of the December 2022 Supplemental Proposal.<sup>334</sup> Please also see section XI.B of the preamble to the final rule which details EPA’s final standards related to advanced methane detection technology, which includes the finalization of technology-neutral matrix approach, and the specific combinations of screening frequencies and minimum detection thresholds where annual OGI would also be required.

Comment: Commenter (0775-CDPHE) believes alternative screening methods (*e.g.*, aerial surveys) should complement, and not yet completely replace, traditional IR camera/AIMM inspections. The commenter also has concerns with the specificity of the protocols for EPA’s November 2021 alternative screening proposal. The commenter suggests that EPA instead let states have the flexibility to employ alternative screening after individualized review of the appropriateness of the technology, frequencies, follow-up and repair timelines, as is most effective in the region and for the sites for which the alternative screening is deployed. The commenter does not believe that EPA approval of a state’s approval of alternative screening methods is necessary or should be required.

Response I-7-138: In response to the comments received on the November 2021 Proposal, EPA proposed a different regulatory approach for alternative screening using advanced methane detection technologies in the December 2022 Supplemental Proposal. For details, please see the discussion in section IV.B.1 of the December 2022 Supplemental Proposal.<sup>335</sup> Please also see section XI.B of the preamble to the final rule which details EPA’s final standards related to advanced methane detection technology, which includes the finalization of technology-neutral matrix approach, and the specific combinations of screening frequencies and minimum detection thresholds where annual OGI would also be required.

Comment: Commenter (0782-BHE) adds because existing source regulations will likely result in EPA’s voluntary methane reduction programs becoming obsolete, new program or method development could be implemented through pilot studies under the umbrella of the Methane Challenge program. The commenter also recommends addressing challenges related to ensuring leak detection and mitigation programs during program development, such as standard methods and equivalency definitions for measurement and monitoring technologies; the decision basis for leak repair alternatives or tier-based programs that consider “leak size;” and standard practices and procedures (*e.g.*, training, certification) for implementation.

Response I-7-139: In response to the comments received on the November 2021 Proposal, EPA proposed a different regulatory approach for alternative screening using advanced methane detection technologies in the December 2022 Supplemental Proposal. Please also see section

---

<sup>334</sup> 87 FR 74740 (December 6, 2022).

<sup>335</sup> 87 FR 74740 (December 6, 2022).

XI.B of the preamble to the final rule which details EPA's final standards related to advanced methane detection technology, which includes the finalization of technology-neutral matrix approach, and the specific combinations of screening frequencies and minimum detection thresholds of the screening technology.

Comment: Commenter (0932-GHGSat, Inc.) understands that simulation models can assist in the understanding of monitoring equivalence. Kemp *et al.*, found that the cost effectiveness of tiered LDAR programs can achieve equivalent emissions reductions at lower costs when compared with OGI only by varying survey frequency.<sup>336</sup> The purpose of the equivalence model is to analyze the different technologies and understand if the alternative tiered approach is cost-effective when compared to the default technology. The default technology is an OGI camera, as currently mandated by US regulations, with a frequency of four surveys per year. The commenter asked a third-party analytics company to perform a methane emissions equivalency report utilizing GHGSat's aircraft technology and corresponding capabilities. The executive summary of this equivalency modeling is included in Appendix B of the commenter's letter. Overall, the modeled results showed the cost-effectiveness of implementing GHGSat's aircraft technology six times per year and one annual OGI survey, as proposed by this rule. Using the alternate technology resulted in same methane reductions but at two thirds of the cost when compared to typical OGI surveys costs.

Response I-7-140: In response to the comments received on the November 2021 Proposal, EPA proposed a different regulatory approach for alternative screening using advanced methane detection technologies in the December 2022 Supplemental Proposal. For details, please see the discussion in section IV.B.1 of the December 2022 Supplemental Proposal.<sup>337</sup> Please also see section XI.B of the preamble to the final rule which details EPA's final standards related to advanced methane detection technology, which includes the finalization of technology-neutral matrix approach, and the specific combinations of screening frequencies and minimum detection thresholds where annual OGI would also be required.

Comment: Commenter (0763-TCEQ/RRC) encourages allowing EPA Method 21 to remain an option for fugitive monitoring, as this EPA method is integrated into LDAR programs recognized in the commenter's authorization mechanisms used for emissions representations in permitting programs. Removing EPA Method 21 as a fugitive monitoring method would increase the regulatory overlap, as authorization mechanisms do not allow for the use of OGI fugitive monitoring outside of the Alternative Work Practice in 40 CFR §60.18.

The commenter (0763-TCEQ/RRC) supports the use of advanced measurement technologies and alternative screening approaches for fugitive monitoring with verification using OGI or other fugitive emission monitoring programs; however, this technology is not currently recognized in state authorization mechanisms and would be in addition to EPA Method 21 monitoring required by state authorization mechanisms and LDAR programs. The commenter has concerns on how these advanced measurement technologies would be implemented and verified and the additional

---

<sup>336</sup> Kemp, et al., 2021.

<sup>337</sup> 87 FR 74740 (December 6, 2022).

requirements applicable for monitoring and operation of these technologies creating a burden on review of representations.

Response I-7-141: In response to the comments received on the November 2021 Proposal, EPA proposed a different regulatory approach for alternative screening using advanced methane detection technologies in the December 2022 Supplemental Proposal. For details, please see the discussion in section IV.B.1 of the December 2022 Supplemental Proposal.<sup>338</sup> Please also see section XI.B of the preamble to the final rule which details EPA's final standards related to advanced methane detection technology, which includes the finalization of technology-neutral matrix approach, and the specific combinations of screening frequencies and minimum detection thresholds where annual OGI would also be required.

#### ***7.2.4 Costs of Advanced Technologies***

Comment: Commenters (0831-AXPC, 0844-EDF *et al.*, 0915/1290-Bridger Photonics) provided feedback related to the widespread availability of advanced technologies and specific information on costs.

Commenter (0831-AXPC) reports that costs associated with six-times-per-year aerial survey plus one OGI is greater than the cost of quarterly OGI and will disincentivize the use of alternative technology. The commenter recommends three or four times-a-year frequency, which would likely yield greater emissions reductions than with four OGI surveys on the ground and operators would realize a cost savings, which would further incentivize the use of new technology.

Commenter (0844-EDF *et al.*) notes that advanced monitoring technologies are already widely available and in use by leading operators.<sup>339</sup> Many of these technologies are highly effective and inexpensive. And many companies providing advanced methane mitigation services are domestic and provide well-paying jobs in geographies across the country. These technologies are particularly capable and efficient at screening large areas for emissions, although layered approaches utilizing multiple techniques may be most appropriate for finding and fixing smaller (but collectively significant) leaks. Operator experience, scientific use and testing, and simulation modeling provide estimates of the cost and effectiveness of different approaches that can inform regulatory approaches.

The commenter (0844-EDF *et al.*) cites a recent comprehensive survey from Datu Research shows that advanced leak detection services are widely-available. Datu's survey of services firms offering advanced methane monitoring reveals their ability and plans to scale up in response to new federal methane regulations.<sup>340</sup> Firms offering advanced monitoring services have nearly doubled in the past four years alone, and more than a quarter are already capable of surveying

---

<sup>338</sup> 87 FR 74740 (December 6, 2022).

<sup>339</sup> See Datu Research, Find, Measure, Fix: Jobs in the U.S. Methane Emissions Mitigation Industry (2021); EPA, Methane Detection Technology Workshops, <https://www.epa.gov/controlling-air-pollution-oil-and-natural-gas-industry/epa-methane-detection-technology-workshop>.

<sup>340</sup> Marcy Lowe, Advanced Methane Monitoring: Gauging the Ability of U.S. Service Firms to Scale Up, Datu Research (July 22, 2021), [http://blogs.edf.org/energyexchange/files/2021/08/Advanced-Methane-Monitoring-Survey\\_Datu-Research\\_8-10-2021.pdf](http://blogs.edf.org/energyexchange/files/2021/08/Advanced-Methane-Monitoring-Survey_Datu-Research_8-10-2021.pdf)

over 300 well sites per day. More than half of firms surveyed said they could serve at least 100 more well sites per day than they currently serve by 2023. Nearly half (47 percent) said they could scale up to serve more than 500 well sites per day; these respondents comprised those using fixed sensors, airplanes, satellites, or a combination of these technologies. Eighty-nine percent of the firms surveyed can detect emissions at the equipment level, while 53 percent can detect at the component level. According to the research cited by the commenter, the firms also operate broadly across major oil and gas basins, with at least 32 percent having a presence in every basin, and 74 percent operating in the Permian.

The commenter (0844-EDF *et al.*) also points to EPA's 2021 Methane Detection Technology Workshop and summarizes the following key takeaways and conclusions:

- Layered approaches are needed.<sup>341</sup>
- Advanced technologies are cost-effective and significantly reduce emissions.<sup>342</sup>
- Comprehensive coverage is already deployed by leading operators.<sup>343</sup>
- Workshop cost estimates:
  - OGI – \$600/site/inspection<sup>344</sup>
  - Aerial – \$100-300/site, quarterly for \$1,600/facility<sup>345</sup>
  - Drone – \$2,700-3,500/annually<sup>346</sup>
  - Continuous – \$1,000-5,000 annually<sup>347</sup>

Commenter (0915/1290-Bridger Photonics) performed a detailed analysis and comparison of both cost and emissions reduction between the standard quarterly OGI program and the aerial alternative work practice in the proposed rule using Bridger's Gas Mapping LiDAR [(1 × OGI) + (6 × GML)]. The main conclusions include a lower gross GML program cost, large net savings when gas is recaptured, and low cost per ton of emissions reduced. Specific details on these main conclusions are included in the commenter's letter.<sup>348</sup>

The commenter (0915/1290-Bridger Photonics) also highlights other benefits associated with alternative programs that are not easily quantified, including safety, efficiency, impact, objectivity, insensitivity to temperature, and self-auditing.<sup>349</sup>

Response I-7-142: EPA acknowledges the information provided by commenters related to the use of and cost of different alternative technology solutions. See discussion in section IV.B of the December 2022 Supplemental Proposal related to advanced methane detection

technologies.<sup>350</sup> Please also see section X.B.2 of the preamble to the final rule which details EPA’s final standards related to the use of alternative technologies for detection of fugitive emissions under the advanced methane detection technology program, and section XI.B.1.b of the preamble to the final rule for a specific discussion on technology flexibility.

### ***7.2.5 Periodic Screening Frequency***

Comment: Commenter (0915/1290-Bridger Photonics) recommends that EPA adopt quarterly rather than bi-monthly scan frequency until sufficient temporal data exists to inform policy.

The commenter (0915/1290-Bridger Photonics) notes that due to uncertainty in the modeling, and the financial, operational, and logistical burden on the industry for an “instant” ramp up to bi-monthly scanning, the commenter urges the EPA to adopt quarterly rather than bi-monthly scan frequency in the final rule (in addition to annual OGI) for the alternative aerial work practice as long as (a) the adopted detection sensitivity metric is no worse than 10 kg/hr with >50 percent probability of detection in typical conditions, and (b) there is a built-in mechanism to change (increase or decrease) that scan frequency when the aggregate temporal data becomes available to establish that a different scan frequency achieves the goal of detecting 75 percent of annual emissions. The commenter also advocates more generally for a built-in mechanism to allow individual operators with demonstrated low emissions to use lower scan frequencies.

The commenter (0915/1290-Bridger Photonics) also emphasize that Bridger’s aerial scans have been demonstrated in typical operational conditions to perform better than a one-to-one replacement for OGI scans. Yet the aerial scanning AWP in the November 2021 Proposal implies that two aerial scans replace each of three OGI surveys (*i.e.*, 1:2 swap). If EPA’s intent is to use OGI scans as the benchmark for performance, then quarterly scanning plus annual OGI is certainly more than justified. This is supported by third-party studies showing that Bridger’s aerial LiDAR scans detect more, not less, emissions than OGI scans with ground crews.<sup>351</sup> Moreover, the same study finds that the aerial scans result in far fewer repair events due to the larger emission events uncovered by Bridger’s scans. These findings have been repeated on much larger scale with consistent results.<sup>352</sup>

Response I-7-143: In response to the comments received on the November 2021 Proposal, EPA proposed a different regulatory approach for alternative screening using advanced methane detection technologies in the December 2022 Supplemental Proposal. For details, please see the discussion in section IV.B.1 of the December 2022 Supplemental Proposal.<sup>353</sup> Please also see section XI.B of the preamble to the final rule which details EPA’s final standards related to advanced methane detection technology, which includes the finalization of technology-neutral matrix approach, and the specific combinations of screening frequencies and minimum detection thresholds for screening frequencies.

<sup>351</sup> David R. Tyner, et al., Where the Methane Is—Insights from Novel Airborne LiDAR Measurements Combined with Ground Survey Data, *Environmental Science & Technology* 2021 55 (14), 9773-9783 DOI: 10.1021/acs.est.1c01572.

<sup>352</sup> Matt Johnson group at University of Carleton, manuscript in preparation.

<sup>353</sup> 87 FR 74740 (December 6, 2022).

Comment: Commenter (0740-UPA) states the November 2021 Proposal would require alternative screening surveys using advanced measurement technology to be done every other month.<sup>354</sup> The commenter argues this frequency is too high, puts an unnecessary burden on operators and especially on smaller operators who have less flexibility among their workforces, a burden made worse by the labor shortage, and conflicts with the need described above to be able to employ different technologies for each monitoring event throughout the year. Leak detection monitoring with advanced measurement technologies should require no more than the same frequency as leak detection by other methods.<sup>355</sup>

Response I-7-144: In response to the comments received on the November 2021 Proposal, EPA proposed a different regulatory approach for alternative screening using advanced methane detection technologies in the December 2022 Supplemental Proposal. For details, please see the discussion in section IV.B.1 of the December 2022 Supplemental Proposal.<sup>356</sup> Please also see section XI.B of the preamble to the final rule which details EPA's final standards related to advanced methane detection technology, which includes the finalization of technology-neutral matrix approach, and the specific combinations of screening frequencies and minimum detection thresholds for screening frequencies.

Comment: Commenter (0932-GHGSat, Inc.) believes an important part of the proposed revision is that the program is designed to focus monitoring efforts on sites and equipment that are most likely to have large emissions. The commenter agrees that an effective method of reducing emissions is by monitoring and detecting the larger leaks, which tend to occur stochastically and sporadically, but when they occur tend to considerably affect the emissions inventory of an entity. The commenter notes this effect has been observed in different studies, in which the effects of few large events can correspond to comprehend more than 50 percent by volume of the methane emitted (Brandt, *et al.*, 2016). Using Brandt's study and accounting for EPA's proposed 10 kg/hr threshold for alternative monitoring methods, this can provide an opportunity to detect more than 90 percent by volume of the methane emitted. The commenter agrees with the proposed revisions in the sense that they provide owners and operators with the flexibility to use advanced technologies that can find major leaks more rapidly and at a lower cost than ever before.

Response I-7-145: EPA acknowledges the commenters' support for the November 2021 Proposal's standards related to alternative methane detection; because comment is supportive, no response is required.

Comment: Commenter (0391-KBIC, 0428-Kirk Frost, 0781-NTAA, 0788-350 Seattle, 0796-Asthma and Allergy Foundation of America – Michigan Chapter (AAFA-MI) *et al.*, 1330-Catskill Mountainkeeper) believe that the shortest duration of time between monitoring should be used in the final rule. Because many large emission events occur because of leaking

---

<sup>354</sup> Proposal, p. 63175.

<sup>355</sup> A modeling study using the LDARSim model shows that EPA's proposed alternative screening surveys using advanced measurement technology six times per year results in a far more rigorous LDAR program than quarterly OGI monitoring. See "EPA OOOOb/c Alternative Monitoring Recommendations" by Ryan Streams, January 13, 2022, located at [https://kairos aerospace.com/wp-content/uploads/2022/01/KairosEPA-OOOOb-c-Recommendations\\_220112\\_FINAL.pdf](https://kairos aerospace.com/wp-content/uploads/2022/01/KairosEPA-OOOOb-c-Recommendations_220112_FINAL.pdf) (accessed on January 27, 2022).

<sup>356</sup> 87 FR 74740 (December 6, 2022).

equipment, longer monitoring periods would allow leaks to continue to emit unchecked for longer periods of time. Commenter (0796-AAFA-MI *et al.*) stresses requiring frequent monitoring and modern/zero-emitting equipment is critical to protecting public health.

Response I-7-146: In response to the comments received on the November 2021 Proposal, EPA proposed a different regulatory approach for alternative screening using advanced methane detection technologies in the December 2022 Supplemental Proposal. For details, please see the discussion in section IV.B.1 of the December 2022 Supplemental Proposal.<sup>357</sup> Please also see section XI.B of the preamble to the final rule which details EPA's final standards related to advanced methane detection technology, which includes the finalization of technology-neutral matrix approach, and the specific combinations of screening frequencies and minimum detection thresholds for screening frequencies.

Comment: Commenter (0586-Navajo EPA)) supports the November 2021 Proposal to use advanced measurement technologies for well sites and compressor stations on a bimonthly basis, provided that these advanced measurement technologies are demonstrated to detect leaks to the same degree that OGI would (at a low level of emissions).

Response I-7-147: EPA acknowledges the commenter's support. In response to the comments received on the November 2021 Proposal, EPA proposed a different regulatory approach for alternative screening using advanced methane detection technologies in the December 2022 Supplemental Proposal. For details, please see the discussion in section IV.B.1 of the December 2022 Supplemental Proposal.<sup>358</sup> Please also see section XI.B of the preamble to the final rule which details EPA's final standards related to advanced methane detection technology, which includes the finalization of technology-neutral matrix approach, and the specific combinations of screening frequencies and minimum detection thresholds for screening frequencies.

Comment: Commenter (0425-Darrah) states the more flexibility EPA provides in methods of monitoring the easier it will be for operators to comply with the rule. Flexibility will allow for more innovation in monitoring methods as well as reduced costs in monitoring with more diversity in options.

Response I-7-148: See the discussion in section IV.B.1 of the December 2022 Supplemental Proposal.<sup>359</sup>

Comment: Commenter (0747-SENST) recommends EPA develop a rigorous, transparent methodology and metrics to estimate emissions reductions from different screening programs relative to the proposed BSER or another benchmark. The commenter asserts that EPA must assess the logistical feasibility and costs of programs that incorporate screening surveys, follow-up at flagged sites, and full annual OGI at all other sites emitting greater than or equal to 3 tpy not flagged by screening methods. The commenter also says that EPA should develop a rigorous,

---

<sup>357</sup> 87 FR 74740 (December 6, 2022).

<sup>358</sup> 87 FR 74740 (December 6, 2022).

<sup>359</sup> 87 FR 74740 (December 6, 2022).

transparent methodology to estimate the full cost of screening programs using a common metric for program evaluation such as cost to emissions mitigation ratio (\$/t CO<sub>2</sub>e).

Response I-7-149: In response to the comments received on the November 2021 Proposal, EPA proposed a different regulatory approach for alternative screening using advanced methane detection technologies in the December 2022 Supplemental Proposal. For details, please see the discussion in section IV.B.1 of the December 2022 Supplemental Proposal.<sup>360</sup>

Comment: Commenter (0801-Carbon Mapper/RMI) recommends adding an option for bi-weekly (14 day) remote-sensing surveys with a 100 kg/hr detection limit would provide equivalent detection completeness to bi-monthly surveys with a 10 kg/hr detection limit. Both approaches would achieve a cumulative completeness of nearly 90 percent. The commenter finds that both bi-weekly and bi-monthly remote sensing surveys would likely provide dramatically better overall detection completeness compared to quarterly OGI surveys, largely because of the limited spatial and temporal completeness of the latter. The commenter's analysis suggests that detailed, spatially and temporally resolved models of oil and gas upstream and midstream infrastructure could be used to further optimize for detection completeness between the 10 and 100 kg/hr detection limit and bi-weekly and bi-monthly sampling targets.

Response I-7-150: In response to the comments received on the November 2021 Proposal, EPA proposed a different regulatory approach for alternative screening using advanced methane detection technologies in the December 2022 Supplemental Proposal. For details, please see the discussion in section IV.B.1 of the December 2022 Supplemental Proposal.<sup>361</sup>

Comment: Commenter (0777-Ascent) supports EPA's November 2021 Proposal to provide for alternative screening for fugitive emissions sources using advanced measurement technologies; however, as described in the November 2021 Proposal, EPA is proposing a significant impediment to the program that will serve as a disincentive to the regulated community.

The commenter (0777-Ascent) notes that the frequency of the aerial screening (and potential associated ground-based OGI surveys) is too high to properly incentivize the regulated community. The November 2021 Proposal would require quarterly (or in some cases semiannual) OGI monitoring as the "default." Conducting aerial surveys six times per year, with the potential for ground-based OGI follow-up surveys – in addition to the mandated full OGI ground survey that must be conducted irrespective of the results of the aerial surveys – threatens to add to the burden of fugitive emission monitoring when compared to the default regulatory requirement.

For that reason, commenter (0777-Ascent) recommends that the EPA propose quarterly, rather than bimonthly, aerial surveys as part of the alternative screening method. The EPA should embrace these advanced technologies and promote their use by regulated community. One way to do that would be to relieve the burden associated with those technologies by reducing the frequency of required aerial screening from bimonthly to quarterly.

---

<sup>360</sup> 87 FR 74740 (December 6, 2022).

<sup>361</sup> 87 FR 74740 (December 6, 2022).

The commenter (0777-Ascent) argues quarterly aerial surveys will ensure monitoring takes place on at least the same frequency as the default regulatory requirement for most sites, while at least potentially allowing owners and operators to conduct that monitoring more efficiently with the advanced measurement technologies.

Response I-7-151: In response to the comments received on the November 2021 Proposal, EPA proposed a different regulatory approach for alternative screening using advanced methane detection technologies in the December 2022 Supplemental Proposal. For details, please see the discussion in section IV.B.1 of the December 2022 Supplemental Proposal.<sup>362</sup>

Comment: Commenter (0831-AXPC) has concerns with EPA's singular approach of requiring that the alternative must meet a minimum threshold of 10 kg/hr and be conducted bimonthly along with an annual site-by-site survey utilizing OGI. The commenter says EPA's justification for this threshold and frequency as comparable OGI surveys in yielding emission reductions is unclear. Many of these technology companies are able to produce data that demonstrates the effectiveness of their technologies even at higher thresholds and/or less frequent surveys than those proposed. In these cases, a bimonthly requirement with an annual OGI would be much more stringent than, rather than comparable to, the corresponding proposal for a quarterly LDAR requirement utilizing OGI. The commenter believes a frequency of three or four times a year is a more comparable to quarterly OGI surveys, based on even conservative modeling estimates.

The commenter (0831-AXPC) adds a bimonthly frequency for something like flyover screening technologies, creates operational feasibility challenges to execute when also considering the associated timelines for data processing, quality assurance/quality control (QA/QC) analysis, and on-the-ground follow-up and repair. Depending on the number of sites surveyed, flyovers generally take seven-to-ten days depending on the weather, and then often another ten days before the data is received. Operators must then analyze the information provided before they can send out teams to make repairs. Under the November 2021 Proposal, companies would only have a few days for repairing leaks across an entire survey area, which is not practically feasible and significantly shorter than the timeframe provided for walk-around OGI surveys. On a bimonthly cadence, realistically, operators would still be working to perform repairs when it comes time to do the next flyover, creating material operational inefficiencies and shrinking the emission reduction per survey with the overlap.

Responses I-7-152: In response to the comments received on the November 2021 Proposal, EPA proposed a different regulatory approach for alternative screening using advanced methane detection technologies in the December 2022 Supplemental Proposal. For details, please see the discussion in section IV.B.1 of the December 2022 Supplemental Proposal.<sup>363</sup>

Comment: Commenter (0785-John Crane Inc.) recommends that total site-level baseline emissions thresholds should be used to determine frequency of monitoring, and subsequently allow alternative emissions screening technology for the same. Prescriptive policies that dictate

---

<sup>362</sup> 87 FR 74740 (December 6, 2022).

<sup>363</sup> 87 FR 74740 (December 6, 2022).

specific technologies could potentially disincentivize emissions reduction from large quantities of emissions left out of scope.

Response I-7-153: In response to the comments received on the November 2021 Proposal, EPA proposed a different regulatory approach for alternative screening using advanced methane detection technologies in the December 2022 Supplemental Proposal. For details, please see the discussion in section IV.B.1 of the December 2022 Supplemental Proposal.<sup>364</sup>

Comment: Commenter (0826-Kairos Aerospace) studied the percent of emissions mitigated by performing four, five, and six aerial surveys per year, with and without annual OGI. Two distribution models were used: The Chen *et al.* Permian distribution and Omara distribution, both discussed in further detail in the commenter's attachment. The Permian distribution shows aerial surveys exceeding performance of OGI under all scenarios. The modeling report states, "we recommend that the EPA consider the average mitigation, as the Omara distribution does not consider super-emitters known to exist, which are of high consequence to overall emissions. Programs with average emissions in bold are deemed to reduce emissions to a greater extent than the EPA's regulatory OGI program."

Based on this approach, the commenter (0826-Kairos Aerospace) provides a matrix of sensitivities and survey frequencies that will achieve at least equivalent emission reductions compared to quarterly OGI surveys. While the Permian distribution supports detection limits of greater than 40 kg/hr at a variety of frequencies and sensitivities, the commenter has selected a more cautious approach that gives additional weight to the Omara results, despite these being conservative due to a lack of super emitters. The commenter's reasoning is that the Permian may have more super emitters than other basins, and despite representing nearly half of U.S. oil production, EPA may want to take an approach that does not solely rely on the Permian as the basis for an emission distribution.

The commenter (0826-Kairos Aerospace) states the proposed table within the commenter's document attempts to strike that balance between the Permian and Omara modeling results but is arguably more heavily weighted towards the Omara results in order to provide EPA a more conservative framework. The commenter does believe EPA could select higher detection limits and still achieve equivalence, but their work here is intended to provide EPA a well-reasoned and conservative starting point for a matrix-based approach to alternative leak detection requirements.

Response I-7-154 In response to the comments received on the November 2021 Proposal, EPA proposed a different regulatory approach for alternative screening using advanced methane detection technologies in the December 2022 Supplemental Proposal. For details, please see the discussion in section IV.B.1 of the December 2022 Supplemental Proposal.<sup>365</sup>

Comment: Commenter (0846-Arolytics Inc.) notes that some new gas methane certification standards already require alternative measurement of different types, at frequencies beyond those of regulation. These market-based standards may cause significant friction with EPA's approach

---

<sup>364</sup> 87 FR 74740 (December 6, 2022).

<sup>365</sup> 87 FR 74740 (December 6, 2022).

in that the market-based approaches may propose different technologies and frequencies. If a producer/operator wants to adopt a standard that achieves a far better methane reduction outcome than the EPA's approach but must be added in parallel to EPA's inflexible regulatory approach, this provides disincentive for the producer/operator to pursue the market-based certification standard because the producer/regulator would have to implement and pay for both programs. These producers/operators with an interest in these standards, and better methane performance than their peers, should have the ability to show, with modelling and/or field results, that their more rigorous certification-related practices meet or exceed the EPA's rules.

Response I-7-155: In response to the comments received on the November 2021 Proposal, EPA proposed a different regulatory approach for alternative screening using advanced methane detection technologies in the December 2022 Supplemental Proposal. For details, please see the discussion in section IV.B.1 of the December 2022 Supplemental Proposal.<sup>366</sup>

### ***7.2.6 Minimum Detection Threshold***

Comment: Commenter (0811-ABB) believes EPA should comprehensively study commercially available methane leak detection technologies to understand the features in the current state-of-the-art. This will inform what minimum detection thresholds should be part of an EPA regulatory regime. The commenter urges EPA to consider establishing as rigorous a minimum detection threshold as commercially available technologies allow and also consider other important performance parameters such as time response, linearity, and overall accuracy.

Response I-7-156: In response to the comments received on the November 2021 Proposal, EPA proposed a different regulatory approach for alternative screening using advanced methane detection technologies in the December 2022 Supplemental Proposal. For details, please see the discussion in section IV.B.1 of the December 2022 Supplemental Proposal.<sup>367</sup>

Comment: Commenters (0785-John Crane Inc., 0932-GHGSat, Inc.) recommend adopting the threshold of 10 kg/hr as it is inclusive of many types of commercial technologies and detection modalities appropriate for surveying all manner of asset types included in the proposed regulations.

The commenter (0932-GHGSat, Inc.) reports that there are functional and commercially available aircraft technology capable of meeting that threshold right now. For example, GHGSat's aircraft-based sensor has been flying over multiple U.S. oil and gas basins since 2019. The aircraft sensor technology has a nominal detection threshold of 10 kg/hr (an order of magnitude better than the satellite) and a pixel resolution of two feet.<sup>368</sup>

Response I-7-157: In response to the comments received on the November 2021 Proposal, EPA proposed a different regulatory approach for alternative screening using advanced methane

---

<sup>366</sup> 87 FR 74740 (December 6, 2022).

<sup>367</sup> 87 FR 74740 (December 6, 2022).

<sup>368</sup> Id.

detection technologies in the December 2022 Supplemental Proposal. For details, please see the discussion in section IV.B.1 of the December 2022 Supplemental Proposal.<sup>369</sup>

Comment: Commenters (0586-Navajo EPA, 0835-CMES, 0935-COGA) express concern whether the proposed threshold of 10 kg/hr is appropriate.

The commenter (0586-Navajo EPA) is concerned whether the minimum detection threshold of 10 kg/hr is sufficient to detect leaks that are still significant and would be detected by OGI. Provided these measurement technologies are properly able to detect fugitive emissions in an equivalent degree as OGI, the increased frequency of these measurements should help detect leaks sooner and lead to quicker repairs.

The commenter (0835-CMES) is concerned that if the proposed threshold of 10 kg/hr is implemented, their experience in the field indicates that many leaks (more than 90 percent of all leaks) would be missed. The commenter believes a gap of this size is unnecessary and EPA should consider revising it.

Commenter (0935-COGA) believes EPA's November 2021 Proposal to require a minimum detection threshold of 10 kg/hr for alternative technologies is not technically supported and should be reconsidered. Detector sensitivity is only one factor impacting the effectiveness of a leak detection program and should not be considered in isolation. Program effectiveness is also impacted by inspection frequency, software algorithms, and particularly the ability to detect large emission events. The alternative standard should allow the use of any alternative leak detection technology or program where modeling shows that it will achieve equivalent or better emission reductions than OGI.

Response I-7-158: In response to the comments received on the November 2021 Proposal, EPA proposed a different regulatory approach for alternative screening using advanced methane detection technologies in the December 2022 Supplemental Proposal. For details, please see the discussion in section IV.B.1 of the December 2022 Supplemental Proposal.<sup>370</sup>

Comment: Commenter (0775-CDPHE) states that detection sensitivity can vary based on conditions in the field, which must be accounted for with each alternative screening advanced measurement technology if detection sensitivity is to be used as a basis at all for any requirement in the proposed regulation. Currently, Colorado requires controlled and field testing results confirming the detection threshold of the technology. The commenter's position on advanced screening is that advanced screening must be looked at as part of a holistic program to minimize emissions. The commenter believes that finding and mitigating emissions involves more than simple focus on a detection threshold, especially in terms of the method and work practice(s) used with or for the monitoring technology. The commenter encourages EPA to refer to the information provided through the EPA Methane Detection Workshop held July 2021 for initial information provided by several technology providers about detection thresholds. The commenter also suggests that EPA convene a workgroup across states and technology providers

---

<sup>369</sup> 87 FR 74740 (December 6, 2022).

<sup>370</sup> 87 FR 74740 (December 6, 2022).

to come up with guidance for states and operators seeking to employ alternative screening in their LDAR programs -outside of the regulation.

Response I-7-159: In response to the comments received on the November 2021 Proposal, EPA proposed a different regulatory approach for alternative screening using advanced methane detection technologies in the December 2022 Supplemental Proposal. For details, please see the discussion in section IV.B.1 of the December 2022 Supplemental Proposal.<sup>371</sup>

Comment: Commenter (0826-Kairos Aerospace) states the proposed requirement for a 10 kg/hr sensitivity is infeasible because it would require a fleet of approximately 250 aircraft flying at extremely low altitudes to implement on a national scale. This would be very difficult to implement while adhering Federal Aviation Administration safety requirements on aircraft spacing.

The commenter (0826-Kairos Aerospace<sup>372</sup>) utilizes a passive infrared spectrometer system, which allows for higher altitude flight and wider survey swath widths when compared to active measurement systems. Passive systems survey a larger area in a single pass and more facilities in a single flight day compared to active measurement systems. The Kairos system can detect leaks as small as 2 kg/hr under ideal conditions, but it cannot perform at 10 kg/hr under all normal operating conditions. Meeting the 10 kg/hr standard under all conditions would create several significant technical and economic hurdles and would not provide commensurate environmental benefit.

The commenter (0826-Kairos Aerospace) notes EPA's November 2021 Proposal to use a fixed minimum detection limit does little to ensure equivalence. Equivalence should be assessed by evaluating overall program performance, not by evaluating the detection sensitivity as an isolated variable. The Appendix K Technical Support Document prepared for EPA by Eastern Research Group acknowledges that "the detection limit of an OGI camera can be thought of as more of a continuum versus a single point."<sup>373</sup> Similarly, Dan Zimmerle of Colorado State University noted that "[l]eak detection solution performance should be characterized as an integrated solution, not as a 'sensor' or a 'deployment method.'" In addition, "[a]nalytics will have as much or more impact on the performance than the sensor or the deployment."<sup>374</sup> Comparative modeling performed by Highwood shows equivalence of airborne technologies at much higher detection thresholds.

The commenter (0826-Kairos Aerospace) fully supports EPA's decision to approach the detection limit question with a flux-based unit of measurement rather than a concentration-based measurement. A concentration-based metric such as ppm is inappropriate for evaluating instrument performance because the concentration varies spatially and temporally, making it difficult to select a representative concentration. In addition, a concentration metric does not capture the size of the leak point; a high-concentration pinhole leak may emit less than a low-

---

<sup>371</sup> 87 FR 74740 (December 6, 2022).

<sup>372</sup> Note that a duplicate letter from the commenter appears in the docket as EPA-HQ-OAR-2021-0317-1374.

<sup>373</sup> Appx. K TSD at 48.

<sup>374</sup> Zimmerle, Daniel, CSU Energy Institute, Next-Generation Leak Detection Solutions, slide 8.

concentration leak from a larger opening, such as an open thief hatch. Flux-based approaches more accurately capture remote sensor performance in real world conditions.<sup>375</sup>

Response I-7-160: In response to the comments received on the November 2021 Proposal, EPA proposed a different regulatory approach for alternative screening using advanced methane detection technologies in the December 2022 Supplemental Proposal. For details, please see the discussion in section IV.B.1 of the December 2022 Supplemental Proposal.<sup>376</sup>

Comment: Commenter (0831-AXPC) states that minimum detection threshold should be based on modeling (e.g., FEAST, LDAR-Sim) that demonstrates that the alternate technology is expected to achieve the required emission reductions.

Response I-7-161: In response to the comments received on the November 2021 Proposal, EPA proposed a different regulatory approach for alternative screening using advanced methane detection technologies in the December 2022 Supplemental Proposal. For details, please see the discussion in section IV.B.1 of the December 2022 Supplemental Proposal.<sup>377</sup>

Comment: Commenter (0826-Kairos Aerospace) states small leaks contribute little to the total emissions rate; system-wide emissions and emission reductions are dominated by large emission events (LEEs) that can be observed using low-sensitivity sensors. Chen *et al.* reported that leaks of at least 308 kg/hr are responsible for 50 percent of total methane loss, while Cusworth *et al.* 2021 and Duren *et al.* 2019 observed a similarly skewed distribution.<sup>378</sup> A detection sensitivity of 10 kg/hr is not necessary to find 308 kg/hr leaks. If a large proportion of total methane is coming from leaks emitting hundreds of kg/hr or greater, the difference in performance between a system with a 5 or 10 or 25 kg/hr detection limit is of little significance, as those relatively small leaks do not represent a significant portion of overall emissions. Rather, speed and efficiency at identifying and eliminating LEEs are the most important metrics for an effective aerial screening program.

Response I-7-162: In response to the comments received on the November 2021 Proposal, EPA proposed a different regulatory approach for alternative screening using advanced methane detection technologies in the December 2022 Supplemental Proposal. For details, please see the discussion in section IV.B.1 of the December 2022 Supplemental Proposal.<sup>379</sup>

Comment: Commenters (0604-Providence, 0831-AXPC, 0932-GHGSat, Inc., 0938-TXOGA) note that consideration of the detection limit for technologies should be a principal consideration in establishing the required intervals. This would ensure that the requirements are sufficient to identify and quantify methane emissions without being needlessly burdensome.

---

<sup>375</sup> See also Appx. K TSD at 46 (“A detection limit in ppm-m is limited in its usefulness, whereas a detection limit in grams per hour (gph) is more important in assessing emission factors.”).

<sup>376</sup> 87 FR 74740 (December 6, 2022).

<sup>377</sup> 87 FR 74740 (December 6, 2022).

<sup>378</sup> Cusworth et al. 2021.

<sup>379</sup> 87 FR 74740 (December 6, 2022).

The commenter (0604-Providence) notes that the key to achieving a successful and equitable outcome is to set the detection threshold and screening frequency in such a manner so that the net emissions between the alternative screening options and the ground-level OGI based compliance method required by this rule will be equivalent. The commenter notes that the 10 kg/hr threshold is either much too high, or the frequency must be much higher than the proposed bi-monthly schedule to provide equivalency. The commenter encourages EPA to conduct a more detailed analysis to support both the threshold and frequency for advanced measurement technologies so that the matrix provides equivalent environmental benefit to the baseline OGI program. The commenter hope that such analysis will also include a scenario in which the frequency will be high enough (*e.g.*, hourly, 15-minute) to include new technologies that provide continuous leak monitoring. This would establish a threshold and mechanism for any advanced technology which can provide continuous monitoring of fugitive emissions, allowing for the potential to provide the same (or better) environmental benefit at a lower cost to the operator.

Response I-7-163: In response to the comments received on the November 2021 Proposal, EPA proposed a different regulatory approach for alternative screening using advanced methane detection technologies in the December 2022 Supplemental Proposal. For details, please see the discussion in section IV.B.1 of the December 2022 Supplemental Proposal.<sup>380</sup>

Comment: Commenter (0932-GHGSat, Inc.) believes that a minimum detection threshold must incorporate a more representative limit by incorporating a specific probability of detection, with a proposed unit of mass emission rate of methane per wind speed or mass emission rate of methane referenced to a specific winds speed be accompanied by a probability of detection and by a referenced wind speed or the minimum detection threshold expressed as mass emission per unit of wind speed. The commenter proposes the following:

- Minimum detection threshold of 4 kg/hr/m/s with 50 percent probability of detection; and
- Minimum detection threshold of 8 kg/hr/m/s with 90 percent probability of detection.

Response I-7-164: In response to the comments received on the November 2021 Proposal, EPA proposed a different regulatory approach for alternative screening using advanced methane detection technologies in the December 2022 Supplemental Proposal. For details, please see the discussion in section IV.B.1 of the December 2022 Supplemental Proposal.<sup>381</sup>

Comment: Commenter (0747-SENST) urges EPA to carefully investigate the effect of a fixed minimum detection threshold for screening methods versus a matrix of minimum detection thresholds versus survey frequency should be based on a rigorous assessment of real or potential emissions reductions. In addition, the commenter recommends that EPA determine if a fixed minimum detection threshold is futureproof because as emissions decrease with time progressively lower minimum detection threshold will be needed to support future reductions.

The commenter (0747-SENST) further suggests that EPA distinguish between a screening technology and a screening method and develop standard tests and test criteria for evaluating detection sensitivity and real or potential emissions reductions. If requiring a minimum detection

---

<sup>380</sup> 87 FR 74740 (December 6, 2022).

<sup>381</sup> 87 FR 74740 (December 6, 2022).

threshold, the commenter suggests that EPA explicitly define how this minimum detection threshold relates to the more common probability of detection (POD) curves, which account for uncertainty. Additionally, the commenter recommends that EPA require that detection performance and uncertainty are established using independent single-blind controlled release testing. Testing should be designed to account for factors that affect detection sensitivity and representative operating envelopes, in the commenter's opinion. The commenter states that EPA should require that detection methods be aware of and control for the conditions that increase the minimum detection threshold or lower the POD to ensure that performance is not adversely affected, and important leaks are missed. Lastly, the commenter indicates that EPA must differentiate between minimum detection threshold or POD and follow-up threshold. Screening methods with minimum detection thresholds that are lower than the regulated level may require the use of emissions quantification to flag facilities for follow-up (or other approaches), but quantification accuracy and uncertainty are not well constrained for most screening technologies presently.

Response I-7-165: In response to the comments received on the November 2021 Proposal, EPA proposed a different regulatory approach for alternative screening using advanced methane detection technologies in the December 2022 Supplemental Proposal. For details, please see the discussion in section IV.B.1 of the December 2022 Supplemental Proposal.<sup>382</sup>

#### ***7.2.7 Follow-Up OGI Survey***

Comment: Commenter (0586-Navajo EPA) supports the use of an expeditious follow up OGI if fugitive emissions have been detected. The commenter also supports the continued use of full OGI at least annually, if not more frequently (*e.g.*, semiannually).

Several commenters (0391-KBIC, 0781-NTAA, 0943-Sault EPD) also believe that the use of OGI technologies should be emphasized over EPA Method 21 for monitoring and that Method 21 should not be used for follow-up surveys after emissions were detected. The commenters believe OGI is more efficient and effective at identifying leaks and fugitive emissions.

Response I-7-166: See the discussion in section IV.B.1 of the December 2022 Supplemental Proposal.<sup>383</sup>

Comment: Commenter (0932-GHGSat, Inc.) understands the need to repair, as soon as practicable, methane emissions sources detected with alternative monitoring technologies. The commenter agrees with the understanding that large emissions events contribute disproportionately to the overall emissions within a region and/or facility. The commenter wants to comment on the classification of leaks based on severity and the associated tiered repair deadlines. The categories and tiered repair deadlines proposed provide for the repair deadline flexibility proposed in this rule, but with increased emphasis and sense of urgency on repairing the largest. Therefore, the commenter agrees that the process of scheduling repairs at compressor stations should be tiered based on the severity of the emissions found.

---

<sup>382</sup> 87 FR 74740 (December 6, 2022).

<sup>383</sup> 87 FR 74740 (December 6, 2022).

The commenter (0932-GHGSat, Inc.) proposes a 15-day deadline for the first repair attempt for emission between 10 and 100 kg/hr of methane. This, deadline gives an extra day in case the OGI survey is conducted near the 14-day limit and materials and/or replacement parts are not available. Please note that a tighter deadline is proposed for equal or larger than 100 kg/hr methane leaks.

Response I-7-167: See the discussion in section IV.B.1 of the December 2022 Supplemental Proposal.<sup>384</sup>

Comment: Commenters (0777-Ascent, 0780-LongPath<sup>385</sup>, 0785-John Crane Inc. LLC, 0807-BP) urge EPA to consider flexibility surrounding the requirements for the follow-up ground-based OGI survey.

The commenter (0777-Ascent) indicates that the deadline to complete the follow-up ground-based OGI survey in the November 2021 Proposal's alternative screening method is another disincentive for the regulated community. In the commenter's opinion, allowing only 14 days from aerial survey to conducting the full ground-based OGI survey will create compliance concerns for the regulated community. The time period to process and evaluate the data generated by an aerial survey can vary greatly, depending on what technology and vendor conducts the survey. Based on past experience, Ascent expects that it will take up to 10 days from the completion of the aerial survey to identify the sites for which a follow-up survey is required. Taking into account the potential for a survey to trigger ground-based surveys at multiple sites, Ascent Resources is concerned about a scenario where it would simply not have enough time to complete all the ground-based follow-up surveys within 14 days of the aerial survey.

For that reason, the commenter (0777-Ascent) suggests that EPA propose a deadline to conduct the follow-up OGI survey of 45 days from the screening survey. Extending that deadline would have little, if any, environmental impact, while eliminating a deadline that the commenter considers a significant disincentive to the November 2021 Proposal's alternative screening program – particularly for those larger companies that would survey many sites at the same time.

The commenter (0780-LongPath) adds if a matrix approach is undertaken, then regions of the matrix with higher frequency of readings (faster refresh rate, for example, continuous monitors) could be paired with a wider set of follow-up options before the requirement of an OGI visit. This is justifiable given the more detailed wealth of information and context regarding emissions that is afforded by continuous and higher-frequency monitors.

The commenter (0785-John Crane Inc.) recommends adopting a 30-day deadline for the first year of rule implementation as the number of assets requiring OGI surveys would be increasing significantly and the OGI infrastructure across companies may not be scaled appropriately for some time.

---

<sup>384</sup> 87 FR 74740 (December 6, 2022).

<sup>385</sup> Note that a duplicate letter from the commenter appears in the docket as EPA-HQ-OAR-2021-0317-0933.

The commenter (0785-John Crane Inc.) recommends the EPA adopt a tiered structure that is component/repair type specific rather than emissions level specific as some large emitters are able to be repaired very quickly whereas some process components require shutting down an operation for extended periods, or other highly disruptive process changes that require extensive planning, and intermediate or temporary solutions for emissions control until equipment overhaul or replacement can be completed.

The commenter (0807-BP) adds EPA should include an OGI follow-up survey exemption in the advanced screening proposal to address proven, intermittent emissions events. Under EPA's November 2021 Proposal, an OGI operator would be dispatched to a wellsite within 14 days of an emission detection from an advanced measurement survey. However, in some instances, the emissions detected during an advanced measurement survey may be intermittent — in some instances, not persisting beyond the duration of the survey itself. For example, water dump valve actuation or routine operational repairs may result in gas being discharged intermittently. Given the short emissions duration, these events should not require a follow-up OGI inspection. The commenter estimates that approximately 75 percent of detected fugitive methane emissions at its U.S. onshore sites come from detections on separators, heater treaters and well heads that are intermittently venting. Given the short duration of these intermittent events, by the time an OGI operator is deployed to the site the emissions source may be resolved.

The commenter (0807-BP) argues if intermittent emissions events can be corroborated by another technology or data source, and this two-step verification is appropriately documented by the operator, regulations should provide for an exemption from the follow-up OGI survey. For example, compressor or planned equipment blowdowns are permitted events that may be captured by aerial surveillance. However, based on the imagery provided by the vendor and available Supervisory Control and Data Acquisition (SCADA) data the commenter is able to determine, with sufficient confidence, that the emissions are connected to a known, planned, intermittent event. So that this exemption is employed only in appropriate circumstances, EPA may wish to require reasonable recordkeeping that would be available to regulators upon inspection.

As safety is a top priority for commenter (0807-BP), it is important to identify opportunities that minimize their employee and contractor drive time, which is a leading cause of fatality in the commenter's industry. If the commenter is required to send people out to sites despite having collected and recorded sufficient data evidence to demonstrate that an emissions source no longer persists, the commenter may be creating additional and avoidable safety risk to their people.

Response I-7-168: See the discussion in section IV.B.1 of the December 2022 Supplemental Proposal.<sup>386</sup>

Comment: Commenters (0775-CDPHE, 0830-Devon Energy, 0932-GHGSat, Inc., 1267-CA AG *et al.*) suggest that flexibility be provided around the timing for follow-up survey based on the severity of the leak.

---

<sup>386</sup> 87 FR 74740 (December 6, 2022).

The commenter (0775-CDPHE) questions whether one time frame is sufficient to address the myriad of issues that arise from advanced screening. For example, for just one site, the commenter believes that 14 days is generally too much time; Colorado's regulations require either first attempt at repair or completed repair within five days of detection of a leak. The commenter recognizes that under certain circumstances it is possible that aerial surveys could detect a significant number of emission events that would require a follow-up inspection, and that it may not be feasible to conduct all follow-up inspections within a truncated time frame. If an operator is scheduling certain advanced screening, such as aerial monitoring, it may be appropriate for that operator to also plan to have follow-up survey teams ready to deploy to visit locations with detected emissions within a reasonable timeframe. EPA may also want to consider tiering requirements for follow-up surveys so that those locations with the highest or most severe emissions are visited first. To reiterate, the commenter believes that programmatic flexibility is inherently necessary.

The commenter (0775-CDPHE) generally recommends that repair deadlines be advanced from EPA's November 2021 Proposal. Colorado's repair deadlines are also more stringent for leaks detection within 1,000 feet of an occupied area or within a disproportionately impacted community. If EPA established a tiered requirement for follow-up OGI surveys, then a tiered repair deadline may not be necessary. If there is no tiered requirement for follow-up surveys, then the commenter would agree that it would be appropriate to prioritize repair of the most severe or egregious fugitive emissions. The commenter notes that the "severity" of the fugitive emissions as detected by a monitoring technology can be variable based on field conditions, such as wind and weather, but also the location of the source. Because EPA would need to account for these variations and not simply rate or volume of emissions, the commenter reiterates the need for state flexibility in crafting appropriate advanced screening protocols to appropriately address the environmental and health impacts of fugitive emissions.

The commenter (0830-Devon Energy) encourages EPA to consider whether the proposed follow-up and repair timeframes are appropriate in every circumstance, particularly given the large amount of data obtained during a flyover screening survey. Operators should be given flexibility to prioritize those events with the highest estimated emission rate when using technologies that have the capability of providing a quantification estimate. Lower priority emission events (*i.e.*, those events with a lower estimated emission rate) should be allowed additional time for follow-up so that available operator resources can be utilized to address higher estimated emission rate events first.

The commenter (0932-GHGSat, Inc.) believes that EPA should consider implementing deadlines for first and final attempts for repairing and verifying the leak based on severity regardless of the component type or infrastructure. Satellite monitoring can detect the largest leaks (greater or equal than 100 kg/hr) and notify operators more quickly than other methods. This in turn could trigger a rapid repair response followed by OGI to verify the repair and survey the entire site, the latter representing an opportunity to detect lower emission rates synergistically.

Commenter (1267-CA AG *et al.*) recommends that EPA require a shorter repair period if the well site is located in proximity to an already overburdened community in terms of the follow-up survey. For instance, Colorado regulations require that a first attempt at the repair of a leaking

component be made within five days if a site is located within 1,000 feet of an occupied area or within a disproportionately impacted community.<sup>387</sup>

Response I-7-169: See the discussion in section IV.B.1 of the December 2022 Supplemental Proposal.<sup>388</sup>

Comment: Commenter (0830-Devon Energy) encourages EPA to consider how operators should follow up on methane emissions events detected by advanced continuous, near-continuous, and non-continuous detection technologies. In many cases, the cause and mitigation of an identified emission event can be determined remotely using operational information, including SCADA data, negating the need for a follow-up OGI inspection. This has an additive safety and environmental benefit of reducing the number of miles driven and the resulting emissions from travel to and from the site in question.

Response I-7-170: See the discussion in section IV.B.1 of the December 2022 Supplemental Proposal.<sup>389</sup>

Comment: Commenter (0807-BP) states EPA should clarify regulatory text indicating follow up actions within 14 days of “receiving the data” from the alternative screening survey. In the supplemental rule, EPA should clarify that the 14-day window for a follow-up OGI survey commences upon the operator’s receipt of the advanced screening survey results from the vendor. There are situations where operators may not receive the final survey data from third-party vendors on the day of inspection. Should the language remain as written, delays in data receipt could unintentionally consume several days afforded in the 14-day window for follow-up OGI surveys. In so doing, operators would end up with less time to execute follow-up surveys. Assuming the intent is to provide operators with a full 14 days to perform the follow-up surveys, EPA should clarify that this window begins at the time of data receipt, not the survey itself.

Response I-7-171: See the discussion in section IV.B.1 of the December 2022 Supplemental Proposal.<sup>390</sup>

### ***7.2.8 Incentivize Advanced Technology***

Comment: Commenter (0787-Atmos<sup>391</sup>) believes that the EPA should incentivize the use of advanced fugitive emissions monitoring technology. It is crucial that EPA make it as easy as possible for companies to quickly adopt and install advanced fugitive emissions monitoring technologies. For context, the commenter installed a Gas Cloud Imaging (GCI) system<sup>392</sup> in 2021 at a large storage and compression facility that can identify leaks from up to 1.7 miles away and continuously scans the site using pan and zoom functions to provide real-time leak detection

---

<sup>388</sup> 87 FR 74740 (December 6, 2022).

<sup>389</sup> 87 FR 74740 (December 6, 2022).

<sup>390</sup> 87 FR 74740 (December 6, 2022).

<sup>391</sup> Note that a duplicate letter from the commenter appears in the docket as EPA-HQ-OAR-2021-0317-1280.

<sup>392</sup> Honeywell, GCI – Standard, <https://sps.honeywell.com/us/en/products/safety/gas-and-flame-detection/gas-cloudimaging/gci-standard>.

This technology is far more sensitive than the 10 kg/hr threshold that EPA proposes.<sup>393</sup> The GCI camera's advanced imaging technology analyzes hyperspectral data from every pixel at a rate of 60 times per second to identify more than 50 gases, each of which have a unique emission in the long-wave infrared spectrum that the camera detects.<sup>394</sup> Additionally, the GCI camera depicts the size of the gas cloud and the direction the plume is moving in real time.<sup>395</sup> Removing barriers to companies installing such systems like the current application process would benefit the environment and further the purpose of the November 2021 Proposal.

Response I-7-172: See discussion in section IV.B.2 of the December 2022 Supplemental Proposal for a discussion on alternative methane detection technologies, including where EPA specifically discussed the goal of incentivizing new technologies, plus requested additional feedback from owners and operators on ways to improve and further incentivize use of alternative technologies.<sup>396</sup> Please also see section X.B.2 of the preamble to the final rule which details EPA's final standards related to the use of alternative technologies for detection of fugitive emissions under the advanced methane detection technology program, and section XI.B.1.b of the preamble to the final rule for a specific discussion on technology flexibility.

Comment: Commenter (0610-Oxy) believes streamlining the use of advanced measurement technology framework will allow for increased efficiencies for the on-going surveys. The proactive approach of reducing fugitive potential is more effective than increased survey frequency. Compared to facilities with higher potential for fugitives, the commenter believes lower emitting facilities should have reduced survey frequency. However, the commenter does see value in on-going surveys at these locations and does not think a one-time survey is appropriate.

Response I-7-173: See discussion in section IV.B of the December 2022 Supplemental Proposal for a discussion on alternative methane detection technologies, including where EPA specifically discussed establishing a clear and streamlined pathway for EPA approval for the use of advanced measurement technologies alternative periodic screening and alternative continuous monitoring. Under this alternative screening option. Please also see section X.B.2 of the preamble to the final rule which details EPA's final standards related to the use of alternative technologies for detection of fugitive emissions under the advanced methane detection technology program.

Comment: Commenter (0844-EDF *et al.*) indicates that by incorporating a flexible alternative, which may be more cost-effective for many operators and is likely to become less expensive over time, EPA can support innovative new approaches that will allow LDAR and methane mitigation markets to grow and become more efficient. EPA can also set parameters that achieve reductions equivalent to or greater than OGI in a manner that can further spur development of new technologies. Building in this flexibility will ensure that new technologies can qualify for regulatory use and will allow companies to innovate around clear parameters. A strong OGI-based BSER that rests on longstanding analytical methods and relies on proven technologies and

---

<sup>393</sup>86 Fed. Reg. at 63,175.

<sup>394</sup>Honeywell, Honeywell Rebellion GCI System, 2, (July 2020), <https://www.honeywellprocess.com/library/marketing/notes/Rebellion-Gas-Cloud-Imaging-PIN.pdf>.

<sup>395</sup>*Id.*

<sup>396</sup> 87 FR 74744-74745 (December 6, 2022).

approaches provides a clear pathway for compliance and helps to ensure any approved alternative is rigorous and can achieve equivalent or better reductions.

The commenter (0844-EDF *et al.*) says that as proposed, the advanced monitoring alternative requires annual OGI at all sites, regardless of PTE. This means EPA's proposed alternative is more comprehensive and is likely to achieve greater emission reductions, at least at smaller sites, than the BSER and would apply to many more sites. EPA must ensure that the BSER is no less protective than the alternative and should therefore strengthen the OGI program to remove any disparities in the stringency or coverage of the two potential approaches.<sup>397</sup>

The commenter (0844-EDF *et al.*) believes EPA should allow companies to use advanced monitoring technology as an alternative to OGI only when equivalent emission reductions can be demonstrated across a range of emission distributions. To do so, EPA could establish a framework that includes several pre-approved alternatives reflecting different combinations of detection threshold, frequency, regular OGI inspections, and OGI follow-up requirements. Critically, this framework should center on emission reductions, and need not necessarily reflect technologies or practices that are already “in actual routine use somewhere,”<sup>398</sup> (although many are) so long as they are not “purely theoretical or experimental” or “based on a ‘crystal ball’ inquiry.” As discussed earlier in these comments, CAA is a technology forcing statute,<sup>399</sup> and section 111 “looks toward what may fairly be projected for the regulatory future, rather than the state of the art at present.”<sup>400</sup> EPA could thus design frameworks that accommodate reasonably anticipated improvements in detection capabilities, rather than the limitations of currently in-use technologies. Alongside this preapproved framework, EPA could also consider allowing for submission of alternatives that may have more limited applicability (for instance, in higher emitting basins like the Permian) for specific approval.

The commenter (0844-EDF *et al.*) continues, with available methods for comparing emission reductions across different LDAR approaches, EPA need not foreclose the use of new and existing technologies that can effectively reduce emissions. However, EPA must only allow technologies that can be proven to satisfy rigorous parameters and achieve the same or greater emission reductions under a variety of scenarios. To ensure equivalent emission reductions, EPA could finalize multiple approved alternatives by evaluating monitoring frequency and detection capabilities—meaning that technologies with better detection capabilities could be used less frequently and those with higher detection limits could be used more frequently.

The commenter (0844-EDF *et al.*) states for large emission events detected through screening, operators should be required to immediately report to a publicly-accessible database any detected emissions, and additionally, report when the repair is complete. As EPA has recognized, super-emitters should not occur at well designed and well-maintained sites. Mitigating super-emitters, while extremely important, is the bare-minimum that EPA should seek to achieve through the LDAR program. If a super-emitter is detected, the operator should be required to submit

---

<sup>397</sup>See, e.g., OOOOa TSD at 56-57 (comparing Method 21 effectiveness at 500 and 10,000 ppm and finalizing 500 ppm as alternative in order to achieve reductions equal to or greater than OGI BSER).

<sup>398</sup>Portland Cement Ass'n v. Ruckelshaus, 486 F.2d 375, 391 (D.C. Cir. 1973).

<sup>399</sup>Union Elec. Co. v. EPA, 427 U.S. 246, 257 (1976).

<sup>400</sup>Portland Cement Ass'n, 486 F.2d at 391.

supporting documentation and explain the likely cause. Operators who could prove the emissions resulted from a permissible event, like a scheduled blowdown, would not have to undertake additional action. However, where the cause of the emissions is unknown, or where multiple events have been detected at the same source or from the same operator, EPA should require a full engineering analysis.

Though commenter (0844-EDF *et al.*) supports the alternative framework as set forth by EPA, there are also various other ways in which the LDAR program could be structured within the CAA framework—including layered approaches and advanced monitoring for compliance assurance. Section 114 of the CAA grants EPA authority to require screening with advanced technologies for compliance assurance purposes. Under CAA section 114(a)(3), EPA “may require any person who owns or operates any emission source . . . to install, use, and maintain . . . monitoring equipment” and “may . . . require enhanced monitoring and submission of compliance certifications.” For major sources, EPA is statutorily required to promulgate enhanced compliance assurance monitoring standards,<sup>401</sup> as it has done in the past.<sup>402</sup> Requiring enhanced monitoring for oil and gas sources would be a well-justified use of EPA’s discretion because of the severe and widespread problem of fugitive emissions in this sector. Under this alternate approach, EPA could designate OGI as the BSER for fugitive emissions and require advanced screening at all sites periodically for compliance assurance purposes.

The commenter (0844-EDF *et al.*) states as EPA has recognized, a well-maintained site that is following the work practice standards included in the proposed rulemaking (and as strengthened in the ways described in these comments) should not experience super-emitter events.<sup>403</sup> Nonetheless, these large emission events occur frequently across the industry—including at sites owned by major oil and gas companies.<sup>404</sup> Using advanced methods to periodically screen for super-emitter events would allow EPA to ensure compliance with the underlying work practice standards and could be used to prevent operators experiencing super-emitters from certifying compliance in those instances.

The commenter (0844-EDF *et al.*) notes as a CAA section 114 requirement, advanced monitoring would create further incentives for operators to comply with the work practice standards and take preventative measures against abnormal process emissions. It would also help ensure that reported emissions and inventories are accurate.<sup>405</sup> Furthermore, operators could pool

---

<sup>401</sup>42 U.S.C. § 7414(a)(3) (“The Administrator shall in the case of any person which is the owner or operator of a major stationary source, and may, in the case of any other person, require enhanced monitoring and submission of compliance certifications.”).

<sup>402</sup>See, e.g., Compliance Assurance Monitoring, 62 Fed. Reg. 54,900 (Oct. 22, 1997).

<sup>403</sup>See Refinery Standards at 75,190 (explaining that the fenceline monitoring pollutant level that triggered corrective action “was consistent with the emissions projected from fugitive sources compliant with the provisions of the . . . standards”).

<sup>404</sup>See Permian Methane Analysis Project, Operator Emissions, <https://data.permianmap.org/pages/operators> (showing the ten operators with the highest number of detected emissions with emission rates greater than 1000 kg/hr, including ConocoPhillips, BPX, and Occidental).

<sup>405</sup>Refineries RTC at 13 (“The fenceline monitoring approach was proposed largely to address concerns that emissions, particularly from fugitive sources . . . , are difficult to characterize and studies have shown measured emissions to be many times higher than inventory reported values.”).

resources and hire a single LDAR contractor to conduct aerial surveys across an entire basin.<sup>406</sup> This is a low-cost solution (\$100-200/site) for ensuring compliance and allowing for quick detection and mitigation of large emission events. Accordingly, the commenter encourages EPA to consider how the compliance assurance benefits of these technologies may be integrated into EPA's proposal in a manner that helps to further support emission reductions.

Response I-7-174: EPA acknowledges the commenters support for the use of alternative technologies. EPA has taken this comment into account as they designed the alternative technology program in the December 2022 Supplemental Proposal. See discussion in section IV.B of the December 2022 Supplemental Proposal related to advanced methane detection technologies.<sup>407</sup> See discussion in section IV.B.2 of the December 2022 Supplemental Proposal for a discussion on alternative methane detection technologies, including where EPA specifically discussed the goal of incentivizing new technologies, plus requested additional feedback from owners and operators on ways to improve and further incentivize use of alternative technologies.<sup>408</sup> Please also see section X.B.2 of the preamble to the final rule which details EPA's final standards related to the use of alternative technologies for detection of fugitive emissions under the advanced methane detection technology program, and section XI.B.1.b of the preamble to the final rule for a specific discussion on technology flexibility.

Comment: Commenter (0787-Atmos) fully supports the EPA's November 2021 Proposal to allow for bimonthly screening surveys using advanced leak detection technology and annual OGI or EPA Method 21 monitoring at each individual well site or compressor station.<sup>409</sup> In order to maximize the incentives for companies in the natural gas sector to adopt advanced emissions monitoring technology, the commenter recommends that the EPA (1) publish a list of approved technologies that are as good or better than OGI and (2) adopt a matrix approach for monitoring requirements.

Response I-7-175: EPA acknowledges the commenter's support. In response to the comments received on the November 2021 Proposal, EPA proposed a different regulatory approach for alternative screening using advanced methane detection technologies in the December 2022 Supplemental Proposal. For details, please see the discussion in section IV.B.1 of the December 2022 Supplemental Proposal.<sup>410</sup>

Comment: Commenter (0934-Leak Surveys, Inc.) argues if an aerial survey triggers a OGI ground survey, as proposed in November 2021, it would be adding additional cost to the site operator. This response penalizes commercial operators and would discourage the site from even considering these advanced technologies.

Response I-7-176: In response to the comments received on the November 2021 Proposal, EPA proposed a different regulatory approach for alternative screening using advanced methane

detection technologies in the December 2022 Supplemental Proposal. For details, please see the discussion in section IV.B.1 of the December 2022 Supplemental Proposal.<sup>411</sup>

### ***7.2.9 Publish List of Approved Technologies/Alternatives to Approval Process***

Comment: Commenters (0787-Atmos, 0807-BP) suggests that EPA publish a list of approved alternative fugitive emissions monitoring technologies for companies to use.

The commenter (0787-Atmos) says that the NSPS and EG rules should largely retain existing regulations that require companies to submit individual applications to the agency to utilize AMEL.<sup>412</sup> However, AMEL applications can take one to two years before EPA approves them, which delays the implementation of technologies. A published list of approved technologies, with the ability for companies to notify EPA of a new monitoring technology as it becomes available, would help eliminate the innovation barriers embedded in the November 2021 Proposal.

The commenter (0787-Atmos) suggests that for technologies not on EPA's published list, or while EPA gathers the technical expertise to develop such a list, EPA should amend its regulations to allow a notification to the agency that the company has conducted a performance test demonstrating that the AMEL technology exceeds the applicable OGI standard for at least a six-month period. So long as a company submits proof to EPA that the technology is as good or better than OGI, EPA should automatically allow its use for fugitive emissions monitoring at facilities that meet the technology's operating criteria (*e.g.*, line of sight). Note that any equipment that is out of the technology's operating criteria should remain subject to the applicable regulatory fugitive emissions monitoring requirements. Amending and developing the NSPS and EG regulations in this manner would accelerate the adoption of advanced, highly sensitive fugitive emissions monitoring technology and ease the administrative burden EPA would otherwise have to deal with in processing applications.

The commenter (0807-BP) believes EPA should clarify and streamline how operators demonstrate that a technology achieves the emissions detection threshold. Industry needs clear guidance and procedures for how to demonstrate a technology meets the specified emission detection limit. The commenter specifically encourages EPA consider, and take comment on, the potential role that third-party certification organizations and technology vendors can play in the verification process. According to the commenter, EPA already follows this approach in closely related contexts. For example, third-party organizations like the National Physical Laboratory confirm that FLIR OGI cameras can image gas at the required NSPS OOOOa concentration and flow rates. Similarly here, EPA could allow operators to rely on third-party certification organizations and technology vendors to demonstrate that their technology meets the alternative screening standard requirements.

Commenter (0807-BP) adds EPA could streamline the verification process by maintaining a regularly updated list of approved technologies. With only a few proven methane technology vendors in the market today, companies may find themselves duplicating efforts in

---

<sup>411</sup> 87 FR 74740 (December 6, 2022).

<sup>412</sup>Id. at 63,166.

demonstrating and verifying compliance. As proposed, each individual operator would have to undertake the process of verifying their advanced screening technology for compliance, even if the technology has already been verified for use by another operator. The commenter states by maintaining a list of approved technologies, EPA could reduce these duplicative efforts and maintain a list, posted on its website, for approved technologies that meet methane detection thresholds. To expedite the use of advanced methane technologies and to make alternative screening more widely available, the commenter recommends that EPA consider pre-verifying existing, proven technologies that meet the standard in advance of the rule's compliance deadlines.

Response I-7-177: See discussion in section IV.B.3 of the December 2022 Supplemental Proposal.<sup>413</sup>

Comment: The commenter (0831-AXPC) states that given the challenges with approving alternative means of emission limitation (AMEL) under section 111(h)(3) of the CAA, the commenter strongly supports EPA's effort to explore other routes that could ease the ability for new technologies to be utilized for compliance.

Response I-7-178: EPA acknowledges the commenter's support.

Comment: Commenter (0749-PAW, 0810-Petroleum Alliance-OK, 0820-Pioneer, 0831-AXPC) note that with the quickly evolving space of emission technologies, a clear path for approved technologies is needed.

The commenter (0810-Petroleum Alliance-OK) says that should simplify the approval process and not delay or hold emerging alternative technologies to higher standards than existing OGI requirements. For this type of technology, as well as continuous monitoring technologies, the commenter encourages EPA to develop a framework that will allow technologies to be used without going through an additional approval process (*e.g.*, specified surveys per year if the technology has a specified detection limit).

The commenters (0820-Pioneer, 0831-AXPC) recommend EPA establish clear and consistent parameters under which a technology will be able to detect methane emissions and site-specific variables can be addressed in conditions required for the use of the technology. The commenters also recommend that EPA should allow for basin-wide equivalency determinations or basin-wide approvals, once equivalency has been demonstrated, and incorporation by reference of emerging technologies to other sites.

The commenter (0820-Pioneer, 0831-AXPC) support the allowance for modeling and testing at a controlled test environment to demonstrate performance of a new technologies. The commenters supports EPA allowing for vendors and manufacturers as applicants for approval of emerging technology and not limiting the submissions to oil and natural gas companies with sites. Artificially limiting submissions to oil and natural gas companies prohibits the experts that are

---

<sup>413</sup> 87 FR 74747 (December 6, 2022).

developing these new and emerging technologies from working with EPA and other stakeholders to implement the technologies as broadly as possible to reduce emissions at a lower cost.

The commenter (0749-PAW) adds to promote innovation and ingenuity, any prescriptive language that could limit development of technology should be avoided. Instead, language should be included to allow states to incorporate these technologies.

Response I-7-179: See discussion in section IV.B.3 of the December 2022 Supplemental Proposal.<sup>414</sup>

Comment: Commenter (0747-SENST) believes that EPA should develop a rigorous review process to evaluate screening programs before they are approved and implemented as alternatives to the BSER. The commenter believes that EPA should investigate in detail the role of modeling for informing regulations regarding screening methods and how results can vary by changing model inputs and parameter settings. Further, the use of models to evaluate or approve different programs with screening methods requires further evaluation.

Response I-7-180: See discussion in section IV.B.3 of the December 2022 Supplemental Proposal.<sup>415</sup>

### ***7.2.10 Clarifications/Questions***

Comment: Commenter (0604-Providence) states that the proposed 10 kg/hr threshold was not clearly defined. The commenter asks additional questions such as whether it matters if the 10 kg/hr originates from a single leaking component or whether it is a site-wide emission threshold. The commenter was also unclear whether the advanced measurement technology is required to distinguish between fugitive emissions and emissions from permitted sources. The commenter further asks questions on what follow-up action would be required when a detection is made if the technology does not distinguish between fugitive emissions from a permitted source, and what would be required during the follow-up OGI survey. The commenter questioned the benefit of the alternative program if the alternative screening always triggers a follow-up OGI survey.

Response I-7-181: In response to the comments received on the November 2021 Proposal, EPA proposed a different regulatory approach for alternative screening using advanced methane detection technologies in the December 2022 Supplemental Proposal. For details, please see the discussion in section IV.B.1 of the December 2022 Supplemental Proposal.<sup>416</sup>

## **7.3 Continuous Monitoring**

### ***7.3.1 General Support/Technology Information***

Comment: Several commenters (0437-NYOSC, 0588-Project Canary, 0590-Honeywell, 0791-Airdar, 0767-Scientific Aviation, 0756-Baker Hughes, 0759-LongPath Technologies, Inc.

---

<sup>414</sup> 87 FR 74747 (December 6, 2022).

<sup>415</sup> 87 FR 74747 (December 6, 2022).

<sup>416</sup> 87 FR 74740 (December 6, 2022).

(LongPath) *et al.* are in favor of including continuous monitoring as an alternative to the fugitive emissions monitoring requirements in the rule. The commenters report that continuous monitoring technologies are available and can be cost-effective reliable alternative methods to traditional detection methods.

Commenter (0588-Project Canary) specifically indicates that continuous monitoring systems possess multiple advantages including:

- Detecting methane emissions faster both from the site and specific leak location,
- Capturing intermittent emissions that periodic surveys may not,
- Providing rapid verification of repairs, and
- Collecting additional temporal information that can help in developing future EPA regulations.

Commenter (0588-Project Canary) states their continuous monitoring system has been tested at the Colorado State University METEC, where METEC simulated leaks of various sizes from oil and natural gas production equipment by releasing methane gas at a known rate. Testing has been conducted in multiple seasons, wind conditions, and leak rates. Several rounds of testing have occurred for methane, specifically in February 2021, August 2021, and September 2021. In all cases, leaks have been detected rapidly (within minutes of any release).

Commenter (0590-Honeywell) points out that although methane is the main component of natural gas, a leak may not be pure methane. Monitoring for other gas compounds, in addition to methane, can be another benefit of continuous monitoring technology.

Commenter (0437-NYOSC) believes the rule should take advantage of the expanding availability of cost-effective continuous methane monitoring technology to phase in a continuous methane monitoring requirement, perhaps starting with sites with the potential for large emissions.<sup>417</sup>

Commenter (0759-LongPath *et al.*) states that continuous monitoring must be included in upcoming regulations to keep up with the pace of innovation that has occurred over the last year. The commenter believes that not including continuous monitoring in the regulations would make companies less likely to implement continuous monitoring, and companies who have already invested in continuous monitoring programs will suffer an additional cost burden in comparison to peers using inferior methodologies.

The commenter (0759-LongPath *et al.*) further notes that environmental damage depends on the cumulative amounts of methane, VOC, and other pollutants that enter the atmosphere over time, not the instantaneous rate of emissions. Continuous monitoring is the only way that total pollution can be assessed unambiguously because it measures the duration of emissions events. Relatedly, continuous monitoring enables more rapid mitigation of emissions, such that total

---

<sup>417</sup> See: Maamary, Rabih, et al. "A Quantum Cascade Laser-Based Optical Sensor for Continuous Monitoring of Environmental Methane in Dunkirk (France)" *Sensors* 16, no. 2: 224. 2016. See also: Titchener, James et al. "Single Photon Lidar Gas Imagers for Practical and Widespread Continuous Methane Monitoring," *Applied Energy*, Volume 306, Part B, January 15, 2022.

cumulative emissions over time are much lower with continuous monitoring technologies compared with survey technologies.

The commenter (0759-LongPath *et al.*) states continuous monitoring has been extensively evaluated by scientists and engineers at NGOs, academic institutions, and industry through both laboratory and field testing, including controlled releases and validation against Best Available Technology in controlled settings. Additional tests of continuous monitors are being undertaken through the Advancing Development of Emissions Detection (ADED) study.<sup>418</sup> Testing has also been conducted in field settings, both through comparing different measurement techniques<sup>419</sup>, as well as through controlled releases.<sup>420</sup>

The commenter (0759-LongPath *et al.*) notes industry adoption has been growing rapidly. Operators have been active in research projects and industry consortia. For example, the EPA Methane Workshop<sup>421</sup> included producers such as TRP Energy, Jonah Energy, and Occidental Petroleum Corporation. Moreover, numerous companies have publicly announced their adoption of continuous monitoring. In 2021, Southwestern Energy announced its plans to continuously monitor its Appalachia basin operations,<sup>422</sup> and ExxonMobil announced that it had expanded use of continuous monitoring.<sup>423,424</sup> By the end of 2021, 5,000 continuous emission monitoring systems were deployed in North America versus less than 1,000 at beginning of the year.

Response I-7-182: EPA acknowledges the commenters support for the use of continuous monitoring. See discussion in section IV.B.2 of the December 2022 Supplemental Proposal.<sup>425</sup>

Comment: Commenter (0588-Project Canary) states numerous peer-reviewed studies have demonstrated that emissions from oil and natural gas operations are intermittent.<sup>426</sup> This effect

<sup>425</sup> 87 FR 74744-74745 (December 6, 2022).

<sup>426</sup> Allen, David T., Felipe J. Cardoso-Saldaña, and Yosuke Kimura, Variability in spatially and temporally resolved emissions and hydrocarbon source fingerprints for oil and gas sources in shale gas production regions, *Environmental science & technology* 51, no. 20 (2017): 12016-12026; Valeria Di Filippo, Ammar Abdilghanie Mohammed, Jianmin (Jimmy) Zhang, Ashraf El-Messidi, Pejman Kazempoor, Nasr Alkadi, Measurement-Based Emission Factors Using BHGE Advanced Methane Sensing Technologies and Analytics (Mar. 31, 2019), Environment and Climate Change Canada (ECCC) Project GCXE18S024. Technical Report; Cardoso-Saldaña, Felipe J. and David T. Allen, Projecting the Temporal Evolution of Methane Emissions from Oil and Gas Production Sites, *Environmental Science & Technology* 54, no. 22 (2020): 14172-14181; Variability observed over time in methane emissions from abandoned oil and gas wells, *International Journal of Greenhouse Gas Control* 100

may be more pronounced with respect to high emissions events: one study<sup>427</sup> found that high emission events are brief and concluded that “short-term sampling is likely to miss them.” Additionally, the variability in emissions rate is not caused by changes in production rate: one study found that production variability only accounts for 10 percent of the observed variability in emissions rate.<sup>428</sup>

The commenter (0588-Project Canary) states this variability is due to the underlying engineering of an oil and natural gas production site. Intermittent emissions are the most typical type of emissions detected from locations. This is caused by intermittent pressure fluctuations that are constantly being managed at a production facility. Tank levels and pressures rise and fall, separators dump periodically, slugs and flow rate fluctuations from the wells themselves occur, and seal and valve effectiveness can vary with ambient temperature fluctuations and environmental factors.

The commenter’s (0588-Project Canary) data shows that, while one individual day may present a high emissions event, these levels are seldom observed on the following day or days. This data also demonstrates that sampling on any one individual day may mischaracterize the emissions distribution of a given site, a conclusion that is echoed in the peer reviewed studies.<sup>429</sup>

The commenter (0588-Project Canary) adds when an operator is armed with a situational awareness on a continuous basis of when and where emissions are occurring, that operator has a much greater ability to find and fix non-routine/non-allowable emission events. That operator also gains a greater awareness of the types of routine/allowable emission events that it may wish to target for voluntary future emissions reduction projects. Such projects include addition of liquid loadout control systems, well blowdown combustion rather than venting, replacement of higher emitting valves/pneumatics, and chemical programs to prevent waxes/hydrates.

Response I-7-183: See discussion in section IV.B.2 of the December 2022 Supplemental Proposal.<sup>430</sup>

Comment: Commenters (0588-Project Canary, 0756-Baker Hughes, 0759-LongPath *et al.*, 0791-Airdar) state continuous monitoring can help provide on-the-ground information that the sector currently lacks. This will, among other things, ensure federal and state decisions in this area are made with the best available information. One of the areas of general agreement in the oil and natural gas sector is that, according to multiple studies on the topic, fugitive emissions estimates

---

Cardoso-Saldaña, and Yosuke Kimura, Variability in spatially and temporally resolved emissions and hydrocarbon source fingerprints for oil and gas sources in shale gas production regions, *Environmental Science & Technology* 51, no. 20 (2017): 12016-12026.

<sup>430</sup> 87 FR 74744-74745 (December 6, 2022).

have been underestimated.<sup>431</sup> The commenter (0588-Project Canary) believes their view is supported by not only Project Canary's data, but by analysis using outside and independent sources as well. The commenter's analysis, using the FEAST model<sup>432</sup>, an open-source software tool that compares the efficacy of different leak detection programs, demonstrates that using a continuous monitoring program for LDAR with the use of a follow-up OGI camera avoids more than 80 percent of emissions and reduces emissions by more than 2 times compared with bi-annual surveys.

Commenter (0791-Airdar) cites to several studies showing that a small fraction of emission sources comprises the majority of total emissions.<sup>433,434,435,436,437</sup> These studies indicate a significant potential to reduce emissions by resolving a few large leaks. It is important to understand the nature of fugitive emissions to overcome challenges in monitoring emissions and address deficiencies in current methodologies.

The commenter (0588-Project Canary) speculates that continuous monitoring would result in emissions reductions well above those estimated in the November 2021 Proposal, in an amount between about 370 million short tons of methane to about 3,700 million short tons of methane.<sup>438,439</sup> According to EPA, all the requirements from its proposed regulations for new and existing sources together result in a reduction of 41.1 million short tons of methane. Thus, even at the lower bound, if only 12 percent of sources choose to implement continuous monitoring (or

<sup>438</sup> For convenience, we provide calculations with respect to methane emission reductions. CM offers similar reductions for VOC as well.

<sup>439</sup> As stated previously, this assumes that EPA approves the use of CM as an alternative compliance standard for meeting the requirements for OOOOb and OOOOc and that all sources choose to comply using that method. We are also assuming that repair occurs within the same timeframe regardless of the detection device, so there would be no difference in emissions reductions when comparing the various alternatives with respect to detection (i.e., we do not assume that detection to repair is Y number of days for CM and detection to repair is Z number of days for periodic OGI).

if all sources so chose but total leaks were only 12 percent of those estimated), that would double the methane reductions from the regulation.

The commenter (0759-LongPath *et al.*) provides another example, consider a super-emitting event that emits methane at a rate of 100 kg/hr. Most continuous monitoring solutions would detect this event and notify the operator within an hour, leading to immediate response. If continuous monitoring was not used and the event continued until the next operator rounds, several days or weeks could pass until identified. If the issue was not identified until the next quarterly LDAR inspection, up to 3 months could pass. The commenter indicates that based on the estimated response times, continuous monitoring could achieve a 99.5 percent reduction in methane emissions compared to only 75.3 percent under quarterly LDAR (assuming worst case scenario for detection timelines).

The commenter (0759-LongPath *et al.*) also notes that analysis using FEAST<sup>440</sup> demonstrates that using a continuous monitoring program for LDAR with the use of a follow-up handheld OGI inspection avoids more than 80 percent of emissions and reduces emissions by more than two times compared with bi-annual surveys.

The commenters (0588-Project Canary, 0759-LongPath *et al.*) give an example, if a site had a 10 kg/hr emission rate or higher, OGI, flyovers, drones, and/or satellites could detect this. A continuous monitor would pick up a 10 kg/hr emission within seconds, whereas other technologies would detect this when they were active or aimed directly at the emissions source. The commenter (0588-Project Canary) states instead of only two to six measurements per year, continuous monitoring systems provide hundreds to millions of measurements per year. The commenter (0759-LongPath *et al.*) gives the example of a continuous monitor detecting a single, constant emissions event of 10 kg/h within hours -instead of within an average of 30 days for bi-monthly inspection-based screening (such as airborne detection) -results in incremental reduction of 7.2 tons of methane (30 days x 24 hr x 10 kg/hr). At a social cost of methane of \$1,800 per ton the Incremental emission reduction provides \$12,960 in climate benefits beyond the reductions accomplished by bi-monthly inspection-based screening.

The commenter (0588-Project Canary) adds continuous monitoring also has a clear advantage in detecting small emission events, due to continuous monitoring's sensitivity and continuous functioning. By contrast, flyovers and satellites cannot detect very small emission sources at a given location. OGI cameras may be able to find smaller leaks, but given the periodic nature of OGI inspections, they will always result in fewer emissions avoided than continuous monitoring. Intermittent emissions are inherently difficult to detect with non-continuous systems.

Response I-7-184: See discussion in section IV.B.2 of the December 2022 Supplemental Proposal.<sup>441</sup>

<sup>441</sup> 87 FR 74744-74745 (December 6, 2022).

Comment: Commenters (0588-Project Canary, 0756-Baker Hughes, 0759-LongPath *et al.*, 0791-Airdar, 0844-EDF *et al.*) state continuous monitoring provides more accurate quantification of emissions than those offered by periodic surveys. Emission rates may not be constant and can vary due to many factors including changing weather conditions, facility operations, third-party activities, and the time of day. Periodic surveys using EPA Method 21 or handheld OGI cameras are unable to capture the variability of emissions over time.

The commenter (0759-LongPath *et al.*) states numerous studies have demonstrated that a significant fraction of both small and large emission sources – including super-emitters – are intermittent.<sup>442,443,444,445,446</sup> Additionally, the variability in emissions rate is not caused only by changes in production rate. One study found that production variability explains only 10 percent of the observed variability in the emissions rate<sup>447</sup>, meaning that production rates are not generally the cause of this variability.

