Response II-7-3: The EPA considered the recommended changes but determined that the original language was clear and that the recommended changes are not necessary to convey the meaning of the terms. Therefore, the EPA has not made the suggested changes to these definitions in the final rule.

Comment: Commenter (2403- The Petroleum Alliance of Oklahoma (PAO)) requests EPA include a provision that allows operators to replace high-bleed controllers with low-bleed controllers without becoming an affected facility.

Commenter (2399-GPA) supports the proposed definition of “affected facility” for natural gas driven pneumatic controllers that allows for replacements without triggering the modification requirements. The commenter states that an “in-kind” replacement of a natural gas driven pneumatic controller would not be a modification “provided that less than 50 percent of the controllers are replaced at the same time.” The commenter notes that this is a reasonable approach, as if EPA did not allow this, operators would be discouraged from voluntarily replacing high-bleed natural gas-driven controllers with low-bleed controllers.

Response II-7-4: The EPA disagrees with the commenters that sites should be allowed to replace high-bleed controllers with low-bleed controllers without becoming an affected facility. First, we note that the final EG requires that existing sites outside of Alaska and those in Alaska with access to electrical power replace both high-bleed and low-bleed controllers with zero-emitting controllers or route the controller emissions to a process, such that there are zero emissions of methane and VOC. As both the EG for existing sources and the NSPS for new sources require zero emissions from controllers at most sites (i.e., sites outside of Alaska and those in Alaska with access to electrical power), all of these sites will essentially have process controller affected facilities that require zero-emissions. For sites in Alaska without access to electrical power, the NSPS will only apply if more than half of the controllers are replaced in a 24-month period, thereby meeting the definition of reconstruction.

Comment: Commenter (2326- American Exploration & Production Council (AXPC)) states that the EPA proposes best system of emission reduction (BSER) that would result in no volatile organic compound (VOC) or methane emissions from pneumatic controllers, pneumatic pumps, or gas well liquids operations. Thus, compliance with EPA’s proposed BSER ensures that pneumatic controllers, pneumatic pumps, and gas well liquids operations are not “stationary sources” because compliance will not, and could not, result in emissions. According to the commenter, this exceeds EPA’s authority granted under CAA §111. The commenter requests that EPA define the NSPS OOOOb pneumatic controller and pneumatic pump affected facilities as equipment designed to emit VOC and/or methane and similarly define the emission guidelines (EG) OOOOc designated facility to include equipment designed to emit methane. Failing to define the affected/designated facility in this manner would result in the inappropriate imposition of onerous recordkeeping and reporting requirements on equipment that is not a stationary source.

Response II-7-5: It appears the commenter mistakenly believed the EPA included all process controllers in the affected facility definition. The December 2022 Supplemental Proposal only included process controllers driven by natural gas in the affected facility definition in §60.5365b(d); however, it did require that records be kept of the process controllers that were not driven by natural gas and not included in the affected facility definition. The process controller affected facility was defined as follows in the December 2022 Supplemental Proposal:

Each pneumatic controller affected facility, which is the collection of natural gas-driven pneumatic controllers at a well site, centralized production facility, onshore natural gas processing plant, or a compressor station. Natural gas-driven pneumatic controllers that function as emergency shutdown devices and pneumatic controllers that are not driven by natural gas are exempt from the affected facility, provided the records in §60.5420b(c)(6)(i)(A) or (B) are maintained, as applicable.

The EPA agrees that process controllers with no potential to emit methane or VOC to the atmosphere should not be included in the affected facility and is finalizing this aspect of the affected facility definition. After considering these comments regarding the recordkeeping and reporting requirements for process controllers with zero emissions, we have determined that it is appropriate in this instance to require identification of the equipment that is included in the affected facility, rather than the equipment that is not part of the affected facility. The process controllers included in the affected facility are those that are subject to the emissions standards in the rule, whereas process controllers not included in the affected facility are not subject to the emissions standards in the rule, and also have no potential to emit methane or VOCs. Therefore, we have revised the recordkeeping and reporting requirements to require identification only of process controllers that meet the finalized definition of an affected facility, which are those process controllers that are driven by natural gas and are not emergency shutdown devices.

### ***7.1.3 Modification/Reconstruction***

Comment: Commenter (2399-GPA) supports the December 2022 proposal's definitions of "modification" and "reconstruction."

Commenter (2254- Permian Basin Petroleum Association (PBPA)) states EPA should clarify in the rule text that, for purposes of the collection of controllers or pumps at a site, a modification occurs only when a natural gas-driven pneumatic controller is added.

Response II-7-6: The EPA notes that the definitions of modification and reconstruction have been revised in the final rule to further clarify that the occurrence of a modification or reconstruction is based on natural gas-driven process controllers. These changes clarify but do not change the intent of the definitions included in the December 2022 Supplemental Proposal.

Comment: Commenter (2446-IPAA) requests that the EPA replace references to "site" in the relevant definitions of modification and reconstruction with "pneumatic controller affected facility." The commenter suggests that a similar clarification be considered for all sections of the rule, so that it is made completely clear that the owner or operator is responsible only for the collectives of equipment that it owns at a site, even though a "site" might comprise equipment that is under separate ownership and control. This includes but is not limited to (1) the "affected facility" for fugitive emission control purposes, which, like "pneumatic controllers," is defined by reference to the totality of equipment at a site, and (2) the super emitter response program, which purports to impose obligations on a site, when it needs to be clear that the obligations are imposed on the owner or operator of the individual equipment item that is responsible for any alleged super-emitting event.

Commenter (2446-IPAA) states if EPA proceeds to describe the collective of all controllers at a site as the "affected facility," it must revise its proposed regulatory text to make clear that regulated entities will not be responsible for equipment that they neither own nor operate at shared production sites.

The commenter (2446-IPAA) explains that, as proposed, "modification" and "reconstruction" of a pneumatic controller affected facility can be triggered by installation of new pneumatic controllers at a "site." The term "site" is undefined and creates uncertainty where, as is common, multiple companies operate in close proximity. The commenter notes that owners and operators cannot be responsible for equipment over which they have no control. The commenter recommends that the EPA revise the definition of "pneumatic controller affected facility" to read:

Each pneumatic controller affected facility, which is the collection of natural gas-driven pneumatic controllers that you own or operate at a well site, centralized production facility, onshore natural gas processing plant, or a compressor station.

Response II-7-7: To clarify that the modification and reconstruction provisions are related to the affected facility, we have revised the modification and reconstruction provisions in the final rule for process controllers and pumps to specify that the provisions apply to the affected facility rather than the site. These revisions should clear up any potential confusion that a change made to the site, such as the addition of a process controller, that is owned or operated by another entity could affect the status of an affected facility owned or operated by another entity.

Comment: Commenter (2483-INGAA) states there are likely instances in which a natural gas-driven pneumatic controller has been installed between November 15, 2021, and December 6, 2022, with operators unaware of the implications related to NSPS OOOOb due to the changes that occurred between the November 2021 and December 2022 proposal. The commenter asserts that this drastic change in the definition of a pneumatic controller affected facility that occurred between the November 2021 and the December 2022 proposals require that EPA change the applicability date of NSPS OOOOb for pneumatic controllers to the date of the actual proposal of the regulatory language – i.e., December 6, 2022 – even if EPA continues to maintain that the rest of NSPS OOOOb should have an applicability date of November 15, 2021. If EPA does not change the applicability date of the NSPS OOOOb standards for pneumatic controllers, the commenter requests that EPA seek to mitigate the retroactive effect of the proposed rule by giving operators the option to convert the natural gas-driven pneumatic controller installed before December 6, 2022, to zero-emissions within 60 days after NSPS OOOOb becomes final and avoid having triggered a modification of the entire affected facility without full knowledge of the implications for modifying the group of controllers. The commenter proposes the following reg text for section 40 CFR 60.5365b(d)(1)(i):

Natural gas-driven pneumatic controllers installed between November 15, 2021, and December 6, 2022, that comply with the zero-emissions requirements in §60.5390b(a) by [INSERT DATE 60 DAYS AFTER PUBLICATION OF FINAL RULE IN THE FEDERAL REGISTER] shall not constitute a modification of the affected facility.

Response II-7-8: The applicability date for process controllers under NSPS OOOOb is the date of publication of the December 2022 supplemental proposal, December 6, 2022.

Owners/operators have 60 days after publication of the final rule in the Federal Register to comply with the requirements of the NSPS.

Comment: Commenter (2258- Marcellus Shale Coalition (MSC)) notes that 40 CFR 60.5365b(d)(1) states that facilities shall become subject to 40 CFR 60.5390b upon an increase in a facility pneumatic controller count of one or more. The commenter requests a revision to the definition in 40 CFR 60.14 or specific additional language in 40 CFR 60.5365b(d)(1) as follows:

a modification occurs when the number of natural gas-driven pneumatic controllers at a site is increased by one or more, unless the new controller(s) result in a reduction of emissions.

The commenter (2258-MSC) also suggests that language be included in this section similar to the process unit equipment affected facility stating that addition (or replacement) of natural gas-driven pneumatic controllers for the purpose of process improvement which is accomplished without a capital expenditure shall not be considered a modification.

Commenter (2483- Interstate Natural Gas Association of America (INGAA)) indicates that, as proposed, the regulations would consider the installation of a zero-emitting gas-driven pneumatic controller as triggering a modification (where there would not be a corresponding emissions increase). To rectify this issue, the commenter suggests that the definition of pneumatic controller affected facility in 40 CFR 60.5365b(d) be modified as follows (underlined text indicates new text):<sup>1</sup>

*40 CFR 60.5365b(d)-*

(d) Each pneumatic controller affected facility, which is the collection of natural gas-driven pneumatic controllers at a well site, centralized production facility, onshore natural gas processing plant, or a compressor station. Natural gas-driven pneumatic controllers that function as emergency shutdown devices or have zero-emissions in accordance with §60.5390b(a), and pneumatic controllers that are not driven by natural gas are exempt from the affected facility, provided that the records in §60.5420b(c)(6)(i)(A) or (B) are maintained, as applicable.

Commenters (2283- Endeavor Energy Resources, L.P. (Endeavor Energy), 2305- Williams Companies, Inc. (Williams), 2446-IPAA, 2483-INGAA) states that an emissions increase must occur to be considered a “modification” and that the proposed definition of “modification” conflicts with the statutory definition of “modification” in Section 111 of the CAA and with the

---

<sup>1</sup> The proposed regulatory text for the definition of pneumatic controlled designated facility in 40 CFR 60.5386c(d) should similarly be revised as follows: “(d) Each pneumatic controller designated facility, which is the collection of natural gas-driven pneumatic controllers at a well site, centralized production facility, onshore natural gas processing plant, or a compressor station. Natural gas-driven pneumatic controllers that function as emergency shutdown devices or have zero-emissions in accordance with §60.5394c(a), and pneumatic controllers that are not driven by natural gas are exempt from the designated facility, provided that the records in §60.5420c(c)(5)(i)(A) or (B) are maintained, as applicable.”

Agency's own definition of "modification" in 40 CFR 60.14. In both of these definitions, an emissions increase must occur for a physical or operational change to be considered a "modification". According to the commenter, as proposed, 40 CFR 60.5365b(d)(1) focuses only on an increase in the number or count of pneumatic controllers at an affected facility irrespective of whether there is an accompanying emissions increase. They note that such a definition would result in a facility being "modified" even if it adds a non-natural gas pneumatic controller to an affected facility. Having now undergone a "modification", the commenter explains that an owner or operator must now transition all of its pneumatic controllers to zero-emitting devices. The commenters contend that this is an unreasonable and impermissible result under the CAA and conflicts with EPA's own regulations.

Commenter (2403-PAO) states if an operator can provide information that emissions have not increased with the addition of one or more controllers at the site, then EPA should not consider this a modification. The commenter requests EPA include a provision in the rule that allows operators to provide information showing that if emissions have not increased by the addition of a pneumatic controller, then it does not constitute a modification that makes the entire collection of pneumatic controllers at the site a pneumatic controller affected facility.

Commenter (2283-Endeavor Energy) states EPA's current proposal regarding pneumatic controllers and pumps ignores the practical realities of upstream oil and gas operations and unjustifiably deviates from past practice in defining a "modification" that would trigger the NSPS requirements. To create a durable and workable rule for both new and existing sources, the commenter requests that the EPA reconsider and revise the provisions to better comport with the existing CAA regime and better reflect the true costs of its proposed provisions.

Comment: Commenter (2428-API) states that throughout the proposed NSPS OOOOb and EG OOOOc, EPA uses the terms 'natural gas-driven pneumatic controller' and 'pneumatic controller' interchangeably. The commenter recommends that the EPA be clear that the affected facility and other applicability language is specific to natural gas-driven pneumatic controllers. This clarification is especially important as these terms are used within the description for modification and reconstruction. For example, they note that an existing well site that is already connected to grid power should not trigger a modification with the addition of one or more electric controllers at the well site as this addition would not generate methane or VOC emissions. The commenter offers the following suggested regulation changes (underlined text indicates new text and struck out text indicates deleted text):

*40 CFR 60.5365b(d)(1)-*

(1) For the purposes of §60.5390b, in addition to the definition in §60.14, a modification occurs when the number of natural gas-driven pneumatic controllers at a site is increased by one or more.

Response II-7-9: To clarify that a modification is triggered only if there is the potential for an emissions increase from the addition of a process controller, we have revised the modification provisions of §60.5390b(d)(1) to specify that a modification occurs when the number of natural gas-driven process controllers is increased by one or more.

The EPA disagrees that natural gas-driven process controllers added to the site for the purpose of process improvement without capital expense should not be considered a modification and that the process controllers and pumps requirements for modifications do not comport with the existing CAA regime for modifications. Modifications are determined based on an increase in emissions from a change in the facility processes or equipment, rather than capital costs. For process controllers, there are many zero-emissions controller options available to owners/operators if a change in process is necessary, which requires a change in the process controller. Therefore, there is no reason to allow an increase in emissions without considering it a modification, and the EPA has not revised the rule to accommodate those situations.

Comment: Commenter (2428-API) states it is unclear how the notifications from 40 CFR 60.15 apply to the reconstruction provision proposed in 40 CFR 60.5365b(d)(2). The proposed language in 40 CFR 60.5365b(d)(2)(ii), suggests that reconstructed natural gas-driven pneumatic controllers would be subject to some of the requirements included in 40 CFR 60.15, which include 60-day notification and Administrator approval. The commenter states that this directly conflicts with information presented in Table 5 that states 40 CFR 60.15(d) does not apply to pneumatic controllers. The commenter believes it was EPA's intent to not apply the additional notification and approval, given the number of facilities that will trigger reconstruction over time.

Commenter (2305-Williams) states if one owner or operator makes changes to its portion of the facility so that it triggers a "modification", these actions should not affect the rest of the facility that is under control of a separate owner or operator. And the commenter proposes the following changes (struck out language indicates deleted text):

...a modification occurs when an owner or operator increases the number of natural gas-driven pneumatic controllers at the pneumatic controller affected facility that it owns or operates ~~at a site is increased~~ by one or more which results in a net emissions increase from the affected facility.

Response II-7-10: We agree that we did not intend for facilities to be required to notify the Administrator of upcoming process controller replacements that would constitute a reconstruction or for the Administrator to be required to review the notification and determine whether the replacements constitute a reconstruction. We have revised the final regulatory text to not refer to the requirements of 40 CFR 60.15(d) and have kept the information presented in Table 5 of the proposed regulatory text, which states that 40 CFR 60.15(d) does not apply to process controllers.

Comment: Commenter (2326-AXPC) states that the number of pneumatic controllers that trigger a modification must warrant the additional capital expenditure at the facility of retrofitting the entire facility to be non-emitting. The commenter suggests that the EPA increase the number of pneumatic controllers that require a modification to a meaningful number that would justify the implementation of retrofits at an existing facility. In most cases, according to the commenter, one pneumatic controller addition would not warrant such additional capital expenditure.

Response II-7-11: The EPA is not redefining what constitutes a modification under 40 CFR part 60 in §60.5390b(d)(1). The definition of modification in §60.2 states that any physical change in, or change in the method of operation of, an existing facility which increases the amount of any air pollutant emitted into the atmosphere by that facility is a modification. The language of §60.5390b(d)(1) only clarifies that the addition of one natural gas-driven process controller to an affected facility would be considered a modification because such an addition has the potential to increase emissions of methane and VOC to the atmosphere. As any increase in emissions triggers the modification status, and the addition of one natural gas-driven process controller meets this threshold, the EPA has not revised this modification provision in the final rule.

Comment: Commenter (2337- Kansas Department of Health and Environment (KDHE)) notes that heretofore, natural gas discharged from natural gas-driven pneumatic controllers or natural gas-driven pumps has not been considered a fugitive emission if the device is operating properly and in accordance with manufacturer's specifications. The commenter recommends that in light of the very heavy financial burden this proposed rule places on oil and gas owners and operators, EPA provide a moratorium on implementing modification requirements for at least five years.

Response II-7-12: The EPA has determined that the costs of using zero-emitting process controller technologies for new sources and changing to zero-emitting technologies for existing sources is reasonable, considering the emissions reductions that will be achieved. This same principal applies to affected sources undergoing a modification. Therefore, the EPA has not revised the modification requirements to provide a moratorium on implementation of the process controller requirements for any period of time.

Comment: Commenter (2428- API) offered a suggested regulatory language for reconstruction, primarily to clarify that the affected facility and other applicability language is specific to natural gas-driven pneumatic controllers as shown below:

*40 CFR 60.5365b(d)(2)-*

(2) For the purposes of §60.5390b, owners and operators may choose to apply reconstruction as defined in §60.15(b) based on the fixed capital cost of the new natural gas-driven pneumatic controllers in accordance with paragraph (d)(2)(i) of this section, or the definition of reconstruction based on the number of existing natural gas-driven pneumatic controllers at the site in accordance with paragraph (d)(2)(ii) of this section. Owners and operators may choose which definition of reconstruction to apply and whether to comply with paragraph (d)(2)(i) or (ii); they do not need to apply both. If owners and operators choose to comply with paragraph (d)(2)(ii) they may demonstrate compliance with §60.15(b)(1) by showing that more than 50 percent of the number of natural gas-driven pneumatic controllers is replaced. That is, if an owner or operator meets the definition of reconstruction through the “number of controllers” criterion in (d)(2)(ii), they will have shown that the “fixed capital cost of the new components exceeds 50 percent of the fixed capital cost that would be required to construct a comparable entirely new facility,” as required in §60.15(b)(1). Therefore, an owner or operator may comply with the remaining provisions of §60.15 that reference “fixed capital cost” through an initial showing that the number of controllers replaced exceeds

50 percent. For purposes of paragraphs (d)(2)(i) and (ii), “commenced” means that an owner or operator has undertaken a continuous program of natural gas-driven pneumatic controller replacement or that an owner or operator has entered into a contractual obligation to undertake and complete, within a reasonable time, a continuous program of natural gas-driven pneumatic controller replacement. Replacement of an individual natural gas-driven controller with a continuous bleed rate greater than 6 scfh with either a natural gas-driven controller with a continuous bleed rate less than 6 scfh or with an intermittent vent natural gas-driven pneumatic controller is excluded from this determination.

If the owner or operator applies the definition of reconstruction in §60.15(b)(1), reconstruction occurs when the fixed capital cost of the new natural gas-driven pneumatic controllers exceeds 50 percent of the fixed capital cost that would be required to replace all the natural gas-driven pneumatic controllers at the site. The “fixed capital cost of the new pneumatic controllers” includes the fixed capital cost of all natural gas-driven pneumatic controllers which are or will be replaced pursuant to all continuous programs of natural gas-driven pneumatic controller replacement which are commenced within any 2-year rolling period following [INSERT DATE OF PUBLICATION OF THE PROPOSED RULE IN THE FEDERAL REGISTER].

If the owner or operator applies the definition of reconstruction based on the percentage of natural gas-driven pneumatic controllers replaced, reconstruction occurs when greater than 50 percent of the natural gas-driven pneumatic controllers at a site are replaced. The percentage includes all pneumatic controllers which are or will be replaced pursuant to all continuous programs of pneumatic controller replacement which are commenced within any 2-year rolling period following [INSERT DATE OF PUBLICATION OF THE PROPOSED RULE IN THE FEDERAL REGISTER]. If an owner or operator determines reconstruction based on the percentage of natural gas-driven pneumatic controllers that are replaced, the owner or operator must also comply with §60.15(a), as well as the notification provisions specified in §60.15(d), and the provisions of §60.15(e) and (f) related to the Administrator’s review.

Commenter (2428-API) asserts that reconstruction for natural gas-driven pneumatic controllers should not include replacement of a high-bleed natural gas-driven controller with a low-bleed or intermittent controller. Replacement of these last remaining high-bleed controllers with low-bleed or intermittent controllers would equate to an overall reduction in methane and VOC emissions and should not be included in the reconstruction provisions as this could disincentivize short-term benefits of this type of replacement. With the implementation of EG OOOOc coinciding with proposed NSPS OOOOb, they state that this clarification will only delay conversion to non-emitting without impacting current investment in equipment upgrades in the near term that provide immediate environmental benefit.

Response II-7-13: To clarify that reconstruction is triggered only when natural gas-driven process controllers are replaced, we have revised the reconstruction provisions of §60.5390b(d)(e) to specify that a modification occurs when the number of natural gas-driven process controllers in the affected facility replaced is 50% or more. As the EGs require for most

sites (i.e., those outside of Alaska and those in Alaska with access to electrical power) that process controllers have zero emissions, these existing sites will be required to replace all high-bleed process controllers on the schedule set out by the EG or the NSPS, if there is a modification or reconstruction of the affected facility. Therefore, the EPA believes any disincentive to act quickly to change out the remaining high-bleed process controllers is outweighed by the impending requirements to do so.

Comment: Commenter (2446-IPAA) notes that the EPA solicits comment on their proposed two-year rolling aggregation period for all continuous programs of pneumatic controller and pneumatic pump replacements. The commenter provides that they support the concept of a fixed two-year aggregation period, but NOT a rolling two-year period. The commenter believes that the administrative burden of keeping-up with a rolling two-year period outweighs the benefits of the approach.

Response II-7-14: The EPA is clarifying in the final rule that the rolling two-year period means a 24-month look-back period. For example, if an owner/operator wishes to replace 10 of 24 natural gas-driven process controllers in April of 2024, the period of time that would need to be considered is the past 24 months, or to April of 2022. If the owner/operator wishes to replace an additional 6 of 24 natural gas-driven process controllers in August of 2025, the period of time that would need to be considered is again the past 24 months, or to August of 2023. In April of 2024, 10 of 24 controllers would be replaced, which would not be considered to be a reconstruction since 10 is less than 50% of 24 controllers will have been replaced. However, in August 2025, if an additional 6 controllers will be replaced, considering the 10 controllers replaced in 2024, 16 of 24 controllers will have been replaced in a 24-month period, and this would be considered to be a reconstruction. As the recordkeeping requirements of the NSPS require records to be kept for 5 years, the EPA has determined that owners/operators will have records available regarding equipment changes over the past 24 months. Therefore, the 24-month look-back period is being promulgated in the final NSPS.