The commenter (0759-LongPath *et al.*) states intermittent emitters are potentially missed by systems that are employed only a few times per year because survey visits may not intersect with the time at which an emission occurs<sup>448</sup>. In order to improve the efficiency and effectiveness of methane emission control rules, EPA needs to better understand the temporal variability of emissions. These data can only be provided by continuous monitoring systems. Indeed, the ability to assess intermittent vs. sustained emissions profiles is a unique strength of continuous monitoring that cannot be provided by survey technologies. Continuous monitoring systems are the most likely to capture intermittent emitters and assess their importance.

The commenter (0791-Airdar) notes that five separate inspections were performed over the 18-months using an OGI camera and a hi-flow sampler to quantify emissions. When compared to emission rates obtained by the continuous monitoring system, the values agreed. However, there are times emission rates are high, which is not captured by the periodic surveys. The average emission rate measured by continuous measurements were five to seven times larger than the average emission rate determined through periodic monitoring. This shows how emissions may be underestimated through periodic methods and are less accurate in determining the exact

impact of a leak on the environment. Continuous monitoring technologies are better at capturing intermittent emission than any other method. All other methods currently available today including airplanes, drones, vehicles, and handheld gas detectors provide only periodic screening for emissions.

The commenter (0791-Airdar) states the effectiveness of continuous monitoring systems has been demonstrated by industry and eagerness is growing to adopt continuous monitoring technologies. Since 2005, the commenter has worked with industry to conduct several projects that have demonstrated the capabilities of our continuous monitoring system and has seen support from industry since that time for continuous monitoring technologies. In 2009, the commenter won an Alberta Science and Technology Award (ASTECH) with several letters of recommendation from industry showing their support for Airdar.

The commenter (0791-Airdar) states while most of their projects are confidential, projects that can be shared publicly include our work at three oil and gas facilities<sup>449,450,451</sup>, a wastewater treatment plant<sup>452</sup>, and a composting facility. The work completed at the wastewater treatment plant was presented at the 2019 Air Quality Measurements and Technology Conference sponsored by the Air and Waste Management Association (AWMA). This project also won an award from the Consulting Engineers of Alberta. In 2010, the commenter worked with an industry group who saw the value and capabilities of Airdar to develop a GHG offset protocol in Alberta that would see GHG credit be awarded for reduction in fugitive methane emissions that were authenticated by Airdar or a similar continuous monitoring technology.<sup>453</sup> This moved to the final stage of approval but was not approved in the end. The proposed protocol would have generated GHG credits worth much more than the cost of the Airdar monitoring, which the industry group saw as a way for paying the extra monitoring efforts in addition to performing the required LDAR surveys.

Commenters (0588-Project Canary, 0844-EDF *et al.*) states many continuous monitoring systems already meet the parameters EPA has outlined for advanced monitoring: they screen sites at least six times per year at a 10 kg/hr detection threshold. In fact, many screen sites far more often than the bimonthly minimum required and have greater detection capabilities. Because of this, EPA can develop an alternative framework for continuous monitoring by making adjustments to account for some of the differences and potential concerns EPA has outlined with respect to continuous monitoring. EPA may need to develop separate, detailed work practice follow-up requirements for continuous monitoring that are technology-specific, similar to the proposed Appendix K for OGI.<sup>454</sup>

<sup>451</sup> Dennis Prince et al., 2019.

<sup>452</sup> Dennis Prince et al., 2019.

<sup>453</sup> Dennis Prince et al., 2010.

<sup>454</sup> See, e.g., Comment from Kuva Systems, Teledyne FLIR, CleanConnect.AI, Honeywell Rebellion (Proposed Alternative Work Practice for C-OGI).

The commenter (0588-Project Canary) believes continuous monitoring meets the statutory requirements for a work practice standard.<sup>455</sup> Continuous monitoring has been demonstrated as an effective method of assisting companies in reducing their emissions. It has no non-air quality health and environmental impacts. And its energy requirements are minimal because continuous monitoring systems operate on solar panels and/or small, internally located batteries. The commenter urges EPA in its forthcoming supplemental proposal to solicit public comment on whether continuous monitoring is appropriate for inclusion as an alternative compliance mechanism in the final rule. And when it finalizes this proposed rule, EPA should expressly allow sources to use continuous monitoring as an AWP standard to comply with the requirements contained in that final rule.

The commenter (0844-EDF *et al.*) is aware that the capabilities of continuous monitors (as well as other advanced screening technologies) are rapidly improving, and so the commenter encourages EPA to create incentives within its framework that will encourage operators to deploy continuous monitors and other advanced technologies in a manner that is maximally protective, consistent with these technological advances. For instance, the agency might consider how approaches that exceed its required standards have implications for community monitoring, subpart W reporting, and potentially other related areas.

The commenter (0791-Airdar) adds that detection and monitoring of fugitive emissions is a challenge due to their intermittent and stochastic nature. Currently, LDAR surveys of equipment components using EPA Method 21 or handheld OGI cameras are required a few times a year. The infrequency at which these surveys are performed allows super-emitting events to go undetected for a while before they are discovered, prolonging the impact of these emissions on the environment. An emission event that occurs in-between inspections may go undetected for several days or weeks. The current proposed rule requires LDAR inspections to be performed quarterly, meaning that it may be up to 3 months before the leak is discovered. Continuous monitoring technologies provide 24/7 monitoring of a facility, allowing super-emitting sources to be detected quickly and repairs to be made in a timely manner.

The commenter (0791-Airdar) notes that specific components are regulated and must be included in an LDAR monitoring program. Components classified as unsafe or difficult-to-monitor are not included in these programs and are not monitored in an LDAR survey. However, through Airdar's experiences, some leaks do not occur at these regulated components or expected locations. In a case study at a midstream oil and gas facility<sup>456</sup>, the commenter found a large methane leak coming from a vent located 1.2 m off the top of the compressor building, which was supposed to be blowing pure air. Instead, the vent was releasing 4 percent air and 96 percent total hydrocarbons of which 94 percent was methane. Such a vent would not have been included in a traditional LDAR program. A survey of the compressor building with handheld detectors

---

<sup>455</sup> Specifically, CAA Section 111(h)(1) authorizes the administrator to promulgate work practice standards that reflect "technological system[s] of continuous emission reduction . . . taking into consideration the cost of achieving such emission reduction, and any non-air quality health and environmental impacts and energy requirements."

<sup>456</sup> Dennis Prince et al., "Remote Detection and Quantification of Fugitive Emission Sources Using Ambient Measurements," in 2010 Air and Waste Management Association Annual Conference Online Proceedings (Calgary, AB, 2010).

had previously been completed, but technicians were unable to detect and locate the leak, resulting in this leak going undetected.

The commenter (0791-Airdar) adds that handheld gas detectors or OGI cameras must be aimed directly at a specific component to detect a leak. This can be labor intensive for the technician and introduces confirmation bias into the monitoring. Confirmation bias in an emission monitoring setting occurs when an assumption to the location or timing of the emission source is made, and monitoring activities are then focused on these assumptions. The possibility of emission sources or events at other locations and times are not considered. Continuous monitoring systems like Airdar that can intercept and detect plumes at low concentrations remotely do not suffer from confirmation bias and do not miss important sources. Surveillance can be provided over a great area, enabling monitoring of emission sources both on- and off-site without the need to aim an instrument directly at the emission source.

Commenters (0756-Baker Hughes, 0791-Airdar) state accurate quantification provided by continuous monitoring can determine the relative importance of emissions, helping operators to prioritize work and direct resources to the right problem. This was seen in a project at a steam assisted drainage (SAGD) facility where high levels of hydrogen sulfide were being detected.<sup>457</sup> This facility was under pressure from the regulator to address the problem. Several potential sources were identified, including a hot lime softening (HLS) system that was known to emit hydrogen sulfide. An intervention to tie the HLS system was being considered, but it was a costly solution. The facility wanted to make sure the HLS system was the main problem contributing to hydrogen sulfide emissions before moving ahead with the intervention.

The commenter (0791-Airdar) installed a continuous monitoring system measuring hydrogen sulfide and total hydrocarbons (THC). It found that the HLS system was not the main cause of the issue and that the tanks on site were the largest emitters. A significant off-site source was also found and was one that was not previously identified. This information allowed operations to perform interventions at their tank farm, which dramatically reduced hydrogen sulfide and THC emissions, saving the facility from performing a costly intervention. Quantification of emissions before and after an intervention based on a real observation of the emissions and not an estimate based off a point measurement allowed for the effectiveness of the intervention to be evaluated. This case study demonstrates that continuous monitoring enables quick verification of any repairs, allows operators to be confident in the interventions made, and ensure that resources were directed to the right problem.

Commenter's (0791-Airdar) approach using concentration measurements and wind data (speed and direction) collected continuously and used to locate and quantify emission sources has been tested in several field trials. This method has been tested in a controlled release study performed in 2008. Details of this study are publicly available in U.S. Patent 8,510,059.<sup>458</sup> This control study describes the quantification of a controlled release of natural gas, obtained by breaking a

<sup>457</sup> Dennis Prince et al., "Cost Reduction of Leak Detection and Fence Line Monitoring Activities Through Automation," in 2019 Air Quality Measurement Methods and Technology Conference Proceedings (Durham, NC, 2019).

<sup>458</sup> Dennis Prince, Method and System for Measuring Emission and Quantifying Emission Source, U.S. Patent 8,510,059, filed April 14, 2009 and issued August 13, 2013.

visualized emission plume into small elements, calculating the flux of the compound for each element, and summing up elements that are determined to be within the boundaries of the plume. The control study showed that emission rates obtained through the Airdar system were within 10 percent of the actual values under ideal conditions where background levels of the compound measured was stable and when measurements are taken at several heights. Continuous monitoring technologies are capable of providing an accurate quantification of emissions. Accuracy in emissions quantification is important to knowing the extent of emissions and track progress in remediation efforts.

The commenter (0780-LongPath Technologies, Inc. (LongPath)) states methane emissions from oil and gas are intermittent and vary through time, at both producing and abandoned well sites<sup>459,460</sup>, with intermittent emissions contributing substantially to overall emissions. Continuous monitoring is therefore unparalleled in the value it provides. Snapshot monitoring approaches (OGI, aircraft, satellite surveys) cannot provide adequate information for operators to mitigate intermittent emissions. Continuous monitors can mitigate intermittent emissions by revealing temporal context about deviations from baseline rates, which can be linked with SCADA data for root cause analysis. Off-site diagnosis and even repair can be accomplished. Further, continuous monitors don't mistake intermittent emissions for persistent emissions, as can be the case for snapshot-in-time surveys, resulting in wasted OGI follow-ups.

The commenter (0780-LongPath) states the temporal context and coverage provided by continuous monitors also means that leak repairs can be immediately verified. LongPath has found linked leaks that it took more than one attempt to repair – without continuous monitoring, the first repair would not have mitigated all emissions, and the operator wouldn't have known that other problems persisted.

Commenter (0780-LongPath) states LDAR-Sim model results<sup>461</sup> show expected emissions given a LongPath emissions mitigation program, a quarterly LDAR program (with efficacy matching Zimmerle *et al.*<sup>462</sup>) and no LDAR program. Interestingly, in this simulation, a super-emitter event occurs just following an OGI visit. While this would seem to be a rare event, commenter (0780-LongPath) has documented occurrences of this scenario in customer monitoring. In periods of both normal operations and during a fugitive event, LongPath's overall emissions reductions are substantially better than quarterly OGI.

Response I-7-185: See discussion in section IV.B.2 of the December 2022 Supplemental Proposal.<sup>463</sup>

Comment: Commenter (0831-AXPC) argues EPA's framework should support the use of continuous monitoring technologies. While continuous monitoring technologies may not lend themselves specifically to a sample matrix, EPA should establish simple and effective

requirements for the use of continuous monitoring technologies in a similar manner suitable to the parameters for continuous monitoring technologies.

The commenter (0780-LongPath) also supports a matrix of AWP's with dimensions of survey frequency and effective detection threshold. Requirements for root cause or OGI follow-ups, repair validation, regional applicability, and sensor validation checks would be specified for each area of the matrix. Whether in matrix form or in a simple survey vs. continuous monitor form, commenter (0780-LongPath) defines the following critical elements for high-frequency (continuous) monitoring AWP:

- OGI should not be a required follow-up for every emission detected by continuous monitors.
- The continuous monitor should be used for verification of leak repair.
- Operators should be able to use continuous monitors on a site-by-site basis instead of mandating that one type of screening be broadly applied across geographic areas.
- Daily verification checks should not be required of continuous monitors.

Response I-7-186: See discussion in section IV.B.2 of the December 2022 Supplemental Proposal.<sup>464</sup>

Comment: Commenter (0780-LongPath) states the industry is already using continuous monitoring. The commenter alone is providing continuous monitoring coverage across more than 120,000 acres of oil and gas operations in the DJ, Anadarko, Delaware and Midland basins. The operators the commenter monitors would like the regulations to recognize their use of this gold standard of monitoring by allowing them to eliminate duplicate spending on relatively less effective OGI surveys for compliance. Most importantly, local communities, the environment, and the climate need the fastest and most effective solutions to be employed for reducing methane emissions from oil and gas.

This year, commenter (0780-LongPath) was awarded the highly competitive ARPA-E SCALEUP funding,<sup>465</sup> an indicator of the federal government's firm belief and investment in LongPath's continuous monitoring as an enduring solution for mitigating methane emissions from oil and gas. The commenter has demonstrated the reliability of the system for accurately detecting and quantifying methane emissions, including intermittent emissions<sup>466,467</sup> in extensive third-party blind testing at the METEC facility.<sup>468</sup> LongPath's proven dynamic range for continuous methane monitoring includes both very small emission rates (2000 kg/hr), for example from fugitive events caught and mitigated on natural gas production sites.

Comment: Commenter (0588-Project Canary) states that multiple operators first started implementing different continuous monitoring systems over two years ago. There have been several key learnings in the implementation process that can assist in the development of performance-based standards. In addition, the commenter is providing an example of an SOP that has been used as a template for multiple different operators.<sup>470</sup> Within the commenter's attachment they provide a detailed operation summary of their continuous monitoring system including the selection of the monitoring technology, monitor factor calibration and set-up, siting, the initial 60-day period, and their operations 60 days and beyond.

Response I-7-188: See discussion in section IV.B.2 of the December 2022 Supplemental Proposal for a discussion on alternative continuous monitoring systems.<sup>471</sup> Please also see section X.B.2 of the preamble to the final rule which details EPA's final standards related to the use of continuous monitoring systems for detection of fugitive emissions under the advanced methane detection technology program, including the requirement to provide the standard operating procedures that apply to continuous monitoring technologies seeking ATM approval.

### ***7.3.2 Technology-Neutral/Matrix Approach***

Comment: Commenter (0588-Project Canary, 0590-Honeywell, 0756-Baker Hughes, 0760-Airdar *et al.*, 0780-LongPath) believes, along with other stakeholders, that the final rule should be technology neutral. All technology types should be acceptable, provided they can demonstrate sufficient effectiveness in detecting and measuring methane emissions, as determined by the rule, and if they are validated in third-party blind testing under expected operating conditions. If continuous monitoring is pushed into the AMEL process, the protracted application and approval processes will disincentivize operators from using this highest standard of monitoring and will not allow the most radical emissions reductions to occur.

The commenter (0588-Project Canary) adds QA/QC requirements should be determined by the sensor manufacturer. These more detailed requirements could be built out over time by EPA. But, given the variety of technologies that meet continuous monitoring, it would be premature at this time for EPA to promulgate specific QA/QC requirements. Overly prescriptive requirements at this stage in the development of new and promising technology may stifle the full emergence of that technology.

The commenter (0590-Honeywell) believes that EPA's continuous monitoring framework should be outcome and performance-based, rather than prescriptive, thereby enabling operators to choose the technology and system design best suited to achieve the specified performance for their facility. Such an approach would focus on detecting leaks at a certain leak rate and frequency of monitoring to achieve the specified level of performance. The commenter suggests a 10 kg/hr minimum detection threshold with daily readings coupled with an annual OGI survey

---

<sup>469</sup> 87 FR 74744-74745 (December 6, 2022).

<sup>470</sup> See Appendix B of the commenter's letter.

<sup>471</sup> 87 FR 74744-74745 (December 6, 2022).

as an initial approach for continuous monitoring systems. EPA should establish a regulatory framework that allows the Agency to easily increase the level of required performance in leak detection as the pace of innovation accelerates and continuous monitoring technologies continue to improve and become increasingly cost-effective over time. An outcome-based approach would also allow operators flexibility to choose one technology, such as a particular continuous monitoring solution, or to choose a combination of technologies if the performance objectives are satisfied. EPA should also consider incentives that reward greater emission reductions that exceed minimum requirements at the same or lower cost.

Commenter (0756-Baker Hughes) states that a fit-for-purpose framework supports the efforts of maintaining flexibility for multiple technologies. Performance can be defined as the number of emission events and the cumulative total of emissions that are detected and subsequently repaired. Multiple technologies exist capable of high-performance emission reduction that have already been widely accepted in industry separate from regulatory influence. Continuous monitoring is one of these technologies, potentially offering the most comprehensive performance capabilities and should be seen as an option in the new framework.

The commenter (0760-Airdar *et al.*) supports the expansion of the 10 kg/hr detection limit into a matrix-based approach. The matrix solution could be designed to achieve the same emission reduction as a 10 kg/hr limit and bi-monthly screening. Dimensions of this matrix would include 1) a technology's minimum effective detection threshold, and 2) a technology's detection (*i.e.*, "survey") frequency.

The commenter (0780-LongPath) states operators should be able to use continuous monitors on a site-by-site basis instead of mandating that one type of screening be broadly applied across geographic areas. Operators should be given the flexibility to "mix and match" the use of continuous monitors and other BSER for regulatory compliance across the same geographic region. Additionally, daily verification checks should not be required of continuous monitors. Quality control metrics are built into continuous monitoring systems. Submitted fugitive emission monitoring plans should outline QA/QC steps and validation with third-party testing.

The commenter (0780-LongPath) endorses the use of a matrix that would allow for equivalent overall emissions reductions by specifying trade-offs between frequency of screening and the size of emission requiring action (leak definition). The commenter provides an example of such a matrix shown below, in which, for more rapid screening frequencies, a larger leak definition is allowable (leak definition and, interchangeably, minimum effective detection threshold, see definitions below).

| Screening Frequency | Effective Threshold of Detection | Leak Definition           |
|---------------------|----------------------------------|---------------------------|
| Monthly             | 10 kg/hr                         | 10 kg/hr (same as left)   |
| Bi-Weekly           | >10 kg/hr                        | >10 kg/hr (same as left)  |
| Weekly              | >>10 kg/hr                       | >>10 kg/hr (same as left) |

Commenter (0780-LongPath) also recommends that if continuous monitoring downtime exceeds an EPA defined reasonable percentage, then EPA require that BSER require supplement

measurements. For example, the commenter recommends that if sensor malfunctions for a continuous monitor exceed 3 months (one quarter) then quarterly OGI BSER should be initiated to supplement lost fugitive emissions monitoring coverage.

The commenter (0780-LongPath) notes that continuous monitor downtime can occur due to a variety of factors, such as sensor malfunction, communications failures, or inability to operate due to extreme conditions (environmental conditions that are outside of what is expected for the operating environment). The commenter contends that it is important to differentiate between downtime due to shortcomings of the continuous monitor itself from downtime due to external factors (for example, extreme weather events). For each category, the commenter recommends that EPA define reasonable percentages of downtime to be expected during the normal course of operation.

Commenter (0760-Airdar *et al.*) agrees with EPA that a single AWP is not suited for continuous monitoring technologies, and instead propose that continuous monitoring be regulated as a separate AWP based on the same concepts or as part of a matrix of alternatives.

The commenter (0760-Airdar *et al.*) indicates that continuous monitors provide several advantages for emissions detection, particularly for the fast detection of large emissions and intermittent emissions that are widely observed. Indeed, continuous monitoring is an established modality that is highly effective in reducing methane and VOC emissions from oil and gas infrastructure. Among alternative and traditional monitoring techniques, continuous monitoring is uniquely suited to provide information about intermittent emissions. This modality can be used not only to identify and prioritize problematic emissions, but to verify if and when emissions reductions occur following repair. Continuous monitoring can detect fugitive emissions many times faster than survey technologies (including BESR), with consequent multi-factor reductions in overall cumulative emissions to the atmosphere from a given fugitive event. The costs of continuous monitors are comparable to quarterly OGI and bimonthly surveys, with differences offset by the gas loss savings of finding emissions faster and not missing or misinterpreting intermittent events. Finally, industry adoption of this methane monitoring strategy is widespread, with field data demonstrating its efficacy.

The commenter (0760-Airdar *et al.*) notes that continuous monitors comprise a broad class of sensors covering many styles of monitoring, including the following five different styles:

1. Networks of point sensors (*e.g.*, Baker Hughes, Project Canary, Qube, and Sensirion),
2. Individual point sensors (*e.g.*, Aeris and Quanta3),
3. Shared point sensors (*e.g.*, Project Astra),
4. Open path laser sensors (*e.g.*, LongPath Technologies and Mirico)
5. OGI Camera sensors (*e.g.*, CleanConnect.AI, Honeywell, and Kuva Systems).

Commenter (0760-Airdar *et al.*) states in order to provide for technology neutral regulation, this diversity of continuous monitors must be considered in any regulation that covers continuous monitors. All these solutions have the potential to detect the same or more emissions than inspection-based screening solutions such as airborne detections plus annual OGI. For some items relevant to the regulation of continuous monitors—such as the number of monitors on a site

and the minimum response factor to methane—values for each style of continuous monitor are intended to be different and may be measured in different units. For other items—such as the minimum detection level—values should be consistent across all styles of continuous monitors and should correspond to values for other types of screening solutions. The commenter suggests that the latter elements form the basis for a common Continuous Monitoring Framework as part of an AWP, and that the former elements be required for inclusion in a given operator or owner’s fugitive emissions monitoring plan.

Response I-7-189: See discussion in section IV.B.2 of the December 2022 Supplemental Proposal.<sup>472</sup>

Comment: Commenter (0756-Baker Hughes) believes continuous monitoring should be viewed as equivalent to OGI-based solutions. There exist various validation methods, either controlled release testing or periodic field calibration or “bump tests” to verify system performance. Because it is not necessary to conduct OGI confirmation upon notification of every detection event, removing this requirement would mitigate the concern that continuous monitoring is cost prohibitive. In short, the commenter encourages EPA to expeditiously develop and deploy the proposed framework for advanced measurement technologies that monitor sites continuously.

Response I-7-190: See discussion in section IV.B.2 of the December 2022 Supplemental Proposal.<sup>473</sup>

Comment: Commenter (0807-BP) discourages comparing continuous monitoring to OGI technology, as such a comparison cannot do justice to the fundamental paradigm shift represented by, and the significant methane leak detection and mitigation potential of, continuous monitoring. An attempt to narrowly compare the two technologies risks undermining the potential of continuous monitoring to help reduce emissions. The commenter recognizes continuous monitoring must demonstrate equivalent or greater emissions reductions compared to OGI, but that comparison should focus on the emission reduction results achieved by both technologies, *i.e.*, a performance-based comparison, rather than a comparison based on the supposed similarities of these different approaches.

The commenter (0807-BP) recognizes that continuous methane monitoring is vastly different from the low-frequency, handheld analyzers and cameras historically relied on by industry and regulators alike.

Response I-7-191: See discussion in section IV.B.2 of the December 2022 Supplemental Proposal.<sup>474</sup>

### ***7.3.3 Specific Technologies***

Comment: Commenter (0762-CleanConnect.AI *et al.*) states continuous OGI cameras (C-OGI) are an established class of continuous monitoring technologies for methane and VOC emissions;

---

<sup>472</sup> 87 FR 74744-74745 (December 6, 2022).

<sup>473</sup> 87 FR 74744-74745 (December 6, 2022).

<sup>474</sup> 87 FR 74744-74745 (December 6, 2022).

other classes of continuous monitoring include non-visual solutions based on point sensors, open path detectors and scanning laser towers. C-OGI cameras are closely related or exactly like the cameras used for handheld OGI inspections in that they are based on infrared imaging technology engineered to detect and visualize emissions based on absorption characteristics of specific compounds, generally methane and VOCs. Multiple types of C-OGI cameras are commercially available from several solution providers and they are being successfully operated by several dozen oil and gas operators at several hundred sites for the detection of fugitive emissions, vents, and operational upsets.

The commenter (0762-CleanConnect.AI *et al.*) states the key feature of C-OGI cameras is the provision of images of emissions at or near their source—similar to the images provided by handheld OGI inspections. Moreover, C-OGI cameras operate continuously, generate consistent, automated emission detections and create a record of emission events or absence of emissions. The commenter reports a number of benefits associated with C-OGI cameras, including:

- a. Continuous operation to detect emission events and intermittent emissions quickly which enables faster repair.
- b. Ability to pinpoint by remote visual inspection what component or equipment is leaking and to determine if an emission event is resulting from a normal, allowable emission (for example compressor methane slip), or by abnormal operation, nuisance events or leaks.
- c. Provides follow clearly defined, transparent and standardized procedures on how to react to a detected emission event before sending personnel to the event site.
- d. Enables the collection of time-series data for individual emission sources which provide insights about the behavior of the emission (intermittent, persistent, rising, or falling).
- e. Provides consistency in detection.
- f. Repair validation by visual inspection without the expense of a site visit.
- g. Continuous quantification of leak rate or concentration.
- h. Because C-OGI is image based, it can be regulated using the same concepts used for handheld OGI inspections, especially the concepts of an “operating envelope” as well as clearly defined criteria for what steps are to be taken upon detection of emissions.

The commenter (0762-CleanConnect.AI *et al.*) finds for the example of a C-OGI camera detecting a single, constant emissions event of 10 kg/hr within hours—instead of within an average of 30 days for bi-monthly inspection-based screening (such as airborne detection) - results in incremental reduction of 7.2 tons of methane (30 days x 24h x 10 kg/hr). At a social cost of Methane of \$1,800 per ton the incremental emission reduction provides \$12,960 in climate benefits beyond the reductions accomplished by bi-monthly inspection-based screening when assuming the same speed of repair.

The commenter (0762-CleanConnect.AI *et al.*) states the key differences of the proposed C-OGI AWP compared to EPA’s proposed screening protocol are the following four aspects:

1. Instead of the requirement for handheld OGI follow-up on detected emissions during screening, C-OGI is utilized for root-cause analysis and repair planning.
2. Instead of requiring handheld OGI to validate repairs, C-OGI images are utilized for repair validation.

3. Instead of mandatory use of one type of screening across a county or region, Operators are permitted to use C-OGI on a site-by-site basis and other screening methods or quarterly handheld OGI inspections elsewhere.
4. Removal of daily verification check requirement as the C-OGI technology will be developed based on operating envelopes and is connected to a data platform for quality control.

Response I-7-192: See discussion in section IV.B.2 of the December 2022 Supplemental Proposal.<sup>475</sup>

Comment: Commenter (0762-CleanConnect.AI *et al.*) agrees with EPA that the proposed screening with advanced measurement technologies approach is not suited for mentioned continuous monitoring technologies, sensor networks or open-path technology, and emphasize that C-OGI has been proven as a technology that would be separate to the specific inspection-based screening technologies referenced in the proposed regulation. As such, the commenter instead proposes that C-OGI cameras be regulated as a separate AWP, however based on the same “screening” concept.

Response I-7-193: See discussion in section IV.B.2 of the December 2022 Supplemental Proposal.<sup>476</sup>

Comment: Commenters (0944-Kuva Systems (Kuva), 0780-Longpath) provided cost information for their particular continuous monitoring solutions.

Commenter (0944-Kuva) reports that their camera solution is available commercially today. The commenter has provided the current price and cost of ownership for operators as confidential business information (CBI). The price of the solution is expected to fall if EPA were to mandate or to incentivize large scale deployment. The commenter expects to be able to increase manufacturing capacity to meet very large-scale demand (tens of thousands of cameras per year) with a 9-month lead time, and large-scale demand (thousands of cameras per year) with a shorter lead time.

Commenter (0780-LongPath) also submitted detailed cost information for their continuous monitoring as CBI by mail. The commenter points out that it is critical to recognize the efforts of operators who are paying for both continuous monitoring and for LDAR compliance inspections with OGI. It is unreasonable for these operators, who are voluntarily using the highest standard of continuous monitoring, to be required to also pay for regular OGI surveys simply because regulations have not yet kept pace with technological advancements. The commenter reports that according to a potential customer the current rules are discouraging operators from using alternative technologies and emission reduction goals would be met a lot faster if continuous monitoring is permitted to meet the industry’s LDAR requirements.

---

<sup>475</sup> 87 FR 74744-74745 (December 6, 2022).

<sup>476</sup> 87 FR 74744-74745 (December 6, 2022).

Response I-7-194: See discussion in section IV.B.2 of the December 2022 Supplemental Proposal.<sup>477</sup>

Comment: Commenter (0756-Baker Hughes) offers the LUMEN Sky, UAV-based OGI technology, capable of approximately 6 scfh, or 0.12 kg/hr minimum quantification detection. The combination of high-resolution OGI technology and low-altitude drone flights provides the ability for quantification of emissions down to this low level. This detection limit can be inherently difficult for alternative aerial inspections that use OGI technology from higher altitudes or, conversely, low-altitude drone flights using alternative detection technologies such as non-dispersive “sniffing” sensors or LiDAR. The commenter states LUMEN Terrain, continuous monitoring, is capable of approximately 20 scfh, or 0.43 kg/hr minimum quantification detection.

Response I-7-195: See discussion in section IV.B.2 of the December 2022 Supplemental Proposal.<sup>478</sup>

Comment: Commenter (0756-Baker Hughes) adds their LUMEN Terrain continuous monitoring system is pre-programmed with process equipment and operational data allowing the platform’s analytics to identify and locate the source of the emission and trigger alerts pursuant to thresholds set during user configuration. For optimum detection and quantification performance, LUMEN Terrain utilizes a proprietary “Sensor Placement Optimization Tool” or SPOT. This uses AI and computer vision to analyze satellite imagery of a potential site. The commenter identifies and classifies assets and components on site, prioritizing likely emission leak sources over normal process venting sources.

The commenter (0756-Baker Hughes) then uses historical weather data, primarily wind speeds and directions to locate the optimum positioning of detection nodes. This allows operators to measure and account for planned releases while allowing the operator to also screen for and assess the severity of unplanned releases. With this technology, operators using continuous monitoring devices can cost effectively deploy resources to repair leaks while also generating a comprehensive picture of a site’s emissions.

Response I-7-196: See discussion in section IV.B.2 of the December 2022 Supplemental Proposal.<sup>479</sup>

Comment: Commenter (0590-Honeywell) states potential leak locations that are further apart or subject to obstructions may require more devices or cameras. Sometimes, a single monitor can achieve a particular leak rate detection threshold, but other times a site needs multiple monitors to achieve the same leak rate detection threshold. Generally, for C-OGI systems, the capability of detecting leak size is dependent on the distance the leak is from the system. For a C-OGI system, the number of monitors for a given site factor in the size of the site and ensure all monitored equipment is within the specified distance for its target leak size.

---

<sup>477</sup> 87 FR 74744-74745 (December 6, 2022).

<sup>478</sup> 87 FR 74744-74745 (December 6, 2022).

<sup>479</sup> 87 FR 74744-74745 (December 6, 2022).

Response I-7-197: See discussion in section IV.B.2 of the December 2022 Supplemental Proposal.<sup>480</sup>

Comment: Commenter (0604-Providence) indicates that one technology that is not mentioned in the November 2021 Proposal, but that has the ability to overcome the shortcoming of aforementioned continuous monitoring systems is autonomous and continuous OGI systems. ExxonMobil and the commenter jointly developed such a technology about a decade ago,<sup>481</sup> which uses an OGI camera connected to a computer with plume recognition algorithms to identify leaks and alert operators. It has some of the same benefits of an OGI leak survey but on a continuous basis, effectively combining the advanced screening and follow-up OGI survey into a single system. It can pinpoint the leak location and separate the fugitive emissions from other sources. The system developed jointly by ExxonMobil and Providence has not been widely used primarily due to the high cost of OGI cameras as the core component of the system. Recently Teledyne FLIR has made a methane focused, uncooled, and less expensive OGI camera commercially available. With the lower cost of the OGI camera core, the commenter is developing a new autonomous/continuous leak detection and alarm system which is undergoing field testing. If successful, such a system should be considered an advanced measurement system that would not need an OGI follow-up if a large leak is detected. The commenter encourages the EPA to structure the rule with the possibility of such a technology in mind so the regulations will be progressive in adopting future technologies. Specifically, the commenter is suggesting that if the continuous monitoring system is OGI based, a follow-up OGI survey to locate the leak is not required because the system has already located the leak.

Response I-7-198: See discussion in section IV.B.2 of the December 2022 Supplemental Proposal.<sup>482</sup>

Comment: Commenter (0807-BP) believes continuous monitoring can provide a rapid, cost-competitive and autonomous alert system to notify operators of potentially anomalous, unplanned or fugitive emissions events. As an alert system, continuous monitors can trigger additional action to assess conditions and determine the appropriate course of action, including deployment of personnel for further investigation and repair.

Response I-7-199: See discussion in section IV.B.2 of the December 2022 Supplemental Proposal.<sup>483</sup>

### **7.3.4 General Framework Recommendations**

Comment: Commenters (0767-Scientific Aviation *et al.*, 0780-LongPath) express support for incorporating continuous monitoring under an alternative methane detection technology

---

<sup>480</sup> 87 FR 74744-74745 (December 6, 2022).

<sup>481</sup> H.M. Abdel-Moati, J.M. Morris, Y. Ruan, Y. Zeng (2013), “Remote Gas Detection System Using Infrared Camera Technology and Sophisticated Gas Plume Detection Computer Algorithm”. Paper presented at the SPE the SPE Annual Technical Conference and Exhibition, New Orleans, September 30th – October 2nd. Also see Exhibit 2.

<sup>482</sup> 87 FR 74744-74745 (December 6, 2022).

<sup>483</sup> 87 FR 74744-74745 (December 6, 2022).

framework and provide specific recommendations to the elements EPA proposed for a framework and requested comment on.

Commenter (0767-Scientific Aviation *et al.*) fully supports the development of a framework for advanced technologies that monitor sites continuously. Certain emission sources tend to be unpredictable, some of which can be large. Frequent, recurrent inspections result in discovery of those large (and a number of moderate and some small) emission sources sooner, thereby reducing total emissions. Since manual inspections tend to be episodic and resource intensive, continuous monitors have been developed to provide these frequent, recurrent inspections automatically, thereby detecting emission events more quickly than would occur under manual methods.

The commenter (0767-Scientific Aviation *et al.*) notes that EPA correctly identifies that continuous technology requires a different framework than that proposed for episodic screening technologies. EPA notes that triggering OGI surveys too frequently would disincentivize the use of continuous monitoring systems. The commenter believes that this is a risk for disincentivizing the use of episodic screening technologies as well. An annual component level OGI survey is sufficient to identify and mitigate small leaks that are missed by alternative technologies with higher detection limits. The scientific literature<sup>484,485,486</sup> has shown that a small number of large sources constitute the majority of total emissions from leaks and other malfunctions. Accordingly, the majority of these emissions (the target of the more frequent surveys) are addressable by both screening and continuous monitoring technologies. Therefore, an OGI survey should not be required more than annually when alternative monitoring technologies are deployed, even under the screening options.

The commenter (0767-Scientific Aviation *et al.*) states that a fundamental difference in modality between episodic and continuous technologies is that a continuous technology is in position to confirm the reduction in emissions associated with an emission source repair much more rapidly than even the most frequent OGI schedule could deliver.

The commenter (0767-Scientific Aviation *et al.*) provides in their comment letter a number of recommendations in response to the elements EPA proposed for a framework and requested comment on. The commenter provides in their letter comment on the context of equivalency to quarterly OGI inspections and leveraging these systems to speed discovery of large emissions sources. Key features of the commenters letter ask that operators should develop site specific monitoring plans and continuous monitoring alerting criteria should result in an analysis to identify the source and take corrective action considering the following. The commenter additionally provides detailed recommendations on the following:

---

<sup>484</sup>Zavala-Araiza, D., Alvarez, R., Lyon, D. et al. Super-emitters in natural gas infrastructure are caused by abnormal process conditions. *Nat Commun* 8, 14012 (2017). <https://doi.org/10.1038/ncomms14012>.

<sup>485</sup>Adam P. Pacsi, Tom Ferrara, Kailin Schwan, Paul Tupper, Miriam Lev-On, Reid Smith, Karin Ritter; Equipment leak detection and quantification at 67 oil and gas sites in the Western United States. *Elementa: Science of the Anthropocene* 1 January 2019; 7 29. doi: <https://doi.org/10.1525/elementa>.

<sup>486</sup>Adam R. Brandt, Garvin A. Heath, and Daniel Cooley *Environmental Science & Technology* 2016 SO (22), 12512-12520 DOI: 10.1021/acs.est.6b04303.

- The number of monitors needed and the placement of the monitors.
- Minimum response factor to methane/ Minimum detection level.
- Frequency of data readings.
- Interpretation of the monitor data to determine what emissions are a detection versus baseline emissions / How to determine allowable emissions versus leaks.
- Meteorological data criteria/ Measurement systems data quality indicators/ Calibration requirements and frequency of calibration checks.
- How to handle situations where the source of emissions cannot be identified even when the monitor registers a leak.
- Approach to determining equivalency to BSER.

Commenter (0780-LongPath) states that continuous monitors are uniquely suited to provide information on the sustained versus intermittent nature of emissions. If the rule is not written correctly to acknowledge the strengths of continuous monitoring systems, requiring OGI follow-up of all emissions (regardless of type, duration, or size) identified by continuous monitors could disincentivize their use.

The commenter (0780-LongPath) says that the first concern (regardless of type) applies to all survey monitors. It will be incumbent upon the owner or operator to interpret the survey or continuous monitor data to determine root cause and corrective action. Indeed, continuous monitors provide a strong advantage over snapshot-in-time approaches, because the size and temporal context of emissions can drive more effective off-site root cause investigation (and even repair). For the second concern (regardless of duration), the commenter views this as a critical part of the follow-up protocols that will leverage the unique strengths of continuous monitoring. For the third concern (regardless of size), the commenter believes it is critically important that the EPA create leak definitions with units of emission rate (not concentration) and that data readings be required in the same units of emission rate (not concentration). With those criteria in place, alerts will only be triggered for emissions that exceed the leak definition.

First, commenter (0780-LongPath) considers the issue of intermittency. In addition to information about the size of the emission (leak definition), continuous monitors can provide information about the “intermittency” or “continuity” of the emission. To avoid putting an undue burden on operators who choose to employ continuous monitors, commenter (0780-LongPath) recommends that these different types of emissions (“intermittent” vs. “continuous”) require different sets of follow-up actions. Further, the commenter recommends that in either case (intermittent or continuous), off-site and, if needed, on-site root cause analyses be allowed before OGI, and that, in the case of intermittent emissions, OGI follow-up not be required at all.

Commenter (0780-LongPath) states the intermittency of emissions, to guide follow-up, could be defined in one of several ways:

- Intermittency could be defined based on peer-reviewed bottom-up modeling studies.<sup>487</sup>

---

<sup>487</sup> Vaughn et al., “Temporal Variability Largely Explains Top-down/Bottom-up Difference in Methane Emission Estimates from a Natural Gas Production Region.”

- Intermittency could be defined based on available field-level studies employing continuous monitors (however, given that this data is private, little has been published).
- Intermittency could be defined based on expert knowledge. For example, many operators state that an event exceeding a sustained (*e.g.*, present in 80 percent or more of readings) duration of 24 hours is highly unlikely to be due to planned on-site operations.

Commenter (0780-LongPath) recommends the third option (expert knowledge) as a starting point.

Response I-7-200: See discussion in section IV.B of the December 2022 Supplemental Proposal for a discussion on advanced methane detection technologies using alternative continuous monitoring systems.<sup>488</sup> The EPA proposed a specific framework for the use of alternative continuous monitoring systems in the December 2022 Supplemental Proposal based on comments received on the November 2021 Proposal. The EPA is finalizing the use of alternative continuous monitoring systems for detection of fugitive emissions under the advanced methane detection technology program. See section X.B of the preamble to the final rule which details EPA's final standards. The final rule specifies the required elements that must be included in the request for ATM approval of alternative continuous monitoring where this alternative technology will be used to demonstrate compliance.

Comment: Commenters (0807-BP, 0932-GHGSat, Inc.) state that continuous monitoring system has the potential to detect fugitive methane emissions at a materially higher frequency than any traditional, handheld device deployed on a semiannual or quarterly schedule. While a significant upside of the technology—more visibility than previously possible—it also presents some unique challenges, particularly as it relates to sending personnel to the field to address potential emission events. EPA, in consultation with representatives from industry, technology vendors, academia, and civil society, should develop a guideline for program plans prepared and maintained by operators for their continuous monitoring systems.

The commenter (0807-BP) believes EPA should leverage precedent and existing requirements for fugitive emissions monitoring plans in NSPS OOOOa to document continuous monitoring systems. The commenter believes the responsibility should continue to be on operators to prepare and maintain these plans, with the plans available for inspection upon request to EPA. At a minimum, the commenter thinks a transparent continuous monitoring program plan would include: (1) the number of sensors deployed; (2) type of sensor; (3) sensor placement; (4) justification for how the system delivers on the performance standard defined by EPA; (5) description of maintenance plan and procedures; and (6) downtime contingency procedures, including plan and recordkeeping if defaulting to OGI surveys or an advanced screening technology.

The commenter (0585-KOGA) agrees a general monitoring plan in place of a site-specific monitoring plan for each inspection to be performed. Site-specific maps increase administrative costs without a reduction in emissions. A general operating procedure is capable of

---

<sup>488</sup> 87 FR 74741-74745 (December 6, 2022).

accomplishing the same objective without the need to create and maintain site-specific monitoring plans.

Response I-7-201: See discussion in section IV.B of the December 2022 Supplemental Proposal for a discussion on advanced methane detection technologies, including alternative periodic screening and alternative continuous monitoring systems.<sup>489</sup> Please also see section X.B of the preamble to the final rule which details EPA's final standards related to the use of alternative periodic screening and alternative continuous monitoring systems for detection of fugitive emissions under the advanced methane detection technology program. The final rule specifies the elements the fugitive emissions monitoring plan must contain where alternative technologies will be used to demonstrate compliance and the elements required to be included in the request for ATM approval.

### ***7.3.5 Follow-Up Survey***

Comment: Commenters (0588-Project Canary, 0759-LongPath *et al.*) note continuous monitoring systems provide an advantage over all other types of inspections because they can almost immediately provide evidence of the leak being repaired. Not only can continuous monitoring systems identify the leak faster, but continuous monitoring systems can also identify faster whether the fix was effective (as the continuous monitoring system would immediately register no leak instead of needing to wait for another periodic test). Continuous monitoring systems also show the longer-term effectiveness of the repair by continuously showing that a leak is not detected after the repair occurs. This is different than OGI. With OGI, the repair can be verified immediately upon service, but whether the repair is effective over a longer duration cannot be determined. Even a subsequent OGI inspection may or may not detect an emission event if the event is intermittent.

The commenter (0588-Project Canary) adds rapid leak verification is also a service provided automatically by Project Canary's software. Currently, this is implemented by ensuring that a level falls back below a given threshold (*e.g.*, 20 ppm) for a set period of time.

Response I-7-202: EPA acknowledges the commenters support for the use of continuous monitoring. See discussion in section IV.B.2 of the December 2022 Supplemental Proposal for a discussion on alternative continuous monitoring systems.<sup>490</sup> Please also see section X.B.2 of the preamble to the final rule which details EPA's final standards related to the use of continuous monitoring systems for detection of fugitive emissions under the advanced methane detection technology program.

Comment: Commenters (0588-Project Canary, 0807-BP, 0844-EDF *et al.*, 0780-LongPath) argue the continuous monitor should be used for verification of leak repair. Continuous monitors can demonstrate whether emission rates have gone down or returned to baseline conditions following repair. This strength should be leveraged in the AWP for verification of repair, rather

---

<sup>489</sup> 87 FR 74741-74745 (December 6, 2022).

<sup>490</sup> 87 FR 74744-74745 (December 6, 2022).

than forcing operators to employ overlapping methods and thereby incur unnecessary costs by using other technologies to validate repair.

The commenter (0844-EDF *et al.*) states under this approach, the detection limit of the continuous monitoring technology would need to be lower than 10 kg/hr, but not necessarily as low as OGI. The equivalent detection limit for estimated with FEAST or other similar approaches by modeling it as a very high-frequency discrete screening. The operator would need to continuously model the expected emission rate to determine when there are excess emissions, and operators would have a set time to repair detected excess emissions.

The commenters (0844-EDF *et al.*, 0780-LongPath) state, with continuous monitoring solutions, the follow-up work practices are extremely important. It is critical to clearly define which emissions will require follow-up and which will not. Otherwise, there is a significant risk that operators will be alerted to emissions but determine they do not need to be fixed or cannot be fixed. This problem also exists with other LDAR approaches, but is more pronounced with continuous monitoring where emissions will be more frequently detected. With the potential to be alerted to a wide variety of emission events, absent rigorous protocols, operators may be more likely to avoid following up on each event and will be incentivized to view it as part of normal operations to avoid OGI follow-up costs. EPA must therefore very clearly define the events that require inspection and repair. This might be done by clearly defining the range of the site's baseline emissions. Above the range, there would be a presumption of an abnormality and, unless the operator could prove with records that it resulted from a permissible event, the operator would be required to conduct a ground survey and repair.

The commenter (0780-LongPath) adds after a leak is detected, a root cause analysis is the most logical first step in assessing emissions information from continuous monitors. Importantly, continuous monitors also monitor intermittent emissions. Follow up on intermittent emissions with an OGI camera has low odds of coinciding with the presence of the intermittent event and therefore has low odds of success. Therefore, intermittent emissions should not require OGI follow up at all.

Response I-7-203: EPA acknowledges the commenters recommendations related to the use of continuous monitoring for follow-up identification and verification of leaks being repaired. See discussion in section IV.B.2 of the December 2022 Supplemental Proposal for a discussion on alternative continuous monitoring systems.<sup>491</sup> Please also see section X.B.2 of the preamble to the final rule which details EPA's final standards related to the use of continuous monitoring systems for detection of fugitive emissions under the advanced methane detection technology program. This includes details on the investigative analysis that is required when action levels have been exceeded. A follow-up survey using OGI is not required under these circumstances.

Comment: Commenters (0590-Honeywell, 0760-Airdar *et al.*, 0780-LongPath) provide recommendations on requiring annual OGI surveys in combination with continuous monitoring.

Commenter (0590-Honeywell) recommends EPA initially require an annual OGI survey after installation of a continuous monitoring system, and as more data are received from continuous

---

<sup>491</sup> 87 FR 74744-74745 (December 6, 2022).

monitoring systems demonstrating effectiveness, the period between OGI surveys may be reduced and possibly eliminated.

Commenter (0760-Airdar *et al.*) believes that EPA's November 2021 Proposal for continuous monitoring should exist in combination with OGI inspections. For continuous monitors that demonstrate that equivalent OGI products are part of the continuous monitoring data, the commenter believes this requirement can be waived. The commenter suggests that OGI surveys remain a requirement on some cadence, for example, annual. The commenter suggests that any OGI survey that takes place as part of an emission follow-up or other on-site activity counts toward this requirement, such that the clock is "reset." In addition, the commenter is also in support of a required cadence of OGI surveys that is a function of other capabilities of continuous monitors. For example, less frequent OGI surveys might be required for technologies with lower (more sensitive) detection limits. Further, the frequency of OGI surveys could be adjusted in the future using demonstration data.

Commenter (0780-LongPath) suggests that it is reasonable for EPA to require annual OGI surveys to accompany continuous monitoring, with the clock restarting upon any OGI follow-up survey that might occur in the course of the year. The commenter believes this requirement is justifiable if the leak definition is to be set at a value as high as 10 kg/hr. If thresholds for follow-up are not based on specific emission rate numbers but rather on changes from baseline emissions, then OGI surveys should be completed during any periods that baseline emission rates are established (to ensure that poor operating conditions are not allowed to be defined as baseline emissions).

Commenter (0780-LongPath) states regions of the matrix with higher sensitivity to emissions (lower detection threshold and leak definition), or higher frequency of readings (faster refresh rate), and/or higher percent site coverage could have less stringent requirements for additional OGI.

Commenter (0780-LongPath) states in a matrix approach, regions of the matrix with higher frequency monitoring (*e.g.*, continuous monitoring) could employ alternative monitoring for verification of repair, whereas regions of the matrix with less frequent monitoring or less sensitive detection thresholds would require OGI. The commenter has documented important examples of OGI-based repairs providing incomplete or insufficient emissions reductions.

The commenter (0780-LongPath) offers an additional consideration on repair validation. Continuous monitors provide temporally ongoing information about emissions, including the onset of problematic emissions and their resolution following repair. Therefore, continuous monitoring solutions should be used to validate repair success without also requiring separate OGI inspection. Requiring OGI follow-up for repair validation would unfairly burden owners and operators by doubling up on costs of overlapping monitoring methods.

The commenter (0780-LongPath) has documented important examples of OGI-based repairs providing incomplete or insufficient emissions reductions. The commenter describes an example of where heightened emissions prompted on-site repair. Despite OGI identification and mitigation of one leak, high emissions persisted. A follow-up OGI visit identified a separate leak,

which was repaired. When emissions still were not reduced to baseline levels, a third and final OGI visit identified four additional small leaks, which were repaired. Following this last repair, the commenter indicates that the site finally returned to baseline emission rates and was considered to be repaired. Snapshot approaches such as OGI or aircraft surveys would not be capable of providing the necessary “eyes on” to ensure that all leaks were identified and repaired.

Response I-7-204: EPA acknowledges the comments on requiring annual OGI surveys in combination with continuous monitoring. See discussion in section IV.B.2 of the December 2022 Supplemental Proposal for a discussion on alternative continuous monitoring systems.<sup>492</sup> Please also see section X.B.2 of the preamble to the final rule which details EPA’s final standards related to the use of continuous monitoring systems for detection of fugitive emissions under the advanced methane detection technology program, including the investigative analysis that is required when action levels have been exceeded.

### ***7.3.6 Specific Recommendations***

#### ***7.3.6.1 Definitions***

Comment: Commenters (0780-LongPath, 0807-BP) provide relevant suggested definitions to be used under the continuous monitoring framework. The various definitions recommended by commenters follow below.

Commenter (0780-LongPath) states many continuous monitors are capable of accurately detecting and quantifying emissions well below a 10 kg/hr threshold (*e.g.*, LongPath Technologies’ threshold of detection is greater than 50 times below that level.) It is therefore important for a continuous monitoring framework to define not only the effective minimum threshold of detection but also the leak definition (see definitions for both below). Functionally, the requirements for these values can be the same (*e.g.*, 10 kg/hr), but for reasons of clarity, the commenter suggests the inclusion of both terms.

*Minimum Effective Detection Threshold:* the minimum emission rate value that must be detectable by a sensor under any envelope of operating conditions, and with “effective” coverage of all important equipment on-site.

*Leak Definition:* an emission rate that requires action to mitigate. In the proposed AWP, this value is functionally equivalent to the minimum effective detection threshold, given that in the EPA proposed rules, anything above the detection threshold requires action. LongPath Technologies, for example, has a minimum detection threshold of 0.2 kg/hr, but under the proposed AWP would not alert operators to emissions requiring attention until a 10 kg/hr or larger leak were detected.

*Minimum Effective Detection Threshold (units kg/hr):* the minimum emission rate value that must be detectable by a sensor under any envelope of operating conditions, and with “effective” coverage of all important equipment on-site.

---

<sup>492</sup> 87 FR 74744-74745 (December 6, 2022).

*Data Reading (units kg/hr):* a “data reading” could be considered to be an individual datapoint readout from an individual sensor (e.g., methane sensor, wind sensor, temperature sensor), or a “data reading” could be considered to constitute a unit of detection or quantification of emission rates from monitored pads. For response to EPA’s question, the commenter speaks to both elements, but define data reading as the latter (an emission rate reading). A “data reading” should not be defined as the readout from a given sensor, such as a concentration or wind value. It is important that EPA ask technology providers to differentiate between sensor readouts (which can be as frequent as many Hz) and data readings, which require aggregation of data from various sensors and some averaging time through turbulent atmospheric conditions (and are therefore less frequent in time than sensor readouts).

The commenter (0780-LongPath) suggests, as a starting point, that EPA use 10 kg/hr for the minimum effective detection threshold and related leak definition, as proposed for the survey AWP.

Commenter (0780-LongPath) offers the following definitions for clarity before describing the AWP follow up procedures:

*Continuous Emission:* an emission that is observed to be present [tbd] percent or more of the observable time over a period of [tbd] hours or longer.

*Intermittent Emission:* an emission that is observed to be present less than [tbd] percent of the observable time over a period of [tbd] hours or longer.

*Detected Emission:* an emission rate (units kg/hr) recorded over any period of time that exceeds the defined leak definition (emission rate in units kg/hr) set by the EPA.

*Alarm Candidate:* when a detected emission exceeds the leak definition (which will be equal to the minimum detection threshold), then an alarm candidate is generated.

*Continuous Alarm-Candidate:* generated for a detected emission that is a continuous emission.

*Intermittent Alarm-Candidate:* generated for a detected emission that is an intermittent emission.

*Emission Event:* an alarm-candidate that requires initiation of follow-up mitigation procedures (e.g., root cause and, if unsuccessful, OGI).

Commenter (0807-BP) states that since there is not a common definition of continuous monitoring, EPA should propose a new definition that provides clarity on what falls within this classification and is sufficiently broad to be agnostic as to specific technologies and approaches. The definition of continuous monitoring should reflect both the intended use case for such a solution, as well as the inherent temporality of the system’s readings—most “continuous”

monitors do not, in actuality, take continuous readings. Instead, they may activate and take readings several times per day, multiple times per hour, or potentially several times per minute.

Commenter (0807-BP) recognizes that there may be diverse views on the use case for continuous monitors and thus the most appropriate definition. EPA might consider convening a series of workshops with stakeholders from industry, academia and civil society to capture these views and ultimately inform the definition EPA proposes for public comment.

Response I-7-205: The EPA acknowledges recommendations for various definitions to incorporate into the continuous monitoring framework. See discussion in section IV.B.2 of the December 2022 Supplemental Proposal for a discussion on alternative continuous monitoring systems.<sup>493</sup> Please also see section X.B.2 of the preamble to the final rule which details EPA's final standards related to the use of continuous monitoring systems for detection of fugitive emissions under the advanced methane detection technology program, including definitions and all requirements that apply to continuous monitoring.

#### 7.3.6.2 Number and Placement of Monitors

Comment: Several commenters (0588-Project Canary, 0756-Baker Hughes, 0760-Airdar *et al.*, 0791-Airdar, 0780-LongPath, 0844-EDF *et al.*) indicate that the effectiveness of continuous monitors is dependent on a number of different factors.

Commenter (0588-Project Canary) adds that continuous monitors can detect the area of the site leaking using the triangulation of continuous monitoring sensors and Gaussian plume models. Continuous monitoring systems achieve this because they contain meteorological systems that communicate wind speed and wind direction to the sensors dashboard. This allows for the use of GIS overlays of the site, which in turn allows the use of ML to help continuous monitoring systems determine the approximate source of the emission. The GIS-based analysis can pinpoint the equipment type that is leaking. This leak source identification process can eliminate or reduce the need to conduct a full OGI survey, because the approximate source of the leak is already identified.

The commenter (0588-Project Canary) states flyover and satellite-based systems do not have sufficient resolution to specifically pinpoint the source of the leak. These systems only inform the operator of a leak on the location at a point in time; operators using those systems then need to be follow up with an OGI inspection to find and fix the leak. Of note, continuous monitors can additionally determine if emissions are coming from off-site sources using the same triangulation method. By contrast, flyovers and satellites simply provide a large heat map showing where emissions are coming from in a more general sense. Thus, continuous monitors allow for a more directed site inspection to find and fix the emission source faster than other methods and mitigate the need for unnecessary OGI inspections that are based on off-site sources.

Commenter (0756-Baker Hughes) states performance of continuous monitoring system, and consequently the number of sensors, is variable and depends on the size of the site, level of congestion, type of components, emission sources, and weather. The commenter's Terrain

---

<sup>493</sup> 87 FR 74744-74745 (December 6, 2022).

system analyzes site characteristics in combination with weather to determine the optimum number of sensors for maximum performance.

Commenter (0760-Airdar *et al.*) states OGI cameras that operate in the thermal region of the infrared spectrum (above 3  $\mu\text{m}$ ) are impacted by the  $\Delta T$  between gas and background. To take account of these parameters for OGI inspections, EPA is introducing the concept of an “operating envelope” (see Section 8.4 of Appendix K). Commenters are proposing to utilize the same concept of an operating envelope for determining the placement and number of continuous monitors required to cover a specific site.

The commenter (0760-Airdar *et al.*) states the operating envelope should specify a minimum leak rate detection level, a maximum distance and a range of environmental conditions. The 10 kg/hr minimum leak rate detection level is described throughout the comment to be consistent with EPA’s November 2021 Proposal of 10 kg/hr for bimonthly survey. The required number of monitors per site has to be chosen such that all (or a certain percentage of) relevant pieces of equipment on the site are covered. Fugitive emissions monitoring plans will cover demonstration (and third-party validation testing) of operating envelopes being met.

The commenter (0760-Airdar *et al.*) states an important parameter that impacts absolute emission reductions is the portion of equipment that is covered with a detection limit lower than 10 kg/hr. A sensor placement where the majority of equipment is within for example a 5 kg/hr detection limit and one piece of equipment is covered only at a 15 kg/hr detection limit is preferable over a placement where all components are just within a 10 kg/hr limit. Operating envelopes can be simulated with, for example, atmospheric modeling, or demonstrated in empirical settings.

Commenters (0780-LongPath, 0791-Airdar) note overall site emission rates can be measured with a relatively small number of properly placed sensors. For example, a small wellsite may only need one or two sensors to continuously monitor and quantify emissions. For larger facilities, several monitors may be needed around the fence line of the facility, and some positioned at heights to isolate key pieces of equipment. If the focus of the monitoring is to locate small and medium sized individual sources that are spaced close together, more sensors placed throughout the facility may be needed to isolate small plumes that blend together and become difficult to separate when observed from the fence line.

The commenters (0780-LongPath, 0791-Airdar, 0844-EDF *et al.*) state the placement of monitors is dependent on the focus of the monitoring program. Overall site monitoring requires the sensors to be placed at a distance from potential sources, such as on the fence line with some installed at varying heights. This arrangement will be able to measure the overall site emission rate and locations of the large sources. Commenters (0780-LongPath, 0791-Airdar, 0844-EDF *et al.*) add if pinpointing the location of small to medium sized leaks is the focus of a monitoring program, the sensors need to be placed closer to the potential sources and positioned such that smaller, similar sized plumes can be isolated from each other. This will allow individual smaller sources to be located and quantified.

The commenters (0780-LongPath, 0844-EDF *et al.*) note EPA can create a model for determining proper sensor placement, as it has for refineries fenceline monitoring. In most cases,

the commenter anticipates sensors would be placed close to the largest emission sources, but EPA should also ensure any equipment located farther away can be reliably screened. At larger sites, and depending on technology, this may require multiple sensors to ensure adequate coverage. By contrast, tower-based solutions may be able to reliably screen multiple sites with a single sensor. Sensors must not only be within a horizontal range of emission sources, but must also be able to detect all emission sources vertically.

The commenter (0791-Airdar) states continuous monitoring systems can provide source location to within approximately 3 to 6 meters using sensors positioned roughly 150 meters away. To provide a precise location for the leak to operators, follow-up with a handheld detector or OGI camera is used to pinpoint the exact leak location. Depending on the facility, continuous monitoring systems are able to pinpoint and confirm the exact leak location, making follow-up in the field not necessary. The commenter has observed through several of their projects that continuous monitoring has the potential to satisfy both LDAR and fence line monitoring requirements.<sup>494</sup> The placement of the monitors on the fence line of the facility can allow continuous monitoring of the fence line and LDAR monitoring to take place concurrently.

Commenters (0791-Airdar, 0780-LongPath) state the effectiveness of any methane sensing technology is subject to the distance from sensor to emission source, size of the facility, density of components at the facility, detection limit of the sensor, and micrometeorological and other environmental conditions.

Response I-7-206: The EPA acknowledges the commenters' remarks regarding the effectiveness of any methane sensing technology. See discussion in section IV.B.2 of the December 2022 Supplemental Proposal for a discussion on alternative continuous monitoring systems.<sup>495</sup> Please also see section X.B.2 of the preamble to the final rule which details EPA's final standards related to the use of continuous monitoring systems for detection of fugitive emissions under the advanced methane detection technology program, including the operational downtime requirements that apply to continuous monitoring.

#### 7.3.6.3 Minimum Response Factor

Comment: Commenter (0791-Airdar) states the minimum detection level of the sensors or monitors should be below the background level of the compound of interest to have the ability to identify plumes from sources at great distances. Sensors with higher detection limits can still identify sources but only at closer ranges. Sensors with detection limits below the ambient background level of the compound can see large sources at several kilometer ranges. For methane, a detection limit below background level of approximately 1.9 ppm<sup>496</sup> is needed. The stability of the sensor output is also important as this will determine how often calibrations are needed.

---

<sup>494</sup> Dennis Prince et al., 2019.

<sup>495</sup> 87 FR 74744-74745 (December 6, 2022).

<sup>496</sup> Ed Dlugokencky, "Trends in Atmospheric Methane," NOAA/GML, accessed January 26, 2022, [gml.noaa.gov/ccgg/trends\\_ch4/](https://gml.noaa.gov/ccgg/trends_ch4/).

The commenters (0590-Honeywell, 0791-Airdar.) state that documenting the baseline over a period of normal operations helps identify anomalies attributed to emission events. For continuous monitoring systems, a specific set of criteria is encoded into the algorithm to determine if the detected emissions are an “alarm” or not. For example, C-OGI systems allow alarms to be assigned to a piece of equipment within a field-of-view based on the concentration of gas detected, duration of the emissions, and the number of detections from the field-of-view over a preset time interval within the daily monitoring period. For a C-OGI system, alarms are accompanied with an image or video for review by operators for final confirmation.

Response I-7-207: The EPA acknowledges the commenters’ input. See discussion in section IV.B.2 of the December 2022 Supplemental Proposal for a discussion on alternative continuous monitoring systems.<sup>497</sup> Please also see section X.B.2 of the preamble to the final rule which details EPA’s final standards related to the use of continuous monitoring systems for detection of fugitive emissions under the advanced methane detection technology program, including all requirements that apply to continuous monitoring.

Comment: Commenters (0760-Airdar *et al.*, 0791-Airdar) provide feedback in response to EPA’s request for information related to minimum response factors to methane.

Commenter (0760-Airdar *et al.*) indicates that continuous monitors typically detect methane concentration (measured in units like ppm) or path-integrated methane concentration (measured in units like ppm-m). However, concentration targets, alone, are less meaningful than emission rate targets. Concentration values alone are subject not only to emission rates, but also to meteorological and micrometeorological conditions, sensor distance from the source, inbound plumes from emissions on neighboring sites, rapid fluctuations in ambient or “background” concentrations, and other factors that can severely complicate interpretation. Given that most technologies now offer emission rate metrics (*i.e.*, quantification), it is time for EPA to recast rules in terms of the metric that matters to the Agency, that is, gas emitted to the atmosphere (and not local, distance-dependent and temporally ephemeral concentration enhancements). The commenter therefore recommends replacing “Minimum response factor to methane” with “Emission rate detection threshold.”

Commenter (0760-Airdar *et al.*) suggests, as a starting point, an emission rate detection threshold of 10 kg/hr, if the continuous monitor is expected to work only once every two months. That is, if a matrix were to define gradations of sensitivity alongside gradations of survey frequency, the commenter would recommend, as a starting point, equivalency to the Optional BSER for bimonthly surveys with a threshold of 10 kg/hr. If the continuous monitor is expected to work more frequently, the 10 kg/hr threshold could, for example, be increased to acknowledge faster find-and-fix timelines afforded by higher frequency monitoring. On a sensor-by-sensor basis, the minimum response factor to methane will remain an important element for inclusion into the fugitive emissions monitoring plan submitted by any owner or operator seeking to use alternative monitoring methods.

Commenter (0791-Airdar) states a continuous sensor measuring methane that is responsive enough to distinguish 0.1 ppm above the 1.9 ppm ambient background concentration should be

---

<sup>497</sup> 87 FR 74744-74745 (December 6, 2022).

able to detect a source releasing 6 L/min (approximately 0.26 kg/hr) methane at 150 meters distance. In the commenter's control study published in their patent<sup>498</sup>, a 6 L/min source located 60 meters from the monitor (a less sensitive Photovac microFID) was quantified. This demonstrated that the system could measure a methane leak to within 10 percent to 20 percent of the actual emission rate at a range of 60 meters. This is more than enough to meet the 10 kg/hr leak detection limit of other intermittent leak detection approaches which have been approved by the EPA.

The commenter's (0791-Airdar) sensors that are less responsive can still be used in a continuous monitoring system, but the sensor may need to be placed closer to potential sources. These sensors may only be able to detect larger sources. Monitoring of small sources at great distances can best be achieved using sensors with a good response factor. Continuous monitoring systems use many different sensors depending on the compounds being measured. For methane, the commenter deploys a system that can detect and quantify methane sources of 0.26 kg/hr at a range of 60 m away from the source and can detect larger sources even further away.

Response I-7-208: See discussion in section IV.B.2 of the December 2022 Supplemental Proposal for a discussion on alternative continuous monitoring systems.<sup>499</sup> Please also see section X.B.2 of the preamble to the final rule which details EPA's final standards related to the use of continuous monitoring systems for detection of fugitive emissions under the advanced methane detection technology program, including all requirements that apply to continuous monitoring.

Comment: Commenter (0588-Project Canary) recommends using an alert system, similar to their own, to best determine which events require an OGI survey. The four alerts are described below and additional details are provided in the commenter's letter:

- Alert Type 1 – High concentration event as defined by the company (typically greater than 10 ppm methane above background concentration) over a short period of time (about less than one hour) or longer.
- Alert Type 2 – Lower concentration event as defined by the company (typically set between about 5 – 10 ppm methane above background concentration) that is continuous.
- Alert Type 3 – Very low concentration event as defined by the company (typically set at 1 – 2 ppm methane above background concentration) over a 24 hour period or longer.
- Alert Type 4 – High or low concentration event as defined by the company that is intermittent.

Response I-7-209: See discussion in section IV.B.2 of the December 2022 Supplemental Proposal for a discussion on alternative continuous monitoring systems.<sup>500</sup> Please also see section X.B.2 of the preamble to the final rule which details EPA's final standards related to the use of continuous monitoring systems for detection of fugitive emissions under the advanced

methane detection technology program, including the final action levels that apply to continuous monitoring.

#### 7.3.6.4 Minimum Detection Level

Comment: Commenters (0590-Honeywell, 0844-EDF *et al.*, 1172-Qube Technologies Inc. (Qube)) provide feedback in response to EPA's request on how to incorporate minimum detection levels in the continuous monitoring system framework.

Commenter (0590-Honeywell) states a continuous monitoring system's minimum detection level depends on the distance of the monitor to the system. Since these systems monitor continuously as compared to semiannual or quarterly OGI surveys, the commenter suggests EPA set the minimum detection level for continuous monitoring systems higher than the OGI detection level. For the sake of consistency, the commenter suggests EPA set the minimum detection threshold at 10 kg/hr, which aligns with EPA's alternative screening method.

Commenter (0844-EDF *et al.*) believes EPA should allow for continuous monitoring approaches with detection limits as low as permissible screening approaches as long as equivalent emission reductions can be demonstrated. Most continuous monitoring approaches must also be paired with some degree of OGI follow-up. Operators should be required to perform a follow-up OGI survey if emissions are detected in excess of predicted, permitted emissions. To minimize false alarms, this would require quantitative measurement technology, continuous emissions modeling, and extensive recordkeeping.

The commenter (0844-EDF *et al.*) states if EPA targets a 90 percent reduction, for example, it can work backwards to determine the (a) detection capabilities, (b) frequency of screening, and (c) follow up work practices that together would achieve this goal. To ensure a technology can reliably detect at a given threshold like 10 kg/hr, EPA will have to consider at least five parameters: distance from the source, probability of detection, frequency of detection, wind speed, and temperature/atmospheric-stability class. EPA will also have to evaluate the follow-up work practices associated with detections to ensure a certain reduction target is met. For example, emissions detected by a screening technology that is only capable of 100 kg/hr will be very large, may require repair on short timelines to achieve significant reductions (and in many cases may not be able to show equivalency regardless of repair speed). In most screening approaches, there will also be challenges in determining fugitive emissions versus allowable high emission events and situations where emissions cannot be pinpointed or have disappeared since being detected by screening.

Commenter (1172-Qube Technologies Inc. (Qube)) has demonstrated through controlled testing the ability to reliably detect emission rates below 1 kg/hr. Many continuous measurement systems on the market, including the commenter's, can easily detect emission rates of 10 kg/hr. Continuous measurement has the added benefit of surveying more than six times a year; it surveys 365 days of the year, meaning that emissions reductions would greatly exceed those of the mobile approach. The commenter therefore also believes that the 10 kg/hr threshold is unnecessarily high based on available continuous measurement technology and would propose a screening threshold of 1 kg/hr to ensure that all important sources are captured.

The commenter (1172-Qube) states that rigorous evidence must be presented to demonstrate that the method chosen achieves the performance metrics required. Many technology providers claim to achieve certain performance but without sufficient evidence. Rigorous controlled release testing should be mandatory across a broad range of conditions to develop probability of detection curves and/or surfaces that, at a minimum, establish probability of detection of a method as a function of emissions rate, wind speed, and any other relevant variables than impact detection. Testing must be performed under a broad range of environmental conditions.

Response I-7-210: See discussion in section IV.B.2 of the December 2022 Supplemental Proposal for a discussion on alternative continuous monitoring systems.<sup>501</sup> Please also see section X.B.2 of the preamble to the final rule which details EPA’s final standards related to the use of continuous monitoring systems for detection of fugitive emissions under the advanced methane detection technology program, including the final action levels that apply to continuous monitoring.

#### 7.3.6.5 Frequency of Data Readings

Comment: Commenters (0590-Honeywell, 0780-LongPath, 0791-Airdar) provide feedback in response to EPA’s request on appropriate frequencies of data readings under the continuous monitoring system framework.

Commenter (0590-Honeywell) urges EPA to define continuous monitoring broadly to be as inclusive as reasonably possible, rather than limiting what qualifies as continuous monitoring to a detailed set of technology specifications. The commenter suggests for a system to be considered continuous, it should at a minimum have a daily reading to align improved environmental benefits as predicted by the literature.<sup>502</sup>

Commenter (0780-LongPath) believes the frequency of data readings or reported emission rate values (whether detection or quantification readings), should be defined so as to differentiate between spot-check survey methods and continuous monitors. That is, a definition is needed to differentiate a “survey” technology from a “continuous monitoring” technology in terms of data frequency. If a matrix approach is adopted, frequency of data readings are needed to differentiate different areas of the matrix. The commenter recommends, as a starting point, defining “continuous monitoring” as a data reading of all important equipment once weekly.

The commenter (0780-LongPath) provides the following definitions. A “data reading” should be defined as a unit of detection or quantification of emissions from a monitored pad. A “data reading” should not be defined as the readout from a given sensor, such as a concentration or wind value. It is important that EPA ask technology providers to differentiate between sensor readouts (which can be as frequent as many Hz) and data readings, which require aggregation of data from various sensors and some averaging time through turbulent atmospheric conditions (and are therefore less frequent in time than sensor readouts).

---

<sup>501</sup> 87 FR 74744-74745 (December 6, 2022).

<sup>502</sup> See Kemp & Ravikumar Study.

Commenter (0791-Airdar) technology and other similar continuous monitoring technologies use concentration measurements to locate and quantify emissions. With a higher frequency of data, a more accurate analysis can be completed and the more the monitoring system can “see.” Airdar prefers data at a 10 second frequency for optimal performance.

The commenter (0760-Airdar *et al.*) states the framework for continuous monitoring (or a matrix describing performance requirements) will need to define frequency of data readings as a key performance requirement. A starting point could be at least once every two months with a 10 kg/hr detection threshold, to match the proposed Optional BSER for bimonthly surveys. To satisfy the less stringent emission follow-up requirements proposed here, however, the commenter would suggest a starting point of at least once every week with a 10 kg/hr detection threshold.

Response I-7-211: See discussion in section IV.B.2 of the December 2022 Supplemental Proposal for a discussion on alternative continuous monitoring systems.<sup>503</sup> Please also see section X.B.2 of the preamble to the final rule which details EPA’s final standards related to the use of continuous monitoring systems for detection of fugitive emissions under the advanced methane detection technology program, including the short-term and long-term rolling average action levels that apply to continuous monitoring.

#### 7.3.6.6 How to interpret the monitor data to determine what emissions are a detection versus baseline emissions

Comment: Commenter (0780-LongPath) believes the rule should be written with emission rate targets and not concentration value targets. With a target of emission rate rather than concentration value, the question of what constitutes a breach of the leak definition no longer becomes relevant; it is implied directly in the data reading. Instead, validation testing of the stated ability to detect can provide the assurances needed for regulators and owners and operators to know that compliance measures are being satisfied.

The commenter (0780-LongPath) adds that in terms of whether the leak definition should be defined as a static value (*e.g.*, 10 kg/hr) or as an increase over baseline conditions, some continuous monitoring systems, such as LongPath, offer customers a data product in which operations are assessed during a spin up period to establish a baseline emission rate and other characteristics for a given site. Alerts are then sent out when emission rates exceed expected baseline values with some statistical certainty. Many statistical tests can be used to determine statistically significant aberrations from baseline conditions.

The commenter (0780-LongPath) indicates that the leak definition could be arrived at in one of several ways:

- An emission rate in exceedance of a static threshold, determined for facility-types or other basis according to specific site characteristics.
- An emission rate in exceedance of a predetermined variance from the site-specific baseline emission rate.

---

<sup>503</sup> 87 FR 74744-74745 (December 6, 2022).

- An emission rate in exceedance of some factor above the site-specific subpart W reported rate.
- An emission rate in exceedance of some increment above a predetermined emissions intensity target.

The commenter (0780-LongPath) recommends a leak definition based on static values, if that is what will be applied to the survey AWP. Ultimately, agreement between alternative technology options will provide the most clarity and ease of compliance for operators. If it were determined to be the best path forward, the commenter would, however, also support an EPA framework for continuous monitoring that is based on aberrations from a baseline value. However, the commenter points out that care must be taken under this approach. Many sites have substantially lower baseline values than others; EPA would not want to inadvertently permit some operators to maintain higher-emitting operations than others. Aberrations from a very low baseline value should not be penalized in the same way as aberrations from a very high baseline value from a site with the same number and types of equipment. Further, “natural” variability of emissions is much higher for some sites compared with other sites, complicating the statistical tests required to parse problematic emissions from normal operations.

The commenter (0780-LongPath) believes ultimately, whatever the leak definition, each technology will need to demonstrate, in blinded third-party validation testing, the ability to consistently and accurately (no or minimal false negative detections or missed leaks) identify when emissions from a monitored site are in exceedance of the leak definition rate. The CSU / METEC ADED program would be an excellent testbed for establishing these targets.<sup>504</sup> Validation demonstration results will be an important component of submitted fugitive emissions monitoring plans.

Response I-7-212: See discussion in section IV.B.2 of the December 2022 Supplemental Proposal for a discussion on alternative continuous monitoring systems.<sup>505</sup> Please also see section X.B.2 of the preamble to the final rule which details EPA’s final standards related to the use of continuous monitoring systems for detection of fugitive emissions under the advanced methane detection technology program, including procedures for establishing baseline emissions which are used to determine when emissions are above site-specific baseline and action-levels apply for continuous monitoring.

#### 7.3.6.7 How to determine allowable emissions versus leaks

Comment: Commenters (0756-Baker Hughes, 0760-Airdar *et al.*, 0780-LongPath, 0791-Airdar) provide feedback in response to EPA’s request on how to determine allowable emissions versus leaks.

Commenter (0756-Baker Hughes) is not aware of any detection method-including OGI-that is capable of inherently distinguishing “allowable emissions” from “leaks.” Distinguishing between allowable emissions and leaks are an element of an operator’s implementation plan for OGI, and similarly would be for continuous monitoring. This highlights an additional benefit of continuous

---

<sup>504</sup> Advancing Development of Emissions Detection: <https://energy.colostate.edu/metec/aded/>.

<sup>505</sup> 87 FR 74744-74745 (December 6, 2022).

monitoring-correlating detection emissions data (*e.g.*, times, durations, locations, and quantifications) with the site's process data and history, *i.e.*, timing of known process venting that is detected as an emission by continuous monitoring. Over time, this data will provide a fuller picture of actual emissions (allowable and leaks).

Commenters (0760-Airdar *et al.*, 0780-LongPath) state the continuous monitoring system is to be operated continuously in accordance with the user manual of the specific technology, and the fugitive emissions monitoring plan submitted by the owner or operator, and subject to minimum uptime requirements. When a detected emission occurs, the commenters provided details in their commenter letter that included the following key steps:

- Step 1: "Alarm-candidate" generation
- Step 2: (Optional) Alarm-candidate assignment to equipment
- Step 3: Alarm-candidate classification
- Step 4: Emission Event Investigation Procedures
- Step 5: Repair

Commenter (0791-Airdar) uses a data analysis approach that can identify plumes in concentration and wind data while also providing quantification.<sup>506</sup> According to the commenter, continuous monitoring technologies like Airdar's have the ability to isolate plumes from all sources and quantify the source emission rate. With the ability to quantify emissions from any source, the determination of which emission sources are allowable is dependent on each piece of equipment and their allowable emitting rate. Emissions that exceed these specified allowances will be considered leaks.

The commenter (0791-Airdar) states the new capabilities introduced by continuous monitoring technologies that allow an entire site's emission rate to be determined opens the possibility to reconsider current approaches to fugitive emissions monitoring. Instead of focusing on periodic, component-specific surveys, continuous monitoring allows for the observation of the bigger picture. Existing approaches are missing important emission sources which is resulting in the underreporting of emissions. New continuous sensing approaches can see things that were missed before, but this will create challenges in comparing these new measurements to the old, regulated approaches. Writing the rules to match continuous monitoring systems to traditional EPA Method 21 monitoring may not be the best approach. This would ignore the capabilities of continuous monitoring and would miss the opportunity to innovate and improve. Possibly the simplest way to overcome this challenge is developing an overall site emission limit that would be tied to production of the site. This approach will help the environment and the people as this would drive operators to find innovative ways to stay below the emission limit and improve the accuracy of emission reporting through the capabilities of continuous monitoring technologies. The new approach will give operators the freedom to determine how best to reduce emissions, regardless of what was previously deemed an allowable source as long as overall site emission

---

<sup>506</sup> This approach is published in their patent documents including U.S. Patent 8,510,059<sup>506</sup> and presented in 2019 at the AWMA Air Quality Measurement Methods and Technology Conference.

rates stay below the limit. Efforts spent on micro-managing the process of emission protocols can now be focused on reducing emissions in the most efficient way possible.

Response I-7-213: The EPA acknowledges recommendations received from commenters providing feedback in response to EPA's request on how to determine allowable emissions versus leaks. See discussion in section IV.B.2 of the December 2022 Supplemental Proposal for a discussion on alternative continuous monitoring systems.<sup>507</sup> Please also see section X.B.2 of the preamble to the final rule which details EPA's final standards related to the use of continuous monitoring systems for detection of fugitive emissions under the advanced methane detection technology program, including all requirements that apply to continuous monitoring.

#### 7.3.6.8 Response to other Compounds

Comment: Commenters (0756-Baker Hughes, 0780-LongPath) provide feedback in response to EPA's request for comment on response to other compounds.

Commenters (0756-Baker Hughes, 0780-LongPath) do not recommend that EPA require response to other compounds.

Commenter (0780-LongPath) says that given the urgent need to apply state-of-the-art emissions mitigations measures for methane. Extensive co-benefits of methane mitigation for the mitigation of VOCs will occur even for systems only capable of characterizing methane.

Similarly, commenter (0756-Baker Hughes) states that methane represents an approximate 16 percent of greenhouse gas emissions, however, is approximately 25 times more harmful to the environment. Methane also represents the largest component of fugitive emissions from oil and gas production facilities. Therefore, the commenter recommend that continuous monitoring should focus primarily on methane detection as opposed to other compounds.

Response I-7-214: The EPA acknowledges the commenters' request to not include a requirement for continuous monitors to be able to respond to other compounds besides methane. See discussion in section IV.B.2 of the December 2022 Supplemental Proposal for a discussion on alternative continuous monitoring systems.<sup>508</sup> Please also see section X.B.2 of the preamble to the final rule which details EPA's final standards related to the use of continuous monitoring systems for detection of fugitive emissions under the advanced methane detection technology program, including all requirements that apply to continuous monitoring.

#### 7.3.6.9 Meteorological Data

Comment: Commenters (0756-Baker Hughes, 0760-Airdar *et al.*, 0780-LongPath, 0791-Airdar, 0807-BP) provide feedback in response to EPA's request on how to incorporate meteorological data in the continuous monitoring system framework.

---

<sup>507</sup> 87 FR 74744-74745 (December 6, 2022).

<sup>508</sup> 87 FR 74744-74745 (December 6, 2022).

Commenter (0756-Baker Hughes) states that regarding meteorological station distance, the commenter's LUMEN Terrain uses one base station per monitoring site. These base stations are equipped with a meteorological station and are installed within the site itself providing the real-time weather data for the individual detection nodes in close proximity. Other continuous

Commenter (0780-LongPath) states the specifications listed by each technology in the monitoring plans will need to be vetted and validated as part of third-party blind testing. The commenter indicates that the two types of meteorological data that will need to be submitted as part of the monitoring plan are meteorological data criteria for initial siting of monitors meteorological data criteria for monitoring.

Commenter (0780-LongPath) suggests that EPA restrict the use of gridded datasets for use in emissions monitoring from any platform (ground-based or remote) and instead impose an acceptable radius for local meteorological measurements to be applied (*e.g.*, 10 miles). A recent publication on the impacts of microclimatic conditions provides, in the first paragraph of the introduction, a helpful literature review describing problems with gridded climate data products for parameterizing local-scale conditions<sup>509</sup> (*i.e.*, a clear justification for restricting the use of gridded datasets as a source of meteorological data for emissions characterization from oil and gas).

Commenters (0590-Honeywell, 0791-Airdar, 0780-LongPath) state all monitoring systems are affected by inclement weather conditions, and as such, technology providers should state the weather conditions the continuous monitoring system can operate in to achieve the required detection threshold. Windy day plumes disperse differently than on a calm day, leading to different influences of the same emission on a sensor. Some technologies are additionally impacted by temperature and background conditions (*e.g.*, snow cover for an aircraft or satellite platform). Similar to the operating envelope described in EPA's Appendix K, operating envelopes will need to be established for each alternative monitoring solution as part of the planned sensor placements for each monitored site. Operating envelopes will account for such information as the maximum distance between a given piece of equipment and the physical location at which atmospheric methane is being sampled, given the range of wind, temperature, visibility and humidity conditions expected at the monitored site.

Commenter (0590-Honeywell, 0760-Airdar *et al.*, 0807-BP) adds real time meteorological data can be used to estimate emissions rates. For purposes of operating continuous monitors, real time meteorological data should be used to verify that the continuous monitor is operating within its operating envelope. The location and proximity of meteorological stations for demonstration of this requirement should be included in the submitted fugitive emissions monitoring plan, as requirements vary by vendor and monitoring solution.