Comment: Commenter (2483-INGAA) states the definition of reconstruction for a pneumatic controller affected facility in proposed 40 CFR 60.5365b(d)(2) does not clearly specify that only the capital costs of natural gas-driven pneumatic controllers being added as replacements are considered when determining if reconstruction of the affected facility has occurred. Similarly, they note that when applying the “number of controllers” criterion in 40 CFR 60.6365b(d)(2)(ii), only the addition of natural gas-driven pneumatic controllers as replacements should be considered. The commenter states that the regulatory text should not provide a disincentive for replacing a majority of pneumatic controllers at a site with zero-emissions pneumatic controllers. If all pneumatic controllers are considered in the reconstruction analysis, then replacing a majority of pneumatic controllers at a facility with zero-emissions controllers would subject the balance of the pneumatic controllers to the zero-emissions requirements under the reconstruction provisions. The commenter provides the following suggested regulation changes (underlined text indicates new text and struck out text indicates deleted text):

(2) For the purposes of §60.5390b, owners and operators may choose to apply reconstruction as defined in §60.15(b) based on the fixed capital cost of the new natural gas-driven pneumatic controllers in accordance with paragraph (d)(2)(i) of this section, or the definition of reconstruction based on the number of pneumatic controllers at the site in accordance with paragraph (d)(2)(ii) of this section. Owners and operators may choose which definition of reconstruction to apply and whether to comply with paragraph (d)(2)(i) or (ii); they do not need to apply both. If owners and operators choose to comply with paragraph (d)(2)(ii) they may demonstrate compliance with §60.15(b)(1) by showing that more than 50 percent of the number of pneumatic controllers is replaced. That is, if an owner or operator meets the definition of reconstruction through the “number of controllers” criterion in (d)(2)(ii), they will have shown that the “fixed capital cost of the new components exceeds 50 percent of the fixed capital cost that would be required to construct a comparable entirely new facility,” as required in §60.15(b)(1). Therefore, an owner or operator may comply with the remaining provisions of §60.15 that reference “fixed capital cost” through an initial showing that the number of controllers replaced exceeds 50 percent. For purposes of paragraphs (d)(2)(i) and (ii), “commenced” means that an owner or operator has undertaken a continuous program of pneumatic controller replacement or that an owner or operator has entered into a contractual obligation to undertake and complete, within a reasonable time, a continuous program of pneumatic controller replacement.

(i) If the owner or operator applies the definition of reconstruction in §60.15(b)(1), reconstruction occurs when the fixed capital cost of the new natural gas-driven pneumatic controllers exceeds 50 percent of the fixed capital cost that would be required to replace all the pneumatic controllers at the site. The “fixed capital cost of the new natural gas-driven pneumatic controllers” includes the fixed capital cost of all pneumatic controllers which are or will be replaced pursuant to all continuous programs of component replacement which are commenced within any 2-year rolling period following [INSERT DATE OF PUBLICATION OF THE PROPOSED RULE IN THE FEDERAL REGISTER]

(ii) If the owner or operator applies the definition of reconstruction based on the percentage of pneumatic controllers replaced, reconstruction occurs when greater than 50 percent of the pneumatic controllers at a site are replaced with natural gas-driven pneumatic controllers. The percentage includes all pneumatic controllers which are or will be replaced pursuant to all continuous programs of pneumatic controller replacement which are commenced within any 2-year rolling period following [INSERT DATE OF PUBLICATION OF THE PROPOSED RULE IN THE FEDERAL REGISTER]. If an owner or operator determines reconstruction based on the percentage of pneumatic controllers that are replaced, the owner or operator must also comply with §60.15(a), as well as the notification provisions specified in § 60.15(d), and the provisions of § 60.15(e) and (f) related to the Administrator’s review.

Response II-7-15: The EPA intends for owners/operators to replace all process controllers with zero-emissions controllers when 50% or more of the controllers are replaced at the site with zero-emissions controllers. As commenters on the November 2021 proposal pointed out, converting a single pneumatic controller to a zero-emitting device typically requires a conversion of all controllers at the facility to zero-emitting devices.<sup>2</sup>

#### ***7.1.4 Affected Facility - Collection of Controllers***

Comment: Commenter (2202-TXOGA) states newly expanded definitions of what constitutes an “affected facility” for pneumatic controllers and pumps increases the scope of EPA’s control over the regulated community, while providing little meaningful emissions reduction. They add that it is also unclear why the definition of “affected facility” for pneumatic controllers has changed from one controller to the collection of all controllers at a site, while just one controller’s presence at a site would make it a “centralized production facility.”

Response II-7-16: As explained in the December 2022 Supplemental Proposal (87 FR 74756) The EPA proposed the change in the affected facility definition based on the consistent recommendation of numerous commenters, particularly commenters from the oil and natural gas industry. Several comments on the November 2021 proposal noted the disconnect between the pneumatic controller affected facility definition (i.e., an individual controller) and the cost analysis, which was based on the replacement of all pneumatic controllers with zero-emitting devices at a site. One commenter pointed out the complexities of tracking and managing the universe of pneumatic controllers at a site when some are affected facilities and others are not and recommended that the EPA propose a simpler and more robust system. Another commenter indicated that defining the affected facility on a site-wide basis aligns with how emissions from pneumatic controllers will likely be handled by owners and operators of oil and natural gas facilities. Another commenter discussed the fact that converting a single pneumatic controller to a zero-emitting device typically requires a conversion of all controllers at the facility to zero-emitting devices.

For the purpose of the fugitive emission standards, the EPA defines a “centralized production facility” based on the presence of major production and processing equipment, and the types of equipment that are major production and processing equipment are listed. The EPA considers natural gas-driven process controllers to be one of several components that are major production and processing equipment. For the sake of clarity in this definition, the EPA specifies the equipment itself rather than using the “affected facility” terminology, but the effect is the same. If a site has only one natural gas-driven process controller, this controller would comprise the entire process controller affected facility. The presence of this affected facility, which is major production and processing equipment, would make the site a “centralized production facility.”

#### ***7.1.5 Affected Facility-Natural Gas-Driven Controllers – Emissions Routed to a Process/Self-Contained Natural-Gas Driven Pneumatic Controllers***

Comment: Commenter (2202-TXOGA) notes that they do not support EPA’s change to the affected facility definition in the December 2022 Supplemental Notice to not exclude natural

---

<sup>2</sup> See Document ID Nos. EPA-HQ-OAR-2021-0317-0808.

gas-driven controllers from which all emissions are collected and routed to a process, as well as self-contained natural gas-driven pneumatic controllers. While such natural gas-driven controllers were excluded from the November 2021 Notice, it is now proposed “to include these types of natural gas-driven controllers because they are driven by natural gas.” The commenter notes that the December 2022 proposal does not explain why additional regulation of such equipment—which assists in the overall improvement of air quality around natural gas facilities—should be required. The commenter states that treating zero-emitting pneumatic controllers and pneumatic pumps as affected facilities will have very little effect on reducing emissions. They added that zero-emitting pneumatics are an example of industry innovation to solve the problem of methane leaks.

Commenters (2227-WEA, 2403-PAO) state that, by treating them as affected facilities, EPA disincentivizes operators to take positive steps to eliminate emissions, and it potentially disincentivizes new technology development. If there were to be a malfunction of a zero-emission pneumatic controller or the gas capture system connected to a pump, the malfunction would be found and subsequently repaired through LDAR. The commenters assert that there is no need to include zero-emissions equipment as affected facilities.

Commenters (2326-AXPC, 2428-API) state that if self-contained natural gas-driven controllers are maintained as affected facilities, given the simplicity and low potential for leaks or defects along the piping, EPA could and should allow increased flexibility in implementation of periodic monitoring along this piece of pipe by incorporating these into the fugitive emission monitoring requirements under 40 CFR 60.5397b instead of adding the provisions that are more relevant for covers and closed vent systems as they pertain to storage vessels in 40 CFR 60.5416b(b). Additionally, they suggest that the EPA also allow inspection of self-contained pneumatic controllers via the alternative screening techniques program when applicable.

Commenter (2399-GPA) states any controllers that are not driven by natural gas (and are, thus, zero emission) should be excluded from the class of applicable facilities. According to the commenter, imposing requirements on sources that do not emit pollutants is unnecessary and beyond EPA’s CAA authority.

Response II-7-17: The EPA has determined that process controllers not driven by natural gas should not be part of the affected facility definition, as by virtue of their operation, they have no potential for emissions of methane or VOC. For process controllers that are driven by natural gas but that have emissions routed to a sales line or a process, there is still the potential for leaks and malfunctions that would result in methane and VOC emissions. There are also requirements for these process controllers to ensure the closed vent systems used to route emissions are functioning without emissions, and there are associated monitoring, recordkeeping, and reporting requirements. Therefore, the EPA is including these process controllers in the affected facility definition.

## 7.1.6 Exemptions

### 7.1.6.1 Temporary Equipment

Comment: Commenter (2433-EDF et al) urges EPA to reject the option of exemption. Temporary equipment moves around and degrades quickly, making it prone to leakage and malfunctions leading to excess venting. As a result, standards for temporary equipment should be at least as stringent as those for permanent installations. One industry commenter noted that an exemption is needed because temporary equipment is often remote, in which case it might be hard to connect to the grid or an onsite control device. Solar panels is a perfectly feasible and cost-effective option.

The commenter (2433-EDF et al) suggests that, if EPA includes an exemption for temporary equipment, it should be at least as protective as the exemption for temporary equipment in Colorado, or more so. That state's Air Quality Control Commission (AQCC) Regulation 7, Part D, Section III.C.4.e<sup>3</sup> allows operators to use controllers that emit natural gas located on temporary or portable equipment that is used (1) for well abandonment activities,<sup>4</sup> (2) prior to or through the end of flowback,<sup>5</sup> (3) for up to 60 days upon notice to the Air Pollution Control Division (APCD)<sup>6</sup>, and (4) for longer than 60 days if the operator submits justification to the Division for continued use at least 14 days before the 60-day period expires.<sup>7</sup> Under this regulation, operators are not permitted to use temporary equipment to increase production or on equipment which would increase the throughput capacity of a facility, as operators should be required to design operations for an increase in production from the start. For use beyond 60 days, the operator may seek an extension from the Division by submitting justification at least 14 days prior to the end of the 60-day period based on certain information.

The commenter (2433-EDF et al) continues to explain that the Colorado regulations also require owners or operators utilizing temporary or portable equipment with pneumatic controllers that emit natural gas to conduct audio, visual and olfactory (AVO) and Approved Instrument Monitoring Method (AIMM) inspections of those controllers on the same schedule as the associated well production facility or compressor station,<sup>8</sup> and to comply with repair, recordkeeping, and reporting requirements.<sup>9</sup>

If EPA decides to include an exemption for temporary equipment (and it should not), the commenter (2433-EDF et al) suggests that it require a similar approach. The commenter states that the EPA should limit any temporary equipment exemption to the activities outlined above, and otherwise enforce a time limit of 30 days. The agency should also require that operators seeking to extend the exemption file a request no later than two weeks before the 30-day limit expires. The request should include the type of equipment being used, the time needed, and the

<sup>3</sup> 5 Colo. Code Regs. § 1001-9-D-III.C.4.e. (2023).

<sup>4</sup> Id. § 1001-9-D-III.C.4.e.(i)(B).

<sup>5</sup> Id. § 1001-9-D-III.C.1.e.(iv)(B).

<sup>6</sup> Id. § 1001-9-D-III.C.4.e.(i)(C).

<sup>7</sup> Id.

<sup>8</sup> Id. § 1001-9-D-III.C.4.e.(i)(C)(2)(a).

<sup>9</sup> Id. § 1001-9-D-II.E.

reasons for the extension request. Finally, the commenter asserts that the EPA be required to review and either approve or reject the extension request before the 30-day limit expires.

Commenters (2383-BH, 2428-API) state retrofitting controllers located on temporary equipment requires significant engineering design that has not been adequately evaluated to identify if these options are even possible, technically achievable, or practically attainable. Commenter (2383-BH) states that an exemption of controllers on temporary equipment is consistent with state regulations in New Mexico and Colorado. The commenter recommends that pneumatic controllers located on temporary or portable equipment be allowed to operate as low-bleed or intermittent as needed for proper functioning of the temporary equipment. The commenter suggests exemptions for:

- Natural gas-driven pneumatic controllers on temporary use equipment that is skid mounted or permanently attached to a platform that is mobile (such as trucks, railcars, barges, or ships) and intended to be located at a site for less than 180 consecutive days,
- Pneumatic controllers associated with drilling and completion equipment.

Commenters (2326-AXPC, 2403-PAO) request that temporary pneumatic controllers be exempt from the proposed requirements. Commenter (2326-AXPC) requests that the EPA clarify that the addition of a temporary pneumatic controller at a site is not a modification of the pneumatic controller affected facility under NSPS OOOOb if the temporary pneumatic controller remains onsite for less than 180 days. The commenter further requests that EPA exempt temporary pneumatic controllers.

Commenter (2326-AXPC) explains that requiring the costly retrofit of an air supply system to accommodate a temporary operating condition is not cost-effective or practical. Second, to route a temporary pneumatic controller to a process would require significant lead time, an engineering analysis, and a facility shutdown. The commenter asserts that this would not be cost-effective for a temporary operating condition. The commenter adds that there is precedent for EPA providing exemptions for other temporary oil and gas equipment, and doing so for pneumatic controllers would be consistent with this precedent. For example, EPA exempts temporary skid-mounted or mobile storage vessels from NSPS OOOOa<sup>10</sup> and provides a similar exemption in NSPS OOOOb and EG OOOOc.

Response II-7-18: In the December 2022 Supplemental Proposal, the EPA requested information related to process controllers on temporary equipment, including specific examples of when temporary equipment is used, the function of the controllers during this time, how they are powered, and the typical duration of their usage. The EPA also requested information explaining in detail why the zero-emission solutions that are used for the permanent equipment at the site cannot be also used for this temporary equipment. Commenters did not provide this type of information, and the EPA does not have other information to justify the use of non-zero-emissions solutions for temporary equipment. Therefore, the final rule has not been revised from

---

<sup>10</sup> 40 CFR 60.5430a (“storage vessel” definition).

the proposal to include an exemption from the process controller standards for temporary equipment.

#### 7.1.6.2 Exemptions Based on Remaining Service Life

Comment: Commenter (2326-AXPC) states EPA does not appropriately consider remaining service life in establishing the non-emitting requirements for existing pneumatic controllers. Based on the normal decline of a well, at some point, natural gas production may decrease below a threshold for which the operator could continue to use natural gas-driven pneumatic controllers. The commenter notes that requiring the expense of replacing or retrofitting pneumatic controllers at a facility that will not use them for a substantial amount of time is not cost-effective. The commenter recommends that the EPA allow exemptions when the remaining service life at the time of the effective date for the requirement is less than 3 years.

Response II-7-19: The EPA notes that the implementing regulations for emission guidelines under CAA 111(d) contained in 40 CFR part 60, subpart Ba include provisions with a process for states to apply a less stringent standard taking into consideration factors such as the remaining useful life of such source. These provisions address applying a less stringent standard due to an unreasonable cost of control resulting from plant age, location, or basic process design. As this provision already exists, and is applicable to development of state plans under EG OOOOc, the EPA has determined that revision to the oil and natural gas emissions guidelines to address the commenter's concerns is not necessary.

#### 7.1.6.3 Emergency Shutdown Devices and Failsafe Safety Applications

Comment: Commenter (2399-GPA) supports the exemption for controllers that act as emergency shutdown devices. However, the commenter requests that EPA clarify that the emergency shutdown device exemption is not limited to those devices at well sites, centralized production facilities, natural gas processing plants, and compressor stations.

Response II-7-20: As natural gas-driven process controllers are only included in an affected facility if they are at a well site, centralized production facility, onshore natural gas processing plant, or a compressor station, any natural gas-driven process controller, including emergency shutdown devices, not at these site types is not part of an affected facility. Process controllers not included in an affected facility are not subject to the rule.

Comment: Commenter (2433-EDF et al) thinks an exemption for emergency shutdown devices (ESDs) is reasonable but urges EPA to include natural gas-driven controllers used for ESDs in the affected facility definition so that EPA can impose specific requirements to ensure that operators only utilize this exemption for these controllers. EPA must then clarify what records must be maintained to allow operators the exemption. The commenter recommends that to utilize this exemption, operators must identify the precise natural gas-driven controllers needed for ESDs in their annual and subsequent reports.

Commenter (2305-Williams) states ESDs and failsafe safety valves serve a vital function at their facilities, and they must have the ability to immediately operate when activated to protect our

employees, the facility and pipeline infrastructure, and neighboring landowners and communities. The commenter asserts that these 2 types of controllers should be exempt from the affected facility definition.

Commenters (2366-BHE, 2483-INGAA) state that ESDs should be exempt. The commenters explain that this is necessary to ensure that an operator's ability to deliver natural gas safely and reliably is not compromised. The commenters also recommend that the final regulation include a pathway where an exemption or alternative can be readily approved. Ideally, this process would result in a class or categorical exemption for a defined application or process. Or it could be allowed on a case-by-case basis to ensure that the final rule does not result in egregious outcomes.

Commenter (2483-INGAA) supports that EPA has exempted ESDs from the requirement to use a zero-emitting electric-driven pneumatic controller. But, the commenter notes that the EPA has defined an ESD as a device that functions "exclusively to protect personnel and/or prevent physical damage to equipment by shutting down equipment or gas flow during unsafe conditions resulting from an unexpected event...." The commenter explains that there are gas-driven pneumatic controllers that serve dual roles: they are used for routine control of operating conditions, and they serve as an ESD. The commenter requests that EPA remove the word "exclusively" from the definition of ESDs and remove the last sentence regarding routine control of operating conditions as follows (struck out text indicates deleted text):

*Emergency shutdown device* means a device which functions ~~exclusively~~ to protect personnel and/or prevent physical damage to equipment by shutting down equipment or gas flow during unsafe conditions resulting from an unexpected event, such as a pipe break or fire. ~~For the purposes of this subpart, an emergency shutdown device is not used for routine control of operating conditions.~~

Alternatively, the commenter (2483-INGAA) suggests that the word "exclusively" could be moved to the last sentence to clarify that pneumatic controllers that are used exclusively for routine control of operating conditions cannot qualify as an ESD. Under this alternate formulation, the definition would read as follows (underlined text indicates new text and struck out text indicates deleted text):

*Emergency shutdown device* means a device which functions ~~exclusively~~ to protect personnel and/or prevent physical damage to equipment by shutting down equipment or gas flow during unsafe conditions resulting from an unexpected event, such as a pipe break or fire. For the purposes of this subpart, an emergency shutdown device is not used exclusively for routine control of operating conditions.

Response II-7-21: The EPA proposed and is finalizing an exemption from the process controller requirements for process controllers that are ESDs. These devices are designed to minimize the consequences of emergency situations and will only emit in certain isolated circumstances, such as if a well must be shut in. A large change in pressure is required to actuate an ESD, which may not be deliverable in a sufficient time by a compressed air or electric controller. In addition, if power is lost, these devices must still be able to function. It is rare that ESDs are activated, and

their emissions impact is minimal, but their functional need is necessary and critical to safe operations. Since it is not technically feasible to require zero-emissions options or to require emissions controls for these devices, the EPA determined it was best to exempt them from the rule by not including them in the affected facility definition. The EPA made this determination with the consideration that devices that function only as ESDs will seldom activate and have few emissions. As this is not the case for process controllers that are used for routine operations, it was not the intention of the EPA to exclude such process controller from the rule requirements, and we have not revised the final rule in the manner suggested. In such cases, owners/operators could add a process controller such that one functions as an ESD and the other performs normal operations. For ESDs, which have few emissions and no emissions control or monitoring requirements, the EPA considered that the limited benefit of keeping records of these devices would be outweighed by the recordkeeping burden imposed. Therefore, no recordkeeping requirements have been added to the final rule.

Comment: Commenter (2483-INGAA) states failsafe safety applications should be exempt and recommends that EPA include the following addition to 40 CFR 60.5430b and 60.5425c:

*Failsafe safety application* means a device which functions to protect personnel and/or prevent physical damage to equipment. For the purposes of this subpart, a failsafe safety application is not used exclusively for routine control of operating conditions.

The commenter (2483-INGAA) explains that intermittent pneumatic controllers, such as those used for failsafe safety applications only contribute approximately 0.4 percent of the total methane emissions for the transmission and storage segment and <0.01 percent of total methane emissions from natural gas operations. Providing an exemption for the failsafe application (e.g., where the worker and monitor valve pneumatic controller emissions are a subset of intermittent pneumatic controllers) results in emissions that are extraordinarily small, comprising less than 0.01 percent of transmission and storage segment emissions and far less than 0.001 percent of total methane emissions. Because these controllers are needed to ensure system safety and because emissions from these controllers are infinitesimal, providing a functional exemption for failsafe safety applications is warranted.

For background, the commenter (2483-INGAA) offers the following:

Control valves are used to limit pressure delivered into a system with a lower pressure rating (e.g., a compressor station process, a lower pressure pipeline, etc.). Without an extremely reliable system to protect against overpressure, facilities are at greater risk of damage, overpressure, flow interruption, and potentially even pipe ruptures. These control valves are commonly referred to as “worker” and “monitor” valves, where the worker valve provides primary pressure control, and the monitor valve provides backup to ensure “failsafe” functionality. The primary worker valve can be zero-emission (e.g., electric, air system), but a different energy source is needed for the backup monitor valve. Because high pressure gas is always available when these valves need to function (i.e., the valve is controlling gas pressure), natural gas pneumatic controllers are the only failsafe source.

These valves also must comply with PHMSA [Pipeline and Hazardous Materials Safety Administration] regulations, specifically 49 C.F.R. §192.195. That regulation requires operators to ensure that a pressure control failure or some other type of failure cannot cause both the worker valve and the monitor valve to fail to function.<sup>11</sup> Thus, the same type of system (e.g., pneumatic air, solar power, electricity, etc.) should not be used to operate both a worker and monitor valve. Doing so would put the operator and general public at risk of pipeline over pressurization when the power source fails. Because the condition managed (i.e., pipeline pressure) ensures that high pressure natural gas is always available to actuate the monitor valve, using natural gas pneumatic controllers on the monitor valve provides failsafe assurance that is not provided by other options and assures conformance with PHMSA requirements.

Evaluation of actuation by an INGAA member showed that while the worker valve may function frequently, the monitor valve actuates rarely, so the emissions implications of retaining a natural gas pneumatic for the monitor valve are inconsequential. Evaluation over a five-month period showed only one actuation of the monitor valve. For this system (i.e., two valves that may require actuation), using a zero-emission controller for the worker valve and a natural gas pneumatic for the monitor valve showed that system emissions were reduced by over 99% compared to a system that uses natural gas drive pneumatics for both controllers.

Response II-7-22: In the situation described by the commenter, in which a controller is used to protect personnel and/or prevent physical damage to equipment, the final definition of “emergency shutdown device” or “ESD” would apply. This definition, as shown below, includes stopping the flow of gas (e.g., via a failsafe device) during unsafe conditions.

*Emergency shutdown device* means a device which functions exclusively to protect personnel and/or prevent physical damage to equipment by shutting down equipment or gas flow during unsafe conditions resulting from an unexpected event, such as a pipe break or fire. For the purposes of this subpart, an emergency shutdown device is not used for routine control of operating conditions.

As the “emergency shutdown device” definition would include failsafe devices (that stop the flow of gas), if they are used exclusively for the purpose of protecting personnel and/or to prevent physical damage to equipment and are not used for routine control of operations, we have not revised the rule to otherwise address failsafe devices. The EPA excluded ESDs from the rule requirements with the consideration that devices that function only as ESDs will seldom activate and have few emissions. As this is not the case for process controllers that are used for routine operations, it was not the intention of the EPA to exclude such process controllers from the rule requirements, and we have not revised the final rule to exclude failsafe devices that are also used for control of routine operations. In such cases, owners/operators could add a process controller such that one functions as an ESD and the other performs normal operations.

---

<sup>11</sup> 49 CFR 192.195(a) (requiring compliance with 49 CFR 192.199 and 192.201).

### **7.1.7 Other**

Comment: Commenter (2351-Jonah Energy) states that the proposed definition for an affected facility, "is defined as the collection of all the natural gas-driven pneumatic controllers at a well site, centralized production facility ... or compressor station."

- Operational considerations for natural gas-driven pneumatic controllers differ in both function and location. Not all pneumatic controllers are created equal. A 'one size fits all' definition does not account for all the varied uses of pneumatic controllers. Gas-actuated controllers used to regulate temperature (e.g., T-12s) do not function the same or actuate as often as gas-actuated devices that regulate dump or flow control. This may have not been taken into consideration during EPA's BSER analyses and needs to be accounted for.
- Many gas-actuated controllers do not operate 8,760 hours per year as they only operate during colder weather months when certain process equipment is necessary for winterization purposes and gas supply during the off-season is shut off minimizing the opportunity for leaks. This may have not been taken into consideration during EPA's BSER analyses and needs to be accounted for.

Response II-7-23: In the BSER analysis, the EPA used the information available regarding controller emissions. These values are averages determined from the study of many controllers, which would have included controllers used for different purposes, such as temperature and flow control. The EPA has assumed that controllers operate throughout the year, as information regarding the average annual use of controllers is not available. However, as the costs for some zero-emitting options are well below the costs at which the EPA has determined costs are reasonable considering the emissions reductions that would be achieved, the BSER determination would not change even if the controllers were not operating during winter months.

## **7.2 NSPS OOOOb and EG OOOOc BSER Control Options**

### **7.2.1 General Support/Opposition of Proposed BSER**

Comment: Several commenters (1581-Kathairos, 1609-Qnergy, 2163-Federated Hermes, 2164-Nordea, 2184-SRC Ambassador, 2190-M/H Investments, 2191-Boston Trust, 2199- RM Farmers Union, 2203-Ceres, 2206- L&G Investment, 2212-UCS, 2303-NTAA, 2347-Clarke, 2348-EWTC, 2410-CA AG et al, 2433-EDF et al) provide general support for EPA's proposed standards. Examples of some of these comments are provided below.

Commenters (1611-ELPC, 1649-Sisters of St. Francis, 2152-CALSTRS, 2156-CCGD, 2163-FHL, 2164-NA Management, 2184-LF, 2185-NY CRF, 2190-MHI, 2191-BTWC, 2199-RMFU, 2203-Ceres, 2206-LGIMA, 2209-PLS, 2212-UCS, 2236-PSR, 2242-SGI, 2285-Bailard, 2287-ICCR, 2348-EWTC, 2352-ETRPC, 2388-ExxonMobil, 2394-Earthworks, 2424-AYS, 2441-HAWC, 2459-Global Asset Management, 2461-CRS, 2766-1000 Grandmothers) express support for phasing out of polluting pneumatic controllers in favor of zero-emitting alternatives. Commenter (2388-ExxonMobil) supports devices being granted limited exemptions where technical or safety limitations exist.

Commenter (2347-Clarke) supports EPA’s proposal to require all new and existing pneumatic controllers at production, processing, transmission, and storage facilities (except certain sites in Alaska) to have zero methane and VOC emissions. The commenter notes that the EPA’s own Natural Gas STAR publications as far back as 2006 and 2011, among others, demonstrate a recognition that it is relatively cost-effective and extremely beneficial in terms of substantially reducing methane emissions to take this step. More recent reports and statements from the oil and gas industry itself, such as the following, corroborate that this is a worthwhile and achievable step.

Commenter (2433-EDF et al) also supports EPA’s proposed standards for pneumatic controllers. The standards acknowledge the variety of cost-effective zero-emitting technologies that are available to operators and give operators more than sufficient time to retrofit existing sites. In supplementary comments, commenter (3820-EDF et al and 3841-EDF et al) provided information from the implementation of process controller regulations in Colorado showing that zero-emissions options are being used there to comply with the regulations. Commenter (2303-NTAA) is pleased to see that EPA maintained the zero-emitting pneumatic equipment requirements for pneumatic controllers and expanded this requirement to include pneumatic pumps.

Response II-7-24: These comments are supportive comments on aspects of the December 2022 Supplemental Proposal that have remained unchanged in the final rule; as such, no response is required.

Comment: Commenter (2227-WEA) states VOC emissions are an especially focused issue because the Uintah and Ouray Indian Reservation area is an ozone non-attainment area. The commenter disagrees, however, that the EPA mandating zero-emissions controllers is necessary or required here and provided reasoning in the proposed Federal Implementation Plan (FIP) for requiring low-bleed pneumatic controllers rather than zero-emissions pneumatic controllers. According to the commenter, it is inappropriate for EPA, on a nationwide basis, to go above and beyond requirements deemed to be sufficient for an ozone nonattainment area.

Response II-7-25: The EPA performed analyses in determining the “best system of emissions reduction” (BSER), which is the degree of emission limitation that has been adequately demonstrated, taking into account the cost of achieving the emissions reduction and any nonair quality health and environmental impact and energy requirements. The BSER is not based on the emissions reductions necessary to reach NAAQS attainment status. For process controllers, zero-emissions was found to represent the BSER, and this is reflected in the NSPS and EG.

### ***7.2.2 Access to Reliable Electricity***

Comment: Commenter (2433-EDF et al) states that first, operators have incorrectly suggested that the feasibility of the zero-emission standard is somehow dependent on the availability of grid connection. The commenter notes that grid connection, however, does not present a barrier to widespread deployment of zero-emitting controllers. In instances where operators do not have access to the grid or grid access is cost prohibitive, the commenter states that the proposed regulation is flexible and provides operators a number of commercially available and cost-

effective options to achieve the standard. Operators that cannot access grid electricity can still use electric or instrument air systems powered by solar energy or can use natural gas-driven controllers that are self-contained or routed to a process, all of which, as discussed, are cost-effective and feasible across the U.S. Accordingly, the commenter notes that the availability of grid connection has no bearing on the reasonableness of EPA's standards.

Second, the commenter (2433-EDF et al) notes that operators have suggested that compliance with the zero-emission standard is infeasible at sites requiring large electricity demand. However, for sites that are already connected, using that connection to power electronic controllers is cost-effective across-the-board, including at sites with high demand. The Analysis Group report shows, for example, that all zero-emitting technologies at extra-large sites using 2,000 kilowatts (kW) are cost effective even when including the cost of electricity.

Response II-7-26: These comments are supportive comments on aspects of the December 2022 Supplemental Proposal that have remained unchanged in the final rule; as such, no response is required.

Comment: Several commenters report that access/reliable access to electricity is an issue. Specific comments provided are included in the following paragraphs.

Commenter (2177-Southern Ute Indian Tribe) states that due to lack of power in many remote locations, the installation of power may be cost-prohibitive, and installation of combustion-generated power may create more emissions than are being reduced. They note that construction projects on Tribal lands require permitting through the National Environmental Policy Act (NEPA) program, which can be extensive and burdensome.

A subsidiary of the commenter (2178-Riverside Energy Carbon Solutions, LLC (RCS)), Riverside Energy Michigan LLC (REM), is the largest producer of natural gas in the state of Michigan. REM operates over 5,000 Antrim shale natural gas wells. These wells are in predominantly rural areas, and access to power is not readily available. More than half of these wells employ an intermittent bleed controller to operate the lift system. Among other undesirable requirements being proposed, requiring replacement of these control valves to be zero-emitting, consistent with current proposed BSER, would be completely unreasonable. Running power to thousands of wells across hundreds of miles of forest would certainly not meet the reasonableness threshold of \$1,970/ton methane emissions reduced or less. From the commenter's own measurements, these controllers vent less than 0.003 metric tons of methane per year on average.

Commenter (2227-WEA) reports that in much of the Uinta Basin, approximately 90 percent of the pneumatic controllers in use are more than a mile from reliable electricity transmission lines, 80 percent are more than 2 miles, and 70 percent are more than 3 miles.

Commenter (2321-AED) states that the EPA's new requirement that equipment must be powered by electricity poses serious challenges to rural oil and natural gas fields that will not have easy access to electric power.

Commenters (2314-Miller Energy Company) and (2200-NuEnergy) state that to transition field equipment onto electrical power sources poses serious challenges in their rural field operations. Many rural locations do not have access to electric power. Additionally, solar power has been tried without success, and solar options are not viable nor reliable throughout Michigan's seasonal weather conditions. The number of solar-qualified days is drastically reduced in Michigan compared to other states. The commenter (2314-Miller Energy Company) has tried implementing various technology (such as tank sensors) powered by solar, and even the vendors have discouraged use based on the number of cloudy days and snow buildup.

Commenter (2314-Miller Energy Company) states that while some equipment may not require a reliable power source, many do. Power outages could cause serious environmental and safety concerns if equipment goes down unexpectedly. The proposed rules need to reflect the reality of access to alternative power sources and offer exceptions when reliable electricity is not viable.

Additionally, commenter (2314-Miller Energy Company) prides themselves at recycling their field-gas waste stream by reusing it to power their field equipment. Should the commenter be required to only use electricity, their emissions would increase as they would need to flare or vent all field fuel not used by their equipment. Plus, additional electrical energy would be consumed that would not have otherwise been needed. The commenter requests the EPA consider removing the universal requirement to use electricity as the sole power source.

Commenter (2399-GPA) states EPA should limit application to facilities with reliable access to grid power. The commenter recommends that to be "readily available" would mean that there is a nearby, operating electricity supply line with sufficient capacity for the site and would not require significant new construction by a third-party provider, such as a new tie-in or the installation of additional substations. With respect to "reliable access to electricity," the commenter recommends that this mean that a power source is not subject to frequent intermittent power losses (brownouts), as continuous power is necessary for safe, reliable operations.

Commenter (2283-Endeavor Energy) notes that many well sites in the Midland Basin are located in remote locations without access to an existing grid. Even if a grid is theoretically accessible, the commenter states that it is not always logistically feasible to connect to that grid due to issues outside of an owner or operator's control.

Commenter (2251-NAM) suggests that retrofitting of all pneumatic controllers where the site has less than 15 controllers and lacks operational access to reliable grid power is unwise. The commenter provides that, just because a local electric utility has a distribution transmission line in the same zip code does not mean that the natural gas production facility is "grid reliant". They add that this provision of the proposed rule might inadvertently make some U.S. oil and natural gas production less economically viable since the producer would have to electrify that location before it is completely known whether the natural gas meets current market value. This issue especially hurts smaller producers (often small businesses) in rural Texas, New Mexico, and North Dakota where these locations are often rural. They go on to say that the proposed requirement also presumes an abundance of electric distribution transformer equipment to install. They note, however, that there is a shortage of electric distribution transformers, and it takes approximately 45-60 months to obtain new distribution transformers. According to the

commenter, imposing new pneumatic controller requirements means electrification of many rural areas that currently do not have electricity. They contend that, given the national transformer shortage, this is not practical or wise.

Other commenters also express that weather conditions can affect access and reliability of electricity delivery. Specific comments include:

- Commenter (2248-NDPC) states harsh weather conditions often interrupt electricity delivery or redirect power demands.
- Commenter (2220-WDEQ) states there are significant concerns that using electricity to power pneumatics in such remote parts of Wyoming is not viable. The frequent frigid temperatures in the wintertime throughout the State would not allow for sufficient battery performance and operators have also raised concerns that solar technologies are not viable to implement, nor reliable enough, to provide sufficient electrical power for their site operations in the wintertime.

Commenter (3838-API) provided information regarding the number of sites without access to electrical power. Based on the results from a survey of its members, the commenter remarked that 72% of production sites, representing 59% of natural gas-driven controllers for that segment, lack access to electricity. In the gathering and boosting segment, 44% of sites representing 40% of controllers lack access to electricity. The commenter added that the transmission and storage segment had more than 99% of sites with access to electrical power. The commenter stated that due to limited access to electrical power, the EPA should reconsider BSER for pneumatic controllers, especially at existing sites.

Response II-7-27: The EPA notes that “access to electrical power” is defined as, “*Access to electrical power* means commercial line power is available onsite, with sufficient capacity to support the required power loading of onsite equipment, and which provides reliable and consistent power.” Although only sites in Alaska might be affected by this definition, as all other sites must have zero emissions from process controllers, the definition makes it clear that electrical power would already need to be onsite for the owner/operator to be considered to have access to electrical power.

The EPA understands that sites with process controllers may not have access to electrical power. There are several options available to such sites to meet the NSPS and EG. These include the use of solar-powered process controllers, the use of electric process controllers powered by a generator, the use of compressed air-driven process controllers powered by a generator, and routing emissions to a process. The EPA also notes that solar-powered process controller systems include batteries that are typically sized to contain a 10-day power supply, and this battery power ensures continuous process controller operations.

The EPA also understands that permitting actions may be required when adding or changing equipment at a facility. However, such permitting is not directly required by this rulemaking and is outside the scope of this action.

Comment: Several commenters specifically highlight infrastructure issues that impact access to reliable electricity. Specific comments are provided in the following paragraphs.

Commenter (2227-WEA) notes there are several reasons why electrification is not always an option for oil and natural gas operations. The commenter explains that integration of renewables into oil and natural gas production must include sufficient planning to cover those times when renewable resources are not available. Utility providers do not prioritize the implementation of infrastructure for oil and gas sites because it is uneconomic for them to do so when they can deploy the same resources to a new subdivision and generate much more revenue. Sparsely populated areas in the west can be significantly lacking in electrical power supply, let alone reliable electrical power supply, and the challenges to expand the availability of the electrical grid can be daunting. Even more developed yet rural areas can be substantially limited in access to a reliable electrical power supply. Even where electrical infrastructure has been developed, sufficient transmission capacity often does not exist. Finding and building infrastructure to which to connect can be a challenge. Transmission lines must go through a series of steps starting with an electricity substation and follow-on steps to transform the high voltage transmission power to a useable source of electricity at the oil and natural gas site. Lack of nearby access to transmission substations adds to the remote nature of some upstream oil and natural gas sites. The commenter adds that going through the engineering, permitting, and construction process of developing the infrastructure to transform the limited high voltage electricity to oil and natural gas useable levels can be prohibitive in some cases to the implementation of electricity as an option as well as time consuming and expensive.

Commenter (2251-NAM) notes that just because a local electric utility has a distribution transmission line in the same zip code does not mean that the natural gas production facility is “grid reliant”.

Commenters (2283-Endeavor Energy, 2301-U.S. CoC) note that there are challenges including (but not limited to) right-of-way issues for placement of power lines, a landowner's right to not install power lines on their property, and/or distance from an available power line that contains sufficient power and capacity to connect the facility. For those well sites that happen to be in proximity to a grid, or where it might be technically feasible to connect them to a grid, current electricity generation in many producing regions (such as the Midland Basin) will not be adequate to accommodate EPA's proposed requirements while also balancing competing load demands. Commenter (2283-Endeavor Energy) suggests that, at the very least, EPA should remove any requirements from EG OOOOc that would require onsite electrification for compliance as it would not be technically feasible and would stress the electric infrastructure.

Response II-7-28: As explained above in Response II-7-37, the EPA notes that “access to electrical power” is defined as, “*Access to electrical power* means commercial line power is available onsite, with sufficient capacity to support the required power loading of onsite equipment, and which provides reliable and consistent power.” Although only sites in Alaska might be affected by this definition, as all other sites must have zero emissions from process controllers, the definition makes it clear that electrical power would already need to be onsite for the owner/operator to be considered to have access to electrical power.

In addition, sites are not required to use electrical power from the grid. There are several other options available to such sites to meet the NSPS and EG. These include the use of solar-powered process controllers, the use of electric process controllers powered by a generator, the use of compressed air-driven process controllers powered by a generator, and routing emissions to a process.

Comment: Commenter (2227-WEA) states that power interruption brings the risk of sending control equipment into “a fail-safe condition.” According to the commenter, being dependent upon the reliability of electricity can be especially risky in rural areas. Relying on renewable energy such as solar or wind power typically involves some manner of backup generation. The intermittent nature of renewable energy requires companies to have backup electricity for those times that renewables are not available. The commenter asserts that solely relying on the intermittent nature of renewables is not an option for oil and natural gas operations since they require power on a full-time basis. The commenter adds that the need for emissions- generating backup can significantly affect the economic feasibility of using renewables.<sup>12</sup> Backup power is most likely to come in the form of onsite generation, which is discouraged by regulation in some regions, or the local power grid.

Response II-7-29: Where an owner/operator is concerned about the reliability of electricity, solar power, or wind power, there are other options available for compliance with the process controller requirements. The owner/operator can use a generator to power either electric controllers or compressed air-driven controllers, use nitrogen canisters to provide compressed air, or route emissions to a process. The EPA is not aware of any situations where a generator of the size needed to power process controllers at a site would not be allowed by regulators.

Comment: Commenter (2220-WDEQ) states that Wyoming is dedicated to protecting the Greater Sage-Grouse, which lives in the sagebrush steppes of our State. Wyoming has devoted significant resources over the years towards developing a conservation plan for this species. The commenter explains that one of the important safeguards for this species is protection of its core habitat areas. According to the commenter, the level of electrical infrastructure needed to meet the requirements for pneumatics in the supplemental proposal would have potential impacts on portions of the Greater Sage-Grouse’s core habitat, as well as issues pertaining to deer and antelope migration corridors, and other species that inhabit Wyoming’s lands.

Response II-7-30: As explained above in Response II-7-37, the EPA notes that “access to electrical power” is defined as, “*Access to electrical power* means commercial line power is available onsite, with sufficient capacity to support the required power loading of onsite equipment, and which provides reliable and consistent power.” Although only sites in Alaska might be affected by this definition, as all other sites must have zero emissions from process controllers, the definition makes it clear that electrical power would already need to be onsite for the owner/operator to be considered to have access to electrical power. Therefore, the EPA does

<sup>12</sup> “New Mexico Methane Advisory Panel Technical Report,” New Mexico Environment Department (NMED) and New Mexico Energy, Minerals and Natural Resources Department, 2019.

Note: This report was generated as a collaboration between NGOs, industry, and the state. It is not an official position document of NMED.

not expect there to be expansion of electrical infrastructure to meet the requirements for process controllers.

Comment: Commenter (2399-GPA) states that, despite the importance of access to reliable grid power, the proposed EG OOOOc does not recognize the clear distinction between existing facilities and truly new facilities, which have some flexibility in where they will be sited, and existing sources that do not. To address existing sources' lack of flexibility, the commenter proposes that EG OOOOc requirements be subject to a site-specific technical and cost effectiveness review for connecting to the power grid or using onsite power generation, such as solar power or natural gas- or diesel-fired generator. It would also consider the costs of conversion, such as the installation of additional instrument air headers and piping. This type of review would be similar to the review for pneumatic pumps. If the review determines that these options are either technically infeasible or not cost-effective (e.g., more than \$5,540 per ton of VOC or \$1,970 per ton of methane), then the owner or operator should be permitted to use natural gas-driving continuous low-bleed and intermittent-bleed controllers.

Response II-7-31: In the analyses performed in determining the BSER, the costs of installation of equipment at an existing site were included. For some equipment types, such as compressed air systems, these costs were assumed to be higher at existing sites than new sites due to the need to work around and with the configuration of existing equipment. With consideration of these costs, the EPA still found that zero-emissions represents the BSER at existing sites and that the costs are reasonable considering the emissions reductions that will be achieved.

Comment: Commenter (2283-Endeavor Energy) notes that, because access to reliable electricity may be a problem for existing sources, they suggest that the EPA remove the pneumatic controller and pump requirements for existing sources, or at the very least consider the effects that its proposed requirements would have on the grid infrastructure, and at the very least analyze these costs before finalizing any requirements.

Response II-7-32: As explained above in Response II-7-37, the EPA notes that "access to electrical power" is defined as, "*Access to electrical power* means commercial line power is available onsite, with sufficient capacity to support the required power loading of onsite equipment, and which provides reliable and consistent power." Although only sites in Alaska might be affected by this definition, as all other sites must have zero emissions from process controllers, the definition makes it clear that electrical power would already need to be onsite for the owner/operator to be considered to have access to electrical power. Therefore, the EPA does not expect there to be expansion of electrical infrastructure to meet the requirements for process controllers or for the electrical grid to be impacted by the process controller requirements.

In addition, if an owner/operator is concerned about the reliability of electricity, solar power, or wind power, there are other options available for compliance with the process controller requirements. Such options include the use of a generator to power either electric controllers or compressed air-driven controllers, use of nitrogen canisters to provide compressed air, or routing emissions to a process.

### 7.2.3 Solar

Comment: Several commenters expressed concerns over the limitations to the use of solar driven pneumatic controllers. Specific comments are provided in the following paragraphs.

Commenter (2227-WEA) states that solar controllers are limited by the availability of sunlight, average ambient temperature, and the prevalence of fog or dust, making them unreliable. In areas like the Uinta Basin, where fog can sit for several weeks, cold weather can also hamper the use of battery power for backup.

Commenter (2399-GPA) reports that the Carbon Limits report focuses on the reliability of solar power systems in colder climates, not areas with limited sun exposure. As a result, the commenter points out that the Carbon Limits study does not address the reliability of solar-powered systems in areas with limited sun exposure, such as West Virginia, or in canyons and mountain valleys.<sup>13</sup> [Discussed further below.]

Commenter (1609-Qnergy) has observed that the intermittency and sensitivity to weather conditions of solar generation, in addition to low availability during the winter, especially in high latitudes, limit adoption. The commenter has installed more than a hundred instrument air units in Alberta and British Columbia, which meet the relevant zero emission requirements. However, despite many attempts, solar generation have not seen a broad adoption in Canada. The commenter itself has considered commercializing a solar solution for small sites and concluded that it is applicable only for powering single controllers but not as a broad instrument air solution.

Commenter (2321-AED) reports that solar alternatives are not reliable in Michigan weather conditions, which could cause a serious problem at a well site if equipment goes down. The commenter states that the proposed rules need to reflect this reality and offer exceptions to this requirement when reliable electricity is not viable.

The commenter (2321-AED) is also concerned that the necessary resources for potential work to achieve compliance will not be available in terms of manpower and battery equipment additions. The commenter provides that it has been a struggle to get work accomplished in the field and the commenter is afraid of how much work they will need to do and who is going to do it when it needs to be done.

Commenter (2399-GPA) note that, regarding the snow covering of solar panels, EPA did not attempt to calculate how much sun exposure is diminished by vertical placement, whether this could also prevent ice accumulation, how much power generation would be diminished through snowpack, or whether solar panels could work with any placement in areas prone to blizzards and other serious winter weather.

Commenter (2428-API) states that snowfall is prevalent at its facility and will reduce efficiency of the optimally angled panels. According to the commenter, vertically oriented arrays to prevent snowfall interference may not be appropriate in all circumstances given the climate, wind, and

---

<sup>13</sup> EPA has properly recognized this as an issue by proposing to exempt Alaska from this requirement.

remote nature of these sites. Commenter (2351-Jonah Energy) recommends that the EPA consider that a redundant system would be required in some instances due to time periods where solar power generation would not be sufficient to satisfy power requirements to production facility operations. The commenter explains that solar panels can be covered with snow and ice or there could be periods of cloudy weather where solar power generation is not sufficient to keep batteries charged enough to supply the amount of power necessary to run operations. Reliability is incredibly important as failure of devices may lead to serious safety and environmental incidents. Absent line power, diesel-fired generators and/or natural gas-fired generators are required to be used as a source of power when solar-powered/battery systems are not operable. The commenter notes that they operate in a basin subject to ozone formation and therefore trading one pollutant for another pollutant may negatively impact the local airshed.

Response II-7-33: Commenters contend that solar power is not a feasible option to use for controllers at some sites. Considering that the electrical power needed by each controller is low,<sup>14</sup> the EPA expects that a solar power system could be sized with the appropriate number of panels and batteries to power process controllers at most, if not all, sites. However, the use of solar power is not required, and an owner or operator may choose not to use solar power for any reason. Another option determined to be cost-effective at all sites was the use of a generator to power electric process controllers, and the use of a generator to power a compressed air system was cost-effective at larger sites. Other options available to meet the zero-emissions standard at sites without grid power and without using solar power include self-contained process controllers, or routing emissions from controllers to a process, although costs were not evaluated for these two options.