The commenters (0590-Honeywell, 0760-Airdar *et al.*) state local weather near an installed site can be monitored and tracked daily to determine the availability of the continuous monitoring system. Even in inclement weather, the continuous monitoring systems are still operational and capable of detecting leaks; however, the minimum detection threshold may be higher than

---

<sup>509</sup> Aalto et al., "Revealing Topoclimatic Heterogeneity Using Meteorological Station Data."

specified. As soon as inclement weather passes, continuous systems will return to their specified performance.

The commenters (0760-Airdar *et al.*) state the continuous monitoring system is required to maintain detailed records of when data quality falls below set levels, and to support with other BSER when specifications are not met. As an example, continuous monitoring systems should record when meteorological conditions are outside the specified operating envelope or when data communication is not available. Supporting data from third-party blind testing is required to demonstrate and verify that the technology meets stated specifications across the conditions representative of each of the geographies and sub-climates for proposed use. These tests determine the operating envelope.

These test variables should include:

- Humidity ranges and impacts on sensors
- Temperature ranges
- Wind speed ranges
- Snow or other groundcover that may affect sensors
- Obstruction of sensors with dust, snow or ice
- Availability of network connectivity
- Availability of power

Response I-7-215: The EPA acknowledges the commenters input on how to incorporate meteorological data in the continuous monitoring system framework. See discussion in section IV.B.2 of the December 2022 Supplemental Proposal for a discussion on alternative continuous monitoring systems.<sup>510</sup> Please also see section X.B.2 of the preamble to the final rule which details EPA's final standards related to the use of continuous monitoring systems for detection of fugitive emissions under the advanced methane detection technology program, including how any meteorological data used are collected or sourced when associated with continuous monitoring.

#### 7.3.6.10 Measurement Systems Data Quality Indicators

Comment: Commenters (0780-LongPath, 0791-Airdar) provide feedback in response to EPA's request on how to incorporate data quality indicators in the continuous monitoring system framework.

Commenter (0780-LongPath) states that with respect to the quality of sensor data, each individual continuous monitoring solution will have different data quality indicators, depending upon the sensor type and usage. Specifications for data quality assurance and quality control will need to be documented and tested in third-party blinded validation under these stated operating specifications. Important operating conditions for demonstration testing include the impacts on sensors and quantification methods of the following variables: humidity, temperature, wind

---

<sup>510</sup> 87 FR 74744-74745 (December 6, 2022).

speed, wind direction, groundcover (*e.g.*, snow), atmospheric conditions (dust, snow, rain, fog), obstruction of sensors (snow, dust, ice) network connectivity, power.

The commenter (0780-LongPath) adds with respect to the quality of emission rate or detection data (the quality of a data reading), each continuous monitoring method will need to demonstrate how uncertainty bars associated with each data reading are calculated and validated. The commenter provides additional technical detailed recommendations related to the quality of emission rate at detection data in their comment letter. The commenter reemphasizes that regardless of the methodologies used for uncertainty characterization by a particular continuous monitor, the validity of the technique must be demonstrated during third-party blind testing. In particular, it must be demonstrated during third-party blind testing that the continuous monitoring system is capable of meeting stated minimum threshold of detection and leak definition targets with statistical robustness, given emission estimate uncertainties as described here. This can functionally be determined by ensuring that false negatives (missed detections) of the target emission rate occur no more than, for example, 90 percent of the time during blinded testing.

Commenter (0791-Airdar) states different data quality objectives may exist depending on the type of monitoring being performed. Many public ambient monitoring stations are concerned with high readings of concentrations while a system like Airdar is concerned with identifying the baseline or zero point to identify emission plumes. Having a stable baseline is advantageous, but if the baseline is not stable, performing calibrations to adjust for a moving baseline will help to overcome this challenge. Properly defining the baseline will give higher confidence to the quantification of emissions and uncertainty in the baseline can introduce errors. Identifying the effects of temperature, humidity, and other variable is also important as these variables can affect the readings taken by the sensor. Identifying these effects will help to define a better baseline.

Response I-7-216: See discussion in section IV.B.2 of the December 2022 Supplemental Proposal for a discussion on alternative continuous monitoring systems.<sup>511</sup> Please also see section X.B.2 of the preamble to the final rule which details EPA's final standards related to the use of continuous monitoring systems for detection of fugitive emissions under the advanced methane detection technology program, including data quality indicator requirements that apply to continuous monitoring technologies seeking ATM approval.

#### 7.3.6.11 Calibration Requirements and Frequency of Calibration Checks

Comment: Commenters (0780-LongPath, 0791-Airdar) provide feedback on EPA's request for comment on calibration requirements and frequency of calibration checks.

Commenter (0780-LongPath) emphasizes that different continuous monitoring technologies have different calibration needs. For example, the differences in calibration requirements or sensitivity to changes in humidity for metal oxide sensors compared with optical point sensors is substantial. Other sensors, such as the dual frequency comb spectrometer used by the commenter

---

<sup>511</sup> 87 FR 74744-74745 (December 6, 2022).

do not require any initial or ongoing calibration at all.<sup>512</sup> Therefore, technology-specific fugitive monitoring plans must accompany technology-agnostic general continuous monitoring frameworks. It is critical that stated specifications for calibration be firmly rooted in the peer reviewed literature. Inability of a monitoring solution to justify stated calibration protocols in the peer reviewed literature should be disqualifying for sensor use – despite a wide variety of monitoring solutions and technologies, all solutions rely on a relatively small set of sensor types, for which academic research is adequately available.

The commenter (0780-LongPath) emphasizes that in addition to requiring calibration specifications in the academic literature, it will be incumbent upon technology providers to prove these requirements in third-party blinded testing. The length of blind testing must span some factor on the stated calibration time frame to ensure that sensor drift within the stated windows does not occur. For example, if a solution states a calibration schedule of once every week, then the sensor should be tested over a period of at least 4 weeks to amass a reasonable statistical sample size demonstrating that the system meets stated drift specifications. The conditions of blind testing should also span all conditions expected in the operating environment shown in the peer reviewed literature to influence drift and calibration needs.

Commenter (0791-Airdar) states to ensure measurement accuracy, a requirement to include calibration checks should be included in the new rule. Calibration data is used to ensure that the correct baseline of emissions is taken to allow for location and accurate quantification of abnormal emission events. The calibration frequency is dependent on the sensor being used, as it is mainly determined by the stability of the sensor's baseline reading. In the commenter's experience, calibration needs to be completed at enough of a frequency to understand how the baseline varies over time and be able to separate the baseline from the emission source(s). Calibration is also required to confirm that the sensors are functioning. This will provide more certainty and provide operators, regulators, and communities with confidence in monitoring emissions.

The commenter (0791-Airdar) notes understandably, a calibration requirement can become labor intensive for operators when there are several sensors located across a large facility. However, the commenter has found a solution for making calibrations more convenient by using a central sensor connected via tubing to several remote sample inlets placed across a facility. The need to calibrate several monitors is reduced to one which can be done remotely, without requiring personnel to be on-site, saving time and effort while allowing for higher frequency of calibrations.

Response I-7-217: See discussion in section IV.B.2 of the December 2022 Supplemental Proposal for a discussion on alternative continuous monitoring systems.<sup>513</sup> Please also see section X.B.2 of the preamble to the final rule which details EPA's final standards related to the use of continuous monitoring systems for detection of fugitive emissions under the advanced methane detection technology program, including the quality assurance/quality control criteria (*i.e.*, initial and ongoing calibration procedures, data quality indicators, and data quality

---

<sup>512</sup> Waxman et al., "Intercomparison of Open-Path Trace Gas Measurements with Two Dual Frequency Comb Spectrometers."

<sup>513</sup> 87 FR 74744-74745 (December 6, 2022).

objectives) that apply to continuous monitoring technologies seeking ATM approval. The final rule specifies that the fugitive emissions monitoring plan where continuous monitoring will be used to demonstrate compliance must include a discussion of the system calibration requirements, including but not limited to, the calibration procedures and calibration schedule for the detection systems and meteorology systems.

#### 7.3.6.12 How Downtime Should be Handled

Comment: Commenters (0588-Project Canary, 0590-Honeywell, 0780-LongPath) provide insight on how operational downtime should be considered in the requirements of the rule.

Commenters (0588-Project Canary, 0780-LongPath) state that continuous monitor downtime can occur due to a variety of factors, such as sensor malfunction, communications failures, lack of cellular connection, lack of sun for long periods of time, or inability to operate due to extreme conditions (that is, environmental conditions that are outside of what is expected for the operating environment). It is important to differentiate between downtime due to shortcomings of the continuous monitor itself (*e.g.*, sensor malfunction, or inability to acquire cellular signal due to a local tower being down) from downtime due to truly external factors (for example, extreme weather events)

The commenter (0588-Project Canary) adds a single monitor is sufficient to find leaks if it is aligned with the correct wind direction. Given that the commenter typically installs three monitors at a location, the probability of having a total site outage is extremely low. As long as one monitor is operational, the commenter can determine whether a leak is potentially coming from the site and can be checked when the other monitors are fixed. The commenter notes that their dashboard system has a “flagging” approach to indicate whether a monitor is not operational or working improperly. While the commenter recommends that the monitor be fixed as soon as possible (considering technical feasibility issues), their system will still detect leaks faster than any sort of periodic monitoring system.

The commenters (0590-Honeywell, 0780-LongPath) recommend, for example, that if sensor malfunctions for a continuous monitor exceed 3 months (one quarter) then quarterly OGI BSER should be initiated to supplement lost fugitive emissions monitoring coverage.

Commenters (0767-Scientific Aviation *et al.*, 0791-Airdar) state when planned maintenance of the monitoring system is scheduled, it is preferable that this downtime does not coincide with other activities on site where a large emission event may occur (such as testing or commissioning of equipment). It is also important that facility operators cannot easily turn off the monitoring system or trigger its shutdown for safety and the accuracy of emissions profiles of the site. Downtime should be logged and explained in a record to demonstrate integrity and reliability of the monitoring program.

The commenter (0767-Scientific Aviation *et al.*) adds any uptime metric should be evaluated on no less than a two-week rolling basis to allow for repair time at remote facilities. Uptime requirements should also allow for an initial 60-day implementation period since a large-scale deployment of sensors can be challenged by fine-tuning parameters such as communications

(often relies on cell service or a need to build/configure existing SCADA), power availability (often relies on solar power), or other issues. Finally, where there is a data outage from a force majeure event there should be an allowable delay of repair for the monitoring system.

Commenter (0780-LongPath) states EPA should define reasonable percentages of downtime to be expected during the normal course of operation. When downtime due to shortcomings of the continuous monitor exceed the allowable percent, then the EPA should specify that other BSER must supplement measurements.

Response I-7-218: See discussion in section IV.B.2 of the December 2022 Supplemental Proposal for a discussion on alternative continuous monitoring systems.<sup>514</sup> Please also see section X.B.2 of the preamble to the final rule which details EPA's final standards related to the use of continuous monitoring systems for detection of fugitive emissions under the advanced methane detection technology program, including the operational downtime requirements that apply to continuous monitoring.

#### 7.3.6.13 How to Handle Situations where the Source of Emissions Cannot be Identified Even when the Monitor Registers a Leak

Comment: Commenters (0756-Baker Hughes, 0780-LongPath, 0791-Airdar) note that EPA is seeking comment on how to handle situations where the source of emissions cannot be identified even when the monitor registers a leak.

The commenter (0780-LongPath) indicates that for circumstances in which an emission event is not mitigated with the prescribed procedures, the root cause and follow-up steps will need to be reinitiated after a stated number of days or weeks have passed.

The commenter (0791-Airdar) states if strong patterns in the ambient data indicate a large source, something must be present to explain this observation. It is possible that a continuous monitoring system could detect a false positive leak, but this is highly unlikely as the sensor outputs would need to fail in a pattern that matches the changing wind.

The commenter (0791-Airdar) adds often, OGI camera inspections are announced visits and a facility may be on their "best behavior" when these inspections are performed. Like smiling and looking your best when getting your picture taken, facilities will want to look their best during these inspections. There are situations where intermittent monitoring techniques like OGI cameras or drones cannot confirm a leak identified by a continuous monitoring system because a facility is on its best behavior when an inspection happens. The commenter's work in several projects has shown that facilities operate differently when an announced inspection is happening.

Commenter (0756-Baker Hughes) recommends that the operator's implementation plan delineate how to evaluate the detection of emissions, including the time, duration, location, and quantity. A site's process data and history provide important context with respect to the source of an emission, such as the timing of known process venting. A plan can provide further detail for

---

<sup>514</sup> 87 FR 74744-74745 (December 6, 2022).

determining those circumstances when a follow up inspection with OGI is appropriate. The source for a leak can be confirmed at such time.

Commenter (0756-Baker Hughes) states emission localization is one the primary features of continuous monitoring along with detection and quantification. As an example, LUMEN Terrain provides the localization of every emission source with an accuracy of approximately +/-5 meters and displays this information as an overlay or “heat map” on aerial site imagery via the platform dashboard. This results in the determination of which equipment group or area of the site an emission originates from. In the majority of instances this provides enough information to identify the exact location without the need for follow-up inspections methods such as handheld OGI cameras. In the rare event localization results point to an area of high congestion with multiple potential leak source, and/or environmental conditions such as extreme winds reduce the accuracy of localization then follow up inspections with alternative technologies might be warranted.

Response I-7-219: See discussion in section IV.B of the December 2022 Supplemental Proposal for a discussion on advanced methane detection technologies, including alternative periodic screening and alternative continuous monitoring systems.<sup>515</sup> Please also see section X.B of the preamble to the final rule which details EPA’s final standards related to the use of alternative periodic screening and alternative continuous monitoring systems for detection of fugitive emissions under the advanced methane detection technology program. The final rule specifies the elements the fugitive emissions monitoring plan must contain where alternative technologies will be used to demonstrate compliance and the elements required to be included in the request for ATM approval.

### ***7.3.7 3<sup>rd</sup> Party Validation Testing***

Comment: Commenters (0756-Baker Hughes, 0780-LongPath) offer recommendations related to 3<sup>rd</sup> party validation testing.

Commenter (0756-Baker Hughes) recommends that third-party labs or testing sites are used to verify the minimum detection level, detection probabilities, and quantification accuracy. For reference, a widely used and accepted testing methodology is that developed by METEC at Colorado State University. The commenter further recommends that the criteria for the data set required for third-party verification should include reasonable timeframes, such as XXX hours or 30 days of field data, and not require data collected from different seasons or weather events. The commenter notes that LUMEN Terrain test data from various customer installations has shown very little impact on system performance as a result of seasonal environmental changes. This technology also has real-time diagnostics for temperature and relative humidity used to make zero-drift corrections to maintain optimum accuracy. Therefore, data collection can occur over a relatively short time span.

Commenter (0780-LongPath) indicates that state-of-the-art facilities now exist that can provide third-party blinded testing of emissions monitoring methods and technologies<sup>516</sup> with protocols

---

<sup>515</sup> 87 FR 74741-74745 (December 6, 2022).

<sup>516</sup> <https://energy.colostate.edu/metec/>.

developed under collaborative and transparent processes involving multiple stakeholders (academics, industry, technology experts).<sup>517</sup> The METEC test facility and ADED protocols were developed with the support of federal funding, signaling the federal government's own investment and support of such methods for validating monitoring technologies.

The commenter (0780-LongPath) states all alternative monitoring technologies (survey and continuous approaches) should be required to perform third-party blind testing at a facility like METEC and under a protocol like ADED. For conditions that cannot be adequately simulated at METEC (like high humidity), but that are known to impact sensor quality, supplemental third-party blind testing must be demonstrated.

The commenter (0780-LongPath) believes the fugitive emissions monitoring plan submitted for a given monitoring technology would need to require response function matrices showing sensitivity to such conditions as wind speed, wind direction and variability, temperature, humidity and groundcover (*e.g.*, snow). This matrix of sensitivities (which, collectively, are the operating envelope) could be generated seasonally for each region or basin using average conditions for the monitoring area and time period.

Response I-7-220: See discussion in section IV.B of the December 2022 Supplemental Proposal for a discussion on advanced methane detection technologies, including alternative periodic screening and alternative continuous monitoring systems.<sup>518</sup> Please also see section X.B of the preamble to the final rule which details EPA's final standards related to the use of alternative periodic screening and alternative continuous monitoring systems for detection of fugitive emissions under the advanced methane detection technology program. The final rule specifies the elements the fugitive emissions monitoring plan must contain where alternative technologies will be used to demonstrate compliance and the elements required to be included in the request for ATM approval.

### ***7.3.8 Fenceline Monitoring***

Comment: Commenter (0809-Earthjustice) believes it is necessary to revise the emission standards to require fenceline monitoring as a control technology for oil and gas sources, as EPA has since required for petroleum refineries. In 2015, EPA determined there were developments in control technologies that required revisions to the MACT standards under CAA section 112(d), particularly to require monitoring and corrective action for benzene at the fenceline of source facilities to assure compliance with the standards and improve control of fugitive emissions.<sup>519</sup> Robust monitoring requirements, including fenceline air monitoring, are necessary to ensure continuous compliance with emissions standards, as required under the CAA.<sup>520</sup>

---

<sup>517</sup> Advancing Development of Emissions Detection: <https://energy.colostate.edu/metec/aded/>.

<sup>518</sup> 87 FR 74741-74745 (December 6, 2022).

<sup>519</sup> See Petroleum Refinery Sector Risk and Technology Review and New Source Performance Standards; Final Rule, 80 Fed. Reg. 75,178, 75,191 (Dec. 1, 2015).

<sup>520</sup> See 42 U.S.C. § 7412(d)(6); see also *id.* § 7602(k).

The commenter (0809-Earthjustice) notes EPA has proposed allowing two refineries in Corpus Christi, Texas, to use LDSN technology as an alternative means of emissions limitation.<sup>521</sup> EPA based this proposed decision on findings that LDSN allows leaks to be detected and repaired more quickly than EPA Method 21 and is more cost-effective, and that LDSN can detect leaks at emission levels below those detectable by OGI and other advanced leak detection technologies.<sup>522</sup> EPA should continue to consider the inclusion of LDSN technology as an LDAR compliance pathway in its NSPS and NESHAP rulemakings more broadly, provided the continuous monitoring is done rigorously and can be shown to achieve equivalent or greater emission reductions.

The commenter (0809-Earthjustice) states as EPA recently stated in support of the 2015 Petroleum Refinery Sector NESHAP rule's ("2015 Refinery Rule") fenceline monitoring provisions, periodic monitoring requirements— such as quarterly LDAR—will “often miss periodic emission events” that “can contribute significantly to a facility’s emissions.”<sup>523</sup> Fenceline monitoring better captures these periodic releases, resulting in more effective management of fugitive emissions from oil and gas facilities. Accordingly, EPA should include fenceline monitoring as an LDAR technology in the final NSPS for the control of VOC and methane emissions, as well as in its reconsideration of the 2012 NESHAP rule and new CAA section 112(d)(6) review for the control of air toxics.

The commenter (0809-Earthjustice) adds, due to recent developments, any new fenceline monitoring requirements should be even stronger than the 2015 Refinery Rule, namely with the inclusion of continuous monitoring. Neighboring communities need a real-time, continuous measure of pollution, and EPA must require oil and gas facilities to quickly fix violations. Since 2015, refineries have now implemented fenceline monitoring nationwide and are implementing plans using real-time technology in Los Angeles. The first national benzene reports have shown how essential fenceline monitoring is to assure compliance with emission standards and identify serious pollution problems and health threats.<sup>524</sup>

The commenter (0809-Earthjustice) states within the oil and gas sector, EPA has tested Methods 325A/B for monitoring VOCs near two oil and gas production well pads in Texas and Colorado with promising results as to the utility of Methods 325A/B for oil and gas sources.<sup>525</sup> EPA also recently required a natural gas processing plant in Pennsylvania to operate a continuous ambient

air monitoring system for VOC and HAP emissions,<sup>526</sup> and similarly required a compressor station in Ohio to operate a continuous ambient air monitoring system for VOC and reduced sulfur compounds,<sup>527</sup> further demonstrating the feasibility and utility of requiring fenceline monitoring more broadly across the oil and gas sector.

Response I-7-221: In response to the solicitation for comment on the development of a framework for continuous monitoring technologies in the November 2021 proposal, the EPA proposed a regulatory approach for alternative continuous monitoring systems in the December 2022 Supplemental Proposal that was akin to the fenceline monitoring work practice promulgated by the EPA in 2015 as part of the National Emissions Standards for Hazardous Air Pollutants (NESHAP) for the petroleum refinery sector (80 FR 75178; December 1, 2015). For details, please see discussion in section IV.B.2 of the December 2022 Supplemental Proposal.<sup>528</sup>

In the final rule, the EPA is preserving the continuing monitoring approach and associated work practice from the December 2022 Supplemental Proposal with some changes including specifying the requirements for operating continuous monitoring systems including using advanced methane monitoring technology to be approved by the EPA for this purpose. Please see section X.B.2 of the preamble to the final rule which details EPA's final standards related to the use of alternative continuous monitoring systems and section XI.B.2 of the preamble to the final rule for EPA's responses to significant comments received on this topic and changes made to the final rule.

### **7.3.9 Continuous Monitoring Cost**

Comment: Commenters (0588-Project Canary, 0756-Baker Hughes, 0759-LongPath *et al.*, 0780-LongPath, 0791-Airdar)) believe continuous monitoring systems can be implemented cost effectively.

The commenter (0588-Project Canary) provides tables comparing the cost-effective values used for OGI in Colorado Reg 7, the cost of a continuous monitoring system per well-site would have to greater than over \$340,000 (low bound) to \$3.8 million (upper bound) a year for it to not be as cost-effective. As continuous monitoring systems last multiple years, these values are significantly greater than what the cost of a continuous monitoring system would be. Additionally, when these costs are viewed in terms of commodity pricing, they appear even more affordable. While the costs can be high for low-producing wells, for most of the wells, the cost of adding three monitors and one anemometer per well site adds well under \$0.50 per barrel of oil equivalent (BOE), and as low as \$0.10/BOE at some well pads. The commenter states that this

---

<sup>526</sup> Consent Decree at 17-18, App. 8, United States v. MarkWest Liberty Midstream & Resources, LLC, No. 2:18-cv-00520-LPL (W.D. Pa. Apr. 24, 2018), ECF No. 2-1 [hereinafter MarkWest Consent Decree], <https://www.epa.gov/sites/default/files/2018-04/documents/markwest-cd.pdf>; MSI Trinity Consultants, Summary of Air Toxics and Meteorological Data from MarkWest's Harmon Creek Monitoring Stations, First Quarter 2020, at 1-1 (April 2020) (describing continuous monitoring of VOCs and air toxics), <https://foiaonline.gov/foiaonline/action/public/submissionDetails?trackingNumber=EPA-R3-2021-001431&type=Request> (record link entitled "Harmon Creek - 2020 1st Quarter - Fence Line Monitoring Data submitted").

<sup>527</sup> See MarkWest Consent Decree, *supra*, at 17, App. 7.

<sup>528</sup> 87 FR 74744-74745 (December 6, 2022).

adds less than one percent to commodity pricing overall and is generally considered cost-effective.

Commenter (0759-LongPath *et al.*) understands their solutions must be cost competitive before operators will adopt them at scale. As such, all providers regardless of the underlying technology (*e.g.*, tunable diode laser absorption spectroscopy (TDLAS), open-path laser, continuous OGI cameras and metal oxide sensors) have made meaningful strides to lower the cost of deployment by reducing the individual cost of each system deployed or increasing the number of sites covered per system. This is evidenced by the number and variety of continuous monitoring systems currently being piloted across industry. The cost competitiveness of continuous monitoring is further highlighted when taking into account the emission volumes. Because continuous monitoring leads to greater reductions in emissions through faster alerting and remediation, the cost of monitoring as a ratio of the volume of emissions reduced can be lower than intermittent technologies. In other words, for each ton of methane reduced, the cost per monitoring can be lower for continuous monitoring when compared to intermittent technologies.

Commenter (0780-LongPath) adds continuous monitoring is highly scalable. With modest capital investment, around 1000 LongPath sensors could provide cost-effective continuous monitoring for most of the Permian Basin of West Texas and Southeastern New Mexico. Already, LongPath is continuously monitoring more than 120,000 acres in the DJ, Anadarko, Delaware and Midland basins. Once LongPath's networked infrastructure is in place, any site in the area can be quickly and cost-effectively subscribed. This includes orphaned wells, which LongPath can monitor, quantify, and prioritize for plugging.

According to the commenter (0780-LongPath Technologies), continuous monitoring affords rapid repair, such that cumulative emissions to the atmosphere are tens to hundreds of times lower than survey approaches can provide. For example, a stuck dump was repaired in 2 days, resulting in a cumulative loss to the atmosphere of 300 Mcf. A bi-monthly or quarterly survey might not have discovered the leak for 2-3 months, which would have resulted in some 30-50 times higher cumulative emissions emitted to the atmosphere. The difference in gas lost between continuous monitoring and a theoretical quarterly survey would have been 13,500 Mcf, or roughly 10.4 t. At a market value of \$3.25/Mcf, a loss of 13,800 Mcf is roughly \$44,850 over 3 months. These losses dwarf the cost of the monitoring itself (and for many years) – a clear proof point that continuous monitoring is cost effective. Similarly, the social cost of methane (\$1,800/t) would equate to \$18,720 saved compared with quarterly LDAR.

Response I-7-222: The EPA acknowledges comments concerning the capabilities and cost of continuous monitoring technologies. However, the EPA does not find that continuous monitoring technology is the BSER for well sites because EPA does not have sufficient information to include this new but rapidly advancing technology in the BSER analysis; however, the EPA supports the use of continuous monitoring systems to detect fugitive emissions. The EPA is providing a pathway for owners and operators to utilize continuous monitoring technologies as part of the advanced methane detection technology provisions of the rule. Please see section X.B.2 of the preamble to the final rule which details EPA's final standards related to advanced methane detection technology.

Comment: Commenter (0791-Airdar) states continuous monitoring technologies that use sensors with a low detection limit are capable of putting an entire area under surveillance. This means that there is potential to develop more efficient and cost-effective emissions monitoring programs by combining fence line monitoring and LDAR programs. Continuous monitoring also ensures that resources are directed to the right problem, as demonstrated by the SAGD case study.<sup>529</sup>

Response I-7-223: EPA acknowledges the commenters support for the use of continuous monitoring. See discussion in section IV.B.2 of the December 2022 Supplemental Proposal for a discussion on alternative continuous monitoring systems.<sup>530</sup> Please also see section X.B.2 of the preamble to the final rule which details EPA's final standards related to the use of continuous monitoring systems for detection of fugitive emissions under the advanced methane detection technology program.

Comment: Commenter (0588-Project Canary) argues although continuous monitoring is a relatively new technology, it has already seen widespread deployment across multiple sectors. It is increasingly used in the exploration, production, and midstream segments of the oil and natural gas industry. The advent of technology solutions such as continuous monitoring has enabled cost-effective technology deployment and data acquisition. In turn, this has allowed operators to improve their operations. Continuous monitoring enables operators to deploy emissions management programs, under which operations are continuously monitored, leaks are more frequently detected, and emissions are more reliably measured.

The commenter (0588-Project Canary) notes 2021 saw a dramatic increase in continuous monitoring technology deployment. According to Darcy Partners, 71 percent of the exploration and production companies that they work with had already implemented or were planning to implement responsibly sourced natural gas (RSG) within two years.<sup>531</sup> According to the commenter, key drivers include encouragement by investors, competitive environmental, social, and governance (ESG) pressures to understand and improve operations, and the ability to employ continuous monitoring to produce differentiated products that can be sold into differentiated, certified, or responsibly sourced gas markets.

The commenter (0588-Project Canary) states that various non-governmental organizations (NGOs) have made statements around continuous monitoring systems for the oil and natural gas industry. For example, Jeremy Nichols, climate, and energy program director for the environmental group WildEarth Guardians, said continuous monitoring of emissions instead of just periodic inspections can provide an indication of what is happening at well sites. The sites typically include multiple wells, tanks, and other equipment.<sup>532</sup> Dan Grossman, senior director of

<sup>532</sup> Judith Kohler, Colorado oil and gas company aims to produce "cleanest molecules" anywhere, Denver Post (May 13, 2021), available at <https://www.denverpost.com/2021/05/13/xcel-energy-crestone-peak-cleaner-gas/>.

regulatory and legislative affairs at the EDF, stated that initiatives that include continuous monitoring systems are positive and might be a good model.<sup>533</sup>

The commenter (0588-Project Canary) states continuous monitoring has enabled the development of domestic and international certified RSG markets. In 2021 alone, nearly 75 operators in the US have committed to devoting resources to RSG markets. It is estimated that between 20 and 25 percent of the US natural gas market will be dedicated to RSG markets, meeting the needs of utilities and liquefied natural gas (LNG) buyers.<sup>534</sup> Continuous monitoring allow operators to demonstrate low emissions production and RSG markets are seeking low methane emissions intensity certificates.<sup>535</sup> Through partnerships with operators, the commenter has seen production-related methane emission reductions of an estimated 80 percent. This type of emissions measurement and performance will enable the industry to meet low or net-zero commitments across the energy sector.

The commenter (0588-Project Canary) notes, Kevin Book, a managing director at ClearView Energy Partners LLC, has observed that RSG is key for parts of the world where efforts are underway to maximize clean, affordable energy output.<sup>536</sup> EQT, the largest U.S. natural gas producer, is working to certify their natural gas from their Appalachian natural gas production.<sup>537</sup> The commenter's (0588-Project Canary) standards for RSG include and build upon the standards set forth by ONE Future, the American Gas Association, NORSOK, ISO, and the API.<sup>538</sup> Continuous monitoring systems allow for American oil and natural gas companies to show how clean our production is – especially relative to other locations around the world.

Response I-7-224: EPA acknowledges the commenters support for the use of continuous monitoring. See discussion in section IV.B.2 of the December 2022 Supplemental Proposal for a discussion on alternative continuous monitoring systems.<sup>539</sup> Please also see section X.B.2 of the preamble to the final rule which details EPA's final standards related to the use of continuous monitoring systems for detection of fugitive emissions under the advanced methane detection technology program.

### ***7.3.10 Other Programs (Colorado and Alberta, Canada)***

Comment: Commenter (0759-LongPath *et al.*) states the AER is a leader in oil and gas methane regulation and has implemented progressive policies to enable the adoption of emerging LDAR technologies. Over the past two years, the AER has approved numerous alternative LDAR schemes that include aerial LiDAR, truck-mounted sensors, and innovative work practices using

<sup>534</sup> Project Canary, What is RSG? A Definitive Guide to Differentiating Gas and the Certification Process (Nov. 19, 2021), available at <https://www.linkedin.com/pulse/what-rsg-definitive-guide-differentiating-gas-certification-/>.

<sup>535</sup> *Id.*

<sup>536</sup> Jamison Cocklin, RSG Seen as Key to Unlocking More Natural Gas Export Demand in Developed Countries, Natural Gas Intelligence (Nov. 24, 2021), available at <https://www.naturalgasintel.com/rsg-seen-as-key-to-unlocking-more-natural-gasexport-demand-in-developed-countries/>.

<sup>537</sup> *Id.*

<sup>538</sup> *Id.*

<sup>539</sup> 87 FR 74744-74745 (December 6, 2022).

handheld instruments. Most recently, the AER has approved at least two alternative LDAR pilot programs based on continuous measurement. Together, these two programs encompass dozens of production facilities across Alberta. Modeling of these programs suggest that they will reduce fugitive methane emissions by more than the conventional AER program that requires annual or triannual OGI. Notices of the approvals are available.<sup>540,541</sup>

Commenter (0759-LongPath *et al.*) states Colorado's Regulation 7 Pre-Production Monitoring rule is the first state regulation to incorporate continuous monitoring into its programs. This was driven by Senate Bill 181 which had a requirement for continuous methane and VOC monitoring in response to public health concerns. The rule is non-prescriptive on the sensor type, sensor placement, and response requirements, and asks producers to submit a monitoring plan detailing their chosen technology, sensor siting, calibration protocols, and validation. Rather than ask producers to respond to every alert detected with a handheld OGI inspection, operators set three levels of alerts, each of which necessitates a different response, and allows for operators to check but not dispatch teams to routine emissions generated as part of normal operators, such as a compressor actuating. Alert levels and operator response are spelled out in each operator's standard operating procedure, detailed as part of the monitoring plan. At the lowest level of alert, operators could review SCADA data; at a secondary alert, operators could decide to review with an internal team; and at the highest level of alert, operators could decide to dispatch a team within the hour. All responses must be logged and submitted to the state as part of monthly reporting. In addition to the state-level continuous monitoring program, continuous monitoring systems are also being adopted by local governments, such as cities and counties including Broomfield, Aurora, Erie, Weld County, and Dacono.

Commenter (0588-Project Canary) similarly states that the implementation of Colorado Regulation 7 allows for the use of continuous monitoring. Under Colorado Regulation 7, the frequencies of OGI inspections decreases over time, from an initial frequency of once every six months. The idea underlying this policy is that continuous monitoring data can be compared to the OGI data for leaks found. There will be times when OGI inspection is not being conducted and the continuous monitor detects an emission. These events would be categorized as upside to the continuous monitoring program and leak rates would be shown to be greatly reduced due to the continuous nature of monitoring. As confidence in the continuous monitoring system grows, routine LDAR inspection frequencies could be lessened and OGI would be used more for pinpointing the leak.

Commenter (0588-Project Canary) states local governments value the importance of continuous monitoring systems and have adopted and implemented requirements in efforts to inform their communities. For example, Broomfield, Colorado has implemented continuous monitoring and

---

<sup>540</sup> <https://www.newswire.ca/news-releases/qube-technologies-and-ember-resources-receive-regulatory-approval-for-fixedmethane-sensor-monitoring-815430339.html>.

<sup>541</sup> <https://www.qubeiot.com/resources-news/blog-post-title-one-pmm28-tgrsf-jslgd>.

installed six monitoring stations.<sup>542</sup> Also, Aurora, Colorado reached an operator agreement with ConocoPhillips for the use of continuous monitoring for the life of their well.<sup>543</sup>

Response I-7-225: EPA acknowledges the commenter's information related to alternatives to traditional fugitive emissions monitoring and repair programs. See discussion in section IV.B.2 of the December 2022 Supplemental Proposal for a discussion on alternative continuous monitoring systems.<sup>544</sup> Please also see section X.B.2 of the preamble to the final rule which details EPA's final standards related to the use of continuous monitoring systems for detection of fugitive emissions under the advanced methane detection technology program.

Comment: Commenters (0776-CDPHE, 0844-EDF *et al.*, 1267-CA AG *et al.*) state Colorado's regulatory approach to leak detection and AIMM inspection of well production facilities is multi-layered. First, as of a December 2021 program update, all new well production facilities must conduct monthly AIMM inspections unless they are constructed and operated with specified design alternatives.<sup>545</sup> Existing well production facilities must conduct inspections at a frequency that depends on the actual, uncontrolled VOC emissions from a storage tank.<sup>546</sup> Frequencies range from annual, for the smallest sites, to monthly for the largest sites and many sites in disproportionately impacted communities.<sup>547</sup>

The commenter (0775-CDPHE) states after Colorado updated the AIMM provisions of its LDAR rules in 2017, Colorado requested that a representative from EPA Region 8 participate as a member of Colorado's AIMM Team to evaluate alternative LDAR technologies and programs seeking approval under Colorado's rules. Since then, an EPA Region 8 representative has been involved in the review of all alternative AIMM applications that have been submitted to Colorado and has acted as a liaison to other EPA offices, including headquarters and Office of Air Quality Planning and Standards (OAQPS), on various matters pertaining to such applications and the alternative LDAR technologies/programs. Colorado has also provided significant feedback to EPA regarding the AMEL as it relates to alternative LDAR technologies and programs for oil and natural gas production, including the current comments being provided here for purposes of EPA's updated proposal.

Response I-7-226: EPA acknowledges information commenters provided that is related to alternatives to traditional fugitive emissions monitoring and repair programs. See discussion in section IV.B.2 of the December 2022 Supplemental Proposal for a discussion on alternative continuous monitoring systems.<sup>548</sup> Please also see section X.B.2 of the preamble to the final rule

which details EPA's final standards related to the use of continuous monitoring systems for detection of fugitive emissions under the advanced methane detection technology program.

Comment: Commenter (0846-Arolytics Inc.) states in only 2 years, Alberta has granted 9 approvals for Alternative LDAR programs that allow for variance in leak detection methodologies, and site visit frequencies. Flexibility is extremely high, though burden of proof is high and rules very specific. To date, many of the largest producers/operators in Canada have received approvals and are now operating innovative Alternative LDAR programs in Alberta. One of the approvals was also granted to a multi-producer consortium. Approvals have also been granted to small/midsize private companies. Unlike Colorado, the AER does NOT approve individual alternative detection technologies. The AER approves only alternative Fugitive Emission Management programs, which may include alternative detection technologies, and or variation in the required visit frequencies.

Commenter (0846-Arolytics Inc.) argues the outcome is well defined, in that any proposal must provide an equivalent level of emissions reduction to that of the default plan. Alberta sets out a clear process for applications, approval, and management of Alternative Programs. Most of the approved plans to date represent a collaboration between the producer/operator and several technology vendors. Normally some company-specific data is used in the formulating the design and in preparing the application, as well as some technology-specific thresholds. Many producers and operators apply for variances in timing and frequency of surveys concomitant with the capability of the detection technology they use, and the conditions expect at the use location. The approval is very much focused on implementation, and the Alternative Plan replaces the regulatory default plan for the company assets in question. The producer/operator must submit progress reports that compare methane reductions achieved vs. proposed.

Commenter (0846-Arolytics Inc.) adds by this mechanism the regulator will learn a lot about alternative technologies and programs. In Alberta, an Alternative Plan normally represents the lowest cost pathway to meet the emission reduction target, as guided by a model. The lowest cost pathway is normally modelled using a scenario model that incorporates cost, detection technology, leak likelihood, *etc.* Several models are available. The models show that lowest cost / most effective and efficient pathway differs for each producer/operator depending on asset type, geographic location. The Alberta regulator has offered several lessons from its early experience (from the regulator's website<sup>549</sup>).

Response I-7-227: EPA acknowledges the commenter's information related to alternatives to traditional fugitive emissions monitoring and repair programs. See discussion in section IV.B of the December 2022 Supplemental Proposal for a discussion on advanced methane detection technologies.<sup>550</sup> Please also see section X.B of the preamble to the final rule which details EPA's final standards related to the use of alternative technologies for detection of fugitive emissions under the advanced methane detection technology program.

## 7.4 Use of Information From Communities and Others

### 7.4.1 General Comments

#### 7.4.1.1 Community Monitoring Program Support

Comment: Several commenters (0195-EEN, 0770-NPRC, 0780-LongPath, 0844-EDF *et al.*, 0949-Liveable Arlington, 1338-Lexington-CAN) request that EPA create a community emissions monitoring program to ensure community members can take action to protect their health and hold drilling accompanys accountable to reduce emissions.

Commenter (0195-EEN) suggests strengthening the proposed rule by developing a process for the incorporation of monitoring data from third parties. The expanded monitoring may result in a major public health benefit.

Commenter (0770-NPRC) believes EPA has an obligation to strengthen its November 2021 Proposal and advance rules that leave no loopholes nor future opportunities for methane pollution from oil and gas infrastructure. As one testifier at EPA's December public hearing noted, "We have learned that most oil and gas operators only respond to that which is required by rule or law." Northern Plains' experience interacting with oil and gas companies in Montana confirms this. The commenter urges EPA to determine a way to incorporate methane pollution monitoring results generated by community groups and other third parties into EPA's standards and prioritization process for fixing major leaks.

Commenter (0780-LongPath) emphasizes that there is no question that, the faster identification and repair of leaks and malfunctions can occur, the greater the benefits to communities disproportionately impacted by emissions, the industry's bottom line, and the global community impacted by climate change. Continuous monitoring affords this. According to the commenter, the benefits of continuous monitoring are many and impact many stakeholders: neighboring communities in oil and gas production areas, the environment and global communities grappling with a changing climate, and an industry that is working to reduce waste and cut emissions.

Commenters (0942-CleanEarth4Kids.org, 0937-Fort Berthoud POWER, 0947- ANHE-CO *et al.*, 1339-Waterway Advocates) suggest developing a community monitoring program for frontline communities that educates and certifies community members as monitors and requires immediate follow up of their complaints.

Response I-7-228: The EPA acknowledges supportive comments.

In the November 2021 proposal, the EPA solicited comment on the use of information collected by communities and others to address large emissions events, which the December 2022 Supplemental Proposal defined as "super-emitter emissions events." The EPA did not propose any standards in the November 2021 Proposal but did so in the December 2022 Supplemental Proposal. For details, please see discussion in section IV.C of the December 2022 Supplemental

Proposal.<sup>551</sup> Please also see section X.C of the preamble to the final rule which details EPA’s final standards related to the super emitter program.

Comment: The commenter (0844-EDF *et al.*) urges EPA to finalize a framework allowing third parties to detect and report emissions to EPA and in response to credible data, the operator would be required to fix the leak. The commenter believes EPA can set parameters to ensure reported data is accurate, ensure the program helps to empower communities to use different technologies and methods, and ensure technologies are used safely and properly. In addition, the commenter believes EPA should also make all reported emissions publicly available. This type of program will foster public trust and accountability, while increasing knowledge on leaks and helping to further reduce emissions.

The commenter (0844-EDF *et al.*) cites to multiple studies to show that super-emitters and abnormal process emissions are often not well-represented and national inventories often underrepresent emissions. This information is summarized in a later section.

Response I-7-229: The EPA acknowledges the commenter’s remarks regarding the need to finalize framework for detecting and reporting large emissions events.

In the November 2021 proposal, the EPA solicited comment on the use of information collected by communities and others to address large emissions events, which the December 2022 Supplemental Proposal defined as “super-emitter emissions events.” The EPA did not propose any standards in the November 2021 Proposal but did so in the December 2022 Supplemental Proposal. For details, please see discussion in section IV.C of the December 2022 Supplemental Proposal.<sup>552</sup> Please also see section X.C of the preamble to the final rule which details EPA’s final standards related to the super emitter program.

#### 7.4.1.2 Enforcement/Third-Party Monitoring Concerns

Comment: Commenter (0946-MOGA) requests that EPA outline their explicit intention, direction and limitations when encouraging community engagement related to oil and gas production related facilities. The commenter notes that their primary concern is safety. Michigan’s oil and gas industry employees are arguably the most highly skilled, trained, insured and safety-oriented workforce in the United States. The commenter urges the EPA to clearly define their proposed “community engagement” intent and provide specific restrictions and associated guidelines to prevent injuries.

Response I-7-230: The EPA acknowledges the commenter’s concerns around safety and community engagement as it relates to the super emitter program.

The EPA proposed specific requirements for the super-emitter program in the December 2022 Supplemental Proposal. For details, please see discussion in section IV.C of the December 2022 Supplemental Proposal.<sup>553</sup> The proposal included provisions stipulating the qualifications and

<sup>551</sup> 87 FR 74746-74755 (December 6, 2022).

<sup>552</sup> 87 FR 74746-74755 (December 6, 2022).

<sup>553</sup> 87 FR 74746-74755 (December 6, 2022).

requirements for notification of super-emitter emissions events by regulatory authorities and qualified third-party notifiers. To address concerns regarding community engagement or the expertise of the third party identifying the super-emitter event, the EPA proposed in December 2022 that any third party interested in identifying and notifying owners and operators of super-emitter emissions events must be preapproved by the Agency for the notification to be valid. The EPA is finalizing this requirement. Please also see section X.C of the preamble to the final rule which details EPA's final standards related to the super emitter program.

Comment: Commenter (0946-MOGA) expresses concern with how community data will be collected, the accuracy of the collected data and how the data will be used. The commenter believes that standards proposed in Appendix K to the proposed NSPS OOOOa and future NSPS OOOOb and EG OOOOc should be consistent and equal for both oil and gas small business and communities. The commenter requests that EPA very clearly determine and define the proposed "expansion of leak detection programs" to ensure consistent and repeatable results across the various platforms and data collection techniques used to collect data. The commenter also requests clarification in the proposed regulations with regards to how community-collected data will be validated for accuracy and how local regulatory agencies will use the data.

Response I-7-231: The EPA understands the commenter's concerns related to collection and use of collected data under the super emitter program.

The EPA proposed specific requirements for the super-emitter response program in the December 2022 Supplemental Proposal. For details, please see discussion in section IV.C of the December 2022 Supplemental Proposal.<sup>554</sup> Please see section X.C of the preamble to the final rule which details EPA's final standards related to third-party notifier certification, which includes requirements for detailing the procedures and processes to ensure the data collected is in compliance with the requirements of the rule.

Comment: Commenter (0831-AXPC) states that, while they support the public being able to participate in development of their communities and believe that they should be provided relevant information on what is going on in their communities, they have significant concerns related to what has been generally called "citizen science" – where members of the public are deputized to act as if they are employees of EPA. The commenter notes that it is difficult for them to comment on a mere concept without something more fleshed out and they state that they will provide additional information if and when EPA proposes regulatory text.

The commenter (0831-AXPC) states that the EPA seeks comment on how to allow for members of the public to use technology to search for super-emitters, but also potentially any types of emissions.<sup>555</sup> EPA and industry professionals are trained in how to operate, inspect, and monitor oil and natural gas sites without causing danger to themselves or others. The commenter contends that it is unclear to them why these requirements are being considered in the first place. According to the commenter, this provision appears to be duplicative of EPA's current system which allows members of the public to submit potential environmental violations.<sup>556</sup> They note

---

<sup>554</sup> 87 FR 74746-74755 (December 6, 2022).

<sup>555</sup> 86 FR 63177.

<sup>556</sup> <https://echo.epa.gov/report-environmental-violations>.

that the EPA does not cite any information that this system is lacking or not capable of meeting the purpose for which it was established. To the extent that members of the public believe that there are not enough resources being allocated to processing allegations of environmental violations, the commenter recommends that additional resources be provided to support that issue before considering deputizing members of the general public.

First, the commenter (0831-AXPC) asserts that there are potential safety concerns associated with members of the public accessing sites without proper notice, personal protection equipment (PPE), and training. For example some sites can contain hydrogen sulfide (H<sub>2</sub>S), a gas that could result in series health issues for members of the public without proper protection. Second, that suggest that well sites located on private property and providing this authority could encourage members of the public to trespass onto private property and to avoid safety signs and considerations. The commenter states that this could result in members of the public hurting themselves or damaging equipment that could result in putting workers in danger. They add that there is also the question of who would be liable for the safety for the members of the public who illegally trespass on the property or for any damage that they may cause.

Third, the commenter (0831-AXPC) notes that other members of the public may be confused or misled by claims of significant unauthorized emissions from well sites by citizens. As members of the public are not aware of permitted activities or where exactly a source of emissions may stem from, the commenter is concerned that they could unintentionally raise alarm to other members of the public unnecessarily.

Fourth, the commenter (0831-AXPC) suggests that, as citizens are not necessarily aware of activities that are permitted or all other potential sources of emissions around the wellsite, there is a high likelihood that this will result in EPA and companies having to chase ghost emissions – *i.e.*, those emissions that are not violations of any permit as they are either permitted activities or not from the wellsite – thus preventing EPA from enforcing actual environmental violations and causing unnecessary burden and harm on companies.

Fifth, the commenter (0831-AXPC) states that if information is gathered from members of the public, there is no clear chain of custody on the information to ensure that it is valid and has not been modified. As this information may be used in enforcement proceedings that could result in significant fines, the commenter notes that it is unclear how EPA and the owners of the site can ensure that the information is valid.

Sixth, the commenter (0831-AXPC) recommends that, while AXPC has raised concerns with the requirements around Appendix K above, if EPA wishes to move forward with this action, members of the public should be held to the same training and accuracy requirements as operators, as it does not make sense that EPA should not require the same standards for citizen inspections as it does for industry compliance.

Finally, the commenter (0831-AXPC) is generally concerned about the location of such a significant potential policy change. According to the commenter, this type of action has broad implications to all other sectors regulated under the CAA, as well as potentially to other environmental laws under EPA's purview. Due to the broad implications and potential

applications, the commenter recommends that if EPA believes that this is appropriate to move forward with, that EPA do this through a different rulemaking activity such that all members of the public, included all other potentially regulated industries, are able to comment and consider the potential impacts of this action.

Commenter (0941-350 Silicon Valley) states that the forthcoming supplemental rule must include requirements for the EPA to offer training to frontline communities in how to monitor and report local pollution. The commenter indicates that their participation in fenceline monitoring or sensor equipped vehicle monitoring could assist in pinpointing super emitting sources in problematic areas identified by satellites. The commenter adds that EPA should be required to log community complaints about air quality as well as excessive bright lights and noise from nighttime flaring. The commenter notes that instruction in how to generate data that is both reliable and acceptable is necessary. The commenter asserts that if valid information is presented by communities, nearby facilities must be required to investigate and mitigate if they are not complying with legal standards.

Commenter (0828-UCS) states that to further ensure that impacted communities are afforded a voice in the implementation of this rule, EPA must provide pathways for actionable responses to community-based data collection and leak identification efforts.

Commenter (0833-UTE EPD) believes that empowering communities impacted by oil and natural gas development is important. The commenter recognizes that there are opportunities to provide communities with resources, training, and support to use sensor technology, and monitors to use as a screening tool for potential leaks or malfunctions, and in addition, hiring technically trained support. For example, the commenter provides that the supplemental proposal could require sources to provide resources to locate passive benzene (similar to those used around petroleum refineries) monitors in neighboring communities. These monitors can indicate the presence of emissions and OGI monitoring then can be used to identify leaks and institute repairs. The commenter also suggests that community organizations can collect and replace monitors, and ship to the lab for processing. They add that the community can then notify the implementing authority and the source that emissions are present. According to the commenter, by allowing the community to be involved there would be more trust in the data and confidence that issues are being identified and addressed.

Commenter (0833-UTE EPD) also believes that an anonymous emissions/malfunction hotline can be made available to workers and community members to report issues when they occur. The commenter suggests that EPA require a root cause analysis and corrective actions when a community member or organization discovers and reports a large emission event. The commenter recommends that this include, at a minimum, a response from the source's owner/operator documenting what investigation was performed, what was discovered, and what corrective actions were taken.

Commenter (0833-UTE EPD) also advocates for an interactive emissions mapping tool for community members to understand the location and potential emissions from the oil and natural gas industry subject to the rules, as well as the location for abandoned and orphaned wells. The commenter recommends that this interactive tool be flexible enough for communities

to add potential new leases and permits for new or modified sources so they can effectively engage in future activities. They add that this tool should also include up-to-date information on the sources' owner/operator, so that the community members can quickly notify the facility of large emission events.

Response I-7-232: The EPA acknowledges supportive comments, concerns around safety and community engagement, and remarks regarding the need to finalize framework for detecting and reporting large emissions events.

In the November 2021 proposal, the EPA solicited comment on the use of information collected by communities and others to address large emissions events, which the December 2022 Supplemental Proposal defined as “super-emitter emissions events.” The EPA did not propose any standards in the November 2021 Proposal but did so in the December 2022 Supplemental Proposal. For details, please see discussion in section IV.C of the December 2022 Supplemental Proposal.<sup>557</sup> Please see section X.C of the preamble to the final rule which details EPA’s final standards related to the super emitter program, which describes the qualifications entities must meet to apply to become approved third-party notifier of super-emitter events.

Comment: Commenter (0924-U.S. Small Business Administration (SBA)) state small businesses have expressed significant concern that these third parties will be held to a less stringent standard for operation of the technology and interpretation of the results. They fear that giving third parties the ability to trigger such actions without quality checks and minimum competency standards will lead to a cycle of unnecessary and duplicative monitoring and remediation exercises. Any third-party use of a monitoring technology that can trigger regulatory action should meet the same standards to which the regulated entities are held, including EPA’s proposed Appendix K.

Response I-7-233: The EPA proposed specific requirements for the super-emitter response program in the December 2022 Supplemental Proposal. For details, please see discussion in section IV.C of the December 2022 Supplemental Proposal.<sup>558</sup> Please see section X.C of the preamble to the final rule which details EPA’s final standards related to becoming a certified third-party notifier, as well as rigorous requirements for detailing the procedures and processes to ensure the data collected is in compliance with the requirements of the rule when submitting notifications of super-emitter events.

Comment: Commenter (1422-Senator Marshall *et al.*) suggests that EPA’s desire to implement a community monitoring program to detect large emission events is troubling. The commenter requests that this regulatory approach be abandoned; however, if EPA is insistent on pursuing this course of action, they state it is vital that the program be carefully crafted to ensure protections from overzealous activists seeking to induce financial hardship on producers with false reports. The commenter notes that the proposed rule states that EPA “generally envision[s] a program for finding large emission events that consists of a requirement that, if emissions are detected above a defined threshold by a community, a Federal or State agency, or any other third party, the owner or operator would be required to investigate the event, do a root cause analysis,

---

<sup>557</sup> 87 FR 74746-74755 (December 6, 2022).

<sup>558</sup> 87 FR 74746-74755 (December 6, 2022).

and take appropriate action to mitigate the emissions, and maintain records and report on such events.” The commenter recommends that, if EPA intends to force expensive compliance costs on producers based on the analysis of “any other third party,” it is vital to set very high standards for what constitutes credible data. They state that there must be training requirements for submitting parties, and producers need to be given adequate time to complete any required compliance actions after notification.

Response I-7-234: The EPA proposed specific requirements for the super-emitter response program in the December 2022 Supplemental Proposal. For details, please see discussion in section IV.C of the December 2022 Supplemental Proposal.<sup>559</sup> Please see section X.C of the preamble to the final rule which details EPA’s final standards related to third-party notifier certification, which includes requirements for detailing the procedures and processes to ensure the data collected is in compliance with the requirements of the rule when submitting notifications of super-emitter events.

Comment: Commenter (0824-WDEQ) has significant concerns regarding EPA’s suggested community program, which creates a number of quandaries for state agencies regarding data submissions, emissions inventories, and monitoring programs, and regulatory actions that may need to be undertaken by the commenter. The commenter states that it is not clear from EPA’s November 2021 Proposal whether the legal basis for such an approach falls within the bounds of NSPS.

The commenter (0824-WDEQ) questions the fundamental basis for creating this additional regulatory requirement. In accordance with Wyoming’s Environmental Quality Act<sup>560</sup>, the commenter has a well-established, well-functioning complaint process through which third parties and members of the general public can report any pollutant emission event of concern - regardless of whether it is a large scale or small scale event -and the agency’s compliance program promptly handles inspections and correspondence with the operator to investigate the situation, and if an issue is discovered, to address it. The requirement in the proposed rule that data gathered by third parties triggers and mandates specific state processes only convolutes the process and diverts the commenter’s resources from providing a more-immediate follow-up to correct the issue, as well as from undertaking other important work.

Commenter (0824-WDEQ) reports that the current state of methane and VOC ambient detection technology is not accurate enough to quantify a leak without extensive modeling to link the ambient detection to a specific leak. There would need to be extensive technical work performed by operators or the state agency to quantify a leak from a detection at a community monitor. This work would include methane background, other methane sources in the area, meteorological monitoring, and pollution transport modeling to determine if a leak meets a threshold. The commenter raises concerns that the threshold could be lowered to a degree where the consideration of all third-party data could obfuscate and even invalidate the well-established ambient air quality monitoring practices and protocols that state agencies must follow under federal law (e.g., 40 CFR part 58). Furthermore, a lowered threshold could result in an unending labyrinth of data. Also, setting a lower threshold for the collection and submission of third-party

---

<sup>559</sup> 87 FR 74746-74755 (December 6, 2022).

<sup>560</sup> W.S. §§ 35-11-101 et seq.

data could result in a scenario where the goalposts are continuously moved in the future. This would result in additional strains on state agency resources, as well as creating further ambiguity regarding which data is most credible.

As an alternative, the commenter (0824-WDEQ) encourages EPA to engage with its state co-regulators to examine existing state frameworks for addressing citizen concerns. State, local, and Tribal air agencies are more accessible to, familiar with, and responsive to their citizens' concerns because they are located in and accountable to those communities.

Commenter (0938-TXOGA) believes that community involvement in large emission events as proposed is too vague and ill-defined to allow for meaningful comment. EPA should treat the November 2021 Proposal as an Advance Notice of Proposed Rulemaking and issue a future proposed rule that includes regulatory language, detailed preamble explanation of the basis for the proposal, and the other elements required under CAA section 307(d)(3) for regulatory proposals to establish a standard of performance under CAA section 111.<sup>561</sup>

The commenter (0938-TXOGA) adds that issues to be addressed in any such proposal would include how these measures would be implemented (*e.g.*, EPA-approved technologies and methods) and the procedural obligations and steps involved (including quality assurance and data validation), on what basis EPA has the authority to expand upon section 304 of the CAA with respect to citizen enforcement by giving direct rights to non-regulators to demand information from facilities, and how EPA would cabin potential abuse of the provision. As the Agency acknowledges,

[I]n order to make this approach viable, the EPA would need to specify what actions an owner or operator must take when notified of a large emission event, including deadlines for taking such actions. These elements could include the specific steps the company would take to investigate the notification and mitigate the event, such as verifying the location of the emissions, conducting ground investigations to identify the specific emission source, conducting a root cause analysis, performing corrective action within a specific timeframe to mitigate the emissions, and preventing ongoing and future chronic or intermittent large emissions from that source.<sup>562</sup>

Commenter (0938-TXOGA) argues these items are not insignificant details and EPA would not be able to issue a final rule based on the current solicitation of comment. Indeed, these are program elements with potentially significant consequences for regulated entities, depending upon how they take shape.

Commenter (0938-TXOGA) states EPA could not (and should not) promulgate a regulation that would require owners or operators to respond to spurious claims that “large emissions events” have occurred at a particular facility. The commenter argues EPA would also need to reconcile its approach with the structure established by Congress under the CAA with respect to the roles of non-regulators, specifically, through participation in the rulemaking process and bringing citizen suits under CAA section 304. The procedural protections and obligations of CAA section

---

<sup>561</sup> See CAA § 307(d)(3), 42 U.S.C. § 7607(d).

<sup>562</sup> 86 Fed. Reg. at 63,177.

304 are important elements of the statute that are not appropriate to override with separate citizen enforcement provisions.

The commenter (0938-TXOGA) adds, to the extent EPA is suggesting that citizens could conduct on-site inspections, the CAA does not contemplate citizen inspections akin to those authorized for governmental authorities under section 113, 114, and Title V.<sup>563</sup> Had Congress intended such an approach, it would be explicitly authorized in the statute.<sup>564</sup> The approach could also have unintended adverse impacts that are important to consider. For example, this approach could implicate property rights of site owners and lessees, the safety of untrained community members who may seek to access property in an unsafe manner, and other issues with attempting to “deputize” citizen inspectors.

The commenter (0938-TXOGA) goes further, to the extent that EPA intends to finalize a regulatory provision that would trigger source obligations based upon emissions detected through third-party monitoring, such monitoring must be held to a high and rigorous standard, similar to the monitoring standards proposed for the regulated industry. EPA’s conceptual proposal to create regulatory obligations based upon third-party monitoring is unprecedented and needs to be carefully considered in light of: (1) the scope of EPA’s authority under CAA section 114 to establish monitoring requirements; (2) the scope of EPA’s CAA section 111 authority to establish standards of performance; and (3) constitutional due process considerations that require fair notice of the conduct that can be penalized under an agency’s regulatory program.

Response I-7-235: The EPA proposed specific requirements for the super-emitter response program in the December 2022 Supplemental Proposal. For details, please see discussion in section IV.C of the December 2022 Supplemental Proposal.<sup>565</sup> The EPA is finalizing a revised structure of the super emitter program targeted to identify large emission events. The final requirements ensure that the program operates with a high degree of accuracy, integrity, and transparency, necessary for addressing super-emitter events. The final rule includes requirements related to third-party notifier certification, which contains specific requirements related to procedures and processes to ensure the data collected is in compliance with the requirements of the rule when submitting notifications of super-emitter events. For details, please see section X.C of the preamble to the final rule.

Comment: Commenter (0738-Exxon) notes that while voluntary efforts by individual companies are important, they only capture a fraction of industry’s overall emissions. Full industry participation is required to maximize the benefits to society. Accordingly, based on their experience and expertise, the commenter supports EPA’s November 2021 Proposal to focus attention and effort on the larger emitting sources, and the related proposal to establish volume-based baselines and exemptions rather than production-based exemptions.

The commenter (0738-Exxon) cautions against EPA improperly delegating its enforcement authorities to third parties. Such reporting by third parties should be provided directly to the Agency for evaluation and communication to companies as warranted before any obligations are

---

<sup>563</sup> See CAA § 304, 42 U.S.C. § 7604.

<sup>564</sup> See *Util. Air Regulatory Grp. v. EPA*, 573 U.S. 302 (2014).

<sup>565</sup> 87 FR 74746-74755 (December 6, 2022).

imposed. Further, the commenter believes that third parties who submit such reports to the Agency must take on some responsibility to ensure sufficient rigor of the data, in the commenter's opinion. The commenter recommends that EPA define approved methodologies, establish quality assurance/quality control standards, and delineate sensible thresholds. Both the Agency and companies should focus their efforts on regulatory enforcement and compliance under the new rules, rather than on potentially unreliable third-party observations.

Response I-7-236: The EPA proposed specific requirements for the super-emitter response program in the December 2022 Supplemental Proposal. For details, please see discussion in section IV.C of the December 2022 Supplemental Proposal.<sup>566</sup> Please see section X.C of the preamble to the final rule which details EPA's final standards related to third-party notifier certification, which includes rigorous requirements for detailing the procedures and processes to ensure the data collected is in compliance with the requirements of the rule when submitting notifications of super-emitter events.

Comment: Commenter (0727-OSEE/ODEQ) asked if EPA is proposing that a separate, unpermitted emission limit apply to facilities, which communities should use as a benchmark for regulatory action. This aspect of the November 2021 Proposal raises concerns and questions, especially considering the technical complexity of identifying and characterizing emissions, as discussed above. For these reasons, the commenter emphasizes that community involvement in finding large emission events would best work in partnership with the delegated regulatory authority.

Response I-7-237: The EPA proposed specific requirements for the super-emitter response program in the December 2022 Supplemental Proposal. For details, please see discussion in section IV.C of the December 2022 Supplemental Proposal.<sup>567</sup> The EPA is finalizing a revised structure of the super emitter program targeted to identify large emission events. The final requirements ensure that the program operates with a high degree of accuracy, integrity, and transparency, necessary for addressing super-emitter events. This includes the EPA having a central role in the program as far as verifying the completeness and accuracy of notifications from certified third-parties before sending them to the appropriate owner or operator. The EPA will also have a central role in approving monitoring technologies, certifying and de-certifying notifiers, requiring that third parties submit notifications in a limited timeframe, and obligating operators to subsequently respond in a timely manner. For details, please see section X.C of the preamble to the final rule.

#### ***7.4.2 Framework Recommendations***

Comment: Commenter (0788-350 Seattle) urges the EPA to strengthen its monitoring requirements. In a study of 37 wells on private property in the Permian Basin of Texas, it was found that seven had methane emissions of as much as 132 grams per hour (g/hr). Similarly, a 2016 study of inactive wells in Colorado, Wyoming, Ohio and Utah, found leaking methane

---

<sup>566</sup> 87 FR 74746-74755 (December 6, 2022).

<sup>567</sup> 87 FR 74746-74755 (December 6, 2022).

equivalent to burning more than 16 million barrels of oil, according to conservative government estimates.

Commenter (0788-350 Seattle) state, in general, EPA monitoring results underestimate methane quantities. The Gas Index, a 2020 report of 71 cities released by Climate Nexus and developed by Global Energy Monitor, using the newest methane science to estimate leakage from the wellhead to the home, indicates rates far higher than the government's estimates, some more than four times higher.

According to the commenter (0788-350 Seattle), technologies to improve measurement, reporting and verification (MRV) are now available, and their wider use would facilitate identification of "super-emitters." Individual facilities responsible for super emissions of methane frequently have malfunctioning equipment that can be repaired fairly quickly. Basins known for their super emissions of methane can typically be identified by their excessive flaring of natural gas.

The commenter (0788-350 Seattle) believes the November 2021 Proposal fails to address the lack of well-defined systems for measuring and mitigating the emissions of methane in the methane production and distribution system. The November 2021 Proposal points out the episodic nature of super-emitter sites. The commenter argues this implies that emissions monitoring needs to be continuously in place. The commenter states this must be rectified by requiring site specific measurement instrumentation operated by independent third parties to monitor methane emissions continuously with rapid response teams in place, manned by the responsible parties, to react to identified leaks. This would be complemented by data from satellites such as TROPOMI/Sentinel-2, GHGSat, PRISMA, and future MethaneSat and Carbon Mapper.

The commenter (0788-350 Seattle) asserts that emissions being monitored quarterly or semiannually are not acceptable when a large leak could occur at the beginning of a measurement cycle and not be detected or repaired for weeks or months. The "endangerment finding" by the CAA must be applied as an emergency basis for action, and not for continuing business as usual.

Response I-7-238: The EPA proposed specific requirements for the super-emitter response program in the December 2022 Supplemental Proposal. For details, please see discussion in section IV.C of the December 2022 Supplemental Proposal.<sup>568</sup> The EPA is finalizing a revised structure of the super emitter program targeted to identify large emission events. The final requirements ensure that the program operates with a high degree of accuracy, integrity, and transparency, necessary for addressing super-emitter events. This includes the EPA having a central role in the program as far as verifying the completeness and accuracy of notifications from certified third-parties before sending them to the appropriate owner or operator. The EPA will also have a central role in approving monitoring technologies, certifying and de-certifying notifiers, requiring that third parties submit notifications in a limited timeframe, and obligating

---

<sup>568</sup> 87 FR 74746-74755 (December 6, 2022).

operators to subsequently respond in a timely manner. For details, please see section X.C of the preamble to the final rule.

Comment: Commenter (0944-Kuva) argues that large emission events are much more likely to be found by continuous monitors like C-OGI cameras, then by quarterly or biannual OGI inspections or bi-monthly screening methods. The commenter strongly urges EPA not to require any additional reporting requirements for large emission events, because they would be a big disincentive for the installation of C-OGI cameras. Similar concerns apply for the adoption of bi-monthly screening technologies. A stringent disclosure requirement would cause oil and gas operators to use primarily OGI inspections, as they are less likely to find such large emission events and cause related negative publicity.

As an alternative approach, the commenter (0944-Kuva) proposes for EPA to implement an anonymous reporting program that provides much more detailed information about root-causes, emission duration, intermittency, total amounts, types of equipment, type of site, age of site, *etc.* then is currently required. The purpose of this program is to collect more data about the nature of intermittent emissions, the distribution of large emission events and the effectiveness of continuous monitoring technologies. Such information can subsequently be used for future BSER determinations.

Response I-7-239: The EPA proposed specific requirements for the super-emitter response program in the December 2022 Supplemental Proposal. For details, please see discussion in section IV.C of the December 2022 Supplemental Proposal.<sup>569</sup> The EPA is finalizing a revised structure of the super emitter program targeted to identify large emission events. The final requirements ensure that the program operates with a high degree of accuracy, integrity, and transparency, necessary for addressing super-emitter events. This includes the EPA having a central role in the program as far as verifying the completeness and accuracy of notifications from certified third-parties before sending them to the appropriate owner or operator. The EPA will also have a central role in approving monitoring technologies, certifying and de-certifying notifiers, requiring that third parties submit notifications in a limited timeframe, and obligating operators to subsequently respond in a timely manner. For details, please see section X.C of the preamble to the final rule.

### ***7.4.3 Super-Emitters/Large Emission Events***

#### ***7.4.3.1 Clarifications Needed***

Comment: Commenter (0727-OSEE/ODEQ) requests clarification on what constitutes a large emission event, *e.g.*, the commenter asked what would define a large emission event without knowing the facility's permit limitations.

Response I-7-240: The EPA proposed specific requirements for the super-emitter response program in the December 2022 Supplemental Proposal. For details, please see discussion in section IV.C of the December 2022 Supplemental Proposal.<sup>570</sup> Please also see section X.C of the

---

<sup>569</sup> 87 FR 74746-74755 (December 6, 2022).

<sup>570</sup> 87 FR 74746-74755 (December 6, 2022).

preamble to the final rule. A super-emitter event is defined as any emissions event that is located at an individual well site, centralized production facility, or compressor station and that is detected using remote detection methods and has quantified emission rate of 100 kg/hr of methane or greater.

Comment: The commenter (0824-WDEQ) notes the November 2021 Proposal's definition of "third party" is ambiguous and requires further clarification and, ultimately, significant refinement. Opening the submission of data to a boundless range of third parties creates the potential that state agencies like the commenter's will be flooded by data of dubious quality. Evaluating the data for quality and usability presents an unworkable strain upon the commenter's emissions inventory, monitoring, and compliance programs.

Response I-7-241: The EPA proposed specific requirements for the super-emitter response program in the December 2022 Supplemental Proposal, including the required qualifications for notification. For details, please see discussion in section IV.C of the December 2022 Supplemental Proposal.<sup>571</sup> For entities seeking to become third-party notifiers, the final rule stipulates specific requirements on how to apply to the Administrator for approval as a third-party notifier. Please see section X.C of the preamble to the final rule.

#### 7.4.3.2 Satellite Technology Available to Identify Super-Emitters

Comment: Commenter (0826-Kairos Aerospace) is in consensus with EPA that the majority of emissions originate from large emission sources. The commenter cites to several studies that similarly conclude that the majority of methane emissions are the result of emissions from a small number of sources.<sup>572,573,574, 575,576,577</sup> In the commenter's opinion, these findings demonstrate the importance of quickly capturing low probability, high-consequence events through basin-wide surveys. The commenter emphasizes that the Omara *et al.* 2018 study results are of particular note as the data collected by this study inform the commenter's model-based recommendations about the appropriate sensitivity and frequency of advanced leak screening technologies. Thus, the commenter believes EPA should prioritize the detection of super-emitters and allow for the use of aerial technology as an alternative performance standard.

Response I-7-242: The EPA proposed specific requirements for the super-emitter response program in the December 2022 Supplemental Proposal. For details, please see discussion in

---

<sup>571</sup> 87 FR 74746-74755 (December 6, 2022).

<sup>572</sup> For example, Chen *et al.* found that 50% of observed emissions from over 90% of New Mexico Permian Basin active wells came from large emission sources with persistence-averaged emission rates over 308 kg/hr.

<sup>573</sup> Chen *et al.* In Revision.

<sup>574</sup> The large meta-study by Omara *et al.* in 2018 found that five percent of sites accounted for 50% of cumulative emissions.

<sup>575</sup> Omara *et al.* 2018.

<sup>576</sup> Robertson *et al.* 2017 found that 72-83% of total measured emissions were from 20% of the well pads surveyed.

<sup>577</sup> EPA TSD citing Robertson, Anna M., Rachel Edie, Dustin Snare, Jeffrey Soltis, Robert A. Field, Matthew D. Burkhart, Clay S. Bell, Daniel Zimmerle, and Shame M. Murphy, "Variation in Methane Emission Rates from Well Pads in Four Oil and Gas Basins with Contrasting Production Volumes and Compositions," *Environmental Science & Technology*, 2017, 51, 15 8832-8840 (June 19, 2017). <https://pubs.acs.org/doi/pdf/10.1021/acs.est.7b00571>. (Hereinafter, "Robertson *et al.* 2017").

section IV.C of the December 2022 Supplemental Proposal.<sup>578</sup> The EPA is finalizing a revised structure of the super emitter program targeted to identify large emission events. The final requirements ensure that the program operates with a high degree of accuracy, integrity, and transparency, necessary for addressing super-emitter events. This includes the use of satellite detection of methane emissions, remote-sensing equipment on aircraft, and mobile monitoring platforms. For details, please see section X.C of the preamble to the final rule.

Comment: Commenter (0738-Exxon) believes that EPA’s focus on very large emissions via satellite detection is a sensible approach, but EPA should review and fully understand the shortcomings of current satellite detection technology. That being said, satellite monitoring is also an area of continuing improvement, as illustrated by the commenter’s recent announcement of working with Scepter, Inc. on satellite detection coupled with data fusion from ground-based and aerial information.<sup>579</sup>

Response I-7-243: The EPA proposed specific requirements for the super-emitter response program in the December 2022 Supplemental Proposal. For details, please see discussion in section IV.C of the December 2022 Supplemental Proposal.<sup>580</sup> The EPA is finalizing a revised structure of the super emitter program targeted to identify large emission events. The final requirements ensure that the program operates with a high degree of accuracy, integrity, and transparency, necessary for addressing super-emitter events. This includes the use of satellite detection of methane emissions, remote-sensing equipment on aircraft, and mobile monitoring platforms. For details, please see section X.C of the preamble to the final rule.

Comment: Commenters (0844-EDF *et al.*, 0932-GHGSat, Inc., 0935-Colorado Oil & Gas Association (COGA)) state that leak detection technology continues to improve. Emerging technologies offer several advantages over traditional OGI inspections, most importantly the ability to detect large emission events/super-emitters.

The commenter (0935-COGA) notes numerous research studies have documented the importance of finding and repairing large emission events. EPA compiled an extensive list of dozens of studies regarding the importance of large emission events in its TSD.<sup>581</sup> The commenter supports the comments submitted by Kairos Aerospace. Kairos’ comments include an analysis performed by Highwood showing that aerial surveys can achieve equivalent or greater emission reductions than OGI surveys by quickly detecting LEEs.

Response I-7-244: The EPA proposed specific requirements for the super-emitter response program in the December 2022 Supplemental Proposal. For details, please see discussion in section IV.C of the December 2022 Supplemental Proposal.<sup>582</sup> The EPA is finalizing a revised structure of the super emitter program targeted to identify large emission events. The final requirements ensure that the program operates with a high degree of accuracy, integrity, and

transparency, necessary for addressing super-emitter events. This includes the use of satellite detection of methane emissions, remote-sensing equipment on aircraft, and mobile monitoring platforms. For details, please see section X.C of the preamble to the final rule.

Comment: Commenter (0405-Dr. Jonas S. Wilzewski) recommends that the EPA:

1. Retain the flexibility to certify satellite-based systems as valid means of practical emission detection throughout the coming years.
2. Regularly revisit the threshold that defines regulation-relevant methane emission events throughout this decade.
3. Require oil and gas companies to report on maintenance activities that lead to considerable methane emissions.
4. Consider providing wind speed measurements near oil and gas infrastructure sites to the public.

Response I-7-245: The EPA proposed specific requirements for the super-emitter response program in the December 2022 Supplemental Proposal. For details, please see discussion in section IV.C of the December 2022 Supplemental Proposal.<sup>583</sup> The EPA is finalizing a revised structure of the super emitter program targeted to identify large emission events. The final requirements ensure that the program operates with a high degree of accuracy, integrity, and transparency, necessary for addressing super-emitter events. This includes the use of satellite detection of methane emissions, remote-sensing equipment on aircraft, and mobile monitoring platforms. For details, please see section X.C of the preamble to the final rule.

Comment: Commenter (0927-Interfaith Center on Corporate Responsibility) recognizes that more frequent inspections are effective at identifying super-emitters that by their nature are unpredictable yet are significant sources of leaks. As technology improves, the commenter acknowledges the importance of regulatory flexibility to enable adoption of the most effective (and cost-effective) technologies to manage methane emissions. The commenter urges companies to adopt direct measurement of methane emissions as an effective means of emissions mitigation by helping companies to identify their major sources of emissions, including many not captured by the standard factor-based reporting regime such as super emitters. With an accurate picture of emissions, companies can take steps to cost-effectively address their most significant leaks. It also greatly increases investor confidence in companies' methane emissions data.

Response I-7-246: The EPA proposed specific requirements for the super-emitter response program in the December 2022 Supplemental Proposal. For details, please see discussion in section IV.C of the December 2022 Supplemental Proposal.<sup>584</sup> The EPA is finalizing a revised structure of the super emitter program targeted to identify large emission events. The final requirements ensure that the program operates with a high degree of accuracy, integrity, and transparency, necessary for addressing super-emitter events. This includes the use of satellite detection of methane emissions, remote-sensing equipment on aircraft, and mobile monitoring platforms. For details, please see section X.C of the preamble to the final rule.

<sup>583</sup> 87 FR 74746-74755 (December 6, 2022).

<sup>584</sup> 87 FR 74746-74755 (December 6, 2022).

#### 7.4.3.3 Emissions Threshold

Comment: Commenter (0932-GHGSat, Inc.) reports that with respect to an emissions threshold that could be used to define these large emission events, there are some satellite systems capable of generally identifying emissions above 100 kg/hr with a spatial resolution which could allow identification of emission events from an individual site. Other satellites systems are available which have wider spatial resolution that can identify large methane emission events, and when combined with finer resolution platforms, could allow identification of emission events from an individual site.

Response I-7-247: The EPA proposed specific requirements for the super-emitter response program in the December 2022 Supplemental Proposal. For details, please see discussion in section IV.C of the December 2022 Supplemental Proposal.<sup>585</sup> Please also see section X.C of the preamble to the final rule. A super-emitter event is defined as any emissions event that is located at an individual well site, centralized production facility, or compressor station and that is detected using remote detection methods and has quantified emission rate of 100 kg/hr of methane or greater.

Comment: The commenter (0932-GHGSat, Inc.) agrees that is relevant to consider methane monitoring by satellites due to the increased survey frequency monitoring for the larger leaks. As stated by Duren *et al.*, detection limits for methane point sources could be relaxed by a factor of ten compared with the survey presented in the research (*i.e.*, aircraft sensor with detection threshold of 10 kg/hr) and still identify 90 percent of super emitters if applied frequently over large areas.<sup>586</sup>

Response I-7-248: The EPA proposed specific requirements for the super-emitter response program in the December 2022 Supplemental Proposal. For details, please see discussion in section IV.C of the December 2022 Supplemental Proposal.<sup>587</sup> Please see section X.C of the preamble to the final rule which details EPA's final standards for the super emitter program.

#### 7.4.3.4 Flexible/Matrix Approach

Comment: Commenter (0935-COGA) urges EPA to promote the use of innovative technologies by creating flexible frameworks for their use.

Response I-7-249: EPA acknowledges the commenters support for the use of alternative technologies. EPA has taken this comment into account as they designed the alternative technology program in the December 2022 Supplemental Proposal. See discussion in section IV.B of the December 2022 Supplemental Proposal related to advanced methane detection technologies.<sup>588</sup> Please also see section X.B of the preamble to the final rule which details EPA's

---

<sup>585</sup> 87 FR 74746-74755 (December 6, 2022).

<sup>586</sup> Duren, et al., 2019.

<sup>587</sup> 87 FR 74746-74755 (December 6, 2022).

<sup>588</sup> 87 FR 74740-74746 (December 6, 2022).

final standards related to advanced methane detection technologies, which includes adoption of flexible frameworks.

Comment: Commenter (0932-GHGSat, Inc.) agrees that prompt action on identifying and ultimately minimizing methane leaks with considerable emission rates is the most cost-effective method to generate immediate environmental, economic, and social impacts. As discussed by Brandt *et al.*, leakage data sets are statistically heavy tailed, with 5 percent of leaks (larger leaks by emission rate) typically contributing over 50 percent of the total leakage volume (Brandt, *et al.*, 2016). Hence, detecting and monitoring for the less frequent large emissions have a greater impact than monitoring for the more frequent and numerous smaller leaks mostly identified by the existing LDAR program requirements.

The commenter (0932-GHGSat, Inc.) agrees with EPA that emissions should be classified or labeled based on a range of emission rates and believes that this classification should contain different bins or ranges and provide different labels. This classification can be very beneficial to the regulated community, and it is in line in how EPA has classified other items (*e.g.*, classification of wells, as proposed in this proposed rule). The commenter suggests the following proposed categorization:

| <b>Emission rate (kg/hr)</b> | <b>Classification</b> | <b>OGI follow-up (days)</b> | <b>Repair – First attempt (days)</b> | <b>Repair – Final attempt (days after first attempt)</b> | <b>Delay of Repair</b> | <b>Root Cause Analysis?</b> |
|------------------------------|-----------------------|-----------------------------|--------------------------------------|----------------------------------------------------------|------------------------|-----------------------------|
| Below 10                     | Process-emitter       | 14                          | 30                                   | 35                                                       | Yes                    | No                          |
| ≥10 to <100                  | Major-emitter         | 14                          | 15                                   | 30                                                       | No                     | Yes                         |
| ≥100 to <1,000               | Super-emitter         | 7                           | 10                                   | 25                                                       | No                     | Yes                         |
| ≥1000                        | Ultra-emitter         | 5                           | 5                                    | 20                                                       | No                     | Yes                         |

The commenter (0932-GHGSat, Inc.) explains that the rationale behind this proposed categorization is based on the fact that large emission events contribute disproportionately to emissions, and therefore, need to be found and repaired as quickly as possible. This classification of emission rates can also be associated with a matrix approach. In this type of approach, the main role of OGI shifts from detection to verification. The commenter believes that a tiered approach can be cost-effective and provide multiple additional benefits to operators, and proposed the following:

| <b>Matrix/Tiered Approach</b> |                            |                                    |                            |                    |
|-------------------------------|----------------------------|------------------------------------|----------------------------|--------------------|
| <b>Tiers</b>                  | <b>Temporal Resolution</b> | <b>Spatial resolution (meters)</b> | <b>Source Localization</b> | <b>Sensitivity</b> |
| Analytics                     | Weekly                     | 1000                               | No                         | Low                |
| Satellites                    | Monthly                    | 25                                 | Yes                        | Medium             |
| Aircraft                      | Bimonthly                  | <1                                 | Yes                        | High               |
| OGI                           | Annual                     | At source                          | Yes                        | High               |

The commenter (0932-GHGSat, Inc.) states an operator can benefit from the tiered approach described by having frequent coverage of all the sites. The analytics tier can provide a weekly resolution by leveraging all the data available to generate insights. With this tier, the operator can develop survey plans and monitor for the ultra-emitters ( $\geq 1,000$  kg/hr). The commenter's analytics platform provides the temporal resolution, generates insights, and cues the commenter's satellites to observe an area of interest defined by the algorithms. The second tier is a targeted methane detection and quantification with the commenter's satellites. The temporal resolution can be defined as monthly, surveying for emissions for super-emitters ( $\geq 100$  to  $< 1,000$  kg/hr). The third tier can be deployed bimonthly, surveying for emissions from major emitters ( $\geq 10$  to  $< 100$  kg/hr). This bimonthly requirement and detection threshold are in line with the proposed rules for alternative monitoring equipment. The fourth tier can be deployed in annual basis or to pinpoint the emission source and verify for successful repairs.

Response I-7-250: The EPA proposed specific requirements for the super-emitter response program in the December 2022 Supplemental Proposal. For details, please see discussion in section IV.C of the December 2022 Supplemental Proposal.<sup>589</sup> The EPA is finalizing a revised structure of the super emitter program targeted to identify large emission events. The final requirements ensure that the program operates with a high degree of accuracy, integrity, and transparency, necessary for addressing super-emitter events. This includes the use of satellite detection of methane emissions, remote-sensing equipment on aircraft, and mobile monitoring platforms. For details, please see section X.C of the preamble to the final rule.

#### 7.4.3.5 Guidelines for credible and actionable data

Comment: Commenter (0824-WDEQ) states it is essential that EPA sets very specific guidelines for credible and actionable data. Current methane and VOC sensor technologies have substantial technical limitations. It is questionable whether current sensors have the detection limits and accuracy to discern methane background from a leak in a downwind community. Extensive work identifying instruments or methods with quantifiable accuracy, precision, and reliability would need to be performed. Additionally, acceptable standards for those quality characteristics must be set along with required quality measures. It seems that credible and actionable data must be collected by sensors or other instruments that meet performance testing similar to 40 CFR part 53 and a documented quality system. Further, data handling provisions must also be covered in these specifications, as well as data collection plans, so interferences from other sources of methane can be minimized.

Response I-7-251: The EPA proposed specific requirements for the super-emitter response program in the December 2022 Supplemental Proposal. For details, please see discussion in section IV.C of the December 2022 Supplemental Proposal.<sup>590</sup> The EPA is finalizing a revised structure of the super emitter program targeted to identify large emission events. The final requirements ensure that the program operates with a high degree of accuracy, integrity, and transparency, necessary for addressing super-emitter events. For details, please see section X.C of the preamble to the final rule.