Comment: Commenter (2399-GPA) states the Carbon Limits report authors relied on interviews with three technology providers and two oil and gas companies, without making any inquiry into whether the technologies could be applied to midstream gathering and boosting operations, which have a larger footprint and substantially greater power needs. The economic models supporting cost-effectiveness are also based on only three well pad site configurations, which are not comparable to gathering and boosting stations that require more powerful air compressors to generate instrument air at 400 standard cubic feet or more. The commenter argues that the EPA should not force the industry-wide adoption of technologies based on only 22 cases of adoption over three countries, which is too small of a sample to support a determination that these technologies are technically feasible and cost-effective nationwide and in so many varying applications. The commenter adds that EPA also lacks experience with the operational use of solar-powered controllers on the scale being considered, and that the agency's reliance on the Canadian provinces of Alberta and British Columbia as examples of successful adoption of non-emitting controller regulations is misleading.

The commenter (2399-GPA) adds that nothing in the December 2022 proposal or the Carbon Limits report addresses the fact that reliance on solar power leaves sites subject to the weather and could be effectively shut down for days. The commenter reports that power loss at a midstream site can disrupt the entire upstream and downstream supply chain and raises

---

<sup>14</sup> Estimate of 0.08 amps/controller in Carbon Limits. (2016) Zero emission technologies for pneumatic controllers in the USA - Applicability and cost effectiveness.

environmental consequences such as additional emissions and the need to flare or vent gas if downstream equipment is not available.

Response II-7-34: While using solar power to provide energy for process controllers is one option available for compliance with the NSPS or EG, the use of solar power is not required. Information provided in a supplemental comment<sup>15</sup> indicates that over half of U.S. gathering and boosting site have access to electrical power, and that the average number of process controllers at gathering and boosting sites without access to electrical power is 17. In our analyses for BSER, we estimated the costs of a generator to power electrical process controllers at a site with 20 controllers and found that the costs were reasonable, considering the emissions reductions that would be achieved from 20 process controllers. Other options include the use of a generator to power a compressed air system, the use of canisters of compressed nitrogen to power controllers, using self-contained controllers, or routing controller emissions to a process.

Comment: Commenter (2428-API) reports that the land requirement for the use of solar for many sites is likely to be between 0.6 – 1.5 acres. Key considerations to consider when installing solar panels at existing well sites that hinder the compatibility include:

- Site area footprints have already been agreed to and installing large arrays will require revisiting existing agreements to modify, a time-consuming and costly process. Many jurisdictions, including the BLM, prefer smaller facility footprints.
- Site layout is already optimized for existing infrastructure to fit within a facility area. Adding in solar infrastructure of panels, wiring, battery, etc. could lead to complications and unnecessary safety hazards as batteries are introduced near hydrocarbons.

The commenter (2428-API) urges EPA to also consider other factors including:

- the cost of land acquisition; right-of-way and easement concerns/limitations; projection of further land-use change requirements for solar installations; and
- percent of further land use change required for solar installations on designated wetlands.

Response II-7-35: If an owner/operator chooses to use a solar system to power the process controllers on site, only enough energy needs to be generated to power the process controllers, not all the operations at the site. As the average power needed per controller is approximately 1 watt, a 140-watt solar panel is capable of powering several process controllers. In addition, solar panels can be vertically stacked on stands so they take up less space. Due to the relatively few solar panels needed to power process controllers and the space-saving solutions available, the EPA does not anticipate land use or infrastructure problems associated with the use of solar systems.

#### ***7.2.4 Electric Controllers***

Comment: Commenter (2383-BH) states a power failure in a singular electrical source could cause failures in any valves drawing from that power supply, including potentially both the

---

<sup>15</sup> API – AXPC Supplemental Comment to EPA Regarding Pneumatics.

primary and backup valves in a single station. The commenter also states that in the absence of backup power supplies, electric actuators could be designed to close in the event of a power loss, but this goes against traditional design philosophy for gas pipelines/distributors in the U.S., where the goal in the past has been to avoid shutting off the gas supply in any but the most extreme circumstances.

Response II-7-36: There are many options available to owner/operators for compliance with the process controller standards. We note that emergency shutdown devices (ESDs) are not included in the process controller affected source definition and are not subject to the process controller requirements. If an owner/operator chooses to use electric process controllers and is concerned about power failures, an ESD could be installed to protect personnel and/or prevent physical damage to equipment. Other options include using generators, which are assumed to be reliable power sources, to power compressed air systems or electric controllers, using nitrogen canisters to power process controllers, using self-contained process controllers, or routing process controller emissions to a process.

Comment: Commenter (2383-BH) states electric actuators on the market today are not intended for continuous use and may not be suitable for applications where continuous modulation is required (pneumatic actuators are suitable for this service).

Commenter (2227-WEA) states electrical controllers can generally only be used to control valves. So even in situations where electricity is available, often it won't be sufficient to reliably keep the entire facility operating safely.

Commenter (2399-GPA) states electric controllers tend to have inadequate duty cycle ratings and their torque ratings are typically too low for reliable performance. This significantly limits the utility of electrically actuated controllers. Even if they performed comparably to gas-powered actuators, electrically actuated controllers have a higher failure rate, especially for throttle service where the actuator is constantly adjusting based on process conditions to maintain a set point.

Response II-7-37: The EPA notes that a wide range of electrical controllers are on the market today, which have addressed the limitations of previously available electrical process controllers. However, the use of electrical controllers is not required for compliance with the standards, and an owner/operator may choose another option, such as the use of a compressed air system or nitrogen canisters to power pneumatic controllers.

Comment: Commenter (2399-GPA) reports that a controller failure is a serious concern for midstream operations, which have significant unmanned facilities. Hence, they report that any repair requires sending personnel out to those facilities that are frequently found in remote locations. The commenter states controller failures can result in overpressure events, releasing far more methane than that saved by electrically actuated controllers.

Commenter (2248-NDPC) explains that reconfiguring the way controllers operate using drivers such as electricity and instrument air introduces increased reliability issues. With electricity, the harsh weather conditions often interrupt electricity delivery or redirect power demands. They add

that, with instrument air, additional equipment, an air compressor, is required and compressor failures will interrupt delivery of instrument air.

Response II-7-38: The EPA has no information to suggest that electrically actuated controllers have failures more often than pneumatic controllers. In contrast, the information available to the EPA suggests that electronic systems are more reliable than gas-driven pneumatic control systems. According to one report, operation of gas-driven systems with even slightly wet gas can lead to condensation issues, which over time will impact the performance of the system.<sup>16</sup> This report also indicated there can be corrosion issues with sour gas used for pneumatic controllers and pumps. The EPA also has no information, nor does the commenter provide any information, to suggest that air compressor failures are common or present an issue for the operation of site equipment.

### **7.2.5 Generators**

Comment: Several commenters (2177-Southern Ute Indian Tribe, 2220-WDEQ, 2252-PAW, 2305-Williams) indicate that secondary criteria emissions from the use of gas-fired generators/combustion devices may occur.

Commenter (2220-WDEQ) states even though gas-powered generators would have to undertake state permitting process, their operation nevertheless could result in increased cumulative nitrogen oxide (NO<sub>x</sub>) and VOC emissions. Gas-powered generators would run at all times as opposed to the intermittent function of pneumatics that periodically vent emissions, which is problematic for marginal ozone nonattainment areas such as Upper Green River Basin (UGRB).

Commenter (2252-PAW) states diesel- and natural gas-fired combustion would generate criteria pollutant emissions and other hazardous air pollutants (HAP). Some companies in Wyoming operate in an ozone non-attainment area and therefore trading one pollutant for another pollutant may negatively impact the local airshed and prevent the region from re-attaining ozone attainment status. Therefore, the commenter suggests diesel-fired generators and/or natural gas-fired generators should be expected to be used as a source of power when solar-powered/battery systems are not operable and line power is not available as an option.

Commenter (2177-Southern Ute Indian Tribe) states there is not an environmental benefit in increasing overall emissions to reduce the potential of methane emissions from pneumatic equipment. Due to the difficulties in getting infrastructure projects approved through the NEPA process on Tribal lands it is likely that the regulations would result in many small natural gas-fired engines being installed. This has the possibility to effect other regional pollutants, such as ozone, and need to be taken into consideration.

Commenter (2305-Williams) states that these generators will also have secondary emissions impacts greater than what the EPA has provided in the December 2022 supplemental proposal for a 200-brake horsepower (bhp) unit.

---

<sup>16</sup> Carbon Limits. Zero Emission Technologies for Pneumatic Controllers in the USA. Applicability and Cost Effectiveness. August 1, 2016.

Response II-7-39: Generators, which produce power by burning a fuel, such as natural gas or diesel, will generate a small amount of emissions from this process. As we assumed some sites would choose to install an electric generator to power compressed air-driven or electrical process controllers, we estimated the emissions that would be created by such generators. For this analysis, we included natural gas generators of 5 to 10 horsepower, which should be sufficient sizes to accommodate 4 to 100 process controllers. We estimate that a natural gas-powered generator would produce between 0.006 and 0.025 tons of VOC and between 0.15 and 0.6 tons of NO<sub>x</sub> per year, depending on the number of controllers and the size of the generator needed to power the controllers. However, the emissions reduced through the use of zero-emission process controllers powered by such generators would range from 1.7 to 41. Tons of VOC and 6 and 150 tons of methane per year. Therefore, we found the emissions created by generators to be relatively small and are outweighed by the emissions reductions that would be reduced from the process controllers.

Comment: Commenter (2399-GPA) states both diesel- and gas-fired generators should be allowed. The commenter urges EPA to confirm in the final rule as it recognized in the November that diesel- and natural gas-fired generators may be used to supply onsite power for instrument air systems or other electrical source needs (e.g., electric valves, pumps, heat tracing, etc.). Although natural gas-fired generators are more commonly used, operators need flexibility in choosing which fuel source provides the more reliable and safer power generating option for the specific location. Issues affecting diesel- versus natural gas-fueled generators may include horsepower requirements, fuel quality, site elevation, access to fuel, available space for installation (diesel fuel requires additional storage vessel(s) for onsite fuel storage), etc.

Response II-7-40: The final rule does not include any restrictions for generators used at any oil and natural gas sites.

Comment: Commenter (1609-Qnergy) notes that EPA states the following:

The EPA recognizes that if owners and operators elect to comply by installing and operating a generator, there will be secondary emissions generated from the fuel combustion. However, we also point out that, for a site with 100 controllers (a size cited by the commenter requiring a large instrument air system), these secondary emissions would represent approximately a 77 percent decrease in CO<sub>2</sub> equivalent emissions and a 96 percent decrease in VOC emissions from a site with 25 low bleed and 75 intermittent bleed controllers.<sup>17</sup>

The commenter (1609-Qnergy) believes that the EPA's values are too conservative. They provide that a 100-controller site, as mentioned in the EPA example, will consume nearly 12 standard cubic feet per minute (scfm) of instrument air. The commenter adds that the instrument air system will abate about 126 tons per year (tpy) of methane. The commenter states that the abatement efficiency is 99 percent or higher, and the emissions are 10-30 tons of CO<sub>2</sub>-equivalent (tCO<sub>2e</sub>) per year and the abatement 120 tons of methane, which is equivalent to nearly four thousand tCO<sub>2e</sub> per year.

---

<sup>17</sup> See Proposed Rule.

Response II-7-41: We agree with the commenter that the abatement in CO<sub>2</sub>-equivalent emissions is over 99% when zero-emissions controllers are used and powered by a natural gas-fired generator. As detailed in the final TSD, for a 100-controller site in the production segment, the EPA's estimate of methane emissions is approximately 150 tons per year. This is based on the number of low-bleed and intermittent vent process controllers expected at the site, the emission factors for those process controllers, and the proportion of natural gas that is methane for the production segment. We assume 100% of these emissions would be reduced with zero-emissions process controllers. Using a methane global warming potential of 25 times that of CO<sub>2</sub>, the CO<sub>2</sub>e is 3,750 tons of emissions reduced through zero-emitting controllers. The EPA estimated the global warming potential of GHG emissions from a 20 HP compressor at 23 tons CO<sub>2</sub>e. The resulting CO<sub>2</sub>e saved is approximately 3,727 tons, which is over a 99% reduction.

### ***7.2.6 Instrument/Compressed Air Systems***

Comment: Commenter (1609-Qnergy) requests EPA to clarify explicitly that instrument air systems with zero methane emissions in the power generation stage are considered BSER for pneumatic controller applications.

Response II-7-42: The EPA confirms that process controllers powered by instrument air and that do not use natural gas to drive the process controller or its valves are considered the BSER. Any air compressors or generators used to power process controllers are not part of the process controller affected facility and are not regulated by the process controller requirements.

Comment: Commenter (2258-MSD) explains that 40 CFR 60.5365b(d) excludes pneumatic controllers from applicability only if they function as emergency shutdown devices or are not powered by natural gas. EPA then goes on to suggest operators meet the "zero emissions" standard by utilizing alternatives such as compressed air or electrically-driven devices powered by line power or solar. The are concerned that no option is provided to allow the operator to conduct a study to demonstrate the feasibility of these alternatives. The commenter recommends excluding devices which cannot operate on compressed air due to safety concerns that the potential introduction of air to the gas stream may create. The commenter also suggests allowing evaluation of technical and economic feasibility of these options.

Response II-7-43: As many sites throughout the states of Colorado and New Mexico as well as sties in the Canadian provinces of Alberta and British Columbia have successfully switched to using zero-emitting process controllers, the EPA has determined that there are technically feasible zero-emitting options that have been adequately demonstrated. The EPA also performed analyses of the costs for several zero-emissions options and determined that the costs of several available options to achieve zero emissions from process controllers are reasonable, considering the emissions reductions that would be achieved. Therefore, with consideration of both the technical and economic feasibility of zero-emissions process controllers, the EPA determined that zero-emissions represents the BSER, and this reflected in the NSPS and EG.

Comment: Commenter (2428-API) notes that during construction, an instrument air header and compressor skid must be added to the facility. The air compressors must sit outside of classified areas and therefore, some older reclaimed facilities may not have adequate space to add

necessary equipment for the instrument air system because the air compressor must be placed outside of a safe radius from existing flares and other hydrocarbon-containing equipment (e.g., limitations due to electrical classifications). If accessible grid power is not available, a generator would have to be installed to power the air compressor, which would emit other pollutants.

Commenters (2428-API, 2227-WEA) note that existing well site sites, central production facilities or compressor stations may have sizing constraints for the proper placement (due to safety and other permitting constraints) of instrument air control systems. Examples include an instrument air compressor that must sit outside of classified areas, generators, and/or or solar panels. To retrofit a facility with an instrument air system, an engineer first verifies that adequate power is available and then applies for necessary state level permits, which takes approximately 60 days to acquire (if approved). On federal lands, this type of project would require reopening permits pursuant to NEPA, which is around a 12 to 18 month permitting process. On private lands, an operator may not be able to purchase additional land from the private owner.

Response II-7-44: Air compressors and generators of the size needed to power process controllers are generally not large systems that require much space. However, it may be possible in some limited instances that owners/operators of existing sites wishing to use a compressed air system may need to move equipment or buy or lease more space to accommodate the new system. In such instances, owner/operators may choose to make these accommodations or may choose to use another of the several compliance methods available.

### ***7.2.7 Self Contained/Route to Process***

Comment: Commenter (2211-Lambda Energy) states zero bleed devices are impractical in many situations in northern climates such as Michigan, with limited electric service and diminished solar power due to indirect sunlight and snow cover in Winter. In such situations, the zero-bleed devices are an unnecessary and ineffective requirement that is not justified by the marginal potential benefits. The commenter notes that, where zero bleed devices are used, the proposed increased monitoring is duplicative and unnecessary, since by design the zero bleed devices do not allow emissions. The commenter recommends that the EPA consider retrofitting pneumatic devices to non-emitting devices as a reasonable alternative to a new technology (zero bleed) not widely used or available in this industry, and with unknown effectiveness, costs, or availability.

Response II-7-45: As zero-emitting process controllers was determined to be the BSER, the NSPS and EG reflect this determination. The EPA notes that process controllers that are not powered by natural gas are not included in the affected facility definition and the final rule does not require owner/operators to perform recordkeeping or reporting for them. In addition, owner/operators may comply with the EG for existing sources by converting natural gas-driven pneumatic process controllers to compressed air or nitrogen-driven controllers. Other options available for compliance include the use of electrical controllers, self-contained controllers, or controllers routed to a process.

Comment: Commenter (2326-AXPC) states that current requirements do not articulate repair or contain delay of repair provisions or timelines. The commenter explains that self-contained pneumatic controllers would more commonly occur on pressure control valves, where the

operator would likely need to shut-in the well or shutdown equipment to conduct any sort of repair (if any were found). The commenter suggests that repair timelines in 40 CFR 60.5397b(h) and specifically the delay of repair provisions as described in 40 CFR 60.5397b(h)(3) apply to self-contained natural gas-driven pneumatic controllers. Commenter (2428-API) provides similar comments.

Response II-7-46: Delay of repair provisions are more appropriate for equipment that can still function with the potential for only small amounts of emissions until repairs can be made. For self-contained process controllers that are not operating as designed or if emissions are not directed, as designed, into downstream piping, repairs to the equipment should be made as soon as possible. For process controllers that are found to be leaking through a fugitive emissions survey, the repair and delay of repair provisions would apply.

Comment: Commenter (2399-GPA) suggests that the EPA incorrectly assumes no emissions would be associated with routing pneumatic controller emissions to a process. The commenter provides that the compressor would result in direct emissions from a gas-fired engine driver or in indirect emissions from an electric driver. Either way, they report that air emissions would be created to capture these pneumatic streams and send them to a process stream.

Response II-7-47: The EPA recognizes that if owners/operators comply by installing and operating a generator, there will be secondary emissions generated from the fuel combustion. However, as there would be no direct emissions from the process controllers themselves, they are referred to as zero-emissions controllers.

Comment: Commenter (2326-AXPC) notes that while it is feasible for operators to route pneumatic controller vents to a downstream process that operates at a lower pressure, a vapor recovery unit (VRU) is necessary if no such lower-pressure destination exists or is of limited availability. They report that the installation of a VRU is capital intensive, and VRU maintenance is costly and challenging, especially in extreme weather climates. Further, as production declines, the commenter notes that there may be insufficient low-pressure gas to keep VRU systems online, leaving pneumatic controller vent gas with no downstream process destination. Where downstream process pressure exceeds vent gas pressure, the commenter states that pneumatic controller vent gas cannot feasibly be routed to a downstream process without compression.

Commenter (2177-Southern Ute Indian Tribe) states that routing vapors to a process likely requires some kind of compression to increase the pressure of the vapors from near atmospheric, to something higher than the pressure of the process they are being introduced into. In many instances they report that this will require additional equipment to be installed, resulting in an increase in facility emissions, and should be taken into consideration when requiring these types of controls.

Response II-7-48: The EPA recognizes that the use of a VRU is likely necessary for process controller vent gas to be introduced to a downstream process. We have accounted for the costs of a VRU in our analyses of the control options available as well as the emissions that would be produced from the electricity used to power a VRU.

Comment: Commenter (2391-Chesapeake Energy) supports routing pneumatic controllers to an existing process where that is an available, technologically feasible, and cost-effective option, and requests that EPA maintain routing to control as an option.

Response II-7-49: The EPA has retained routing controller emissions to a process as a zero-emissions option in the final rule.

Comment: Commenter (2383-BH) asserts that pneumatic controllers/positioners that capture natural gas, either for reinjection into the pipeline or for use by ancillary equipment, should not be restricted. Such systems may require a provision whereby they may be allowed to bleed gas to maintain function when conditions do not allow gas to be reinjected into the pipeline, though reasonable guidelines/limitations may be applied here.

Response II-7-50: For natural gas-driven process controllers routed to a process or a pipeline to have zero emissions, they must continuously have all emissions routed to that process or pipeline and not have emissions to the atmosphere. Therefore, the EPA is not including provisions in the final rule to include bleeding of natural gas to the atmosphere at any time.

Comment: Commenter (2433-EDF et al) agrees that it is reasonable to include natural gas-driven routed to a process and self-contained controllers under the proposed standards. Though grid-powered, solar, and instrument air controllers are all readily available and cost effective, and operators can replace their fleets within EPA's proposed timeline using non-natural gas-driven alternatives, they believe that allowing routed and self-contained controllers provides operators with more technological flexibility. If EPA does permit the use of these controllers, they assert that it must (as it has proposed) apply protective leak monitoring requirements. Specifically, they state that EPA should ensure that natural gas-driven controllers (even if self-contained or routed to a process) are inspected quarterly with optical gas imaging (OGI) cameras (or the equivalent alternative).

Response II-7-51: The final rule includes provisions for the monitoring of leaks from natural gas-driven process controllers. For self-contained process controllers and for the closed vent system for controllers with emissions routed to a process, initial and quarterly monitoring is required using OGI or EPA Method 21.

### ***7.2.8 Route to Control***

Comment: Several commenters provide insights on industry practices related to routing emissions from pneumatic controllers to a control device. Examples of specific comments received are provided in the following paragraphs.

Commenter (2227-WEA) states mechanical controllers are not reliable and can't be used in higher pressure implementations, and therefore, in situations where control devices and flares are adequate at reducing methane emissions by 95 percent, routing to control should be allowed.

Commenter (2247-OH EPA) notes that many operators today route emissions from some pneumatic bleed controls to existing processes or to the flare for control. The commenter states

that the requirement for all controllers to be zero bleed seems too strict when the existing controls are almost equivalent.

Commenter (2248-NDPC) states that routing to control can reduce the emission by at least 95+ percent and can be achieved with fewer supply chain issues. The commenter provides that Colorado and New Mexico have taken this approach, and it seems reasonable.

Commenter (2258-MSD) reports that many of its member companies currently utilize existing control technologies to reduce pneumatic vent emissions. The commenter notes that the proposed regulation allows 95 percent control as an option for other source categories. In the case of site modifications, they contend that it may not be feasible to route pneumatic vents to existing processes; therefore, some new beneficial process may need to be installed, potentially with the risk of adding new emissions. Also, considering the difference in volume between pneumatic sources and others, such as storage vessels, 95 percent control of pneumatic venting should be considered. According to the commenter, this option is also critical for existing pneumatic devices that, as noted above, are currently controlled. They conclude by saying that requiring a zero-emission standard for units already controlled by 95 percent or more requires the same capital and annual investment, but with little additional emission reduction over the baseline.

Commenter (2326-AXPC) notes that the EPA conservatively assumes a control device will achieve only 95 percent reduction. In many cases, the commenter provides that the actual performance of a control device exceeds 98 percent control. The commenter asserts that the EPA's analysis fails to account for the cost-effectiveness of the incremental 5 percent of methane and VOC emissions reductions achieved when comparing routing to process against routing to a control device. Commenter (2428-API) provides similar comments.

Commenter (2446-IPAA) contends that the EPA's exclusion of routing to control contradicts Subpart W and is misleading, mischaracterized, and inaccurate, at best AND willfully exaggerates emissions from pneumatic devices with clear undertones of a political agenda, at worst. In Subpart W, the commenter states that the EPA acknowledges that historical greenhouse gas (GHG) inventories, including those from the 2021 GHG Inventory (GHGI) for 2019 emissions, are significantly overstated. The commenter provides that emissions are overstated by approximately 35 percent at least and over 90 percent or more at most for intermittent-bleed pneumatic devices, which represent most of the pneumatic devices in operation within the petroleum and natural gas system segments today. As such, a 5 percent difference in emission reduction by allowing the use of existing or new control devices is hardly a "significant increase" and they believe should absolutely be an acceptable alternative BSER.

Commenter (2326-AXPC) proposes that, if EPA is unwilling to allow routing of pneumatic controller vent gas to a control device as an emissions reduction standard on the same footing as routing to a process, EPA should allow routing to a control device where routing to a process is infeasible (taking into account technical and economic considerations), and define infeasibility to include scenarios where routing to a process requires a VRU. Also, they propose that an operator need not install a control device for the sole purpose of complying with the pneumatic controller standards if there are less than four individual natural gas-driven pneumatic controllers that emit or may emit vent gas to atmosphere.

Commenter (2403-PAO) reports that, in many situations, onsite control devices exist that would be a cost-effective solution. The commenter provides that the EPA has requirements for control devices to obtain a 95 percent reduction in methane and VOCs emissions. Even, according to the commenter, EPA acknowledges that this is a viable option to achieve emission reductions from natural gas-driven pneumatic controllers.

Commenter (2391-Chesapeake Energy) states that they invested heavily in reducing methane emissions from controllers and in many instances, routing to controls was not only the most cost-effective means of capturing emissions but the only feasible option. They report that, in some cases where both routing to process and routing to control are possible, the distance between pneumatic devices and process units makes this option infeasible or cost prohibitive. Even if it were possible to route emissions over longer distances to a process unit, they suggest that this would increase the risk of leaks along the way. In these cases, physically shorter routes reduce the chance for leaks that might completely offset the marginal benefit of routing emissions to a process unit rather than to a control device.

Response II-7-52: We evaluated the use of control devices achieving 95 percent control in our analyses for the December 2022 Supplemental Proposal, and this control option was determined not to be the BSER and was not used to develop the process controller standards for the NSPS or the presumptive standards for the EG. For the final rule, the EPA refreshed its analysis of the costs and emissions reductions associated with the identified emissions reductions options, which included using updated emissions factors and cost information for emission reduction techniques and technologies. Zero emissions from process controllers was shown in both the analyses conducted for the December 2022 Supplemental Proposal and the refreshed analysis conducted for the final rule to be technically achievable and cost-effective at all model plant configurations through several available options, including the use of electrical controllers powered by electricity from the grid, solar power systems, and generators. Other zero-emissions process controller options are available that are technically achievable and cost-effective for some sites include, but are not limited to, pneumatic controllers powered by compressed air using electricity from the grid, electric generators, or compressed nitrogen canisters; routing controller emissions to a process; and using self-contained process controllers. Since all of these options achieve a rate of zero methane and VOC emissions, compared to an emission rate of up to 5 percent of the baseline emissions through the use of a control device, we have not changed our determination that a zero-emissions option is the best system of emissions reductions. However, when developing state plans for the implementation of the EG for existing sources, States have the ability to apply a less stringent standard in accordance with 40 CFR 60.24a(c) when “Other factors specific to the facility (or class of facilities) that make application of a less stringent standard or final compliance time significantly more reasonable.” If a state can demonstrate that the costs necessary for a particular source or class of sources, such those with emissions already controlled by 95 percent or greater, to switch to a zero emissions option is not reasonable considering the emissions reduction that would be achieved, the state could apply an alternate standard for such sources.

### ***7.2.9 Nitrogen-Powered Controllers***

Comment: Commenter (1581-Kathairos) reports that their nitrogen-powered controller system solution for pneumatics can be quickly scaled across industry. They provide the following as support:

- The commenter has a contractual agreement with U.S.-based Chart Industries, a leading manufacturer of cryogenic industrial gas products. Chart Industries has the capacity to produce thousands of specialized nitrogen tanks every month and can scale up as needed (they did this with oxygen tanks during the COVID-19 pandemic).
- No supply chain concerns: the system has few parts, and all tanks are manufactured in the U.S.
- Nitrogen supply is readily available, with air separation facilities located in oil and gas producing regions across the U.S. With air being the main feedstock, there are no concerns of supply issues or price fluctuation.
- Simple tie-ins, tanks can be installed and tied-in in half a day.
- Nitrogen distribution networks are already being established in the Marcellus (WV, PA, OH), Permian (TX, NM), D-J (CO), Haynesville (LA, TX) and Bakken (ND) basins (see Appendix B of their comment letter).

The commenter also states the use of nitrogen in their nitrogen-powered controller systems provides a highly simple and reliable solution to eliminating the practice of routine methane venting. They provide the following as support:

- Nitrogen systems require no on-site power, relying solely on thermodynamics.
- No grid connection or solar set up is necessary, only road access is required.
- Nitrogen systems can convert all pneumatic devices simultaneously, as all devices are tied into a single nitrogen tank.
- No need to replace existing pneumatic devices; the nitrogen system simply ties in to existing systems, replacing methane for instrument power.
- With level sensors and on-site telemetry units, nitrogen systems provide extremely accurate data on methane mitigated. Given that it's a closed loop system, by tracking nitrogen consumption and applying a gas equivalence ratio, we can determine exactly how much methane otherwise would have been emitted. All this data is tracked in real-time and uploaded to the commenter's cloud-based portal for producers to use for compliance and reporting purposes.

Response II-7-53: Although the EPA did not specifically include the use of nitrogen canisters as a zero-emissions option in our BSER analyses due to a lack of nation-wide availability, we acknowledge that it is a technically feasible option and may be cost-effective for some sites to use for powering pneumatic process controllers.

### ***7.2.10 Regional Area Considerations***

Comment: Several commenters (2220-WDEQ, 2225-WESTAR, 2227-WEA, 2297-Petro-Vest, 2483-INGAA, Others) specifically point out regional rural infrastructure and weather considerations as impacting access to reliable electricity.

Commenter (2225-WESTAR) states there are oil and gas facility locations in Montana, Wyoming, and North Dakota that are extremely remote, that do not have access to electrical power, and experience extreme temperature shifts that make certain technology like solar and/or batteries infeasible.

Commenter (2227-WEA) expresses that regionally differing economic, operational, and development parameters in the lower 48 states, just as with Alaska, play a key role in the resulting economic impacts that oil and natural gas rules create, including revenue and costs, and the feasibility of the implementation of proposed rules such as NSPS OOOOb and EG OOOOc. EPA's publication describes a framework where all gas-driven pneumatic controllers would be eliminated from new and existing sources, except for those controllers in Alaska where electricity and solar power is not available. At the facilities in Alaska, low-bleed pneumatics would be required. The commenter believes that the EPA has not adequately demonstrated the reasoning for the equivalent criteria not being extended to the lower 48 states. The comments notes that the EPA's reasoning is particularly perplexing given the availability of existing reliable electric power throughout the Alaskan oil fields required to operate well sites in cold temperatures and dark conditions.

Commenter (2220-WDEQ) states Wyoming requests the same exemption as provided to pneumatic controller designated facilities located at a site in Alaska. The commenter provides that the EPA's rationale for providing such an exemption is that there are facilities in Alaska that do not have access to electrical power due to Alaska's remote geography and the infeasibility of solar or other options. The commenter explains that Wyoming's geography and climate are similarly remote in many parts of the state and operators run into the same infeasibilities as in Alaska. According to the commenter, it is unfair for EPA to provide such an exemption specifically for sites in one state when there are other states that face essentially the exact same challenges. The commenter also requests that EPA consider the harsh winter conditions in Wyoming with regards to how it poses compliance timing challenges in certain instances. They explain that there are potential situations where the frigid winter temperatures might not allow certain sites to perform required compliance duties within a 30-day period because the temperatures are so cold that it would require an operator to shut in a well in order to undertake compliance activities. Put simply, they assert that a "one-size-fits-all" rule does not account for these meteorological or geographical challenges and EPA should take this into consideration when revising the supplemental proposal.

Commenter (2483-INGAA) states EPA believes that are no sites outside of Alaska where it is infeasible to (1) have electric controllers powered by the grid or by solar power; (2) have instrument air systems powered by the grid, a generator, or by solar power; and (3) collect the emissions and route them to a process (i.e., have self-contained controllers). The commenter provides that, if that is the case, then allowing the exemption more broadly does not cause any

harm because the alternative standard would never come into play. In contrast, the commenter states that providing the exemption provides protection against a situation where none of the identified methods will work. They suggest the following proposed regulatory text change for 40 CFR 60.5390b(b) and 60.5394c(b) (struckout language indicates deleted text):

(b) For each pneumatic controller designated facility located at a site ~~in Alaska~~ that does not have access to electrical power, you may comply with either paragraphs (b)(1) and (2) of this section or with paragraph (b)(3) of this section, as an alternative to complying with paragraph (a) of this section.

Response II-7-54: One reason the exemption from the zero-emissions standard was provided for process controllers in Alaska at sites without access to electrical power is that solar panels are less likely to be able to provide the necessary power generation due to the hours of darkness that occur in the fall and winter months owing to Alaska's northern latitudes. The use of solar panels to power process controllers is one of the options the EPA found was technically feasible and cost-effective at most sites; however, the EPA does not believe solar panels could feasibly be used to power process controllers at most sites in Alaska. The EPA also recognized that most sites in Alaska have access to electrical power and will be able to comply with the zero-emissions standards through the use of electrical controllers or grid-powered compressed air systems and did not expect the exemption to be widely available to sites there.

The NSPS and EG are required by the CAA to be based on the BSER. In the BSER analysis conducted for the December 2022 Supplemental Proposal and in the refreshed analysis conducted for the final rule, zero emissions from process controllers was shown to be technically achievable and cost-effective at all model plant configurations (outside of Alaska) through several available options, including the use of electrical controllers powered by electricity from the grid, solar power systems, and generators. As such, the EPA determined that zero-emissions represents the BSER and is the basis for the requirements of the NSPS and EG. In addition, other zero-emissions process controller options are available that are technically achievable and cost-effective for some sites include, but are not limited to, pneumatic controllers powered by compressed air using electricity from the grid, electric generators, or compressed nitrogen canisters; routing controller emissions to a process; and using self-contained process controllers.

Comment: Commenters (2326-AXPC, 2353-CrownQuest) express that the EPA has not completed a comprehensive analysis of which locations, basins, and portions of basins can timely and adequately obtain line power. The commenter recommends that the EPA exempt sites from the zero-emitting requirements (as it did for Alaska) after requiring a demonstration that line power cannot be obtained or cannot be obtained timely based on technical, safety and economic considerations.

Commenter (2446-IPAA) recommends that EPA allow operators of affected facilities to perform their own cost-effectiveness evaluations specific to their equipment, geographic location, and other unique operational complexities. The commenter mentions that the problem is acknowledged for Alaska-based sites, but the same issues of remoteness can affect almost every basin in which domestic production occurs.

Commenter (2177-Southern Ute Indian Tribe) states all exemptions for facilities located in Alaska should be allowable for any facilities that can demonstrate that the exemption is appropriate.

Response II-7-55: The EPA understands that sites with process controllers may not have access to electrical power. There are several options available to such sites to meet the NSPS and EG. These include, but are not limited to, the use of solar-powered process controllers, the use of electric process controllers powered by a generator, the use of compressed air-driven process controllers powered by a generator, and routing emissions to a process.

As explained above in Response II-7-73, one reason the exemption from the zero-emissions standard was provided for process controllers in Alaska at sites without access to electrical power is that solar panels are less likely to be able to provide the necessary power generation due to the hours of darkness that occur in the fall and winter months owing to Alaska's northern latitudes. The use of solar panels to power process controllers is one of the options the EPA found was technically feasible and cost-effective at most sites; however, the EPA does not believe solar panels could feasibly be used to power process controllers at most sites in Alaska. The EPA also recognized that most sites in Alaska have access to electrical power and will be able to comply with the zero-emissions standards through the use of electrical controllers or grid-powered compressed air systems and did not expect the exemption to be widely available to sites there.

In the BSER analysis conducted for the December 2022 Supplemental Proposal and in the refreshed analysis conducted for the final rule, zero emissions from process controllers was shown to be technically achievable and cost-effective at all model plant configurations (outside of Alaska) through several available options, including the use of electrical controllers powered by electricity from the grid, solar power systems, and generators. As such, the EPA determined that zero-emissions represents the BSER and is the basis for the requirements of the NSPS and EG. As the EPA has already determined through this analysis that there are technically feasible zero-emissions options for all sites with electricity and those without electricity located outside of Alaska, additional analyses performed by others for individual sites is not necessary.

#### ***7.2.11 Intermittent Vent Controllers***

Comment: Commenter (2351-Jonah Energy) states that, in the Technical Support Document (TSD), EPA uses a 0.29 standard cubic feet (scf)/hour (hr) emission factor for a normally functioning intermittent-bleed pneumatic device. The commenter notes that this would suggest that the focus should be on malfunctioning intermittent-bleed pneumatics, rather than all pneumatics since a normally functioning pneumatic device has minimal emissions. As the commenter already conducts monthly LDAR inspections and a minimum of quarterly LDAR inspections at their production facilities, they find and repair the malfunctioning devices within 24 hours if possible and in a much shorter duration than the annual basis that EPA assumes in the 8.8 scf/hr intermittent-bleed emission factor. The commenter suggests that a more robust LDAR program to identify and repair malfunctioning intermittent-bleed pneumatics should be proposed, rather than including the malfunctioning pneumatic devices in the intermittent-bleed emission factor.

The commenter (2351-Jonah Energy) notes that the EPA acknowledges that a robust monitoring and repair program can achieve the same benefits of reduced emissions for intermittent-bleed pneumatics. The commenter states that they have such a robust monitoring and repair program in place. They assert that the EPA should not penalize companies that have such a robust monitoring and repair program currently implemented by mandating an expensive facility upgrade program that would result in minimal emission reductions. The commenter recommends EPA allow for the option to implement a robust monitoring and repair program to capture malfunctioning pneumatic devices that would serve the same purpose.

The commenter (2351-Jonah Energy) provides that through their United Nations Environment Programme's (UNEP) Oil and Gas Methane Partnership 2.0 (OGMP 2.0) measurement campaign, they have collected 72 separate measurement readings from intermittent-bleed pneumatic device vents at 24 of our production facility locations in the Jonah Field during various times of the year. The average from their measurement readings resulted in a 0.55 set/hr/device. [They provide a chart of their measurement data in a chart in their comment letter.] They noted that their 0.55 set/hr/device is consistent with EPA's 0.29 scf/hr emission factor for a normally functioning intermittent-bleed device and provides further support that EPA should not base their cost-benefit analysis on an 8.8 scf/hr intermittent-bleed emission factor that includes malfunctioning devices as that will skew the benefit to cost ratio. [Comment letter includes a Figure showing the average scf/hr/device for 24 intermittent-bleed pneumatic device vents]

Commenter (2252-PAW) notes that the EPA uses a 0.29 scf/hr emission factor for a normally functioning intermittent-bleed pneumatic device. The commenter states that this would suggest that the focus should be on malfunctioning intermittent-bleed pneumatics, rather than all pneumatics, since a normally functioning pneumatic device has minimal emissions. The commenter recommends that the EPA allow for a LDAR program to identify and repair malfunctioning intermittent-bleed pneumatics, rather than including the malfunctioning pneumatic devices in the intermittent-bleed emission factor.

Commenter (2446-IPAA) states that the EPA utilizes inaccurate data to justify “zero-emitting” BSER for pneumatic controllers. The commenter reports that concurrent with the EPA’s NSPS OOOOb and EG OOOOc proposal, EPA proposed revisions to the current Greenhouse Gas Reporting Program (GHGRP) requirements. The commenter states that the GHGRP data used as a basis for EPA’s NSPS OOOOb and EG OOOOc proposal overstates methane emissions for intermittent controllers by as much as 96 percent. To demonstrate how GHG emissions from intermittent-bleed pneumatic devices are significantly overstated by the current GHGRP subpart W rules versus proposed GHGRP revisions, the commenter includes a Table in their comment letter [pdf pages 26 through 28 of their comment letter] that presents comparisons of methane emissions associated with intermittent-bleed pneumatic devices as determined by the current GHGRP "Eq. W-1" versus the proposed GHGRP "Eq. W-1A" versus the proposed GHGRP "Eq. W-1B" using member's operations and actual voluntary LDAR program results. Based on the comparisons, current GHGRP requirements ("Eq. W-1") overstate methane emissions associated with intermittent-bleed pneumatic devices by approximately 35 percent compared to proposed GHGRP alternative 1 ("Eq. W-1A") and by approximately 96 percent compared to proposed GHGRP alternative 2 ("Eq. W-1B"). If the same 1 percent leak rate was assumed AND quarterly LDAR surveys were performed, such that all leak durations were 2,190 hours vs. the default of

8,760 hours, the commenter reports that the GHG emissions would be overstated by approximately 97.4 percent when using proposed GHGRP alternative 2 ("Eq. W-1B").

Response II-7-56: The EPA agrees that a more robust LDAR program applied nationwide would likely reduce emissions from intermittent vent process controllers. However, the NSPS and EG are required by the CAA to reflect the degree of emission limitation achievable through the application of the best system emission reduction that has been adequately demonstrated, considering the cost of achieving such reduction and any non-air quality health and environmental impact and energy requirements. While a more robust LDAR program is one method to reduce emissions nationwide from process controllers, such a program would not impact continuous bleed controllers and would not reduce emissions from intermittent vent controllers to the degree that other options available are capable of achieving. The EPA found in its BSER analysis that there are several zero-emissions process controller options available for which the costs are reasonable, considering the emissions reductions that would be achieved and other impacts resulting from the use of those options. For this reason, the EPA found that zero-emissions process controllers is the BSER, rather than other options resulting in lesser degrees of emission reductions, including enhanced LDAR program for intermittent vent controllers. We note that in our refreshed BSER analysis conducted for the final rule, the most up-to-date emissions factors were used, which included those used in the final GHGRP revisions.

Comment: Commenter (2180-PA DEP) supports EPA's proposal to require all new and existing pneumatic controllers, including intermittent vent pneumatic controllers, to produce zero methane and VOC emissions.

Response II-7-57: This comment is a supportive comment on an aspect of the December 2022 Supplemental Proposal that has remained unchanged in the final rule; as such, no response is required.

Comment: Commenter (2383-BH) states that should the EPA choose to adopt the zero-emission threshold, they recommend that pneumatic controllers/positioners be allowed as long as they do not bleed continuously at steady state, and bleed to atmosphere be allowed only if the valve is in motion.

Commenter (2211-Lambda Energy) reports that they utilize intermittent bleed devices that rarely activate as the existing marginal wells produce very little gas and result in very limited activation and emissions. According to the commenter, such devices on most of its sites sit idle, emitting very little to no methane.

Response II-7-58: The EPA notes that intermittent vent process controllers are those that are designed to not continuously bleed natural gas and to emit natural gas only when actuated. When properly operating, the emissions from these controllers can be relatively low; however, when malfunctioning, the emissions from this controller type can be very high and may emit continuously rather than just when actuated. This high emissions rate when malfunctioning combined with a large percentage of malfunctions in this controller type results in high overall emissions from intermittent vent process controllers. The final NSPS and EG will largely

eliminate these emissions by requiring process controllers to have zero emissions at most sites (*i.e.*, those outside of Alaska and those in Alaska with access to electrical power).

### ***7.2.12 Technology-Neutral Standard***

Comment: Commenter (2399-GPA) recommends that instead of requiring the use of specific types of equipment, EPA use a technology-neutral standard. As they provided in their November 2021 comments (and included as Exhibit A at page 26 of their comment letter), they state that they do not support the requirement for zero-emission controllers for all applications and believe that EPA overlooked significant technical difficulties and costs in the use of solar powered electrical controllers. The commenter requests that EPA consider a technology-neutral standard, which would include the use of generators at sites without access to electricity and allow for certain exemptions for reliability and safety concerns.

Response II-7-59: For process controllers both the December 2022 Supplemental Proposal and the final rule are technology-neutral. The standards require that each process controller affected facility (outside of Alaska and in Alaska at sites with access to electrical power) have zero emissions of methane and VOC to the atmosphere. Owners/operators are free to choose the technology or method to use to comply with this requirement. Owners/operators are not required to use solar-powered process controllers and may use generators or other methods to attain zero emissions from process controllers.

### ***7.2.13 Other***

Comment: Commenters (2252-PAW, 2351-Jonah Energy) state that the EPA is proposing emission reduction mandates for gas-actuated pneumatic controllers using emission factor-based emissions estimates, rather than measurement-based emissions estimates. The commenters assert that the EPA should allow the option for an alternative periodic screening approach. One such approach could be if site-level emissions measurements show methane emissions to be less than a minimum detection threshold that operators should not be required to spend extensive capital to implement emission controls that would have minimal impact on reducing emissions.

Response II-7-60: The EPA acknowledges that emission factors were used in its analysis of the emissions and emission reduction potential of control options for process controllers. These emission factors are based on the averages of controller emissions observed in the field from various studies. For intermittent vent controllers, which represent the majority of process controller types, emission factors are especially important to use when considering the total emissions that occur from process controllers, as they incorporate the emissions that result from both properly functioning and malfunctioning equipment. Such malfunctions may not occur all the time and may not be observed on a particular day during a site assessment but may later be present and would be unaccounted for. As malfunctioning intermittent controllers have been found to be quite prevalent<sup>18</sup>, accounting for their existence is an important component of overall process controller emissions. To achieve site-specific emissions reductions as well as emission

---

<sup>18</sup> Greenhouse Gas Reporting Rule: Technical Support for Revisions and Confidentiality Determinations for Data Elements Under the Greenhouse Gas Reporting Rule; Proposed Rule— Petroleum and Natural Gas Systems, hereafter referred to as the “subpart W TSD,” available in Docket Id. No. EPA–HQ–OAR–2023–0234.

reductions on a nationwide scale, it is important to use an approach that accounts for all emissions, and the use of emissions accomplishes that for process controllers.

Comment: Commenter (2351-Jonah Energy) requests that EPA consider a tiered approach to compliance with pneumatic controller emissions as follows:

- Control gas-actuated pneumatic controller vents that regulate dump or process flow control to an emission control device if the operator does not have reasonable access to line power.
- Permit emergency pneumatic controllers, which operate only in the case of an upset condition, such as remote well shut-in controllers, to continue to operate as gas motive with LOAR inspections in accordance with these proposed rules to demonstrate they are not venting.
- Replace gas-motive pneumatic controllers with zero vent controllers where an operator has reasonable access to power.

As the rule is currently proposed, the commenter (2351-Jonah Energy) states that the EPA is mandating operators spend capital on emission sources that may not be large contributors to site-level emissions, especially for small production facility locations. Companies that are part of OGMP 2.0 are learning where capital expenditures can best be utilized to reduce emissions. The commenter provides that, if EPA mandates that capital be spent on small production facilities with very few normally functioning natural gas-actuated controllers, that capital is not available to be spent elsewhere where it may be better served and have a larger impact in reducing emissions.

Response II-7-61: In the BSER analyses conducted by the EPA for the December 2022 Supplemental Proposal and the final rule, the EPA evaluated the emissions and emissions control options available to owners/operators for process controllers. In these analyses, the EPA found that there are technically feasible zero-emissions options available at sites both with access to electrical power and those without access to electrical power that have costs the Agency regards as reasonable, considering the emissions reductions that would be achieved. Therefore, process controllers with zero emissions was determined to be the BSER and the basis for the NSPS and EG. The EPA notes that emergency process controllers that only function in an upset condition would meet the definition of “emergency shutdown device,” and these devices are not subject to the process controller requirements.

## **7.3 NSPS OOOOb and EG OOOOc BSER Analysis/Emissions/Costs**

### ***7.3.1 Emissions/Emission Factors***

Comment: Several commenters assert that the basis for emissions used in pneumatic controller BSER analyses are overstated. Examples of specific comments are provided in the following paragraphs.

Commenter (2248-NDPC) takes the position that the pneumatic controller emission factors in 40 CFR 98 overestimated the emissions from this source category and that the EPA’s focus on

regulating these sources is unwarranted. The commenter contends that voluntary LDAR programs can assure that maintenance of pneumatic controllers is performed promptly.