<sup>589</sup> 87 FR 74746-74755 (December 6, 2022).

<sup>590</sup> 87 FR 74746-74755 (December 6, 2022).

#### 7.4.3.6 Emissions are Underestimated

Comment: The commenter (0844-EDF *et al.*) cites to numerous studies to show that super-emitters and abnormal process emissions are often not well-represented and national inventories often underrepresent emissions from these sources, especially where bottom-up approaches have been used.<sup>591,592,593</sup> Accounting for these emission events can increase inventory estimates by 60-70 percent, underscoring the importance of quickly detecting and fixing major leaks.<sup>594</sup> The commenter provides a figure of Alvarez Synthesis Model Inventory Estimates.<sup>595</sup>

In 2012, the commenter (0844-EDF *et al.*) launched a series of research studies to quantify methane emissions from the U.S. oil and gas supply chain with diverse, measurement-based methodologies.<sup>596</sup> This collaborative work with over one hundred and forty experts from academia, industry, and government has resulted in more than forty peer-reviewed papers. The commenter cites to additional studies performed that conclude that EPA's inventories are underestimating emissions.<sup>597,598,599</sup>

The commenter (0844-EDF *et al.*) states that recent research has found several common characteristics of oil and gas industry methane emissions:

1. Emissions occur across the value chain from well to end use, but are concentrated in the production and gathering segments, including well pads, tank batteries, and gathering compressor stations. The commenter's emission inventory, derived from the Alvarez

<sup>599</sup> IEA, Methane Tracker Database (October 2021), <https://www.iea.org/articles/methane-tracker-database> (summary of inventory estimates).

synthesis model, estimates that production segment fugitive emissions represent nearly 50 percent of all oil and gas sector methane emissions.

2. All oil and gas facility types have a skewed distribution in which 5-10 percent of the highest emitting sites are responsible for about half of total emissions; however, the identity of these high-emitting sites can change with time and is difficult to predict.
3. Low production or marginal wells tend to have lower absolute emissions than high production wells, but much higher loss rates as a percentage of gas production. And because roughly three quarters of all wells are marginal, they cumulatively contribute a substantial fraction of total emissions—up to 50 percent of production sector emissions according to a forthcoming study.<sup>600</sup>
4. Emissions can almost always be mitigated once detected, sometimes with a simple repair to stop a leak, and other times by implementing operational or equipment changes that improve a site's efficiency.

The commenter's (0844-EDF *et al.*) Permian Methane Analysis Project (PermianMAP) uses several peer-reviewed measurement approaches to quantify oil and gas methane emissions in the Permian Basin, the nation's largest oil field, and then posts the emissions data on the public website PermianMAP.org to facilitate mitigation. This project and the associated studies have generated several important findings, which the commenter briefly summarizes here.

The commenter (0844-EDF *et al.*) notes that one study estimates the Permian Basin loss rate is 3.7 percent of gas production, substantially higher than the national average.<sup>601</sup> Another study found a similar loss rate of 3.3 percent in the core production area of the Delaware sub-basin in March 2020 using aircraft and tower-based measurements. The paper reports that the loss rate temporarily dropped to 1.9 percent in April 2020 when oil prices declined, but recovered to prior levels by summer 2020.<sup>602</sup> The authors hypothesize that the Permian Basin typically has a high loss rate because wells are developed faster than the pipelines and compressor stations needed to transport the gas to market. This leads to both high rates of associated gas flaring and abnormal emissions due to gathering systems with inadequate capacity. Therefore, the decline in well development during low oil prices temporarily relieved capacity issues and reduced emissions, bringing the leak rate closer to but still higher than EPA estimates. This study suggests that permanent reductions could be achieved by ensuring adequate gathering infrastructure before permitting new well development.<sup>603</sup>

The commenter (0844-EDF *et al.*) notes Robertson *et al.*, a 2020 paper, determined that New Mexico Permian well pad emissions were five to nine times higher than EPA estimates; complex pads including tanks or compressors had about twenty times higher average emissions than

<sup>603</sup> See Part IV.XX (associated gas at oil wells).

simple pads with only a wellhead.<sup>604</sup> Finally, Cusworth *et al.* in 2021 used an aerial remote sensing approach to quantify over 1,100 large methane sources in the Permian.<sup>605</sup> In support of previous research, the paper found that both the gathering sector and flares are large sources of emissions. They also assess the intermittency of large sources and determine that, on average, large emission sources are emitting 26 percent of the time.

The commenter (0844-EDF *et al.*) has also assessed flare performance in the Permian with a series of helicopter-based infrared camera surveys showing that approximately 5 percent of large flares are unlit and venting gas at any given time, and another 5 percent have visible slip of methane or other hydrocarbons—meaning the flare is only partially combusting the methane and the rest is escaping to the atmosphere. On-the-ground flare combustion efficiency is thus much worse than EPA has assumed and regulatory standards require. Flares are consequently one of the largest sources of methane in the Permian Basin, and the latest surveys have found even worse performance among smaller, intermittent flares.<sup>606</sup>

The commenter (0844-EDF *et al.*) states the scientific understanding of oil and gas methane emissions has expanded greatly over the last decade and can inform effective regulations for reducing emissions, especially fugitive monitoring programs. First, since emissions can occur across the supply chain regulations must have comprehensive coverage. Second, due to the skewed distribution of emission rates and the intermittency of some large emission events, the speed of detecting and stopping large emission sources is most critical for reducing total emissions—underscoring the importance of frequent monitoring and quick repair timelines. Third, because emissions are often episodic, after a screening approach finds a high emitting site, follow-up surveys must not only look for ongoing leaks, but include a root-cause analysis evaluating equipment and operational issues that could trigger high emission events. For example, an undersized tank control system could cause the tank hatch to intermittently pop open; closing the hatch will temporarily reduce emissions, but the problem will likely recur until the control system is fixed. And finally, smaller sites are disproportionate emitters of methane and should not be exempted from LDAR or other regulatory requirements.

Response I-7-252: The EPA proposed specific requirements for the super-emitter response program in the December 2022 Supplemental Proposal. For details, please see discussion in section IV.C of the December 2022 Supplemental Proposal.<sup>607</sup> The EPA is finalizing a revised structure of the super emitter program targeted to identify large emission events. The final requirements ensure that the program operates with a high degree of accuracy, integrity, and transparency, necessary for addressing super-emitter events. For details, please see section X.C of the preamble to the final rule. For details, please see section X.C of the preamble to the final rule.

#### ***7.4.4 Follow-Up Action/Root Cause Analysis***

Comment: Commenters (0586-Navajo EPA, 0605-Muscogee (Creek) Nation, 0781-NTAA, 0833-UTE EPD, 0932-GHGSat, Inc., 0943-Sault EPD) support the requirement that the owner/operator perform a root cause analysis to determine why the emissions are present and prevent reoccurrences of the emissions upon detecting emissions from equipment where emissions are not expected to occur, in addition to expeditious corrective action.

The commenter (0932-GHGSat, Inc.) believes that performing and documenting a root cause analysis for each detected methane leak should be part of a quality control/quality assurance process that can be modeled after ISO 140001. Documentation of the corrective action and proposed preventive maintenance should be included for each methane leak. The commenter believes that this documentation should be kept on site and not been part of a periodic report. Instead, the operator should integrate this documentation with the periodic and preventative maintenance program.

Commenter (0941-350 Silicon Valley) states the EPA might identify the sources of methane super emissions documented by TROPOspheric Monitoring Instrument (TROPOMI) using follow up flights by planes equipped with methane sensors, such as certain NASA Jet Propulsion Lab planes, and regional oil and gas field maps of wells, tanks, pipelines and processing plants. This might enable prompt notification so repairs could begin immediately.

Response I-7-253: See section X.C of the preamble to the final rule describing the requirements that are being finalized for the super emitter program. The final program includes specific requirements for qualifications for third-party notifiers, third-party notifier certification, notification of super-emitter events, identification of super-emitter events, and super-emitter event reporting requirements.

Comment: Commenters (0808-API, 0938-TXOGA) express various concerns around the term root cause analysis and request that EPA clarify terminology and requirements in the rule.

The commenter (0808-API) states that the process for assessing the cause of equipment malfunctions and operational upsets should be streamlined with appropriate completion and reporting schedules. The specific term “root cause analysis” has other meanings in various regulations and in the oil and gas industry. The commenter recommends that instead of using the term directly within NSPS OOOOb and EG OOOOc, the commenter suggests the following description be used in its place as it targets what information and action should occur during the analysis:

“Identify the primary cause, and any other contributing cause(s), of a malfunction or operational upset of a control device or the equipment itself.”

The commenter (0808-API) also suggests EPA streamline the recordkeeping and reporting of information related to the assessment.

The commenter (0938-TXOGA) says there are significant challenges in terms of defining the event that would trigger the analysis and would need to ensure that any such analysis is

calibrated to the magnitude of the event/concern. Especially given the remote location of many of these sources, a root cause analysis requirement could be extremely burdensome and impractical to achieve in the time frames that EPA typically requires in other rules for such analyses. In addition, there are numerous methods already in place that work to prevent such events and address them when they occur, indicating that such a requirement is not needed.

Response I-7-254: The EPA understands commenters concerns related to the term “root cause analysis.” The final rule uses the term “investigation” in order to minimize any confusion related to the final regulatory requirements for the super emitter program. Please see section X.C of the preamble to the final rule describing the requirements that are being finalized for the super emitter program.

Comment: Commenter (0598-CER, 0814-IPAA *et al.*) disagree with EPA’s proposed root cause analysis requirement.

The commenter (0598-CER) believes that conducting a root cause analysis is a business decision and not an activity in which EPA should be investing resources. In the event of a major malfunction, completing a root cause analysis is in the best interest of the operator. The goal of the activity is to investigate, mitigate, and then return the equipment to service without the discovered emissions. Maintaining their assets in good working condition and available for operations is how the commenter generates revenue.

The commenter (0814-IPAA *et al.*) states, introduced in the context of fugitive emission components, EPA introduces and proposes the results of emissions surveys to require a root cause analysis. EPA cites no authority for requiring such analysis by industry. Respectfully the commenter believes their individual member companies are in the best position to determine when a root cause analysis is necessary and what that analysis should entail. Adding additional reporting and recording keeping associated with some vague, undefined concept of “root cause” is as best tangentially related to potentially reducing emissions at some point in the future. Introduction of requirements that address “root cause” are more properly addressed by OSHA and process safety management.

Response I-7-255: The EPA understands commenters concerns related to the term “root cause analysis.” The final rule uses the term “investigation” in order to minimize any confusion related to the final regulatory requirements for the super emitter program. The final rule describes the specific requirements an owner/operator must follow to investigate and to identify the source of the super-emitter event. Please see section X.C of the preamble to the final rule describing the requirements that are being finalized for the super emitter program.

Comment: Commenters (0760-Airdar *et al.*, 0780-LongPath) note that for certain root-causes a repair can be implemented remotely, such as change in operational set-points for vapor-recovery units, change in separator cycle timing or other control parameters that can be remotely adjusted. In these cases, a site-visit is not required.

Response I-7-256: The final rule uses the term “investigation” in order to minimize any confusion related to the final regulatory requirements for the super emitter program. The final

rule describes the specific requirements an owner/operator must follow to investigate and to identify the source of the super-emitter event. Please see section X.C of the preamble to the final rule describing the requirements that are being finalized for the super emitter program.

Comment: Commenter (0780-LongPath) suggests that for circumstances in which an emission event is not mitigated with the prescribed procedures, the root cause and follow-up steps will need to be reinitiated after a stated number of days or weeks have passed.

Response I-7-257: The final rule describes the specific requirements an owner/operator must follow to investigate to identify the source of the super-emitter event and address cause of the emissions, including the timeline for doing so. Please see section X.C of the preamble to the final rule describing the requirements that are being finalized for the super response program.

Comment: Commenter (0785-John Crane Inc.) recommends a root cause analysis approach which provides 30 days for the operator or owner to complete a root cause analysis of the process where the leak occurs and submit to the EPA a minimum set of information when the root cause analysis is completed. This information should include all identified root causes, planned corrective actions and their costs, expected timeline with a requirement that all actions are completed within six months.

Response I-7-258: The final rule describes the specific requirements an owner/operator must follow to investigate to identify the source of the super-emitter event and address cause of the emissions, including the timeline for doing so. Please see section X.C of the preamble to the final rule describing the requirements that are being finalized for the super emitter program.

Comment: Commenter (0760-Airdar *et al.*) reports that another advantage of continuous monitors is the ability to provide some information about the root cause of an emission—to create an AWP where continuous monitors are used for inspection, but OGI surveys are not triggered for events where the continuous monitor provides sufficient data to suggest an OGI survey would not likely be successful. By combining the advantages of continuous monitors regarding both time to detect and root cause analysis, the commenter believes a continuous monitoring AWP can be constructed that is both environmentally and economically beneficial.

Response I-7-259: The final rule describes the specific requirements an owner/operator must follow to investigate to identify the source of the super-emitter event and address cause of the emissions. Please see section X.C of the preamble to the final rule describing the requirements that are being finalized for the super emitter program.

#### **7.4.5 Satellite Technologies**

Comment: Several commenters (0454-Kayros, 0753-IGSD/CHRE, 0785-John Crane Inc., 0844-EDF *et al.*) state that satellites are currently available and additional ones are in development that are capable of remote-sensing methane from oil and gas facilities. Several commenters find that satellite technology is very promising because of its widespread monitoring potential and environmental benefits to its implementation.

Commenter (0844-EDF *et al.*) notes that many methane-sensing satellites currently exist, and still more are in development; these systems are diverse in form and function. Many have very high minimum detection limits and therefore are better suited to detect large plumes and super-emitters rather than to pinpoint emission sources. However, proposed satellites should offer improved sensitivity and thus afford greater precision in locating emission sources.<sup>608,609</sup>

Commenter (0454-Kayros) states the detection threshold for point sources of methane has fallen by an order of magnitude (from 5 tons per hour to less than 500 kg/hr) in the past three years, and the next generation of satellites due to enter service by 2025 may deliver another 10-fold improvement by lowering the threshold to approximately 50 kg/hr of methane. And as the number of monitoring satellites grows, the frequency of observations increases.

Response I-7-260: The EPA acknowledges the commenters' statements regarding the capabilities of satellite methane detection technology.

The EPA proposed specific requirements for the super-emitter response program in the December 2022 Supplemental Proposal. For details, please see discussion in section IV.C of the December 2022 Supplemental Proposal.<sup>610</sup> The EPA is finalizing a revised structure of the super emitter program targeted to identify large emission events. The final requirements ensure that the program operates with a high degree of accuracy, integrity, and transparency, necessary for addressing super-emitter events. This includes the use of satellite detection of methane emissions as an option for remote detection technology, if approved under the ATM program of the final rule. For details, please see section X.C of the preamble to the final rule.

Comment: Commenters (0454-Kayros, 0785-John Crane Inc., 0844-EDF *et al.*) states although satellite technology is promising, today's technology limits its resolution, sensitivity and scanning scope compared to the wider scan survey approach of aerial aircraft mounted technology.

Commenter (0454-Kayros) states satellite monitoring is more than just a promising technology. Current monitoring systems already provide unprecedented insights into the methane footprint of the energy sector that are based on an extremely robust scientific foundation, which cannot be obtained through other means. The scientific integrity of satellite monitoring as a tool to detect and quantify methane sources is by now well established and beyond doubt. Peer-reviewed research by the commenter and its academic partners shows that super emitters account for 8-12 percent of total emissions from the oil and gas sector. In addition, the commenter estimates that basin-level monitoring captures 90 percent of emissions from the monitored areas.

Commenter (0785-John Crane Inc.) states as a result of satellite's resolution, satellites are adequate when monitoring "super emitters", but must be pre-programmed with asset GPS coordinates. The commenter argues satellite monitoring can be used after initial aerial or ground surveys as an efficient post-remediation lifecycle monitoring medium with negligible incremental costs. Its initial high capital costs can represent a challenge at this early stage of the

---

<sup>608</sup> Id.

<sup>609</sup> See, e.g., EDF, MethaneSAT, <https://www.methanesat.org/>.

<sup>610</sup> 87 FR 74746-74755 (December 6, 2022).

technology maturity curve. The commenter believes satellites will play an important role in the future, particularly in the ongoing monitoring of assets.

Commenter (0844-EDF *et al.*) states minimum detection limits of satellites have been estimated to be between 1,000 and 7,100 kg CH<sub>4</sub>/hr.<sup>611</sup> GHGSat has claimed facility-scale detection limits as low as 100 kg/h, but these have not yet been independently verified.<sup>612</sup> Independent efforts using satellites to monitor for super-emitters around the world will help reduce emissions and hold companies accountable. A planned initiative by Carbon Mapper and EDF (MethaneSAT) will provide independent coverage and accountability for regions and producers prone to large methane emission events.

Commenter (0727-OSEE/ODEQ) notes that the use of satellite data as the threshold could be problematic. For example, there could be large emission events that are not visible on satellite due to cloud cover or inadequate timing of satellite imagery for emissions that do not have a constant temporal profile, among other factors.

Response I-7-261: The EPA acknowledges the commenters' statements regarding the capabilities, as well as limitations of satellite methane detection technology.

The EPA proposed specific requirements for the super-emitter response program in the December 2022 Supplemental Proposal. For details, please see discussion in section IV.C of the December 2022 Supplemental Proposal.<sup>613</sup> The EPA is finalizing a revised structure of the super emitter program targeted to identify large emission events. The final requirements ensure that the program operates with a high degree of accuracy, integrity, and transparency, necessary for addressing super-emitter events. This includes the use of satellite detection of methane emissions as an option for remote detection technology, if approved under the ATM program of the final rule, as well as remote-sensing equipment on aircraft or mobile monitoring platforms. Any of these technologies would be subject to rigorous requirements prior to potential approval under the ATM program. For details, please see section X.C of the preamble to the final rule.

Comment: Commenters (0454-Kayrros, 0753-IGSD/CHRE) state satellite monitoring can support EPA's objectives by helping oil and natural gas companies optimize their methane abatement efforts; by improving the accuracy and trustworthiness of reporting; by involving local communities; and by making it possible to benchmark the methane footprint of U.S. energy against the rest of the world.

Commenters (0753-IGSD/CHRE) encourage the EPA to determine how best to use satellite data, given that the data will become increasingly robust as more satellites are deployed. At minimum, EPA's monitoring system should be able to effectively and quickly incorporate growing data sets in order to best protect the public from hazardous leaks and plumes.

Commenters (0753-IGSD/CHRE) support the EPA's November 2021 Proposal to use satellite and other data to empower communities to participate in identifying and reporting large

---

<sup>611</sup> Highwood 2022.

<sup>612</sup> Id.

<sup>613</sup> 87 FR 74746-74755 (December 6, 2022).

emissions events.<sup>614</sup> Such a policy advances environmental justice and would better protect public health and the environment by achieving quicker recognition and abatement of leaks. EPA should work with satellite operators to ensure that data is openly and publicly shared, at no cost to the user, and in a format that is practical and useful for diverse stakeholders. This may include engaging with state agencies and institutions, as well as foreign countries, that collect satellite data and promoting the sharing and harmonization of emissions data.

Response I-7-262: The EPA acknowledges the commenter's statements regarding the capabilities of satellite methane detection technology.

The EPA proposed specific requirements for the super-emitter response program in the December 2022 Supplemental Proposal. For details, please see discussion in section IV.C of the December 2022 Supplemental Proposal.<sup>615</sup> The EPA is finalizing a revised structure of the super emitter program targeted to identify large emission events. The final requirements ensure that the program operates with a high degree of accuracy, integrity, and transparency, necessary for addressing super-emitter events. This includes the use of satellite detection of methane emissions as an option for remote detection technology, if approved under the ATM program of the final rule. For details, please see section X.C of the preamble to the final rule.

Comment: Commenter (0454-Kayros) provides updates on their success with satellite-based systems, emerging satellite technology, and image processing efforts. The commenter discusses the following key topics in detail below:

1. Current satellite technology provides unique actionable insights.
  - a. Monitoring satellites identify methane super emitters.
  - b. Monitoring satellites measure total methane emissions at the scale of a basin.
  - c. Satellite monitoring complements traditional technologies
2. The credibility of satellite monitoring is well established.
  - a. Field tests.
  - b. Independent verification of satellite detection and quantification.
  - c. Validation of satellite-based basin-level quantification.
3. Satellite monitoring supports EPA objectives.
  - a. Improved accuracy.
  - b. Benchmark U.S. performance versus other countries.

Commenter (0454-Kayros) states satellite-based systems such as the Methane Watch platform developed by Kayros provide broad geographical coverage and can detect super emitter events, often missed by other methods, through a combination of satellites with different capabilities in terms of spatial resolution, frequency of revisit, detection threshold and data bandwidth. The commenter leverages raw data from NASA's Landsat 8, the European Space Agency's Sentinel-2 and Sentinel-5P and other government and commercial satellites through complex AI and machine learning (ML) algorithms to extract precise signals about very large emission events. The commenter states advanced satellite monitoring can also measure methane emissions aggregated at the scale of an oil and natural gas basin. The commenter has implemented

---

<sup>614</sup> Proposed Rule at 63,177.

<sup>615</sup> 87 FR 74746-74755 (December 6, 2022).

advanced satellite-based models to quantify emissions from the Permian, Anadarko and Marcellus/Appalachian Basins that account for half of oil and gas production in the U.S.

Commenter (0454-Kayros) adds in the United States alone, the Kayros Methane Watch platform has identified over 500 such events since January 2019, based on satellite data from the TROPOMI instrument aboard Sentinel-5P. Kayros Methane Watch has also detected large numbers of super emitters in other countries.

The commenter focuses much of its R&D efforts on the integration of data and inputs from multiple sensors, including, but not limited to, data from multiple satellite constellations. Much of the recent developments in atmospheric measurements of greenhouse gas emissions have come not only from the availability of new earth-observation sensing instruments, but from advances in image processing and system integration. In December 2020, the European Space Agency acknowledged the satellite monitoring technologies developed by Kayros as “major technical breakthrough”.

The commenter (0454-Kayros) states field tests that consist of controlled releases of a given volume of methane provide further opportunities for validating and calibrating satellite-based monitoring systems. Most recently, Stanford University conducted a series of controlled releases in Arizona and the commenter submitted its measurements as part of a blind test. The results of this exercise will become public in early 2022.

The commenter (0454-Kayros) states several operators in the oil & gas industry have verified satellite observations. Reporters at Bloomberg News with access to the commenter’s monitoring platform have investigated dozens of super emitters by contacting the companies that operate oil and natural gas assets in the vicinity of the locations identified as the likely sources of those emissions. This investigative work has helped create a public record of super emitters confirmed by operators and associated with specific facilities.

The commenter (0454-Kayros) adds independent surveys also have validated satellite observations. For example, an aerial campaign conducted by the Environmental Defense Fund on September 23-25, 2020, identified a super emitter at a gas compressor station in Texas. The commenter’s analysis of the same facility during that period resulted in three separate measurements that were fully consistent with those of the airborne sensor. In addition, further analysis of satellite data indicated that the facility had been releasing large volumes of methane for three months prior to the campaign.

The commenter (0454-Kayros) argues separate studies of methane emissions in the Permian basin, conducted independently by the commenter and EDF using Sentinel-5P data on overlapping periods in 2018-19 estimated total emissions from oil & gas at 2.7 million tons per annum. The fact that two separate teams reached nearly identical results is further validation of the technology.

The commenter (0454-Kayros) goes further, regional inventories based on satellite observations are fully consistent with global inventories from the Intergovernmental Panel on Climate Change. By focusing on average methane concentrations, rather than individual super emitters,

so-called basin inversion models provide a comprehensive measure of total emissions at the scale of an oil and gas basin. These regional inventories can be used to determine the average methane intensity of hydrocarbon production, measured in kilograms of methane per barrel of oil equivalent. Commenter (0454-Kayros) analysis of several basins in the U.S. (Permian, Anadarko, Marcellus), as well as of basins in Kuwait and Turkmenistan yields results that are highly consistent with the country-level estimates of the International Energy Agency.

Commenter (0454-Kayros) believes satellite monitoring can support the objectives of the EPA by increasing the frequency of measurements. Semiannual or quarterly OGI surveys are likely to miss most super-emitters, whereas a satellite-based system with a weekly frequency of observation will provide a more effective coverage.

Commenter (0454-Kayros) notes satellite monitoring can improve the accuracy of methane inventories. First, the frequency, volume, and location of super emitters can inform assumptions about emission factors and result in more realistic estimates, particularly for the type of facilities associated with super emitters. Second, total emissions aggregated at the scale of an oil and gas basin make it possible to benchmark emission factors and reflect regional differences in the observed methane intensity of hydrocarbon production. It is critical to reconcile methane inventories based on emissions factors with atmospheric observations. Monitoring satellites provide a comprehensive view of methane emissions at the scale of an oil and gas basin, and this provides a benchmark against which to calibrate emission factors. For some facilities, emission factors could be phased out altogether in favor of direct measurements.

Commenter (0454-Kayros) notes methane inventories, and reduction targets by extension, should be based on basin-level measurements rather than emission factors. It is equally important to define methane reduction targets against the correct baseline. Monitoring satellites and other types of atmospheric observations are likely to result in an upward revision to the methane footprint of the oil and gas industry. EPA should consider this scenario when proposing mitigation targets.

The commenter (0454-Kayros) states a further benefit of satellite monitoring is that it can be applied to other countries and does not need permission, which makes it possible to benchmark and compare the performance of U.S. operators against its peers. This is important to quantify because the range of methane intensities around the world can vary by a factor of 20 across the oil and gas basins analyzed by Kayros. The global context, including indicators of progress toward the Global Methane Pledge, can inform domestic targets and policies.

Commenter (0454-Kayros) states this matters because climate change is a global problem and climate action must be global. The U.S. must be able to monitor the progress of other countries with respect to their sustainability goals and pledges. Satellite monitoring also provides a basis for dialogue with other countries. The raw data from public satellites is available to all stakeholders and is essential to a shared view of methane sources and trends. The International Methane Emissions Observatory is a case in point: By integrating satellite monitoring in its methane rule, EPA will be at the forefront of climate policy.

Response I-7-263: The EPA acknowledges the commenter's statements regarding the capabilities of satellite methane detection technology.

The EPA proposed specific requirements for the super-emitter response program in the December 2022 Supplemental Proposal. For details, please see discussion in section IV.C of the December 2022 Supplemental Proposal.<sup>616</sup> The EPA is finalizing a revised structure of the super emitter program targeted to identify large emission events. The final requirements ensure that the program operates with a high degree of accuracy, integrity, and transparency, necessary for addressing super-emitter events. This includes the use of satellite detection of methane emissions as an option for remote detection technology, if approved under the ATM program of the final rule. For details, please see section X.C of the preamble to the final rule.

Comment: Commenters (0932-GHGSat, Inc., 0941-350 Silicon Valley) note satellite technology is available with a nominal detection threshold of 100 kg/hr and a pixel resolution of less than 30 meters.<sup>617</sup> For example, two commercial GHGSat satellites with these capabilities are currently orbiting the earth, providing monitoring across the world. Three more GHGSat satellites are scheduled for launch this summer towards the goal of a ten-satellite constellation within two years. This deployment timeline is well aligned with the regulatory impact analysis (RIA) for the proposed regulation, which anticipates a start date in 2023. Any individual satellite can revisit precisely the same orbital track every two weeks. In other words, each satellite can have an opportunity to measure the same geographical point every two weeks; therefore, the time between opportunities effectively halves with the addition of each satellite. Having a constellation of this size, coupled with aircraft campaigns and data analytics, effectively provides a tiered system for monitoring methane leaks of significance.

The commenter (0941-350 Silicon Valley) adds the EDF's MethaneSAT is scheduled for launch this October and two Carbon Mapper satellites for 2023. Methane SAT's instruments will be able to detect methane at concentrations of 2 to 3 parts per billion with resolutions of about 100 meters by 400 meters. They will also be able to do "inversions" which will indicate where methane plumes originated. Carbon Mapper's two satellites will carry sensors with resolutions of 30 meters square, enabling them to identify point source polluters. So, by 2024 EPA should have sufficient satellite data to quickly identify not only individual facilities responsible for super emissions, but those responsible for smaller, persistent emissions.

Response I-7-264: The EPA proposed specific requirements for the super-emitter response program in the December 2022 Supplemental Proposal. For details, please see discussion in section IV.C of the December 2022 Supplemental Proposal.<sup>618</sup> The EPA is finalizing a revised structure of the super emitter program targeted to identify large emission events. The final requirements ensure that the program operates with a high degree of accuracy, integrity, and transparency, necessary for addressing super-emitter events. This includes the use of satellite detection of methane emissions as an option for remote detection technology, if approved under

<sup>617</sup> Esparza, et al., 2021.

<sup>618</sup> 87 FR 74746-74755 (December 6, 2022).

the ATM program of the final rule. For details, please see section X.C of the preamble to the final rule.

#### **7.4.6 Other Recommendations**

Comment: Commenters (0801-Carbon Mapper/RMI, 0807-BP) provide recommendations on how to integrate third-party reports of large emission events.

Commenter (0801-Carbon Mapper/RMI) recommends that EPA establish a U.S. Methane Data Analysis Center (MDAC)<sup>619</sup> and workflow for responding to reports by communities and other third parties of potential larger emission events, defined as so-called “super-emitters” with the potential for emission rates exceeding 100 kg/hr due to leaks, malfunctions or excessive venting. The commenter also recommends that EPA evaluate the broader co-benefits that a third-party reporting program might provide to other programs within EPA and other agencies.

Commenter (0807-BP) encourages EPA to consider, and take comment on, the potential role that third-party certification organizations and technology vendors can play in the verification process. EPA already follows this approach in closely related contexts. For example, third-party organizations like the National Physical Laboratory confirm that FLIR OGI cameras can image gas at the required NSPS OOOOa concentration and flow rates. Similarly here, EPA could allow operators to rely on third-party certification organizations and technology vendors to demonstrate that their technology meets the alternative screening standard requirements.

The commenter (0807-BP) adds, EPA could streamline the verification process by maintaining a regularly updated list of approved technologies. With only a few proven methane technology vendors in the market today, companies may find themselves duplicating efforts in demonstrating and verifying compliance. As proposed, each individual operator would have to undertake the process of verifying their advanced screening technology for compliance, even if the technology has already been verified for use by another operator.

The commenter (0807-BP) states by maintaining a list of approved technologies, EPA could reduce these duplicative efforts. EPA currently does this for other control devices subject to NSPS OOOOa by maintaining a list of control devices where “manufacturers have demonstrated compliance with the testing requirements, including achieving a destruction efficiency of at least 95 percent.” EPA could maintain a similar list, posted on its website, for approved technologies that meet methane detection thresholds. To expedite the use of advanced methane technologies and to make alternative screening more widely available, the commenter recommends that EPA consider pre-verifying existing, proven technologies that meet the standard in advance of the rule’s compliance deadlines.

Response I-7-265: The EPA proposed specific requirements for the super-emitter response program in the December 2022 Supplemental Proposal. For details, please see discussion in

---

<sup>619</sup> The MDAC could be implemented as a single new EPA center, by the EPA regional offices, non-profit cooperative institutions funded jointly by EPA and other federal and state agencies, or a federation of third-party organizations certified under an EPA-specified protocol.

section IV.C of the December 2022 Supplemental Proposal.<sup>620</sup> The EPA is finalizing a revised structure of the super emitter program targeted to identify large emission events. The final requirements ensure that the program operates with a high degree of accuracy, integrity, and transparency, necessary for addressing super-emitter events. Please see section X.C of the preamble to the final rule which details EPA's final standards related to third-party notifier certification, which includes requirements for detailing the procedures and processes to ensure the data collected is in compliance with the requirements of the rule when submitting notifications of super-emitter events. Additionally, EPA has separated the review process for the technologies used to report super-emitter events from the third-party notifiers. Technologies will be approved by EPA under the advanced methane detection technology program in 40 CFR 60.5398b(d) and, once approved, posted to EPA's website.

---

<sup>620</sup> 87 FR 74746-74755 (December 6, 2022).

## Chapter 8. Fugitive Emissions Components at Compressor Stations

### 8.1 General Support

Comment: Commenter (1267-California Office of the Attorney General (CA AG) *et al.*) supports EPA's adoption of a presumptive standard for compressor stations in the EG OOOOc that follows the same fugitive monitoring and repair program as for new sources.

Response I-8-1: Comment is a supportive comment on an aspect of the November 2021 Proposal that has remained unchanged in the final rule; as such, no response is required.

### 8.2 Monitoring Frequency/Subcategorization

#### 8.2.1 Cost-effectiveness of Monitoring

Comment: Commenter (0844-Environmental Defense Fund (EDF) *et al.*) suggests that EPA should increase the monitoring frequency for fugitive emissions components located at compressor stations from the proposed quarterly monitoring to either monthly or bimonthly monitoring and states that any subcategorization based on throughput for the compressor station is not warranted.

The commenter (0844-EDF *et al.*) supports their position by stating that compressor station fugitive emissions are significant, particularly gathering and boosting compressor stations. The commenter provides that research has found “that CH<sub>4</sub> emissions from gathering are substantially higher than the current EPA GHGI [Greenhouse Gas Inventory] estimate and are equivalent to 30 percent of the total net CH<sub>4</sub> emissions in the natural gas systems [2014] GHGI,” with the majority coming from gathering facilities.<sup>1</sup> Another more recent study found that combustion slip from compressor engines was the single greatest source of emissions at gathering stations.<sup>2</sup> The commenter notes that the study report<sup>3</sup> states, “Because throughput was a direct function of operating compressors, and 82 percent of compressors in the field campaign were operating at time of measurement, combustion slip was the single strongest driver of the relationship between station throughput and total methane emissions.” To evaluate emissions and reductions from fugitive emissions monitoring and repair at compressor stations, the commenter states that EPA relied on a model plant analysis. The commenter notes using model plants greatly underestimates actual emissions because the analysis does not account for super-emitter events.<sup>4</sup>

[https://www.edf.org/sites/default/files/content/Joint\\_Environmental\\_Comments\\_on\\_EPAs\\_Proposed\\_NSPS\\_Reconsideration.pdf](https://www.edf.org/sites/default/files/content/Joint_Environmental_Comments_on_EPAs_Proposed_NSPS_Reconsideration.pdf).

In addition, the commenter (0844-EDF *et al.*) notes that EPA found the weighted average for single pollutant cost-effectiveness of monitoring at compressor stations (without gas savings) to be \$855/ton of methane for quarterly inspections and \$1,807/ton for monthly inspections.<sup>5</sup> On a multipollutant basis, these values drop to \$428 and \$903, respectively.<sup>6</sup> In 2016, the commenter states that EPA considered values as high as \$2,185/ton to be cost-effective for methane reductions. Thus, the commenter suggests that, because the weighted average, even without gas savings, is well within EPA's traditional cost-effectiveness range and because compressor stations are significant sources of fugitive emissions, EPA should increase the required monitoring at these sources to monthly. If for some reason EPA concludes that monthly monitoring is not cost-effective for all compressor stations, the commenter believes that EPA should then require bi-monthly inspections for the tier of compressor stations where monthly inspections would exceed EPA's cost-effectiveness threshold.

In the commenter's opinion (0844-EDF *et al.*), in analyzing monitoring costs at compressor stations, EPA has likely (and significantly) overestimated the cost per optical gas imaging (OGI) survey by assuming each survey will take between 10.6 and 28.1 hours.<sup>7</sup> The commenter reports that an analysis conducted by MJ Bradley of Air Emission Reports submitted to EPA by oil and gas companies shows that an average compressor station leak detection and repair (LDAR) survey takes just 2.8 hours.<sup>8</sup> Based on this, the commenter believes that EPA's assumed OGI survey costs for compressor stations are likely too high. Additionally, the commenter believes that the double-counting and overestimating of various cost components described earlier in this section also apply to EPA's estimates for compressor stations. Because of these overestimates, the commenter believes that EPA should revise its cost-effectiveness numbers for compressor stations too.

The commenter (0844-EDF *et al.*) emphasizes that EPA should revisit its repair cost assumptions for compressor stations to ensure it is not double counting costs that should be or already are attributed to other work practice standards, like those for reciprocating and centrifugal compressors. The commenter states that, if an operator discovers that a compressor is malfunctioning through an OGI survey, that repair cost is properly attributed to the underlying compressor standards that require operators to have functioning compressors that operate without significant combustion slip.

In the paragraphs below, the commenter (0844-EDF *et al.*) summarizes EPA's cost-effectiveness findings for different classes of compressor stations. The commenter states that these data reveal that monthly monitoring requirements are appropriate for each kind of facility, notwithstanding that they are overestimates of costs.

***Gathering and Boosting Compressor Stations.*** For quarterly monitoring at gathering and boosting compressor stations, the cost per ton of methane reduced is \$1,006 and with gas

---

<sup>5</sup> November 2021 Proposal TSD at 12-40.

<sup>6</sup> November 2021 Proposal TSD at 12-41.

<sup>7</sup> November 2021 Proposal TSD at 12-19, 12-20.

<sup>8</sup> Attachment C to the comment, available at EPA-HQ-OAR-2021-3017-2433; <https://cfpub.epa.gov/webfire/>.

savings considered, the cost per ton of methane reduced is \$824. For monthly monitoring, the cost per ton of methane reduced is \$2,219 and if gas savings are considered, the cost per ton of methane reduced is \$2,038.

**Transmission Compressor Stations.** For quarterly monitoring, the cost per ton of methane reduced is \$617. For monthly monitoring, the cost per ton of methane reduced is \$2,219 and if gas savings are considered, the cost per ton of methane reduced is \$2,021. Transmission facilities do not own the natural gas; therefore, revenues from reducing the amount of natural gas emitted as the result of equipment leaks was not further analyzed for this segment.

**Storage Compressor Stations.** For quarterly monitoring, the cost per ton of methane reduced is \$211. For monthly monitoring at storage compressor stations, the cost per ton of methane reduced is \$1,094. Once again, storage facilities do not own the natural gas; therefore, revenues from reducing the amount of natural gas emitted as the result of equipment leaks was not estimated for this segment.

The commenter (0844-EDF *et al.*) contends that monthly monitoring at all compressor stations is within the range EPA considers cost-effective. Even ignoring cost savings, the commenter notes that the cost for monthly inspections at gathering and boosting and transmission compressor stations – \$2,219 – is only slightly higher than values that EPA has in the past found cost-effective (\$2,185). Adjusted for inflation, the commenter notes that the \$2,219 value may even be lower than \$2,185. And they add that many other available estimates of costs suggest that monthly monitoring is even cheaper and more cost-effective than EPA’s analysis indicates.

According to commenter (0844-EDF *et al.*), EPA justifies its selection of quarterly rather than monthly monitoring on incremental cost-effectiveness. However, the commenter states that the agency has not explained why incremental cost-effectiveness should matter more than overall cost-effectiveness, nor has it examined whether bi-monthly (six times per year) monitoring might be incrementally cost-effective. Furthermore, the commenters adds, if emissions from super-emitters are considered, monthly monitoring will be far more effective at reducing emissions and more incrementally cost-effective as well. In Colorado’s most recent rulemaking, the commenter reports that the Air Pollution Control Division estimated the cost-effectiveness of quarterly inspections at compressor stations to be \$3,279.14 per ton VOC and \$46.04 per mtCO<sub>2e</sub>, without incorporating the estimated annual value of recovered gas.<sup>9</sup> With gas savings, the commenter reports that the numbers fell to \$2,659.55 and \$37.63, respectively. The commenter adds that New Mexico also recently evaluated the cost-effectiveness of quarterly OGI at compressor stations and estimated a value of \$3,331/ton VOC. According to the commenter, these VOC-designated costs are considerably lower than the level that EPA has identified in the November 2021 Proposal for determining the cost-effectiveness of VOC controls. Likewise, the commenter states that the CO<sub>2e</sub>-designated costs values are markedly lower than the central 2022 values

reported in the Interagency Working Group's Interim Global Social Cost of Carbon Technical Support Document (TSD).<sup>10</sup> As noted above, the commenter notes that the Interagency Working Group's values represent a highly conservative estimate of the true social cost of greenhouse gases, and any compliance costs falling below those figures should certainly be considered cost-effective.

Response I-8-2: Regarding the frequency and cost-effectiveness of surveys at compressor stations, EPA received a similar comment on the December 2022 Supplemental Proposal. EPA's response to this comment is provided in Volume II, Chapter 4, section 4.2.1 (Proposed BSER).

Regarding combustion slip from compressor engines, this comment is outside the scope of this rulemaking. Combustion slip is addressed via other regulations, including the National Emission Standards for Hazardous Air Pollutants for Reciprocating Internal Combustion Engines (40 CFR part 63, subpart ZZZZ), New Source Performance Standards for Stationary Compression Ignition Internal Combustion Engines (40 CFR part 60, subpart IIII), and New Source Performance Standards for Stationary Spark Ignition Internal Combustion Engines (40 CFR part 60, subpart JJJJ).

Consistent with our discussion in section XII.A.b of the November 2021 Proposal preamble, EPA continues to find that the model plant approach is effective for estimating baseline fugitive emissions from compressor stations. Under the final rule, EPA is also establishing a Super Emitter Program separate from the fugitive emission detection and repair program for compressor stations to address super-emitter events. Please see Preamble section X.C which details EPA's final standards related to the Super Emitter Program. Because emissions from super-emitter events at compressor stations are accounted for under the Super Emitter Program, we see no reason that even if they were underestimated by the model plant approach, we would alter our approach to calculating the baseline emissions at compressor stations.

In the November 2021 Proposal, EPA solicited comments on whether compressor stations should be subcategorized, specifically seeking information related to throughputs where fugitive emissions of methane are demonstrated to be minimal below a certain capacity. Because EPA did not receive such information in response to the November 2021 Proposal or December 2022 Supplemental Proposal demonstrating the reasonableness or appropriateness of subcategorization, EPA has not included subcategorization of compressor stations in the final rule.

With regard to the costs associated with OGI surveys of compressor stations, EPA disagrees that the cost estimate is a significant overestimation. Although the estimated times to conduct OGI surveys at different types of compressor stations, ranging between 10.6 and 28.1 hours, are presented in the November 2021 TSD, the cost for a compressor station OGI survey is not calculated based on an hourly rate. Instead, the \$2,492 cost is on a per-survey basis and is

---

<sup>10</sup> Interagency Working Group on Social Cost of Greenhouse Gases, Technical Support Document: Social Cost of Carbon, Methane, and Nitrous Oxide Interim Estimates under Executive Order 13990, Table A-1: Annual SC-CO<sub>2</sub>, 2020 – 2050 (February 2021).

derived from Appendix 1 in the Carbon Limits Report CL-13-27, Quantifying Cost-effectiveness of Systemic Leak Detection and Repair Programs Using Infrared Cameras (March 2014), updated to \$2019. As such, EPA did not overestimate cost based on an overestimation of survey time because the cost estimation was independent of survey time.

With regard to double-counting and overestimating of various cost components described earlier in this section, EPA takes this to mean the use of API cost data for reporting, recordkeeping, and data management as described in section 7.1.7 of the 2021 RTC. Because EPA did not use an hourly labor rate for OGI camera surveys for or travel to compressor stations and the rate used specifically excluded any internal administrative costs, EPA does not believe that it double counted recordkeeping and reporting or travel time costs. EPA also believes that the use of average values for recordkeeping costs instead of the weighted average values suggested by the commenter are appropriate because no specific recordkeeping or data management system is required by the rule, so the proportion of facilities using any specific system is subject to change.

Regarding not attributing costs of malfunctioning compressors to fugitive emissions monitoring and repair costs, EPA does not believe that we have done so and the commenter offered no place in the calculation demonstrating such attribution.

### ***8.2.2 Monitoring Frequency***

Comment: Commenter (0744-New York State Department of Environmental Conservation (NYSDEC)) supports EPA's requirements for quarterly LDAR for gathering and boosting stations but would recommend requiring more frequent LDAR for compressor stations. In the commenter's rulemaking for this sector, New York compression station operators will be subject to bimonthly LDAR requirements based on a determination that bimonthly LDAR would be cost-effective and result in more meaningful reductions in fugitive emissions.

Response I-8-3: We understand that "LDAR" refers to the fugitive emission detection and repair program. In response to comments received on the November 2021 Proposal, EPA proposed additional monthly AVO monitoring and repair requirements for compressor stations in the December 2022 Supplemental Proposal. For details, please see discussion in section IV.A.2.a of the December 2022 Supplemental Proposal.<sup>11</sup> Regarding the frequency and cost-effectiveness of surveys at compressor stations, EPA received a similar comment on the December 2022 Supplemental Proposal. EPA's response to this comment is provided in Volume II, Chapter, 4, section 4.2.1 (Proposed BSER).

Comment: Commenter (0755-Texas Pipeline Association (TPA)) contends that a requirement for more frequent monitoring than semiannually would be unduly burdensome, given that one pipeline system could have numerous compressor stations that are often located in remote areas. In addition, the commenter states that the resources (both personnel and equipment) to comply with survey requirements may be limited, a concern that EPA itself acknowledged in the

---

<sup>11</sup> See 87 FR 74739 (December 6, 2022).

preamble for the initial NSPS OOOOa proposal.<sup>12</sup> Moreover, the commenter notes that the leak rate in the gathering and boosting industry segment is particularly low.<sup>13</sup>

The commenter (0755-TPA) suggests that including prescriptive monitoring requirements are unnecessary and would unduly burden regulated parties with little environmental benefit. As recently as September 2020, the commenter states that EPA concluded that semiannual monitoring was sufficient. The commenter does not believe that little more than a year later, EPA has uncovered a sufficient basis to reject that conclusion and to cut in half the required monitoring interval. The commenter urges EPA to retain the current requirement of semiannual monitoring for fugitive emissions at compressor stations, including gathering and boosting compressor stations.

Response I-8-4: EPA disagrees with the commenter's suggestion that semiannual monitoring for fugitive emissions at compressor stations is appropriate. Consistent with the November 2021 Proposal, EPA proposed to retain quarterly OGI monitoring for compressor stations in the December 2022 Supplemental Proposal. As discussed in the November 2021 Proposal, quarterly OGI monitoring was determined to be the best system of emissions reduction (BSER) for reducing methane and VOC emissions from all compressor stations, including gathering and boosting stations, transmission stations, and storage stations because it produced significant, cost-effective emissions reductions.<sup>14</sup> Consistent with that determination, EPA is retaining quarterly monitoring. In addition, in the December 2022 Supplemental Proposal, EPA proposed to add a requirement to conduct monthly AVO monitoring at compressor stations and any fugitive emissions detected via AVO would be subject to repair, noting that the comments on the November 2021 Proposal indicated that compressor stations are visited on a weekly, if not daily, basis. Please also see section X.A.2 of the preamble of the final rule which details EPA's final standards related to compressor station fugitive emissions. As discussed in section X.A.2 of the November 2021 Proposal, EPA acknowledged in the 2020 Technical Rule that the costs for quarterly monitoring of compressor stations were considered reasonable.<sup>15</sup> EPA instead supported semi-annual monitoring by citing "significant financial hardship" in the industry and asserting that there may be efficiencies and cost savings with applying the same monitoring frequencies for well sites and compressor stations. However, EPA did not offer any data to support the change to semi-annual monitoring. In contrast, compliance records for the 2016 NSPS demonstrate no indication that compressor stations experienced hardship or difficulty in complying with the quarterly monitoring requirement. Further, several state agencies have rules that require quarterly or more frequent monitoring at compressor stations. In addition, EPA received comments in response to the November 2021 Proposal that even compressor stations owned by small companies were visited at least on a weekly basis.<sup>16</sup> EPA finds that AVO monitoring requirements can be conducted by any personnel at the site and disagrees that these

<sup>15</sup> See 86 FR 63159 (November 15, 2021) and 85 FR 57421 (September 15, 2020).

<sup>16</sup> See comments at Document ID Nos. EPA-HQ-OAR-2021-0317-0585 and EPA-HQ-OAR-2021-0317-0814.

requirements are unduly burdensome.<sup>17</sup> The commenter also provided no data to support the assertion that the proposed monitoring requirements would unduly burden regulated parties with little environmental benefit. In contrast, EPA anticipates reasonable costs and significant emissions reductions from compressor stations under this rule.<sup>18</sup>

Comment: Commenter (0817-GPA Midstream Association (GPA)) states that semiannual monitoring at compressor stations provides the most cost-effective system to reduce methane and VOC emissions. (The commenter discussed this in detail in comments submitted on the 2016 and 2020 NSPS OOOOa rulemakings). Once an initial monitoring event occurs at a compressor station, observed leaks and emissions from those leaks remain low. The commenter previously provided sector-specific data to EPA demonstrating a substantially lower leak frequency for the gathering and boosting sector than that assumed by EPA in its TSD documents.<sup>19</sup> The commenter notes that the data set found in Attachment 1 to EPA-HQ-OAR-2017-0483-1261 represents 11 companies and 262 sites across the country. They report that the trend demonstrated by these data is clear: initial leak percentages start low and remain low. Specifically, the commenter's data shows the following:

- *Initial monitoring frequencies:* Across the 11 companies and 262 sites, the average initial leak frequency is 0.24 percent. The data includes both OGI monitoring and EPA Method 21 monitoring. When Method 21 monitored sites are excluded, the initial leak frequency average drops even further to 0.23 percent.
- *Final frequency:* The data also show a clear trend that the leak frequencies start low but reduce further as monitoring continues. Using data from 203 sites, the final leak frequency was 0.17 percent. Facilities that had not performed at least four quarterly monitoring events were not included in the average. The final leak frequency was obtained by averaging the percentage of total leaking components from the last monitoring event where available.

The data that the commenter (0817-GPA) has gathered and presented also clearly show that once the initial survey is performed, leaks from the facilities will remain at low frequencies. Therefore, the commenter states that a semiannual monitoring schedule would reduce burden and cost on industry while still reducing methane and VOC emissions. As shown by Table 12-14a in the November 2021 Proposal TSD, semiannual monitoring provides the lowest cost while still significantly reducing emissions. The commenter states that the November 2021 Proposal never addresses the leak rate data that the commenter provided. In the commenter's opinion, this is a significant oversight given that EPA previously credited that data in the 2020 Technical Rule.<sup>20</sup>

<sup>18</sup> See section XII.A.b in 86 FR 63110 (November 15, 2021) for discussion.

<sup>19</sup> See, e.g., Company Data – Compressor Station Leak Rates – Final, *available at* EPA-HQ-OAR-2017-0483-0027 and Comments Submitted by GPA Midstream *available at* EPA-HQ-OAR-2017-0483-1261. The most recent data set provided by GPA Midstream is included as Attachment 1 to EPA-HQ-OAR-2017-0483-1261.

<sup>20</sup> See 85 FR 57414 and 57418 (September 15, 2020).

Response I-8-5: As discussed in the November 2021 Proposal, EPA evaluated the BSER for compressor stations. EPA analyzed OGI monitoring frequencies ranging between monthly and annual but determined in the November 2021 Proposal that quarterly OGI monitoring was cost effective and that additional emissions reductions could not be achieved at a reasonable cost. Therefore, EPA found in November 2021 based on the cost analysis conducted at that time, that the cost effectiveness of quarterly OGI monitoring for compressor stations is reasonable and determined to be the BSER. The December 2022 Supplemental Proposal analysis was consistent with the November 2021 Proposal determination, and EPA proposed to retain quarterly OGI monitoring for all types of compressor stations. In addition, in the December 2022 Supplemental Proposal, EPA proposed to add a requirement to conduct monthly AVO monitoring at compressor stations and any fugitive emissions detected via AVO would be subject to repair. EPA finds that AVO monitoring requirements can be conducted by any personnel at the site and are not unduly burdensome. EPA agrees that Tables 12-14a in the November 2021 TSD show that semiannual modeling provides the lowest cost per ton of methane or VOC emission reduction; however, EPA also finds that quarterly OGI monitoring is also cost effective in total and incremental costs and provides additional methane and VOC emissions reductions, making it the BSER. In addition, as discussed in the November 2021 Proposal, multiple states have found that quarterly OGI monitoring for compressor stations is cost effective. The leak frequency data provided by the commenter was addressed in the 2020 Policy Rule TSD.<sup>21</sup> In summary, EPA received comments on the 2018 NSPS OOOOa proposal that indicated that the use of the emission factors from Table 2-4 in EPA Equipment Leaks Protocol for components in gas service overestimated fugitive emissions, while other comments provided analyses suggesting that the use of the emission factors underestimated fugitive emissions. After considering submissions by all commenters and analyzing a July 2019 study that measured fugitive emissions from well sites and gathering and boosting stations, EPA determined that the use of the 1995 Protocol factors was still appropriate. EPA finds that the use of these factors is still appropriate for this rule.

### ***8.2.3 Subcategorization***

Comment: Commenter (1291-Cumberland Valley Resources, LLC (CVR)) appreciates that EPA's November 2021 Proposal does not require fugitive emission surveys for wellhead only wellsites and small wellhead compressors under the proposed NSPS OOOOb and EG OOOOc. However, the commenter is afraid EPA has overlooked new problems for small operators caused by NSPS OOOOb where a relatively small compressor associated with another small piece of equipment, such as a dehydrator, makes a small compressor station that would have been exempt under NSPS OOOOa, a centralized production facility that will have to have an LDAR program, expensive quarterly fugitive emission surveys, and the burden of recordkeeping that goes with it.

---

<sup>21</sup> See Oil and Natural Gas Sector: Emission Standards for New, Reconstructed, and Modified Sources Background Technical Support Document for the Final Reconsideration of the New Source Performance Standards 40 CFR Part 60, subpart OOOOa available at EPA-HQ-OAR-2017-0483-2290.

For small companies with legacy wells that would be exempt from NSPS OOOOb and EG OOOOc otherwise, the presence of an old separator or dehydrator becomes a significant burden.

Commenter (1291-CVR) suggests that there needs to be consideration for these numerous small compressor stations that will become centralized production facilities under NSPS OOOOb. With production volumes of 100 to 150 thousand cubic feet per day (Mcf/day), suction pressure of 10 pounds per square inch (psi) and discharge pressures of less than 250 psi, the potential to emit fugitive methane is very small. EPA estimates that compliance costs for a compressor station, whether large and producing 1,000 Mcf/day or a small compressor station like the commenter's producing 100 Mcf/day, is \$13,400 per year. For compressor stations that deliver 100 Mcf/day, that is an additional cost of \$0.372 per Mcf or 11.9 percent of the gross price for our gas, before any other operating costs are deducted. The commenter states that these kinds of costs would be devastating to legacy gas wells. Fields that might otherwise have decades more life would immediately become uneconomical to produce.

Commenter (1291-CVR) makes the following specific recommendations to EPA:

1. Compressor stations that include a compressors and other equipment such as a dehydrator and separator, producing less than 55 MMcf/year (average 150 Mcf per day) and have a maximum discharge pressure of 350 psi, be exempt from NSPS OOOOb regulation, specifically fugitive emission surveys and recordkeeping requirements.
2. Small compressors stations, including those with other equipment such as dehydrators and separator, producing from 55 MMcf/year (an average 150 Mcf/day) to 128 MMcf/year (an average 350 Mcf/day) be allowed a more workable and affordable fugitive emission survey program that would utilize AVO surveys, on a quarterly basis and allow simplified "in house" recordkeeping of the surveys.

Another commenter (0585-Kentucky Oil and Gas Association (KOGA)) believes that EPA is either unaware of or does not understand the impact that the proposed NSPS OOOOb regulations will have on the large number and variety of existing gathering and boosting compressor stations in the gas fields of the Appalachian Basin. According to the commenter, most of the compressor stations are operated by small locally owned companies that meet the definition of a Small Business Entity. Under the 2016 NSPS OOOOb regulations, existing compressor stations were exempt from fugitive emission surveys, but the commenter explains that NSPS OOOOb now proposes to regulate all compressor stations; even small wellhead compressors that were previously exempt. NSPS OOOOb will require small operators to implement expensive fugitive emission surveys and recordkeeping, resulting in little or no reduction of methane emissions.

Commenter (0585-KOGA) states that most of the low volume and low-pressure wells in the Appalachian Basin use a compressor to get their produced gas to market. Most of these wells consist of just a wellhead, which EPA has correctly proposed to exempt from the NSPS OOOOb or EG OOOOc regulations. The commenter explains that compressors used by the small companies are of two types, booster and field compressors. The booster compressors are typically small single stage units with low horsepower drivers connected to a well or groups of low-pressure wells that would not be able to deliver gas into a gathering system without an

external source to increase pressure, the commenter notes. A typical configuration gathers small volumes of gas at very low pressures from groups of legacy oil wells found in many areas of the Appalachian Basin. These wellhead compressors (see Figure 6 of the commenter's letter), which were exempt under the 2016 NSPS OOOOa regulations, typically move around 10 Mcf/d with a suction pressure as low as 0 psi and discharge pressures of between 8 and 20 psi. Because of the pressures at which these compressors operate, they have a very small potential for fugitive emissions and should continue to be exempt from NSPS OOOOb in the commenter's opinion. (See Figure 6 and Figure 7 of the commenter's letter for a Typical Field Booster Compressor and an example Compressor Station with Desiccant Dehydrator.)

The commenter (0585-KOGA) explains that field compressors and the stations where they are located are of almost as many configurations as there are well configurations and include gas compressors and their drivers, and often include dehydration equipment. The operating parameters and designs of compressor stations are dependent on the volume and pressure of gas available from the wells it serves, the pressure of the pipeline the gas is being delivered into, and the water content of the gas moving through it. The larger field compressor stations, which can deliver several hundred Mcf per day into gas gathering systems or transmission pipelines usually include compressors with natural gas fueled engines of 150 to 350 horsepower and include glycol dehydration equipment. The commenter indicates that by far the most prevalent compressor stations operated by the small companies in the Appalachian Basin include compressors that move between 100 and 200 Mcf/day and driven by either electric motors or natural gas fueled engines of 150 horsepower or less. The majority of these size compressor stations only have compressors and their drivers, but glycol or desiccant dehydrators may be required in cases where water content of the gas is high.

The commenter (0585-KOGA) further states that the typical Appalachian Basin small field compressor stations are not large facilities. The commenter notes that these units cannot be compared to the large, high volume and pressure compressor stations and gas processing plants associated with deep unconventional shale gas production of the Marcellus and Utica in Pennsylvania, Ohio and West Virginia, even though EPA is proposing to regulate them as if this was the case. A compressor and driver only station operated by small Appalachian Basin companies, do not have much more plumbing than a typical Appalachian Basin wellhead. The suction side plumbing will be operated at the low suction pressures of the compressor and only a very short distance of discharge plumbing is operated at discharge pressures typically less than 300 psi. As with wellheads, thread leaks or vented gas associated with the brief blowing of a drip tank at a compressor station, are not significant emission sources. The leaks can usually be identified using soap bubbles, and they can easily be corrected with a pipe wrench at the time of inspection. Even though small company compressor stations are not manned 24 hours a day, they are visited weekly, if not daily. According to the commenter, AVO surveys during these frequent visits are far more cost effective for the small companies than quarterly OGI surveys. The commenter explains that leaks do not go unnoticed for any length of time.

The commenter (0585-KOGA) suggests that EPA's estimate of 16 tons per year emissions from these small compressor stations is a dramatic overstatement of methane emissions. The

commenter reports that the Department of Energy methane emissions study, conducted by GSI Environmental Inc. (GSI) and soon to be published, found average methane emissions at the compressors they surveyed in the eastern US of 1.3 kg/day, or less than a half ton per year. The commenter contends that, because of the low suction and discharge pressures at which they are operated, compressors and compressor station equipment typical of small company operations are not large fugitive emission emitters.

Finally, the commenter (0585-KOGA) explains that the fugitive emission surveys of compressor stations using OGI as will be required under NSPS OOOOb, is a service not readily available in their area. The commenter reports that the costs to bring in the equipment necessary from other areas of the country four times a year are prohibitive. The commenter states that EPA estimates that cost to be \$13,400 per year per compressor station. For compressor stations that deliver 100 Mcf per day, that is an additional cost of \$0.372 per Mcf or 11.9 percent of a gross price for gas as estimated by EPA to be \$3.13 before any operating costs. The commenter notes that this is a significant cost for small companies making some gas fields uneconomical to continue to produce. The commenter contends that booster compressors gathering associated gas from oil wells would disappear completely.

Response I-8-6: As stated in EPA's response to comments on amendments to NSPS OOOOa in the 2020 Technical Rule,<sup>22</sup> EPA considers the booster compressors described by these commenters as part of wellsite equipment and not as a separate compressor station, even when located near a well site. A compressor station is defined, in part, as one or more compressors that move natural gas at increased pressures through gathering pipelines. Booster compressors, as described by the commenters, are used to increase the pressure of gas produced from a low pressure well so it can first enter a pipeline. These compressors are integral to the operation of the well site, and as such, are considered part of the well site. Further, as stated in the definition of a compressor station, compressors located at a well site are not considered compressor stations. Therefore, if the well site is subject to fugitive emissions monitoring, then the booster compressor would also be subject to the well site monitoring requirements.

EPA proposed a different regulatory approach for well site fugitive emissions monitoring in the December 2022 Supplemental Proposal. For details, please see discussion in section IV.A.1.ii of the December 2022 Supplemental Proposal.<sup>23</sup> Please also see section X.A of the preamble of the final rule which details EPA's final standards related to compressor station and wellsite fugitive emissions.

Comment: Commenter (0787-Atmos Energy Corporation (Atmos), 1289-AEC) recommends subcategorizing compressor stations based upon potential VOC and methane emissions, rather than natural gas throughput. The commenter states that fugitive emissions are estimated using a number of equipment components, assuming that piping components remain in service all year, and are not throughput-dependent.

---

<sup>22</sup> See Document ID No. EPA-HQ-OAR-2017-0483-2291, page 8-172.

<sup>23</sup> See 87 FR 74722 (December 6, 2022).

Response I-8-7: In the November 2021 Proposal, EPA solicited comments on whether compressor stations should be subcategorized, specifically seeking information related to throughputs where fugitive emissions of methane are demonstrated to be minimal below a certain capacity. Because EPA did not receive such information, EPA has not included subcategorization of compressor stations in the final rule. Please see section X.A.2 of the preamble of the final rule which details EPA's final standards related to compressor station fugitive emissions.

Comment: Commenter (0923-Lambda Energy Resources, LLC (Lambda)) contends it is overly burdensome to require quarterly monitoring at compressor stations in respect to surveys and recordkeeping. The commenter states that the value of increased monitoring to reduce small amounts of methane and VOCs does not offset the associated expense and manpower required to fulfill the proposed regulations. The commenter suggests that a baseline for compressor stations could be undertaken as a similar proposal for less than 3 tons per year (tpy) well sites to determine future requirements of a particular site. The commenter believes the most feasible and cost-effective solution to accomplish fugitive emission reduction is to undertake periodic AVO inspections and documentation to assess a facility or wellsite for leaks.

Response I-8-8: EPA disagrees that quarterly monitoring at compressor stations is overly burdensome. As discussed in the November 2021 Proposal, EPA evaluated the BSER for compressor stations. EPA analyzed OGI monitoring frequencies ranging between monthly and annual but determined in the November 2021 Proposal that quarterly OGI monitoring was cost effective and that additional emissions reductions could not be achieved at a reasonable cost. Therefore, EPA found in November 2021 based on the cost analysis conducted at that time, that the cost effectiveness of quarterly OGI monitoring for compressor stations is reasonable and determined to be the BSER. The December 2022 Supplemental Proposal analysis was consistent with the November 2021 Proposal determination, and EPA proposed to retain quarterly OGI monitoring for all types of compressor stations and add monthly AVO inspections. The commenter did not provide any additional data demonstrating that quarterly monitoring for compressor stations is overly burdensome. In the November 2021 Proposal, EPA solicited comments on whether compressor stations should be subcategorized, specifically seeking information related to throughputs where fugitive emissions of methane are demonstrated to be minimal below a certain capacity. Because EPA did not receive such information, EPA has not included subcategorization of compressor stations in the final rule. The commenter provided no data to support that periodic AVO alone is the most feasible and cost-effective solution to accomplish emission reductions. Even if periodic AVO alone is feasible and cost-effective, it may not be the BSER for compressor stations because additional monitoring could provide additional cost-effective emissions reductions. Please see section X.A.2 of the preamble of the final rule which details EPA's final standards related to compressor station fugitive emissions.

## 8.3 Delay of Repair/Availability of Parts

### 8.3.1 *Environmental Justice*

Comment: Commenter (1267-CA EG *et al.*) responds to the EPA solicitation of comment on delayed repairs by existing sources when parts are not readily available and must be specially ordered. The commenter recommends that EPA consider disallowing or limiting delayed repairs at facilities close to an environmental justice community.

Response I-8-9: EPA disagrees that delayed repairs should not be allowed or limited at facilities close to an environmental justice community. Unique provisions for facilities close to an environmental justice community would require defining an “environmental justice community” and “close,” which is outside the scope of this rulemaking. The commenter did not provide additional rationale supporting the need for unique provisions for facilities close to an environmental justice community. Please see section X.A.2 of the preamble of the final rule which details EPA’s final standards related to compressor station fugitive emissions.

### 8.3.2 *Allow Delay of Repair*

Comment: Commenter (1391-Interstate Natural Gas Association of America (INGAA)) responds to the EPA solicitation for comment on delayed repairs by existing sources when parts are not readily available and must be specially ordered. The commenter suggests that EPA provide for a delay of repair (DOR) that is caused by the lack of availability of parts in EG OOOOc.

Commenter (1391-INGAA) adds that the proposed rule solicits comment on delay of repair requirements to address the availability of replacement parts for existing compressor stations, an important matter that is of particular concern to the commenter and its members. As explained in the commenter’s Pre-Rulemaking Comments, which are included as Attachment 4 to the commenter’s letter, the parts necessary to repair a leak are not always readily available or in stock.<sup>24</sup> The commenter believes that EG OOOOc needs to contain a DOR provision for parts availability to avoid reliability impacts to customers and system disruptions. Including a DOR provision for parts availability is a practical necessity, sound policy, and is protective of the environment, according to the commenter. The commenter notes that its recommendations on DOR are modeled after regulations adopted by several states, including Colorado and Maryland.<sup>25</sup>

Commenter (1391-INGAA) requests the following for when DOR provisions of EG OOOOc should mirror DOR provisions in NSPS OOOOa:

- If parts are not available and need to be ordered, repair may be delayed until they are received.

---

<sup>24</sup> See INGAA Pre-Rulemaking Comments at 4-7 & Apps. A, B.

<sup>25</sup> See 5 COLO. CODE REGS. § 1001-9:D.I.L5.; MD. CODE REGS. 26.11.41.03.A(9)(c)(i)

- Once parts have been received, operators will need to schedule the repair after receipt of the replacement part to ensure that adequate skilled labor is available, the parts have been integrity tested, and the timing of the repair will not impair reliability of the natural gas system.
- If the leak cannot be repaired without a shutdown or blowdown, then EPA should allow operators to delay making a repair until the next scheduled shutdown for maintenance that occurs after the parts have been received, not to exceed two years from discovery of the leak.

Commenter (1391-INGAA) states that EPA solicited comment and data to better understand (1) the breadth of this issue with replacement parts for existing compressor stations, (2) whether 30 days following receipt of the replacement part is appropriate for completing delayed repairs at existing compressor stations, (3) whether there should be any limit on delays in repairs under these circumstances, and (4) whether this compliance flexibility should be limited or disallowed based on the severity of the leak to be repaired.

The commenter (1391-INGAA) states that equipment utilized for gas transmission is highly specialized and is made to stringent engineering specifications. Some existing source compressors may be more than 50 years old, and compressors have changed over time. If a part breaks on an older piece of equipment, the comparable part that is used for new compressors may not be the right size or configuration for that older equipment. For example, the commenter notes that the specifications of an older compressor valve might not be standard, the system associated with an older unit might have additional connections for recirculation piping, or there might be additional changes that the operator needs to make to that system to address other regulatory requirements, such as the Pipeline and Hazardous Materials Safety Administration regulations. In such cases, the commenter states that the appropriate parts for that equipment will need to be custom ordered and/or manufactured, and it may take several months to fabricate such parts. The commenter further explains the general timeframe of replacement for several parts, details of which can be found in their comment letter.

The commenter (1391-INGAA) further explains the enormity of the challenge posed by part availability for existing compressor stations by providing examples of the types of equipment and potential leak sources that are most likely at compressor stations. The commenter explains that a typical compressor house will have multiple compressors within the building and a compressor station may have several compressor houses. The appendix to their comments provides photographs and diagrams of just some of the key equipment located in these compressor houses to illustrate the scale and breadth of the issue for the industry. The examples reviewed in Appendix B begin with integral reciprocating compressors, which are common in gas transmission.<sup>26</sup> These units include flanges, cover plates, and bolted surfaces encasing natural gas, and each of these components is a potential leak source and piece of equipment that

---

<sup>26</sup> See EPA-HQ-OAR-2021-0317-1391.

may need to be replaced.<sup>27</sup> Looking at a cross-section of the integral reciprocating compressor itself, Appendix B further identifies the engine fuel system and compressors, and the flanges and cover plates associated with the compressor variable valve pockets and distance piece as additional potential leak sources.<sup>28</sup>

The commenter (1391-INGAA) goes more in-depth on valves and includes an explanation as to why keeping an inventory of parts on hand is infeasible due to the scale of the issue.

The commenter (1391-INGAA) states that, given that the number of parts that may potentially require replacement at any given facility is enormous and given that the time to obtain some of these parts can be several months, the only reasonable solution that preserves reliability of the gas supply is to include in EG OOOOc a DOR provision related to parts availability.

Response I-8-10: EPA received a similar comment on the December 2022 Supplemental Proposal. EPA's response to this comment is provided at Volume II, Chapter, 4, section 4.2.2 (Delay of Repair for Lack of Availability of Parts) .

Comment: Commenter (0787-Atmos, 1289-AEC) discusses repair timelines to avoid unnecessary emissions, as well as repairs to underground storage facilities in the full comment. The commenter supports requiring compressor station repairs in circumstances where parts are not readily available and must be special ordered to be completed 30 days following the receipt of the replacement part, provided that conducting the repair would not require a unit or wellhead shutdown.

If a shutdown is required, the commenter (1289-AEC) suggests that the repair occur during the next scheduled maintenance shutdown, especially if the emissions associated with a shutdown and startup just to repair the leak would cause more emissions than letting the leak continue until the next scheduled maintenance shutdown. The commenter agrees with other industry stakeholders that, because existing sources are older pieces of equipment, there is a higher likelihood that replacement parts will not be readily available, making lack of available parts an appropriate reason to delay a repair.

The commenter (1289-AEC) also supports keeping purchase and delivery records of the equipment that was not readily available and necessary for the repair. Likewise, if there is a delay, the commenter supports a requirement to maintain records pertaining to the delay. The company should also have records of when the repair occurred, and there should be five-year record retention requirements, thereby aligning with Clean Air Act (CAA) Title V permit renewal timelines.

Response I-8-11: EPA received a similar comment on the December 2022 Supplemental Proposal. EPA's response to this comment is provided at Volume II, Chapter, 4, section 4.2.2 (Delay of Repair for Lack of Availability of Parts). With respect to the recordkeeping

---

<sup>27</sup> Id.

<sup>28</sup> Id.

requirements, EPA agrees that records pertaining to the delay and when the repair occurred should be kept for five years. The rule specifies the recordkeeping requirements at §60.5420b(c)(14)(v)(I).

Comment: Commenter (0787-Atmos) believes EPA should exclude leak repairs that require evacuation and rewatering of an underground storage cavern from the two-year maximum delayed repair requirement because, although leaks could be repaired within two years, there may be additional emissions associated with evacuating the cavern.

Response I-8-12: EPA disagrees that leak repairs that require evacuation and rewatering of an underground storage cavern should be excluded from the two-year maximum delayed repair requirement. Both EPA and the commenter conclude that leaks could be repaired within two years; given the 2-year timeframe for repair, the commenter can plan the next shutdown for maintenance purposes in a manner that minimizes additional emissions. For these reasons, EPA is finalizing the two-year maximum delay of repair for fugitive emissions.

### ***8.3.3 Opposed to Delay of Repair***

Comment: Commenter (0844-EDF *et al.*) contends that the availability of parts is not a valid concern for compressor stations.

Commenter (0844-EDF *et al.*) asserts that replacement parts can be easily procured. The commenter states that existing compressor station owners and operators are aware they will be subject to fugitive monitoring and repair requirements in the coming years. They have at least three years to begin preparing for compliance—including by ordering and stockpiling parts they know are likely to fail and cause large leaks. The commenter contends that this is more than sufficient time for these operators to plan and avoid a situation where a component fails and they are unable to obtain that component without specially ordering it. The commenter suggests that EPA focus on ensuring major leaks are quickly fixed, and not on hypothetical parts shortages occurring in 2025 and beyond.

Commenter (0844-EDF *et al.*) adds that many of the same components and pieces of equipment exist across the oil and gas supply chain. And many of those same components and pieces of equipment are known as sources of fugitive emissions and ones that commonly malfunction. The commenter notes that compressor station operators already know which parts are likely to fail and cause fugitive emissions and will therefore require repair. And if they don't know already, they have the next three years to prepare by inspecting sites, determining which components need to be upgraded or are likely to fail, and begin ordering spare parts.

Further, commenter (0844-EDF *et al.*) believes that if EPA were to allow delayed repairs based on the availability of parts, which it should not, the delay should not be permitted for major leaks. The commenter recommends that operators at a bare minimum have at least one replacement part on hand for any major leak event. According to the commenter, this type of poor planning cannot excuse delays in the repair of large emission events. Additionally, to the

extent EPA does permit some degree of compliance flexibility due to the lack of availability of certain equipment parts, the commenter states it must require the operator to support its claim through rigorous documentation, including but not limited to: a reasonable explanation of why the operator did not have a spare part on hand; a justification of why the equipment failure was not foreseeable at any point from the date of the proposed regulations until the date of failure; proof that such failures are not common at similar compressor stations of similar age; maintenance and inspection records supporting the non-foreseeability of the failure; proof and date that the replacement part was ordered immediately upon detection; and proof that the part was installed as quickly as possible upon receipt.

Response I-8-13: EPA disagrees that availability of parts is not a valid concern for compressor stations. Similar to the delay of repair provisions related to equipment leaks from equipment located at onshore natural gas processing plants, EPA is including provisions to allow the delay of repairs due to the lack of availability of parts in specific circumstances in the final rule. As described by several commenters for this action, and in previous comments on amendments to NSPS OOOOa, there are exceptional circumstances that do occur where the repair cannot be completed successfully without replacement of a part that requires custom fabrication. Please see Volume II, Chapter, 4, section 4.2.2 (Delay of Repair for Lack of Availability of Parts) for discussion of EPA's decision to allow delay of repair due to unavailability of parts. The commenter states that replacement parts can be easily procured but does not cite underlying data demonstrating this. In contrast, other commenters give examples of the lead time that can be required for parts requiring custom fabrication, which was up to 12 months depending on the size and complexity of the part. The commenter also states that compressor station operators can order and stockpile parts that may fail but does not cite underlying data demonstrating this. In contrast, other commenters contend that it is not possible to maintain an inventory of parts to avoid delaying repairs and provide supporting information about the wide variety of equipment types, models, and ages at compressor stations. EPA also disagrees that delay of repair should be disallowed for "major leaks". In order to disallow delay of leaks for "major" repairs, the term "major leaks" would have to be defined; the commenter did not offer a definition for the term "major leaks". Additionally, EPA's reasons for allowing delay of repair for parts unavailability applies equally to all leaks. EPA agrees that an operator should support its claim of delay of repair due to unavailability of parts; however, EPA partially disagrees with which data are needed to support that claim. EPA agrees that the dates the part was ordered and installed should be required. EPA disagrees that the remaining suggested documentation should be required because the remaining criteria are unrelated to the delay of repair requirements in the final rule. Please see section X.A.2 of the preamble of the final rule which details EPA's final standards related to compressor station fugitive emissions.

## **8.4 Proposed Appendix K**

Comment: Commenters (0808-American Petroleum Institute (API), 0599-Marcellus Shale Coalition (MSC), 0817-GPA) state that the proposed appendix K requirements are burdensome and not necessary for OGI monitoring at compressor stations.

Commenter (0808-API) suggests that OGI monitoring protocols for production facilities and compressor stations should be based on NSPS OOOOa requirements, not appendix K. While the commenter supports the use of OGI, appendix K as drafted is unnecessarily burdensome for utilization in upstream production facilities, gathering and boosting compressor stations, and transmission compressor stations. The commenter notes that the requirements specified in NSPS OOOOa that are currently used by operators have consistently proven to be effective and are more appropriate for use in upstream applications. Accordingly, the commenter recommends EPA revise its November 2021 Proposal to limit the applicability of appendix K to refineries; gas plants; and, potentially, similar larger process operations in other industries.

Commenter (0808-API) includes key differences between production facilities and compressor stations versus refineries and gas plants:

- Upstream and midstream facilities are smaller, less complex, and have fewer regulated emission components. A typical well pad size is up to a few acres versus up to thousands of acres for a refinery and well sites contain tens to hundreds of components versus tens of thousands of components at a refinery.
- There are many more well sites and compressor stations. There are hundreds of thousands of well sites and compressor stations in the U.S. versus approximately 129 refineries and approximately 500 gas plants.
- Most new and existing well sites, centralized production facilities, and compressor stations are unmanned sites. Additionally, these sites are often in remote locations. Refineries and gas plants have onsite LDAR personnel.

The commenter (0808-API) lists many elements of appendix K that are impractical to implement upstream and midstream (other than gas plants).

- The dwell time and break requirements in appendix K are overly complicated, particularly for well sites, centralized production facilities, and compressor stations, where the density of fugitive emission components (number of components to view in each area) is less than for a refinery or gas plant. These dwell time and break requirements would double or triple the time required for an OGI survey and have not been demonstrated to be more effective at detecting leaks. One company estimates that 40 or more hours would be needed to conduct an OGI survey of a single site following the appendix K requirements. Unnecessarily long dwell times result in inefficient emission reductions and take time and resources away from other compliance activities with a greater environmental benefit. Furthermore, prescriptive dwell time is unnecessary and inefficient as an experienced camera operator will determine dwell time based on the circumstances that are occurring at the facility. Some components may require an extended dwell time, while other components may need less.

For these reasons noted above, the commenter (0808-API) recommends that OGI requirements for new and existing well sites, centralized production facilities, and compressor stations be based on NSPS OOOOa requirements, not appendix K.

Similarly, commenter (0599-MSD) suggests the proposed appendix K requirements for OGI surveys are overly onerous and would drastically increase the time and cost of conducting required surveys without a significant reduction in fugitive emissions. Additionally, the commenter notes that training and quality assurance requirements in the proposed appendix would result in an immediate shortage of qualified camera operators being available to conduct the required surveys. The commenter provides that they have successfully implemented OGI monitoring programs in the Marcellus region that efficiently identify and repair leaks without adding unnecessary burdens that will increase effort and cost.

According to the commenter (0599-MSD), most affected compressor stations in their region currently observe leaking components in the low single digits per survey while monitoring thousands of components present at each facility. According to the Colorado State University SU 001 Efficacy Study, there is a 60 percent increase in detection of leaks with more experienced operators and that higher rate leaks are more likely to be detected by operators with any level of experience. The commenter notes that, given the typical number of leaking components detected during a survey as noted above, increased surveys would result in very few additional leaks being detected despite the onerous additional requirements detailed in the proposed appendix K. The study also notes a 90 percent probability of detection as a threshold as opposed to 100 percent detection. See Attachment 2 of the commenter's letter for detailed comments on appendix K by section.

Commenter (0817-GPA) disagrees with significant aspects of the November 2021 Proposal's approach to equipment leaks. The commenter states that equipment leak monitoring and repair activities are already among the most resource-intensive requirements under the NSPS. Based on the November 2021 Proposal, EPA is proposing to impose a very rigid set of guidelines for OGI monitoring, outlined in proposed appendix K, without addressing the existing OGI requirements or discussing any potential need for revisions. The commenter states that they could support the use of appendix K for natural gas processing plants provided that certain revisions discussed below were implemented. Appendix K, however, according to the commenter, is unsuited for use at compressor stations. The commenter contends that, for compressor stations, appendix K would make OGI surveys extraordinarily burdensome and unnecessarily expensive. Further, even without these additional costs and burdens, the commenter believes that semiannual monitoring is the only cost-effective option.

Commenter (0817-GPA) states that appendix K would impose significant new burdens on the use of OGI at compressor stations, limiting its utility for this purpose. The commenter notes that EPA provides no explanation as to why current practices require such a significant overhaul. According to the commenter, these unwarranted burdens include the development of the operating envelope, the requirement to take breaks to avoid fatigue at such a relatively small facilities, the rigorous OGI camera operator training, and—probably most burdensome—the daily and quarterly audits. The commenter adds that these are not only a significant new burden on compressor station operators, but it eliminates much of the advantage that OGI provided over EPA Method 21. Any further proposal must definitively account for the additional costs and time

that would now be required for OGI monitoring - burdens which only create a significant disincentive against OGI monitoring.

Commenter (0817-GPA) believes it is inappropriate to apply proposed appendix K to compressor stations. Having closely reviewed appendix K, the commenter would urge EPA to reconsider its wholesale application to the midstream sector. Appendix K was developed for petroleum refineries. In a refinery setting, implementing appendix K is more feasible and cost-effective. For example, the commenter notes that refineries are more likely to be located in or near urban areas and have full-time, on-site employees or contractors to handle OGI monitoring duties. By contrast, the commenter states that compressor stations are often unmanned and located in remote areas, requiring contractors to travel to perform OGI monitoring, accompanied by operator personnel to provide access to the site.

Further, commenter (0817-GPA) suggests compressor stations have far fewer components to monitor, eliminating the economy of scale present at petroleum refineries, which often have tens of thousands of components. The commenter's data shows that gathering and boosting compressor stations would monitor an average of 1,800 components, less than half of EPA's model plant estimates. The EPA Gathering and Boosting Model Facility created for the November 2021 Proposal assumes a facility with 3,901 components.

Commenter (0817-GPA) explains that the model plant's overestimation of the number of components is important because it is the key to estimating emission reductions through OGI monitoring and the cost-effectiveness of such requirements. Unlike with a petroleum refinery, which distributes fixed monitoring overhead costs across tens of thousands of components, gathering and boosting stations will typically have less than 2,000 components.

Commenter (0817-GPA) believes that existing current OGI monitoring requirements have proven to be efficient and effective, where multiple components (*i.e.*, bolts on a tank hatch) can be scanned at a time and leaking components can be identified and tagged for repair. Under proposed appendix K, OGI camera operators would be required to view components individually from at least two different angles for a total of ten seconds.<sup>29</sup> Using the commenter's (0817-GPA) component model (1,800 components), survey time for a single facility would be five hours, with an additional 1.25 hours of breaks, one hour for calibration, and travel time. The commenter notes that, combined with increasing the frequency of monitoring and audit requirements, facility operators will expend substantially more time on OGI monitoring. Further, as explained in more detail below, the commenter contends that appendix K would add significant new costs through new audit requirements and needing to use contractors instead of in-house personnel. The commenter explains that the midstream industry uses OGI monitoring at compressor stations due to the efficiencies it can provide over EPA Method 21. The proposed appendix K, when applied to compressor stations, eliminates that utility.

---

<sup>29</sup> The minimum dwell time appears to be ten seconds per component but, as described below, appendix K appears to provide conflicting dwell times.

Further, as described below, there are a number of other inconsistencies, questions, and issues with proposed appendix K that the commenter (0817-GPA) urges EPA to consider fully before moving forward to include appendix K as a required element of OGI monitoring. According to the commenter, these issues not only incorporate significant uncertainty into OGI monitoring, but unnecessarily increase time and costs while reducing the utility of using OGI. Importantly, the commenter states that the November 2021 Proposal provides no explanation as to why it proposes to dramatically revise existing OGI monitoring requirements by the incorporation of instructions at the level of detail in appendix K. The commenter recommends that EPA reassess the rationale for making the change and provide that information to stakeholders to allow for adequate opportunity to comment.

Response I-8-14: In response to comments received on the November 2021 Proposal, EPA proposed a different regulatory approach for fugitive emissions monitoring methods in the December 2022 Supplemental Proposal. See discussion in section IV.A.1.a.ii of the December 2022 Supplemental Proposal related to the use of Appendix K at compressor stations.<sup>30</sup> Please also see 2021 Response to Comment Chapter 22 for additional responses to this comment regarding cost estimates and operator training.

Regarding the estimation of the number of components at gathering and boosting stations, EPA did use the component count for gathering and boosting compressor stations provided by GPA Midstream in comments located at Docket ID EPA-HQ-OAR-2021-0317 in the calculations. For further information on component counts, please see the Final TSD.

Comment: Commenter (0817-GPA) suggests that the November 2021 Proposal underestimates appendix K's cost for compressor stations. The commenter suggests that EPA re-evaluate the full costs that would be associated with requiring appendix K for compressor stations surveys, as it does not appear that the November 2021 Proposal's TSD accounted for several costs. The commenter reports that these include, but are not limited to, increased rates for contractors with camera expertise, quarterly comparative audits, side-by-side audits, training and re-training requirements, additional hours and personnel to conduct surveys, and data storage. The commenter explains that these costs will be even higher if EPA maintains the proposed operating envelope with respect to wind speed. As explained in more detail below, the commenter notes that rural locations where midstream facilities are often sited frequently experience winds far above the operating envelope requirements. This is likely to require contractors to make multiple visits before finding a day where surveys could be performed. Further, the commenter adds, unlike with petroleum refineries, because compressor stations tend to be unmanned and located in remote areas, EPA should factor in travel costs for both the contractor camera operators and facility employees who must provide access to the site.

Moreover, the commenter (0817-GPA) asserts that any cost estimate must assume an even greater increase in contractor costs for compressor stations. The commenter states that, establishing a 500-survey requirement to qualify as an OGI senior camera operator effectively

---

<sup>30</sup> 87 FR 74722 (December 6, 2022).

rules out the use of in-house personnel for this role at compressor stations. According to the commenter, this means that operators will have to rely on a relatively limited number of contractors, increasing rates due to the increased demand and, for the foreseeable future, relatively small supply of qualified camera operators and senior camera operators. The commenter notes that increased contractor costs carry over to, not just the surveys themselves, but the cost of auditing requirements, side-by-side audits (involving two camera operators), and training and retraining requirements. In fact, the requirement for OGI senior camera operators to train other operators, *see* Appx. K §§ 10.2.2.110.2.2.4, and perform quarterly audits, in addition to component monitoring duties, would dramatically increase the demand for the relatively limited pool of OGI senior camera operators while simultaneously slowing the qualification of new OGI senior camera operators.

The commenter (0817-GPA) urges EPA to consider reducing these measures. For example, the commenter recommends that EPA eliminate the requirement for quarterly auditing through comparative monitoring for every camera operator. *See* Appx. K §§ 10.4-10.4.1.2. This involves two camera operators – one of them being an OGI senior camera operator —performing the same survey of at least four hours, every quarter, which will impose a significant additional cost. Similarly, the commenter recommends that EPA eliminate the requirement to record a five-minute quality assurance verification video that documents dwell times, angles, distances, and background at least once each monitoring day. According to the commenter, this requirement is unduly burdensome and continues to add to the recordkeeping nightmare that appendix K, as written, will create. At a minimum, EPA should document for stakeholders why these multiple layers of requirements are justified.

Finally, it does not appear that EPA’s cost estimates in the TSD accounted for any of the additional costs the commenter (0817-GPA) has identified above. The commenter states that EPA notes in section 12.5.4 of the November 2021 Proposal TSD that it did not update the costs associated with OGI monitoring other than adjusting for inflation and updating annual recordkeeping cost. The commenter asserts that this is inappropriate given that proposed appendix K would dramatically change how OGI monitoring would be performed in a way that would significantly increase costs. The commenter requests that EPA provide an updated cost analysis that includes the increased costs involved in following appendix K at midstream facilities, as described above. Due to the significant additional costs, the commenter also suggests that EPA re-assess the cost effectiveness of OGI monitoring under Appendix K for compressor stations prior to selecting a final frequency for leak surveys.

Response I-8-15: In response to comments received on the November 2021 Proposal, EPA proposed a different regulatory approach for fugitive emissions monitoring methods in the December 2022 Supplemental Proposal. *See* discussion in section IV.A.1.a.ii of the December 2022 Supplemental Proposal related to the use of Appendix K at compressor stations.<sup>31</sup> Please

---

<sup>31</sup> 87 FR 74722 (December 6, 2022).

also see Volume II, Chapter 22, section 22.9.2 (Burden and Cost) for additional responses to this comment regarding cost estimates and operator training.

## 8.5 Other Comments

### 8.5.1 *Fugitive Emissions Definition*

Comment: Commenter (0414-Waterspirit) urges EPA to include all methane emissions within the fugitive emissions definition of the proposed rule, including the unburned methane emitted from exhaust smokestacks from natural gas fired compressor units, generators, and boilers located at many compressor station facilities.

Commenter (0427-Private Citizen) urges EPA to include all methane emissions from all methane sources, including the unburned methane emitted out of the exhaust smokestacks from natural gas fired compressor units, generators and boilers located at many compressor station facilities along the natural gas supply chain. The commenter states that the November 2021 Proposal appears to be primarily focused on fugitive sources for methane emissions, citing the following related to fugitive emissions sources:

“As natural gas is comprised primarily of methane, every natural gas leak, or intentional release of natural gas through venting or other processes, constitutes a release of methane.” (86 FR 63114)

“Fugitive emissions component” is proposed to be any component that has the potential to emit fugitive emissions of methane and VOC at a well site or compressor station, including valves, connectors, PRDs, open-ended lines, flanges, all covers and closed vent systems, all thief hatches or other openings on a controlled storage vessel, compressors, instruments, meters, natural gas-driven pneumatic controllers or natural gas-driven pumps. However, natural gas discharged from natural gas-driven pneumatic controllers or natural gas-driven pumps are not considered fugitive emissions if the device is operating properly and in accordance with manufacturers specifications. Control devices, including flares, with emissions resulting from the device operating in a manner that is not in full compliance with any Federal rule, State rule, or permit, are also considered fugitive emissions components.<sup>32</sup>”

The commenter (0427-Private Citizen) notes that it is not clear that any of the above two cited references specifies or includes unburned methane emissions from the exhaust of natural gas fired combustion units, such as natural gas fired turbines. They explain that all compressor stations that use natural gas fired turbines emit unburned methane in the exhaust of the turbine, according to the commenter, and the emissions of unburned natural gas in the turbine exhaust ranges from 10 to 20 tons per year per turbine. In applications to Federal Energy Regulatory Commission (FERC) in 2018 and earlier, transmission pipeline companies used to identify this

---

<sup>32</sup> 86 FR 63170.

methane emissions from the turbine exhaust as methane. In recent FERC applications, transmission companies have reported this emission as unburned hydrocarbons (UHC). In the new UHC format, UHC consists of 20 percent VOC and 80 percent methane.

The commenter (0427-Private Citizen) asserts that since the methane was not burned by the turbine and escaped into the exhaust as methane, the commenter proposes that this methane emissions should also be considered as “fugitive methane emissions” and included in the component list of fugitive emissions. Either way, the commenter urges EPA to spell out this methane emissions source since some state agencies (*e.g.*, New Jersey Department of Environmental Protection), do not even recognize that methane is emitted in the smokestack of a natural gas fired turbine. In the commenter’s opinion, all agencies should be aware of this source and enforcing emissions monitoring of this source.

As an example of methane emissions in the exhaust, the commenter (0427-Private Citizen) includes two snapshots in the Appendix taken from FERC Docket CP21-95, Transco Regional Energy Access Expansion project. The second snapshot details the emissions of a Solar MARS 100 turbine. It shows the turbine as emitting 18.37 tons of UHC per year and below in the table, it specifies 80 percent of that emission as methane in 14.70 tons released in the exhaust of the solar turbine as unburned methane emission per year. This is just an estimate and greatly depends on the operational efficiency of the natural gas turbine. Over time, this unburned methane emission can increase in output.

The commenter (0427-Private Citizen) urges EPA to ensure all methane emissions from all sources at all facilities in the natural gas and oil supply chains are incorporated into the methane emissions for each facility. Especially including the methane emissions from natural gas fired units in the exhaust.

Response I-8-16: This comment on unburned methane exhausted from natural gas fired compressors, generators, and boilers (combustion slip) is outside the scope of this rulemaking. Combustion slip is addressed via other regulations, including the National Emission Standards for Hazardous Air Pollutants for Reciprocating Internal Combustion Engines (40 CFR part 63, subpart ZZZZ), New Source Performance Standards for Stationary Compression Ignition Internal Combustion Engines (40 CFR part 60, subpart IIII), and New Source Performance Standards for Stationary Spark Ignition Internal Combustion Engines (40 CFR part 60, subpart JJJJ).

### ***8.5.2 Independently Funded Monitors and FLIR Cameras***

Comment: Commenter (0414-Waterspirit) requests that EPA mandate independently funded monitors and FLIR cameras at all facilities to standardize and capture emissions.

Response I-8-17: Independently funded monitors and FLIR cameras at all facilities was not determined to be the BSER; the BSER is defined separately for each type of source.

## Chapter 9. Storage Vessels

### 9.1 General Support/Opposition

Comment: Commenter (0437-New York Office of the State Comptroller (NYOSC)) supports the proposed measures to require emissions reductions from storage tank batteries. Commenters (0781-National Tribal Air Association (NTAA), 0943-Sault Ste. Marie Tribe of Chippewa Indians, Sault Tribe Environmental Department (Sault EPD), 0391-Keweenaw Bay Indian Community (KBIC), 0605-Muscogee (Creek) Nation, 0444-Damascus Citizens for Sustainability (DCS), 0833-Environmental Programs Department, Ute Mountain Ute Tribe (Ute EPD), 1267-California Office of the Attorney General (CA AG) *et al.*) also generally support the proposed measures to require emission reductions from storage tank batteries. Commenters (0781-NTAA, 0605-Muscogee (Creek) Nation) support the strengthening of compliance requirements and monitoring for tank hatches or openings. Commenter (0444-DCS) states that the new rule will also go a long way to meeting U.S. obligations under the Global Methane Pledge, which requires a reduction of methane emissions by 30 percent by 2030. Commenters (0727-Oklahoma Secretary of Energy and Environment (OSEE) and Oklahoma Department of Environmental Quality (ODEQ), 0844-Environmental Defense Fund (EDF) *et al.*, 0789-Pennsylvania Department of Environmental Protection (PA DEP), 0425-Darrah Oil Company, LLC (Darrah)) support EPA's November 2021 Proposal to move away from calculating the potential to emit (PTE) for each storage vessel individually towards calculating the PTE based on each tank battery. One commenter (0727-ODEQ/OSEE) states that doing so would improve the ability of industry to determine if a well site/compressor station is an affected facility and would also improve the ability of regulatory agencies to determine compliance with federally enforceable limits, lessening confusion for all parties and allowing for a more straightforward determination of applicable requirements. The commenter (0727-ODEQ/OSEE) states that this would align with their practice to limit emissions from new and existing storage vessels and tank batteries, including their use of a successfully piloted low-emission storage tank design that further maximizes gas recovery, eliminates the need to flare tank vapors during normal operation and minimizes emissions through a reduction in the number of potential leak sources, as well as components that can lead to common equipment failures, including open thief hatches.<sup>1</sup>

Commenter (0808-American Petroleum Institute (API)) supports the proposed 6 tons per year (tpy) VOC threshold for a single storage vessel or tank battery affected facility at completely new well sites, centralized production facilities, and compressor stations. The commenter also generally supports EPA's November 2021 Proposal for 95 percent emission reduction for existing storage vessels and tank batteries with potential methane emissions of 20 tpy or more under EG OOOOc.

Commenter (0817-GPA Midstream Association (GPA)) generally supports the proposed 6 tpy VOC threshold for storage vessels, and the retention of a 95 percent control efficiency standard.

---

<sup>1</sup> [https://www.devonenergy.com/documents/Sustainability/DVN\\_2021\\_SustainabilityReport.pdf](https://www.devonenergy.com/documents/Sustainability/DVN_2021_SustainabilityReport.pdf).

The commenter does not oppose a threshold of 20 tpy for methane emissions from existing storage vessels but cannot support a lower threshold.

Commenter (0831-American Exploration and Production Council (AXPC)) generally supports EPA's approach to regulate storage vessels as a single storage vessel or tank battery and does not take issue on the 6 tpy VOC threshold for completely new sites and a 20 tpy threshold for existing sites.

Several commenters (0844-EDF *et al.*, 0425-Darrah, 0831-AXPC, 1267-CA AG *et al.*) support the proposed amended definition of "storage vessel" to include tank batteries. Commenter (0844-EDF *et al.*) notes it is a marked improvement over the current regulations, which define storage vessel affected facilities based only on an individual vessel's PTE and allows for tanks within the same battery to be treated separately, either as an affected facility (and thus subject to NSPS OOOO) or not (and thus subject to no standard).

Commenter (0425-Darrah) supports the tank battery approach instead of determining applicability for individual tanks, noting that the tanks work together, not separately, and thus should be considered as emission sources in that way. The commenter further states that separating storage vessel affected facilities into [single] vessels will only create confusion and unnecessary burdensome work in compliance and monitoring.

Response I-9-1: EPA acknowledges the commenters support. Comment is a supportive comment on an aspect of the November 2021 Proposal that has remained unchanged in the final rule; as such, no response is required.

Comment: Commenter (0777-Ascent Resources, LLC (Ascent)) recommends that EPA retain the current practice of basing applicability on the individual storage vessel. The commenter adds that if EPA seeks to extend the 95 percent control requirement to additional tanks that are not currently considered affected facilities under NSPS OOOO or NSPS OOOOa, they recommend that EPA propose a different emissions threshold for individual storage vessels and justify that the 95 percent control requirement for those individual storage vessels will be cost-effective. The commenter rationalizes that determining the applicability of the rule on an individual vessel-by-vessel basis will help avoid unreasonable capture and control requirements for small vessels that are part of a larger tank battery and will assist owners and operators in assessing the potential need to install NSPS OOOOb or EG OOOOc compliant emissions controls, when evaluating the purchase and construction of a storage vessel.

Response I-9-2: EPA disagrees with the commenter that there needs to be a different applicability threshold for a tank battery. While both NSPS OOOO and NSPS OOOOa define individual storage vessels as affected facilities if they exceed the applicability threshold of 6 tpy VOC (potential for emissions), EPA has provided clear rationale and basis for treating all storage vessels in a tank battery, as defined in the rule, as a single unit for purposes of determining applicability. The final rule defines a tank battery as a "group of all storage vessels that are manifolded together for liquid transfer. A tank battery may consist of a single storage vessel if only one storage vessel is present." While not clear in the comment, EPA believes that this definition would alleviate any concern of small tanks being subject to control when part of a

large battery if those small tanks are not manifolded together for liquid transfer. For the EPA analysis of cost effectiveness for storage vessels, the Docket Item No. EPA-HQ-OAR-2021-0317-0039. In this analysis EPA addresses the applicability threshold for tanks and tank batteries with respect to the cost of controls on single tanks with emissions of 6 tpy VOC and 20 tpy methane.

## 9.2 Applicability

### 9.2.1 Definition of Storage Vessel

Comment: Commenter (0817-GPA) requests that the definition of “storage vessel” in NSPS OOOOb match the definition found in the existing NSPS OOOOa rule as the November 2021 Proposal does not discuss any definition of “storage vessel.”<sup>2</sup> The commenter states that EPA’s prior record on the definition of storage vessel began with an overly broad view of what constitutes a storage vessel, such as including flow through vessels, process vessels, and tanks storing materials with little or no potential for VOC emissions, such as used oil, glycol, or molecular sieve,<sup>3</sup> but subsequently corrected the “storage vessel” definition in NSPS OOOOa to be consistent with that provided in 40 CFR 63.671: “a tank or other vessel that contains an accumulation of crude oil, condensate, intermediate hydrocarbon liquids, or produced water....” See 81 FR 35824 and 35936 (June 3, 2016) (codified at 40 CFR 60.5430a). The commenter explains that confirming that EPA will use the NSPS OOOOa definition will provide continuity and certainty to regulated entities.

Response I-9-3: The final rule for NSPS OOOOb defines storage vessel as follows:

*Storage vessel* means a tank or other vessel that contains an accumulation of crude oil, condensate, intermediate hydrocarbon liquids, or produced water, and that is constructed primarily of nonearthen materials (such as wood, concrete, steel, fiberglass, or plastic) which provide structural support. A well completion vessel that receives recovered liquids from a well after startup of production following flowback for a period which exceeds 60 days is considered a storage vessel under this subpart. A tank or other vessel shall not be considered a storage vessel if it has been removed from service in accordance with the requirements of §60.5395b(c)(1) until such time as such tank or other vessel has been returned to service. For the purposes of this subpart, the following are not considered storage vessels:

- (1) Vessels that are skid-mounted or permanently attached to something that is mobile (such as trucks, railcars, barges, or ships), and are intended to be located at a site for less than 180 consecutive days. If you do not keep or are not able to produce records, as required by §60.5420b(c)(5)(iv), showing that the vessel has been located at a site

---

<sup>2</sup> The Proposed Rule states that it is carrying over some definitions from NSPS OOOOa to proposed NSPS OOOOb, such as “well site,” 86 Fed. Reg. at 63,165, but does not mention other definitions. Absent some statement that all definitions from NSPS OOOOa will be used in NSPS OOOOb, selectively carrying over some definitions but not others creates uncertainty for owners and operators.

<sup>3</sup> For instance, in its 2012 NSPS OOOO rulemaking, EPA defined a storage vessel as one that is “designed to contain an accumulation of liquids and other materials.” 77 Fed. Reg. 49,490, 49,566 (Aug. 16, 2012).

for less than 180 consecutive days, the vessel described herein is considered to be a storage vessel from the date the original vessel was first located at the site. This exclusion does not apply to a well completion vessel as described above.

- (2) Process vessels such as surge control vessels, bottoms receivers, or knockout vessels.
- (3) Pressure vessels designed to operate in excess of 204.9 kilopascals and without emissions to the atmosphere.

This same definition is also included in the final EG OOOOc, with reference to specific sections in the model rule language for EG OOOOc replacing the NSPS OOOOb references. Other than these references the definition is identical to the definition in NSPS OOOOa.

### **9.2.2 Definition of Tank Battery**

Comment: Commenters (0810-The Petroleum Alliance of Oklahoma (Petroleum Alliance-OK), 0814-Independent Petroleum Association of America (IPAA) *et al.*, 0817-GPA) are concerned with the use of the term “adjacent” in the definition of tank battery. Commenters (0810-Petroleum Alliance-OK, 0817-GPA) recommend not including this term as it is vague and unclear, and commenter (0814-IPAA *et al.*) believes that both EPA and Title V sources understand the challenges and problems with defining and understanding what “adjacent” means. By way of example, commenter (0810-Petroleum Alliance-OK), explains that tanks on a site may receive fluids from the same source but are separated by significant distances for various reasons such as safety. The commenter suggests that these types of tanks should undergo a separate emission calculation as compared to the tanks manifolded together elsewhere on the location.

Commenter (0817-GPA) states that any proposal to aggregate “physically adjacent” storage vessels, or groups of storage vessels, is problematic because, among other reasons, adjacency is not defined. The commenter is concerned that this deprives owners and operators of fair notice as to what is required, let alone the certainty that is essential for operations and planning. The commenter provides by way of example, that it is not clear how close the tanks would have to be to be deemed adjacent—such as whether two tanks on opposite sides of a facility would be considered “physically adjacent.” Using this type of vague term, the commenter explains, would leave it open for interpretation, which leads to uncertainty and inconsistent application of the regulation. The commenter reminds EPA that when a similar concept of “adjacency” was left to interpretation in other contexts under air regulations, different EPA inspectors and different states interpreted “adjacent” differently, resulting in disputes, permit challenges, extensive EPA investment of time in explanatory guidance that did not provide real clarity, and costly litigation—that ultimately found against EPA. *See Summit Petroleum Corp. v. U.S. EPA*, 690 F.3d 733 (6th Cir. 2012) (rejecting EPA’s interpretation of “adjacent” with respect to aggregating oil and gas wells into a single source). The commenter urges EPA to avoid this thicket and remove the term “physically adjacent.” The commenter further states that regardless, even where equipment are truly immediately adjacent to one another under a realistic, physical sense, EPA has proffered no justification for considering them to be a single emission source, simply due to physical proximity and having throughput from the “same source,” and has offered no data or other evidence to suggest this definition would provide any meaningful benefit in the form of material emissions reductions warranting additional regulation. The commenter explains

that storage vessels may be arranged this way merely due to the size of and space available at a particular location, yet they are entirely independent emission sources, meaning that one can be removed from service without affecting the other. The commenter states that if storage vessels operate independently, then they should be treated as separate equipment and separate affected facilities. Further, the commenter states that EPA should limit the definition to encompass vessels that are manifolded together for liquid transfer—not for vapor transfer. The commenter believes that it is inappropriate to assume that because multiple storage vessels share a vapor header, they should be considered the same source; explaining that multiple sources routinely share a common closed vent system for routing emissions to a control device, including other non-tank sources. By way of example, the commenter provides that if a storage vessel shares the same closed vent system as a pneumatic pump, this does not justify considering the storage vessel and pneumatic pump as the same source and is equally true for storage vessels that share a common vapor header but operate independently. The commenter also is concerned that if sharing a common vapor header would make storage vessels subject to new source regulation, operators could respond by using multiple (and therefore inefficient) vapor collection systems. Finally, the commenter states that limiting the scope to vessels manifolded together for transferring liquids is consistent with the approach taken by states<sup>4</sup> that have considered the issue.

Commenters (0831-AXPC, 1267-CA AG *et al.*) generally support EPA's approach to regulate storage vessels as a single storage vessel or a tank battery affected facility. However, the commenter (0831-AXPC) does have concerns with the definition of tank battery as they believe it is overly complex and would create confusion potentially leading to unintended consequences. Commenters (0831-AXPC, 0814-IPAA *et al.*, 0810-Petroleum Alliance-OK, 0817-GPA) suggest a clearer delineation, would be a definition of tank battery based on tanks that are manifolded by liquid line (and not by vapor line) as per the modified definition offered below, which commenter (0831-AXPC) states would avoid confusion around applicability and align with existing state programs.

Commenter (0808-API) also suggests the proposed definition of tank battery should be based on manifolded tanks by liquid line. EPA's November 2021 proposed definition of a tank battery is overly complex given the objective of including a tank battery as a storage vessel affected facility. Based on the definition of a "storage tank" in Colorado Regulation 7, "manifolded by liquid line" is a simple and clear criterion for defining a group of storage vessels as a tank battery. The Colorado Air Quality Control Commission established a definition for a "storage tank" for Regulation 7 by expanding upon the definition of a storage vessel in NSPS OOOO and OOOOa to include storage vessels manifolded together by liquid line. The other criteria (e.g.,

---

<sup>4</sup> For example, Colorado Regulation 7 recognizes that storage tank batteries manifolded via liquids lines are appropriately combined as one source because the smaller vessels could be effectively replaced with one larger vessel. The same is not necessarily true about vessels sharing a common vapor header or merely physically adjacent and receiving liquids from the same source. In 2014 revisions to Regulation 7's definition of "storage tank," the Colorado Department of Public Health and Environment Air Quality Control Commission explained that to "further clarify the concept of manifolded within the definition of 'storage tank,' the Commission revises the definition of storage tank to specify that a storage tank battery must be manifolded by liquid line, and not just by gas or emission line. This revision is in keeping with the rationale that a single tank could have been used to capture liquids in place of multiple small storage tanks in a battery." See Code of Colorado Regulations, 5 CCR 1001-9-F, Statements of Basis, Specific Statutory Authority and Purpose (Dec. 21, 1995).

physically adjacent, manifolded for vapor transfer) in EPA's November 2021 proposed definition would cause potential confusion around applicability. The commenter offers a suggested definition of a tank battery edit based on EPA's November 2021 proposal language as follows:

The EPA proposes to define a tank battery as a group of storage vessels that are physically adjacent and that receive fluids from the same source (e.g., well, process unit, compressor station, or set of wells, process units, or compressor stations) or which are manifolded together for liquid or vapor transfer.

Commenter (1421-DePuy Oil and Gas Co. (DePuy)) states that NSPS OOOOa, NSPS OOOOb, and EG OOOOc are duplicative as they relate to storage tanks and other equipment used in emissions calculations for baseline methane emissions. The commenter states that there is overlap of single tanks at a well site versus storage tanks at a central facility and requests that EPA provide clarity on how to address this. The commenter is concerned that any overlap of tank emissions calculations or calculations related to other well site equipment artificially increases the calculation of baseline emissions.

Response I-9-4: See discussion in section IV.J.1.b of the December 2022 Supplemental Proposal.<sup>5</sup>

With respect to the determination of baseline methane emissions, in the November 2021 Proposal, EPA requested comment on whether facilities should use uncontrolled PTE calculations for their storage vessels in their site-level baseline estimates for determining the frequency of monitoring of fugitive emissions components at well sites. This determination is separate and distinct from the determination under 60.5365b(e)(2). EPA is not finalizing a site-level baseline emissions threshold for fugitives monitoring. See section IV.A.1.a.ii of the December 2022 Supplemental Proposal for discussion and responses to comments regarding site-level baseline emissions.<sup>6</sup>

### ***9.2.3 Definition of Centralized Production Facility***

Comment: Commenters (0847-Mull Drilling Company, Inc. (Mull), 0881-O'Neal Oil & Gas Company (O'Neal), 0598-Countrymark Energy Resources, LLC (CER), 1085-Small Operator Society LLC (SOS), 1331-C. I. McKown & Son, Inc. (McKown), 0938-TXOGA Texas Oil & Gas Association (TXOGA)) state that the final rule needs to clarify the difference between a storage vessel/tank battery and a centralized production facility. Commenter (0847-Mull) questions how EPA plans to treat them for inspection purposes as it has huge implications for the inspection process, time, and cost.

Commenter (0598-CER) states some of their facilities partially meet the definition of a centralized tank battery, but not the complete definition and based on experience with NSPS

---

<sup>5</sup> 87 FR 74800 (December 6, 2022).

<sup>6</sup> 87 FR 74724-74725 (December 6, 2022).

OOOOa, meeting some of the definition does not necessarily mean the facility is exempt from the definition.

Response I-9-5: The final rules define tank batteries and centralized production facilities at §60.5530b as follows:

*Tank battery* means a group of all storage vessels that are manifolded together for liquid transfer. A tank battery may consist of a single storage vessel if only one storage vessel is present.

*Centralized production facility* means one or more storage vessels and all equipment at a single surface site used to gather, for the purpose of sale or processing to sell, crude oil, condensate, produced water, or intermediate hydrocarbon liquid from one or more offsite natural gas or oil production wells. This equipment includes, but is not limited to, equipment used for storage, separation, treating, dehydration, artificial lift, combustion, compression, pumping, metering, monitoring, and flowline. Process vessels and process tanks are not considered storage vessels or storage tanks. A centralized production facility is located upstream of the natural gas processing plant or the crude oil pipeline breakout station and is a part of producing operations.

A tank battery may be located at or on a centralized production facility, but the affected facility status of any fugitive emissions components located at the centralized production facility does not impact the affected facility status of the storage vessels or tank batteries that are located at the centralized production facility. To determine if a tank battery is an affected facility for purposes of the control requirements in §60.5395b, owners/operators must calculate the potential for VOC and potential for methane emissions as specified in §60.5365b(e). If the potential for emissions exceeds the applicability thresholds (6 tpy VOC or 20 tpy methane), then the tank battery is a storage vessel affected facility.

#### **9.2.4 NSPS K, Ka, and Kb**

Comment: Commenter (0938-TXOGA) suggests that EPA include a clarification that storage vessels at well sites and centralized production facilities are subject to NSPS OOOOb (if new, constructed, or modified) and EG OOOOc (if existing) instead of NSPS K, Ka, or Kb.

Commenter (0808-API) also supports the proposed alternative approach to specify, within NSPS OOOOb and EG OOOOc, that storage vessels at well sites and centralized production facilities are subject to requirements in those regulations instead of NSPS K, Ka, or Kb, as the commenter believes that this approach provides a clearer path for determining regulatory applicability for storage vessels in the production segment. The commenter notes that some storage vessels at production facilities store liquids that do not contain dissolved gases and for those tanks, facilities could still opt to control emissions using a floating roof, as is currently allowed under NSPS OOOOa (See 40 CFR 60.5395a(b)).

Response I-9-6: In the 2021 proposal, in response to questions regarding whether NSPS Kb would apply to storage vessels at oil and gas centralized production facilities, the EPA discussed

the history of an exemption in NSPS Kb and solicited comment on “whether it would be more appropriate to specify within the proposed NSPS OOOOb and EG OOOOc that storage vessels at well sites and centralized production facilities are subject to the requirements in NSPS OOOOb and EG OOOOc instead of NSPS K, Ka, or Kb.” 86 FR 63184. However, EPA did not propose, and therefore has not included in the final rule, any clarifying statements on this matter. The EPA continues to believe that the applicability of, and any exemption from, standards in a rule is best specified in that rule or its rulemaking record in order to provide clarity and adequate notice. The EPA notes that October 4, 2023, the EPA published a proposed subpart Kc based on its review of NSPS Kb pursuant to CAA section 111(b).<sup>7</sup> To the extent further clarification is needed regarding the applicability of NSPS K, Ka, or Kb, an owner or operator may also request that EPA make an applicability determination for any specific storage vessels. Finally, as the commenter points out the final rule allows the use of a floating roof for compliance with the standards for storage vessel affected facilities at 40 CFR 60.5395b(b)(2) where the storage vessel affected facility is not located at well sites or centralized production facilities and where flash emissions are not a concern. In contrast a floating roof tank cannot be used at production and centralized production facilities because flashing emissions are of concern for storage vessels at production and centralized production facilities. The final OOOOb and OOOOc (and OOOO and OOOOa before them) standards require the use of a closed vent system, control device, and fixed roof for storage vessel affected facilities at well sites or centralized production facilities and preclude the use of a floating roof tank to meet compliance requirements.

### ***9.2.5 Emissions Threshold for Tank Battery Applicability***

Comment: Several commenters (0789-PA DEP, 0781-NTAA, 0943-Sault EPD, 0844-EDF *et al.*, 0832-New Mexico Environment Department (NMED), 0715-Dayenu Circle of Jewish Silicon Valley (DCJSV), 0391-KBIC, 0605-Muscogee (Creek) Nation, 0444-DCS, 0833-Ute EPD, 1267-CA AG *et al.*) recommend that EPA use a lower emissions threshold for determining applicability for tank batteries.

Commenter (0789-PA DEP) recommends a single 2.7 tpy threshold for VOC emissions based on potential emissions, which has been used by the commenter for applicability since 2013 and it has proven to be successful, as opposed to the proposed bifurcated thresholds for VOC emissions (potential to emit limit of 6.0 tpy or actual emissions of 4.0 tpy).

Commenters (0781-NTAA, 0943-Sault EPD, 0391-KBIC, 0605-Muscogee (Creek) Nation, 0833-Ute EPD) suggest that EPA apply the requirements to storage tanks with potential to emit of 4 tpy or more of VOC rather than 6 tpy for new sources and a lower threshold such as 12 tpy of methane rather than 20 tpy for existing sources.

Commenter (0844-EDF *et al.*) states that based on what the states with heavy oil and gas development have required, or proposed, in their storage vessel requirements, EPA’s November 2021 proposed applicability thresholds are too high and must be lowered. The commenter believes that EPA’s high thresholds are based on unrealistically high estimates for the costs of emission controls for tanks, compared to the emission control costs estimates used by the states. The commenter surmises that EPA’s reasoning for the proposed high control thresholds of 6 tpy

---

<sup>7</sup> See 88 FR 68535 (October 4, 2023).

for VOC for new and modified tanks and 20 tpy for methane for existing tanks arises from EPA's very high estimate of the costs of tank controls. The commenter provides, by way of example, that EPA estimates (*i.e.*, the annualized cost of a combustor to control tank emissions is \$31,552 at a new site and \$34,166 at an existing site<sup>8</sup>) for even the lowest-emitting sites are more than a factor of four higher than the cost estimates used by Colorado in support of its rulemaking for existing tanks. The commenter recommends that EPA re-examine its methodology for estimating the costs of controls for tanks and consider lower thresholds for control of new and existing tanks.

By further way of example, the commenter (0844-EDF *et al.*) references the State of Colorado (CO), Wyoming (WY), Pennsylvania (PA), California (CA) and New Mexico (NM). The commenter states that notably, when CO lowered its applicability threshold to 2 tpy in 2019, CO performed a cost-effectiveness analysis for three different applicability thresholds (2-3 tpy; 3-4 tpy; and 4-6 tpy), looking at four different classes of storage vessels.<sup>9</sup> In Figure 19 ("Average Control Cost (\$/ton VOC)") of their letter, the commenter summarizes the results of the analysis performed by CO, and states that CO found that control of all tanks with actual uncontrolled emissions over 2 tpy was cost-effective in every single class of storage vessel the state looked at<sup>10</sup> and that even looking at the lowest threshold of 2-3 tpy, every class of tank was cost-effective to control. The commenter (0844-EDF *et al.*) also references requirements in WY where any new<sup>11</sup> or existing<sup>12</sup> storage vessels with potential flash emissions exceeding 4 tpy in the Upper Green River Basin Nonattainment Area are required to be controlled by destroying VOC by 98 percent; and since at least 2013, requires the control of all flash emissions from any new<sup>13</sup> storage vessels located at a new site statewide with more than one well producing any significant amount of associated gas, without any applicability threshold.<sup>14</sup>

In PA, the commenter (0844-EDF *et al.*) reports that since 2013 all new storage tanks emitting more than 2.7 tpy of VOC at production sites are required to be controlled<sup>15</sup> and the VOC applicability threshold was extended to new storage vessels at natural gas compressor stations and processing plants in 2018.<sup>16</sup> The commenter also cites the State of California, which requires

<sup>15</sup> Pennsylvania Dept. of Environ. Protection (2018), General Plan Approval And/Or General Operating Permit GP5A, Section E(1)(b), (c).

<sup>16</sup> Pennsylvania Dept. of Environ. Protection (2018), General Plan Approval And/Or General Operating Permit GP5, Section E(1)(b).

control of new and existing tanks emitting more than 10 metric tpy of methane,<sup>17</sup> which the commenter states is comparable to EPA's November 2021 proposed applicability threshold of 20 short tpy of methane for existing tanks. Finally, the commenter references NM's proposed regulations that would require the control of new tanks with potential emissions greater than 2 tpy and existing tanks with potential emissions of 3 tpy VOC for tanks in multi-tank batteries, and 4 tpy for existing tanks in single tank batteries.<sup>18</sup>

Commenter (0832-NMED) recommends that EPA consider a lower applicability threshold for new and existing storage vessel control requirements. The commenter explains that the applicability threshold should be set lower, considering that VOC emissions from new and existing storage vessels and tank batteries are a significant source of emissions from the oil and gas sector. The commenter suggests that EPA consider the NMED proposed Part 50 applicability thresholds for new and existing storage vessels, which require controls for new storage vessels with a potential to emit (PTE)  $\geq 2$  tpy of VOC, existing storage vessels in multi-tank batteries with a PTE  $\geq 3$  tpy of VOC, and existing storage vessels in single tank batteries with a PTE  $\geq 4$  tpy of VOC.

Commenters (0715-DCJSV, 1267-CA AG *et al.*) recommend that EPA address smaller storage tanks and require lower leak rates, such as required by CO and NM.

Commenter (0739-Citation Oil & Gas Corp. (Citation)) states that the addition of a 20 tpy or greater methane emissions threshold for existing tank batteries would require such tank batteries to reduce emissions by 95 percent, would result in a significant increase in demand for new storage vessels, capture, and control equipment, as well as associated closed tank venting and control systems.

Commenter (0820-Pioneer Natural Resources USA, Inc. (Pioneer)) requests that EPA provide their intent and reasoning for selecting the 6 tpy VOC limit for new tank batteries and the 20 tpy methane limit for existing sources, as it differs from the approach taken in NSPS OOOOa.

Commenter (0599-Marcellus Shale Coalition (MSC)) states that doing so will allow for full stakeholder transparency and involvement in the rulemaking process. Commenter (0577-Kansas Independent Oil & Gas Association (KIOGA)) inquires whether the proposed GHG standards for 95 percent methane reduction for storage tanks with PTE > 20 tpy shown in table 3 at 86 Fed. Reg. 63121 is more stringent than the current 6 tpy VOC threshold for tank emission reductions.

Commenter (0793-PBPA Permian Basin Petroleum Association (PBPA)) stated that EPA's November 2021 Proposal would significantly expand the number of storage tanks, both new and existing, that will be forced to install vapor recovery units (VRUs) at a tremendous cost and unjustified by the minor reductions in methane and VOC emissions. The commenter explains that both the NSPS and EG are expected to directly impact hundreds of thousands of storage

<sup>17</sup> Cal. Code Reg. tit. 17 § 95668(a)(6), (7).

<sup>18</sup> New Mexico Environment Department, Proposed 20.2.50 NMAC (Jan. 20, 2022 version), at 20.2.50.123(A). Available at: <https://www.env.nm.gov/opf/wp-content/uploads/sites/13/2022/01/Attachment-1-NMED-ProposedPart-20.2.50-January-20-2022-Version.pdf>.

facilities, requiring additional emissions controls, many of which will have their own emissions and will provide only limited emission reductions at smaller operations.

Response I-9-7: EPA discussed the results of the analysis which was used to establish emissions limits for storage vessels in section XII.B.1.e of the November 2021 Proposal. See 86 FR 63199.

EPA cannot support a threshold of 2.7 tpy or 4 tpy VOC because our determination of cost-effectiveness is over \$8,000 per ton of VOC for either level.<sup>19</sup>

In another response to the question of selecting a lower threshold, a commenter suggested that EPA cost calculations were higher than for the state of Colorado, and that EPA should adopt a lower threshold based on the Colorado cost analysis. The EPA reviewed the costs estimates used to support the CO rule and we disagree with the comment because we found significant differences in assumptions used in the analysis and concluded that the Colorado cost estimate did not fully assess all costs that would be incurred by the facility, particularly with respect to the requirements in the final rule. We found our cost for the flare itself is very close to the cost of the flare in the CO evaluation. However, our costs included additional equipment such as a flame arrestor, flare header piping, and a continuous monitoring system for the pilot flame, the latter is required as part of the final rule. Our costs also included sales tax and much higher installation costs, including foundation, contractor fees, contingency costs, and testing costs (initial visible emissions monitoring). Our operating costs are also higher than those projected by Colorado, including operating labor, which includes labor needed to perform required inspections and visible emission monitoring, maintenance labor, and maintenance materials rather than just maintenance costs as estimated by Colorado. We also projected higher natural gas use costs, likely because we require a pilot flame present at all times. Our costs also included indirect operating costs for overhead on labor and materials costs, property tax and insurance, none of which were included in the Colorado cost estimate. Finally, we used higher rate of return (7% rather than 5%) to amortize the capital costs. Together, our cost estimates led to significantly higher annualized costs for the storage tank control. Based on our review of the two cost estimates, we found that the Colorado analysis may not be complete and representative on a national basis of the costs operators will incur to meet the control requirements as provided in the final rule. The commenter did not explain why Colorado's assumptions are better than EPA's assumptions in this analysis. For these reasons, the EPA disagrees with the comment and will finalize the threshold as proposed.

#### ***9.2.6 Legally and Practicably Enforceable Limits***

Comment: Several commenters (0755-Texas Pipeline Association (TPA), 1341-Pennsylvania Grade Crude Oil Coalition (PGCC) *et al.*, 0599-MSD, 0820-Pioneer, 0808-API, 0817-GPA, 0844-EDF *et al.*, 0938-TXOGA, 0456-Air Management Program, Wisconsin Department of Natural Resources (WDNR), 0776-Air Pollution Control Division, Colorado Department of Public Health and Environment (CDPHE), 0944-Kuva, 1267-CA AG *et al.*) express concerns

<sup>19</sup> See spreadsheet "StTanks Control Costs v6.0" (document EPA-HQ-OAR-2021-0317-@@@@, attachment ??), sheet "New", cells U9 through U11, and U40.

regarding elements of the November 2021 Proposal that EPA proposes for “legally and practicably enforceable” limits.

Commenter (0755-TPA) states that the November 2021 proposed revisions to the concept of legally and practically enforceable emissions limits, within the context the storage vessel applicability thresholds, are unduly prescriptive and unnecessary. The commenter states that EPA now proposes a complex and cumbersome regulatory scheme whereby the owner or operator of a storage vessel, to claim a limit that keeps the vessel under threshold limits, would have to show that all the following elements are in place:

- i. A quantitative production limit and quantitative operational limit(s) for the equipment, or quantitative operational limits for the equipment;
- ii. An averaging time period for the production limit in (i) (if a production-based limit is used) that is equal to or less than 30 days;
- iii. Established parametric limits for the production and/or operational limit(s) in (i), and where a control device is used to achieve an operational limit, an initial compliance demonstration (i.e., performance test) for the control device that establishes the parametric limits;
- iv. Ongoing monitoring of the parametric limits in (iii) that demonstrates continuous compliance with the production and/or operational limit(s) in (i);
- v. Recordkeeping by the owner or operator that demonstrates continuous compliance with the limit(s) in (i-iv); and
- vi. Periodic reporting that demonstrates continuous compliance.

The commenter (0755-TPA) states that EPA is proposing to cast aside the traditional means of assessing PTE limits for threshold applicability purposes, and to put in its place a highly prescriptive scheme that would constitute regulatory overkill and add uncertainty to whether and how limits could be claimed going forward. The commenter notes that where a rule contains an emissions threshold under which a given piece of equipment is not subject to the rule's requirements, it is fair and logical that the equipment be considered outside of rule coverage, where emission controls or limitations are in place to keep emissions below the threshold, even though in an uncontrolled state the equipment is capable of producing emissions above threshold levels. The commenter adds that this concept has been embodied in EPA rules for decades<sup>20</sup> and was incorporated into NSPS OOOOa in 2016.<sup>21</sup> The commenter states that they are not aware that it has caused any significant problems or compliance issues in the context of NSPS OOOOa or more generally.

Commenter (0944-KUVA) proposes for EPA to consider conducting an analysis as to whether relocatable or continuous installed OGI cameras could be utilized in connection with the definition for legally and practicably enforceable.

Commenters (1341-PGCC et al.) state that EPAs clarifying definition of a legally and practicably enforceable limit is in contravention of long- established air permit exemptions for de minimis individual sources, such as those in existence in PA, NY, and elsewhere. See 25 PA. Code

---

<sup>20</sup> See, e.g., 40 CFR § 51.165(a)(1)(iii); 40 CFR § 51.166(6)(4); 40 CFR § 52.21(b)(4).

<sup>21</sup> 81 FR 31500 (June 3, 2016).

127.14 and 6 CCR-NY 201-3.2 (both allowing pa department of environmental protection (dep) and the NY state (NYS) department of environmental conservation (DEC) to exempt from air permitting certain sources). The commenter suggests that the November 2021 proposed "clarifying" definition of "legally and practicably enforceable limit" would appear to require that all storage tanks within a tank battery be covered under an air permit that imposes production limits, monitoring, recordkeeping, and potentially other explicit requirements to maintain an exemption from the proposed expanded requirements. See 86 FR 63201-63,202. The commenters believe that EPA's November 2021 proposal could lead to significant numbers of storage tanks being covered (and potentially retroactively covered) under NSPS OOOOa, proposed NSPS OOOOb, and proposed e.g. OOOOc and questions EPA's legal authority to upset state air permitting programs and exemptions in this manner.

Response i-9-8: The proposed criteria, which EPA is finalizing, are for evaluating whether a facility is subject to legally and practicably enforceable emission limits for new and modified facilities under new and modified sources under OOOOb and existing sources under OOOOc e.g. See 86 FR 63201 (the EPA is clarifying the term "legally and practicably enforceable limits" as it related to storage vessel affected facilities in the proposed NSPS OOOOb and EG OOOOc). These criteria will apply going forward, and will not be used to assess whether owners and operators correctly determined that their storage vessels are not subject to OOOO or OOOOa. As the EPA stated in our proposal and supplemental proposal, the enforcement record shows<sup>22</sup> that the EPA must further specify what legally and practicably enforceable emissions limitation means in the oil and gas sector because we have found through enforcement actions that sources have relied on inadequate limitations to support their status as exempt from the storage vessel provisions of the NSPS. However, the EPA disagrees with the comment that our action results in the need for all storage tank owners and operators to obtain site-specific permits. A permit-by-rule or general permit system that creates legally and practicably enforceable limits that meet the criteria would not require a site-specific permit. Further, no owner or operator is required under this provision to obtain any minor source permit. The owner or operator could instead comply with storage vessel requirements under OOOOb.

As mentioned above, the provisions finalized in this action are applicable to new, modified, and reconstructed sources under the NSPS OOOOb generation of sources, and existing source designated facilities under OOOOc, and are not retroactively applicable to OOOO or OOOOa sources. The EPA enforcement cases to date have relied on EPA guidance and the provisions of OOOO and OOOOa, and will continue to do so to determine whether legally and practicably enforceable limits are met in permits or other requirement established under federal, state, local or tribal authority.

Comment: Commenter (0599-MS) states that the terms "legally and practically enforceable" are currently defined and codified by EPA in synthetic minor determinations under the title V operating permit program and in the prevention of significant deterioration and nonattainment

---

<sup>22</sup> See the preamble to final rule, section XI.J.1 for further discussion.

new source review programs. The commenter stated that the proposed NSPS OOOOb and EG OOOOc definitions should remain consistent with existing regulations.

Response I-9-9: The criteria for a "legally and practically enforceable" limit (LPE criteria) that we are finalizing in this action are for a specific use. They are specifically designed to assure that credible limitations on storage vessels in the oil and gas sector and their controls are in place when determining whether these storage vessels are affected facilities under OOOOb or designated facilities under EG OOOOc. As such, the EPA disagrees that these criteria must be identical to the title v program terms, which are by their programmatic nature more general than would be found in a category-specific rule. The EPA does not agree that legally and practicably enforceable criteria under the title V, PSD, or NNSR programs are inconsistent with the specifications in NSPS OOOOb and OOOOc. Further, the commenters are incorrect that EPA's title V (40 CFR part 70 and 71), PSD, or NNSR regulations currently define legally and practicably enforceable. The only place EPA has defined legally and practicably enforceable in the NSR program is in part 49 for tribal minor NSR. That definition in 40 CFR 49.167 defines enforceable as a practical matter and not legally and practically enforceable. This difference notwithstanding, the description of practical enforceability as a practical matter requires nothing different. It requires the following<sup>23</sup>:

Practical enforceability for an emission limitation or for other standards (design standards, equipment standards, work practices, operational standards, pollution prevention techniques) in a permit for a source is achieved if the permanence provisions specify:

- i. A limitation or standard and the emission units or activities at the source subject to the limitation or standard;
  - ii. The time period for the limitation or standard (e.g., hourly, daily, monthly, and/or annual limits such as rolling annual limit) and
  - iii. The method to determine compliance, including appropriate monitoring, recordkeeping, reporting, and testing.
3. For rules and general permits that apply to categories of sources, practical enforceability additionally requires that the provisions: (i) Identify the types or categories of sources that are covered by the rule of general permit; (ii) Where coverage is optional, provide for notice to the reviewing authority of the source's election to be covered by the rule or general permit and (iii) specify the enforcement consequences relevant to the rule of general permanent.

Each of these is consistent with the requirements that EPA has finalized for legally and practicably enforceable under OOOOb and OOOOc EG. The criteria of legally and practicably enforceable proposed for this rule are the sector-specific application of prior efforts to define the terms in guidance documents in Title V and elsewhere, including in the example cited by the commenter.

Comment: Commenter (0599-MS) stated that the additional prescriptive requirements in the proposed definition would require permitting authorities to re-write existing permit conditions to exactly match the language in the proposed rule.

---

<sup>23</sup> 40 CFR 49.16.

Response I-9-10: The EPA disagrees that our proposal necessitates that all existing permits be re-written. These specific criteria do not retroactively apply to permit limits or other requirements that owners and operators had previously relied upon in determining OOOO or OOOOOa applicability to their storage vessels. The criteria will apply to determining OOOOb applicability to new storage vessels, i.e., those for which construction, reconstruction or modification commenced after December 6, 2022 (the supplemental proposal date) and for determining applicability for existing storage vessels covered by the EG OOOOc. For new storage vessels already constructed, reconstructed or modified before the effective date of this final rule, to the extent their owners or operators decided to obtain legally and practicably enforceable limits to cap the potential emissions from their storage vessels below the proposed OOOOb applicability thresholds, they were on notice of EPA's proposed LPE criteria when obtaining such limits. With regard to existing sources, as states develop their state plans to implement OOOOc EG, they may adopt these criteria for legally and practicably enforceable emission limitations or develop their own criteria as long as they are equivalent to the EPA criteria (i.e., equally effective in capping potential emissions) for purposes of determining storage vessel designated facility status under their plans. States that use permit-by-rule or general permits should evaluate the substance of these rules to ensure that those rules incorporate provisions that achieve the intent of the final rule with respect to legally and practicably enforceable limitations.

Comment: Commenter (0599-MS) provided specific comments on the proposed legally and practicably enforceable emission limitations definition. The commenter states that they understand the proposed definition to state that only those limits that include the elements proposed will be considered "legally and practicably enforceable," for purposes of determining the potential for VOC emissions from a single storage vessel or tank battery, and thus applicability (or non-applicability) of each single storage vessel or tank battery as an affected facility under the rule. The commenter recommends that other factors, including the maximum capacity under the physical and operational design and state regulations that include rolling 12-month emission limits (without a specific throughput limitation), should be considered legally and practically enforceable.

Response I-9-11: The EPA agrees with the commenter that the maximum capacity under the physical and operational design may be considered to be quantitative production limits and quantitative operational limits and therefore legally and practicably enforceable, if the other criteria of legally and practicably enforceable are met. The EPA agrees that state regulations that include rolling 12-month emission limits are sufficient to be practicably enforceable language without a specific throughput limitation, provided that a record of how the standard was met is produced every 30 days as part of the annual rolling average recording system, and as long as the operational, monitoring, recordkeeping, and reporting elements of legally and practicably enforceable limits are also met.

Comment: Commenters (0820-Pioneer, 0808-API) commend EPA for proposing to clarify applicability of the storage vessel emissions standards by defining the term "legally and practicably enforceable limit," but state that this issue has implications that go far beyond the narrow confines of the storage vessel standard and suggests that EPA defer final action on the

proposed definition until such time as the Agency undertakes a broad-based rule that would provide a single, consistent approach across all affected Clean Air Act (CAA) programs.

Response I-9-12: The EPA does not see a need to delay finalizing the definition of a “legally and practicably enforceable limit” that is specific to storage vessel applicability determination in this rule. The legally and practicably enforceable criteria we proposed are specific to oil and gas storage vessels. EPA anticipates that any subsequent action on defining legally and practicably enforceable limits meant to cover a wider variety of source categories would be more general and, as such, would not conflict with the category-specific criteria tailored to oil and gas storage vessels in this final rule. EPA could also in that later action address potential conflicts, if any, with the category specific definition for a LPE limit in this oil and gas rule.

Comment: Commenters (0820-Pioneer, 0808-API) are concerned that addressing legally and practicably enforceable specifications in a piecemeal, rule-by-rule fashion will ultimately cause confusion and potential inconsistency across EPA's CAA stationary source programs: from major source permitting under New Source Review (NSR)/Prevention of Significant Deterioration (PSD), to the Title V operating permit program, to all manner of federal and state emissions control programs (of which CAA§ 111 is just one). The commenters state that what constitutes an acceptable and effective "legally and practicably enforceable limit" has been an open question since the mid-1990s, when the prior "federal enforceability" requirement was remanded or vacated across EPA's programs. See *National Mining Ass'n v. EPA*, 59 F. 3d 1351 (D. C. Cir. 1995); *Chemical Mfrs. Ass'n v. EPA*, 70 F. 3d 637 (D.C. Cir. 1995); *Clean Air Implementation Project v. EPA*, 1996 WL 393118 (1995). The commenters note that EPA once announced its intent to conduct a comprehensive rulemaking to address the holdings in these cases but has not yet taken action almost 30 years after the decisions were handed down.<sup>24</sup> The commenters state that affected facilities and states now have years of experience implementing the NSPS OOOO and OOOOa storage vessel standards, including substantial experience in crafting appropriate emissions limitations to govern applicability of these standards. The commenters believe that creating new mandatory procedural requirements is unnecessary, given that no systemic problem has emerged during this long implementation period and that such requirements would add to the cost and burden of implementing these standards, without delivering any commensurate benefit.

Commenter (0820-Pioneer) is further concerned that the proposed elements could inadvertently call into question existing permitting and regulatory regimes that do not specifically include the parameters proposed by EPA. The commenter states that the Texas Commission on Environmental Quality (TCEQ) permits appear to show all of the proposed elements, but the proposed requirements are vague. The commenter believes that the first requirement, "*quantitative production limit and quantitative operational limit*" is shown in the state TCEQ permit, but requests clarification on EPA's intent. The commenter asks if operators need to obtain a federal permit on top of the state permit and strongly recommends that EPA specify that the certified state permit suffices in demonstrating that tank batteries are under the required threshold limits of either 6 or 20 tpy. The commenter also recommends that the air permitting

---

<sup>24</sup> Memorandum from John S. Seitz to Regional Office Addressees, Release of Interim Policy on Federal Enforceability of Limitations on Potential to Emit (Jan 22, 1996).

State Implementation Plan (SIP) that was approved by EPA and TCEQ's delegation to run the permitting program should provide the assurances EPA needs to rely on the state agency.

Response I-9-13: See Response I-9-8. The new criteria will not be applied to sources subject to OOOO and OOOOa, and apply going forward to sources subject to OOOOb. The criteria will apply to designated sources under OOOOc in the future after state rulemaking is pursued under CAA section 111(d).

Comment: Commenter (0820-Pioneer) requests that EPA define "*parametric limits*" to mean the ongoing monitoring of production.

Response I-9-14: "Parametric limits" refers to limits on a parameter that can act as a reliable indicator of an emissions-producing (or emissions-reducing) activity or process. As the commenter suggests, such limits could include ongoing monitoring of production and/or operational limits.

Comment: Commenter (0938-TXOGA) states, that beyond citing to the holding of *National Mining Ass'n v. EPA*, 59 F.3d 1351 (D.C. Cir. 1995)<sup>25</sup> and statements in the November 2021 Proposal that certain limits do not adequately serve to limit the emissions from storage tanks. EPA does not provide record evidence that a new definition of "legally or practicably enforceable limits" is needed. The commenter states that while EPA referenced example permit limits that "do not require a reduction in emissions; they are often self-imposed or of such a general nature as to be unenforceable or otherwise lack measures to assure the required emission reduction,"<sup>26</sup> EPA does not cite to any specific permits. Although the commenter agrees with *National Mining's* holding that unenforceable voluntary actions do not serve to limit PTE, the November 2021 Proposal record does not indicate that the provisions EPA proposes are necessary, and the commenter is concerned that the proposed requirements go beyond what is necessary.

Response I-9-15: The EPA cannot disclose information related to ongoing enforcement actions. Further, the EPA cannot disclose confidential information shared during the course of settlement negotiations. Excerpts of specific permits that the EPA has reviewed and determined to be lacking legally and practicably enforceable limits include:

Permit 1—Applicable Emissions Limitations or Control Measures.

- In order to comply with the tons per month emission limit, utilize one or more of the following controls: Use of add-on control (vapor recovery, flare or equivalent)

---

<sup>25</sup> See also *Nat'l Mining Ass'n*, 59 F.3d at 1364 ("As presented in its briefs, EPA's core justifications for its federal enforceability policy are the need to avoid the administrative burden that EPA would have to bear were it obligated to evaluate the effectiveness of state and local controls and the desirability of uniformity in environmental enforcement. These, of course, are not illegitimate agency objectives. Administrative problems, in particular, can under certain circumstances inform an agency's construction of imprecise statutory language. See *Drummond Coal Co. v. Hodel*, 796 F.2d 503, 507 (D.C. Cir. 1986). Here, however, EPA would have us accept a rather strained interpretation of the statute based on what appears to be only its unwillingness to evaluate any state or local controls that are not federalized.").

<sup>26</sup> 86 FR 63201.

to control emissions from storage vessels as needed to comply with the annual VOC emission limitations.

- The permittee accepts a voluntarily limit to restrict the potential VOC emissions from each storage vessel to less than 6 tons per year.

In Permit 1, the control device is not specified and the permit terms do not specify a destruction rate efficiency, combustion rate, or availability for a vapor recovery unit. The provision also does not specify emissions testing, operational parameter monitoring, inspection requirements or recordkeeping or reporting requirements for the add-on control. Additionally, the terms “voluntarily limit” in the second provision do not include site-specific emissions calculations that demonstrate that this storage vessel is below 6 TPY. The terminology also indicates that controlling emissions below 6 TPY of VOCs is not a requirement.

#### Permit 2—Combustor/Flare Requirements

- All exhaust gas/vapors from the oil storage tanks shall be routed to the operating combustor/flare.
- The combustor/flare shall operate with no visible emissions.
- Visual determination of smoke emissions from flares shall be conducted according to 40 CFR 60, Appendix A, Method 22.

In Permit 2, a destruction rate efficiency of 95% or greater is not specified. There is no testing requirement for the control device, no continuous pilot light monitoring or inspection requirement, no indication of how frequently Method 22 inspections must be conducted, and no recordkeeping or reporting requirements. Both Permit 1 and Permit 2 demonstrate provisions from permits that do not have operational or parametric limits and therefore, that the EPA has determined not to be legally and practicably enforceable.

Comment: Commenter (0938-TXOGA) requests that EPA adequately explain and examine how these state limits are not applying adequate controls, before requiring such burdensome production and operational restrictions on such permit limits.<sup>27</sup> The commenter provides specific comments on the definition. First, the commenter states that the suggested definition seemingly conflicts with how PTE is calculated for storage vessels under the rule, and specifically, the regulatory standard for “maximum average daily throughput,”<sup>28</sup> where emissions determinations are to be based on a legally and practicably enforceable limit to keep emissions under 6 tpy, or otherwise based upon an analysis of 30 days of production. The commenter states that EPA appears to be reversing this position in the preamble (without identifying that they are taking such action) and the suggested definition for “legally and practicably enforceable limits”

---

<sup>27</sup> As stated by the D.C. Circuit in *National Mining*, “By no means does that suggest that Congress necessarily intended for state emissions controls to be disregarded in determining whether a source is classified as “major” or “area” under that national standard. Nor did Congress mandate that EPA assume the administration and enforcement of all governmental efforts at emissions limits. If such administration and enforcement is necessary to ensure that controls are effective in the context of the extant regulatory environment, EPA has certainly not made that case and has not indicated how that consideration supports its claim that its interpretation of the statute is reasonable.” 59 F.3d at 1365.

<sup>28</sup> The commenter (0938-TXOGA) cites to §60.5430a, definition of “maximum average daily throughput.”

confounds the method for a determination of “maximum average daily throughput,” because application of the definition will require sources that take such a limit to employ calculations and monitoring on an ongoing basis (e.g., to revise PTE calculations to reestablish a production or operational limit).

Response I-9-16: EPA takes issue with the commenter’s implication that legally and practicably enforceable criteria “seemingly conflicts’ with the threshold determination to apply standards to storage vessels. The standards could not more clearly state that upon summing the emissions over a 30-day period, the sum may be reduced by the reduction determined by the control efficiency of control devices specified in a legally and practicably enforceable emission limitation. We disagree with the assertion that a demonstration of ongoing compliance with an emission limit through parametric monitoring constitutes a re-determination of affected facility status. However, if the potential for VOC or methane emissions is limited through a legally and practicably enforceable limit, there will be a requirement to conduct on-going monitoring and compliance determinations with respect to those limits. The EPA has asserted in prior guidance<sup>29</sup> and re-asserts here in the form of new requirements specific to the oil and gas industry that for periodic monitoring of ongoing compliance to be practicably enforceable, the averaging period may be no more than 30 days. As discussed in Response 1-9-17, EPA agrees that a rolling 12-month average is an acceptable alternative to a month-by-month determination. See also the response to I-9-15.

The EPA’s record of enforcement reflects that state limits as they have been implemented have in select cases not resulted in adequate control of emissions. The EPA cannot disclose information related to ongoing enforcement actions. The EPA can refer to settled enforcement cases with oil and gas operators that hold state general permits that lack sufficient substance to provide legally and practicably enforceable limits, such as unenforceable voluntary actions that do not serve to limit PTE below NSPS applicability thresholds. Commenters may review publicly available settlement documents of completed enforcement cases with oil and gas operators for specific examples.

Comment: Commenter (0938-TXOGA) further states that EPA suggests in the list of “legally and practicably enforceable limits” that the averaging period would need to be “equal to or less than 30 days,” when the initial demonstration using “maximum average daily throughput” was established based on 30 days of production. The commenter states that a tpy limit typically is established based on a rolling 12-month sum, and this was plainly authorized under the prior version of the regulations; therefore, the commenter states, there is no question that limits of this form have long been considered by EPA to be both legally and practically enforceable. The commenter states that by making the limits tied to PTE determined from 30 days or less of production, the applicability threshold is dramatically more stringent and expands applicability, than would otherwise be the case. The commenter requests that EPA explain the significant change since the November 2021 Proposal did not provide adequate explanation as to why it is necessary. Further, the commenter requests that EPA explains why a 30-day (or less) averaging period is required, because the commenter does not believe it is required for legal and practical

---

<sup>29</sup> Memorandum from John S. Seitz to Regional Office Addressees, Release of Interim Policy on Federal Enforceability of Limitations on Potential to Emit (Jan 22, 1996).

enforceability. The commenter states that further explanation by EPA is needed to be able to provide the required meaningful opportunity to comment.

Response I-9-17: The EPA agrees that a rolling 12-month average is an acceptable alternative to a month-by-month determination, where the rolling 12-month average is supported by 30-day subtotals, and redetermined every month. EPA guidance<sup>30</sup> clearly states that for an emission limitation to be legally and practicably enforceable, the monitoring period must be no more than a 30-day period of production. A tons-per-year cap alone, using 12 months of production, is insufficient to be considered legally and practicably enforceable under OOOO and OOOOa, specifically because such a provision would be unenforceable for the initial 11 months of production. When establishing permit limits on production or operation, EPA believes that such limits should not exceed 30 days. EPA also points out that a violation of a 12-month standard without any prior interval to verify compliance has the potential to create a full year of non-compliance and associated penalties for failure to demonstrate ongoing compliance.

Comment: Commenter (0938-TXOGA) states that they do not dispute that sources choosing to accept restrictions on emissions below the applicability threshold must ensure that they are both legally and practically enforceable, but EPA seems to impugn generally its state partners' ability to issue enforceable limits in permits and further, the language provided in the preamble goes well beyond what is needed for such a limit to be established. The commenter references the TCEQ comments on the 2021 November Proposal and states that TCEQ issues limits that are both practically and legally enforceable, and which also is true for other oil and gas producing states where commenter's members operate. The commenter states there is no reason to think that experienced state permitting authorities who have been delegated authority to implement NSPS requirements through their Title V programs and under section 111 of the CAA since their Title V programs were approved in the 1990s have been unable to assess the information needs or that their permits would be inadequate.

Response I-9-18: EPA disagrees that the criteria for legally and practicably enforceable goes beyond what is necessary to demonstrate ongoing compliance. EPA responded in Response I-9-15 with examples of how specific permits failed to provide sufficient provisions for enforceability. EPA responded in I-9-12 and I-9-9 how the criteria are tailored to sources subject to OOOOb and OOOOc EG, and are consistent with guidance in other programs including Title V and NSR, and provided an example of that consistency when compared to similar provisions under 40 CFR 49.16. EPA responded in I-9-8 that EPA has agreed with commenters that the criteria are not a reiteration of guidance, but new regulatory criteria that our enforcement history demonstrates are necessary going forward for sources to have the certainty of what requirements will apply to them.

We point out that the provisions finalized in this action are applicable to new, modified, and reconstructed sources under the NSPS OOOOb generation of sources, and existing source affected facilities under OOOOc EG, and are not retroactively applicable to OOOO or OOOOa

---

<sup>30</sup> Memorandum from John S. Seitz to Regional Office Addressees, Release of Interim Policy on Federal Enforceability of Limitations on Potential to Emit (Jan 22, 1996).

sources. The EPA enforcement cases to date have relied on EPA guidance and the provisions of OOOO and OOOOa, as applicable and will continue to do so for those enforcement cases.

EPA is not asserting that states universally have been unable to assess the information needs or that their permits would be inadequate. Rather, enforcement inspections have led us to conclude that specific LPE criteria are needed to ensure that tanks with potential emissions at or above the thresholds are subject to OOOOb/OOOOc.

Comment: Commenter (0938-TXOGA) states that EPA should revise or eliminate its proposed definition to remove references to production limits and a need to recalculate, on an ongoing basis, the PTE for a storage tank, because such limits are addressed by the manner in which EPA requires storage vessel sources which do not take a permit limit to determine of “maximum average daily throughput.” The commenter notes that in cases where a permit limit is taken (as EPA correctly notes) the burden is on the source to comply and demonstrate that it complies with the limit.

Response I-9-19: EPA clarifies that a source will not need to recalculate, on an ongoing basis, the PTE for a storage tank. The potential to emit calculation for the purpose of determining applicability is a one-time occurrence (absent any actions that would meet the definition of modification or reconstruction) to determine applicability within 30 days of startup. However, if the potential for VOC or methane emissions is limited through a legally and practicably enforceable limit, such limit would include a requirement to conduct on-going monitoring and compliance determinations with respect to those limits. When establishing permit limits on production or operation, EPA believes that such limits should not exceed 30 days. This requirement allows for EPA to determine compliance more quickly and serves to protect the regulated community from extended periods of non-compliance with resulting multi-day penalties. For example, measurement for 12 consecutive months would allow the source and EPA to determine, after 12 months, at what point a violation may have occurred or began. In the absence of such data, it would not be clear at what point over the 12 months a violation may have begun.

Comment: Commenter (0938-TXOGA) states that to the extent EPA continues with the November 2021 proposed approach, it is important that, if a previously issued limit needs to be revised to meet the final rule’s requirements, that sources that have complied with and operated below the 6 tpy applicability threshold should, as a matter of due process, have the opportunity to amend their permits without threat of enforcement. The commenter requests that EPA clarify that facilities currently operating below the 6 tpy threshold pursuant to permit limitations on their PTE are not subject to the proposed legally and practicable enforceability requirements until their next permit renewal or two years from the effective date of the final rule, whichever is later.

Response I-9-20: See Response I-9-18.

Comment: Commenter (0776-CDPHE) states they are concerned that EPA’s November 2021 proposed criteria will prompt the need to revise existing permits and/or adopt duplicative and unnecessary recordkeeping and reporting regulations in order to ensure compliance with the NSPS or to submit an approvable CAA 111(d) plan. The commenter explains that Colorado has

relied both on Regulation 7<sup>31</sup> and minor source permits as the basis of operators' limiting potential to emit below the applicable control thresholds. Further, the commenter is concerned that EPA's November 2021 Proposal fails to recognize the opportunity to use technologies and methods that ensure better control and accuracy of measurement, and instead relies on traditional calculation methodologies and recordkeeping/reporting. Specifically, the commenter provides comments on particular elements of the proposed definition of "legally and practicably enforceable:"

*(ii) - an averaging time period for the production limit that is equal to or less than 30 days.* The commenter specifically is concerned with these criteria given the typical production curve associated with new well production facility operations, explaining that these facilities typically have high production during the first several months before reaching a steadier production rate later in the life of the well. The commenter states that this production decline curve represents substantial variation which makes monthly or shorter production limits impractical, as acknowledged in the June 13, 1989, Memorandum, "Guidance on Limiting Potential to Emit in New Source Permitting" which states on page 9:

*EPA recognizes that in some rare situations, it is not reasonable to hold a source to a one month limit. In these cases, a limit spanning a longer time is appropriate if it is a rolling limit. However, the limit should not exceed an annual limit rolled on a monthly basis. EPA cannot now set out all-inclusive categories of sources where a production limit longer than a month will be acceptable because every situation that may arise in the future cannot now be anticipated. However permits where longer rolling limits are used to restrict production be issued only to sources with substantial and unpredictable annual variation in production...*

*(iii) - a compliance demonstration or mandatory initial performance testing requirement* that is not flexible enough to account for the different types of compliance demonstrations that should be made. The commenter requests an approach that leaves it to the state agency to determine what is a sufficient compliance demonstration; for example, state agencies should not be required to mandate an initial performance test on all air pollution control equipment used to establish practicably enforceable limits and instead should be allowed to use sound judgment on when to require initial performance tests.

*(v) - prescriptive recordkeeping requirements.* The commenter requests that states should have the ability to determine what records are sufficient for the state to determine whether an operator is in compliance.

*(vi) - mandatory, and prescriptive, periodic reporting.*

The commenter (0776-CDPHE) explains that Colorado already has periodic reporting of emissions and other data (e.g., emission factors, gas speciation, performance testing information)

---

<sup>31</sup> Colorado notes that its control thresholds for storage tanks (as opposed to storage vessels) is 2 tpy VOC (and 4 tpy VOC in the state's ozone SIP). See Regulation 7, Part D, Sections I.D.3 and II.C.1.c.

and they should not be obligated to amend its regulations to include additional, and potentially duplicative and less efficacious, reporting. The commenter requests that EPA not mandate periodic reporting and that EPA clarify that legally and practicably enforceable limits established through permits and associated records may be reported upon request of the agency rather than require records to be submitted on a mandatory periodic schedule. The commenter believes this would ensure states have the ability to focus their compliance resources on targeted compliance evaluations.

Response I-9-21: See Response I-9-17 regarding rolling 12-month averages. The EPA continues to believe that measuring and recording throughput each 30-day period towards showing continuous compliance with a 12-month rolling annual standard is reasonable for these sources. The commenter points out that storage vessel throughput is typically higher in the initial months after the startup of production and tends to be lower and more consistent over time. The EPA does not see how such falling production rates would pose a problem for determining compliance with a limit that would have been established during the highest periods of a well's production and where such limits are intended to limit a source's potential for emissions. The EPA therefore considers it practicable to be able to review the most recent 30 days of data upon inspection to ensure continuous compliance with an enforceable limit over the previous 12 periods of 30 days.

We also point out that the provisions finalized in this action are applicable to new, modified, and reconstructed sources under the NSPS OOOOb generation of sources, and existing source designated facilities under OOOOc, and are not retroactively applicable to OOOO or OOOOa sources. The EPA enforcement cases to date have relied on EPA guidance and the provisions of OOOO and OOOOa, as applicable, and will continue to do so to determine whether legally and practicably enforceable limits are met in permits or other requirement established under Federal, state, local, or tribal authority.

The EPA agrees with the commenter with respect to different methods of showing compliance. The EPA has elaborated here in the response to comments and preamble to better explain the intent of periodic monitoring for compliance. See Responses I-9-15 with examples of how specific permits failed to provide sufficient provisions for enforceability. EPA responded in I-9-12 and I-9-9 how the criteria are tailored to sources subject to OOOOb and OOOOc EG, and are consistent with guidance in other programs including Title V and NSR, and provided an example of that consistency when compared to similar provisions under 40 CFR 49.16. EPA responded in I-9-8 that EPA has agreed with commenters that the criteria are not a reiteration of guidance, but new regulatory criteria that our enforcement history demonstrates are necessary going forward for sources to have the certainty of what requirements will apply to them.

Comment: Commenter (0456-WDNR) recommends that EPA not propose a definition of a "legally and practicably enforceable limit" for purposes of determining whether a single storage vessel or tank battery is an affected facility, because establishing such a definition in the proposed rule could have significant impact on the implementation of CAA sections 111(b) and 111(d) that goes beyond the oil and natural gas sector. The commenter states that the definition could also affect how NSR and operating permit programs operate in the states. The commenter suggests that past EPA guidance on legally and practicably enforceable limits has not provided the needed clarity to ensure consistency among the states in synthetic-minor permitting and notes

that the EPA Office of Inspector General Report on EPA Oversight of Synthetic-Minor-Source Permitting (Report No. 21-P-0175) published in July 2021 recommended that EPA update its practical enforceability guidance, and develop and issue new guidance that includes key EPA expectations for synthetic-minor-source permitting. The commenter recommends that EPA update its guidance on legal and practical enforceability and seek public comment on the updated guidance before proposing any definitions of a “legally and practicably enforceability limit” that would be included in a federal standard.

Commenter (1267-CA AG *et al.*) suggests that EPA consider states’ existing frameworks for a “legally and practically enforceable limit” to ensure that states are not unnecessarily required to adopt duplicative recordkeeping and reporting regulations nor are forced to use alternative technologies and methods in a situation where state regulations ensure better control and accuracy than the November 2021 Proposal.

Response I-9-22: EPA disagrees that changes to the NSPS will affect how NSR and Title V operates among states. EPA responded in I-9-12 and I-9-9 how the criteria tailored to sources subject to OOOOb and OOOOc EG, are consistent with guidance in other programs including Title V and NSR, and provided an example of that consistency when compared to similar provisions under 40 CFR 49.16. EPA responded in I-9-8 that EPA has agreed with commenters that the criteria are not a reiteration of guidance, but new regulatory criteria that our enforcement history demonstrates is necessary going forward for sources to have the certainty of what requirements will apply to them.

The EPA has opted to promulgate legally and practicably enforceable criteria specific to oil and gas storage vessels over issuing additional guidance. With the next generation of sources subject to OOOOb and existing sources to be designated subject to OOOOc and a new standard for methane, EPA considers this the opportune time to provide greater clarity and certainty than guidance can provide.

The EPA has agreed with comments to the effect that the promulgation of a methane standard applicable to the sources affected by this final action may require amendments to permits, permits by rule, minor source, or synthetic minor permits. The EPA is choosing to add regulatory certainty to describe legally and practicably enforceable emissions limitations now because of the number of changes to the NSPS and the EG finalized in this action. If the EPA were to choose to issue another round of guidance, states and sources would not have the same level of certainty as to what EPA considers legally and practicably enforceable for the next generation of sources. This level of specificity and certainty will serve to guide states as they consider how to apply these criteria through state requirements promulgated under OOOOc EG and through permits issued for OOOOb sources.

Comment: Commenter (0844-EDF *et al.*) states that to the extent that EPA retains a potential to emit based on legally and practicably enforceable limits, they support using the factors stated by EPA. Further, the commenter suggests that EPA should include in its definition of “legally and practicably enforceable limits” a requirement that operators report actual deviations from normal operations for a source. The commenter notes that if a large emission event occurs, it is likely that the “potential” that is articulated in a permit has been exceeded, and therefore, in order to

fully ensure that the “potential” is represented, the deviation should be reported in a manner that will allow EPA to determine whether the permit limit was exceeded. The commenter further suggests, that along with the type of deviation, the actual deviation report should include the date and time that the deviation was discovered, the date and time of the last confirmed normal operation, and the parametric data that accompanied that source during those times the deviation occurred.

Response I-9-23: The comment is focused on deviations, malfunctions, and the resulting emissions. Emissions that result from malfunctions are not the result of normal operation and are not contemplated in a storage vessel’s maximum potential to emit, and therefore the comment is beyond the scope of the discussion of legally and practicably enforceable emissions limitations. See general discussion in section IV.J.1.a of the December 2022 Supplemental Proposal regarding legally and practicably enforceable limits.<sup>32</sup>

Comment: Commenters (0817-GPA, 0832-NMED) request that EPA allow additional time to comply with proposed NSPS OOOOb requirements for storage vessels (and for other equipment). Commenter (0817-GPA) explains that due to the changes in definition of “legally and practicably enforceable,” compliance will turn on the speed with which state regulatory agencies can re-open and re-issue or renew permits, not on any action by regulated owners and operators. Further, if existing source applicability is based on methane emissions, each facility would need to revise its permit to either include methane emission rates or enforceable limits for an existing control. Such updates to permits to include a separate methane emissions limit, the commenter points out, will necessitate more time for compliance, as midstream companies cannot control the speed with which permitting authorities will re-open or re-issue permits to include methane limitations for the first time. The commenter suggests that for some states, this could require revisions to tens of thousands of permits, and it may take several years for midstream companies to receive revised or reissued permits. The commenter recommends that EPA require compliance only upon the issuance of a new or revised permit from the permitting authority rather than establishing an arbitrary time limit for compliance as it would be unfair to subject operators to enforcement actions merely because state permitting agencies could not issue revised permits at the pace EPA desired.

Response I-9-24: See Response I-9-8.

Comment: Commenter (0832-NMED) recommends that EPA provide sufficient time for owners and operators to comply with the control requirements, as part of a phased compliance timeline. The commenter explains that during the new NMED Part 50 rulemaking hearing, affected owners and operators and industry stakeholders raised concerns about having sufficient numbers of control devices available to implement controls simultaneously. To address this, NMED Part 50 proposes a phased compliance deadline in order to ensure there are sufficient control devices available over the course of the compliance timeline. The commenter states that the lower applicability thresholds for both new and existing vessels, with a reasonable compliance

---

<sup>32</sup> 87 FR 74800 (December 6, 2022).

deadline, would result in important additional emissions reductions from new and existing storage vessel affected facilities.

Response I-9-25: The final NSPS OOOOb requires compliance with the 95 percent emission reduction standard within 30 days after startup of production or within 30 days after reconstruction or modification of the storage vessel affected facility for each storage vessel affected facility located at a well site or centralized production facility. See §60.5370b(a)(3). For storage vessel affected facilities located at a compressor station or onshore natural gas processing plant, the final NSPS OOOOb requires compliance prior to startup of the facility or within 30 days after reconstruction or modification of the storage vessel affected facility. The requirements that EPA is finalizing do not apply to existing sources before states have the opportunity to submit 111(d) implementation plans after state rulemaking takes place to reflect the emission guidelines. EPA has allowed states 18 months to carry out state rulemaking activity to adopt the appropriate emission guidelines and standards. In addition to the 18 months, EPA has recommended that states adopt compliance deadlines within 36 months, providing over 4 years for existing sources to adapt their systems to new federal and state standards.

Comment: Commenter (0817-GPA) asserts that, contrary to what the November 2021 Proposal appears to presume, the term “legally and practicably enforceable” is already defined. The commenter cites the preamble to the proposed rulemaking, *Prevention of Significant Deterioration and Nonattainment New Source Review: Debottlenecking, Aggregation, and Project Netting*, 71 Fed. Reg. 54,235 (Sept. 14, 2006) which explained the term as follows:

“Enforcement as a practical matter” will be achieved if a requirement is both legally and practicably enforceable. A requirement is “legally enforceable” if some authority has the right to enforce the restriction ... practicable enforceability for a source-specific permit will be achieved if:

1. A technically accurate limitation and the portions of the source subject to the limitation;
2. The time period for the limitation (hourly, daily, monthly, and annual limits such as rolling annual limits);
3. The method to determine compliance, including appropriate monitoring, recordkeeping, and reporting.

For rules and general permits that apply to categories of sources, practicable enforceability additionally requires that the provisions:

1. Identify the types or categories of sources that are covered by the rule;
2. Where coverage is optional, provide for notice to the permitting authority of the source’s election to be covered by the rule;
3. Specify the enforcement consequences relevant to the rule.

71 Fed. Reg. at 54,240, n. 13.

The commenter (0817-GPA) further provides that EPA later codified the definition of “legally and practicable enforceable,” with revisions from its prior interpretation, in its regulations for the *Federal Minor New Source Review Program in Indian Country*. 76 Fed. Reg. 38,748 (July 1, 2011). That definition is:

Enforceable as a practical matter means that an emission limitation or other standard is both legally and practicably enforceable as follows:

(1) An emission limitation or other standard is legally enforceable if the reviewing authority has the right to enforce it.

(2) Practical enforceability for an emission limitation or for other standards (design standards, equipment standards, work practices, operational standards, pollution prevention techniques) in a permit for a source is achieved if the permit’s provisions specify:

- i. A limitation or standard and the emissions units or activities at the source subject to the limitation or standard;
- ii. The time period for the limitation or standard (g., hourly, daily, monthly, and/or annual limits such as rolling annual limits) and
- iii. The method to determine compliance, including appropriate monitoring, recordkeeping, reporting and testing.

(3) For rules and general permits that apply to categories of sources, practical enforceability additionally requires that the provisions:

- i. Identify the types or categories of sources that are covered by the rule or general permit;
- ii. Where coverage is optional, provide for notice to the reviewing authority of the source’s election to be covered by the rule or general permit and
- iii. Specify the enforcement consequences relevant to the rule or general permit.

40 C.F.R. §§ 49.152, 49.167.

The commenter (0817-GPA) contends that there are several differences between EPA’s current definition of the term and the revised definition EPA has outlined in the November 2021 Proposal—but without providing any legitimate basis for proposing to change long-standing practice and regulation:

- EPA’s November 2021 Proposal eliminates the use of “other standards,” defined in current law as including “design standards, equipment standards, work practices, operational standards, [and] pollution prevention techniques.” These are sensible ways in

which requirements can be made enforceable as a practical matter and should be retained. Instead, EPA apparently proposes to allow only “[a] quantitative production limit and quantitative operation limit(s) for the equipment, or quantitative operation limits for the equipment.” 86 Fed. Reg. at 63,201. EPA offered no explanation in the November 2021 Proposal for why it proposed to change its position to exclude the use of design standards, equipment standards, work practices, operational standard, or pollution prevention techniques.

- The existing definition specifically allows for “hourly, daily, monthly, and/or annual limits, such as rolling annual limits.” Yet, where production limits are used, the November 2021 Proposal mandates an averaging time “that is equal to or less than 30 days.” The November 2021 Proposal does not explain the basis for requiring 30 days or less and does not explain why it is rejecting its current allowance of other limits, including a rolling annual limit that has often been included in permits and settlement documents. An annual or 12-month rolling average affords more flexibility and thereby minimizes the unduly prescriptive burden of a shorter averaging time, while still providing a mechanism for practical enforceability.
- Under the current definition, permitting authorities must determine the appropriate “method to determine compliance, including appropriate monitoring, recordkeeping, reporting and testing.” The November 2021 Proposal would require that, where a control device is used, it must be subject to an initial performance test “that establishes the parametric limits.” EPA again provides no explanation as to why it is proposing to specifically require a performance test and again offers no analysis of the additional benefit and cost of this change, a change that eliminates the discretion that long has been the well-established approach granted to permitting authorities in accordance with the fundamental value of cooperative federalism established by the Clean Air Act.
- The November 2021 Proposal also appears to raise conflicts with existing regulations. The proposed definition would appear to hold that combustors, certified by EPA as compliance with NSPS OOOOa, and compliant flares under 40 C.F.R. § 60.18, would no longer be recognized as valid. If EPA is proposing to rescind these existing regulations it should say so explicitly and provide an explanation of why these methods are no longer valid.
- The November 2021 Proposal also would deviate from the current definition in that it is proposing to require “ongoing monitoring of the parametric limits” to “demonstrate[ ] continuous compliance with the production and/or operational limit(s).” This is another instance of eliminating the discretion of permitting authorities. Here, EPA apparently is proposing to require a continuous emission or other continuous monitoring requirement without explanation or consideration of any other potential standards, such as design or work practice standards that have long been established as a fully effective approach. Again, the November 2021 Proposal does not offer an explanation for why this change would be made.
- EPA also ignores and would apparently eviscerate the long-standing practice of recognizing permits by rule or general permits as legally and federally enforceable. A significant number of midstream sources rely on these types of permits, and have done so for decades, but the November 2021 Proposal appears to eliminate them sub silentio and

without any reasoned explanation. EPA should clarify its position on the use of permits by rule and general permits.