Commenter (2173-Northeast Natural Energy) states EPA acknowledges that historical GHG inventories, including those from the 2021 GHGI for 2019 emissions, are overstated. The commenter specifically points out that emissions are overstated by approximately 35 percent at least and over 90 percent at most for intermittent-bleed pneumatic devices, which represent most of the pneumatic devices in operation within the petroleum and natural gas system segments today. As such, according to the commenter, a 5 percent difference in emission reduction by allowing the use of existing or new control devices is hardly a "significant increase" as stated in the *Federal Register* at page 74765 and should absolutely be an acceptable alternative BSER.

Commenter (2252-PAW) reports that their members have experience with collecting measurement data, including many non-zero measurement readings from intermittent-bleed pneumatic device vents at production facilities during different times of the year. The commenter states that the average measurement readings from its members resulted in a 0.55 standard cubic feet (scf)/hour (hr)/device, which is consistent with the EPA's 0.29 scf/hr emission factor for a normally functioning intermittent-bleed device and provides support that EPA should not base their cost-benefit analysis on an 8.8 scf/hr intermittent-bleed emission factor that includes malfunctioning devices.

Commenter (2403-PAO) notes that EPA's use of emission factors and methodologies overestimates emissions from these devices which has led to excessive requirements.

Commenter (2446-IPAA) notes that the EPA's analysis of BSER for pneumatic controllers and pneumatic pumps relies on information that overstates the emissions from these sources. It is particularly an issue for intermittent pneumatic controllers that are widely used at existing oil and natural gas production operations and therefore, according to the commenter, badly skews the cost-effectiveness analysis. The commenter also states that the GHGRP emissions factors are flawed and being reviewed by EPA for revision; and that even the revisions are at issue. The commenter reports that their use produces a faulty analysis. Although many Subpart W reporters currently perform voluntary (and mandated) NSPS OOOOa compliant LDAR surveys utilizing OGI cameras, in-line with the proposed GHGRP revisions, and can identify properly operating devices versus malfunctioning devices, the commenter states that the current rules do not allow the data to be used. As such, the commenter asserts that the GHGRP data significantly overstates GHG emissions from intermittent-bleed pneumatic devices.

Commenter (2428-API) notes that within the TSD, EPA includes a scenario for monitoring intermittent vent controllers. Based on EPA's assumptions, this kind of program can achieve 96.7 percent reductions in emissions (based on emission factors) for an overall site-level control efficiency of 65 percent based on semi-annual OGI monitoring. Since many large facilities within the proposal will be required to conduct quarterly OGI, the commenter anticipates that this control efficiency could be even higher. In EPA's analysis, the emission reductions from inspections of intermittent vents are based on emission rates assumed to be halfway between perfectly operating post-inspection controllers and the overall emission rate that includes both perfectly operating and malfunctioning controllers. The commenter notes that this suggests that

EPA has no data or understanding of how often intermittent bleed devices may not function properly, which is an important distinction given the expected costs of implementing these requirements at all locations as proposed under EG OOOOc.

Response II-7-62: We note that in our refreshed BSER analysis conducted for the final rule, the most up-to-date emissions factors were used, which included those used in the final GHGRP revisions. However, the final GHGRP does not include an emission factor for intermittent vent controllers, and instead requires that sites calculate emissions for each site based on site-specific measurements. Therefore, to estimate emissions from intermittent vents, the EPA used an average emission factor of intermittent vent emissions from a recent study that includes both properly functioning and malfunctioning intermittent vent process controllers.<sup>19</sup> As these emission factors have been updated recently and are based on data from field studies of emissions from process controllers, these emission factors are the best data available to estimate nationwide emissions from process controllers. The EPA does not anticipate that the use of these emission factors significantly overstate or understate emissions.

The EPA agrees that a more robust LDAR program applied nationwide would likely reduce emissions from intermittent vent process controllers. However, the NSPS and EG are required by the CAA to reflect the degree of emission limitation achievable through the application of the best system emission reduction that has been adequately demonstrated, considering the cost of achieving such reduction and any non-air quality health and environmental impact and energy requirements. While a more robust LDAR program is one method to reduce emissions nationwide from process controllers, such a program would not impact continuous bleed controllers and would not reduce emissions from intermittent vent controllers to the degree that other options available are capable of achieving. The EPA found in its BSER analysis that there are several zero-emissions process controller options available for which the costs are reasonable, considering the emissions reductions that would be achieved and other impacts resulting from the use of those options. For this reason, the EPA found that zero-emissions process controllers is the BSER, rather than other options resulting in lesser degrees of emission reductions, including enhanced LDAR program for intermittent vent controllers.

Comment: Commenter (2383-BH) recommends against adopting the proposed requirements in NSPS OOOOb and EG OOOOc that operators design and operate each pneumatic controller affected facility with zero methane and VOC emissions to the atmosphere. The commenter expresses that there are valid safety and production considerations associated with such a requirement that justify a non-zero emission threshold for these devices, and recommends EPA adopt an emission rate for natural gas-driven pneumatic controllers of less than or equal to 6 scfh, as included in the 2016 NSPS OOOOa rule. According to the commenter, such a threshold would serve as a backstop to operator performance. The commenter points out that other safety backup and devices on older facilities may only actuate a few times/day or even per week. The default 8,760 hours are used when calculating their emissions, which the commenter states leads to an over-estimation of emissions.

---

<sup>19</sup> Luck, B., D. Zimmerle, T. Vaughn, T. Lauderdale, K. Keen, M. Harrison, A. Marchese, L. Williams, and D. Allen. 2019. "Multi-Day Measurements of Pneumatic Controller Emissions Reveal Frequency of Abnormal Emissions Behavior at Natural Gas Gathering Stations."

Response II-7-63: In the BSER analyses conducted by the EPA for the December 2022 Supplemental Proposal and the final rule, the EPA evaluated the emissions and emissions control options available to owners/operators for process controllers. In these analyses, the EPA found that there are technically feasible zero-emissions options available at sites both with access to electrical power and those without access to electrical power that have costs the Agency regards as reasonable, considering the emissions reductions that would be achieved. Considering comments on the zero-emissions standards included in the 2021 proposal and information available to the EPA regarding process controllers, the EPA determined that it was appropriate to not include emergency shutdown devices, which perform important safety functions, in the process controller affected facility definition. The EPA notes that these devices, which actuate infrequently, are also not included in the analyses of emissions resulting from the operation of natural gas-driven process controllers. Therefore, the EPA expects that the commenter's concerns regarding safety and emissions from these infrequently actuating devices have been addressed and accounted for in the final rule.

### ***7.3.2 Model Facilities***

Comment: Commenter (2399-GPA) recommends that EPA gather additional information to create a representative gathering and boosting compressor station model plant. The commenter provides the following for consideration:

- Gathering and boosting compressor stations typically have many more than 20 controllers and require air compressors larger than 20 horsepower, as EPA assumed in the “Large Model Plant” for production sites.
- The total capital cost for installing an air compressor for new controllers with grid power is between \$250,000 and \$1,000,000, depending upon the compressor station's size, layout, and the number of devices.
- EPA appears to assume that any existing source switching from gas-driven devices to electric devices can still use the same valves. However, in most cases, new valves would be required due to actuator setup changes.

Response II-7-64: In the refreshed BSER analysis conducted for the final rule, the EPA included a large model plant to address gathering and boosting stations that would not be represented by 20 controllers. We characterized this model plant as a “large midstream” plant with 100 controllers. In the analysis, we found that there are zero emissions process controller options at this model plant size with costs that the EPA has determined are reasonable, considering the associated emissions reductions. The EPA notes that if an air compression system is used, the process controller requirements do not require other equipment at the site to be powered by that system, and this may reduce the size of the system the commenter has stated is needed. In addition, in our BSER analysis, we assumed that existing natural gas-driven pneumatic devices could be used if the owner/operator switches to a compressed air system, since the devices are capable of using any type of compressed air or gas. We also note that in the past, switching to electric controllers required a switch in the control valve associated with the retrofitted controller. However, the technology of electric process controllers has advanced, and most electric controllers and actuators can be connected to existing valves.

Comment: Commenter (2428-API) identifies errors and assumptions in the December 2022 proposal's TSD model plant analysis:

- While a solar panel lifespan of 10 years was stated, a value of 15 years was used in the annualization, resulting in a 30 percent annual cost difference.<sup>20</sup>
- EPA capital cost analysis for electric compressor retrofit at existing transmission, storage, and production sites does not consider applications greater than 10 hp (highest compressor and associated equipment (e.g., dryers, wet air receivers) is capped at \$32,000). Larger-sized systems should be evaluated.
- For electric powered compressed air systems, EPA applied an annualization period of 15 years. If the compressor equipment life is updated to reflect the 2021 Carbon Limits Study provided value of 6 years, this option is not economically feasible. It is unclear why EPA deviated from the Carbon Limits study for this assumption and not others.
- The Carbon Limits report assumed a greenfield installation factor of 1.5 times major equipment costs without any adequate explanation. Commenter's member experience suggests this is closer to 3 to 4 times equipment costs.
- EPA continues to assume at least 1 high-bleed pneumatic controller is present at existing source model plants, when the data submitted to EPA pursuant to 40 CFR Part 98, Subpart W suggests this is an incorrect assumption given the low number of high-bleed controllers still being reported.<sup>21</sup>
- The EPA deflated costs provided in 2021 dollars to 2019 dollars. As inflation continues to be elevated, this is an unrealistic assumption and not reflective of actual, or anticipated costs. Costs continue to increase across the economy. A more appropriate assumption would be to assume 2021 dollars are equal to 2019 dollars.

Response II-7-65: In consideration of these comments, we have addressed several of these items in the refreshed BSER analysis. This includes matching the annualization for solar panels to a 10-year lifespan, adding a compressor retrofit model plant assuming that a 20 hp system would be needed, and assuming that a compressor lifespan is 6 years. For the increased costs for installation of equipment at an existing site, the EPA included an

### **7.3.3 Costs**

#### **7.3.3.1 Proposed Pneumatic Controller Standard is Cost-Effective and Feasible**

Comment: Commenter (2433-EDF et al) expresses that the EPA's proposed pneumatic controller standard is cost-effective and feasible. The commenter provides that the EPA updated its cost analysis and continues to find that the zero-emitting controller standard is cost-effective overall. Specifically, it finds in the production segment that grid-connected, solar, and compressed air controllers are cost-effective at small sites (\$81/ton, \$119/ton, and \$984/ton, respectively), medium sites (\$48/ton, \$84/ton, and \$531/ton, respectively), and large sites (\$31/ton, \$65/ton, and \$297/ton, respectively) (using a multipollutant approach), all of which are reasonable and below EPA's \$1,970/ton benchmark for this proposal and the \$2,185/ton benchmark used in

---

<sup>20</sup> See tabs in Supplemental TSD Ch 3 Pneumatic Controllers.xlsx tabs BSER T&S new, BSER T&S existing, BSER Production new, and BSER Production existing.

<sup>21</sup> See Attachment C in EPA-HQ-OAR-2021-0317-0808.

previous rules. They add that the EPA also finds cost-effectiveness for these technologies across model plants in the transmission and storage segments (except for instrument air at some sites). The commenter describes and supports changes EPA made in its updated analyses.

The commenter (2433-EDF et al) believes that the EPA's updated cost analysis is more robust, and they support its cost-effectiveness determination. The commenter states that the EPA incorporated a number of changes to its cost analysis that are warranted by the underlying record evidence. They believe that it is now properly accounting for annual maintenance costs of both natural gas pneumatic systems and electric/instrument air systems in accordance with the Carbon Limits cost model. For natural gas pneumatic systems, it averages maintenance costs of systems with wet and dry gas. For zero-emitting systems, it accounts for annual maintenance of electric controllers, periodic replacement of solar panels and batteries (for solar-powered sites), and the cost of grid electricity (for grid-powered sites).

Commenter (2433-EDF et al) provides that the EPA also adjusted its cost analysis to distinguish new sites from existing sites in a few ways. First, capital costs for new sites will now include net costs to "represent the difference in the capital cost between the pneumatic controller system not driven by natural gas and the natural gas-driven controllers that would be used in the absence of a zero-emissions requirement." Additionally, EPA updated the emission factors so that they are now consistent with recent proposed GHGRP updates.

Though the commenter states that the EPA's analysis has improved significantly, the commenter (2433-EDF et al) still believes that the EPA likely still overestimates the costs, and underestimates the cost-effectiveness, of zero-emitting pneumatic controllers. First, EPA's small, medium, and large model plants do not reflect the actual average size of transmission and storage facilities (based on the average size reported in EPA's GHGI). The commenter states that the EPA did not address this issue in response to comments and continues to inaccurately size its model plants. According to the commenter, this has likely resulted in EPA underestimating cost-effectiveness, as zero-bleed conversion becomes more cost-effective as the size of the plant increases. The commenter recommends that EPA increase the size of its model plants to accurately reflect average plant sizes.

Second, the commenter (2433-EDF et al) suggests that the EPA inappropriately increased installation cost estimates for electric controller systems in its updated analysis. As described in a new 2023 memo from Carbon Limits,<sup>22</sup> EPA's new, higher installation costs may be appropriate for certain remote sites (such as those in Northern Alberta) where travel costs can be fairly high. EPA's estimates therefore now represent the upper range of installation costs that are applicable only to a small number of sites. But in proposing a national standard, EPA should consider average installation costs, or costs that will be representative of sites nationally. Those average installation costs are presented in the Carbon Limits tool and are much lower than EPA's current estimates, meaning EPA is likely overestimating installation costs and underestimating cost-effectiveness. The commenter recommends that EPA use Carbon Limits' average installation cost estimates.

---

<sup>22</sup> Carbon Limits, 2023 Memo, *supra* note 257.

The commenter (2433-EDF et al) also states EPA has demonstrated solar is cost-effective and feasible at remote locations without electricity. The commenter notes that the EPA soundly addressed purported limitations associated with solar systems – including geographic conditions, temperature, battery capacity, snow cover and particle accumulation on panels, and large-scale applicability. It noted that Canadian provinces with colder temperatures and significant snowfall have successfully implemented non-emitting controller regulations that include solar as a primary remote compliance option; that it received comments by vendors that reported successful installation and operation of emission controller systems in a variety of climate conditions and one who commented on the installation of solar-driven instrument air systems in several states, including Wyoming and Colorado; that technology providers interviewed for the Carbon Limits report have solar-powered controllers installed at well sites in remote and cold locations in places like Northern Alberta and British Columbia without major reliability issues; that one provider interviewed by Carbon Limits installed solar systems at over 400 well-sites in Alberta and British Columbia; that solar panels are placed vertically to eliminate snow cover during winter months; and that solar technology has improved significantly over the years.

The commenter (2433-EDF et al) suggests that the EPA can add to the record in support of solar feasibility by noting that (1) the Carbon Limits report, which EPA uses in its updated cost analysis, accounts for low temperatures and reduced battery capacity;<sup>23</sup> (2) that an independent report by Analysis Group considers region-specific solar capacity factors at all sites, including extra-large sites, and finds cost-effectiveness across all regions;<sup>24</sup> (3) that the same report accounts for particle accumulation on solar panels,<sup>25</sup> (4) and that the Carbon Limits model, which EPA relies on, has a default assumption to oversize the solar panel by 50 percent for electric controllers and 30 percent for solar-powered instrument air systems, so that a loss of generation due to factors such as particle accumulation will not degrade system performance.<sup>26</sup>

The commenter (2433-EDF et al) adds that the EPA has also demonstrated that the zero-emission standard is cost-effective and feasible at large and small sites. The commenter explains that the EPA performed an analysis of the cost effectiveness of the use of electric controllers and solar-powered controllers at sites with a single controller. For sites with only one high-bleed controller, the cost effectiveness was estimated to be \$379 and \$437 per ton of methane reduced for electric and solar-powered controllers, respectively. For a site with one intermittent vent controller, the cost effectiveness values were estimated as \$913 per ton for electric controllers, and \$1,053 per ton for solar-powered controllers. For a site with one low-bleed controller, the cost effectiveness values were \$1,181 per ton for electric controllers and \$1,363 per ton for solar-powered controllers. The commenter reports that these all fall below EPA's cost-effectiveness benchmark. The commenter suggests that the EPA can further bolster its analysis by noting that

<sup>24</sup> Analysis Group, Methane Reduction Technology Electricity and Abatement Costs: The Cost to Power Zero-Emission Pneumatic Controllers and Pumps in Grid-Connected and Remote Locations, at 17–18, 46 (May 6, 2022) [hereinafter Analysis Group Report] (included as Attachment M).

<sup>25</sup> Analysis Group, Methane Reduction Technology Electricity and Abatement Costs: Summary Presentation for EPA (May 10, 2022) [hereinafter Analysis Group Presentation] (included as Attachment N).

<sup>26</sup> Carbon Limits, 2021 Report, *supra* note 268, at Appendix A: List of assumptions, Table A. 1: Quantitative assumptions for the model.

the 2021 Carbon Limits report found cost-effectiveness for solar-powered instrument air systems at smaller sites.

The commenter (2433-EDF et al) also notes that there is an independent report by Analysis Group assessing the costs to operate zero-emission technologies that further demonstrates the cost-effectiveness of EPA's pneumatic controller proposal, with specific emphasis on the cost-effectiveness of these technologies by region, including the Midwest, Mid-Atlantic, South, Rocky Mountains, and Alaska. The report concludes that, after incorporating electricity and net maintenance costs, all technologies considered (grid-connected, solar, and instrument air) are cost-effective at small, medium, and large plants in all regions, even when gas savings are not considered. Some highlights of the report provided by the commenter include:

- *Solar Controller Analysis Considers Regional Conditions, Particle Accumulation, and Large Solar Sites:* The report's solar controller evaluation accounts for a potential decrease in solar/storage output in colder climates and due to particle accumulation on panels. The model assumes ten days of energy storage at a maximum depth discharge of 80 percent. Additionally, solar levelized costs were adjusted regionally based on differences in solar capacity factors. Even after incorporating these variances into the model, the report finds that the installation of zero-emitting pneumatic controllers is cost-effective in each region, including Alaska, countering claims that facilities in colder and cloud-covered states cannot feasibly install solar-driven controllers and that particle accumulation makes solar infeasible. The report also considers oversizing the solar array and battery storage to the extent necessary to ensure sufficient generation to power controllers. Based on these assumptions, in combination with its use of independent regional levelized costs of solar and storage, the report finds that large facilities can use solar controller systems cost-effectively.<sup>27</sup>
- *Consideration of Extra-Large Sites:* The report supplements EPA's analysis by considering extra-large sites. It considers sites with electricity demand reaching 2,000 kW by modeling an extra-large plant size of 200 controllers for production and transmission and storage sites and finds that nearly all technologies would be cost effective. This counters certain industry commenters' claims that zero-emitting technologies are not cost-effective at plants that are larger than EPA's model plants or at sites requiring 2,000 kW of electricity.<sup>28</sup>
- *Adjusted Capital Expenditures:* The report's grid-powered, solar, and instrument air controller analyses all include adjusted capital expenditures for equipment, prepared independently of EPA's analysis.<sup>29</sup>
- *Maintenance Costs:* Unlike EPA's original analysis (but like the analysis for its supplemental proposal), the analyses for all three technologies incorporate net maintenance costs, which result in savings associated with replacing gas-driven controllers with zero-emitting controllers.<sup>30</sup>
- *Costs of Service Extension:* The report further supplements EPA's costs analysis by considering the costs for locations that do not have electricity supply on-site but are

---

<sup>27</sup> See Analysis Group Report.

<sup>28</sup> Id.

<sup>29</sup> Id.

<sup>30</sup> Id.

located close enough to the local electric distribution system to consider developing a line extension from the closest spot on the grid. The report finds that, in most situations, the cost of constructing a distribution line when an operator is 0.5 miles away from access plus electricity use results in cost-effective methane abatement. While cost-effectiveness may decrease with more distance from the grid, this conclusion rebuts certain industry commenters' claims that the cost to obtain grid access is prohibitive.<sup>31</sup>

- *Electricity Costs*: The report's grid-powered and instrument air analyses consider electricity costs by region. The report estimates the cost of delivered electricity as the average of state prices for electricity to ultimate customers and finds that installation of zero-emitting pneumatic controllers would be cost-effective in all regions.<sup>32</sup>

Response II-7-66: The EPA has refreshed its BSER analysis for process controllers to incorporate updated data. This includes the following changes to the controller model plants.

- Two new "midstream" model plants were added to represent gathering and boosting stations. The small midstream model plant contains 20 pneumatic controllers, and the large midstream model plant contains 100 pneumatic controllers.
- The three transmission and storage model plants used in the supplemental analysis were replaced by a small transmission and storage model plant (30 pneumatic controllers) and a large transmission and storage model plant (50 pneumatic controllers).
- The breakdown of controllers at the new small production model plants was changed to reflect a higher percentage of intermittent vent controllers. For new sources, the supplemental analysis assumed 2 low bleed and 2 intermittent vent controllers. This was changed to 1 low bleed and 3 intermittent.

The EPA found in the refreshed BSER analysis that solar-powered electric process controllers have costs that are reasonable considering the emissions reductions that would be achieved at all model plants studied.

#### 7.3.3.2 EPA Has Underestimated the Costs of its Proposal

Comment: Several commenters submitted comments indicating that they believed that the EPA had underestimated the costs of its proposal. Examples of some of the comments received are provided in the following paragraphs.

Commenter (2227-WEA) believes that the EPA has significantly underestimated the cost and difficulty of retrofitting facilities to comply with the regulation. The commenter reports that their member estimates from actual retrofit projects range to as high as \$250,000 per facility for large facilities with many controllers, which is a price point far outside the range described in EPA's publication. According to the commenter, while these costs may be lower for lower-producing

---

<sup>31</sup> See Amer. Petroleum Inst., Comments on EPA's Standards of Performance for New, Reconstructed, and Modified Sources and Emissions Guidelines for Existing Sources: Oil and Natural Gas Sector Climate Review 7–8 (Jan. 31, 2022), <https://www.regulations.gov/comment/EPA-HQ-OAR-2021-0317-0808> [hereinafter 2022 API Comments].

<sup>32</sup> See Analysis Group Report.

facilities, the fact that EPA estimated the top end for the range for large facilities to be only \$96,000 signals there is a flaw in the calculation for it to be that far off actual project execution.

Commenter (2305-Williams) states for sites without reliable electricity, upgrading utility power to the facility to accommodate zero-emitting or zero-venting pneumatic controllers could cost over a million dollars, or require installation of natural gas-fired generators at a cost of \$600,000 to \$750,000. Scoping of the appropriate generator size will require an owner and operator to power more than the air compressors at these facilities since the generator will generate power for other equipment such as replacing gas pneumatic pumps. The commenter reports that these natural gas generators will range from 600 - 1114 bhp with a minimum delivery time of 15 months (separate and apart from the delivery time for an air compressor).

Commenter (2283-Endeavor Energy) states EPA also drastically underestimates the costs of its proposed pneumatic equipment. The commenter estimates that it would cost about \$85,500 per well site to convert pneumatic equipment to instrument air.

Commenter (1609-Qnergy) states typical installations are medium facilities with 16 controllers and above and about 2 scfm. At \$4/MMBtu of natural gas, a 9 scfm site is highly profitable, where the operator enjoys about \$13,000 of net profit each year (about \$135 profit from each ton of abated methane). At 6 scfm and \$2/MMBtu the operator breaks even while offsetting the whole site entire emissions.