Response I-9-26: The EPA disagrees that the criteria do not allow the use of design standards, equipment standards, work practices, operational standard, or pollution prevention techniques. For example, a design standard that limits production by physical limitation to a known and documented quantity, under appropriate operations conditions, constitutes a legally and practicably enforceable limit. See Response I-9-17 for a discussion of rolling averages for one year. EPA disagrees that the criteria for legally and practicably enforceable limits conflicts with the requirements related to enclosed combustion devices. The enclosed combustion devices that have been tested by the manufacturer must comply with continuous parametric monitoring requirements. Data showing the device has been operated within those parameters would be part of what EPA would use to verify adherence to the legally and practicably enforceable limit. Likewise, EPA did not propose that a flare designed and operated in accordance with 40 CFR 60.18 would no longer be a valid control device. EPA proposed continuous monitoring requirements for flares to ensure the flares meet the requirements outlined in the part 60 General Provisions on an ongoing basis.

The legally and practicably enforceable specifications provided by this rule are specific to oil and gas storage vessels. Nothing in this rule prohibits permits by rule or general permits from providing legally and practicably enforceable requirements that a source can take into account when calculating its potential emissions, provided those LPE requirements meet the specifications provided by the rule.

Comment: Commenter (0817-GPA) asserts that EPA's purported justification for the new definition is flawed. The commenter states that EPA's attempts to justify its November 2021 Proposal to define "legally and practicably enforceable," by stating that it has "learned that numerous owners and operators claim that their storage vessels are not affected facilities" and EPA disagrees. 86 Fed. Reg. at 63,201. However, they suggest that EPA has not offered any actual record-based evidence to support its statement. They add that EPA further states that it reviewed "the limits considered by these" unspecified "facilities" in unspecified jurisdictions and EPA has "become aware that the limits do not require a reduction in emissions; they are often self-imposed or of such a general nature as to be unenforceable or otherwise lack measures to the required emission reduction." Id. By way of example, EPA claims that one permit "for a single storage vessel, does not contain any performance testing requirements, continuous or other monitoring requirements, recordkeeping or reporting, or other requirements that would ensure that emissions are maintained below the emissions limit in the permit." Id. According to the commenter, however, EPA does not, provide any of these examples for stakeholders to review. The commenter requests that EPA provide the details surrounding that cited example, so interested stakeholders may respond and comment.

Response I-9-27: The EPA cannot disclose information related to ongoing enforcement actions. The EPA can refer to settled enforcement cases with oil and gas operators that hold state general permits that lack sufficient substance to provide legally and practicably enforceable limits, such as unenforceable voluntary actions that do not serve to limit PTE below NSPS applicability thresholds. Commenters may review publicly available settlement documents of completed

enforcement cases with oil and gas operators for specific examples. EPA responded in Response I-9-15 with examples of how specific permits failed to provide sufficient provisions for enforceability.

Comment: Commenter (0817-GPA) notes that, even without the ability to review the single permit cited by EPA as justification, the November 2021 Proposal begins with erroneous assumptions that the commenter would urge EPA to reconsider before proceeding with this change. First, the commenter notes that permits limiting a potential to emit through various means (emission limits, work practice standards, operational limitations, design standards, *etc.*) do not “require a reduction in emissions.” They require emissions to stay below a certain ceiling. The commenter asserts that the current definition of “legally and practicably enforceable” does not require an emission reduction nor does EPA explain why it believes that an emission reduction is required for a limit on a facility’s potential to emit to be enforceable.

Response I-9-28: By “emissions reduction standard” EPA understands that the commenter is describing a numerical limit on emissions to the atmosphere. Legally and practicably enforceable limits which meet the specifications in this rule and which ensure that potential emissions are not above the NSPS applicability threshold, are acceptable. However, the purpose of any legally and practicably enforceable limit, which is used to limit emissions below the applicability threshold, is to result in a “reduction in emissions.” If the legally and practicably enforceable limit does not set a numerical limit on emissions to the atmosphere, the quantitative operational and quantitative production limits must reduce emissions.

Comment: Commenter (0817-GPA) contends that EPA should explain why the fact that a limit is “self-imposed” is a relevant factor, as all permits limiting a potential to emit are “self-imposed” in that operators request them from permitting authorities. This request is often accompanied by an offer to abide by binding and enforceable limits (emission limits, work practice standards, operational limitations, design standards, *etc.*) to reduce the facility’s potential to emit. By definition, this is “self-imposed” yet fully in accordance with the current definition of “legally and practicably enforceable.” The commenter states that, if EPA’s reference to “self-imposed” limits was intended to mean something different, then the commenter asks the Agency to clarify its position so stakeholders may comment. Moreover, before proceeding with this change in approach, the commenter asks EPA to also provide specific examples of the “self-imposed” limits it is finding, why it believes they are not legally and practicably enforceable, and sufficient supporting information so that interested parties can comment on EPA’s reasoning, such as information about the particular storage tanks, relevant permit terms, and the jurisdiction or issuing authority.

Response I-9-29: EPA believes there is confusion over what we meant by “self-imposed.” A self-imposed limit for which there is no means of enforcement, or no penalty for non-compliance is not legally or practicably enforceable. However, a limit that was requested by the permit holder and which is accompanied by binding and enforceable (as the commenter characterizes them) limits would be acceptable to take into account when calculating potential emissions, provided those limits meet the specifications of legally and practicably enforceable under the

NSPS. See response I-9-15 for anonymized examples of permits that EPA determined did not meet the criteria EPA requires for a limit to be legally and practicably enforceable.

Comment: Commenter (0817-GPA) asserts that EPA's claim in the November 2021 Proposal that its cited example lacks performance testing and continuous monitoring is misplaced, as neither is required for limits to be "legally and practicably enforceable". Indeed, the November 2021 Proposal does not identify any regulation, federal or state, that requires performance testing and continuous monitoring to ensure a limit is enforceable. Instead, the commenter suggests that the November 2021 Proposal appears to assume, without explanation, that the only "appropriate monitoring" is continuous emissions monitoring and the only "appropriate testing" is performance testing. Yet, the commenter explains that individual and general permits, as well as permits by rule, have required a wide array of monitoring and testing requirements to suit the wide array of emission sources that have taken a voluntary limit on their potential to emit. The commenter urges EPA to reconsider these well-established options and/or explain and document why it now finds all other forms of monitoring and testing to be deficient for all applications so that the public can understand why EPA is changing its position and can provide input and comment.

To the extent that there are genuine concerns with the permits EPA reviewed, such as overly vague terms that do not identify the limitation or standard or a complete absence of any type of monitoring, reporting, or recordkeeping obligations, then the commenter (0817-GPA) states that EPA has the authority to raise those issues with the delegated permitting authorities that issued the permits. Because EPA provided no details regarding the permits it reviewed, or the permitting authorities that issued the permits, the commenter notes that they cannot provide any further comment on the perceived deficiencies and requests EPA to provide this information for notice and comment before moving forward to apply any changes to this important framework. However, they adamantly believe that an operator should not be the subject of an enforcement action due to disagreements between EPA and the permitting authority over permit terms. The commenter provides that operators have a due process right to rely in good faith upon the permits issued to them by permitting authorities so long as the operator complies with the permit terms. See, e.g., *Wisconsin Resources Protection Council v. Flambeau Mining Co.*, 727 F.3d 700, 707 (7<sup>th</sup> Cir. 2013) ("even if Flambeau's permit were legally invalid, we cannot, consistent with the requirements of due process, impose a penalty on Flambeau for complying with what Wisconsin deemed a valid ... permit.").

Response I-9-30: There is no requirement in the NSPS or EG for a permitting authority to include all of the criteria EPA is proposing for the oil and gas sector regarding legally and practicably enforceable limits in its permits. Therefore, EPA has no disagreement with the permitting authority if permits do not include such limits, and indeed such permits may be sufficient to meet other state requirements. However, the concern is with holders of permits that lack legally and practicably enforceable limits who attempt to use those permits to limit their potential for emissions from applicability under the NSPS when in fact there is no legally and practicably enforceable restriction on the source's potential for emissions. Regarding the commenter's assertion that the legally and practicably enforceable monitoring criteria require continuous emissions monitoring, this is not true. Just as we explained that legally and

practicably enforceable limits do not require a numerical emissions standard, the monitoring of parameters, while continuous, do not have to continuously monitor emissions.

EPA is not adding regulatory language for legally and practicably enforceable limits in an effort to correct state permit programs. EPA enforces the NSPS as written and has chosen to add regulatory language for new affected sources under OOOOb to facilitate compliance on the part of owners and operators. EPA has obtained consent decrees for sources that failed to show compliance with the NSPS from owners and operators. The EPA did not obtain those consent decrees with state agencies.

To the commenters concern about enforcement action as a result of the terms of a permit, the EPA has expressed this concern in the past. See, e.g., 83 FR 52085 and 85 FR 57425. In addition, over the years, the EPA has expended extensive resources in enforcement actions to review permits, general permits, and permits-by-rule and found that for nearly in all cases, these permits or other requirements across an estimated 400 storage vessel facilities owned by several operators located in different states are not legally and practicably enforceable. The EPA is adopting these criteria in an attempt to reduce or eliminate such cases.

Comment: Commenter (0817-GPA) argues that the November 2021 Proposal's legal rationale for the change in definition is also problematic, relying largely on dicta from *National Mining Association v. EPA*, 59 F.3d 1351 (D.C. Cir. 1995). This case held only that the term "has the potential to emit considering controls," as used in 42 U.S.C. § 7412(a)(1), may include, as "controls," any effective state or local regulation or permit limitation and that EPA failed to justify its position that only "federally enforceable" controls are authorized under the statute. It is true that EPA was not "obliged to take into account controls that are only chimeras and do not really restrain an operator from emitting pollution," 59 F.3d at 1362, but this only explains the court's holding "that Congress intended the term to stand for effective controls" without regard to whether they were federal, state, or local. *Id.* The commenter adds that there is a wide expanse of options between ineffective "chimeras" and "effective controls," yet they contend that the EPA asserts that *National Mining Association* dictates the use of a very narrow band of specific permit terms in order to be "effective," which we submit is an incorrect reading of the court's ruling.

In fact, the commenter (0817-GPA) contends that nothing in *National Mining Association* discusses, much less compels, the November 2021 Proposal's revisions to the definition of "legally and practicably enforceable." There, EPA argued that "[g]eneral, as opposed to source-specific, permits can also be issued under a [federally enforceable state operating permit program], or under a state general permitting program similarly approved for inclusion within the [state implementation plan (SIP)]. And a state can impose constraints by general prohibitory or exclusionary rules, so long as they are included within its SIP. Finally, the SIP could be amended to reflect special source-specific limitations." 59 F.3d at 1363. The court rejected EPA's argument that tools such as general permits or permits by rule had to be federally enforceable. "What EPA has not explained is" its "refusal to credit controls imposed by a state or locality even if they are unquestionably effective. Under EPA's regime, the commenter notes that even a state program of unassailable effectiveness would not qualify in computing a source's capacity to emit unless it had been submitted not only for EPA approval, but also for inclusion in

the SIP.” Id. at 1364. But more importantly, the commenter states that the November 2021 Proposal now seems to reject EPA’s own position in that case, which endorsed the use of general permits and permits by rule. The commenter suggests that the November 2021 Proposal appears to preclude any form of general permit or permit by rule, contrary to what it argued in *National Mining Association*, not because they are voluntary and unenforceable, but because they lack the stringent and specific terms EPA has now decided to propose, once it provides regulatory text. The commenter asserts that EPA neither acknowledges nor explains this change in position.

To conclude, the commenter (0817-GPA) provides that they strongly oppose incorporating EPA’s new proposed definition of “legally and practicably enforceable” into a future NSPS OOOOb regulation. However, if EPA nonetheless determines to propose the new definition despite the numerous legal deficiencies, the commenter recommends that EPA provide appropriate flexibility to implement any new requirements. When sources fall within NSPS OOOOb requirements, owners and operators will be required to work with permitting authorities to establish new permit limitations, monitoring requirements, and recordkeeping obligations. Reopening permits for review and revision would take a significant amount of time, especially in states with a large number of upstream and midstream operations, such as North Dakota, New Mexico, Oklahoma, Pennsylvania, and Texas. The time required to implement these new permit terms will depend upon the resources and priorities of the permitting authorities, not the regulated midstream companies. Further, state and local permitting authorities may opt for existing permits to expire before implementing new terms. The commenter states that this could take several years. Thus, if EPA adopts its new definition of “legally and practicably enforceable,” the commenter suggests that EPA require compliance only upon the issuance of a new or revised permit from the permitting authority instead of establishing an arbitrary time limit for compliance. Under such a scenario, the commenter asserts that midstream companies should not be unfairly penalized for a permitting authority’s delay in updating permit terms.

Response I-9-31: The EPA disagrees with the statement made by the commenter that “What EPA has not explained is” its “refusal to credit controls imposed by a state or locality even if they are unquestionably effective.” The EPA does not agree that a control can be unquestionably effective without site-specific data showing a control system is operating within the parameters that show with actual data that it complies with a legally and practicably enforceable limit. The EPA does not reject the use of permits by rule or general permits to meet legally and practicably enforceable limits. Rather EPA is putting into regulatory text the requirements that EPA requires to ensure compliance. The legally and practicably enforceable specifications provided by this rule are specific to oil and gas storage vessels. Nothing in this rule prohibits permits by rule or general permits from providing legally and practicably enforceable requirements that a source can take into account when calculating its potential emissions, provided those LPE requirements meet the specifications provided by the rule.

#### **9.2.7 Potential to Emit**

Comment: Commenter (0803-Ohio Oil and Gas Association (OOGA)) states that EPA should not require sites to use the uncontrolled PTE calculation for storage vessels in the site-level baseline estimate to account for times when these vessels are not operating as designed (see 86 FR 63171). The commenter submits that normal operations should be assumed for purposes of

the baseline estimate, because consideration of abnormal operations will result in overestimating emissions and, thus, increased control costs with little environmental benefit. The commenter states that EPA has recognized that legally and practicably enforceable emissions limits and control requirements may be accounted for as it relates to storage vessel affected facilities and that requiring the use of assumed uncontrolled PTE for a particular source for purposes of one aspect of the proposed rule, but account for controlled emissions (which are legally and practically enforceable) in another aspect of the proposed rule would be perplexing to say the least.

In response to EPA's request for comment on whether the rule should use "uncontrolled PTE" to determine storage tank applicability, commenter (0793-PBPA), states that it should not do so for three reasons: (1) the impact to upstream sources would increase exponentially, both in terms of increased storage tank applicability and costs; (2) the impact on longstanding applicability triggers in federal and state air programs that account for and establish via permit "legally and practicably enforceable limit[s]" would increase; (3) because state NSR rules and permits address storage tanks, the existence of "large emission events" upon which EPA bases its request for comment can and should be addressed through NSR enforcement and not NSPS applicability.

Commenter (0844-EDF *et al.*) states that for EPA's storage vessel requirements to work as intended, it is critical that the PTE be calculated as accurately as possible and that EPA should consider defining storage vessels as affected facilities based on actual uncontrolled emissions, rather than defining a vessel as an affected facility based on potential to emit after a "legally and practicably enforceable limit" is taken into account. The commenter points out that there is a significant difference between actual uncontrolled emissions and EPA's PTE calculation; a tank with uncontrolled actual emissions of 120 tpy VOC, subject to a "legally and practicably enforceable limit" requiring 95 percent control of emissions, would have a PTE of 6 tpy VOC. However, the commenter states that controls frequently fail, and it is well established that storage vessels are often the source of large emission events due to open thief hatches, deterioration of the vessel, failure of control equipment, and many other reasons. The commenter recommends that EPA consider adopting Colorado's approach, which relies on actual uncontrolled emissions, rather than PTE.

Commenter (0817-GPA) states that EPA should make accommodations in its proposed EG OOOOc for those storage tanks that are already equipped with legally and practicably enforceable VOC controls, as those storage tanks are already required to reduce methane emissions, as a co-benefit to enforceable VOC reduction requirements. The commenter recommends that any estimate of methane emissions from these sources include the controls already imposed and that absent existing controls, EPA allow sources to take an enforceable limit to keep methane emissions below the 20 tpy threshold in lieu of satisfying any other existing source requirements.

For new sources, the commenter (0817-GPA) recommends that EPA establish only a VOC limit for storage vessels, to simplify rule compliance and state permitting actions for these facilities. The commenter cites to section 6.5.1 of the November 2021 Proposal Technical Support Document (TSD) which states that "the inclusion of a potential methane emissions limit is expected to have very limited impacts for new sources. Based on the E&P TANKS modeling

runs, only 9 of 103 storage vessels were projected to have methane emissions greater the VOC emissions.” The commenter states that they expect most storage vessels in the gathering and boosting (G&B) sector will have higher VOC emissions than methane emissions and based on this data from EPA, and since VOCs and methane are co-pollutants, they recommend that EPA should establish only a VOC limit for storage vessels.

Response I-9-32: See discussion in section IV.J.1.b of the December 2022 Supplemental Proposal regarding EPA’s rationale for including a potential for methane emissions in storage vessel applicability for new sources.<sup>33</sup>

In the November 2021 Proposal, EPA requested comment on whether facilities should use uncontrolled PTE calculations for their storage vessels in their site-level baseline estimates for determining the frequency of monitoring of fugitive emissions components at well sites, not for determining storage vessel applicability. EPA is not finalizing a site-level baseline emissions threshold for fugitives monitoring. See section IV.A.1.a.ii of the December 2022 Supplemental Proposal for discussion and responses to comments regarding site-level baseline emissions.<sup>34</sup>

### ***9.2.8 Determination of Potential Emissions***

Comment: Commenter (0598-CER) recommends that EPA develop a calculator for operators to use for calculating emissions from storage vessels. The commenter explains that they have been using the E&P TANKS program for the past several years to estimate emissions from storage vessels and recommends that EPA use the E&P TANKS program as a foundation to develop a web-based calculator, including methane emissions, for estimating emissions from storage facilities. The commenter further recommends that the calculator should be available no later than the date that operators are required to begin compliance with the revised regulation. The commenter explains that a web-based calculator is preferred because it will be easily accessible for operators, new software does not need to be installed on company managed computers, and EPA would be able to easily update the calculator to add new features.

Commenter (0599-MSC) states that current NSPS OOOOa requires that potential VOC emissions must be calculated using a generally accepted model or calculation methodology. The commenter requests that EPA confirm that potential methane emissions also shall be calculated using a generally accepted model or calculation methodology.

Response I-9-33: See discussion in section IV.J.1.b of the December 2022 Supplemental Proposal regarding “generally accepted” models or calculation methodologies for estimating storage vessel methane and VOC emissions.<sup>35</sup>

### **9.2.9 State Program Alternatives**

Comment: Commenter (0831-AXPC) recommends that EPA continue its allowance of state program alternatives for the regulation of storage vessels or tank batteries to reduce what would otherwise be duplicative control, recordkeeping, and reporting requirements.

Response I-9-34: The final NSPS OOOOb and EG OOOOc continue to allow owners/operators to take into account requirements under a legally and practicably enforceable limit in an operating permit or other requirement established under a federal, state, local, or Tribal authority.

### **9.2.10 Modification of Storage Vessel Affected Facility**

Comment: Several commenters (0820-Pioneer, 0911-North Dakota Petroleum Council (NDPC), 0938-TXOGA, 0831-AXPC, 0808-API, 0817-GPA) suggest that the November 2021 proposed definition of what constitutes a modification of a tank battery is inconsistent with the definition of modification with CAA 111 (codified at 40 CFR §60.14), which generally is defined as “any physical or operational change to an existing facility which results in an increase in the emission rate to the atmosphere of any pollutant to which a standard applies.”

Commenter (0911-NDPC) disagrees with the November 2021 proposed changes to the definition of modification with respect to storage vessel because EPA has not demonstrated the necessity of this change nor how its implementation will benefit the environment. The commenter further states that the proposed activities are not a “physical change in, or change in the method of operation of, a stationary source.” See 42 U.S.C. § 7411(a)(3). The commenter (0911-NDPC) provides by way of example, that as currently proposed, this could include the relocation or replacement of a storage vessel. The commenter recommends that the definition of modification with respect to storage vessels remain unchanged to remain consistent with the definition of “modification” under the CAA.

Commenter (0938-TXOGA) states that the November 2021 proposed activities which trigger modification in the rule are inconsistent with the statutory definition. The commenter provides the CAA definition of modification<sup>36</sup> which states, “[t]he term ‘modification’ means any physical change in, or change in the method of operation of, a stationary source which increases the amount of any air pollutant emitted by such source or which results in the emission of any air pollutant not previously emitted” and points out that in the November 2021 Proposal, EPA used “shorthand” language that refers to “change in operation,” and does not include the statutorily-referenced “change in *method* of operation” (emphasis added). The commenter states that they expect that when EPA provides regulatory language (to create a proposal) for comment, that EPA intends to use the statutory language, as it has in 40 CFR part 60 previously, and that the references in this notice to “operational change” are merely for convenience. The commenter explains that the “method of operation” language is important, given that EPA proposes that a

---

<sup>36</sup> 42 U.S.C. § 7411(a)(4).

modification occurs “when physical or operational changes are made to the single storage vessel or tank battery that result in an increase in the potential methane or VOC emissions.”<sup>37</sup>

Commenter (0938-TXOGA) goes on to provide comment on specific aspects of the November 2021 proposed physical changes or changes in what the commenter believes EPA means to be changes in the method of operation. The commenter states that the first two - the addition of a storage vessel to an existing tank battery and the replacement of a storage vessel such that the cumulative storage capacity of the existing tank battery increases (as opposed to the replacement of a tank that does not increase aggregate storage capacity, which should not constitute a modification)<sup>38</sup> seem typical of physical changes to the tank battery, in that they involve both construction and an increase in capacity. The commenter states that the last activity which is a modification trigger; *i.e.*, the receipt of additional crude oil, condensate, intermediate hydrocarbons, or produced water throughput (from actions such as refracturing a well or adding a new well that sends these liquids to the tank battery), is not a physical change and it does not constitute a change in the method of operation of the vessel or battery.

According to the commenter (0938-TXOGA), EPA is making two potential errors in their analysis. First, the commenter states that a tank is a tank and if there is not a change to the tank itself (*e.g.*, no accommodation that needs to be made to accept the increased throughput), then the “affected facility” – *i.e.*, the tank/battery – has not been physically changed. Second, the commenter states that the method of operation of a tank is to receive, store, and dispense its contents and that receiving more or less, short of the actual capacity of the tank, cannot logically be a change in its method of operation. The commenter states that the NSPS general provisions exclude from the definition of “modification” “an increase in production rate of an existing facility, if that increase can be accomplished without a capital expenditure on that facility.”<sup>39</sup> Third, the commenter states that there appears to be an assumption by EPA that an “increase” in throughput necessarily meets the requirement for an increase in potential emissions and it is not necessarily going to hold true across the board and should not be presumed. The commenter states that they think that EPA may be recognizing this in the statement that the rule would require the owner or operator to “recalculate the potential VOC emissions” in such instances, but because there is no proposed regulatory text, the commenter is unable to ascertain EPA’s intent and for this reason, among others, cannot meaningfully comment on the issue at this time. Later in the preamble,<sup>40</sup> the commenter explains, EPA states that a “single storage vessel or tank battery *is modified* when any of the following physical or operational changes are made” and then lists these same activities (*i.e.*, addition of a tank to an existing tank battery, replacement of a tank that increases battery capacity, increasing throughput to an existing tank). The commenter references EPA’s reasoning from the preamble<sup>41</sup> that for the first two activities, “the increased storage capacity will lead to higher breathing losses and thereby increase the VOC emissions” and with respect to the throughput criterion, EPA states that it will “increase the volumetric

---

<sup>37</sup> See 86 FR 63178. The commenter (0938-TXOGA) interprets EPA’s shorthand references to physical or operational change as meaning “physical change, or change in the method of operation” and does not ascribe legal significance to the “operational change” on its own. 40 C.F.R. § 60.14.

<sup>38</sup> The commenter (0938-TXOGA) emphasizes that the relocation of an affected facility does not constitute construction of a facility under 40 C.F.R. § 60.14.

<sup>39</sup> 40 C.F.R. §60.14(e)(2).

<sup>40</sup> 86 FR 63198.

<sup>41</sup> 86 FR 63199.

throughput of the tank battery relative to the throughput prior to storage of the additional fluid.” The commenter counters that this rationale does not consider that an increase in throughput does not necessarily lead to an increase in emissions, depending on the capacity of the existing storage vessel, and that it is not appropriate to bypass the emissions increase step in the modification analysis which is required by the statutory modification definition.

Commenter (0938-TXOGA) references the Background Technical Support Document<sup>42</sup> and EPA’s description of storage vessel emissions therein, where EPA describes that throughput for storage vessels may vary for a number of operational reasons, which leads to variations in the type and nature of emissions. The commenter states that such variations are not physical changes or changes in the method of operation, rather, they reflect the normal operation of the existing tanks as the production from a particular well or wells that are utilizing the tank vary and that such variations occur without any actual change to the tank itself. The commenter states that the parenthetical in the preamble “from actions such as refracturing a well or adding a new well that sends these liquids to the tank battery”<sup>43</sup> is confusing and inaccurate because it reaches beyond the defined affected facility, and, even if it were appropriate (which it is not), the “such as” language is unclear as to what EPA would consider to be a physical or operational change beyond those two specific examples. The commenter recommends that to the extent that EPA seeks to identify specific activities that constitute changes for which a source would evaluate if an emissions increase will occur, EPA should list those actions specifically (and should limit it to the affected facility in question). Finally, for sources that have restricted potential emissions from the vessel and/or battery to below 6 tpy, the commenter states that the requirement to “recalculate” VOC PTE is duplicative. The commenter explains, that in practice, to ensure that they do not trigger the requirements of the rule, many operators accept limits on their PTE and in such instances, no recalculation would be needed, as a modification could not occur since it requires both a change and an increase in potential emissions. The commenter requests that EPA clarify that this is not the intended result.

Commenter (0831-AXPC) asserts that the definition for what constitutes a modification of a tank battery is inconsistent with the definition of modification within the CAA 111 (40 CFR 60.14) and provides by way of example, that contrary to EPA’s November 2021 Proposal that a single storage vessel or a tank battery is modified when it “receives additional crude oil, condensate, intermediate hydrocarbons, or produced water throughput (from activities such as refracturing a well or adding a new well that sends these liquids to the tank battery),” the storage vessel or tank battery is neither physically changed nor operationally changed as the change occurred at a different affected facility. The commenter states that the example does not speak to a demonstration that the additional throughput resulted in an increase in the emission rate of the storage tank or tank battery. The commenter explains that practically speaking, operators would not be able to compliantly send additional throughput to a vessel or battery that would cause the facility to exceed its permitted emissions. The commenter adds that it is also important to note there will be circumstances that an operator may have need to replace a storage vessel, which should not trigger modification unless it increases the potential to emit at the facility. In

<sup>42</sup> “Background Technical Support Document for the Proposed New Source Performance Standards (NSPS) and Emissions Guidelines (EG) 40 C.F.R. Part 60, subpart OOOOb (NSPS), 40 C.F.R. Part 60, subpart OOOOc (EG),” at 6-1 (Oct. 2021), Docket ID No. EPA-HQ-OAR-2021-0317-0166 (Background Technical Support Document).

<sup>43</sup> 86 FR 63198.

summary, the commenter recommends that EPA adhere to the statutory definition for modification as it relates to a single storage vessel or a tank battery.

Commenter (0808-API) states the November 2021 proposed definitions have two flaws and are not consistent with the CAA because (1) they do not require a physical or operational change at the given affected facility; and (2) they presume an emissions increase where such an increase often would not occur. Regarding the perceived first flaw, the commenter explains that according to EPA's November 2021 Proposal, a physical change or change in the method of operation is deemed to occur at a given centralized production facility (CPF) or tank/tank battery, even though no physical or operational change has occurred at that CPF or tank/tank battery. Under these definitions, the commenter states that the relevant physical or operational change occurs at a different affected facility, which does not satisfy the statutory requirement that the modification of a given affected facility must entail a physical change or change in the method of operation at that same facility. The commenter explains the second flaw is that EPA has not demonstrated that these activities necessarily result in an emissions increase at the given CPF **or tank/tank battery** [emphasis added]. By way of example, the commenter provides that the fact that an upstream well is modified does not necessarily mean that a downstream CPF or tank/tank battery would have an actual emissions increase. More importantly, the commenter states, there is even less likelihood that the downstream operations would have a regulatory emissions increase, given that the 40 CFR part 60 definition of "modification" requires an increase in the short-term potential to emit of an affected facility. 40 CFR. 60.14(b).

Commenter (0820-Pioneer) recommends several revisions to the activities which trigger modification in the 2021 November Proposal:

- i. *Addition of a tank to an existing tank battery.* The commenter recommends that this modification trigger should be removed unless there is a corresponding increase in production at the tank battery. The commenter explains that adding a tank to an existing battery, which is already controlled under existing rules/regulations, does not increase emissions. The commenter also stated that their tank storage systems are all manifolded, such that the addition of one or more tanks, without a corresponding increase in production, would not increase emissions.
- ii. *Replacement of a tank that increases battery capacity.* Commenter recommends that this modification trigger should be removed for the same reasons the commenter provides above. The commenter further states that an increase in capacity does not equal an increase in emissions and, therefore, should not be considered a modification under any rule.
- iii. *Increasing throughput to an existing tank.* The commenter recommends that EPA define "increasing throughput" in accordance with how storage tanks are managed through the state permitting process. The commenter explains that storage vessels typically are permitted at the maximum physical production throughput based on equipment at the site. The commenter explains that this is done as a safety factor, but the storage vessel emissions never actually operate at the maximum PTE. The commenter

suggests that EPA include language that specifies an increase in throughput above current permitted PTE would be considered a modification.

Commenter (0817-GPA) suggests the following change to the definition of “modification” (underlined text represents suggested additions, and cross-outs represent suggested deletions):

Physical or operational changes would be defined to include: (1) The addition of a storage vessel to an existing tank battery; or (2) replacement of a storage vessel such that the cumulative storage capacity of the existing tank battery increases; and/or ~~(3) an existing tank battery or single storage vessel that receives additional crude oil, condensate, intermediate hydrocarbons, or produced water throughput.~~

The commenter (0817-GPA) explains that the receipt of additional product to an existing storage vessel should not be defined as a modification as 40 CFR 60.14(e)(2) explicitly excludes from the definition of “modification” any “increase in production rate of an existing facility, if that increase can be accomplished without a capital expenditure on that facility.” Further, the commenter believes the proposed definition disregards whether the addition of product would actually result in emissions increases from the storage vessel.

Although the commenter (0817-GPA) stresses that EPA must require both a physical change to the storage vessel and an emissions increase, as currently required by 40 CFR 60.14(a), if EPA is intent on changing the definition of “modification” to include a reference to throughput, the commenter recommends that EPA specify any increase in throughput to exceed existing permitted limits, instead of defining a “modification” as any increase in throughput. Particularly with respect to the midstream sector, the commenter asks EPA to understand that liquid throughput volumes at midstream facilities are not impacted significantly by the addition or refracturing of a well at an upstream site; these are not physical or operational changes at midstream facilities, but somewhere else. The commenter explains that for midstream facilities, an upstream facility adding or refracturing a well simply means receiving a relatively minor volume of additional product, which is part of routine operations and is evaluated in potential to emit calculations during permitting activities and that the receipt of additional product is not a change to the regulated facility itself and the routine changes in product volume are already accounted for by permitting agencies as part of the facility design.

Commenter (0814-IPAA *et al.*) states that EPA’s November 2021 Proposal for changing the modification threshold based on new production directed to a tank battery creates unnecessary complications based on poorly understand industry practices. The commenter explains that tank batteries are designed based on the initial production from a grouping of oil or natural gas well sites, but later will operate at a throughput well below their design rate. Because of this, the commenter explains it is common industry practice for wells to be redirected to different tank batteries at new or existing well sites to consolidate operations. The commenter states that at low production well sites, these redirected wells are frequently low production wells, but regardless will deplete further over time. The commenter references EPA’s statements that applying vapor capture to existing tanks is more costly and can confront structural challenges compared to new tanks. Further, the commenter references EPA’s determination that the cost effectiveness for regulating methane emissions from storage tanks differs from VOC when setting the emissions

threshold at 20 tpy. The commenter believes that EPA's new definition of modification triggers a convoluted decision process that can drive expensive tank reconstruction expenditures for temporal changes in emissions. By way of example, the commenter references EPA's proposed EG OOOOc which would not require vapor capture from an existing tank if its methane emissions are less than 20 tpy. Further, the commenter cites to E&P TANK documentation that shows that there are circumstances where a condensate or crude oil tank with less than 20 tpy of methane emissions could have VOC emissions exceeding 6 tons/year. The commenter states that EPA's revision to the definition of modification provides that the addition of production from any well new to a tank battery will be considered a modification because it alters the tank battery emissions even though the emissions may be well below the design capacity of the tank battery and even though the change may be temporal when the new well's production declines. Further, the commenter explains, even though the emissions increase might not cause the tank to exceed 20 tpy of methane, if the tank was already emitting more than 6 tpy of VOC, vapor capture would be required (and even though emissions could fall below 6 tpy of VOC when the production decline). Additional considerations, the commenter provides, is that an operator with a battery already controlled well over 95 percent under a state permit (but that doesn't meet the legally and practically enforceable requirements), would become a NSPS OOOOb tank battery which will not result in any additional reduction in emissions and actual environmental benefit but will add regulatory burden. The commenter suggests that EPA did not anticipate this scenario, which increases regulatory burden without some environmental benefit.

The commenter (0814-IPAA *et al.*) believes that these cyclical emissions circumstances can drive capital costs for low production operations that result from minor increases in emissions (or no overall emissions increase if an existing well is being transferred from one tank battery to another) and can result in the perverse effect of keeping uncontrolled tank batteries in operation because the cost of retrofitting vapor capture on the "modified" tank battery is too costly. As an alternative, the commenter suggests that EPA should use intermediate control strategies that can provide cost effective emissions reductions, particularly for the universe of low production wells. The commenter provides the specific example that where a tank battery is modified because a well is newly added to it but where all of the wells feeding it are low production wells, a cost-effective action would be to require an audio, visual and olfactory (AVO) inspection of these tanks to assure that thief hatches are closed, and seals maintained until the tank battery emissions exceed 20 tpy of methane. The commenter believes that such an approach would be consistent with EPA's determination that tank battery emissions of 20 tpy of methane is the cost effectiveness threshold for vapor capture while achieving emissions reductions from thief hatches and seals that have been identified as a significant component of tank emissions.

Commenter (0777-Ascent) suggests that EPA include an exception from the definition of "modification" for a nominal increase in capacity. The commenter is concerned that the definitions of "modification" and "physical or operational change" as applied to tank batteries is overbroad and will capture de minimis changes at tank batteries that are not associated with an attempt to build out the capacity of the tank battery with a new tank or any increase in throughput of the tank battery. To accomplish this, the commenter recommends that EPA exclude tank replacements not associated with a throughput increase from the definition of "physical or operational change" for purposes of tank batteries. The commenter proposes that physical or operational changes would be defined to include: (1) The addition of a storage vessel

to an existing tank battery; ~~(2) replacement of a storage vessel such that the cumulative storage capacity of the existing tank battery increases;~~ and/or ~~(2)(3)~~ an existing tank battery or single storage vessel that receives additional crude oil, condensate, intermediate hydrocarbons, or produced water throughput (from actions such as refracturing a well or adding a new well that sends these liquids to the tank battery). The commenter notes that this definition would capture the addition of new tanks and increases in throughput and emissions, but it will not capture a change where, for example, an existing vessel is replaced with a slightly larger vessel where the owner or operator is not making the change to accommodate increased throughput. Owners and operators may need to replace a vessel and the available replacement options are slightly larger, though the increase in capacity is not the driver for the change, the commenter maintains. In those circumstances, the commenter states, the vessel replacement should not be considered a modification, or a physical or operational change, of the tank battery. The commenter requests that, if EPA continues to propose storage vessel applicability on a tank battery basis, EPA propose a definition of “physical or operational change” that includes the addition of a new storage vessel and the tank battery’s receipt of additional throughput, but does not make the replacement of an individual storage vessel with increased capacity, where there is no associated change in throughput, a change that could be considered a modification of the storage vessel affected facility.

Commenter (0739-Citation) states that EPA is proposing that a single storage vessel or tank battery is considered modified when an existing tank battery or single storage vessel receives additional crude oil, condensate, intermediate hydrocarbons, or produced water throughput (from actions such as refracturing a well or adding a new well that sends these liquids to the tank battery). The commenter adds that historically, an increase in production rate of an existing facility is not a modification if that increase can be accomplished without a capital expenditure on that facility. The commenter requests that EPA exempt storage vessels or tank batteries which are subject to a legally and practicably enforceable limit in an operating permit or other requirement established under a federal, state, local or Tribal authority from this modification definition.

Conversely, commenter (0844-EDF *et al.*) supports EPA’s November 2021 proposed definition of “modification” for storage vessels. The commenter states that adding a storage tank to a tank battery is a physical change to a storage vessel affected facility that results in an increase in emissions. The commenter contends that replacing a storage vessel with one that has a larger volumetric capacity is also a physical change that increases emissions and it is the commenter’s understanding that this frequently occurs at facilities that are space-constrained; rather than clear new land or space for a new storage vessel, operators who need increased storage capacity will choose a taller vessel that fits the same footprint as the one being replaced, thus increasing capacity without taking up more space. Finally, the commenter states that a tank battery that receives increased throughput that results from the refracturing or addition of a well increases its emissions beyond the projected emissions without that operational change. The commenter states that each of these three actions are modifications as defined by the CAA.<sup>44</sup> Additionally, the commenter recommends that an operator be required to reevaluate a storage vessel affected facility’s PTE after a modification has occurred; for example, replacement of a tank indicates that either there was something wrong with the older tank, or that there was a need for more

---

<sup>44</sup> 42 U.S.C. 7411(a)(4).

capacity. Similarly, the commenter argues, the addition of a tank indicates a need for more capacity. In both instances, the commenter states, the facility is undergoing a physical change that inherently affects its emissions, hence the PTE for the source in question should be reevaluated, (as it should also be whenever increased throughput is set to occur). The commenter adds that even with the same controls, the replacement of a smaller storage vessel with a larger one, or the addition of a new vessel to a battery, can change the potential to emit and because there are applicability thresholds where a new storage vessel could be unregulated because its PTE is below 6 tpy, an operator should have to demonstrate that the modified facility's PTE is in the same category (affected vs. unaffected) as it was prior to the modification.

Response I-9-35: With regard to the general definition of modification of tank batteries, see discussion in section IV.J.1.b of the December 2022 Supplemental Proposal.<sup>45</sup>

EPA disagrees with commenters that the definition of modification of tank batteries is inconsistent with the definition of modification within the General Provisions at 40 CFR 60.14. The definition included in the final rule (section 60.5365b(e)(3)(ii)) includes both a physical/operational change and a resulting emissions increase, which is consistent with the General Provisions definition. The final rule defines modification of a tank battery occurring when any of the actions below result in the potential for VOC or methane emissions to meet or exceed either of the thresholds (6 tpy VOC or 20 tpy methane):

- (1) a storage vessel is added to an existing tank battery,
- (2) one or more storage vessels are replaced such that the cumulative storage capacity of the existing tank battery increases,
- (3) for tank batteries at well sites or centralized production facilities, an existing tank battery receives additional crude oil, condensate, intermediate hydrocarbons, or produced water throughput from actions, includes but not limited to, the addition of a process unit or production well, or changes to a process unit or production well (including hydraulic fracturing or refracturing of the well), or
- (4) for tank batteries at compressor stations or onshore natural gas processing plants, an existing tank battery receives additional fluids which cumulatively exceed the throughput used in the most recent determination of the potential for VOC or methane emissions.

An existing tank battery or single storage vessel will become subject to the NSPS if one of the actions in this definition of modification occur and the potential VOC or methane emissions are greater than or equal to the 6 tpy VOC/20 tpy methane emissions threshold. Commenters contend that the addition of a process unit or production well, or changes to a process unit or production well (including hydraulic fracturing or refracturing of the well) does not require a physical or operational change at the given affected facility (i.e., the tank battery); and presumes an increase in emissions where such an increase often would not occur. The EPA disagrees with the commenter for the following reasons. As explained in the November 2021 preamble<sup>46</sup>, those

---

<sup>45</sup> 87 FR 74801 (December 6, 2022).

<sup>46</sup> 86 FR 63199 (November 15, 2021).

actions (e.g., addition of a process unit or production well, or changes to a process unit or production well (including hydraulic fracturing or refracturing of the well) which result in the receipt of additional regulated fluids will increase the volumetric throughput of the tank battery relative to the throughput prior to storage of the additional fluid which constitutes an operational change. Further, this increase in volumetric throughput will result in an increase in working losses and potentially flashing losses from the tank battery which constitutes an increase in emissions. However, in order to determine if these actions result in applicability to the NSPS, the owner or operator must recalculate the potential for VOC and methane emissions using the methodologies at §60.6535b(e). In those instances where the potential to emit remains below 6 tpy VOC or 20 tpy methane, the NSPS will not apply; where these changes result in potential emissions at or above those thresholds, the NSPS applies.

Other commenters contend that since the emissions rate has not increased, a modification has not occurred. The EPA dismisses this out of hand, because of the inherent difference in sources that emit vastly different quantities of emissions when controlled with a control device that meets a control efficiency of 95 percent. The EPA continues to assert that actions described in the definition of modification result in emissions increase to the atmosphere, either through an increase in capacity or an increase in throughput. Those additional working, breathing or flashing losses result in an increase in emissions to atmosphere, even if controlled, unless the control efficiency is increased to mitigate those additional emissions. This comment also misses the point of having a 6 tpy threshold for affected facility status, to distinguish between those for which control is cost effective, and for those that control is not cost effective. The foundation of nearly all CAA rules is to ascribe controls appropriate to the potential for emissions. Regarding the comments related to capital expenditure, the EPA disagrees that a capital expenditure is requisite to the definition of modification. 40 CFR 60.14(f) allows EPA to set provisions specific to an applicable subpart, which we have done here. As other commenters have noted, the General Provisions at 40 CFR 60.14. defines a modification as both a physical or operational change and a resulting emissions increase to the atmosphere. The definition of modification reflects both of these elements, and need not include any reference with respect to capital expenditure.

## **9.3 BSER**

### ***9.3.1 General***

Comment: Commenter (0424-Division of Air Quality, West Virginia Department of Environmental Protection (WVDEP)) requests clarification whether the proposed GHG standards for 95 percent methane reduction for storage tanks (battery) with PTE  $\geq$ 20 tpy shown in Table 3 of the November 2021 Proposal are more stringent than the current 6 tpy VOC threshold for tank emission reductions.

Response I-9-36: The BSER for storage vessel affected facilities has not changed in stringency from the NSPS OOOO and NSPS OOOOa requirements to reduce VOC emissions by 95 percent. The stringency of the applicability, however, has changed in such a way as to consider

both the methane and VOC emissions from an entire tank battery, instead of each individual storage vessel.

Comment: Commenters (0781-NTAA, 0943-Sault EPD, 0391-KBIC, 0605-Muscogee (Creek) Nation, 0833-Ute EPD) request that EPA consider requiring higher control than 95 percent reduction in emissions where it is feasible.

Commenter (0756-Baker Hughes (BH)) states that EPA should consider raising the targeted VOC and methane minimum allowable control efficiency to 98 percent. The commenter explains that there are thief hatch technologies (*e.g.*, thief hatch elimination devices) in late-stage development that will eliminate the vent to atmosphere from thief hatches and therefore will achieve higher reductions in storage vessel emissions associated with thief hatches. The commenter states that this device would retrofit on to existing storage tanks and would replace thief hatches on new storage tanks and would eliminate virtually 100 percent of the emissions resulting from thief hatches, as it provides a pipe-away configuration to a vapor recovery system while still providing access to the tank contents for gaging and sampling purposes and has the added benefit of protecting the worker from being exposed to flammable atmosphere at the thief hatch port as well as toxic vapors from the storage tank head space.

Response I-9-37: Regarding the comment that EPA consider requiring higher control than 95 percent reduction in emissions where it is feasible, EPA discussed the results of the analysis which was used to establish emissions limits for storage vessels in section XII.B.1.e. of the November 2021 Proposal. The commenter did not dispute this analysis nor provide additional information for the EPA to consider.

EPA acknowledges the commenter's statements regarding thief hatch technologies and encourages owners and operators to utilize new technologies, such as those described by the commenter. However, the commenter did not provide enough information to allow EPA to evaluate the costs and feasibility of the use of these technologies for consideration in revisions to the BSER for storage vessel affected facilities at this time. Therefore, the BSER for storage vessel affected/designated facilities in the final rules is 95 percent reduction of VOC and methane emissions (for new sources) and 95 percent reduction of methane emissions (for existing sources).

Comment: Commenter (0786-Enerplus Resources (USA) Corporation (Enerplus)) describes other thief hatch improvements such as lock-down thief hatch systems. The commenter explains that while a traditional thief hatch designs provide three potential leak points per thief hatch (a total of 24 potential leak points for a typical eight storage vessel battery), lock-down thief hatch systems eliminate those potential leak points and replaces them with only three, significantly more reliable, pressure and vacuum relief points for the same eight storage vessel battery. The commenter explains that their new storage vessels are rated to 32 ounces of pressure as compared to a typical API 12f storage vessel rated to 16 ounces and that this difference provides cushion for pressure swings and pressure relief is pallet-weighted to relieve at a higher pressure without fluttering open prior to the relief setpoint. The commenter requests reduced inspection

frequencies for facilities engineered to eliminate and prevent leaks to encourage technological innovation across the industry.

Response I-9-38: See Response I-9-37.

Comment: Commenter (0817-GPA) suggests that EPA should consider existing enforceable controls for storage vessels. The commenter states that they do not oppose a threshold of 20 tpy for methane emissions from existing storage vessels, but do not support a lower threshold. Further, the commenter states that EPA should make accommodations in its proposed guidelines for those storage tanks that are already equipped with legally and practicably enforceable VOC controls as those storage tanks are already required to reduce methane emissions as a co-benefit to enforceable VOC reduction requirements. The commenter recommends that any estimate of methane emissions from these sources include the controls already imposed and that absent existing controls, and that EPA allow sources to take an enforceable limit to keep methane emissions below the 20 tpy threshold in lieu of satisfying any other existing source requirements. The commenter states that doing so could alleviate some of the logistical difficulties on state agencies, as methane emission limits are not currently included in most permits. The commenter is concerned that without considering existing controls, state and local permitting agencies would be required to re-open thousands of existing permits in order to create new methane emission limits.

Response I-9-39: EPA agrees with the commenter that controls of VOC are equally effective for methane, and that sources that are controlling VOC emissions will be controlling methane emissions to the same degree. Addressing the concern of re-opening existing permits, provisions finalized in this action are applicable to new, modified, and reconstructed sources under the NSPS OOOOb generation of sources, and existing source designated facilities under OOOOc, and are not retroactively applicable to OOOO or OOOOa sources. As states develop their plans under OOOOc EG, the requirements as applicable to designated sources, multiple options exist to implement the criteria that EPA is promulgating to define legally and practicably enforceable emission limitations.

Comment: Commenter (0446-Artex Oil Company (Artex)) requests that EPA establish an explicit exemption for existing conventional oil and gas wells, as the cost of applying the November 2021 proposed emissions guidelines for control of emissions from storage vessels will force many owners and operators to either shut-in or, in some cases, potentially abandon these assets. The commenter believes that the resulting loss of these valuable natural resources runs counter to the directive of the Ohio Department of Natural Resources (ODNR) to preserve the responsible use of existing natural resources in their states of jurisdiction.<sup>47</sup>

Response I-9-40: The commenter has not provided any information on the potential for VOC or methane emissions from storage vessels associated with conventional wells. Therefore, EPA is unable to evaluate if a categorical exemption for conventional wells is appropriate.

---

<sup>47</sup> See, for example, Ohio Revised Code [ORC] 1509.20 which requires “every reasonable precaution in accordance with the most approved methods of operation to stop and prevent waste of oil or gas, or both.”

Comment: Commenter (0814-IPAA *et al.*) recommends that EPA develop emissions management strategies that do not require vapor capture for lower emissions tank batteries. By way of example, the commenter states that data collected by GSI Environmental, Inc, and even environmental groups, show that significant emissions sources at tank batteries are open thief hatches and deteriorated seals around tank openings, which can be addressed through routine operational and maintenance programs.

Response I-9-41: See discussion in section IV.A.1.a.ii of the December 2022 Supplemental Proposal.<sup>48</sup>

Comment: Commenter (0911-NDPC) requests that EPA clarify what type of storage vessels are covered under the November 2021 Proposal, as the BSER analysis appears to only cover fixed roof tanks.

Response I-9-42: The final rule for NSPS OOOOb defines storage vessel at 60.5430b as follows:

*Storage vessel* means a tank or other vessel that contains an accumulation of crude oil, condensate, intermediate hydrocarbon liquids, or produced water, and that is constructed primarily of nonearthen materials (such as wood, concrete, steel, fiberglass, or plastic) which provide structural support. A well completion vessel that receives recovered liquids from a well after startup of production following flowback for a period which exceeds 60 days is considered a storage vessel under this subpart. A tank or other vessel shall not be considered a storage vessel if it has been removed from service in accordance with the requirements of §60.5395b(c)(1) until such time as such tank or other vessel has been returned to service. For the purposes of this subpart, the following are not considered storage vessels:

- Vessels that are skid-mounted or permanently attached to something that is mobile (such as trucks, railcars, barges, or ships), and are intended to be located at a site for less than 180 consecutive days. If you do not keep or are not able to produce records, as required by §60.5420b(c)(5)(iv), showing that the vessel has been located at a site for less than 180 consecutive days, the vessel described herein is considered to be a storage vessel from the date the original vessel was first located at the site. This exclusion does not apply to a well completion vessel as described above.
- Process vessels such as surge control vessels, bottoms receivers, or knockout vessels.
- Pressure vessels designed to operate in excess of 204.9 kilopascals and without emissions to the atmosphere.

This same definition is also included in the final EG OOOOc, with reference to specific sections in the model rule language for EG OOOOc replacing the NSPS OOOOb references. This definition is consistent with the definition in NSPS OOOOa.

The final rules apply to all storage vessels, as defined in the rules, that exceed the applicability threshold and is not limited to fixed roof tanks. Owners/operators may use a floating roof to meet

---

<sup>48</sup> 87 FR 74730 (December 6, 2022).

the required standards as specified in 40 CFR 60.5395b(b)(2) (i.e., where the storage vessel affected facilities does not have flashing emissions and is not located at a well site or centralized production facility).

### ***9.3.2 Costs of Control are Underestimated***

Comment: Commenters (1341-PGCC *et al.*) state that the November 2021 Proposal is unreasonable and must not be applied to their members.<sup>49</sup> The commenters explain that the storage tanks used by their members<sup>50</sup> are relatively small and often not designed to hold fluids at pressure and that EPA's model tank batteries are materially and significantly different from the tanks used by their members. The commenters state that EPA's cost-effectiveness calculations are therefore flawed and substantially underestimate the costs that would be imposed on their members if they were required to take all the steps necessary to install and operate a flare, enclosed combustor, or VRU to control what are already exceedingly small amounts of emissions. Specifically, the commenters explain that requiring any type of emission control device for these tanks would require that they be modified, if possible, or likely replaced altogether to install the control devices that EPA proposes to require and that EPA's cost evaluation only analyzes the estimated cost for *controlling* emissions. *See* November 2021 Proposal TSD, §6.4.3.3 (evaluating only the cost of control systems). The commenters suggest that such costs would be exorbitant, especially for the many small businesses in their member Conventional Groups and recommend that EPA gather information on the number and types of tanks employed by conventional oil and gas operators, and analyze this information, to determine BSER for these tanks.

Commenter (0808-API) requests additional consideration regarding costs of control for certain scenarios. The commenter states that as oil production declines, operators may need to replace the original storage vessel or tank battery combustion device with a smaller capacity device. The commenter states that applying the same threshold as a single storage vessel to a tank battery means that a control device will be required for a longer duration and that this longer control duration (and potential additional costs for a smaller replacement control device) were not considered in EPA's cost analysis.

Commenter (0793-PBPA) contends that the requirement to install VRUs will have an excessive impact on small business operators, which they state EPA has not considered. The commenter goes on to explain that each oil and gas facility is operated differently depending on, among other things, the location (basin), the type of product produced, the amount of product produced and stored, the age of the field where the product originates, various treatment options at the production site, the age of the production and storage equipment, and the available transportation infrastructure. The commenter states that all of these considerations play a role in determining the amount of emissions associated with oil and gas production and storage operations; yet EPA's November 2021 Proposal effectively treats all storage tanks the same. In particular, the commenter explains that section 111 of the CAA requires that EPA consider a number of factors,

---

<sup>49</sup> 1341- Pennsylvania Grade Crude Oil Coalition, Pennsylvania Independent Petroleum Producers, Pennsylvania Independent Oil & Gas Association, and Independent Oil & Gas Association of New York identify as the "Conventional Groups."

<sup>50</sup> The "Conventional Groups."

including cost, in determining “the best system of emission reduction . . . adequately demonstrated”<sup>18</sup> but that when evaluating the cost of emission controls per ton of emission reduction, EPA evaluated potential emission reductions and associated control costs on an industry-wide basis and did not adequately considered the impacts to those smaller operators, whose emissions may be so small that the requirement to install VRUs is cost prohibitive or those operators who lack the operational economy of scale and in-house environmental, health, and safety personnel to implement the required emission controls in a cost-effective manner. The commenter also cites to the Boston University’s Institute for Sustainable Energy, which states that “in practice VRUs are only practical at larger facilities.”<sup>19</sup>

Regarding existing sources, the commenter (0793-PBPA) explains that as wells and fields age, production decreases and storage tanks that were full when a well was new and highly productive may be operated at significantly less than capacity as oil and gas fields become depleted, but operational costs associated with running and maintaining emission control devices do not. The commenter states that section 111(d) of the CAA requires that EPA allow states, when applying the EG, to take into consideration, “among other factors,” the remaining useful life of the existing sources<sup>51</sup> but that EPA’s proposed EG OOOOc does not account for remaining useful life or “other factors” (*e.g.*, unreasonable cost of control resulting from plant age, location (basin), or basic process design; physical impossibility of installing necessary control equipment; or other factors specific to classes of facilities that make application of a less stringent standard or final compliance time significantly more reasonable).<sup>52</sup>

Specific to costs for a VRU, the commenter (0793-PBPA) states that EPA estimated capital costs for a VRU (sized for a source with potential VOC emissions of 6 tpy) to be approximately \$32,000 and the estimated annualized costs are estimated at approximately \$24,000/yr, but that these numbers significantly understates the cost of a VRU on a tank because of the potential for oxygen to enter the pipeline through the VRU’s series of pipe connections and fittings, which presents a prominent safety issue and can result in extensive down time, resulting in annual operating expenses that are much higher due to the costs associated with preventing oxygen contamination. The commenter states that since 2012 Texas has added approximately 15,750 wells per year, resulting in 142,000 wells becoming subject to NSPS OOOO and that in general, each storage tank supports four wells; thus as many as 35,500 facilities will need to add VRUs and at a cost of \$32,000 per VRU, the November 2021 Proposal would cost \$1.4 billion in Texas alone. The commenter states that this is not an incidental cost to propose without quantifying the emission reductions from this requirement and that while some operators will already have VRU-type equipment, EPA has not estimated the impact of this rule nor the proportional cost benefit.

Commenter (0808-API) generally supports EPA’s November 2021 Proposal for existing storage tank batteries under EG OOOOc but provides one additional consideration for existing storage vessels or tank batteries. The commenter explains that there is additional cost for control at sites in dry gas plays with produced water storage vessels or tank batteries only which was not included in EPA’s cost analysis - some of the produced water storage vessels are fiberglass tanks and would have to be replaced with steel tanks to support the installation of a closed vent system

---

<sup>51</sup> 42 U.S.C. §7411(d)(1).

<sup>52</sup> See, *e.g.*, 40 C.F.R. §60.24(f).

and control device due to backpressure. The commenter suggests that if the capital costs to replace a storage vessel(s) are \$20,000 or more this would result in a cost effectiveness of over \$1,900 per ton of methane reduced for a combustion control device, using EPA's own cost analysis, and this was not included.

Commenter (0817-GPA) states that while EPA acknowledges that it will be more costly to install a combustor control device or VRU at an existing facility than at a new facility, the estimated 30 percent increase in the capital cost at existing facilities to account for the additional costs is not supported. The commenter references EPA's costs for a flare system ranging from \$23,806 to \$43,598. The commenter believes the additional cost required to install a tank control system at an existing facility will be higher than EPA's estimate, due to the additional engineering design that would be required to add an ignition source to an existing facility, the additional construction costs required for an extended flow line to locate the flare away from other ignition sources, such as compressor engines that would be present at most sites, and the additional costs needed to upgrade tanks to prepare for a closed vent system. Instead of a 30 percent factor, the commenter suggests that EPA assume 50 percent for the capital expense needed to retrofit an existing gathering and boosting facility. Based on this change and since the gas recovered is not owned by the gathering and boosting facility, the commenter provides suggested revisions to Tables 6-13 ("Thermal Combustion Control System Costs for Existing Tank Batteries") and 6-14 ("Vapor Recovery Control System Costs for Existing Tank Batteries") of the November 2021 Proposal TSD in their comment letter.

The commenter (0817-GPA) also suggests that EPA underestimated the cost to install a flare for low emission tanks. The commenter explains that because gathering and boosting facilities will not own the natural gas that flows through the facilities, they will have limited economic benefits associated with installing a VRU system on a low emission storage vessel battery. The commenter recommends that EPA update Table 6-15 ("Average Control System Costs for Model Control Systems for New Tank Batteries") and 6-17 ("Average Control System Costs for Model Control Systems for Existing Tank Batteries") of the November 2021 Proposal TSD to reflect that facilities will install flares instead of VRUs up through model control system number 5 (i.e., EPA should discount the capital costs for lower emitting tank batteries with the assumption that 50 percent of the facilities will install VRU systems). The commenter included a revised Table 6-15 and Table 6-17 from what EPA includes in the November 2021 Proposal TSD in their comment letter. The commenter also provided revisions to Table 6-17 in their comment letter, to reflect prior comments that the capital cost to install a control device will be 50 percent higher than at a new facility, which is an increase from the 30 percent adjustment included by EPA.

The commenter (0817-GPA) provides a table ("Cost Effectiveness for Existing Sources") in their comment letter that summarizes the impacts that adjustments for control device selection and additional capital costs for existing sources will have on cost effectiveness. To summarize, the commenter states that in general, the cost effectiveness is affected more for the lower emission tanks, since the flare installation will be an increase in capital cost and may affect the point where methane emission control alone would be considered cost effective.

Response I-9-43: EPA discussed the results of the analysis which was used to establish emissions limits for storage vessels in section XII.B.1 of the November 2021 Proposal.

See discussion in section IV.H.2 of the December 2022 Supplemental Proposal where EPA evaluated the costs associated with requiring 98 percent reduction of methane and VOC emissions from storage vessels in order to compare the cost-effectiveness for this option against the costs associated with requiring 95 percent reduction.

With regards to comments that indicated that storage tanks used by conventional wells are relatively small and often not designed to hold fluids at pressure, we take the comment to refer to existing storage vessels to which EG OOOOc would apply. The standards for an affected facility are cost effective relative to the emissions reductions obtained for existing facilities [See Response I-9-36]. The commenter also points out that existing facilities may require retrofitting to meet emission control requirements. The existing source requirements developed and implemented by states under EG OOOOc offer the opportunity for the commenter to work with their permit authorities to develop appropriate standards for existing sources. States are able to design standards that account for the remaining useful life of affected facilities, which may be less stringent than standards applicable to new sources. Generally, the standards developed for existing sources reflect retrofitting costs that do not apply to new sources.

With regards to the need to clarify what type of storage vessels are covered under the proposed rule, the EPA clarifies that production operators may not use floating roof tanks to meet the requirements of NSPS OOOOb, or EG OOOOc at well sites and centralized production facilities, because floating roofs are not designed to handle flash emissions. See 86 FR 63184. The NSPS Kb specifically exempts storage vessels with a design capacity less than or equal to 420,000 gallons (1,589.874 m<sup>3</sup>) used for petroleum or condensate stored, processed, or treated prior to custody transfer. These storage vessels that are exempt from NSPS Kb are only subject to NSPS OOOOb or EG OOOOc and must comply with the control requirements in NSPS OOOOb or EG OOOOc, as applicable. Storage vessels that do not have flashing emissions and that are not located at well sites or centralized production facilities may use floating roof controls following the provisions in NSPS Kb. We also note that NSPS OOOOb and EG OOOOc do not apply to storage vessels subject to and controlled in accordance with the requirements for storage vessels in 40 CFR part 60, subpart Kb, and 40 CFR part 63, subparts G, CC, HH, or WW. With regards to the need to clarify what type of storage vessels are covered under the proposed rule, the EPA clarifies that production operators may not use floating roof tanks to meet the requirements of OOOOb, or OOOOc EG at well sites and centralized production facilities, because floating roofs are not designed to handle flash emissions. See 86 FR 63184. We note that subpart Kb specifically exempts storage vessels with a design capacity less than or equal to 420,000 gallons (1,589.874 m<sup>3</sup>) used for petroleum or condensate stored, processed, or treated prior to custody transfer. These storage vessels that are exempt from subpart Kb are only subject to subpart OOOOb or OOOOc EG and must comply with the control requirements in subpart OOOOb or OOOOc EG, as applicable. Storage vessels that do not have flashing emissions and that are not located at well sites or centralized production facilities may use floating roof controls following the provisions in subpart Kb. We also note that Subparts OOOOb and OOOOc EG do not apply to storage vessels subject to and controlled in accordance with the requirements for storage vessels in 40 CFR part 60, subpart Kb, and 40 CFR part 63, subparts G, CC, HH, or WW.

With regards to comments that indicate that the EPA's high thresholds are based on unrealistically high estimates for the costs of emissions controls for tanks, compared to the emission control cost estimates provided by states, see Response I-9-7.

The change of applicability threshold to tanks and batteries reflects cost effective control down to 6 tpy. While operators are free to change their control systems to accommodate current conditions that may differ from the production conditions at startup (provided the control device reduces emissions by 95% or greater), the decision to change control equipment is at the discretion of the operator and not a function of applicability thresholds, which remain unchanged in the example provided by the commenter.

We specifically evaluated a wide range of potential emission rates from tank batteries. We agree that the capital and operating costs for the control device has economies of scale, which is why we established emission thresholds below which control is not required. We also note that we do not mandate the use of a VRU. We also estimated costs for flares and thermal oxidizers, and these control systems had similar costs to the VRU. We expect all operators, regardless of size, would have the expertise needed to operate a flare.

In response to commenters that indicated that they believed that VRU costs are underestimated, nearly all VRU include automation to prevent pulling a vacuum from the tank. Typically, they use a check-valve that prevents any flow from the storage vessel below a set operating pressure. When the valve is open, the VRU compressor/vacuum pump will start. The compressor (or vacuum pump) has a variable speed drive to pull more gas when the pressure in the line from the tanks increases. Thus, by selecting an appropriate VRU design, oxygen ingress can be minimized or eliminated. Additionally, we also note that we do not mandate the use of a VRU to control emissions from storage vessels; flares and thermal combustors can also be used to control emissions from storage vessels.

With regards to comments indicating that there is an additional cost for control at sites in dry gas plays with produced water storage vessels or tank batteries, we developed costs reflective of national averages. We understand that some facilities may experience costs that are less than those projected while other facilities may experience somewhat higher costs. For existing storage vessels or tank batteries, the storage vessel/tank battery would have to have emissions of 20 tpy methane or more to require controls. We expect that few produced water tanks at existing facilities would have emissions exceeding this threshold. Additionally, states may consider the remaining useful life of existing facilities in their EG. That said, in the very rare situation where a high-emitting produced water storage vessel, as described by the commenter, is at a facility with significant useful life, this would be an example where the costs to control are higher than the average costs we projected. We included retrofit costs for existing sources to vent the emissions from existing storage vessels to a control device. We determined that the costs we developed are reasonable for national standards, even if, in rare conditions, this may require upgrading the storage vessel itself. In response to the commenter that expresses that they believe that the additional cost required to install a tank control system at an existing facility will be higher than EPA's estimate, the EPA explains that, when estimating the cost of flare controls, we specifically included 200 feet of piping to transport the storage vessel vapors to a remote location. The flare costs also include engineering costs associated with sizing and locating the

flare (assumed to be 10% of equipment costs). We included the retrofit costs primarily to cover costs associated with upgrading the tanks to prepare for closed vent system, but some of these costs can also cover additional piping and engineering assessments. We consider that the cost assumptions we used for the new sources are reasonably conservative and that the 30% retrofit factor adequately covers additional expenses associated with applying these controls to existing sources.

In response to commenters that suggested that the EPA underestimated the cost to install a flare for low emission tanks, the EPA explains that the change of applicability threshold to tanks and batteries reflects cost effective control down to 6 tpy VOC and 20 tpy methane. We specifically evaluated a wide range of potential emission rates from tank batteries. We agree that the capital and operating costs for the control device has economies of scale, which is why we established emission thresholds below which control is not required.

### **9.3.3 Technical Considerations with BSER**

Comment: Commenters (1341-PGCC *et al.*) state that EPA also must consider the costs associated with significant infrastructure changes to install controls on these tanks and the fact that requiring continuous ignition could create unsafe conditions. The commenters state that installing and operating a VRU or flare would also require the installation and operation of technologies to prevent oxygen from entering the storage tank vent gas that would be collected and notes that EPA's "Standard Stock Vapor Recovery System for Storage Vessels" does not show an oxygen monitor and therefore, EPA's calculated control costs fail to consider costs associated with oxygen monitors. See the November 2021 Proposal TSD, Figure 6-1.

Commenter (0793-PBPA) states that the potential for oxygen to enter the pipeline through the VRU's series of pipe connections and fittings, presents a prominent safety issue and can result in extensive down time and also is likely to cause increased downstream emissions due to corrosion caused by the oxygen.

Commenters (1341-PGCC *et al.*) state that tanks used by their members are often located in rural, sometimes forested, areas that can be miles from available electrical sources, requiring the installation of electric line (because EPA notes a vapor recovery system used to control storage tank emissions "uses electricity to run the vapor recovery compressor." November 2021 Proposal TSD, 6.4.3.2). The commenters provide that even where electrical service is available, it is often available in single-phase and would be incapable of transmitting power over long distances. For intermittent flow and operational reasons, they state that tank emissions also would be insufficient to power a generator needed to operate a VRU, requiring manual operation of any vapor recovery unit and would result in additional costs (and emissions), which EPA did not consider.

Commenters (1341-PGCC *et al.*) posit that there is no plausible scenario where installing and operating a VRU to control storage tank emissions at well or tank sites operated by their members would be cost-effective. The commenters argue that the November 2021 Proposal, if finalized, will create more emissions at well sites owned by their members, because unlike tanks in the unconventional gas industry, which manage significantly large volumes of liquids at very

high pressures, flow into on-site tanks at conventional sites is intermittent. Because of the intermittent and low flows of liquids into the tanks, the commenters state that their members would be forced to pipe or store auxiliary fuel at the location of the flare or enclosed combustor because there is no fuel to allow for continuous operation of a flare or enclosed combustor. The commenters provide examples at conventional oil well sites where liquids are pumped at intervals ranging from once-per-day to once-per-week and conventional gas well sites where flow into tanks occurs only as necessary in the cycling of a rabbit or when sufficient fluid exists in the separator.

The commenters (1341-PGCC *et al.*) summarize their concerns by stating that EPA's model tank batteries are materially and significantly different from the tanks used by their members. According to the commenters, EPA's cost-effectiveness calculations are therefore flawed and substantially underestimate the costs that would be imposed on their members if they were required to take all the steps necessary to install and operate a flare, enclosed combustor, or VRU to control what are already exceedingly small amounts of emissions. They add that for all these reasons, EPA's November 2021 Proposal is unreasonable and must not be applied to their members.

Commenters (0808-API, 0831-AXPC) state that EPA should allow for an exemption from control requirements due to technical infeasibility if the control device would require supplemental fuel. The commenter explains that this type of exemption has been rationalized by state regulations for storage vessels and tank batteries, such as in Colorado, where there is an exemption from control requirements for tanks if use of a control device would be technically infeasible without supplemental fuel for pilot or other purposes.

Response I-9-44 We disagree with commenters that controlling emissions from storage vessels is technically infeasible when supplemental fuel is required. All flares or combustors will require supplemental fuel, either by natural gas or propane, for use for pilot gas and for sweep or purge gas. While we assumed most facilities would have natural gas available, propane can also be used. Perhaps because our control costs are higher than those used by Colorado (leading Colorado to select a much lower emissions threshold for storage vessels), the impact of using propane rather than natural gas does not significantly alter the cost-effectiveness of the emission controls at the applicability thresholds selected. Based on our analyses, we do not consider that it is technically infeasible to require control.

Comment: Commenter (0763-Texas Commission on Environmental Quality (TCEQ) and Railroad Commission (RRC)) recommends that EPA allow for thermal control of methane and VOC emissions from storage tanks, which are often vented to tanks routed to control devices with less than 100 percent destruction efficiency. The commenter believes that further consideration should be given to allow for control methodologies for this activity in line with typical oil and gas facilities, including thermal control using flares which typically represent less than 100 percent destruction efficiency.

Response I-9-45: We take the comment to be a concern for a requirement to capture and route associated gas to a sales line, use the recovered gas as an onsite fuel source, use the recovered gas for another useful purpose that a purchased fuel or raw material would serve, reinject the

recovered gas into the well or inject the recovered gas into another well for enhanced oil recovery. This is not the case, as flaring as a means of control for storage vessels is not affected by the requirements in 60.5377b intended to reduce the flaring of associated gas from a separator.

#### ***9.3.4 Model Plant Emissions Estimates***

Comment: Commenter (0814-IPAA *et al.*) questions EPA's data source for tank emissions and tank estimates based on assumptions that more production drives the need for more tanks. The commenter explains that the following is their understanding of the framework that EPA used to justify its regulatory actions for storage tanks.

- First, EPA relied on an array of approximately 100 tanks created for the 2012 Subpart OOOO regulations and then developed emissions estimates for these tanks using the API E&P TANKS program, assuming a 500 b/d throughput and dividing the tank list based on API Gravity to define condensate and crude oil.
- Second, EPA adjusted the tank emissions projections based on flow rates for different size categories and developed a tank inventory based on a ratio of a baseline production value scaled to a projected future value related to total U.S. production.
- Third, EPA projects the number of current wells with and without NSPS OOOO controls.

The commenter believes that these estimates are suspect. The commenter explains that while the assumption that more production drives the need for more tanks is valid at some level such as new unconventional oil and natural gas development, low production well sites (particularly in developed basins) will use existing tanks where capacity is available.

Commenter (0814-IPAA *et al.*) states it is difficult to address the validity of all of EPA's assumptions without access to its various referenced sources and many are not readily available. The commenter believes it is apparent that EPA relied on estimates based on ratios from total production volumes to project the number of tanks in different size categories. For example, where EPA used condensate production reported in the Greenhouse Gas Inventory (GHGI), EPA states:

The 2019 GHGI data indicated that condensate production increased from a level of 145 million barrels per year (MMbbl/yr) in 1992 to 454 MMbbl/yr in 2019 (approximately 288 percent). This 288 percent increase in condensate production was distributed across the model condensate tank batteries in the same proportion as was done for the NESHAP HH rulemaking. Based on this approach, it was estimated that there was a total of 36,501 existing condensate tank batteries in 2019.

Commenter (0814-IPAA *et al.*) believes that other information would produce very different results. By way of example, the commenter states that the Energy Information Administration (EIA) has developed extensive data on oil and natural gas production by size of well. The commenter provides a table in their comment letter which compares 1992 and 2019 (comparable to the years used by EPA), and states that the EIA data shows that condensate production did not

increase by 288 percent; instead, it increased by about 46 percent and also shows that for smaller wells, production changes were on the order of 10 to 15 percent – far less than the total increases.

Commenter (0814-IPAA *et al.*) states that EPA makes a similar error regarding crude oil in estimating the number of new tank batteries, “[u]sing the assumption of four tanks per tank battery (as shown in Table 6-1), EPA scaled the 2006 crude oil storage vessel population to represent 2019 crude oil tank batteries using a ratio of the 2019 and 2006 crude oil tank throughput values from the 2019 GHGI. According to the 2019 GHGI, crude oil throughput increased from 1,679 MMbbl/yr in 2006 to 4,666 MMbbl/yr (an increase of approximately 278 percent) in 2019” but that using EIA information from 2006 and 2019 shows a different result; crude oil production increased by 137.5 percent, and production for smaller wells decreased. The commenter also included a table in their comment letter which summarizes these results.

Commenter (0814-IPAA *et al.*) summarizes that this information calls into question EPA's fundamental assessment that tank construction is producing the substantial numbers of new tanks and inherently using total production increases as a basis to scale up tank numbers is inherently flawed. The commenter states that while oil and natural gas production has increased over the past fifteen years, primarily because of shale oil and shale gas production, production from small wells has been essentially flat and therefore tanks related to smaller operations would not be constructed in any significant amounts. The commenter explains that because of natural depletion, existing tank batteries will have excess capacity that can be used by new wells and these actions will not result in emissions beyond the original design.

Response I-9-46: The commenter appears to suggest that the impacts analysis for storage vessels is inaccurate because we incorrectly assumed that production increases would equally impact small and large producers. The data provided by the commenter suggests that production at small producers (those under 15 bbl/day) is flat and that EPA’s methodology greatly exaggerated the number of new tanks at these small producers. Available EIA data support the commenter’s argument that the increase in production has occurred predominately at higher production rate sites and that production has not increased significantly at the low production rate sites (see: <https://www.eia.gov/petroleum/wells/>). However, we disagree that this suggests our that our national impact analysis is inaccurate. Under nearly all cases, our lowest production model tank battery (with a model throughput of 15 bbl/day) had emissions below the applicability threshold. Thus, while we had assumed a large number of new small tank batteries, these tank batteries were not subject to control requirements, so there were no costs or emission reductions associated with those tanks. We could have assumed, as the commenter suggests, that the number of small tank batteries is flat and it would not have made an appreciable change in our projected nationwide costs and emission reductions. For the larger model tanks batteries (those that we did project would be above the applicability thresholds), we maintain that the percent increase we estimated for these sites is reasonable, considering the commenter’s data. Therefore, we conclude that our projected nationwide costs and emission reductions are accurate, despite our poor assumption regarding the number of new small tank batteries. Other points made by the commenter are addressed in the following paragraphs.

While we have difficulties finding the data used by the commenter because no direct reference was provided, we find that the values in the tables and the commenter’s statements do not appear

to be consistent. For example, for crude oil, the GHGI values and the commenter's values on the increase in production are much more similar than stated by the commenter. Using GHGI data, we estimated crude production increased from 1,679 MMbbl/yr in 2006 to 4,666 MMbbl/yr in 2019. From this, we developed an increase factor of 2.78 (4,666/1,679). The commenter reported total crude production of 1,643 MMbbl/yr in 2006 and 3,902 MMbbl/yr in 2019. While the 2019 value is lower than the GHGI, the increase factor is 2.375. The commenter characterized this as an increase of 137.5 percent and compared it with a 278 percent increase using EPA data. However, if the commenter used a consistent method for characterizing how the "increase" is calculated, the difference is much less stark than indicated by the commenter. Because the higher production facilities are projected to have production increases and because our assumptions for the rate of production increase for these higher production facilities (which are those that are impacted by the rule's control requirements) appears reasonable, we conclude that our national impact estimates for the storage vessel control requirements are reasonable.

With respect to the comment that existing tank batteries will have excess capacity that can be used by new wells, we agree that some facilities may elect to re-use existing tanks. However, with our proposed definition of modification, the owners of these tanks would be required to assess the potential emissions from the tank battery as used in its new service. If the potential emissions from the tank battery exceed the VOC or methane emissions thresholds specified in the rule, this tank battery would be considered to be modified and would be subject to the NSPS standards. Thus, re-use of existing tanks may not increase the total number of storage vessels in operation, it could result in an increased number of storage vessel affected facilities subject to NSPS OOOOb.

### ***9.3.5 Removal of Controls***

Comment: Several commenters (0599-MSC, 0808-API, 0831-AXPC) recommend that EPA preserve the alternative control standard in NSPS OOOOa that allows for a sustained uncontrolled VOC emission rate of less than 4 tpy as an alternative emission limit to the 95 percent control requirement, similar to the 4 tpy provisions for VOC found at 40 CFR 60.5395a(a)(3). Commenter (0808-API) notes that EPA has previously determined that removal of control at 4 tpy VOC will reduce emissions from burning more pilot gas than the waste gas being burned.<sup>53</sup> Commenter (0831-AXPC) states that over time, due to inevitable production declines, there may be an inflection point after which an operator would have to supplementally feed the flare in order to get it to operate, which would result in the emissions from operating the control device exceeding the emissions that would otherwise be vented to the atmosphere and the 4 tpy alternative standard provides the pathway to avoid those unnecessary excess emissions.

Response I-9-47: The final NSPS OOOOb and EG OOOOc allow owners/operators to remove the control device when the actual uncontrolled emissions are maintained below specific thresholds. For NSPS OOOOb, the actual uncontrolled VOC emissions must be maintained below 4 tpy and the actual uncontrolled methane emissions must be maintained below 14 tpy. For EG OOOOc, the actual uncontrolled methane emissions must be maintained below 14 tpy. In

---

<sup>53</sup> 5 Federal Register Vol. 78, No. 71, 22133-22134.

both rules, these uncontrolled emissions must be determined monthly for 12 consecutive months. See additional discussion in section IV.J.1.c of the December 2022 Supplemental Proposal.<sup>54</sup>

## 9.4 Cover and Closed Vent System Monitoring

Comment: Commenter (0749-Petroleum Association of Wyoming (PAW)) suggests that EPA allow the use of optical gas imaging (OGI) or other advanced technology (*e.g.*, drone options) for cover and closed vent system monitoring and allow for monitoring with the required fugitive emissions monitoring frequencies to prevent redundancy and undue burden.

Commenters (0781-NTAA, 0605-Muscogee (Creek) Nation) support the strengthening of compliance requirements and monitoring for tank hatches or openings.

Response I-9-48: EPA acknowledges the commenter's support for the requirements for monitoring covers and closed vent systems associated with storage vessel affected facilities. See discussion in section IV.K.1.b of the December 2022 Supplemental Proposal regarding the use of OGI technology and frequency of inspections.<sup>55</sup> See section IV.B of the December 2022 Supplemental Proposal for discussions regarding the use of advanced methane detection technologies for closed vent systems associated with storage vessel affected facilities.<sup>56</sup>

## 9.5 Miscellaneous

Comment: Commenter (0946- Michigan Oil and Gas Association (MOGA)MOGA) felt a disconnect and general lack of understanding of the EPA's previous rulemaking intentions and how the state environmental regulators understood and implemented several of the source definitions and regulations. The commenter states that the storage tank segment particularly is difficult to understand and implement.

Response I-9-49: The commenter did not provide specific details regarding what provisions of the storage segment are difficult to understand and implement, there EPA is unable to respond to the comment.

Comment: Commenter (0809-California Communities Against Toxics (CCAT) *et al.*) states that given EPA's recognition of the importance of regulating all storage vessels that emit significant amounts of VOCs, and the agency's recognition that enhanced regulation of existing sources is needed, EPA should also take this time to revisit the 2012 national emissions standard for hazardous air pollutant (NESHAP) rule's inadequate coverage of this emission source. The commenter explains that the current oil and gas NESHAP covers only storage vessels with the potential for flash emissions (PFE), and only those in the production segment, not the transmission and storage segment.<sup>57</sup> The commenter states that in the 2012 NESHAP rule, EPA stated that it considered promulgating Maximum Achievable Control Technology (MACT)

---

<sup>54</sup> 87 FR 74803 (December 6, 2022).

<sup>55</sup> 87 FR 74805-74806 (December 6, 2022).

<sup>56</sup> 87 FR 74740-74741 (December 6, 2022).

<sup>57</sup> See Oil and Natural Gas Sector: New Source Performance Standards and National Emission Standards for Hazardous Air Pollutants Reviews; Final Rule, 77 Fed. Reg. at 49,503.

standards for storage vessels without PFE but determined that it did not have adequate data to do so.<sup>58</sup> The commenter states that the failure to act was a violation of EPA's duties under section 112(d)(6), a violation further compounded by the agency's unreasonably long delay in addressing this issue for reconsideration. See *LEAN*, 955 F.3d at 1096. The commenter is concerned that nearly a decade later, EPA has still not fixed this data gap through formal data collection or any other means and states that lack of information cannot be a reason for EPA to not fulfill its duties under the CAA. See *U.S. Sugar Corp. v. EPA*, 830 F.3d 579, 644 (D.C. Cir. 2016) ("The Agency was obligated to collect the data it needed, and Congress gave it the authority to do so."). The commenter notes that EPA is specifically aware that adequate and accurate data regarding this significant emissions source within the oil and gas sector is essential for the creation of robust rules<sup>59</sup> and the commenter recommends that accordingly, the agency should take swift action to use its information gathering authority to collect whatever data will assist the agency's needed reconsideration and review of the NESHAP rule, while also serving—and not delaying—completion of the supplemental NSPS proposal and final NSPS rule in the process.

Response I-9-50: These comments are out of scope of this rulemaking.

Comment: Commenter (0782-Berkshire Hathaway Energy Company (BHE)) states that without proposed regulatory text, it is not clear what EPA is considering for tanks in the transmission and storage segment. If something in addition to the NSPS OOOOa requirements is being considered, the commenter encourages EPA to convene discussions with transmission and storage operators to review the NSPS OOOOa requirements and other/additional requirements being considered, including the basis and assumptions that EPA is using to revise or expand requirements. In addition, the commenter recommends including in the Supplemental Notice clear indication that tanks subject to another NSPS, such as NSPS Kb, are exempt from requirements under NSPS OOOOb or EG OOOOc. The commenter suggests that other than the current affected sources in NSPS OOOOa (*i.e.*, transmission and storage tanks with annual VOC emissions exceeding 6 tpy), there is no need for additional requirements for storage vessels located in the transmission and storage segment.

Response I-9-51: See section IV.J of the December 2022 Supplemental Proposal for a discussion of the requirements for storage vessels in all segments of Crude Oil and Natural Gas source category, including storage vessels in the transmission and storage segment.<sup>60</sup> Consistent with the exemption at 60.5395a(e) in NSPS OOOOa, EPA is finalizing language in NSPS OOOOb and OOOOc, stating the requirements for NSPS OOOOb and EG OOOOc do not apply to storage vessels subject to and controlled in accordance with the requirements for storage vessels in 40 CFR part 60, subpart Kb, and 40 CFR part 63, subparts G, CC, HH, or WW.

## Chapter 10. Pneumatic Controllers

### 10.1 General Support/Opposition for Proposed Pneumatic Controller Standards

#### 10.1.1 General Support for Zero Emissions Standard for Pneumatic Controllers

Comment: Several commenters (0185-Mokveld Valves BV (Mokveld), 0391-Keweenaw Bay Indian Community (KBIC), 0401-Mercy Investment Services, Inc. (Mercy), 0434-Impax Asset Management, LLC (Impax), 0435-Wespath Benefits and Investments (Wespath), 0437-New York Office of the State Comptroller (NYOSC), 0443-Seventh Generation Interfaith Inc. (SGI), 0444-Damascus Citizens for Sustainability (DCS), 0460-Trinity Health, 0538-Change Finance, PBC (Change Finance), 0560-Legal & General Investment Management America, Inc. (LGIM America), 0605-Muscogee (Creek) Nation, 0720-Miller/Howard Investments, Inc. (MHI), 0723-Ceres, 0724-Boston Trust Walden (BTW), 0728-Calvert Research and Management (Calvert), 0729-Energy Workforce & Technology Council (EWTC), 0737-Clarke Valve, 0781-National Tribal Air Association (NTAA), 0812-Ohio Farmers Union (OFU) *et al.*, 0823-Qnergy, 0833-Environmental Programs Department, Ute Mountain Ute Tribe (Ute EPD), 0844-Environmental Defense Fund (EDF) *et al.*, 0918-Colorado Local Government Coalition (COLGC), 0941-350 Silicon Valley, 0943-Sault Ste. Marie Tribe of Chippewa Indians, Sault Tribe Environmental Department (Sault EPD), 1267-California Office of the Attorney General (CA AG) *et al.*, 1282-Earthworks, 1372-Generate Capital, PBC (Generate), 1389-VERIS Wealth Partners) support the requirement for new sources to use zero emitting technologies. These commenters also support the November 2021 Proposal to remove the exemption for higher bleed pneumatic controllers based on functional needs, except in very limited circumstances. Commenters also provide support for EPA's November 2021 Proposal to apply presumptive emissions limitation standards for existing pneumatic controllers that are the same as those required for new sources. Commenters note that the experience of leading operators demonstrate zero-emitting pneumatics are widely available and cost-effective to deploy.

Commenter (0844-EDF *et al.*) encourages EPA to include in its final rule a requirement that operators use zero-bleed technology for intermittent controllers. The commenter notes that EPA studies have shown that even when operating properly, intermittent controllers emit a significant amount of methane, and often function improperly by emitting continuously rather than only when actuating. Although the specific percentage of malfunctioning devices varies considerably, the commenter notes that studies confirm that intermittent controllers can and often do emit far more than their advertised design values indicate. The commenter contends that these excess emissions can be easily and cost-effectively avoided by requiring operators to use the zero-emitting options discussed above for intermittent controllers.

Commenter (0823-Qnergy) states that through their company's technology, the industry has demonstrated the ability to reduce emissions from pneumatic controllers and pumps to the degree identified in the November 2021 Proposal and that their technology should form the basis of the proposed BSER for pneumatic controllers and pumps. The commenter cites specific CAP3 product and technology performance data. The commenter adds that its technology can replace all controller types, regardless of whether they are continuous bleed natural gas driven or

intermittent natural gas driven. The commenter notes that, with zero- or near-zero emissions technology that uses compressed air available, the natural gas bleed rate becomes irrelevant.

Response I-10-1: The EPA is requiring zero emissions from process controllers in the final NSPS and EG. See discussion in section IV.D.1.b.ii. and iii. of the December 2022 Supplemental Proposal preamble (87 FR 74760-74766) and section XI.D.3 regarding the EPA's conclusions regarding zero-emissions technologies as the BSER for process controllers.

### ***10.1.2 General Opposition to Proposed Standards***

#### **10.1.2.1 Zero Emission Intermittent Vent Controller Exemption Request**

Comment: Commenter (0810-Petroleum Alliance of Oklahoma (Petroleum Alliance-OK)) states that it is not reasonable, cost-effective or efficient for operators, especially marginal/low production well operators to now replace well-functioning intermittent vent controllers or retrofit their sites to use air-driven, solar, electric, or self-contained controllers. According to the commenter, many of these options are not feasible, reliable, safe, or economic for all sites. In addition, the commenter notes that the replacement devices are not readily available or field-tested in a way that would make them safe for mass deployment. The commenter recommends that EPA remove this requirement for zero-emission intermittent vent controllers. As an alternative, they suggest that EPA could include these under the fugitive emission monitoring requirements to ensure malfunctioning controllers are addressed.

Response I-10-2: See discussion in section IV.D.2.c. of the December 2022 Supplemental Proposal preamble (87 FR 74768) and section XI.D. 3 of the preamble to the final rule regarding the zero-emissions requirement for existing sources.

#### **10.1.2.2 Zero-emitting Pneumatics are Overly Burdensome and Not Cost-Effective**

Comment: Commenter (0764/0564-Arkansas Independent Producers and Royalty Owners (AIPRO)) notes that another commenter (0808-American Petroleum Institute (API)) has presented EPA with detailed comments regarding the technical feasibility and cost effectiveness for moving to zero-emitting pneumatic devices and controllers at existing facilities. The commenter supports the comments provided by the commenter (0808-API) on this topic. As proposed, the commenter states that the requirements for zero-emitting pneumatics are overly burdensome and not cost-effective. According to the commenter, the consequences to low production wells and small business would be significant. Most importantly, the commenter adds that the reduction in emissions for many companies will be negligible as pneumatic process emissions, when using EPA default factors and methodologies, are vastly overstated, in some cases by 90 percent or more. The commenter states that there are additional issues with grid power availability, right-of-way for grid power, off set emissions for combustion sources to provide electricity for electric pneumatics or compressed air, reliability of either grid power or

solar power, and operating ranges of battery storage for different geographical locations among other issues.

Another commenter (0938-Texas Oil & Gas Association (TXOGA)) contends that EPA's November 2021 Proposal is not cost-effective or feasible in all situations and suggests that EPA reconsider its approach. The commenter reports that their members would oppose any requirement to use non-emitting controllers at existing sites; among other considerations, electrifying existing sites would likely be problematic due to right-of-way issues and the availability of electricity. According to the commenter, problems include issues with implementing alternate power sources, such as solar, and other considerations that they contend that EPA's November 2021 Proposal does not properly address.

Response I-10-3: See discussion in section IV.D.2.c. of the December 2022 Supplemental Proposal preamble (87 FR 74768) and section XI.D. 3 of the preamble to the final rule regarding the zero-emissions requirement for existing sources.

#### 10.1.2.3 Request to Allow the Use of Low Bleed Pneumatic Controllers under Emissions Guidelines

Comment: Commenter (0911-North Dakota Petroleum Council (NDPC)) posits that the pneumatic controller emission factors in 40 CFR 98 overestimated the emissions from this source category and that EPA's focus on regulating these sources is unwarranted. The commenter notes that the leak detection and repair (LDAR) programs, as required by new source performance standards (NSPS) OOOOa, states, and voluntary programs, will assure that maintenance of pneumatic controllers is performed promptly. On existing sources in particular, the commenter recommends that EPA allow for the use of low bleed pneumatic controllers under emission guidelines (EG) OOOOc. The commenter explains that this would appropriately balance significant environmental benefits with the multitude of challenges associated with implementing changes to pneumatic controllers for all existing sources. The commenter also believes the secondary emissions created by these proposed requirements to make the pneumatic controllers non-emitting (*e.g.*, from manufacturing of new equipment and installation of alternative equipment) could be more significant than what the source emits during its useful life.

Response I-10-4: See discussion in section IV.D.2.c. of the December 2022 Supplemental Proposal preamble. See 87 FR 74768. See also the response to similar comments submitted regarding the December 2022 Supplemental Proposal, in Volume II, Chapter 7 (Process Controllers), subsection 7.3.1 (NSPS OOOOb and EG OOOOc BSER Analysis/Emissions/Costs, Emissions/Emission Factors), Response II-7-62.

#### 10.1.2.4 Zero-emitting Pneumatics Present Challenges in Some Locations and Applications

Comment: Commenter (0817-GPA Midstream Association (GPA)) does not support a requirement for zero-emission controllers for all locations and applications because of what they contend are various practical challenges with imposing that requirement. Nonetheless, the commenter suggests that, if EPA finalizes such a standard, it should do so without requiring the use of any particular technology. The commenter states that the November 2021 Proposal leans

heavily on the use of electrically actuated controllers and solar-powered controllers. The commenter suggests, however, that EPA overestimates the effectiveness and reliability of both, which have significant drawbacks. If a standard is mandated, the commenter notes that a technology-neutral standard would allow companies to achieve a zero-emission standard based on the particular circumstances of each midstream facility, such as location and access to electricity. Regardless of the technology used, the commenter states that the logistical difficulties require a longer compliance period. Finally, the commenter adds that although a zero-emission standard can be implemented for many applications, other applications should be exempted for safety and environmental reasons.

Response I-10-5: See discussion in section IV.D.1.b.i. of the December 2022 Supplemental Proposal preamble for discussion of exemptions (87 FR 74759). See also section XI.D.2 (Zero-emissions standard) of the final rule preamble for the EPA's responses to comments received on the proposed zero-emissions standard for process controllers. See section XI.D.4 (Compliance dates) of the final rule preamble for the EPA's response to comments on the need for a longer compliance period for new sources. See Volume II, Chapter 7 (Process Controllers), subsection 7.4 (Low Production/Small Sites), and 7.5 (Applicability and Compliance Date Considerations) Responses II-7-80 and II-7-82 for the EPA's response to comments on the need for a longer compliance period for existing sources.

## **10.2 Affected Facility, Modification and Reconstruction Definitions**

### ***10.2.1 Affected Facility Definition***

Comment: Several commenters (0599-Marcellus Shale Coalition (MSC), 0777-Ascent Resources, LLC (Ascent), 0808-API, 0817-GPA, 0938-TXOGA) contend that there is a disconnect between the pneumatic controller affected facility definition (*i.e.*, an individual controller) and the cost analysis, which was based on the replacement of all pneumatic controllers with zero-emitting devices at a site. The commenters recommend that EPA not define the affected facility as each individual controller but rather as the group of all controllers at a site. Commenters (0599-MSC, 0831-American Exploration and Production Council (AXPC)) add that this approach would be more consistent with EPA's cost analysis which assumed the control options would occur at the site level and not just for an individual controller. Commenters (0777-Ascent, 0817-GPA) state that defining the affected facility on a site-wide basis aligns with how emissions from pneumatic controllers will likely be handled by owners and operators of oil and natural gas facilities and provide flexibility that will help owners and operators in designing and operating the kind of capture-and-control system that would ensure a 95 percent volatile organic compound (VOC) or methane reduction from the entire population of gas driven pneumatic controllers at a particular site. Commenter (0808-API) suggests the following affected facility definition:

Each pneumatic controller affected facility, which is the collection of natural gas driven pneumatic controllers that vent to the atmosphere located at a well site, centralized production facility, or compressor station.

Another commenter (0742-Alaska Department of Environmental Conservation (ADEC)) suggests that there are complexities of tracking and managing the universe of pneumatic controllers at a site when only a portion of the universe of pneumatic controllers are affected facilities and recommends that EPA propose a simpler system to ease compliance efforts.

Response I-10-6: See discussion in section IV.D.1.b.i. of the December 2022 Supplemental Proposal. See 87 FR 74756-74757.

As noted above, the pneumatic controller affected facility definition changed from being based on a single continuous bleed or intermittent vent controller in the November 2021 Proposal to the collection of continuous bleed and intermittent vent controllers at a site in the December 2022 Supplemental Proposal. EPA is proposing this change based on information received from commenters.

We agree with the commenters that defining the pneumatic controller affected facility as the collection of all controllers at a site is the most practical approach. Significantly, most of the zero emissions measures for pneumatic controllers are site-wide solutions. For instance, a compressed air system installed at a site would be used to power all the pneumatic controllers at the site, rather than a separate system for each controller. Similarly, a solution based on solar energy would likely utilize a single array of solar panels to provide power to all the controllers at the site. In fact, as pointed out by the commenters, the analysis for the November 2021 proposed rule was conducted on a “model plant” site-wide basis.

Comment: Commenter (0782-Berkshire Hathaway Energy Company (BHE)) recommends limiting pneumatic controller provisions applicability to compressor stations, and not to locations along natural gas transmission pipelines (*i.e.*, exclude the limited applications along transmission pipelines). The commenter states that for pipeline applications, EPA could consider the Department of Transportation (DOT) Pipeline and Hazardous Materials Safety Administration (PHMSA) programs under development that are reviewing pipeline-related emissions, and coordinate with that process. The commenter suggests that applicability be limited to compressor stations because pipeline emissions are relatively low, and PHMSA has required operators to update operation and maintenance (O&M) procedures to ensure methane emissions are reduced. In response to that 2021 PHMSA requirements, the commenter states that the agency is implementing a review program in 2022 to test progress and assess O&M Plans.

Response I-10-7: The EPA has found the BSER for all location types to be zero emissions, except at sites in Alaska without access to electrical power. The NSPS and EG incorporate the BSER, and therefore, regardless of other standards or requirements instituted by other programs or agencies, all locations, except sites in Alaska without access to electrical power, are required to have zero emissions.

### ***10.2.2 “Non-emitting” Versus “Zero emitting” Pneumatic Controller Terminology***

Comment: Commenters (0425-Darrah Oil Company, LLC (Darrah), 0764-AIPRO, 0808-API, 0831-AXPC) support efforts to reduce emissions from pneumatic devices and the approach of moving towards non-emitting pneumatics at newly constructed sites. However, the commenters

believe some clarification is needed and recommend that EPA use the term “non-emitting” versus “zero-emitting.” As a practical matter, they explain that the term “zero-emissions” is apt because the object of the November 2021 proposed standards is to eliminate methane and VOC emissions from the affected facility. But as a legal matter, the commenters state that the term “zero-emissions” is imprecise and in error because these standards impose equipment or work practice obligations and do not impose a numeric emissions limitation of zero.

Commenter (0425-Darrah) states any requirement of “zero” creates a likelihood of waste as incremental gains come at higher and higher costs. To have “extremely low” as acceptable emissions may be reasonable, but the word zero may set goals where you do more environmental damage by replacing or retiring equipment before the end of its useful life in the name of “zero.”

According to the commenters (0764-AIPRO, 0808-API, 0831-AXPC), the legal distinction is important because a fully compliant pneumatic controller or liquids unloading event may still have incidental VOC and methane emissions. The commenters state that no piece of equipment or work practice is perfect – even if implemented according to best practices. Thus, the term “zero-emissions” expresses an idealized outcome that is belied by reality. A zero-emissions numeric standard would unreasonably cause incidental emissions to be a violation of the standard. EPA should correct its terminology in the Final Rule by stating that non-emitting control measures under this rule are work practices.

Response I-10-8: See discussion in section IV.D.1.b.i of the December 2022 Supplemental Proposal (87 FR 74759 and footnote 126) regarding the term “zero-emissions.”

### ***10.2.3 Modification or Reconstruction of Affected Facility***

Comment: Commenters (0817-GPA, 0831-AXPC) recommend that EPA allow like-kind replacement of existing individual controllers without causing the controller to become an affected facility under the November 2021 proposed NSPS OOOOb. The commenters indicate that if EPA does not allow this, operators who are voluntarily replacing high-bleed natural gas-driven controllers with low-bleed controllers would likely stop doing so. Other commenters (0564-AIPRO, 0599-MSC, 0808-API) state that they were unable to assess the feasibility of proposed requirements for modified sites because EPA has not delineated how modification of controllers is determined given the new control strategy proposed under the November 2021 proposed NSPS OOOOb. The commenters suggest that EPA define a modification to a collection of natural gas driven pneumatic controllers be defined similar to how EPA has defined modification in 40 CFR 60.5365a(i) and (j) for well sites, tank batteries, and compressor stations. Under this concept, when a modification occurs, the operator would be required to retrofit the collection of pneumatic controllers at the well site, tank battery, or compressor station to non-emitting controllers.

Response I-10-9: See section IV.D.1.b.i. of the December 2022 Supplemental Proposal (87 FR 74758-74759) for the EPA’s response to this comment.

## 10.3 Alternative Control Options

### 10.3.1 *Allow for Flexibility of Technologies Used to Achieve Standards*

Comment: Commenters (0599-MS, 0727-Oklahoma Secretary of Energy and Environment (OSEE) and Oklahoma Department of Environmental Quality (ODEQ), 0831-AXPC, 0919-TEP Rocky Mountain, LLC) recommend that EPA allow for the use of various technologies to achieve “non-emitting” status, including the option of routing to an existing control device if it is feasible to do so. Commenters note that the best path to achieve a “non-emitting” threshold for pneumatic devices will be different for each site based on the specific site design, operation, and circumstances. For example, upstream facilities are often located in remote locations without access to grid power, which may necessitate multiple solutions to achieve a “non-emitting” standard. According to commenters, developing adequate power supply to remote locations, such as are typical in upstream development, can present significant challenges. As most upstream site locations are leased, not owned, and facilities are temporary (not permanent) it is not always realistically feasible to electrify a location from the grid due to issues outside the operator’s control. Similarly, the viability of solar-powered technologies is still being evaluated and has presented reliability challenges to several of the commenter’s member companies who have piloted their use in the field. Similarly, commenters add that, where weather can be a limiting factor, operators may need a different suite of solutions to manage that dynamic. Examples provided to reduce these emissions include, but are not limited to, pneumatic controllers driven by compressed instrument air, electric controllers, mechanical controllers, and routing natural gas controllers to a process, sales line, or combustion device.

Commenter (0808-API) notes that state precedents allow flexibility in control options citing regulatory language for Colorado and New Mexico which allows all options mentioned above and describes them as “non-emitting controllers.

Commenter (0743-Western Energy Alliance (WEA)) notes that their members in basins across the country have taken on projects to retrofit facilities with intermittent bleed and low bleed controllers, outfitted facilities with instrument air equipment, and routed emissions from facilities to control devices where possible. However, the commenter reports that these retrofits and equipment modifications are not applicable in all scenarios. For this reason, the commenter recommends that EPA allow more flexibility in any proposed pneumatic controller requirements.

Commenter (0817-GPA) suggests that EPA affirm that the zero-emission standard is technology neutral and not limited to just solar powered electric actuators and instruments. The commenter states that this would allow midstream companies to adopt an approach best suited to a facility’s individual characteristics (*e.g.*, distance from population centers, weather, availability of electricity) and the development of new technologies that may alleviate some of the trade-offs inherent in each type of zero-emission controller.

Response I-10-10: The zero-emissions requirements of the final NSPS and EG are technology-neutral. See section XI.D.2 of the preamble to the final rule for discussion of the determination of BSER for process controllers.

### ***10.3.2 Capture Emissions and Route to a Combustion Device or Process Sales Line***

Comment: Several commenters (0749-Petroleum Association of Wyoming (PAW), 0808-API, 0830-Devon Energy) request that EPA include an option to collect the emissions from natural gas-driven controllers and route them to a flare or combustion device that achieves 95 percent reduction in methane and VOC. These commenters note that in many situations, an onsite control device already exists and that using it would be a cost-effective method of achieving significant emission reductions.

Commenter (0777-Ascent) notes that EPA did not evaluate capture and 95 percent control as a compliance option for pneumatic controllers. Based on the commenter's concerns regarding the elimination of gas-driven controllers, it conducted a recent pilot program in which it has evaluated the technical feasibility of capturing the emissions from gas-driven pneumatic controllers and routing those emissions to a thermal control device. The commenter contends that this manner of control is technically feasible in certain applications and may, provide a way to ensure significant reductions in emissions from pneumatic controllers while addressing the operation and reliability concerns associated with eliminating gas-driven controllers using other zero-emitting technologies.

Another commenter (0749-PAW) states that routing methane emissions from gas-actuated controllers to a combustion device is a control technique that is currently used in the industry in some production facility operations for other emission sources (tanks, dehydrators, *etc.*). Therefore, the commenter states that the additional cost burden would be significantly less and estimated at approximately \$2,000 per well site. The commenter adds that compliance is assured in that leak detection is conducted as part of the required fugitive emissions monitoring and monitoring of pilot temperature can be a method for monitoring the enclosed combustor's performance and assuring effective emission control.

Commenter (0830-Devon Energy) notes that Colorado<sup>1</sup> and New Mexico<sup>2</sup> consider pneumatic controllers that route emissions to be considered "non-emitting controllers" and therefore recognize this control technology to provide sufficient emission reductions under those programs.

Another commenter (0599-MSO) supports routing of pneumatic controllers to a combustion control device or process for new sources, however, the commenter notes that for existing pneumatic controllers, adding a control device specifically for pneumatics would be hindered by cost (older, low-producing pads and smaller facilities), availability, and other constraints such as spacing of a combustion device (setbacks, safety, and smaller locations that may lack the room).

Response I-10-11: See section IV.D.1.b.iv of the December 2022 Supplemental Proposal (87 FR 74765-74766) for the EPA's response to this comment and section XI.D.2 of the preamble to the

<sup>2</sup> <https://www.env.nm.gov/opf/wp-content/uploads/sites/13/2022/01/Attachment-1-NMED-Proposed-Part-20.2.50-January-20-2022-Version.pdf>

final rule for the EPA’s response to similar comments made on the December 2022 Supplemental Proposal.

### ***10.3.3 Limitations to the Use of Solar-powered Controllers***

Comment: Several commenters (0743-WEA, 0749-PAW, 0793-Permian Basin Petroleum Association (PBPA), 0808-API, 0817-GPA, 1391-Interstate Natural Gas Association of America (INGAA)) maintain that there are significant technical limitations to using solar powered controllers to replace pneumatic controller driven by natural gas at sites without electricity.

Commenter (0793-PBPA) states that while EPA has suggested the use of onsite solar generation paired with battery storage as an alternative to grid electricity, such systems are currently “uncommon, unreliable, and will likely increase the frequency of facility upsets, which will increase safety risks such as overpressure events and spills.”

Another commenter (0599-MSD) states that while there may be some pilot projects within the industry, it has not been demonstrated that reliable turnkey packages are available on a widescale basis.

Commenter (0817-GPA) states that EPA relies on a report by Carbon Limits, a Norwegian consultant, called “Zero Emission Technologies for Pneumatic Controllers in the USA, Applicability and Cost Effectiveness” (Aug. 1, 2016) (“Carbon Limits”). (See November 2021 Proposal Technical Support Document (TSD) at 8-24.) Based on interviews, the commenter notes that Carbon Limits identified less than 100 installations of solar powered controllers. Carbon Limits at pg. 34. According to the commenter, these would almost certainly be installed only in the environments most advantageous to solar power, such as sunny, warm, and open areas without terrain that could block sun exposure.

Several commenters note that there are severe geographic limitations to the use of any solar-powered devices. Commenter (0817-GPA) states that West Virginia averages only 164 days of sunshine per year, compared with an average of 205 days for the rest of the U.S. The commenter adds that, even in typically sunny states, operations in canyons or mountain valleys receive significantly limited sunlight exposure. They further add that snow and ice also raise additional reliability concerns during winter months.<sup>3</sup>

Commenter (0599-MSD) states that large-scale solar applications have not yet been tested in winter months when there is more cloud coverage, increased snow cover, and less sunlight in more northern locations (e.g., Colorado, North Dakota, Idaho, and Wyoming).

Other commenters (0740-Utah Petroleum Association (UPA), 0743-WEA) agree that solar power might be an option but report that their member companies have not yet been able to demonstrate this to be universally true in Utah’s Uinta Basin. Commenter (0743-WEA) notes that, as an example, in the Uinta Basin, there are certain times of year where fog can sit over the basin for several weeks, effectively making solar controllers useless. According to the

---

<sup>3</sup> The Carbon Limits Report, based on a single interview, notes snow as a “technical challenge” for solar panels and battery life, Carbon Limits at 15, but did not elaborate further.

commenter, in much of that area electrical power is also unavailable. For this reason, the commenter states that, if portions of Alaska are exempt from the November 2021 proposed requirements, then other areas of the country need to be evaluated as well. The commenter adds that, (1) in the West, line power is often unattainable where endangered species concerns preclude the construction of power lines and other infrastructure; (2) Northern basins have concerns with cloud cover, snow, and battery reliability; and (3) Southern basins have concerns with dust and heat/humidity related battery reliability. The commenter contends that these concerns are not effectively addressed in the November 2021 Proposal.

Commenter (0808-API) also mentions that it is probable that supplemental power via natural gas or diesel-powered generators could be required during winter months and/or severe weather events, which would be necessary to ensure a continuous power supply, and, thus, a controlled operation. This commenter also notes that interruptions within the control system pose safety risks to operators and can damage processing equipment, which could potentially lead to excess emissions associated with equipment malfunctions.

Commenter (0808-API) indicates that they are unaware of any operators converting to solar-powered electric controllers at this time. They note that while the technology seems promising, many of these solar systems have not yet been proven reliable for all remote locations or facility designs and are not ready for deployment across the country at the large-scale EPA's November 2021 Proposal would require. They note that in 2014, EPA stated "solar-powered controllers can replace continuous bleed controllers in certain applications but are not broadly applicable to all segments of the oil and natural gas industry."

Conversely, commenter (0838-TRIDO Solutions LLC) supports EPA's November 2021 Proposal to require zero-emission controllers. The commenter notes that they are a technology company that tackles methane emissions by replacing pneumatic devices and pumps with solar-powered pumps and air compressors. The commenter states that, initially designed for the aerospace industry, their differentiating technology is its high-efficiency motor and controller. The commenter cites several state rules that require all new pneumatic controllers to be non-emitting, including states with colder climates (*e.g.*, CO, WY, OK).

Commenter (0451-Clean Air Task Force (CATF)) states that, in a supplement to their 2022 report that was provided in a late comment, Carbon Limits addressed many of the alleged shortcomings of solar and other zero-emitting controller technologies raised in public comments. They state that, "[a]ddressing the queries on the reliability of solar systems for remote locations and cold states, the technology providers and operators interviewed as part of this assessment have solar-powered controllers installed at well sites in remote and cold locations such as Northern Alberta and British Columbia, without major reliability issues. Some of the interviewed technology providers have installed these systems in over 400 well-sites in these states and provinces. The commenter noted that solar technology has improved drastically from 2014 to 2021. Efficiency has increased while costs have gone down significantly. Solar-powered controllers can operate at low temperatures and remote locations, among different gas sectors. When it comes to snow cover on panels affecting the performance of solar cells, all the interviewees stated that the panels are placed at a low angle, to catch ample sun in the winter

months. Most often, these panels are placed vertically, eliminating snow cover on the solar panels.

Response I-10-12: Similar comments on the reliability of solar-powered process controllers were provided on the December 2022 Supplemental Proposal. For response to this comment, please see Volume II, Chapter 7 (Process Controllers), subsection 7.2.3 (Solar), Responses II-7-33 and II-7-34. See also section XI.D.2 (Zero-emissions standard) of the final rule preamble for EPA's responses to comments received on the proposed zero-emissions standard for process controllers.

Comment: Several commenters note that there are additional costs and risks associated with the implementation of solar-powered controllers that were not considered by EPA in the November 2021 Proposal analysis. The commenters recommend that EPA gather substantially more data and factor in necessary costs and risks, before proposing to impose a standard that assumes solar power is a viable option across the midstream sector. The following specific concerns are noted by commenters:

*Additional costs*

- Dispatching personnel to ensure that solar panels are cleared and functional at unmanned facilities. (0817-GPA)
- The full cost of siting solar power and associated equipment. Even where solar panels have adequate sunlight exposure, relatively small solar panel arrays are unlikely to meet the power demand for controllers and other equipment. The commenter states that a battery bank to supply power to the controllers at an entire compressor station could require as much as two acres of solar panels.<sup>4</sup> The November 2021 Proposal did not consider the potential for the need to acquire land and the cost of land acquisition and related permitting. (0817-GPA)
- EPA estimated a battery life of 15 years. There is no demonstrated experience to support that assumption across even a moderate sample size for this type of activity in the challenging environments where midstream activities are located. Cold weather decreases battery output and overall battery life therefore, batteries will likely have to be replaced far more frequently than 15 years. (0817-GPA)
- Additional labor or contract costs would be incurred to remotely monitor batteries and maintain charging stations to support the operation. (0817-GPA)
- EPA did not consider the costs associated with backup power system. Without adequate field-testing of solar powered systems, it is probable that via natural gas or diesel - powered generators would be required during winter months and/or severe weather events. This is necessary to ensure a continuous power supply, and, thus, controlled operation. (0808-API)

---

<sup>4</sup> According to the commenter, for compressor stations, it is simply not practical to have a solar panel for each controller. The commenter asserts that the Carbon Limits report is not clear, but its discussion of solar powered controllers implies that it examined solar panels to power a relatively small number of controllers at well sites. Carbon Limits at 13-16. Indeed, Carbon Limits states that, because "providers have so far focused mainly on the development of solutions for small sites in remote locations," there "seems to be much less field experience with using electronic controllers at medium and large sites" and is "not aware of any such installations." Id. at 16. 10 Cf. Carbon Limits at 15.

- The type and number of batteries required for remote industrial sites (e.g., gel lead acid batteries and absorbed glass mat (AGM) batteries) are on average higher in cost as compared to household solar panel systems. (0808-API)

*Risk related to practicality and reliability*

- Routine essential maintenance for clearing snow from panels is something that would be impractical for remote areas in winter months. (0817-GPA)
- Industry experience operating unmanned facilities in rural areas is that equipment theft is a significant concern, and large-scale batteries would likely be a prime target for theft, also thus increasing costs.<sup>5</sup> (0817-GPA)
- Where land acquisition is required, an assumption cannot be made the sufficient land is available. (0817-GPA)
- The electrically actuated controllers are less reliable and not appropriate for all process conditions such as throttle service. Adding the uncertainty of solar panels and batteries to these existing limitations will create more issues at these remote, unmanned sites that may lead to additional unplanned downtime. (0817-GPA)
- As a result of unplanned downtime at a compressor station, the compressor station can be forced to blowdown equipment which releases natural gas to the atmosphere. This would be especially true at older, existing compressor stations. Likewise, the upstream well sites can be forced to either vent or flare gas when the downstream compressor station is not available which would create a combination of additional emissions. (0817-GPA)
- Where sites experience significant winter weather or obstructions to sunlight, this type of high-maintenance equipment is impractical to operate. (0817-GPA)
- The potential exists that well sites would not generate enough power with a solar array, which would potentially require large and expensive battery storage system (1341-Conventional Groups)
- Large-scale solar applications have not yet been tested in winter months when there is more cloud coverage, increased snow cover, and less sunlight in more northern locations (Colorado, North Dakota, Idaho, Wyoming, etc.). (0808-API)
- Effect of climate and atmospheric conditions:
  - Reduced sunlight for long periods including fog. In the Uinta Basin, there are certain times of year where fog can sit over the basin for several weeks, effectively making solar controllers useless. In much of that area electrical power is also unavailable. In the West, line power is often unattainable where endangered species concerns preclude the construction of power lines and other infrastructure. Northern basins have concerns with cloud cover, snow, and battery reliability. Southern basins have concerns with dust and heat/humidity related battery reliability. (0743-WEA)
  - Average ambient temperature. At temperatures at or below -20°C (-4°F), solar battery capacity is decreased to 50 percent. This reduces the overall life of the solar battery, which impacts the overall reliability and lifespan of the system. Further, if low temperatures cause freezing, an interruption to power supply for the pneumatic controller system will occur. (0808-API)

---

<sup>5</sup> Cf. Carbon Limits at 15. 11 The Carbon Limits Report stated that a challenge for solar panels was that they “have reportedly been stolen or used as targets for shooting.” Carbon Limits at 15.

- Particulate accumulation. The level of particulate accumulation on the solar panel(s) is not well documented. This is important for remote, unmanned sites as challenges associated with properly cleaning the panels are encountered. The decrease in energy loss due to particle accumulation greatly varies based on several factors including site location, surrounding soil type, dust characteristics, and other surrounding air pollution.<sup>6</sup> One study suggests that in the U.S. over a 3-month period, up to 4.7 percent solar capacity is lost due to particulate accumulation on solar panels.<sup>7</sup> (0808-API)
- The effect of extreme temperatures on the capacity to store and deliver power. Remote oil and gas site applications for solar installations typically require up to 1,600 watt, 24 volts direct current (VDC) capacity with a common battery type being an 8G8D gel cell (number of batteries required per application can range from 2 to more than 10). The exact number of solar sets is greatly variable based on site-specific requirements.<sup>8</sup> When sizing the solar system, in addition to site-specific requirements, the temperature profile of the site also impacts the type, number, and capable performance of batteries for solar packages.

For example, the Deka 8G8D battery has an operating temperature range from -30°C (-22°F) to 50°C (122°F); however, the optimal operating range is above 0°C (32°F) because cold temperatures increase the internal resistance of a battery, thereby reducing capacity. The standard capacity rating of this example battery is based on each cell having an electrolyte temperature of 20°C (68°F).<sup>9</sup> At temperatures below the nominal rate, the battery's effective capacity is reduced, and the time to restore the battery to full charge is increased exponentially with decrease in temperature. Commenter provides a figure depicting the relationship between battery capacity and temperature for a Deka 8G8D solar battery, which indicates at -20°C (-4°F), battery capacity is decreased to 50 percent. The commenter provides a table which shows six states with significant oil and gas operations where temperatures fall in the range for reduced solar battery capacity during winter. Further, it is noted that the recent unprecedented winter storm in Texas (February 2021) saw a low temperature of -27° (-16°F).<sup>10</sup> Unfortunately, during severe weather days including snowstorms, solar panels are often not receiving sunlight and battery power is being used. Sufficient battery power at a high charge is needed for at least 7-10 days without sun. If the decreased sunlight lasts for too many days, batteries can freeze. Solar batteries in the oil field often freeze and stop functioning, particularly in areas where temperatures can drop to -40°C (-40°F).

On the other hand, extreme heat can also negatively affect battery performance and reliability. Though temperatures above 25°C (77°F) will slightly increase capacity, the

<sup>8</sup> Example of solar installations at oil and gas sites: <https://www.scadalink.com/products/remote-power/industrial-solar-panels/>.

<sup>9</sup> Deka battery specifications: <https://www.solarelectricsupply.com/solar-components/solar-batteries/gel-batteries/deka-8g8d-solar-batteries>

<sup>10</sup> Feb. 2021 Texas Winter Storm Details: <https://www.weather.gov/media/ewx/wxevents/ewx-20210218.pdf>.

potential of self-discharge and reduced battery life is increased. Further, as temperatures rise, any cycle life loss due to operating at higher temperatures is not recoverable. During extreme heat events, such as those experienced in Texas and Louisiana, overheating of the battery is possible. In this scenario, the battery lifespan can be shortened, or the battery can be completely damaged. (0808-API)

Response I-10-13: Similar comments on the reliability of solar driven process controllers were provided on the December 2022 Supplemental Proposal. For response to this comment, please see Volume II, Chapter 7 (Process Controllers), subsection 7.2.3 (Solar), Responses II-7-33 and II-7-34.

#### ***10.3.4 Instrument Air***

Comment: Commenter (1341-Conventional Groups) states that even if a reliable electric source were available at the well sites of their industry members, the use of gas-fired compressors to operate instrument air would result in a net increase in emissions. The commenter notes that the EPA acknowledges that instrument air systems are feasible "only at locations with a high concentration of pneumatic control valves" (November 2021 TSD, p. 8-17). The commenter reports that their member company well sites do *not* have a high concentration of such valves.

Response I-10-14: For discussion of secondary emissions from process controllers powered by generators, see section IV.D.1.b.iii. of the December 2022 Supplemental Proposal preamble (87 FR 74765) and section XI. D.2 of the preamble to the final rule. In the 2021 TSD, the EPA did not acknowledge that instrument air systems are infeasible unless there are a high concentration of pneumatic control valves, but rather assumed that other options, such as solar-powered electric process controllers would be used at sites with only a few process controllers. See also section IV.D.2.d.i of the December 2022 Supplemental Proposal (87 FR 74769) and section XI.D.2 of the preamble to the final rule for discussion of small well sites.

Comment: Commenter (0823-Qnergy) states that they produce compressed air pneumatic systems (CAP3) to displace methane and VOC emissions from pneumatic devices. The commenter reports that they developed an application allowing its Stirling generators to power CAP3, even when grid power is not available. The commenter adds that CAP3 leverages the reliability of their power generators to drive compressors that replace methane emissions from pneumatic devices with clean, dry instrument air. According to the commenter, this technology offers a low-emission alternative to the gas-powered pneumatic devices currently used throughout the natural gas industry, particularly in the upstream sector.

Based on a range of capacities and operating conditions, the commenter (0823-Qnergy) notes that each of their CAP3 systems can abate between 500 and 5,000 tons of carbon dioxide (CO<sub>2</sub>) equivalent per year. They add that their CAP3 system meets EPA's proposed standards of performance for zero-emissions controllers and a natural gas emission rate of zero both on and off the grid.<sup>11</sup> The commenter notes that their internal testing has demonstrated that their

---

<sup>11</sup> When operating off the grid, the commenter states that the CAP3 system produces only negligible emissions of CO and NO<sub>x</sub> (ten- to a hundred-fold less than internal combustion engines (ICEs)) from the Stirling engine's power

technology not only eliminates “bleeding” natural gas at well sites effectively, but it does so at the lowest emissions abatement costs of any pneumatic technology.<sup>12</sup> The commenter provides technical descriptions of various CAP3 models and notes that they continue to expand use of their systems in wide-ranging environments on the North American continent. According to the commenter, they recently raised capital from the Oil & Gas Climate Initiative to accelerate deployment of its methane mitigation systems throughout the world, with a focus on the natural gas exploration, production, and transport markets.<sup>13</sup>

In response to EPA’s request for information on specific functional needs that would require a low-bleed or intermittent controller, commenter (0823-Qnergy) provides that their CAP3 technology can be applied to all pneumatic controller types, eliminating the need to vent natural gas to the atmosphere. According to the commenter, while low-bleed and intermittent controllers are prevalent in the industry today, they submit that these controller types produce emissions that the industry can eliminate. Simply put, the commenter contends that there is little need for these controller types when a feasible, cost-effective alternative with no bleeding is available. The commenter reports that they have developed multiple configurations to cover the spectrum of possible well-pad pneumatic emissions, spanning from a minimum of one small “CAP3-nano” providing 1 scfm to a single pad in a low-bleed site up to a double “CAP3-M” providing<sup>14</sup> 24 scfm to a 16-well pad. The commenter provides that their different CAP3 configurations are presented in Appendices D and E of their comment letter (which contain CBI). The commenter concludes that they maintain that there are no specific functional needs that require a low-bleed or intermittent controller that vents natural gas into the atmosphere.

The commenter (0823-Qnergy) suggests that EPA regulations recognize in the BSER and standards of performance the role of innovative technologies such as their CAP3 technology, which they contend virtually eliminates methane emissions from pneumatic devices and provides system monitoring to ensure effective and continuous emission control. The commenter submits to EPA that the CAP3 system’s performance can raise the bar for pneumatic controllers and pumps. They assert that it can serve as a basis for the BSER, as demonstrated by an increasing reliance by leading companies in the industry<sup>15</sup> because of CAP3’s elimination of methane emissions, commercial availability, lowest possible abatement costs and overall environmental

---

generation, which EPA recognizes as only “secondary impacts from the use of instrument air systems” that still allow pneumatic devices to meet the proposed emission rate of zero. 2021 November Proposed Rule at 63208.

<sup>12</sup> See Appendix A of the commenter’s letter submission for more information about their (Qnergy’s) technology and its uses and Appendix E of the commenter’s letter submission for their internal abatement cost data. Appendix E of the commenter’s letter contains Confidential Business Information (CBI).

<sup>13</sup> The commenter (Qnergy) states they close \$16 million series C funding round, led by OGCI Climate investments, QENERGY (Nov. 16, 2021), <https://www.qnergy.com/qnergy-closes-16-million-series-c-funding-round-led-by-ogci-climate-investments/>.

<sup>14</sup> Proposed Rule at 63179, 63207

<sup>15</sup> The commenter states that their technology is well known, and accepted, throughout the industry. Over 80 customers—including regional, national, and global natural gas leaders—have chosen to use the commenter’s (Qnergy) technology in the field to reduce emissions. Appendix B (of the commenter’s letter) provides a partial list of active users among U.S. natural gas producers. Additional users can be found in an attachment to the commenter’s letter (Appendix D of the commenter’s letter). All of these materials contain CBI

performance (e.g., lower CO<sub>2</sub> equivalent emissions and only negligible emissions of non-greenhouse gases (GHGs) or VOCs).<sup>16</sup>

Response I-10-15: The EPA acknowledges that a compressed air system using a generator is one available method through which zero emissions from process controllers may be attained. See section IV.D of the December 2022 Supplemental Proposal (87 FR 74755-74769) for references to the use of compressed air or instrument air systems along with generators to meet a zero-emissions requirement.

Comment: Commenter (0844-EDF *et al.*) states that when electricity is not available to power electronic or instrument air controllers, nitrogen provides a feasible zero-emission alternative to operating pneumatic devices. The commenter explains that, unlike instrument air systems that require electric power, these systems only require the installation of a cryogenic liquid nitrogen cylinder, which is replaced or refilled periodically, and a liquid nitrogen vaporizer.<sup>17</sup> The commenter reports that one company in British Columbia, Kathairos, provides a service that allows operators to store a quantity of liquid nitrogen at a site, which (after on-site gasification) provides a source of dry nitrogen gas to drive pneumatics instead of using natural gas.<sup>18</sup> According to the commenter, the system requires no electricity or on-site power generation.<sup>19</sup> The commenter also states that Instrument air devices can also be powered by solar generators. There are several manufacturers advancing this technology.<sup>20</sup>

Response I-10-16: Although the EPA did not specifically include the use of nitrogen canisters as a zero-emissions option in our BSER analyses due to a lack of nationwide availability, we acknowledge that it is a technically feasible option and may be cost-effective for some sites to use for powering pneumatic process controllers.

---

<sup>16</sup> Appendices C, D, and E of the commenter's letter contain more CBI based on the commenter's internal testing and data collection efforts.

<sup>20</sup> Carbon Limits 2021 at 7-8. A new technology package called the Aurora Eco-System, offered by Air Works Compressors, provides an instrument air system powered by solar PV or wind power installed at the well-sites. As of mid-2021, the solar-powered Aurora Eco-System package has been installed in 22 sites in Alberta, Wyoming, Utah, and Peru. 2021. Carbon Limits 2021 at 7. Additionally, LCO technology markets the Crossfire Instrument Air Compressor (see <https://lco-technologies.com/crossfire-compressor.html>) and WestGen Technology markets the Engineered Power on Demand (EPOD) unit to provide sites with both compressed air and electricity. The unit derives most of its power from solar panels but supplements the solar with a small gas-driven engine (needed particularly in Canadian winters) (see <https://westgentech.com/epod-ap-series/>). Other examples include Alert Control Technologies, <https://alertcontrol.com/air-compressors/> (last visited Jan. 27, 2022); and Axiom Technologies LLC, <https://axiomsafety.com/solar-powered-air-compressors/> (last visited Jan. 27, 2022).

### ***10.3.5 Technical Limitations of Electrically Actuated Controllers***

Comment: Commenters note that there are technical limitations with electrically actuated controllers. Commenter (0743-WEA) states that electric controllers can generally only be used to control valves so their use will not be sufficient to reliably keep an entire facility operating safely.

Commenter (0817-GPA) notes that electrically actuated valves do not have the speed and performance of gas-powered actuators (including air-powered actuators), limiting their utility. In particular, the commenter states they have a higher failure rate than gas-powered actuators, especially for throttle service where the actuator is constantly adjusting based on process conditions, instead of a set point. The commenter adds that the controllers are more expensive and there are few options available on the market which would drive up prices further in the case of any mandate. Also, the commenter states that electrically actuated controllers require the installation of a complex automated control system. The commenter asserts that neither of these additional costs appear to have been included in EPA's estimates.

Commenters (0743-WEA, 0817-GPA) state that back-up systems such as instrument air would likely be required to operate facilities safely. For remote sites where electricity is not available, installation of a generator to supply power for instrument air and/or electric controllers would be necessary, which would cause an offset of the already very low emissions reductions as well as incur additional cost that was not included in EPA's analysis.

Response I-10-17: There are many options available to owner/operators for compliance with the process controller standards. If an owner/operator is concerned about using electric process controllers, other options include using a compressed air system to power pneumatic process controllers, using self-contained process controllers, or routing process controller emissions to a process. For discussion of secondary emissions from process controllers powered by generators, see section IV.D.1.b.iii. of the December 2022 Supplemental Proposal preamble (87 FR 74765) and section XI. D.2 of the preamble to the final rule. For the model plant scenarios evaluated in the BSER analysis and the costs of zero-emissions technologies, including the use of generators and electric process controllers, see section XI.D.1 of the preamble to the final rule.

## **10.4 Access to Electrical Grid**

Comment: Commenter (0808-API) requests that EPA clarify that "access to power" means that commercial line power is available onsite, sufficient to cover the power/capacity requirements of the non-emitting pneumatic controller design of the facility, and which provides reliable and consistent coverage. The commenter goes on to highlight technical challenges with grid power requirements. Specifically, the commenter requests that EPA consider the following aspects of grid power:

- Access to Grid Power. Access to grid power must be limited to commercially available onsite connections with sufficient and reliable power. It is not always logistically feasible to electrify a location from the grid due to issues outside of an owner/operator's control. These challenges include right-of-way (ROW) issues for placement of power lines, a landowner's

right to not install power lines on their property]<sup>21</sup>, and/or distance from an available power line that contains sufficient power and capacity to connect the facility. Therefore, EPA must be clear that running new commercial power lines to any site is not EPA's intent given the practical, technical, and cost challenges this would cause at large scale implementation across the country.

- Sufficient Volume and Quality of Grid Power. Equipment power requirements at oil and gas facilities are quite varied, ranging from instrumentation at a single well pad needing approximately 35 watts to operate all the way up to approximately 2,000 kilowatts at larger sites running more equipment on electrical power. The power demand required to operate equipment determines if single phase power (household) is adequate or if three phase power (industrial) is necessary. Single phase low volume power may be accessible in certain areas, but three phase industrial wattage levels may not be available. Furthermore, even with accessibility, there may not be sufficient levels to run a given site or field. Due to the challenges around the development of adequate power supply to remote locations and the temporary nature of some areas of oilfield demand, many sites are supplied by onsite generation through produced natural gas as a motive source or natural gas generators.
- Right-of-Way Issues. The largest challenge to oil and gas operations having grid power is obtaining ROW access for power lines. On private lands, landowners may choose to never allow ROW, particularly on large ranches. On federal lands, the current lead time for installation is typically between 6 months up to 2 years. It should be noted that the longest lead times have been experienced on federal lands controlled under the Bureau of Land Management (BLM). Additionally, as the Administration pursues updates to other regulatory requirements, such as environmental reviews as proposed by the Council on Environmental Quality in the Phase 1 National Environmental Policy Act (NEPA) revisions, these challenges may be exacerbated by expanding requirements and protracted timelines. A Memorandum of Understanding (MOU) may be needed between EPA and BLM and state land offices to expedite approval of ROW for grid power.

The commenter (0808-API) states that even if logistically possible, it is unlikely to be cost-effective to access off-site grid power to convert a site to non-emitting controllers. According to the commenter, even without the foregoing concerns, the cost and timing to obtain grid access can be prohibitive when it is not readily accessible onsite.

As a point of reference, the commenter (0808-API) states that experiences with their member companies suggest an average estimated cost of approximately \$200,000 per mile for installing an electrical line to a facility where one does not already exist. When this additional cost is considered for 1 mile of new power line and all other EPA assumptions remain, the commenter states that the retrofit of pneumatic controllers is not cost-effective for small and medium model plants. The commenter notes that, since EPA did not include nor consider costs for installing new power lines in its cost benefit analysis, it is assumed EPA did not intend to require operators to run new commercial power lines in order meet proposed control requirements for pneumatic controllers. The commenter notes that they support EPA in this approach, as this would not be

---

<sup>21</sup> According to the commenter, in some states, the utility provider can implement eminent domain, but production companies would not and do not have this authority. Other states, such as North Dakota, do not have eminent domain authority.

cost-effective and would cause other environmental disbenefits (*e.g.*, potential land disturbance) in pursuit of eliminating emissions from a small number of ancillary controllers.

Another commenter (0831-AXPC) states that they believe it is important that the supplemental proposal specify that it is not the agency's intent to require operators to run new commercial power lines, certainly in situations where it would be practically, technically, or economically infeasible to do so.

Response I-10-18: In the NSPS and EG regulatory language for the December 2022 Supplemental Proposal and the final rule, the definition for "Access to electrical power" is that commercial line power is available onsite, with sufficient capacity to support the required power loading of onsite equipment, and which provides reliable and consistent power. See NSPS §60.5430b and EG §60.5430c. The EPA is not requiring and does not expect sites to extend grid power lines to their sites for compliance with the NSPS or EG. See section XI.D.3 of the final rule preamble for further discussion of the BSER for sites without access to electrical power.

Comment: Commenters (0817-GPA, 0938-TXOGA) request that EPA subcategorize existing facilities with and without access to supplied power and then determine BSER separately for each subcategory. Commenter (0938-TXOGA) notes that the availability of electricity is a significant and constraining factor that is within EPA's authority to consider in subcategorization. Commenter (0817-GPA) states that it would also be important to establish that any supplied power is sufficient to support the additional equipment needed to comply with the rule. According to the commenter (0817-GPA), if no provision is given for available supplied power, additional combustion sources would need to be installed to provide it. They add that generators would likely be rented until a permanent power source is constructed which would result in additional costs not considered by EPA as well as increased generator combustion emissions.

Commenter (0803-Ohio Oil and Gas Association (OOGA)) states that their members' operations are located predominantly in rural locations and access to connect to the electric grid is not always readily available. They add that obtaining access to the grid can take several months to years to coordinate with property owners (easements), electric utility providers, and environmental agencies to receive approval installation of new electric lines. Once approval is received it can take several more months to complete construction. Further, the commenter states that much of the timing of this process is out of the hands of the commenter's members. The commenter notes that it is a very large project and EPA has not considered the entire scope much less the timing.

Commenter (0763-Texas Commission on Environmental Quality (TCEQ) and Railroad Commission (RRC)) states that the use of electrical controllers assumes access to the electrical grid, and this may not be the case for all sites, particularly in the Permian Basin, Eagle Ford Shale, or other similarly rural exploration fields.

Commenter (0823-Qnergy) states that because they have demonstrated that it is technically feasible to require the use of zero-emissions pneumatic controller at facilities with or without access to electric or solar power, it requests that EPA base its BSER on the understanding that

any facilities with access to electric or solar power incorporate zero-emissions pneumatic controllers.

Commenter (0844-EDF *et al.*) reports that a significant number of sites already have access to the grid, and an even larger number can connect a line to the grid. According to EPA's assumptions, all processing plants and 40 percent of well sites have access to reliable electricity. The commenter adds that, in a 2015 survey of companies<sup>22</sup>, 34 percent of companies in the U.S. reported that all of their gathering compressor stations have grid access and only 7 percent reported that none of their sites had access, with grid accessibility having likely improved across the industry since 2015.

The commenter (0844-EDF *et al.*) adds that, at sites without grid access, electronic controllers can be powered by solar control systems. The commenter states that these systems are approximately as cost-effective as grid-powered electric controllers and are technologically feasible for both new sites and retrofitting existing sites.<sup>23</sup> The commenter further indicates that the solar resource is sufficient to power these systems in many geographic locations. Consider, for instance, northern Alberta, where substantial oil and gas development occurs: solar panels generate less power than in lower latitudes, sunlight on a clear day is far weaker than in many parts of the U.S., snowfall is higher and winter cloud cover is much more common, and winter temperatures are much lower (affecting battery capacity). Nevertheless, the commenter asserts that solar-powered controllers have been reliable for oil and gas companies operating there.<sup>24</sup> The commenter reports that Calscan, an Alberta vendor of packages that utilize solar-power and batteries to power electric actuators and instrumentation for zero-emission separators,<sup>25</sup> estimates that they have sold about four hundred of these packages in Canada (mainly in Alberta).<sup>26</sup> Moreover, Energy Information Administration (EIA) data demonstrates that the availability of solar power in several regions around the U.S. has increased significantly over the past five years.<sup>27</sup> In addition, the commenter notes that, although solar technology has been most commonly used at small and medium sites in the past, it is now available and cost-effective at larger sites due to the falling prices of photovoltaic (PV) panels and battery systems, improvements in PV output, and the ease of installing solar PV systems. Furthermore, the commenter notes that operators have found that reliability has increased when using additional, vertically stacked solar panels<sup>28</sup> or an additional methanol fuel cell.<sup>29</sup>

Commenter (1391-INGAA) suggests that the exemption available for sites in Alaska should apply throughout the entire U.S. for sites where there is no available electric power. The

<sup>29</sup> Carbon Limits 2021 at 6.

commenter contends that it is arbitrary and capricious that the exemption that applies within Alaska would not also apply to areas in the other 49 states where the same situation exists. The commenter cites as an example that several of their members operate pipelines in a very remote part of a state forest in Pennsylvania and other states where electric power is unavailable.<sup>30</sup> According to the commenter, installation of an electric transmission line is not feasible given the distance to the site and because of the forest (*i.e.*, a large amount of state forest would need to be cleared to install the panels and it is unclear that the state would allow this). The commenter adds that, at a different location in Pennsylvania, some of the metering stations could have power installed to them without too much issue. However, in some instances, electrical lines over 10 miles long in remote areas would need to be installed. The commenter continues by citing problems with solar power (discussed elsewhere in this Chapter). The commenter adds that another member in Texas operates a pipeline on land where the landowner is not welcoming to any future development. The commenter's member has attempted for years to add power to the site, but all efforts have failed. Although the commenter's member was able to borrow a spare circuit from an adjacent transmission operator and run it a couple of hundred feet into the fence, that circuit only provides enough power to run some low-power equipment. The commenter states that the site has nothing close to the power needed to run electric actuators or air compression. They add that there is not enough space to install a solar panel system that would be sizeable enough and that would still have the reliability issues. The commenter contends that these types of landowner issues can make safe and reliable operation almost impossible without the use of gas-driven equipment.

Commenter (0740-UPA) states that EPA has underestimated the costs of electrifying Utah oil and gas operations. As a result, they request that EPA provide an exemption from zero-emission pneumatic controllers in Utah at non-electrified sites, similar to the exemption that EPA proposed to provide for operations in Alaska that lack power.<sup>31</sup>

Response I-10-19: The EPA has determined that the BSER is zero emissions from process controllers except at sites in Alaska without access to electrical power. See discussion in section IV.D.1.b.iii. of the December 2022 Supplemental Proposal preamble (87 FR 74764-74765) and section XI. D.3 of the preamble to the final rule.

## **10.5 Use of Generators at Sites without Electricity**

Comment: Several commenters (0749-PAW, 0808-API, 0831-AXPC) indicate that at sites without electricity, owners or operators would likely install a generator to power an instrument air system. These commenters contended that relying on a generator would result in emissions of criteria pollutants and carbon monoxide (CO) that could potentially offset the emissions reductions from the methane and VOC. One commenter (AXPC) provided an estimate that a natural gas-fired generator of approximately 200 horsepower would be needed to support reliable operation of a large instrument air system without grid power. This commenter estimated emissions from a generator that size to be 1.94 tons per year (tpy) nitrogen oxide (NO<sub>x</sub>), 3.88 tpy

---

<sup>30</sup> The commenter reports that pipelines being in forest land is not unusual. Installation of electric power lines or solar panels on forest land will involve the clearing of acres of forest that may not be permitted by the applicable forest authority.

<sup>31</sup> See November 2021 Proposal, 86 FR 63179 and 63189.

of CO, 1.36 tpy of VOC, 0.12 tpy of particulate meter with a diameter of 10 micrometers or less (PM<sub>10</sub>), 0.14 tpy CH<sub>4</sub> and 730 tpy of CO<sub>2</sub>. Still, to achieve the large-scale deployment of non-emitting pneumatic devices that the November 2021 Proposal envisions the commenter asks EPA to account for these circumstances where an operator cannot obtain grid power (whether for legal or practical reasons), where there are delays in building grid connections, or where renewables may not be a reliable or feasible option and allow for the use of natural gas or diesel generators as the most feasible option to achieve a non-emitting control standard.

Response I-10-20: See discussion of secondary emissions from process controllers powered by generators in section IV.D.1.b.iii. of the December 2022 Supplemental Proposal preamble (87 FR 74765) and section XI. D.2 of the preamble to the final rule. The final rule is technology-neutral and does not require the use of grid power to attain zero emissions from process controllers. See section XI.D.3 of the preamble to the final rule for further discussion of the BSER and the NSPS and EG requirements for process controllers.

Comment: Commenter (0823-Qnergy) states that internal combustion engine (ICE) generators typically are cheaper to purchase than lower emitting generators, and so some owners and operators may be inclined to purchase them to power pneumatic devices. However, the commenter notes that ICE generators require higher maintenance costs compared to their company's technologies. The commenter supports EPA's November 2021 Proposal for BSER and corresponding standards of performance to prohibit the use of such generators, as they are not only unnecessary, but would contravene the emissions reductions the Proposed Rule seeks to implement. By adopting technology like CAP3 [their technology], they contend that oil and gas owners and operators can minimize overall emissions and completely eliminate methane and VOC emissions from pneumatic devices, at a lower total cost of ownership. The commenter requests that the forthcoming rule expressly recognize this and prohibit the use of ICE-powered generators as a power source for pneumatic devices. The commenter notes that their technology achieves demonstrable emissions reductions for pneumatic devices at the lowest abatement cost in the industry, and they believe it should form the basis for EPA's BSER and performance standards for pneumatic controllers and pumps. Upon EPA's request, the commenter states that they are willing to share confidential pricing information with the Agency as well as anonymized user data and benchmarks on air consumption across the industry. The commenter appreciates EPA's attention and welcomes the opportunity for further dialogue regarding their technology and the ways it can promote the important statutory goals EPA seeks to fulfill with this rulemaking.

Response I-10-21: The EPA is not prohibiting the use of ICE-powered generators as a power source for process controllers. As explained in section XI.D.2 of the preamble to the final rule, the EPA's emissions standards are technology-neutral. For discussion of the secondary emissions from process controllers powered by generators, see section IV.D.1.b.iii. of the December 2022 Supplemental Proposal preamble (87 FR 74765) and section XI. D.2 of the preamble to the final rule.

Comment: Commenter (0844-EDF *et al.*) states that some sites without a grid connection may choose to use an on-site generator to power electronic controllers. The commenter provides that this technology is readily available, and many sites already have power generation on-site for

other purposes like lighting, automation, and control systems. The commenter is confident that despite secondary impacts, this option is also environmentally beneficial. The commenter notes that generator-run instrument air can produce NO<sub>x</sub> emissions, but the pollution benefits of using this technology far outweigh the harm from those emissions. The commenter reports that one analysis obtained emissions data from two vendors that supply engine/air compressor packages and found that these types of compressed air packages will prevent at least ninety times more VOC emissions (by weight) than the NO<sub>x</sub> emissions they produce.<sup>32</sup> Beyond natural gas generators, the commenter reports that there are also thermoelectric generators that can convert waste heat in compressor exhaust to electricity.<sup>33</sup> The commenter continues that electronic controllers can also be powered by a hybrid system of solar and gas-fired generation. Prefabricated units are available, and operators can choose between backup power systems using a genset or battery storage depending on cost, available space, and other factors.<sup>34</sup>

Response I-10-22: See Volume II, Chapter 7 (Process Controllers), subsection 7.2.5 (Generators), Response II-7-39, for a summary of EPA's analysis of the secondary emissions that would be created by the use of generators. The secondary emissions that would occur are estimated to be relatively small and are outweighed by the emissions reductions that would be reduced from the process controllers.

## 10.6 Electronic Controllers

Comment: Commenter (0844-EDF *et al.*) states that zero-emitting electronic controllers are readily available and are engineered by a variety of companies, and the technology continues to advance. The commenter reports that one company has installed over 1800 electric actuators at oil and gas sites throughout Western Canada over the past seven years and plans on installing over 1,000 in 2022.<sup>35</sup> The commenter adds that electronic controllers are highly cost-effective, reducing methane at an expense that is far lower than levels that EPA has in the past found were cost-effective.<sup>36</sup> Additionally, the power required for electronic controllers is decreasing. In fact, the commenter states that power demand for electronic controllers is lower than for traditional gas-driven controllers.<sup>37</sup> Furthermore, the commenter notes that electronic systems have much lower maintenance costs than gas-driven controller systems and are longer lasting,<sup>38</sup> and electronic controllers and actuators can be connected to existing valves at well sites, eliminating the need to replace control valves.<sup>39</sup>

Response I-10-23: The EPA appreciates the commenter's provided information. This and other comments received regarding zero-emitting technologies were considered when developing the NSPS OOOOb and EG OOOOc final rule requirements. See section X.D (Process Controllers) of the final rule preamble for a summary of the final process controller NSPS OOOOb and EG OOOOc requirements.

## **10.7 Low and Intermittent Bleed Pneumatic Controllers**

Comment: Commenter (0749-PAW) states that EPA should propose a rule that allows for low or intermittent bleed devices to be used for existing facilities. The commenter explains that, for smaller facilities that have lower production, installing and operating instrument air systems could easily exceed the value of the recoverable production from the wells associated with those facilities, forcing those operators to shut in production. Across the U.S there are thousands of wells that, according to the commenter, would be rendered uneconomic to operate should the framework described in EPA's publication be proposed for existing sources.

Another commenter (0802-Kraken Oil & Gas LLC (Kraken)) urges EPA to allow low and intermittent bleed pneumatic controllers to be used for all new and existing facilities and that retrofitting any pneumatic controllers already compliant with NSPS OOOO/OOOOa is not warranted. The commenter notes that they support reducing emissions from pneumatic controllers, and it is why they have always used intermittent bleed and low bleed pneumatic controllers with bleed rates lower than the requirement set forth in NSPS OOOO/OOOOa, to (less than 6 standard cubic feet (scf)/hour). The commenter states that their operations employ pneumatic controllers with bleed rates well under 1 scf/hour, and some as low as 0.03 scf/hour. Further, the commenter explains that the intermittent bleed and low bleed pneumatic controllers are designed to be tough for operating in the harsh weather and temperature conditions can often result in interrupted electricity delivery or redirected power demands. The commenter indicates that since their facilities are generally unmanned, the controllers need to be reliable and reconfiguring these controllers to operate using electricity and instrument air introduces increased reliability issues.

Commenter (0808-API) recommends that, absent feasibility to retrofit, the use of continuous low bleed and intermittent natural gas controllers at existing facilities be allowed and covered in an operator's existing LDAR monitoring program to monitor proper functioning. The commenter cites potential site physical constraints for small sites and notes that retrofit costs would be prohibitive for low-producing wells which could cause low-production or stripper wells to be forced to shut down. The commenter explains that existing well pads may have sizing constraints for the proper placement (due to safety and other permitting constraints) of control systems and compressors that must sit outside of classified areas, generators, or solar panels. Further, the commenter notes that the state regulations that EPA cites in support of the November 2021 Proposal, including Colorado and the current proposed version of regulations pending in New Mexico<sup>40</sup>, do not require all existing controllers to be retrofitted. The commenter states that

---

<sup>40</sup> <https://www.env.nm.gov/opf/wp-content/uploads/sites/13/2022/01/Attachment-1-NMED-Proposed-Part-20.2.50-January-20-2022-Version.pdf>

Colorado's regulations, as well as the draft regulations pending in New Mexico, concluded this is unwarranted as controller retrofit is not cost-effective nor technically feasible for many facilities.

Response I-10-24: Similar comments were made on the December 2022 Supplemental Proposal, see response in Volume II, Chapter 7 (Process Controllers), subsection 7.4 (Low Production/Small Sites), Response II-7-79.

Comment: Commenters (0810-Petroleum Alliance-OK, 0814-Independent Petroleum Association of America (IPAA) *et al.*) state that the low emissions of backpressure intermittent controllers do not justify regulation. The commenters note that a 2014 study they conducted found that intermittent vent controllers emitted on the average 0.047 tons/year of methane. A comparison of these results with the existing body of work on emissions from these types of controllers found that the other studies overestimated emissions by a factor ranging from 5.4 to 27.5. The study showed that 17 of 77 controller models identified were backpressure controllers (accounting for approximately 40 percent of controllers observed) and that these controllers are often used for overpressure protection that rarely actuated when encountered during field observations. The commenter contends that this information indicates that normally functioning intermittent pneumatic controllers are not an issue and should not be regulated. According to the commenter, it is not reasonable, cost-effective, or efficient for operators, especially marginal/low production well operators, to now replace well-functioning intermittent vent controllers or retrofit their sites to use air-driven, solar, electric, or self-contained controllers.

Response I-10-25: Similar comments were made on the December 2022 Supplemental Proposal, see response in Volume II, Chapter 7 (Process Controllers), subsection 7.3.1 (Emissions/Emission Factors), Response II-7-62.

Comment: Commenter (0787/1289-Atmos Energy Corporation (Atmos)) suggests that EPA further consider subcategorizing low-emitting pneumatic controllers, which are predominantly used in the transmission and storage segment. The commenter notes that in the November 2021 Proposal TSD, EPA presents intermittent vent devices in the transmission and storage segment as making up approximately 2 percent of the methane emissions from pneumatic controllers and approximately 0.03 percent of total methane emissions from the transmission and storage segment.<sup>41</sup> The commenter suggests that EPA allow companies to demonstrate that a site's potential emissions fall within the low-emitting subcategory. They suggest that the demonstration could include submission of actual equipment design parameters (*e.g.*, bleed rate per stroke), maximum actual operations (*i.e.*, maximum anticipated strokes per year for intermittent devices), and the presumption of proper operation.<sup>42</sup> According to the commenter, implementing these options, or a similar approach, would be consistent with EPA's stated purpose. of "limiting super-emitters through actions included in this rule such as reducing fugitive emissions, using lower-emitting equipment where feasible [emphasis added], and

---

<sup>41</sup> TSD at Table 8-2. [23] Id. at 8-27.

<sup>42</sup> The commenter states that EPA should not use 40 C.F.R. 98 Subpart W average emission factors for pneumatic controllers for such a demonstration, because it would be less accurate and, thus, defeat the purpose of creating the subcategory.

employing best management practices [to] not only reduce emissions but to reduce the loss and revenue from this valuable commodity.”<sup>43</sup>

Commenter (0787-Atmos) alternatively suggests that EPA consider subcategorizing natural gas pneumatic controllers for the transmission and storage segment and require that natural gas intermittent vent controllers at small sites be monitored with enhanced maintenance.

Response I-10-26: Similar comments were made on the December 2022 Supplemental Proposal. See response in Volume II, Chapter 7 (Process Controllers), subsection 7.4 (Low Production/Small Sites), Response II-7-79.

Comment: Commenters (0793-PBPA, 0808-API) urge EPA to provide flexibility to use low-bleed controllers where electricity is not available. The commenters note that, as EPA has recognized, low-bleed controllers reduce emissions by a substantial 84 percent compared to high-bleed devices in the production sector. The commenters request that, as EPA has proposed to allow only sources located in Alaska that lack onsite power to use low-bleed controllers, EPA extend the flexibility to use low-bleed controllers to all sources.

Commenter (0808-API) adds that they support EPA’s November 2021 Proposal to retrofit to non-emitting controllers, where the following criteria are met: a) there are at least 15 controllers at the well site, central production facility, or compressor station; and b) there is access to sufficient and reliable grid power onsite. If the above criteria are not met, then any high-bleed natural gas-driven controller should be replaced with a continuous low-bleed and/or with an intermittent controller and included within a company’s LDAR monitoring program to monitor proper functioning. The commenter notes that this approach is similar to and based on the rationale for EPA’s proposed requirements for pneumatic controllers at sites in Alaska without grid access.

Another commenter (1341-Conventional Groups) states that EPA's evaluation provided that “electrical supply is assumed to be on site irrespective of the electronic controllers at the site” and the “costs of the power supply were not included in the analyses of emission reductions and the costs for electronic controllers.” November 2021 Proposal TSD, p. 8-21. The commenter provides that, without a reliable electrical source to convert to instrument air, the only other potential compliance option would be retrofitting existing natural gas-driven controllers with low-bleed controllers. The commenter contends that the capital costs and maintenance costs of even one controller would be unreasonable, for marginal, if any, environmental benefit.

Response I-10-27: The NSPS and EG are required by the CAA to be based on the BSER. In the revised BSER analysis conducted for the December 2022 Supplemental Proposal and in the refreshed analysis conducted for the final rule, zero emissions from process controllers was shown to be technically achievable and cost-effective at all model plant configurations (outside of Alaska) through several available options. As such, the EPA determined that zero emissions represents the BSER and is the basis for the requirements of the NSPS and EG. For further details regarding the revised BSER analyses, see sections IV.D.1.b. ii and iii of the December

---

<sup>43</sup> 86 Fed. Reg. at 63,130 (emphasis added)

2022 Supplemental Proposal preamble (87 FR 74760-74766) and sections XI. D.2 and 3 of the preamble to the final rule.

Comment: Commenter (0808-API) suggests that EPA exempt facilities from the non-emitting controller standard under NSPS OOOOb and EG OOOOc if there is only a single low bleed or intermittent controller present. The commenter provides a cost-effectiveness analysis which indicates that methane costs range from \$7,000 to \$73,000 per ton of methane reduced for single low bleed and intermittent controllers. According to the commenter, the results indicate it is not cost-effective to retrofit a single low bleed or intermittent controller. The commenter notes that this analysis relied on controller system costs as provided in EPA's pneumatic controllers costs and emissions workbook for a small model plant. The commenter reports that their survey suggests minimum costs are at least double the costs estimated by EPA for small model plants, which would best reflect the minimum costs associated with retrofitting a single controller.

Response I-10-28: In the BSER analysis conducted for the final rule, the EPA found there are zero-emissions process controller options with costs that are reasonable, considering the emissions reductions that would be achieved, for all model plants studied. The smallest model plant evaluated included four process controllers. For further details regarding the revised BSER analyses, see sections IV.D.1.b. ii and iii of the December 2022 Supplemental Proposal preamble (87 FR 74760-74766) and sections XI. D.2 and 3 of the preamble to the final rule.

Comment: Commenter (0844-EDF *et al.*) provides that numerous studies indicate that pneumatic controllers often emit more than their design values indicate. They add that intermittent controllers are designed to emit only during the actuation cycle for the controller, but in the field, these devices frequently emit between actuations. For example, the commenter states that Luck *et al.* (2019) reported that 63 percent of the intermittent controllers observed as part of that study were operating abnormally.<sup>44</sup> Similarly, the commenter states that “low-bleed” continuous pneumatic controllers have also been observed to frequently emit more than they are designed to emit, and it is not uncommon for their emissions to exceed the 6 standard cubic feet per hour standard for “low-bleed” devices. Due to the ubiquity of these types of malfunctions, the commenter states that measures designed to merely reduce emissions from pneumatic controllers (such as by requiring that any continuous controller be “low-bleed”) have generally proved to be less effective than anticipated. For this reason, the commenter believes that EPA's November 2021 proposed approach to require all devices to be non-emitting is appropriate.

Response I-10-29: This comment is a supportive comment on an aspect of the November 2021 Supplemental Proposal that has remained unchanged in the final rule; as such, no response is required.

<sup>44</sup> Benjamin Luck et al., Multiday Measurements of Pneumatic Controller Emissions Reveal the Frequency of Abnormal Emissions Behavior at Natural Gas Gathering Stations, *Environ. Sci. Technol. Letters* 6, 348 52 (2019), <https://pubs.acs.org/doi/10.1021/acs.estlett.9b00158>.

## 10.8 Exceptions and Exemptions

### 10.8.1 Functional Need Exemption

#### 10.8.1.1 Opposition to Exemption

Comment: Commenter (0844-EDF *et al.*) recommends that EPA eliminate its November 2021 proposed functional need exemption at processing plants. The commenter states that, if the agency determines it must finalize a functional need exemption for processing plants, it must narrowly tailor the accommodation. The commenter explains that the exemption as proposed in November 2021 would not require processing plant operators to pursue other technologies that would reduce emissions if non-emitting technologies are not feasible. They recommend that EPA require any such operators to first attempt to reduce emissions by at least 95 percent,<sup>45</sup> with a preference for routing to a process rather than a control device. If that target is still not feasible, operators should then reduce emissions to the greatest extent possible. In these instances, operators should be required to provide a functional need justification in their annual report, including documentation as to: (1) why power (either grid-based or solar) is unavailable, (2) where the operator isn't routing to a process or control device or achieving 95 percent reductions, why they are not doing so, and (3) how the operator plans to minimize emissions from their pneumatic controllers to the maximum extent possible. The commenter suggests that, in any instances where operators utilize continuous-bleed or intermittent-bleed controllers, they should, at a bare minimum, be required to comply with the finalized recordkeeping and LDAR standards recommended in Part IV.A of their comments.

Several other commenters (0391-KBIC, 0605-Muscogee (Creek) Nation, 0781-NTAA, 0815-AGA, 0833-Ute EPD, 0943-Sault EPD) express that they support removal of the functional needs exemption for all segments of the oil and natural gas sector including pneumatic controllers in Alaska.

Response I-10-30: See discussion in section IV.D.1.b.i of the December 2022 Supplemental Proposal (87 FR 74759) for response to comments regarding the functional needs exemption.

#### 10.8.1.2 Support for Exemption

##### *Functional Needs/Technical Infeasibility Assessment*

Comment: Several commenters (0599-MSA, 0787/1289-Atmos, 0808-API, 0815-AGA, 0831-AXPC, 1391-INGAA) request that the NSPS OOOOa functional needs exemptions be included in NSPS OOOOb in their entirety based on several reasons, primarily based on concerns about the suitability, reliability, availability and technical feasibility of application (*i.e.*, response time, safety, and positive actuation) of zero-emitting technologies at all sites in the oil and natural gas sector. Commenter (0787/1289-Atmos) states that EPA's belief that "the reasons [for the functional needs exemption] related to the use of low bleed controllers" are no longer applicable

---

<sup>45</sup> For example, the commenter states that operators that can't install zero-emitting technology might nonetheless be able to route to a vapor recovery unit or control device, which aren't zero-emitting in accordance with the proposed standard, but which reduce emissions by 95-98 percent. See November 2021 Proposal TSD 6-16: TSD 9-9.

is premature for at least three reasons. First, the commenter notes that EPA's own field experience has shown that only up to 80 percent of all high-bleed devices can be replaced with low-bleed equipment or retrofitted.<sup>46</sup> Second, the commenter states that electrical supply is not available at every site.<sup>47</sup> Depending upon the location of the site, the commenter notes that the cost of establishing electrical service can far outweigh the cost of installing an electronic controller or compressed air system.<sup>48</sup> Third, the commenter notes that electricity-driven devices may not be suitable for all functions and operating conditions. Natural gas pneumatic controllers can place a valve in a closed, open, or specific position in the event of failure; electric controllers lack fail-safe position features for larger pipes operating at high pressures, with high torque. Similarly, critical valves may require a short actuation time that cannot be accomplished with an electric controller.

At a minimum, commenter (1391-INGAA) suggests that EPA keep the functional needs exemption in place for the transmission and storage segment. The commenter notes that the exact same rationale that applied in 2011 when EPA promulgated NSPS OOOO—and again in 2016 when it promulgated NSPS OOOOa—remains relevant today. They explain that functional requirements related to safety and reliability warrant the use of gas-driven pneumatic controllers in some cases. The commenter states that EPA has not identified anything in the November 2021 Proposal that shows why it has changed its position on this important safety and reliability issue.

Similarly, commenter (0782-BHE) states that, in the original NSPS rulemaking (NSPS OOOO), EPA provided rationale for exemptions due to functional need. They add that the same approach was retained in NSPS OOOOa. Importantly, the commenter notes that the premise has not changed (quotes info from NSPS OOOO proposed rule and NSPS OOOOa TSD). The commenter states that EPA has not provided an explanation as to its perception that a functional need exemption is no longer needed. The commenter notes that, perhaps EPA believes that solar powered electrical controllers provide a solution to address this service and then elaborates how solar power is infeasible and unreliable with respect to: (1) timely actuation of large mainline/ESD valves, and (2) remote metering and regulating stations along a transmission lines and locations where additional siting and permitting are required. The commenter contends that it is imperative that EPA retain pneumatic controller exemptions due to functional need particularly in the transmission and storage segments to ensure safe and reliable operations. The commenter recommends retaining an exemption for functional need, with exceptions documented by the operator. Regarding implementation of the exception, the commenter recommends that recordkeeping analogous to current NSPS OOOOa requirements could be retained for such controllers. The commenter adds that operators could maintain records to support the exemption and that a list of controllers that are exempt due to functional need can be maintained so that the implications of this exception can be characterized.

---

<sup>46</sup> EPA, Lessons Learned from Natural Gas STAR Partners: Options for Reducing Methane Emissions from Pneumatic Devices in the Natural Gas Industry, 2 (Oct. 2006), [https://www.epa.gov/sites/default/files/2016-06/documents/ll\\_pneumatics.pdf](https://www.epa.gov/sites/default/files/2016-06/documents/ll_pneumatics.pdf).

<sup>47</sup> The commenter states that the 2021 Technical Support Document (2021 TSD) incorrectly assumes that electrical supply is available at a given site. See EPA, 2021 TSD for the Proposed New Source Performance Standards (NSPS) and Emissions Guidelines (EG), 40 CFR Part 60, subpart OOOOb (NSPS), 40 CFR Part 60, subpart OOOOc (EG) (2021 TSD), 8-21.

<sup>48</sup> See the Confidential Appendix for an example cost of electrical service installation.

Commenter (0782-BHE) states that the November 2021 Proposal appears to acknowledge that exceptions for functional need are still required for Alaska, where electric power is not available and the efficacy of solar-based electricity is questioned by EPA. According to the commenter, they have no knowledge (1) of an analysis that justifies a conclusion that the same issue does not exist in locations other than Alaska, (2) that solar reliability will not compromise system safety and reliability at other locations, or (3) that a solar-powered electric controller can provide the same motive force and time response as a natural gas driven pneumatic controller utilizing high pressure natural gas available at all transmission and storage sites.

Another commenter (0844-EDF *et al.*) indicates that the technical feasibility or functional needs exemptions should only be allowed in very limited instances and only when justification is provided in an annual report.

Commenter (0782-BHE) states that if EPA does not provide pneumatic controller exceptions for functional use and/or exclude pneumatic controllers in remote locations along transmission pipelines, significant new electricity resources will be required in many locations, *e.g.*, potentially hundreds of relatively remote locations for the commenter's operations. The commenter adds that significant power supply uprate may be necessary at existing facilities for electric actuators that require quick response on a high energy application (*e.g.*, closing a large mainline valve). The commenter believes that it will require time to design, construct, and implement adequate energy resources to meet the demand, and an extended schedule or phased-in implementation may be warranted.

Response I-10-31: See discussion in section IV.D.1.b.i of the December 2022 Supplemental Proposal (87 FR 74759) for response to comments regarding the functional needs exemption. Regarding an implementation timeline for existing sources, similar comments were made on the December 2022 Supplemental Proposal. See response in Volume II, Chapter 7 (Process Controllers), subsection 7.4 (Low Production/Small Sites), Response II-7-80.

Comment: Commenter (0831-AXPC) recommends that retrofitting of existing pneumatic controllers to non-emitting be based on a technical feasibility assessment that includes: (1) that there are more than five controllers at the well site, central production facility, or compressor station; and (2) that the site has access to sufficient grid power onsite and/or that there is a feasible route from specific controllers to an existing combustion device. In circumstances found not feasible, the commenter suggests that EPA allow the use of continuous low-bleed and intermittent natural gas controllers and that they be covered in an operator's existing LDAR monitoring program to monitor proper functioning, similar to EPA's suggested requirements for Alaska.

Response I-10-32: See section IV.D.1.b.i of the December 2022 Supplemental Proposal (87 FR 74765-76766) and also the final rule preamble sections XI.D.2 and XI.D.3 for discussion about the feasibility of attaining zero emissions from process controllers.

Comment: Commenter (0782-BHE) recommends, for existing sources [context: pneumatic controllers] the EGs include a case-specific alternative mitigation review and technological and economic feasibility assessment, analogous to provisions for existing sources common in ozone

state implementation plans. The commenter recommends including in the EGs an option analogous to “alternative [reasonably achievable control technology] RACT” provisions in VOC and NO<sub>x</sub> rules for ozone state implementation plans (SIPs). Case-specific review may indicate significant costs with minimal environmental benefit and other deleterious impacts. The commenter states that case-specific review would likely identify significant hurdles and costs in some instances. The commenter notes that this is standard practice for other existing source regulations and should apply to this GHG/VOC program that follows a similar regulatory paradigm.

Response I-10-33: The EPA has determined that there are zero-emission compliance methods that are implementable at a reasonable cost. See sections IV.D.2.c and d of the December 2022 Supplemental Proposal (87 FR 74768-76769) and also the final rule preamble section XI.D.3 for discussion of the EGs for process controllers.

#### *Case-by-Case Exemptions Based on Engineering Judgement*

Comment: Commenter (0787-Atmos) recommends that EPA allow case-by-case exemptions as in Colorado regulations. The commenter states that, if EPA does proceed to require no-bleed devices, it could allow for companies to submit a justification to the agency that would allow an individual exception in cases where such devices are not appropriate for a particular site due to safety or operational purposes. The commenter notes that this would align with Colorado’s updated pneumatic controller regulations that took effect in February 2021, which explicitly allow high-bleed pneumatic controllers to remain in service due to safety and/or process purposes and require the owner/operator to submit justification for using these controllers.<sup>49</sup> The commenter adds that it would also align with EPA’s November 2021 proposed exemption requirements from using a no-bleed pneumatic controller at natural gas processing plants.<sup>50</sup>

Another commenter (0817-GPA) states that the November 2021 Proposal provides no rationale for removing exemptions “where engineering judgment recommends” the use of natural gas-driven pneumatic controllers “to maintain safety, reliability, or efficiency.” The commenter notes that the November 2021 Proposal assumes, without any record basis, that electric controllers are at least as reliable and functional as gas-powered actuators. In fact, as noted, electric controllers are less reliable and functional, lacking in speed and having a higher failure rate, especially for throttle service. The commenter states that this is confirmed in EPA’s Carbon Limits report. See Carbon Limits at 16 (“As a rule, electric controllers/ actuators will stay in position if the system fails and power is lost, wires are cut, or other failures occur,” not in a “fail safe” position). The commenter requests that EPA reconsider the substantial potential for controller failures, both with respect to increased safety risks and increased emissions.

Response I-10-34: The EPA has determined that exemptions for high-bleed controllers are not necessary and has excluded emergency shutdown devices from the affected source. See sections

---

<sup>49</sup> See, e.g., 5 C.C.R. 1001-9-D-III.C.1.c(ii) (“For high-bleed pneumatic controllers in service prior to February 1, 2009, the owner/operator must submit justification for high-bleed pneumatic controllers to remain in service due to safety and /or process purposes by March 1, 2009.”).

<sup>50</sup> 86 Fed. Reg. at 63,208.

IV. D.1.b.i and IV.D.2.c of the December 2022 Supplemental Proposal ((87 FR 74759 and 74768) and for further discussion of these issues.

### ***10.8.2 Transmission and Storage Segment Exemption***

Comment: Commenters (0782-BHE, 1391-INGAA) recommend that EPA exempt pneumatic controllers in the transmission and storage segment due to very low emissions. The commenters state that, as summarized in EPA's 2021 TSD<sup>51</sup>, pneumatic controller emissions are relatively significant for upstream operations (*i.e.*, greater than 20 percent of methane emissions from all affected segments), while pneumatic controller emissions from the transmission and storage segment are very minor and insignificant. However, the commenters point out that methane emissions from pneumatics in the transmission and storage segment comprise less than one percent of the total methane emissions from pneumatics in the source category.

In November 2019, the commenter (1391-INGAA) states that they met with EPA staff associated with EPA annual GHGI report and Subpart W of the GHGRP. The commenter reports that they provided EPA with a report by the Pipeline Research Council International that presents an analysis of six years of Subpart W reporting data for transmission and storage sources.<sup>52</sup> They note that the report includes a review of pneumatic controller data for hundreds of facilities that report annually. The data indicate that methane emissions from pneumatic controllers in the transmission and storage segment are more than 13 percent lower than the value presented in the EPA annual GHGI, based on a compressor station-level emission factor. Thus, the commenter asserts that the relatively low emission levels discussed above are even lower based on more recent data available from the GHGRP.