Response II-7-67: For the final rule, the EPA refreshed the BSER cost analysis to include updated cost information, updated emission factors, and additional model plant sizes. For this analysis, the EPA reviewed the available information regarding the costs of the control technologies and strategies evaluated and incorporated updated information where it was available. The changes included updates to the costs of some components of solar-powered systems. However, these changes were modest and were reductions in the costs of the equipment, and there no instances where the EPA found that costs had previously been underestimated. The EPA notes that for sites with many controllers beyond the sizes of the model plants evaluated, the costs could be higher than estimated. At such sites though, the emissions reductions would also be higher than estimated. The results of the updated BSER analysis show that there are several zero-emissions options for process controllers that have reasonable costs, considering the emissions reductions that would be achieved.

Comment: Several commenters specifically provided comments on EPA's December 2022 supplemental proposal pneumatic controller BSER cost-effectiveness analyses. Examples of some of the specific comments are provided in the following paragraphs.

Commenter (2399-GPA) states EPA's cost models only considered production and transmission facilities. They do not include gathering and boosting facilities. The commenter states that gathering and boosting facilities have much larger system requirements due to the larger number of controllers and the need for more powerful air compressors. Assuming that gathering and boosting facilities have roughly equivalent system requirements as production facilities dramatically underestimates costs. The commenter provides that owners and operators of gathering and boosting facilities may spend \$500,000 to \$1,000,000 for instrument air systems at

sites with available grid power. For sites that require onsite power generation, the cost could readily increase by an additional \$400,000 to \$1,000,000. The commenter states its facilities and upstream production facilities are simply not comparable for purposes of analyzing the cost-effectiveness of the proposed regulations. The commenter provides the following additional operational and/or cost differences between production sites and gathering and boosting operations included in the Carbon Limits report:

- The pneumatic devices used for the three model production sites are substantially smaller than most gathering and boosting compressor stations. These smaller scale cost metrics will not linearly scale up with larger facilities where new instrument air header and piping, additional pipe supports, or an extended pipe rack may be necessary.
- The installation costs for a header to the pneumatic controllers, in Table 5 of the Carbon Limits report, is for a new installation. Retrofits often require the existing methane pipe header to remain in place as a source of fuel gas to on-site equipment, such as compressors, fired heaters, combustors/ thermal oxidizers, or flares. A new parallel air header needs to be run to all instruments, adding significant costs depending upon the location, site layout, available space, and the need for additional pipe supports. Put simply, the installation costs at a well site are not useful in determining the cost-effectiveness of retrofitting gathering and boosting operations.
- The stated installation costs in the Carbon Limits report are much lower than what GPA Midstream member companies typically see. It does not appear that wire and miscellaneous electrical material were accounted for. Further, the installation labor time per each device does not appear for the time to pull wire to each device. This may not be significant at small production sites with only a handful of devices, but for larger equipment, this will involve significantly more time and higher costs to install.
- In the midstream industry, typical total project costs are three to four times the major equipment cost for brownfield facilities. The Carbon Limits report improperly assumed only two times major equipment cost. It is not clear if the report properly accounted for hydrovacating underground inside the fence line, work permits, additional safety and personal protective equipment costs, and other issues that add to overall brownfields project cost.
- For greenfield sites, total project costs are typically two to three times major equipment costs. For instance, one of our member company's New Mexico central gathering facilities has 34 shutdown valves, 70 other pneumatic devices, and 34 diaphragm pumps. The site will install 150 horsepower of air compression (two 75 horsepower flooded screw compressors) for this relatively large operation. The commenter's vendor quotes indicate that the skid price for these compressors, the dryer, wet/dry air receiver, and off skid star air receiver is approximately \$250,000. See Exhibit E. Total project cost is anticipated to be approximately \$1,050,000, which includes roughly \$175,000 to route sufficient utility power to a location if that is required. This is an installation factor of 3.5 times the major equipment cost (not including utility power costs).<sup>33</sup> Yet, the Carbon Limits report assumed a greenfield installation factor of 1.5 times major equipment costs without any adequate explanation.

---

<sup>33</sup> A second member looked back at projects over the past 2 1/2 years and found a similar installation factor for their projects.

- Table 9 of the Carbon Limits report provides a cost comparison for the Sample C Site, the larger productions site. For the site with no electricity and using solar power, the report calculates \$2,200 per device with the controller accounting for \$2,000 of that cost. This means that the Carbon Limits authors assumed that it would cost only \$200 per device for installing the device, installing a new panel, purchasing wire and miscellaneous electrical materials, and pulling wire from the panel to the device. In the experience of our member companies, these costs are underestimated by one to two orders of magnitude, depending upon the site's size and complexity.
- At a retrofit site with no electricity, the Carbon Limits report assumed approximately \$2,900 to install solar power and electric controllers. As the Carbon Limits report assumes the controllers are \$2,000 each, this leaves only \$900 to retrofit each valve with an electric controller, install a new panel, purchase wire and miscellaneous electrical equipment, and pull wire from the panel to the device. The owner or operator may also have to excavate and remove buried lines. Further, retrofitting goes significantly slower than for new installations. This means that Carbon Limits' installation cost assumptions are underestimated by at least one to two orders of magnitude depending upon site size and complexity.
- In retrofitting a site with no electricity using solar powered electric controllers and new control valves, the Carbon Limits report estimates a cost of \$4,700 per device with each controller costing \$2,000 and each control valve costing \$2,500. This leaves a mere \$200 per device to install the controller, valve, new panel, purchase wire and miscellaneous electrical equipment, and pull the wire. The Carbon Limits report evidently did not consider the need to shut in, isolate, and blow-down the process to be able to physically install the new valves into the piping, then remove isolation valves, purge, and pressure up before putting the equipment back into service.
- In retrofitting a site with electricity, using the electric controller option and existing valves, the Carbon Limits report estimates a cost of \$2,700 per device with the controllers costing \$2,000 each. This would leave only \$700 for installing each controller – a process that goes far slower than installation on a new source and may require excavating buried lines.
- Finally, the Carbon Limits report estimated that retrofitting a site with access to electricity using electronic controllers and new control valves would cost approximately \$4,600 per device with each controller costing \$2,000 and each control valve costing \$2,500. This leaves only \$100 per device to install each controller and valve, involving shutting in, isolating, and blowing down the process, removing isolation valves, purging the system, and then re-pressuring before putting the equipment back into service. This is simply not credible and demonstrates that the Carbon Limits report's authors lack the understanding of midstream operations necessary to apply its findings to the midstream industry.

The commenter (2446-IPAA) notes that the Carbon Limits report assumes that, for a new site with electricity, the electronic controller option is only \$1,950 per device. The commenter suggests that it is not clear why the controller cost is less than that for a site with no access to electricity, but even assuming the lowest potential controller cost - \$1,500 – it is implausible that a company can install the device for only \$450 each. Given the labor and additional materials

described above, the commenter believes that the \$450 in installation costs is severely underestimated.

For a new site with electricity, the commenter (2446-IPAA) provides that the Carbon Limits report also assumes that grid instrumentation will cost only \$50,000 for a 20-horsepower air compressor, leaving approximately \$31,000 for installation. According to the commenter, this is two to three times lower than typical installation costs, which including building a foundation, setting the instrument air skid and air receiver, grounding the skid, running a new air heading to 22 devices, and running power to the new air compressor skid.

Commenter (2294-OOGA) disagrees that the BSER is reasonable from a cost-effectiveness perspective. The commenter reports that it will require existing sources to retrofit every pneumatic controller. Some facilities may even require complete reengineering and design to comply with these standards. The commenter contends that such compliance measures will likely be cost prohibitive, particularly for small business and operators of low production wells. There are also a multitude of technical limitations, such as low pressure, that make each proposed compliance option infeasible.

Commenter (2428-API) states that total project costs, including equipment and labor, to retrofit a large gathering and boosting compressor station could exceed \$1,000,000. Upon the commenter's review of the December 2022 Supplemental Proposal TSD, the commenter asserts that they found EPA's cost-benefit analysis to significantly underestimate the cost (especially for retrofit of existing facilities) and overstate the technical feasibility of making these retrofits as summarized below [greater detail is provided in the commenter's letter]:

- EPA applied an emission factor for low-bleed pneumatic controllers, with a factor that by definition would be a high-bleed pneumatic controller;
- EPA continues to describe application of solar-powered and electric controllers as being directly powered by the grid or solar technology in the model plant analysis;
- Application of solar technologies as it pertains to gathering and boosting compressor stations have not been adequately reviewed in EPA's model plant analysis;
- In a case study published by National Renewable Energy Laboratory (NREL), solar panel capital costs for off-grid production well sites are 2.7 times the cost of grid-connected well sites. This does not align with EPA assumptions;
- EPA's model plant assumptions do not adequately address costs associated with retrofit of existing facilities:
  - Additional Land Requirement for Solar Panel Installation including acquisition costs.
  - Site Preparation - For existing sites with tree lines, trimming may be required to maximize sun exposure. Additionally, for larger sites with more significant solar installations, foundation prep including concrete slabs was not considered.
  - Solar panel maintenance and cleaning particulate accumulation,
  - Permitting<sup>34</sup>, insurance and inclusion of battery boxes to house batteries, and
  - Retrofits often require the existing methane pipe headers to remain in place as a

---

<sup>34</sup> <https://www.solarpermitfees.org/SoCalPVFeeReport.pdf>.

source of fuel gas for on-site equipment (compressors, fired heaters, combustors/thermal oxidizers, flares, etc.) and a new parallel air header needs to be run to all instruments. This can add significant costs depending on the site layout, if there is available space in the existing pipe rack and facility, or if additional pipe supports are also needed.

Response II-7-68: The EPA considered these comments and made some revisions to the BSER analysis. These include adding two new “midstream” model plants to represent gathering and boosting stations. The small midstream model plant contains 20 pneumatic controllers, and the large midstream model plant contains 100 pneumatic controllers. The three transmission and storage model plants used in the supplemental analysis were also replaced by a small transmission and storage model plant (30 pneumatic controllers) and a large transmission and storage model plant (50 pneumatic controllers). The results of the analysis for these new and revised model plants show while the costs for sites with more controllers are higher, the emissions reductions are also higher. The EPA determined that the costs are reasonable, even for these large sites, considering the emissions reductions achieved.

Regarding comments related to installation costs, the EPA has not revised our general estimation methodology. The Carbon Limits reports<sup>35</sup> assume that equipment installation costs are 50% for new sites and 100% for existing sites. The additional costs for existing facilities take into account the existing infrastructure that may need to be changed, such as the parallel air headers remarked on by commenters. This is in line with or even greater than the assumptions in the EPA Cost Control Manual,<sup>36</sup> which the EPA has relied on for estimating emissions control costs for many other rulemakings.

Regarding the emission factor for low-bleed process controllers, the EPA notes that the emission factors are based on measurement studies of process controllers in the field. The emission factor of 6.8 standard cubic feet per hour (scfh) shows that these controllers are not, in fact, operating as they should be with less than 6.0 scfh.

#### 7.3.3.3 Connection to the Electrical Grid

Comment: Commenter (2227-WEA) states there are significant development, operational, and socio-economic considerations for the widespread use of electricity for oil and natural gas operations. Expanding electrical infrastructure in many areas in the west can be slower and more costly than other areas in the U.S. This is particularly true given the lack of existing infrastructure, severe geographic challenges such as mountains and canyons, requirements for enhanced extensive environmental studies, added environmental restrictions, lengthy land development challenges, extreme weather conditions, and other trials that are magnified in some areas. The commenter explains that there are regions of the U.S. where the proposed regulations are likely to result in more significant economic impacts than those across much of the rest of the lower 48 states. There are areas where oil and natural gas products are required to be sold at

---

<sup>35</sup> Carbon Limits. (2016) Zero emission technologies for pneumatic controllers in the USA - Applicability and cost effectiveness. and (2021) Zero emission technologies for pneumatic controllers in the USA – Updated applicability and cost effectiveness.

<sup>36</sup> EPA Air Pollution Control Cost Manual. Sixth Edition. January 2002. EPA/452/B-02-001.

discounted rates for reasons such as the characteristics of the product and unique requirements to process the products. Some regions are severely lacking in pipeline transportation and must use more expensive long-distance transportation modes such as trucking. The commenter provides that the economic challenges that accompany requirements to retrofit operations for the use of electricity in place of pneumatic energy are significant.

Response II-7-69: While the use of electricity supplied by the grid is one method available at some sites to power electric process controllers or to power a compressed air system for pneumatic controllers, the use of grid energy is not the only option available to owner/operators for compliance with the process controller standards. The use of solar-powered electric process controllers, pneumatic process controllers using compressed air systems powered by generators, and routing process controller emissions to a process are examples of other compliance methods available to meet the zero-emissions process controller standard. The EPA found through its BSER analysis that there are cost-effective methods of compliance available for all site types, including remote sites without access to electrical power.

#### 7.3.3.4 Solar

Comment: Commenter (2433-EDF et al) states that the EPA has found the installation of solar-powered systems to be cost-effective, and its determination that these systems are feasible at remote sites without electricity is supported by strong record evidence.

Response II-7-70: This comment is a supportive comment on an aspect of the December 2022 Supplemental Proposal that has remained unchanged in the final rule; as such, no response is required.

#### 7.3.3.5 Electric Controllers

Comment: Commenter (2399-GPA) states electrically actuated controllers require the installation of a complex automated control system, which would require offsite monitoring using a Supervisory Control and Data Acquisition (SCADA) system—which is an additional cost that EPA does not appear to have included in its estimates.

Response II-7-71: While electrically actuated controllers can be operated by a SCADA system, this is not required as they also have local controls on each actuator. Therefore, this cost was not included in our analyses.

Commenter (2166-OH DNR) calculated various implementation costs for a typical Ohio oil and gas operator. Using \$20,593 for the capital investment of an electric controller system and the current market price of \$3.00 per thousand cubic feet (Mcf) of gas, a well would need to produce 6,864 Mcf of gas to pay back the cost of an electric controller system. The commenter notes that a marginal well producing less than 250 Mcf of gas a year would take nearly three decades (27 years) to recoup the investment for a controller system if all revenue from the well was put towards paying for the system. The commenter adds that it would take longer since a well operator incurs costs to operate a well and pay to transport natural gas. At an average market price of \$1.71 per Mcf and \$41.96 for a barrel of oil in 2020, the owner's estimated total gross

revenue for 2020 would have been \$10,761.14. The commenter states that this would mean that two years of total gross revenue would be needed to retrofit one well to an electric controller system.

Response II-7-72: EPA developed a financial analysis of marginal, or stripper, oil and natural gas wells in Chapter 6 of the Final Rule TSD. EPA finds that marginal wells may continue to operate at low or negative profits rather than be shut-in and plugged due to a variety of reasons, including low operating costs, high plugging costs, low state bonding requirements, accounting practices, and tax credits available to the oil and gas industry. To the extent that any marginal wells might be plugged in relation to anything contained within this rulemaking (which is speculative), the analysis suggests that they would be extremely low-producing wells. It is also possible that a less expensive compliance method could be chosen. The EPA notes that for existing sources, States may take remaining useful life and other factors into account when formulating their state plans for implementation of the EG, consistent with the requirements in 40 CFR subpart Ba.

Comment: Commenter (2399-GPA) notes that, although electrically actuated controllers can be installed in certain limited circumstances, they are more expensive with fewer options available on the market. The commenter contends that mandating their use would further drive-up prices with manufacturers being unlikely to catch up to increasing demand until after the December 2022 supplemental proposed rule compliance date.

Response II-7-73: The final rule does not mandate the use of electrically actuated controllers. While owner/operators may use electric process controllers to comply with the zero-emissions standard, other options include the use of pneumatic process controllers driven by a compressed air system or nitrogen canisters and routing emissions to a process.

#### 7.3.3.6 Instrument/Compressed Air Systems

Comment: Commenter (2227-WEA) states that for smaller facilities that have lower production, installing and operating instrument air systems could easily exceed the value of the recoverable production from the wells associated with those facilities, forcing those operators to shut in production.

Response II-7-74: EPA developed a financial analysis of marginal, or stripper, oil and natural gas wells in Chapter 6 of the Final Rule TSD. EPA finds that marginal wells may continue to operate at low or negative profits rather than be shut-in and plugged due to a variety of reasons, including low operating costs, high plugging costs, low state bonding requirements, accounting practices, and tax credits available to the oil and gas industry. To the extent that any marginal wells might be plugged in relation to anything contained within this rulemaking (which is speculative), the analysis suggests that they would be extremely low-producing wells. Information regarding the implementation of a state rule in Colorado with process controller requirements show that less than 7 percent of sites there shut in production.<sup>37</sup> In addition, States

---

<sup>37</sup> EPA-HQ-OAR-2021-0317-3847.

may take remaining useful life and other factors into account when formulating their state plans for implementation of the EG, consistent with the requirements of 40 CFR part 60 subpart Ba.

#### 7.3.3.7 Self Contained/Route to Process

Comment: Commenter (2360-Devon Energy) encourages EPA to consider the benefit and cost-effectiveness of routing existing pneumatic controllers to a process, sales line, or to a combustion device (where one already exists) instead of emitting directly to the atmosphere. The commenter provides that Colorado and New Mexico are actively working to create progressive regulatory frameworks to reduce methane emissions, consider “routed pneumatic controllers” to be “non-emitting controllers,” which facilitates an effective pathway to reduce methane emissions from existing pneumatic controllers. The commenter contends that allowing for the routing of existing pneumatic controllers to a combustion device will significantly enhance the ability for oil and gas operators to effectively reduce the emissions from gas-driven pneumatic controllers within the prescribed compliance timeframe and provide a reasonable level of flexibility to achieve the non-emitting standard without potentially requiring an additional emission source in the form of a generator where electricity is not readily available.

Response II-7-75: The EPA acknowledges that it may be cost-effective for owner/operators to route process controller emissions to a process or sales line, and this is an option available for meeting the zero-emissions standard for process controllers. The EPA considered the costs and emissions reductions associated with routing emissions to a combustion device but found that this method of emissions reduction did not represent the BSER. As methods to attain zero emissions are available, in use at some sites, and have costs and other impacts that are reasonable considering the emissions reductions that would be achieved, the EPA determined that zero emissions represents the BSER for process controllers.

#### 7.3.3.8 Nitrogen-Powered Controllers

Comment: Commenter (1581-Kathairos) states nitrogen systems provide an economical methane elimination solution for pneumatics, even for small, low vent wellsites:

- Costs are scaled to the size of the affected facility. The cost of the system is directly commensurate with the amount of methane that otherwise would have been vented. Small, low-vent wellsites are fitted with small (265 liter (L)) tanks and consume small amounts of nitrogen, resulting in total costs as low as \$2,100 per year.
- No up-front capital required. Tank lease and nitrogen costs paid on monthly basis.
- Oil and gas producers retain the fuel gas that otherwise would have been vented, which is conserved for future sale.
- The exact costs of the nitrogen system for a range of different vent rates provided in Appendix A (Abatement Cost by Vent Rate) of their comment letter.

Response II-7-76: Although the EPA has not performed an analysis of the costs associated with the use of nitrogen systems, the EPA acknowledges that the use of these systems is a technically feasible option available to owners/operators for compliance with the process controller standards.

### ***7.3.4 BSER Based on Regional Considerations***

Comment: Commenter (2353-CrownQuest) states that the EPA's rule is a national rule, not a state-by-state or region-by-region rule. The EPA changing their modeling to three generic sites does not address the massive variance in the type of facilities and oil and gas producing sites. Oil and gas wells' output declines over time. New shale wells can decrease by 80 percent in the first year, and waterfloods can drop as low as 2 percent. The natural makeup of the hydrocarbons in the reservoir can vary wildly from oil sands already exposed to the surface with little associated gas to retrograde gas reservoirs that are primarily gas and a little liquid. The EPA does this with its nationwide approach to zero-emitting pneumatic valves.

The commenter (2353-CrownQuest) points out that pneumatic valves are intermittent and only emit after they are deactivated. The volume of emissions will depend on how often each valve activates. So, a facility making 10 barrels per day will emit less than a facility that makes 100 barrels per day if both have the same number of pneumatic valves. The EPA averages all pneumatic valves (over a million of them) and applies the same standard and expected emission reduction to all facilities. The commenter states that this assumption is not correct. Lower-volume facilities will emit less than higher-volume facilities, and those emissions will drop as the natural decline of oil and gas drops over time.

The commenter (2353-CrownQuest) requests that the EPA reset and take a regional look at developing BSER for each region rather than lumping all 50 states and thousands of different reservoirs in the same national regulation. An example where EPA used an industry BSER is installing instrument air systems on newly constructed facilities. According to the commenter, this example is a practice already becoming common in the industry that is attainable with little impact on design, construction, or operation. There are exceptions, however, where it doesn't make sense to do this, such as shallow wildcat-type wells. The commenter explains that the implementation of installing instrument air applications on newly constructed facilities is a good one. This system and design benefit the operator and environment in emissions reduction. This kind of application is a viable BSER.

Response II-7-77: In the BSER analysis, the EPA used emission factors to estimate emissions from process controllers. These emission factors are averages of emissions that were measured at many sites and incorporate process controllers that actuate frequently and those that actuate infrequently, along with those that are operating properly and those that are malfunctioning. For intermittent vent process controllers, which make up the majority of process controllers currently in use, malfunctioning process controllers account for most of the emissions. These malfunctioning controllers can emit natural gas continuously and can be located at any site, such that even low-output well sites can have high emissions from process controllers. With this consideration, it is important to control emissions from process controllers at all sites.

For all model plants evaluated, the EPA found zero-emissions process controller options that are cost effective. One method of attaining zero-emissions from process controllers is the use of instrument air systems. However, there are other methods available, such as the use of solar-powered electric controllers, that owner/operators may choose to use if an instrument air system is not a good choice for a particular site.

## 7.4 Low Production/Small Sites

Comment: Commenter (2433-EDF et al) agrees with EPA's reasoning set out in the December 2022 proposal preamble<sup>38</sup> and concurs that operators of small sites can cost-effectively implement the standard and does not recommend that the EPA permit an exemption for smaller sites.

Response II-7-78: This comment is a supportive comment on an aspect of the December 2022 Supplemental Proposal that has remained unchanged in the final rule; as such, no response is required.

Comment: Several commenters (2227-WEA, 2238-SOOGA, 2428-API, 2403-PAO) request that the EPA consider allowing the use of low-bleed or intermittent bleed pneumatic controllers at low production/small sites. Specific comments are provided in the following paragraphs.

Commenter (2238-SOOGA) urges U.S. EPA to consider an alternative BSER, including but not limited to allow for low and properly functioning intermittent-bleed controllers in compliance with NSPS OOOOa, based on site-specific cost-effectiveness evaluations that account for the facility's equipment, geographic location, and other unique operational conditions. The commenter recommends that properly functioning pneumatic controllers be assessed through AVO inspections.

Commenter (2428-API) suggests that at existing locations without access to electrical power there be an option to use low continuous bleed or intermittent bleed natural gas-driven pneumatic controllers with proper functioning confirmed through periodic monitoring until modification or reconstruction triggers NSPS OOOOb. At a minimum, the commenter asserts that the EPA must consider an allowance for low production well sites and/or sites with a limited number of natural gas-driven controllers from retrofit within EG OOOOc.

Commenter (2227-WEA) notes that older facilities that currently have very little throughput, and therefore very little emissions from pneumatics due to infrequent activation, installing a gas driven or diesel driven air compressor could increase GHG emissions from the facility, or at the very least result in a very small reduction in emissions. For those facilities, in the EG OOOOc context, the commenter recommends that low-bleed or intermittent bleed controllers be required.

Commenter (2403-PAO) requests EPA establish a separate standard for pneumatics at existing locations, especially low producing, marginal wells. The commenter states that the proposal allows sites in Alaska to use low bleed continuous pneumatic controllers where onsite power is not available. They explain that converting high bleed devices to low bleed devices is a commercially available option at a fraction of the cost of replacing the entire device.