The commenter (1391-INGAA) provides an example from one of their members that operates a station in South Carolina that highlights this point. This station, which sits in a remote area without an electrical power, protects a 22-mile stretch of 8-inch pipe with a lower maximum operating pressure than its upstream source. There are two regulators and two monitors with gas-driven pneumatics at the station. The regulators are redundant, with only one regulator operating under normal conditions and the other regulator serving as a backup. The regulators are controlled with Becker pilots, which will bleed only when the regulator needs to move. The backup regulator does not move unless it must meet downstream pressure requirements. The two monitors are also driven by Becker pilots and only come into service if there was a primary or secondary regulator failure. The monitors will not bleed in normal operating conditions – only in the event of a failure. The commenter notes that, even if there was a regulator failure, these monitors bleed far less gas than a relief valve would. According to the commenter, this example demonstrates that much of the equipment in the transmission segment does not emit frequently because it serves only a backup function.

---

<sup>51</sup> U.S. EPA, Background Technical Support Document for the Proposed New Source Performance Standards (NSPS) and Emissions Guidelines (EG), at Table 8-2 (Oct. 2021) (Docket ID No. EPA-HQOAR-2021-0317-0166).

<sup>52</sup> Pipeline Research Council International (PRCI) White Paper, Methane Emissions from Transmission and Storage Subpart W Sources, PRCI Catalogue No. PR-312-16202-R03 (Aug. 2019). This report is attached to these comments as Attachment 6.

In other words, the commenter (1391-INGAA) contends that, although pneumatic controllers may be a significant contributor to methane emissions from the source category overall, they are not a significant contributor from the transmission and storage segment. As a result, the commenter states that the November 2021 Proposal would introduce pipeline and compressor station safety risks for a nominal emission reduction.

Response I-10-35: In the final NSPS and EG, the EPA is requiring that there be zero emissions from process controllers located at sites meeting certain conditions, which are those that have access to electrical power and those that do not have access to electrical power and are located in Alaska. At these sites, all process controllers in the process controller affected source are required to meet this standard, which includes process controllers in the transmission and storage segment. See sections XI.D.1 through 3 of the final rule preamble for more information on the EPA's BSER analysis and the final emissions standards for process controllers.

#### ***10.8.3 Temporary/Non-stationary/Completion Equipment Exemption***

Comment: Commenters (0599-MSD, 0808-API, 0831-AXPC) encourage EPA to provide an exemption for "temporary sources." Commenter (0831-AXPC) provided the example where an operation may require use of temporary or portable equipment for a short period of time (*i.e.*, less than 180 days) where it may not be possible to connect to the grid or route to an onsite control device. Commenters (0599-MSD, 0808-API) indicate that non-emitting requirements are not justified for short term controller usage related to a non-stationary source, and exemption of controllers on temporary equipment is consistent with state regulations proposed in New Mexico and finalized in Colorado. The commenters indicate that EPA should also make it clear that the requirements for pneumatic controllers are not applicable during drilling or completion.

Response I-10-36: The EPA acknowledged in the December 2022 Supplemental Proposal that the focus of the BSER analysis has been on process controllers that are part of the routine operation of oil and natural gas facilities. We noted that we did not have sufficient information to include an exemption or an alternative standard for process controllers associated with temporary equipment, and we requested more information about these situations. The EPA requested information regarding when temporary equipment is used, the function of the controllers during this time, how they are powered, and the typical duration of their usage. The EPA also requested information explaining in detail why the zero-emission solutions that are used for the permanent equipment at the site cannot be also used for this temporary equipment. As the EPA did not receive this information or further explanation, the EPA has insufficient support for an exemption or alternative standard. Therefore, the final rule has not been revised to separately address process controllers on temporary equipment.

#### ***10.8.4 Need for Gas-Driven Backup System Option***

Comment: Commenters (0749-PAW, 0817-GPA) request that EPA allow companies the option to continue to use, or install, a dual natural gas system as a backup for key controller functions. The commenters note that such a natural gas backup system would be used in the case of electrically actuated controller failure, loss of power, extended insufficient solar generated power, or other contingencies. Another commenter (0599-MSD) adds that, if the zero-emissions

system (*i.e.*, instrument air) goes down, there is no provision within the proposed rule to allow for the temporary use of natural gas. The commenter urges EPA to evaluate the reliability and availability of such systems that would be deployed at such breadth.

Response I-10-37: The information regarding zero-emission process controller technologies available to the EPA does not suggest that a natural gas-driven back-up system is necessary. For compressed air systems used to power pneumatic process controllers, the systems are designed with two compressors to ensure one is always available in the case of a malfunction of the other. If the system uses power from the grid, the system could be designed to have an alternate power source, such as a generator, to ensure the compressed air system does not lose power. If electrical process controllers are used, an alternate power source could also be used to ensure the process controllers continue to function, such as a generator or a battery system. Therefore, the use of natural gas-driven process controllers is not necessary to provide an alternative in the case of a power failure.

#### ***10.8.5 Emergency Shutdown Devices (ESDs) Exemption***

Comment: Several commenters (0411-Riverside Energy Michigan (REM), 0599-MSD, 0808-API, 0831-AXPC) raised the need to utilize natural gas-driven pneumatic controllers associated with ESDs and requested that EPA confirm that emergency shutdown valves or devices are not considered pneumatic devices or that emergency shutdown devices remain exempt from the proposed pneumatic controller requirements. Commenters (0808-API, 0831-AXPC) explain that an ESD is designed to minimize consequences of emergency situations and will only emit in certain isolated circumstances, such as if a well must be shut in. A large change in pressure is required to actuate an ESD, which may not be deliverable in a sufficient time by a compressed air or electric controller. Furthermore, if power is lost, these devices must still be able to function. According to the commenters, it is rare that ESDs are activated, and their emissions impact is minimal, but their functional need is necessary and critical to safe operations. Commenters (0808-API, 0831-AXPC) note that both the current version of the proposed rule in New Mexico and finalized regulations in Colorado offer similar exemptions for ESDs.

Commenters (0782 BHE, 1291-INGAA) indicate that the DOT/PHMSA is undergoing a rulemaking right now that proposes “standards for valve installation, rupture recognition and timely mitigation, and valve shut-off and location requirements for segment isolation.” In order “to minimize consequences from ruptured pipeline segments and improve the effectiveness of emergency response.” The commenters state that EPA needs to be aware of this rulemaking and needs to coordinate with PHMSA to be sure that the requirements contemplated here do not conflict with PHMSA. Commenter (1291-INGAA) provides that catastrophic failure can cause control systems, power systems and compressed air systems to fail. They add that, if battery limit valves (those needed to isolate and blow down the facility) are depending on any of those systems, it becomes impossible to shut down and isolate the station from its associated transmission lines, resulting in a much worse accident. They explain that battery limit valves that are gas powered function independently from the above systems and are usually actuated to a safe position by loss of a gas pilot signal. They add that many have power storage tanks to ensure that they are able to operate even when supply pressure to the actuator is removed or disrupted. They conclude by stating that the bottom line is that the only 100 percent reliable method for

powering important ESDs is stored energy available from the pressurized natural gas in the transmission line.

Commenter (0844-EDF *et al.*) states that ESD systems are reliable control systems designed to protect personnel and the facilities in case of an unexpected event such as over pressurization. The commenter notes that, in 2016, when EPA issued NSPS OOOOa, electric valve systems were generally not considered to be reliable enough for ESD systems, so it was assumed that gas driven controllers would still be used for ESD systems, even when the rest of the facility was converted to electronic controllers. Today, however, the commenter asserts that there are reliable zero-emission ESD systems on the market, including systems utilizing uninterruptible power supply device and systems utilizing a failsafe controller in an emergency shutdown valve electric actuators system.<sup>53</sup>

Commenter (0817-GPA) states that because an intermittent bleed controller that manages an emergency shutdown down (ESD) is only used intermittently, the only associated emissions from such a controller would be no larger than the pneumatic's diaphragm size. The commenter adds that, unless there is a true emergency, ESD systems are usually only tested annually; therefore, the intermittent pneumatic controller would only actuate once per year. According to the commenter, the costs associated with modifying these pneumatics to comply with the November 2021 Proposal are absolutely not outweighed by any potential benefit gained by reducing such de minimis emissions here.

Response I-10-38: The EPA has excluded emergency shutdown devices from the affected source. See sections IV. D.1.b.i and IV.D.2.c of the December 2022 Supplemental Proposal ((87 FR 74759 and 74768) for further discussion of this issue.

#### ***10.8.6 Small Site Exemption***

Comment: Commenter (0814-IPAA *et al.*) requests that EPA include an exemption for small sites with low production and/or a low number of pneumatic controllers. The commenters provide a range of pneumatic controllers that they felt represented a reasonable cut-off, ranging from 3 to 30 controllers. The commenter notes that EPA's cost estimates for electric and solar retrofits in the 2021 TSD and notes that while EPA presents its cost effectiveness assessment in the context of cost per unit of recovered methane and/or VOC, the real impact on a small well site would be overwhelming. The commenter elaborates that even at the current prices for natural gas, it would take the average low-production natural gas well about six years of all its profits to pay for the electric grid option and more than that for the solar option. The commenter adds that for a Pennsylvania well site, the time would be 70 or more years.

The commenter requests that EPA develop its emissions guidelines for existing sources based on well sites normal emissions patterns. The commenter states that the concept of using a well site emissions threshold is appropriate to creating more cost-effective regulations for low production well sites and should be expanded to other components. The commenter contends that pneumatic controllers are an appropriate example. The commenter explains that low production operations have limited numbers of pneumatic controllers and are frequently located in remote areas

---

<sup>53</sup> Carbon Limits 2021 at 7.

without access to power. The commenter notes that EPA has recognized these realities in the past. The commenter asserts that EPA should exclude low production well sites emitting 3 tons/year or less from the scope of its emission guidelines for pneumatic controllers. Alternatively, the commenter suggests that EPA provide for a threshold number of pneumatic controllers to be present at a well site before the pneumatic controller requirements are applied, a threshold that reflects the cost effectiveness of the requirement based on the ability of the well site to absorb the cost.

Commenter (0599-MS) encourages EPA to establish a threshold (*e.g.*, count of components) under which the EG OOOOc does not apply, where the emission reductions would be minimal but expensive to achieve.

Commenter (0777-Ascent) requests that EPA include an exception from the existing source guidelines' pneumatic controller requirements for small well sites with three or fewer pneumatic controllers per well. The commenter states that the cost of converting to an electronic controller or instrument air system will likely result in the shut-in of many small, low-production well sites. The commenter notes that sites have a remaining useful life that will be cut short by the proposed rule's pneumatic controller requirements.

Commenters (1267-CA AG *et al.*) state that Colorado exempts operators from complying with many components of their program requirements if their "total statewide oil and natural gas production average[es] 15 barrels of oil equivalent or less per day per well," *id.* § III.C.4.c.(iv)., in addition to other limited exemptions.

Response I-10-39: See section IV.D.2.d.i of the December 2022 Supplemental Proposal (87 FR 74769) and section XI.D.2 of the preamble to the final rule for discussion of small well sites.

Comment: Commenter (1341-Conventional Groups) states that EPA ignored or failed to address several key recommendations of the Small Entity Representatives Panel Report. The commenter asserts that the recommendations provided in the report are crucial for small conventional well sites. The recommendation that "EPA only propose zero-emission [pneumatic] controllers at sites with reliable and consistent onsite power available and clearly state that the intent is not require the installation of electric services for this purpose." *Id.* at 36. Instead of following the Panel Report's recommendation, EPA's November 2021 Proposal provides that sites without electricity can use mechanical controllers and electronic controllers using solar power.

Response I-10-40: In its BSER analyses, the EPA found there are zero-emitting process controller technologies that are technically feasible and reasonable in terms of costs and other impacts at locations with and without electrical power. See section IV.D.2.c of the December 2022 Supplemental Proposal (87 FR 74768) and the final rule preamble section XI.D.3 for discussion of the BSER. In addition, as noted in Response I-21-6, pursuant to section 603 of the RFA, the EPA prepared an IRFA that examined the impact of the proposed rule on small entities along with regulatory alternatives that could minimize that impact. The complete IRFA is available for review in the 2022 RIA (see section 4.3).

### ***10.8.7 Wellhead-only Sites***

Comment: Commenter (0749-PAW) states that EPA should exempt gas-driven controllers at “wellhead-only sites” as the cost-benefit analysis is not the same at wellhead-only sites as with gas-driven controllers at sites with production equipment (tanks, dehydrators, separators, etc.). The commenter explains that “wellhead-only sites” do not have existing process equipment or control devices that centralized production facilities may have. Further, the commenter adds that EPA excludes “wellhead-only sites” from fugitive emissions monitoring (FEM) provisions. The commenter asserts that EPA should also exclude “wellhead-only sites” from applicability for gas-actuated controllers for similar reasons. EPA states on page 63205 of the November 2021 Proposal preamble, “For the vast majority of situations...we evaluated these zero emission controller options using ‘model’ plants.” The commenter provides that sites exist that only have a single gas-actuated controller (*e.g.*, wellhead-only sites) and therefore ‘model’ plant cost analyses may not accurately reflect the true costs for wellhead-only sites.

Response I-10-41: See section IV.D.2.d.i of the December 2022 Supplemental Proposal (87 FR 74769) and section XI.D.2 of the preamble to the final rule for discussion of small well sites.

### ***10.8.8 Remote Locations not at a Well Pad, Processing Plant or Compressor Station***

Comment: Commenter (0599-MS) states that for new sources regulated under NSPS OOOOb, locations not at well pads or compressor stations (such as interconnections), access to grid power (and zero bleed devices) should be limited to commercially available onsite connections with sufficient and reliable power, which is a subset of sources. The commenter explains that these locations in general have a limited number of pneumatics (less than the number in the small model plants). The commenter notes that a cost analysis has not been performed for these sites. If such an analysis is not included in an updated proposal, these locations should be exempt from the design requirements.

Another commenter (0817-GPA) states that EPA should retain the exemption for natural gas driven-pneumatic controllers for uses other than at a compressor station or natural gas plant, such as along a pipeline, “where engineering judgment recommends their use to maintain safety, reliability or efficiency.” The commenter explains that these would include controllers at remote meter stations, above-ground pipeline junctions, and generally those along the gathering system as well as skid-mounted temporary equipment, and pig launchers and receivers. The commenter adds that these controllers are even less likely than compressor stations to have access to electricity, requiring in most cases the operation of a generator at a small, unmanned, and remote facility. Further, they serve key functions, such as regulating customer inlet to the gathering system or allow for the automatic shutdown of the pipeline. The commenter provides that the loss of power, or a controller failure, could shut customers out of the gathering system or preclude remote or automatic system shutdowns in the event of a rupture. The commenter asserts that these are vital commercial, safety, and environmental functions that should not be compromised. Importantly, the commenter states that EPA provides no explanation for eliminating the exemption for these types of controllers.

Response I-10-42: The EPA has found in its BSER analysis that there are zero-emissions process controller options that have costs that are reasonable considering the emissions reductions that would be achieved at all model plants studied. See section IV.D.2.d.i of the December 2022 Supplemental Proposal (87 FR 74769) and section XI.D.2 of the preamble to the final rule for discussion of small well sites. For discussion of the removal of the functional needs exemption, see section IV.D.2.d.i of the December 2022 Supplemental Proposal (87 FR 74759).

#### ***10.8.9 Categorical Exemption for Sites without Available Electrical Power***

Comment: Commenter (0844-EDF *et al.*) requests that EPA limit the categorical exemption for sites where power is not available to sites in Alaska. The commenter explains that, if the feasibility of zero-emitting technology is growing in Alberta, Alaska and other northern regions, then they do not believe there is any reason to extend the proposed blanket exemption to geographies beyond Alaska.<sup>54</sup>

Response I-10-43: In the final rule, the EPA has not extended the exemption from the zero-emissions requirements to sites beyond those in Alaska without access to electrical power.

### **10.9 BSER Analysis**

#### ***10.9.1 Emissions/Emissions Factors***

Comment: Some commenters object to the emission factors that were used for the 2021 TSD analysis. Commenter (0749-PAW) states that the emission factors used in the GHGRP petroleum and natural gas source category (40 CFR part 98, subpart W, also referred to as “GHGRP subpart W”) for pneumatic controllers were developed in the 1990’s and that they may no longer be applicable considering technological improvements. Another commenter (0918-COLGC) indicates that the factors used underestimate emissions and that recent research indicates that actual average emissions from pneumatic controllers may be higher than estimated.

Response I-10-44: The EPA revised its BSER analysis for the December 2022 Supplemental Proposal and again for the final rule using the most up-to-date emissions factors available. See section IV.D.1.b.ii of the December 2022 Supplemental Proposal (87 FR 74760) and section XI.D.3 of the preamble to the final rule, as well as the TSD for each rulemaking for further information regarding the revised BSER analyses and the specific emission factors used.

---

<sup>54</sup> The commenter notes that feasibility in Alaska is also reason to consider not including a blanket exemption for the state, though we don’t go into detail on that issue in this comment. At the very least, EPA should address the environmental justice concerns that arise because of the exemption. As the National Tribal Air Association has remarked, the proposal as it stands doesn’t adequately protect Alaska Native Villagers and Alaskan Tribes and ensure sufficient consultation and coordination with Tribes. To address that, EPA should develop Tribal Plans, and create systems for tribal governments to participate in monitoring and state plan development. See National Tribal Air Association, NTAA’s Informational Webinar on EPA’s Oil & Natural Gas Rule (Jan. 19, 2022), <https://secureservercdn.net/198.71.233.206/7vv.611.myftpupload.com/wp-content/uploads/2022/01/NTAAPresentation-for-Methane-Informational-Webinar-1.19.22.pdf> We urge EPA to consider these concerns when finalizing its rule.

Comment: Commenter (0808-API) indicates that while they appreciate that EPA utilized emission factors from the API's *Field Measurement Study: Pneumatic Controllers EPA Stakeholder Workshop on Oil and Gas*<sup>55</sup>, they believe that the use of the average intermittent pneumatic device vent rate was incorrect in this application. They state that under the November 2021 Proposal, any intermittent device would be monitored routinely and repaired or replaced if malfunctioning, so the more appropriate emission factor is 0.28 scf whole gas/controller-hour, not the average emission factor of 9.2 scf whole gas/controller-hour that EPA uses in the November 2021 Proposal as documented in API's *2021 GHG Compendium* Table 6-15.<sup>56</sup> The commenter notes that the average emission factor should only be used for controllers that are not routinely monitored as part of a proactive monitoring and repair program or where the monitoring status is unknown. The commenter adds that the normal operation emission factor should be applied to controllers that are found to be operating normally as part of a proactive monitoring and repair program and contends that this approach achieves a nearly similar level of emission reduction for much less investment by operators.

Response I-10-45: EPA agrees with the commenter that the lower emission factor is appropriate to represent the emissions level for intermittent vent controllers that are routinely monitored as part of a proactive monitoring and repair program. While EPA recognizes that some companies have voluntarily implemented such programs, we do not have information to suggest that the majority of the intermittent vent controllers in operation are part of such a program. The average emission factor that EPA used considers those low-emitting properly operating controllers, as well as those that are not operating properly and that are venting during idle. EPA finds that this average factor is the correct factor to represent the "uncontrolled" emissions from the universe of intermittent vent controllers.

We note that in our refreshed BSER analysis conducted for the final rule, the most up-to-date emissions factors were used, which included those used in the final GHGRP revisions. However, the final GHGRP does not include an emission factor for intermittent vent controllers, and instead requires that sites calculate emissions for each site based on site-specific measurements. Therefore, to estimate emissions from intermittent vents, the EPA used an average emission factor of intermittent vent emissions from a recent study that includes both properly functioning and malfunctioning intermittent vent process controllers.<sup>57</sup> The emission factor from this study was used rather than the API's *Field Measurement Study: Pneumatic Controllers EPA Stakeholder Workshop on Oil and Gas* emission factor, as this study underwent review as part of the journal article publication process. As these emission factors have been updated recently and are based on data from field studies of emissions from process controllers, these emission factors are the best data available to estimate nationwide emissions from process controllers. The EPA does not anticipate that the use of these emission factors significantly overstates or understates emissions.

---

<sup>55</sup> API's Field Measurement Study: Pneumatic Controllers EPA Stakeholder Workshop on Oil and Gas." Presented on November 7, 2019, in Pittsburgh PA by Paul Tupper.

<sup>56</sup> <https://www.api.org/~media/Files/Policy/ESG/GHG/2021-API-GHG-Compendium-110921.pdf>

<sup>57</sup> Luck, B., D. Zimmerle, T. Vaughn, T. Lauderdale, K. Keen, M. Harrison, A. Marchese, L. Williams, and D. Allen. 2019. "Multi-Day Measurements of Pneumatic Controller Emissions Reveal Frequency of Abnormal Emissions Behavior at Natural Gas Gathering Stations."

Comment: Commenter (0808-API) states that, in EPA's cost-effectiveness analysis, updating the intermittent controller emission rate to the properly functioning emission rate reduces the baseline emissions for each model plant significantly, which directly reduces the potential emission reductions. When coupled with the fact that EPA underrepresented the actual costs for conversion to non-emitting technologies, the commenter contends that the cost-effectiveness for the November 2021 Proposal under NSPS OOOOb and EG OOOOc quickly becomes not cost-effective either for methane or VOC with or without savings.

Response I-10-46: The EPA used updated emissions factors and cost information in its revised BSER analysis conducted for the December 2022 Supplemental Proposal and the final rule. The EPA continues to find that zero-emissions options are available for process controllers with costs that are reasonable considering the emissions reductions that would be achieved. See section IV.D.1.b.ii of the December 2022 Supplemental Proposal (87 FR 74760) and section XI.D.3 of the preamble to the final rule, for further information regarding the revised BSER analyses.

### ***10.9.2 Costs Used***

Comment: Commenters (0844-EDF *et al.*, 0924-U.S. Small Business Administration (SBA)) disagree with the costs used for the November 2021 Proposal BSER analysis. Commenter (0844-EDF *et al.*) states that EPA's cost estimates were taken directly from the 2016 Pneumatic Controller White Paper and that EPA did not update the cost numbers for zero-emission electronic controllers, solar panels, or batteries. The commenter adds that EPA notes the primary basis for the costs used for the November 2021 analysis was not the White Paper, but rather a 2016 report by Carbon Limits, a consulting company with longstanding experience in supporting efficiency measures in the petroleum industry. The commenter points out that Carbon Limits updated their report in early 2022 and recommends that EPA utilize the more recent information in that report since it includes more up-to-date research on zero-emissions options for pneumatic controllers.

Response I-10-47: We reviewed the updated 2022 Carbon Limits report, and we agree with the commenter that the information presented is well-researched and representative of the costs of zero-emission pneumatic controller technologies. In addition to updating the analysis to reflect the information in the 2022 Carbon Limits report, we also increased the estimate of installation costs and considered operation and maintenance costs for all types of pneumatic controller systems not driven by natural gas.

Comment: Commenter (0749-PAW) states that, for zero emission electrical controller setups, skilled electrical labor is required for wiring, programming, and tuning, which cannot be conducted by lease operators that would otherwise manage this equipment. According to the commenter, one available estimate is as high as \$20,000 in labor costs per multi-well pad.

Response I-10-48: In the BSER analyses, the EPA included separate costs associated with installation of equipment for zero-emissions process controllers, which varies depending on whether the site is new or existing and the type of zero-emissions option shown. These costs are in addition to the equipment costs. See the TSDs for the December 2022 Supplemental Proposal and the final rule for further details regarding the specific labor costs included in the BSER

analyses. See also section IV.D.1.b. ii of the December 2022 Supplemental Proposal preamble (87 FR 74761).

Comment: Commenter (0808-API) states that the emission reduction benefit from fixing improperly functioning controllers [covered by LDAR] is currently already captured in EPA's cost-effective analysis for the proposed LDAR requirements. The commenter notes that this approach achieves nearly a similar level of emission reduction for much less investment by operators. The commenter provides that this is especially true when converting a single existing high-bleed controller with a properly functioning intermittent controller that is part of a company's LDAR program. Furthermore, the commenter adds that if an existing facility only contains properly functioning intermittent controllers confirmed through an LDAR program, then the cost-effectiveness evaluation never becomes cost-effective for any amount of controllers even assuming EPA's own cost assumptions.

Response I-10-49: The EPA agrees that if all intermittent controllers were properly functioning, emissions would be reduced. However, the EPA also found that zero-emissions options are available which reduces emissions from all continuous bleed process controllers as well as intermittent vent controllers. In the EPA's BSER analysis, the EPA determined that technically feasible zero-emissions options are available at costs that are reasonable, considering the emissions reductions that would be achieved. Therefore, the EPA determined that zero emissions represents the BSER for process controllers, and this is reflected in the NSPS and EG.

Comment: Commenter (0808-API) provides estimated costs for an instrument air system driven by a natural gas generator and for an instrument air system powered by solar energy. The commenter states that they conducted a member survey of costs for grid-powered instrument air systems, solar-powered instrument air systems and natural gas generator-powered system. The commenter provides that costs associated with a typical instrument air system include a regenerative dryer, inlet filter, tank to store compressed air, insulated enclosure for the compressor and dryer, junction box, controllers for the compressor system, and voltage boosters. Additional costs for solar based systems would include higher cost gel or AGM batteries, enough batteries, and higher numbers of solar panels required in areas of less sunlight such as for Wyoming and North Dakota. Additional costs associated with the use of natural gas or diesel generators to power instrument air systems might also include monthly rental fees. According to the commenter, all instrument air systems typically require annual maintenance at a cost of between \$2000 and \$4000 per year. Installation of non-emitting controllers also requires shutting-in the well or facility, an additional cost which does not appear to be accounted for in EPA's cost analysis. The commenter states that the results indicate the following:

- For smaller facilities, the average cost for a grid powered instrument air system was estimated at \$51,000 and for a natural gas generator powered instrument air system around \$60,000. The survey had no data for solar powered instrument air system. These costs include equipment and installation costs. There are also annual maintenance costs associated with both types of systems. For their analysis, they assume an average annual maintenance cost of \$3,000.
- For medium facilities, the average cost for a grid powered instrument air system was estimated at \$80,000 and for a natural gas generator powered instrument air system around

\$110,000. The survey had no data for solar powered instrument air system. These costs include equipment and installation costs. There are also annual maintenance costs associated with both types of systems. For their analysis, they assume an average annual maintenance cost of \$3,000.

- For large facilities, noted as multi-well sites, central production facilities or compressor stations (with more than 100 controllers) the average cost for a grid powered instrument air system was estimated at \$143,333; for a natural gas generator powered instrument air system around \$207,250; and for a solar powered instrument air system around \$250,000. These costs include equipment and installation costs. There are also annual maintenance costs associated with both types of systems. For their analysis, they assume an average annual maintenance cost of \$3,000.

The commenter (0808-API) also provides an analysis, *Cost Effectiveness Evaluation for Retrofit of Existing Pneumatic Controllers*, where they evaluated the minimum number of controllers that would be cost effective to retrofit to an instrument air system powered by grid power or a natural gas generator, using the minimum costs they listed in Table 3 of their comment letter [and noted above]. The results indicate that, for a facility containing low bleed controllers and properly functioning intermittent controllers, it would only be cost effective to retrofit if there were at least 15 to 30 controllers, depending on the single/multi-pollutant, with or without savings approach, that EPA analyses.<sup>58</sup> The commenter contends that EPA based their model plant analysis on incorrect assumptions. The commenter notes that, based on blinded data collected from their member companies by a third-party, EPA has underestimated the costs and overestimated the benefits for converting pneumatic controllers to non-emitting. According to the commenter, the variation in the costs estimated by EPA with API member costs is centered on incorrect assumptions by EPA that companies will use grid power or solar based systems to power electric controllers. The commenter states that their members have converted natural gas driven pneumatic controllers to compressed instrument air systems powered by the grid (when accessible) or natural gas generators and are only in the initial phases of testing the reliability of solar based instrument air systems.

Additionally, the commenter (0808-API) notes that their member's experiences have indicated that EPA's distinction between the small and medium model plant is incorrect when it comes to cost variation since a site with either 4 or 8 controllers would be considered a relatively small facility with minimal equipment. Some multi-well sites, central production facilities and compressor stations may contain 100-200 controllers. The commenter reports that these larger facilities are typically the types of facilities that operators have been successful in retrofitting pneumatic controllers to non-emitting in a cost-effective manner by placing the investment of retrofit on the facilities with the most controllers.

---

<sup>58</sup> To estimate baseline emissions, the commenter assumes a mix of controllers onsite of 30 percent low-bleed and 70 percent intermittent, which is consistent with the breakdown of controller types reported to EPA for the 2020 calendar year pursuant to 40 CFR Part 98, subpart W. The commenter contends that EPA was incorrect to assume a high bleed pneumatic controller within their model plant analysis as the count of high bleed controllers is only 1 percent for the production segment and 3 percent for the gathering and boosting segment based on the 2020 Subpart W data (refer to Attachment A, Table C-1). The commenter also applied the properly functioning emission factor from Table 6-15 of API's GHG Compendium based on the comments offered herein.

Response I-10-50: Considering this comment, the EPA updated its BSER analysis to include the information provided. See section IV.D.1.b. ii of the December 2022 Supplemental Proposal preamble (87 FR 74762) and the TSD for the December 2022 Supplemental Proposal for further information on the specific costs used in the BSER analysis.

Comment: Commenter (0743-WEA) states that EPA has significantly underestimated the cost and difficulty of retrofitting facilities to comply with the regulation and that one of their member companies estimates from an actual retrofit project's range to be as high as \$250,000 per facility for large facilities with many controllers. The commenter notes this is a price point far outside the range described in EPA's publication. While these costs may be lower for lower-producing facilities, the commenter states that the fact EPA estimated the top end for the range for large facilities to be only \$96,000 signals there is a flaw in the calculation for it to be that far off actual project execution.

Response I-10-51: Similar comments on costs were provided on the December 2022 Supplemental Proposal. For response to this comment, please see Volume II, Chapter 7 (Process Controllers), subsection 7.3.3 (Costs), Response II-7-67.

Comment: Commenter (0749-PAW) states that costs for zero-emission controllers are high and must be adequately considered. The commenter provides the following cost estimates for control technologies:

- Commenter member companies estimate that zero emission controller setups will cost more than \$13,000 per setup (one water and one oil dump). For new and modified sources, this is nearly 2.5 times more costly than traditional low and intermittent bleed setups.
- Instrument air systems would be easier and significantly less costly for new facilities than existing sources and are estimated to cost between \$33,000 and \$80,000.
- Many locations in Wyoming lack line power and are unable to route line power due to other resource implications such as sage grouse. For these remote locations, the cost for solar power packages (which may not be reliable enough to satisfy safety concerns) is approximately \$50,000 per pad. For locations that can bring line power in, costs range from \$25,000 to \$60,000 per location.
- If electric power is not available at the site, that is a significant additional cost. For instance, a remote well that is 1/4 mile from line power and for 2 phase 120V standard service is estimated to cost \$25,000. For the heavier duty 480V service it is around \$60,000.

Response I-10-52: The EPA used the best available information regarding the costs of zero-emissions controller setups and installation. See section IV.D.1.b. ii of the December 2022 Supplemental Proposal preamble (87 FR 74760-74763) and the TSD for information regarding the specific costs included in the revised BSER analysis. Also see section XI.D.1, 2, and 3 of the preamble to the final rule and the final rule TSD for information regarding the costs included in the refreshed BSER analysis conducted for the final rule.

Comment: Commenter (0844-EDF *et al.*) states that EPA did not calculate cost-effectiveness for routing to a VRU from pneumatic controllers in its November 2021 Proposal, but, for its final rule they urge the agency to consider the faulty premises from which its 2016 and 2021

calculations for VRU cost-effectiveness were based, and to conduct a cost analysis for routing controllers to a VRU that is based on more reliable factors. The commenter notes that EPA's current cost analysis relies on three outdated VRU capital cost estimates, two of which are from the oil and gas industry. The commenter recommends that EPA update its analysis to include a more representative sample, which they believe could result in greater cost-effectiveness for this approach. Indeed, according to the commenter, if EPA omitted the particularly high estimates provided by the Gas Processor Association, the annualized costs for routing controllers to a VRU drops from \$869 to \$624 (2019 USD). Assuming EPA's reported emissions rate of 9.2 scf/hr for intermittent vent controllers, the commenter states that sites with at least 2 controllers will spend about \$200 per ton of methane avoided without savings and will incur modest net savings at a gas price of \$4 per Mcf (about \$6 benefit per ton of methane avoided).<sup>59</sup>

**Response I-10-53:** While the EPA did not evaluate the cost-effectiveness of routing emissions through a VRU to a process, the EPA did find that there are zero-emission process controller options for which the cost-effectiveness is within the ranges considered to be reasonable by the EPA. See section IV.D.1.b. iii of the December 2022 Supplemental Proposal preamble (87 FR 74763). The zero-emissions requirements of the final NSPS and EG are technology-neutral, and owner/operators may choose to route process controller emissions through a VRU to a process. See section XI.D.2 of the preamble to the final rule for discussion of the determination of BSER for process controllers.

### ***10.9.3 Model Plant Analysis***

**Comment:** Commenter (0749-PAW) notes that all three sizes of model plants (small, medium, large) contain one high-bleed natural gas-driven controller. The commenter indicates that some state regulations do not allow for the use of high-bleed controllers and concludes that EPA's baseline emissions analysis was likely skewed high.

**Response I-10-54:** See section IV.D.1.b. ii of the December 2022 Supplemental Proposal preamble (87 FR 74761-74766) for response to this comment. Also see sections XI.D.2 and 3 of the preamble to the final rule for discussion of the BSER analysis conducted for the final rule.

### ***10.9.4 Impact of Rule on Small Businesses***

**Comment:** Commenter (0763-Texas Commission on Environmental Quality (TCEQ) and Railroad Commission (RRC)) asserts that EPA has underestimated the overall number of affected facilities and particularly the potential impact on small businesses. The commenter reports that the requirement to use zero-bleed pneumatic controllers at existing and modified operations will result in many facilities being forced into replacing functioning equipment with a much more costly alternative, with the potential for insufficient zero-bleed pneumatic controller supplies. In addition, the commenter states that on-site power generation using a combustion of

---

<sup>59</sup> The revised capital cost estimate relies on the average of a \$2,000 (EPA's 2016 estimate) and \$5,800 (API's 2016 estimate) expenditure—both of which are included in EPA's 2016 calculations—and is adjusted from 2012 to annualized 2019 dollars using the same price deflator (12.3 percent) and capital recovery factor (.1424) that EPA used in its 2021 TSD. This cost is compared to avoided emissions of 9.2 scf/hr for two intermittent vent controllers at a site (see TSD Table 8-3).

gas could result in the need for additional authorizations, testing, and monitoring of generation equipment and emissions from this equipment.

Response I-10-55: The EPA agrees that switching from natural gas-emitting process controllers to a system that results in zero-emissions from process controllers will require capital expenditures. However, in the revised BSER analysis conducted for the December 2022 Supplemental Proposal and in the refreshed analysis conducted for the final rule, zero emissions from process controllers was shown to be technically achievable and cost-effective at all existing source model plant configurations (outside of Alaska) through several available options. As such, the EPA determined that zero emissions represents the BSER and is the basis for the requirements of the NSPS and EG. For further details regarding the revised BSER analyses, see sections IV.D.1.b. ii and iii of the December 2022 Supplemental Proposal preamble (87 FR 74760-74766) and sections XI. D.2 and 3 of the preamble to the final rule. In addition, pursuant to section 603 of the RFA, EPA prepared an IRFA that examined the impact of the proposed rule on small entities along with regulatory alternatives that could minimize that impact. The complete IRFA is available for review in the 2022 RIA (see section 4.3).

Comment: Commenter (0924-SBA) asserts that EPA overstates the support that other regulatory regimes provide for the November 2021 Proposal, particularly with respect to impacts on small businesses. The commenter notes that EPA cites to California, Colorado, New Mexico, and the Canadian provinces of Alberta and British Colombia as evidence that the November 2021 Proposal is reasonable and that there are no technical barriers. However, the commenter provides that, as the description of these regulatory regimes' notes, none of these regimes require universal retrofit of existing sources. California allows some continuous bleed natural gas-driven pneumatic controllers to remain, Colorado has a small operators exemption, New Mexico's proposed rule does not require zero-emitting controllers if there is no electrical power, Alberta only requires zero-emitting for a subset of existing controllers, and British Columbia's rule only requires new sources to be non-emitting. No other regulatory regime applies to all new sources and all existing sources.

Response I-10-56: The EPA agrees that these programs have more exemptions than the EG for existing sources. However, in the revised BSER analysis conducted for the December 2022 Supplemental Proposal and in the refreshed analysis conducted for the final rule, zero emissions from process controllers was shown to be technically achievable and cost-effective at all existing source model plant configurations (outside of Alaska) through several available options. As such, the EPA determined that zero emissions represents the BSER and is the basis for the requirements of the NSPS and EG. For further details regarding the revised BSER analyses, see sections IV.D.1.b. ii and iii of the December 2022 Supplemental Proposal preamble (87 FR 74760-74766) and sections XI. D.2 and 3 of the preamble to the final rule.

Comment: Commenter (0749-PAW) recommends that EPA consider subsidies or grant programs for smaller companies should retrofitting be required for existing sites.

Response I-10-57: This comment on recommended funding programs for small companies is outside the scope of this rulemaking; as such, no response is required.

Comment: Commenter (0924-SBA) recommends that there be a hardship extension of compliance deadline for Small Entities. The commenter requests that EPA provide flexibilities in implementing pneumatic controller requirements for those circumstances in which small entities cannot obtain and/or retrofit zero-emitting controllers. In addition, the commenter requests that EPA allow states to grant extensions to small entities that can show a good faith effort to procure non-emitting controllers at a reasonable price.

Response I-10-58: Similar comments on the implementation timeline of the EG were provided on the December 2022 Supplemental Proposal. For response to this comment, please see Volume II, Chapter 7 (Process Controllers), subsection 7.4 (Low Production/Small Sites), and 7.5 (Applicability and Compliance Date Considerations) Responses II-7-80, II-7-81, and II-7-82.

## **10.10 Phase-In of Requirements Under EG OOOOc**

Comment: Several commenters (0215-Evangelical Environmental Network (EEN), 0844-EDF *et al.*, 0918-COLGC) support the proposed 2 years from state plan submission for adoption of emission guidelines for implementation of the zero-emitting pneumatic controller requirements (*i.e.*, existing sources should be required to retrofit within two years of the state plan submission deadline). Commenter (0844-EDF *et al.*) notes that natural gas producer EQT Corporation has reported that they will complete a full retrofit within two years, and Diamondback anticipates it will have replaced “nearly all” of its controllers with zero-emitting devices within four years. Further, the commenter notes that the finalized rule will signal to suppliers the need to ramp up production well in advance of the retrofit deadline, increasing the likelihood of sufficient market availability for suppliers by that time.

Several other commenters (0727-OSEE/ODEQ, 0749-PAW, 0807-BP America, Inc. (BP), 0924-SBA, 1341-Conventional Groups) indicate support for a phased-in approach of greater than two years for implementation of the requirements. The commenters cite the need for operators to address higher production or scheduled upgrade facilities first and that to retrofit all existing sources at the same time will place a substantial economic burden on operators as well as a substantial burden on supply chain and vendors.

Another commenter (0807-BP) indicates that they are already implementing a phase-in program. The commenter notes that they have invested over \$100 million of an initial \$300 million portfolio-wide infrastructure investment to build out electrical infrastructure and substations to power their operations in the Permian. The commenter notes that they anticipate over 75 percent of the companies’ operated wells in the Permian will be electrified by the end of 2022 and over 95 percent by 2023. Where they can electrify, they will install instrument air devices. Based on their experience, they encourage EPA to propose a phase-in approach to equipment retrofits so that operators can prioritize and implement retrofits over a reasonable time horizon.

Commenter (0765-ICAC) states that the transition will need to factor in the time and resources involved in retrofitting existing installations and EPA must ensure that timeframes are safe, realistic, and achievable.

Several commenters (0807-BP, 0817-GPA, 1267-CA AG *et al.*) request the adoption of a phase-in approach that is consistent with Colorado and New Mexico requirements where Colorado requires compliance of 40 percent of the sources within two years and 100 percent within four years.

Commenter (0463-Southern Ute Indian Tribe, Colorado) recommends EPA consider allowing a phased approach, with a final compliance deadline of at least 2 years from the date of rule promulgation, where a portion of an operator's facilities must comply within and extended timeframe (*i.e.*, 50 percent of facilities in compliance within 2 years and 100 percent of facilities in compliance within 4 years).

Other commenters recommended various other phase-in timeframes and implementation dates. Some commenters (0743-WEA, 0831-AXPC) recommend a phase-in period of at least 3 years for new and modified facilities to install equipment required to meet a non-emitting standard. Commenter (0743-WEA) recommends a longer period of 5-7 years for existing facilities to retrofit equipment with low-bleed, intermittent bleed, or non-emitting controllers while another commenter (0831-AXPC) states that, at a minimum, EPA should grant additional implementation time considering the global supply chain challenges that are already challenging an operator's ability to secure components.

Commenter (0817-GPA) notes several factors requiring additional implementation time for retrofitting existing sources:

- Retrofitting pneumatic controllers requires a retrofit of other equipment on the instrument gas/ fuel gas system, including pumps.
- Operators will require time for extensive engineering, reliability studies, and retrofitting across multiple sites—up to hundreds for some operators—at widely dispersed, and often remote locations, around the country.
- For the retrofit project, entire facilities need to be retrofitted to accommodate new automation and backup systems which would likely involve shutting down the facility for installation. The commenter further noted timeframe issues (many of which are beyond the source's control) such as time for permit amendments, potential need to purchase land, and uncertainty with land acquisitions and permitting process. The commenter noted that permit revisions alone could take up to two years.

Commenters (0808-API, 0817-GPA, 0938-TXOGA) recommend a minimum of 5 years citing the recent proposed rulemaking in New Mexico that currently employs an eight-year phase in period for existing sources as the state recognized the complexity of replacing these emission sources. Commenter (0938-TXOGA) states that EPA needs to provide sufficient flexibility for states to develop their plans as states will be closest to the issues in their location and best able to determine appropriate compliance time frames. Commenter (0808-API) notes that one retrofit project can take upwards of 4 months to complete from initial planning to full implementation. The commenter adds that there is a 3-year phase-in precedent that has been established for the oil and gas sector which they believe is the minimum timing required for an appropriate phase-in of retrofit requirements. However, this commenter believes that a more appropriate time period

would be 5 years from the finalized rules/guidelines. Another commenter (0911-NDPC) recommends a minimum of 5 years from rule finalization.

Commenter (0807-BP) recommends that a well-designed phase-in program include an ambitious yet realistic time horizon to achieve 100 percent zero emitting devices; a tiered approach that adjusts for operators that are further ahead on existing retrofits; and an exemption program for the rare circumstance where, for safety reasons, an operator must continue to operate an emitting device.

Response I-10-59: Similar comments on the implementation timeline of the EG were provided on the December 2022 Supplemental Proposal. For response to this comment, please see Volume II, Chapter 7 (Process Controllers), subsection 7.4 (Low Production/Small Sites), and 7.5 (Applicability and Compliance Date Considerations) Responses II-7-80 and II-7-82.

## **10.11 Other**

### ***10.11.1 Supply Chain Issues***

Comment: Commenter (0765-Institute of Clean Air Companies (ICAC)) states that the technologies to implement this exist today and are well-vetted. The commenter explains that there are companies specializing in replacing natural gas-driven pneumatics with air-driven pneumatics operating today. The commenter adds that the transition will need to factor in the time and resources involved in retrofitting existing installations and they request that EPA ensure that timeframes are safe, realistic, and achievable.

Response I-10-60: The EPA agrees that there are several zero-emitting technologies available. See also Response I-10-67 of this Chapter.

Comment: Several commenters (0739-Citation Oil & Gas Corp. (Citation), 0814-IPAA *et al.*, 0938-TXOGA) predict that the pneumatic controller requirements will likely generate an immediate and significant increased demand for zero bleed equipment (*i.e.*, solar powered/battery backup systems, and electric, self-contained systems) and will result in supply chain shortages and limited availability. Commenter (0924-SBA) notes that EPA would be requiring the replacement of over 1.7 million controllers over a few short years. Commenters state that it is unclear that the industry will be able to procure that many that quickly and there is concern that small businesses will have the hardest time procuring non-emitting controllers and will have to pay more for those it can procure. Commenters (0743-WEA, 0938-TXOGA) state that EPA has not adequately considered the impacts of the current supply chain interruptions on the ability of operators to comply with the rule. Specialized equipment, such as air compressors, electric controllers, and equipment needed to retrofit facilities have been particularly hard-hit by supply chain constraints related to COVID-19. Commenter (0743-WEA) reports that owners and operators have already experienced delays of several months in acquiring equipment to retrofit facilities to instrument air, all prior to the November 2021 Proposal, and that the increased demand for that equipment given proposed rule requirements would only exacerbate the challenges associated with acquiring that equipment. Another commenter (0739-Citation) requests that EPA provide supporting data demonstrating this technology is widely available.

Commenter (0808-API) states that many solar system packages in use do not feature turnkey solutions available for mass installation and implementation. The commenter explains that technology provided by certain vendors was referenced in the Carbon Limits study published in 2016<sup>60</sup>, which EPA relied upon in its cost effectiveness analysis. Industry representatives reached out to at least one of the vendors within the last six months to find out how much deployment there has been of these solar systems and electric controllers. The commenter reports that the vendor indicated that in the past 10 years, they have conducted 200 retrofits and 300 new installs. Currently, the commenter states that the vendor projects it can only service approximately 200 installs per year.<sup>61</sup> Additionally, the commenter notes that operators are already experiencing 6 to 12-month lead times for solar packages. The commenter concludes by stating that the proposed rules will only exacerbate demand, increase costs, and increase pressure on the supply chain.

Response I-10-61: To address potential delays in the availability of equipment necessary to meet the zero-emissions standards, the EPA is extending the zero-emissions requirements compliance date for the NSPS by one year. Until that date, sites that would otherwise be required to meet the zero-emissions standard must comply with the standards for sites that do not have access to electricity and are located in Alaska. See section XI.D.4 of the final rule preamble for further discussion of this issue and the extended compliance date.

For existing sources, each state must submit a plan to the EPA that establishes standards of performance for each designated facility. For purposes of EG OOOOc, the EPA is finalizing a requirement that each state adopt and submit their state plans incorporating the process controller requirements within 24 months after publication of the final EG OOOOc. The EPA is also finalizing a timeline for compliance with the requirements included in the state plans of 36 months from the deadline for state plan submittals. The combined time allotted for compliance then is 60 months, or 5 years from the publication date of EG OOOOc. This period of time should provide all operators with ample opportunity to determine a compliance strategy and procure and install the necessary equipment.

#### ***10.11.2 Funding for Equipment Replacement at New and Existing Facilities***

Comment: Commenter (0940-Responsible Drilling Alliance (RDA)) states that it is extremely frustrating that a significant portion of emissions from the gas and oil sector is attributed to outdated equipment which operators could detect and fix through cost-effectively replacement with zero-emitting technologies. The commenter suggests that there is a need for Congress to push for the inclusion of a small methane emission fee in currently proposed legislation to set up a fund for operators to borrow, at zero interest, monies necessary for the purchase, installation, and most effective monitoring of zero-emitting pneumatic controllers at both new and existing facilities.

<sup>61</sup> Joint Industry Work Group comments submitted to CDPHE

<https://drive.google.com/drive/folders/1yXOXLue7DqPFutxbq6SeThCMhc5S7DU>

Response I-10-62: This comment on recommended Congressional actions is outside the scope of this rulemaking; as such, no response is required.

### ***10.11.3 Recordkeeping Requirements***

Comment: Commenter (0817-GPA) states that the November 2021 Proposal preamble states that, even though “these ‘zero-emissions controllers’ would not technically be affected facilities because they are not driven by natural gas ... or because they do not vent to the atmosphere, owners and operators should maintain documentation if they would like to be able to demonstrate to permit writers or enforcement officials that there are no methane or VOC emissions from the controllers and that these controllers are not affected facilities subject to the rule.” 86 Fed. Reg. at 63,202. The commenter indicates concern that there is no proposed regulatory language describing what type of documentation would be required and the November 2021 Proposal preamble provides no further summary of what documentation could be needed for compliance purposes. Further, the commenter notes that the November 2021 Proposal provides no explanation of EPA’s authority to require such documentation. The November 2021 Proposal states that zero emission controllers are not affected facilities as they are no longer driven by natural gas. The commenter states that owners and operators would still be required to demonstrate that controllers are zero emission in the case of inspection, but EPA should not dictate the type of documentation required or seek to impose extensive recordkeeping requirements. The commenter reports that operators do not typically keep detailed records of pneumatic controller model types, installation dates, or maintenance events as they are relatively low-cost equipment and not subject to the same recordkeeping practices as equipment requiring capital expenditures. The commenter urges EPA not to issue regulations requiring the maintenance of any particular type of documentation as such regulations would not be permitted as a matter of law and would add unnecessary administrative burdens to operators.

Response I-10-63: As discussed in section XI.D.5 of the final rule preamble, after considering this comment and similar comments received on the December 2022 Supplemental Proposal, we have determined that it is appropriate in this instance to require identification of the equipment that is included in the affected facility, rather than the equipment that is not part of the affected facility. The process controllers included in the affected facility are those that are subject to the emissions standards, whereas process controllers not included in the affected facility are not subject to the emissions standards in the final rule, and also have no potential to emit methane or VOCs. Therefore, we have revised the recordkeeping requirements to require identification only of controllers that meet the finalized definition of an affected facility, which are those process controllers that are driven by natural gas and that are not ESDs.

### ***10.11.4 Effect on Other Industrial Segments***

Comment: Commenter (0922-National Association of Manufacturers (NAM)) expresses concern that because there were 2012 and 2015-2016 rules addressing VOCs and methane it appears that there is an unintended meshing of the lines between existing sources and new sources when an existing source has low bleed pneumatic controllers that might be reclassified as new sources with a zero bleed or zero emissions limit. The commenter argues that the NSPS program was never designed to conflate the lines between new and existing sources. In this case, the

commenter defers to the companies with existing source pneumatic controllers that might be moved into “new” source category when those low bleed pneumatic controllers were installed after the 2016 rule. While this might be something completely isolated to the oil and gas segment because of the industry’s 2012-2016 VOC and methane rules, the commenter requests that EPA clarify so that CAA section 111 rules for other industrial segments do not misinterpret the lines between new and modified and existing sources.

Response I-10-64: See discussion in sections III.B and III.C of the December 2022 Supplemental Proposal preamble regarding the categorization of “new” and “existing” based on the date of construction, modification, and reconstruction for the source category as a whole and section IV.D.1.b.i of the December 2022 Supplemental Proposal preamble for discussion of modification reconstruction for process controllers specifically. See 87 FR 74715-74716 and 74756-74760. See also section XI.D.6 of the final rule preamble for further information regarding modification and reconstruction.

## Chapter 11. Pneumatic Pumps

### 11.1 General Support/Opposition for Proposed Pneumatic Pump Standards

Comment: Several commenters (0844-Environmental Defense Fund (EDF) *et al.*, 0444-Damascus Citizens for Sustainability (DCS), 0781-National Tribal Air Association (NTAA), 0605-Muscogee (Creek) Nation, 0833-Environmental Programs Department, Ute Mountain Ute Tribe (Ute EPD), 0391-Keweenaw Bay Indian Community (KBIC), 0770-Northern Plains Resource Council (NPRC), 0437-New York Office of the State Comptroller (NYOSC), 0808-American Petroleum Institute (API)) support the proposed requirements for new and existing pneumatic pumps.

Commenters (0844-EDF *et al.*, 0770-NPRC) encourage EPA to include in its final rule a requirement that operators use zero-emitting technology for pneumatic pumps across the source category. However, if it [the standard] includes a functional need exemption, the commenters suggest that the exemption's design mirror that of pneumatic controllers. The commenters state that electricity is often readily available at compressor stations, large production sites, and sites near urban areas and is becoming increasingly available at other sites. In addition, solar [-powered] pumps are available and have become widespread over the past five years, and for sites with high demand, thermal electric generators or methanol fuel cells have been used to increase power.<sup>1</sup> The commenters contend that the application of a zero-emitting standard in other jurisdictions and the widespread use of non-emitting pumps by oil and gas operators is further evidence of the feasibility of a zero-emissions standard. The commenters note that Alberta and California currently require zero-emitting new and existing pumps, and New Mexico has proposed a rule requiring zero-emitting pumps at all processing plants and at wellhead sites, gathering and boosting sites, and transmission compressor stations with electricity.<sup>2</sup> Moreover, the commenters state that EOG Resources, which operates throughout the U.S., has started an initiative to "[convert] pneumatic pumps to electric or solar power."<sup>3</sup>

At the very least, the commenters recommend that EPA require zero-emitting pumps at sites that are transitioning to zero-emitting pneumatic controllers (on their own or because of the new standards). According to the commenters, operators who install systems that can operate zero-emitting controllers should easily be able to scale those systems to operate zero-emitting pump equipment as well. For both electric and instrument air systems, the commenters report that converting pneumatic pumps to zero-bleed alongside pneumatic controllers adds to overall capital costs, but this is more than made up for by emission reductions which result in an overall decline in abatement costs. The Carbon Limits model supports requiring a zero-emission standard for pumps at sites installing zero-emitting controllers. The commenters state that it demonstrates that both new and existing sites<sup>4</sup> that convert controllers and convert a pump to

---

<sup>1</sup> Carbon Limits 2016 at 13, 16.

<sup>2</sup> New Mexico (NM) proposed rule, 20.2.50.122(B)(5).

<sup>3</sup> EOG Resources, 2019 Sustainability Report 6 (2019) [https://eogresources-com.s3-us-west-2.amazonaws.com/EOG\\_2019\\_Sustainability\\_Report.pdf](https://eogresources-com.s3-us-west-2.amazonaws.com/EOG_2019_Sustainability_Report.pdf).

<sup>4</sup> Carbon Limits 2016 at 25.

electric <sup>5</sup> have lower abatement costs than sites that only convert controllers.<sup>6</sup> The report notes the net benefit to operators arises because pumps typically emit more per device than controllers.

Though EPA's own analyses show zero-emitting pumps are cost-effective as is, the commenters encourage EPA to consider the costs of controllers and pumps together, as that further improves cost-effectiveness. As the Carbon Limits model shows, sites with controllers that also have one pump that converts to electric power have a much lower abatement cost than sites without such a pump.<sup>7</sup>

Response I-11-1: In the final NSPS and EG, the EPA is requiring that there be zero emissions from pumps located at sites meeting certain conditions, which are those that have access to electrical power and those that do not have access to electrical power that have three or more natural gas-driven diaphragm pumps. At these sites, all pumps in the pumps affected source are required to meet this standard, which includes piston pumps and pumps in the transmission and storage segment. See section XI.E.1 of the final rule preamble for more information on the EPA's BSER analysis and the final emissions standards for pumps.

Regarding the consideration of costs for zero-emitting pumps and controllers together, the EPA acknowledges that some sites may use common equipment for the control of emissions from both pumps and process controllers, such as a compressed air system. However, sites may also use a different compliance method for these types of equipment, such as using solar-powered electric pumps but a compressed air system for its controllers. As it is not necessary for sites to choose the same method of compliance for both equipment types, the EPA determined that it would not be reasonable to assess the BSER on the basis of both equipment types together. However, the EPA notes that even when assessed individually, the analyses show that there are zero-emissions options that are cost-effective for most sites.

## **11.2 Limitations of Use of Solar-Powered Pumps and Solar Generation**

Comment: Commenter (0793-Permian Basin Petroleum Association (PBPA)) states that onsite solar generation paired with battery storage as an alternative to grid electricity systems are currently uncommon and unreliable. According to the commenter, use of these systems would likely increase the frequency of facility upsets, which would increase safety risks such as overpressure events and spills. The commenter concludes that onsite solar should therefore not be deemed an available technology. Moreover, they add that EPA has not explained how onsite power generation is a viable alternative to grid-electricity in states whose electricity regulations may restrict the ability to setup such onsite generation. For example, the commenter notes that an onsite solar installation may be subject to public utility commission regulation, which would complicate the ability of an upstream operator to sell power to itself. Other commenters (0765-Institute of Clean Air Companies (ICAC)) provide specific examples of where pneumatic pumps not driven by natural gas, particularly solar-powered pumps, would likely not be technically

---

<sup>5</sup> Carbon Limits 2016 at 23.

<sup>6</sup> Carbon Limits 2016, 26-27.

<sup>7</sup> Carbon Limits 2016 at 26.

feasible. Some examples of the situations cited include locations with very cold temperatures, extended periods of cloud cover, and heavy snow load.

Response I-11-2: See discussion in section IV.E.1.b.ii. of the supplemental proposal See 87 FR 74775.

### **11.3 Sub-Categorization Based on Access to Electrical Grid**

Comment: Several commenters (0817-GPA Midstream Association (GPA), 0463-Southern Ute Indian Tribe, Colorado, 0844-EDF *et al.*, 0765-ICAC, 0823-Qnergy, 0838-TRIDO Solutions LLC (TRIDO)) support the approach of subcategorizing based on access to electrical power, and then determining BSER for pneumatic pumps separately for sites with and without access to electrical power. One of these commenters (0938-Texas Oil & Gas Association (TXOGA)) notes that the availability of electricity is a significant and constraining factor that is within EPA's authority to consider in subcategorization.

Commenter (0817-GPA) states that they oppose the November 2021 Proposal to extend the zero-emission requirement for pneumatic pumps to gathering and boosting compressor stations. However, the commenter notes that, if EPA determines that electric pumps constitute the BSER, they support EPA's proposal to sub-categorize gathering and boosting compressor stations that lack access to electricity. The commenter further notes that natural gas-driven pneumatic pumps are used minimally at gathering and boosting stations, such as to transfer liquids, or in a temporary capacity. Due to this limited use, the relatively low number of pumps used at compressor stations, and the high cost of implementing a zero-emission standard, the commenter states that the proposed requirement is not cost effective. According to the commenter, the November 2021 Proposal provides little justification for requiring a zero-emission standard at gathering and boosting stations other than to claim that the 2021 U.S. Greenhouse Gas Inventory (GHGI) estimates that these compressor stations emit approximately 26,000 tons of methane. 86 Fed. Reg. at 63,226. The commenter believes this estimate is inaccurate and overstated as operators may overestimate their reports by assuming that pneumatic pumps emit 24 hours per day, seven days a week. Methane emission reductions achieved by a zero-emission standard would, therefore, be a small fraction of EPA's estimate and would not justify the very high costs associated with implementing a zero-emission standard. Electric pumps have lower performance and reliability and would require an electric power supply. Likewise, using solar power where a site lacks access to electricity is impractical, more expensive than EPA estimates, and involves significant maintenance and other concerns. Solar powered pumps are not technically feasible, and the use of electric pumps in general is not technically feasible without the use of an on-site generator. For these reasons, the commenter supports the proposal to sub-categorize sites that lack access to electricity in a manner similar to New Mexico regulations. See 86 Fed. Reg. at 63,227.

Commenter (0463-Southern Ute Indian Tribe, Colorado) provides support for the use of non-natural gas driven pumps as an option at sites where it is technically feasible indicate that requiring these pumps at many of their remote sites would be "burdensome at best and would force site shutdown in many cases."

Commenters (0844-EDF *et al.*, 0765-ICAC) report that options that do not use natural gas-driven pneumatic pumps are available at sites without access to grid electricity systems, and that their use has become widespread over the last five years. One of these commenters (0844-EDF *et al.*) notes that in addition to solar-powered pumps, thermal electric generators or methanol fuel cells have been used to increase power at sites with high demand. Another commenter (0765-ICAC) notes that they are aware of retrofits at remote locations that have no electrical power in which natural gas is used to generate electricity to run controls directly or to power air compressors that drive pneumatic controls.

Commenters (0823-Qnergy, 0838-TRIDO), are equipment vendors and confirm the successful implementation of technologies to utilize pneumatic pumps not driven by natural gas at remote locations without the access to the grid. Commenter (0838-TRIDO) reports that they have deployed solar-driven pneumatic pumps and air compressors in many states throughout the southwestern and northwestern U.S., including a remote location in Wyoming that experienced temperatures down to minus 11 degrees Centigrade (°C). The other vendor (0823-Qnergy) reported that their standalone power generators have been deployed at several sites across the country to power pneumatic pumps. The commenter states that their systems can work on and off the grid and with both renewable and nonrenewable energy sources.<sup>8</sup> They add that all their systems can be connected either to their generators (which are the most reliable power source available on site) or to any other source of power (including grid power), when it exists. According to the commenter, this technology is reasonably affordable and already has been deployed at several sites across the country.

Response I-11-3: See discussion in section IV.E.1.b.ii. of the supplemental proposal. See 87 FR 74772 and 74774-74775. See also the discussion in section XI.E.1 of the final rule preamble for a discussion of the final BSER determination.

## **11.4 Exceptions of Exemptions**

Comment: Commenter (0808-API) provides that, as they noted in their December 4, 2015<sup>9</sup> comments on the proposed NSPS OOOOa<sup>10</sup> there are numerous implications for routing a piston pump to a control device or vapor recovery unit (VRU) and they continue to support EPA in excluding piston pumps from emission guidelines (EG) OOOOc.

Response I-11-4: The commenter's December 4, 2015, remarks regarding piston pumps included concerns that the EPA assumed an equal number of piston pumps and diaphragm pumps exist per site and that the control of piston pumps is not cost-effective. As discussed further in the final rule preamble section XI.E.1, the EPA found that for sites with access to electrical power and for sites without access to electrical power that have at least three natural gas-driven diaphragm pumps, it becomes cost-effective for certain zero-emissions compliance methods to be used for all pumps in the pumps affected source, including both piston pumps and diaphragm pumps. In addition, in a sensitivity analysis performed for the final rule, the EPA found that it is still cost-effective for piston pumps to be controlled when they outnumber diaphragm pumps 3 to 1 (i.e.,

---

<sup>8</sup> Note that the "CAP3G" configuration is the variation of this technology capable of being powered by the grid.

<sup>9</sup> API comments filed December 4, 2015 (EPA-HQ-OAR-2010-0505-4776).

<sup>10</sup> <https://www.regulations.gov/comment/EPA-HQ-OAR-2010-0505-6884>.

10 piston pumps and 3 diaphragm pumps). As the EPA determined that zero-emissions compliance methods for pumps have been adequately demonstrated and at least some are cost-effective means of attaining zero-emissions, the BSER for pumps affected sources at sites with access to electrical power and for sites without access to electrical power that have at least three natural gas-driven diaphragm pumps is zero emissions.

Comment: Commenter (0844-EDF *et al.*) requests that if zero-emitting technology is not feasible for an operator, EPA should require that the operator reduce emissions by 95 percent and submit justification for an exemption in its annual report. Further the commenter states that if EPA includes a feasibility exemption, it should require standards for pumps that closely resemble our suggested standards for pneumatic controllers. That is, EPA should require that operators first attempt to reduce emissions by at least 95 percent, with a preference for routing emissions to a VRU rather than to a combustion device. If that level of control is not feasible, the commenter recommends that operators be required to reduce emissions to the greatest extent possible. In these instances, they suggest that operators be required to provide a functional need justification in their annual report, including documentation as to: (1) why power (either grid-based or solar) is unavailable; (2) if applicable and the operator isn't achieving 95 percent reductions, why reducing emissions by 95 percent is infeasible; and (3) how the operator plans to reduce emissions from their pneumatic pumps to the maximum extent possible.

Response I-11-5: As discussed further in the final rule preamble in section XI.E.1, the final rule requirements for pumps have been revised from the November 2021 Proposal and the December 2022 Supplemental Proposal. The EPA determined it was possible to specify the conditions under which the different pump requirements apply in the NSPS and EG that reflect the BSER and that eliminate the need for demonstrations of technical infeasibility. The analyses for BSER show there are technically feasible zero-emission options, which can be implemented at costs the EPA considers reasonable at sites with access to electricity and at sites without electricity that have three or more natural gas-driven diaphragm pumps. Routing emissions to a process is included as a zero-emissions option, as the EPA recognizes that with proper equipment operation, this option will result in zero emissions from pumps. Sites without electricity and with fewer than three natural gas-driven diaphragm pumps may use zero emissions options or may reduce emissions using existing control devices. At these sites, if a VRU is not onsite to route emissions through to a process, or if no emissions control device is onsite, pump emissions are not required to be reduced. These requirements reflect the BSER determinations regarding emissions reductions, costs, and other impacts.

Comment: Commenter (0789-Pennsylvania Department of Environmental Protection (PDEP)) states that Pennsylvania currently requires emission reductions of 95 percent or greater for all natural gas-driven pneumatic pumps at natural gas well sites, natural gas compressors, and natural gas processing and transmission plants when the methane emission rate is 200 tons per year (tpy) or greater, the volatile organic compound (VOC) emission rate is 2.7 tpy or greater, any specific hazardous air pollutant (HAP) has an emission rate of 0.5 tpy or greater, or when the total of all HAP emissions is 1.0 tpy or greater. Given this, the commenter recommends the EPA consider removing the exemption based on availability of existing controls or processes at the site and require 95 percent control of natural gas from all-natural gas-driven pneumatic pumps, regardless of location.

Response I-11-6: While the EPA agrees that the determination of when to require emissions controls could be made based on the potential or actual emissions from an emissions source, the EPA has not revised the regulatory text for pumps in the final rule to require emissions controls based on an explicit emissions threshold. The use of such a regulatory emissions threshold implies that emissions at that level are high enough to justify emissions control requirements based on the emissions reductions that could be realized and the associated costs and other impacts of the controls. To simplify the applicability determination process for the final rule, we determined the emissions levels that would be necessary to justify emissions control requirements and the conditions under which those emissions levels would occur. Thus, we determined in our BSER analysis the site conditions for which control of pumps is reasonable based on the emissions reductions that would be achieved and the costs and other impacts associated with emissions controls. This up-front determination simplifies the applicability process by not requiring owners or operators to determine potential or actual emissions and by not requiring an air quality agency to review that information.

## **11.5 BSER Analysis**

### ***11.5.1 Emissions/Emissions Factors***

Comment: Commenter (0782-Berkshire Hathaway Energy Company (BHE)) states that pneumatic pumps should not be added as a regulated source for the transmission and storage segment. The commenter reports that the prevalence and use of pneumatic pumps at transmission and storage facilities is very minimal, and thus emissions are very low. The commenter adds that this is supported by EPA's decision to not include this source for transmission and storage in EPA's annual greenhouse gas (GHG) inventory. In addition, the commenter notes that EPA excluded gas-driven piston pumps from the 2016 NSPS OOOOa regulations based on their inherently low emission rates.

Commenter (0782-BHE) states that in the November 2021 Proposal Technical Support Document (TSD), it appears that EPA relied on model assumptions for natural gas processing plants (*e.g.*, see November 2021 Proposal TSD Table 9-14 and related discussion). The commenter notes that the November 2021 Proposal TSD presentation estimates 4 to 100 pumps depending on the compressor size. The commenter notes that these numbers are unsupported for transmission and storage, significantly over-estimate transmission and storage pneumatic pump counts, and do not provide representative prevalence or ranges for cost control estimates. Further, the commenter adds that the EPA baseline emissions assumptions presume that natural gas bleeds from the pump 8,760 hours per year, which significantly overstates emissions from two of the more likely applications that may occur in transmission and storage – portable applications and chemical injection. When located at a transmission and storage facility, the commenter reports that these pumps are operated infrequently, and typically used for periodic liquid transfer service, methanol injection to prevent hydrate formation, or injection of corrosion inhibitors.

Commenter (0782-BHE) suggests that EPA not base its analysis for the transmission and storage segment on model plants and pump counts developed for gas processing plants. If EPA considers including requirements for transmission and storage pneumatic pumps, the commenter

recommends using data and analysis representative of transmission and storage facilities to support the inclusion of transmission and storage pneumatic pumps. The commenter supports earlier determinations by EPA (in NSPS OOOOa, in annual GHGI) to exclude pneumatic pumps for transmission and storage sources. The November 2021 Proposal TSD notes that the decision was due to the lack of available information:

However, EPA did not include pneumatic pumps in the transmission and storage segments in the final 2016 NSPS OOOOa because EPA did not have a reliable source of information indicating the prevalence of pneumatic pumps or their emission rates in the transmission and storage segments.

Similarly, the 2016 CTG [Control Technology Guideline] did not recommend controls for pumps in the transmission and storage sector due to a lack of information on the prevalence of pumps in that sector.

Commenter (0782-BHE) contends that the lack of data is due, in large part, to the limited number of pneumatic pumps and limited annual operating time when pumps are present at transmission and storage facilities. While data is unavailable, the commenter discourages EPA from conducting an analysis for transmission and storage based on model plants in gas processing due to the differences in the systems. The commenter recommends excluding this source for transmission and storage, or conducting an analysis based on transmission and storage data and cost estimates to support inclusion.

Response I-11-7: In the final NSPS and EG, the EPA is requiring that there be zero emissions from pumps located at sites meeting certain conditions, which are those that have access to electrical power and those that do not have access to electrical power that have three or more natural gas-driven diaphragm pumps. At these sites, all pumps in the pumps affected source are required to meet this standard, which includes pumps in the transmission and storage segment. See section XI.E.1 of the final rule preamble for more information on the EPA's BSER analysis and the final emissions standards for pumps.

See section VI.E.1.b.ii.C of the December 2022 Supplemental Proposal preamble (87 FR 74777) for discussion of the 90-day exemption for pumps used only temporarily. **11.5.2 Costs**

Comment: Commenter (0844-EDF *et al.*) states that routing to an existing combustion device or VRU are cost-effective solutions for operators who cannot install zero-emitting pumps. The commenter adds that EPA's costs for routing to a new combustion device and VRU are higher. However, they believe EPA's VRU calculations overestimate costs. As a result, the commenter suggests that EPA reconsider its VRU cost calculations for the final rule.

The commenter (0844-EDF *et al.*) continues that EPA's decision to base its cost analysis for VRUs in the November 2021 Proposal on 2016 estimates is inherently flawed and arbitrary for several reasons. First, those values are outdated, and it's unclear how representative they are. EPA did not explain how it vetted the asserted capital cost increases before accepting them and including them in their final rule. Second, the 2016 cost estimate assumed a \$7,000 (2012 U.S. Dollars) component to account for 200 feet of piping. This accounts for over 80 percent of the

included cost estimate. The commenter contends that this is problematic because few sites will need such a large length of piping. As a result, this heightened cost doesn't apply to a significant number of sites governed by the November 2021 Proposal. The commenter urges the EPA to reconsider its 2016 and 2021 calculations for VRU cost-effectiveness, especially for routing to a new VRU. The commenter recommends that EPA conduct a cost analysis based on more reliable inputs.

Response I-11-8: NSPS OOOOa at §60.5393a(b) requires that natural gas-driven diaphragm pumps at well sites must reduce natural gas emissions by 95% if a control device is onsite and must route those pump emissions to another control device if the only control device(s) at the site achieve less than 95% emissions reductions. If no control device is onsite, OOOOa does not require emissions reductions from pumps. For the December 2022 Supplemental Proposal, we re-evaluated pump options that would result in zero emissions of methane and VOC, and we also evaluated the use of new and existing control devices in our analysis. For the final rule, we have updated the analysis performed for the December 2022 Supplemental Proposal to include more recent cost information for pump zero-emissions options and we also updated our analysis for control of emissions by routing emissions to a process through a new or existing VRU and a new or existing combustion control device. For both the supplemental proposal and the final rule, our analyses showed that zero emissions represents the BSER at sites with certain characteristics, including having access to electricity at the site and having a certain number of diaphragm pumps at the site. The analysis conducted for the final rule using the updated information shows that costs to achieve zero emissions from pumps are reasonable when there is access to electricity and when there are three or more diaphragm pumps at a site without electricity. For sites with access to electricity and for sites without electricity that have three or more natural gas-driven diaphragm pumps, 95% control was not determined to be the BSER and was not used to develop the pump standards for the NSPS or the presumptive standards for the EG. Zero emissions from pumps was shown in our analyses to be technically achievable and cost-effective through several available options, including the use of electrical pumps powered by electricity from the grid or solar power systems, pumps powered by compressed air using electricity from the grid, and by routing emissions to a process. For sites without electricity and with fewer than three natural gas-driven diaphragm pumps, our analysis for the final rule shows that control of emissions through a control device otherwise onsite represents the BSER. At these sites, requiring zero emissions from pumps, requiring the use of a new control device, and requiring the routing of pump emissions to a process through a new vapor recovery unit (VRU) (which is usually required to attain the necessary pressure for the gas to enter a process onsite) does not represent the BSER due to the costs associated with the equipment needed for these options. The NSPS and the EG for these sites reflect the BSER determination by requiring that emissions be routed to a process through a VRU if a VRU is onsite; if a VRU is not onsite, pump emissions are required to be routed to a control device onsite that achieves 95% emissions reductions; if no control device that achieves 95% emissions reduction is onsite, another onsite control device may be used; and if no VRU or control device is onsite, pump emissions are not required to be controlled. For existing sites that have access to electrical power or that have three or more diaphragm pumps, owners/operators currently complying with OOOOa by routing emissions to a control device achieving 95% control will be required to switch to a zero-emissions option for pumps to comply with OOOOc. For existing sites that do not have access to electrical power or that have fewer than three natural gas-driven diaphragm pumps, owners/operators currently

complying with OOOOa by routing emissions to a control device achieving 95% control will be required to switch to routing emissions to a process if a VRU is onsite, otherwise, they may continue to route emissions to a control device achieving 95% control for compliance with OOOOc. See section XI.E.1 of the final rule preamble for more information regarding the BSER analysis.

## 11.6 Other

### 11.6.1 Supply Chain Issues

Comment: Commenters (0739-Citation Oil & Gas Corp. (Citation), 0808-API) indicate that the November 2021 Proposal would exacerbate demand, increase costs, and increase pressure on the supply chain for zero-emissions systems. Commenter (0739-Citation) states that reliability and availability of alternate zero-emission options (*i.e.*, solar-powered/battery backup systems, and electric, self-contained systems) are a major concern for safe and reliable operations. Another commenter (0808-API) indicates that one of their members contacted a vendor within the last six months to find out how much deployment there has been of solar systems and electric controllers. The commenter reports that the vendor indicated that in the past 10 years, they have conducted 200 retrofits and 300 new installs, and the vendor estimates that it can only service approximately 200 installs per year. The commenter adds that operators are already experiencing 6 to 12-month lead times for delivery of solar packages.

Commenter (0739-Citation) states that inclusion of previously exempt piston pumps for new and existing sources will result in a significant increased demand for zero emission pumps. Reliability and availability of alternate zero emission options (*i.e.*, solar powered/battery backup systems, and electric, self-contained systems) are a major concern for safe and reliable operations. If the November 2021 Proposal is finalized, the commenter requests that the EPA provide supporting data demonstrating this technology is widely available and reliable. The commenter is concerned that a hasty conversion to untested technologies could create upset conditions due to failures and result in increases in emissions after significant capital expenditures.

Response I-11-9: See section IV.E.1.b.ii of the December 2022 Supplemental Proposal for discussion of the demonstration of the use of zero-emitting technologies for pumps.

To address potential delays in the available of equipment necessary to meet the zero-emissions standards, the EPA is extending the zero-emissions requirements compliance date for the NSPS by one year. Until that date, sites that would otherwise be required to meet the zero-emissions standard must comply with the standards for sites that do not have access to electricity and have fewer than three natural gas-driven diaphragm pumps. See section XI.E.2 of the final rule preamble for further discussion of this issue and the extended compliance date.

For existing sources, each state must submit a plan to the EPA that establishes standards of performance for each designated facility. For purposes of EG OOOOc, the EPA is finalizing a requirement that each state adopt and submit their state plans incorporating the process controller requirements within 24 months after publication of the final EG OOOOc. The EPA is also

finalizing a timeline for compliance with the requirements included in the state plans of 36 months from the deadline for state plan submittals. The combined time allotted for compliance then is 60 months, or 5 years from the publication date of EG OOOOc. This period of time should provide all operators with ample opportunity to determine a compliance strategy and procure and install the necessary equipment.

#### ***11.6.2 Requirement for Professional Engineer (PE) to Certify Technical Infeasibility***

Comment: Commenters (0923/1376-Lambda Energy Resources LLC (Lambda), 0787/1289-Atmos Energy Corporation (Atmos)) support EPA's November 2021 Proposal to allow in-house engineers to certify facility design and determine situations of technical feasibility. Commenter (0923/1376-Lambda) states that this would align with the 2020 Technical Rule, thereby promoting regulatory consistency, and that an in-house engineer has direct experience with the operating equipment and the relevant site. The commenter states that they are likely to have more knowledge about the site and can therefore apply a higher level of scrutiny to such determinations. Commenter (0755-Texas Pipeline Association (TPA)) supports the November 2021 Proposal to allow in-house engineers to make such certifications. However, the commenter also believes that EPA should expand the universe of persons who could make required certifications and determinations to include non-PE outside personnel such as company-hired contractors or consultants if they have appropriate expertise, *e.g.*, if they have designed the system in question. The commenter contends that this would provide additional flexibility without sacrificing any environmental protections because such third parties would have to have appropriate expertise on design and operation of the system in order to complete a certification or to make a required technical determination.

Response I-11-10: The final rule requirements for pumps have been revised from the November 2021 Proposal and the December 2022 Supplemental Proposal. The EPA determined it was possible to specify the conditions under which the different pump requirements apply in the NSPS and EG that reflect the BSER and that eliminate the need for certified demonstrations of technical infeasibility. The analyses for BSER show there are technically feasible zero-emission options, which can be implemented at costs the EPA considers reasonable at sites with access to electricity and at sites without electricity that have three or more natural gas-driven diaphragm pumps. Routing emissions to a process is included as a zero-emissions option, as the EPA recognizes that with proper equipment operation, this option will result in zero emissions from pumps. Sites without electricity and with fewer than three natural gas-driven diaphragm pumps may use zero emissions options or may reduce emissions using existing control devices. At these sites, if a VRU is not onsite to route emissions through to a process, or if no emissions control device is onsite, pump emissions are not required to be reduced. These requirements reflect the BSER determinations regarding emissions reductions, costs, and other impacts. See also the final rule preamble section XI.E.1 for more discussion of the final BSER analysis.

## Chapter 12. Well Liquids Unloading Operations

### 12.1 Applicability

#### 12.1.1 Modification

##### 12.1.1.1 Support/Opposition to Each Liquids Unloading Event Constituting a Modification

Comment: Commenters (0539-Alaska Oil and Gas Conservation Commission (AOGCC), 0781-National Tribal Air Association (NTAA), 0391-Keweenaw Bay Indian Community (KBIC), 0833-Environmental Programs Department, Ute Mountain Ute Tribe (Ute EPD), 0605-Muscogee (Creek) Nation) agree, in general, with EPA's November 2021 Proposal that each liquid unloading event represents a modification and therefore, would be subject to the requirements of New Source Performance Standard (NSPS) OOOOb.

Conversely, commenter (0424-Division of Air Quality, West Virginia Department of Environmental Protection (WVDEP)) expresses concern that a well that undergoes liquids unloading for the first time would be subject to NSPS OOOOb without any transition period for a source to come into compliance. The commenter notes that, because sources may need to install control equipment, route emissions to control equipment, install zero emissions controllers, *etc.*, they would need time to design and install this equipment prior to operation. The commenter also suggests that defining well liquids unloading events as a modification would create implementation and compliance confusion (for the state and for the facilities it regulates), assuming only the well is subject to the NSPS, instead of the whole well site, as indicated by EPA. The commenter continues to state that from a state permitting and enforcement perspective, this is problematic and would be very difficult to implement.

The commenter (0424-WVDEP) adds that they believe the November 2021 Proposal would create unproductive work for the states to continually recategorize wells for emissions inventory purposes from designated facilities subject to the Emission Guidelines (EGs) to affected facilities subject to the NSPS in the State Plan development and the state annual reports required by the EGs without additional environmental benefit. Further, the commenter states that it would complicate the permitting process because the source would be required to submit a modification application and obtain a revised permit prior to each unloading event. At a minimum, the commenter requests that vertical wells that use a pump jack to transfer the liquids to storage tank as part of their normal operation not be defined as a modification. The commenter urges the EPA to include the best system of emissions reduction (BSER) for liquid unloading events in the EGs and not define these events as modifications. The commenter suggests that it would be more efficient and less confusing from a practical perspective to include the liquids unloading controls within the EGs rather than have the well subject to the NSPS with the remainder of the facility subject to the EGs.

Commenters (0424-WVDEP, 0577-Kansas Independent Oil & Gas Association (KIOGA), 0727-Oklahoma Secretary of Energy and Environment (OSEE) and Oklahoma Department of Environmental Quality (ODEQ)) urge EPA to reconsider its determination that each liquids

unloading event represents a modification, making the well subject to new source standards for purposes of liquids unloading standards.

A couple of the commenters (0424-WVDEP, 0577-KIOGA) state that oil and natural gas wells produce the largest volume at the time they are initially drilled; followed by a declining curve over time. The commenters note that, depending on when the liquid unloading event occurs, the production would only return to where it should have been on the declining production curve assuming the liquid unloading event was successful. The commenters stress that the production never increases to the volume the wells observe early in the production curve for a new well, and further state that liquid unloading events are considered normal operation for well operators.

Commenter (0727-OSEE/ODEQ) notes that liquids unloading would be a relatively small event to constitute a modification under Title I of the Clean Air Act (CAA) and thus, it could potentially create unexpected regulatory complexities. The commenter recommends that EPA reconsider its definition of modification to achieve the goals intended without entangling other requirements. Further, the commenter adds that they are concerned that EPA's definition of a modification could set an unwelcome precedent and a significant departure from standard practice under 40 C.F.R. Part 60.

Response I-12-1: Based on comments received on the November 2021 Proposal, the December 2022 Supplemental Proposal for NSPS OOOOb specified that a modification to an existing well occurs when the definition of modification in 40 Code of Federal Regulations (CFR) 60.14 is met, including when an existing well undergoes hydraulic fracturing or re-fracturing. The final rule maintains what was proposed in the December 2022 Supplemental Proposal. See discussion in sections IV.F.1, IV.F.3.a.i, IV.F.3.a.ii, and IV.F.3.a.iii of the December 2022 Supplemental Proposal preamble related to what EPA proposed as constituting a well affected facility/designated facility, and EPA's request for comments regarding operational scenarios that would constitute a modification for liquids unloading operations.<sup>1</sup> See section 6.4.1 (Applicability) of Volume II of this Response to Comment document (RTC) for comments and responses on the December 2022 Supplemental Proposal on the definition of a well affected/designated facility and what constitutes a modification under the NSPS OOOOb for liquids unloading operations. Lastly, see sections X.F.1 and 3 of the preamble to the final rule which details EPA's final standards related to well affected facilities/designated facilities and what constitutes a modification for existing wells for liquids unloading operations.

Comment: Commenters (0599-Marcellus Shale Coalition (MSC), 0793-Permian Basin Petroleum Association (PBPA), 0831-American Exploration and Production Council (AXPC)) argue that liquids unloading activities should not be considered modifications; stating that unloading is not necessarily a physical or operational change – but instead a routine part of initiating flow in the well production process, nor does it result in the potential for increased emissions when wells do not vent. According to the commenters, almost all wells experience liquid unloading during the natural production of the well, many without any equipment modification and as a stage of “primary” production.

---

<sup>1</sup> 87 FR 74781-74782, December 6, 2022.

Commenter (0599-MS) adds that even gas wells that do not contain any movable liquids in the formation will generate liquids due to condensation of the liquid vapor in the gas as the gas cools during production from the downhole formation to the surface wellhead. According to the commenter, with time this liquid can accumulate in the wellbore and can temporarily load the well until the well pressure increases naturally under this fluid column until there is sufficient pressure/energy to unload the liquid column.