Commenters (2252-PAW, 2326-AXPC, 2351-Jonah Energy) recommend that the EPA allow an alternative option for controlling VOC and methane emissions for small production facility locations with less than some designated count of natural gas-actuated controllers, to allow for

---

<sup>38</sup> See 87 Fed. Reg. at 74769.

routing those controllers to an existing process or control device, similar to what is currently proposed for locations with three or fewer natural gas-actuated pneumatic pumps.

Response II-7-79: In the BSER analysis, the EPA used emission factors to estimate emissions from process controllers. These emission factors are averages of emissions that were measured at many sites and incorporate process controllers that actuate frequently and those that actuate infrequently, along with those that are operating properly and those that are malfunctioning. For intermittent vent process controllers, which make up the majority of process controllers currently in use, malfunctioning process controllers account for most of the emissions. These malfunctioning controllers can emit natural gas continuously and can be located at any site, such that even low-output well sites or sites with few process controllers can have high emissions from process controllers. With this consideration, it is important to control emissions from process controllers at all sites.

The EPA considered the costs and emissions reductions associated several options for emissions control. As methods to attain zero emissions are available, in use at some sites, and have costs and other impacts that are reasonable considering the emissions reductions that would be achieved, the EPA determined that zero emissions represents the BSER for process controllers. The EPA found in its BSER analysis zero-emissions compliance methods were cost-effective at all model plant site types evaluated.

Comment: Commenter (2254-PBPA) states many existing well sites are low producing wells that could be close to end-of-life of their production cycle and may only contain a limited number of controllers. The commenter notes that the complete retrofit of a low-producing facility is likely cost prohibitive based on well economics, which may result in many low production or stripper well sites shutting in production. The commenter requests that the EPA exempt low producing wells from the pneumatic controller requirements.

Commenter (2428-API) requests that the EPA allow additional flexibility for existing sources to allow states to preserve the remaining useful life of facilities. They suggest that EPA provide 1) adequate time and phase-in to properly account for the magnitude and scale of sites converting to non-emitting controllers and 2) focus on the conversion to non-emitting controllers at facilities with the largest number of controllers. To effectively do this, the commenter recommends that the allow the use of low continuous bleed or intermittent natural gas-driven pneumatic controllers and monitored periodically for proper functioning at the frequency specified in 40 CFR 60.5397c.

Response II-7-80: Based on the timing of the steps in the EG implementation process, the EPA believes existing facilities will be able to procure the necessary process controller equipment by the time compliance is required. Under CAA section 111(d), each state must submit a plan to the EPA that establishes standards of performance for each designated facility. For purposes of EG OOOOc, the EPA is finalizing a requirement that each state adopt and submit these plans within 24 months after publication of the final EG OOOOc. The EPA is also finalizing a timeline for compliance with the requirements included in the state plans of no later than 36 months from the deadline for state plan submittals. The combined time allotted for final compliance then could be up to 60 months, or 5 years from the publication date of EG OOOOc. This period of time should

provide all operators with ample opportunity to determine a compliance strategy and procure and install the necessary equipment. In addition, 40 CFR 60.24a(e) also applies to EG OOOOc, which establishes that when applying a standard of performance to a particular source, a state may consider factors, such as the remaining useful life and other factors with respect to specific sources. If there are demonstrable circumstances that make the OOOOc final compliance time unreasonable or unattainable, states have the flexibility to consider these factors consistent with 40 CFR subpart Ba, and propose to incorporate alternative dates in their state plans.

## 7.5 Applicability and Compliance Date Considerations

Comment: Commenter (2433-EDF et al) contends that supply chain considerations do not alter the reasonableness of EPA's proposal. First, operators have generally been able to transition their fleets within EPA's proposed schedule. EQT, the largest natural gas producer in the U.S., retrofit all its sites to eliminate natural gas-driven controllers in less than one and one-half years.<sup>39</sup> And Diamondback anticipates it will have replaced "nearly all" of its controllers with zero-emitting devices within four years.<sup>40</sup> Second, EPA set forth strong record evidence regarding the availability of solar-driven systems, which is an important option for remote sites. For example, EPA the commenter states that the EPA noted one provider that has installed solar systems at over 400 well-sites in Alberta and British Columbia, and cited comments from several providers of solar-driven systems. Critically, as EPA explains in this proposal, operators have thus far not provided evidence that there is inadequate supply of solar-driven technology.

In addition to EPA's own analysis, the commenter (2433-EDF et al) reports that a recent report by Datu Research further underscores that the supply chain for the production of zero-emitting technologies is not a barrier for industry-wide adoption of zero-emission controllers and that, on the contrary, the supply chain is strong enough to support implementation of EPA's proposed standards.<sup>41</sup> Datu's report identifies forty providers of zero-emitting controllers and surveyed nine.<sup>42</sup> Its interviews with these providers demonstrate that suppliers are well equipped to meet anticipated demand within EPA's proposed regulatory timeline. Datu also re-surveyed providers after the Methane Emissions Reduction Program (MERP) passage, and providers indicated that MERP, in addition to EPA's regulations, will further catalyze the production and distribution of zero-emitting devices. Key findings:

- A well-established, capable set of zero-emission controller providers is in place. The report identified 40 providers of zero-emitting pneumatic controller equipment, several of which manufacture long-established technologies used across industries. Many of the 40 listed are mature companies that have served the oil and gas industry for decades, with a

---

<sup>39</sup> EQT Eliminates Nearly 9,000 Natural Gas-Powered Pneumatic Devices, PRNewswire (Jan. 4, 2023) <https://www.prnewswire.com/news-releases/eqt-eliminates-nearly-9-000-natural-gas-powered-pneumatic-devices-301713418.html>.

<sup>40</sup> Diamondback Energy, 2021 Corporate Sustainability Report 8 (2021), <https://www.diamondbackenergy.com/static-files/faf5ab25-5ab5-4404-8c04-c7bd387ae418>.

<sup>41</sup> Datu Research, Zero-emission Alternatives to Pneumatic Control: How Ready are Technology Providers to Meet Increased Demand? (Jan. 2023) (Attachment P).

<sup>42</sup> Id. at 5, 9.

median 43 years in operation.<sup>43</sup> These companies also serve on average five different industries, indicating providers have a wide demand base.<sup>44</sup>

- Zero-emission controller components are mature and designed to integrate into existing systems. Components like electric actuators and instrument air compressors have been in use for decades, and providers of these components emphasize that integrating them into existing natural gas-driven systems is fairly simple.<sup>45</sup>
- Technology providers already see strong demand for retrofits and new installs. In their interviews, providers noted that their oil and gas clients are already choosing alternatives to natural gas-driven controllers not only because of anticipated regulations, but also because of the economic benefits – including preserving saleable product, maintenance cost savings, and less downtime – and the safety benefits associated with reducing flammable product in the workplace.<sup>46</sup> Companies are also preferring electronic systems because of their intelligent connectivity capabilities that keep on-the-ground information flowing continuously.<sup>47</sup> Five companies interviewed indicated that 60-90 percent of their sales were for retrofits.<sup>48</sup>
- Technology providers have strategies for meeting current supply chain challenges. Though procurement delays have been a reality for some suppliers, they have employed strategies like paying higher prices, storing extra quantities of supplies, bringing in more procurement personnel, going to different distributors, spot-buying on the open market, and finding contract manufacturing sites. Larger companies reported facing fewer hurdles.<sup>49</sup>
- Regulatory certainty steadies demand. Even considering supply chain concerns, providers have confidence in their ability to expand production capacity so long as regulatory certainty helps keep demand steady over multiple years.<sup>50</sup>
- MERP is already increasing demand for zero-emitting alternatives and will likely bring innovation and new technology providers into the U.S. market. Providers reported that MERP has resulted in an increase in purchase orders and that they anticipate MERP will accelerate the transition to zero-emitting technologies.<sup>51</sup>

Commenters (2202-TXOGA, 2428-API) suggest that a 60-day compliance deadline for new/modified sources is unrealistic due to supply chain concerns, personnel shortages, and inflation. The commenters propose at least a one-year timeframe for NSPS OOOOb compliance.

Commenter (2326-AXPC) proposes that EPA extend the initial compliance deadline for pneumatic controllers, pneumatic pumps, and storage vessels at least one year for those affected facilities that became NSPS OOOOb affected facilities between the “new” trigger date and the date the final rule is published in the *Federal Register*. Alternatively, the commenter states that, if EPA is unwilling to provide extended initial compliance deadlines as requested, they request

---

<sup>43</sup> Id. at 5.

<sup>44</sup> Id.

<sup>45</sup> Id. at 8.

<sup>46</sup> Id. at 9.

<sup>47</sup> Id. at 14.

<sup>48</sup> Id. at 9.

<sup>49</sup> Id. at 3.

<sup>50</sup> Id. at 11–12.

<sup>51</sup> Id. at 12–13.

that EPA provide extensions where good cause exists, as it did under the recently promulgated Uintah and Ouray Indian Reservation FIP for oil and natural gas sources.

Commenter (2399-GPA) requests that the EPA allow more than one year from publication of a final rule for retrofitting “new” sources subject to NSPS OOOOb to comply with the zero emission controller requirements. The commenter believes that, if EPA finalizes its proposed zero emission controller requirements, supply chain and labor issues will only become worse as the standards are applied nationwide for both new and existing sources.

For “modification” or “reconstruction” facilities, commenter (2305-Williams) reports that they currently experience lead times for the non-natural gas driven pneumatic controllers, generators, and air compressors ranging from 12-24 months. The commenter notes that there is no indication that this will improve in the near future and can be expected to worsen as owners and operators across the country will increase demand in response to the December 2022 supplemental proposal. This leaves even the most responsible owner or operator without the ability to comply within 60 days. The commenter recommends a compliance deadline of 24 months from the publication date of Final Rule.

Commenter (2483-INGAA) requests that EPA give operators 24 months from the publication of the final rule to come into compliance with the zero-emissions requirement for pneumatic controller affected facilities. They also suggest that the applicability date for all of NSPS OOOOb be the date of the publication of the December 2022 supplemental proposed rule: December 6, 2022. The commenter contends that not changing the applicability date for pneumatic controller affected facilities under NSPS OOOOb to December 6, 2022, would violate the due process rights of owners and operators since they had no notice that they would be required to replace all the valves at a facility if a modification occurred and have lost valuable time to accomplish such a task. The commenter states that this lack of notice provides further support for providing 24 months from the publication of the final rule for individual, existing pneumatic controllers, at an affected facility that is modified or reconstructed, to come into compliance with zero-emissions requirements.

Commenter (2258-MSC) notes that, due to severe supply chain shortages and disruptions, generators and other equipment and parts necessary for zero-emission systems can take up to three months or longer for delivery. These supply chain challenges may be exacerbated by this rulemaking, as facilities across the country move to come into compliance. The commenter requests that the EPA establish a reasonable compliance timeframe and allow for a phase-in period for procurement and installation of the systems and equipment necessary (including labor necessary for installation).

Commenter (2279-SBA) recommends that EPA give the state and small businesses flexibility to phase in requirements based on market conditions.

Response II-7-81: Based on these comments and supplemental information submitted by one commenter (API) with updated information to reflect current market conditions, it appears that some equipment may not be available to new facilities or those that have started up or were modified or reconstructed since December 6, 2022, to enable them to install zero-emitting

controllers within 60 days of the publication of the final NSPS.<sup>52</sup> According to this information, some of the operators surveyed report that they are experiencing delays in the availability of process controllers, electrical transformers, generator skids, and compressor skids of up to 12 months. We also considered the information provided by one commenter (EDF) that suggested that extended timeframes would not be warranted, but some equipment providers would need to ramp up production, and some components may not be widely available within 60 days of the publication of the final rule. Considering that the equipment types discussed in the provided information from these commenters are essential to the institution of zero-emitting controllers at a site and the estimated timeframes for the availability of equipment, the EPA is providing a compliance extension of one year for the zero-emissions process controller requirements.

Until the date of compliance of the zero-emissions requirements for process controllers, owner/operators must be in compliance with the requirements for sites in Alaska that do not have access to electrical power. The requirements for such sites are that low-bleed controllers and intermittent vent controllers be used, and that owner/operators perform monitoring of intermittent vent controllers to ensure they do not vent during idle periods. As the current NSPS OOOOa requires these types of controllers to be used, owners/operators of these new and recently modified or reconstructed sites would already be using these types of process controllers if they have not installed zero-emitting process controllers and will only need to begin periodically monitoring natural gas-driven intermittent vent controllers. Therefore, the EPA expects no sites to have any problems complying with these interim requirements within 60 days of publication of the final rule.

Comment: Commenter (2248-NDPC) suggests that, if EPA determines that non-emitting pneumatic controllers should be required under EG OOOOc, it allow for a phase-in period of at least ten (10) years. The commenter explains that factors such as the availability of equipment, personnel capabilities, and location-specific electrification options make it impossible to replace all the emitting pneumatics at sites in any less time.

Commenters (2202-TXOGA, 2428-API) assert that a 3-year compliance deadline will not consider many expected obstacles, such as: supply chain concerns, personnel shortages, and inflation. The commenters propose a five-year timeframe for EG OOOOc compliance.

Commenter (2279-SBA) emphasizes that, because controllers are crucial to oil and natural gas production operations, EPA should provide flexibility in this requirement for those circumstances in which small entities cannot obtain and/or retrofit zero-emitting controllers. They specifically encourage the EPA to phase in any requirement for existing sources. After the phase-in period, they suggest that EPA allow states to grant extensions to small entities that can show a good faith effort to procure non-emitting controllers at a reasonable price.

In the supplemental proposal, the commenter (2279-SBA) notes that the EPA includes a way for state plans to provide some relief for existing sources, through consideration of remaining useful life and other factors (RULOF) in setting emissions standards less stringent than EPA's emission guidelines. EPA provides an example of a state using the RULOF provisions for pneumatic

---

<sup>52</sup> API. Operator Survey of Supply Chain Delays for Equipment Needed for EPA Proposed NSPS OOOOb Methane Rule.

controllers. However, the commenter contends that this flexibility is limited. It requires the state regulatory authority to make findings for a specific facility or class of facilities and identify the facilities in the state plan submitted to EPA. The commenter asserts that this is much earlier in the process than many small businesses will be ready to engage with their state regulators. It also does not give the state and small businesses flexibility to phase in requirements based on market conditions. The commenter recommends that the EPA include these flexibilities directly in the emission guidelines.

Response II-7-82: Based on the timing of the steps in the EG implementation process, the EPA believes existing facilities will be able to procure the necessary process controller equipment by the time compliance is required. Under CAA section 111(d), each state must submit a plan to the EPA that establishes standards of performance for each designated facility. For purposes of EG OOOOc, the EPA is finalizing a requirement that each state adopt and submit these plans within 24 months after publication of the final EG OOOOc. The EPA is also finalizing a timeline for compliance with the requirements included in the state plans of 36 months from the deadline for state plan submittals. The combined time allotted for compliance then is 60 months, or 5 years from the publication date of EG OOOOc. This period of time should provide all operators with ample opportunity to determine a compliance strategy and procure and install the necessary equipment. In addition, information submitted by another commenter on the implementation of a state rule in Colorado, which has similar process controller requirements to those included in the EG, show that both small operators and large operators have been able to comply with the process controller requirements on schedule.<sup>53</sup> Therefore, the EPA has no information to suggest that owner/operators of small operations or large operations will have trouble meeting the EG OOOOc compliance timeline for process controllers.

Comment: Commenter (2483-INGAA) states the “commenced construction date” for applying the definition of commenced construction to pneumatic controllers can be ambiguous under 40 CFR 60.2. The commenter explains that pneumatic controllers are often added or replaced during larger capital projects such as facility expansion or reliability projects. The commenter proposes that for the purposes of pneumatic controller affected facilities installed with capital projects, the commenced construction date be based on the commencement of construction for the overall capital project.

Response II-7-83: The final rule includes in 40 CFR in §60.5365b(d)(2) a definition of “commenced,” which specifies that “For purposes of paragraphs (d)(2)(i) and (ii), ‘commenced’ means that an owner or operator has undertaken a continuous program of natural gas-driven process controller replacement or that an owner or operator has entered into a contractual obligation to undertake and complete, within a reasonable time, a continuous program of natural gas-driven process controller replacement.” In this context, the appropriate commencement date is an identifiable day upon which the process controller replacement program starts. If there is no such delineation of timeframe for the process controller replacement portion of a larger project, the commencement date of the whole project would be the appropriate commencement date.

---

<sup>53</sup> EPA-HQ-OAR-2021-0317-3847.

## 7.6 Miscellaneous Regulatory Text Corrections/Clarifications

Comment: Commenter (2177-Southern Ute Indian Tribe) suggests that EPA recheck citation references. Specifically, they note that 40 CFR 60.5410b(f)(2)(v) and 40 CFR 60.5415b(h)(2)(iv) include a reference to a non-existent 40 CFR 60.5490(b). They also noted that 40 CFR 60.5420c(d) is inappropriately inserted into paragraph (c)(14)(x) and should be formatted as its own paragraph.

Response II-7-84: We corrected the references to section 40 CFR 60.5490b to correctly refer to section 40 CFR 60.5390b and revised the formatting of the paragraph formerly numbered as §60.5420c(c)(14)(x) and now numbered as §60.5420c(c)(14)(viii) to correct the missing separation between it and paragraph §60.5420c(d).

Comment: Commenter (2428-API) EPA includes references to [INSERT DATE OF PUBLICATION OF THE PROPOSED RULE IN THE FEDERAL REGISTER], but it is unclear whether it is based on the November 2021 preamble or the December 2022 proposal.

Response II-7-85: The applicability date for process controllers under NSPS OOOOb is the date of publication of the December 2022 supplemental proposal, December 6, 2022.

Comment: Commenter (2428-API) suggests that the following additional citation be checked for correct cross referencing: 40 CFR 60.5410b(f)(2)(iv)(B).

Response II-7-86: After review, we have found that the December 2022 Supplemental Proposal paragraph §60.5410b(f)(2)(vi)(B) had an incorrect cross-reference to another paragraph in the proposed rule. For the final rule, we have revised and reorganized the regulatory text of 60.5410b(f)(2) such that paragraph §60.5410b(f)(2)(vi)(B) no longer contains the same content that was included in that paragraph at proposal. We have ensured that this incorrect cross-reference is no longer in any paragraph of the final regulatory text.

## 7.7 Other Regulatory Topics

### 7.7.1 Secondary Emissions

Comment: Commenter (2248-NDPC) believes the secondary emissions created by the proposed requirements to make the pneumatic controllers non-emitting (e.g., from the manufacturing of new equipment and installation of alternative equipment) could be more significant than what the source emits during its useful life.

Response II-7-87: The EPA recognizes that if owners and operators elect to comply with the process controller requirements by installing and operating a generator, there will be secondary emissions generated from the fuel combustion; however, we have estimated the emissions that would be created by generators and found that they are far outweighed by the VOC and methane emissions reduction that would be achieved by using process controllers that are not driven by natural gas. For the December 2022 Supplemental Proposal, while we recognized that a

commenter had provided estimates of these emissions, we did not separately analyze the secondary emissions that would be created if a generator was used to power this equipment.

We have now conducted that analysis and estimate that for a natural gas-fired generator to power this equipment, the secondary criteria pollutant emissions would be 43 lbs/yr CO, 306 lbs/yr NO<sub>2</sub>, 6 lbs/yr PM, and 3 lb/yr PM<sub>2.5</sub> for a 5 HP compressor and 172 lbs/yr CO, 1,222 lbs/yr NO<sub>2</sub>, 26 lbs/yr PM, and 13 lb/yr PM<sub>2.5</sub>, for a 20 HP compressor. The secondary GHG emissions generated as a result of this electricity generation are estimated to be 11,654 lbs/yr CO<sub>2</sub>, 0.2 lbs/yr methane, and 0.02 lb/yr N<sub>2</sub>O for a 5 HP compressor and 46,618 lbs/ yr CO<sub>2</sub>, 0.9 lbs/yr methane, and 0.09 lbs/yr N<sub>2</sub>O for a 20 HP compressor. Considering the global warming potential of these GHGs, the total CO<sub>2</sub>e emissions would be 11,667 lbs/yr CO<sub>2</sub>e from a 5 HP compressor and 46,666 lbs/yr CO<sub>2</sub>e from a 20 HP compressor. With the total CO<sub>2</sub>e emissions from process controllers at a small site estimated to be 303,000 lbs/yr and 7.5 million lbs/yr for a large site, the total CO<sub>2</sub>e reduction from the use of zero emissions process controllers powered by a generator running a compressed air system would be more than 95 percent when compared to the uncontrolled methane emissions from natural gas driven controllers. No other secondary impacts are expected. Considering this information regarding secondary emissions, we continue to find that the BSER for reducing methane and VOC emissions from natural gas-driven controllers in the production and transmission and storage segments of the industry to be the use of controllers that have a methane and VOC emission rate of zero.

### ***7.7.2 Flexibility for Existing Sources***

Comment: Commenter (2220-WDEQ) states re-routing to a process on site is not a practical or economically feasible solution for many existing sources and can result in unanticipated emissions increases due to other consequential compliance issues. This, in turn, according to the commenter, could result in an increased workload for their compliance staff who will already face a significantly increased burden in site visits and reports due to the increased number of affected facilities as a result of the supplemental proposal. The commenter reports that Wyoming already has a robust New Source Review (NSR) permitting program that successfully reduces NO<sub>x</sub> and VOC emissions – and, consequently, methane emissions – from pneumatics. Furthermore, they report that their compliance staff performs comprehensive site evaluations and timely correspondence with operators throughout the state to ensure that compliance issues are identified and addressed in the most efficient and effective manner possible. The commenter requests that EPA provide flexibility through an off-ramp for permitting programs like Wyoming's that already effectively address pneumatics; because their state's program is so effective, the benefits of implementing the proposed NSPS OOOOb and EG OOOOc requirements for pneumatics would be marginal compared to the significant cost to operators and on-site technical infeasibilities associated with the supplemental proposal.

Response II-7-88: The EPA recognizes the possibility that changes made to processes or equipment at a facility may initially create unintentional issues or problems at the site. However, as the NSPS and EG requirements reduce emissions by 100% from all process controller affected facilities, the guaranteed benefits of these long-term emissions reductions outweigh any potential initial issues that might arise as process or equipment modifications are made. In addition, the EPA has determined that zero-emissions from process controller are technically feasible and the

costs of the options available to attain zero-emission are reasonable considering the emissions reductions that would be achieved. Therefore, the EPA found that zero-emissions from process controllers is the BSER, and this is reflected in the NSPS and EG. Therefore, all sites must comply with these requirements.

### ***7.7.3 Streamlining of Recordkeeping and Reporting Requirements***

Comment: Commenters (2177-Southern Ute Indian Tribe, 2399-GPA, 2428-API) request that the EPA not impose recordkeeping requirements for exempt controllers (e.g., pneumatic controllers that are not natural gas-driven). Commenter (2428-API) notes that it appears that it was EPA's intent to streamline recordkeeping and reporting to only natural gas-driven controllers, which are the affected facility. However, the commenter suggests that the language proposed within NSPS OOOOb per 40 CFR 60.5420b(c)(6)(i) and EG OOOOc is unclear in this regard.

Response II-7-89: After considering these comments, we have determined that it is appropriate in this instance to require identification of the equipment that is included in the affected facility, rather than the equipment that is not part of the affected facility. The process controllers included in the affected facility are those that are subject to the emissions standards, whereas process controllers not included in the affected facility are not subject to the emissions standards in the final rule, and also have no potential to emit methane or VOCs. Therefore, we have revised the recordkeeping requirements to require identification only of controllers that meet the finalized definition of an affected facility, which are those process controllers that are driven by natural gas and that are not ESDs.

### ***7.7.4 VRU Continuous Monitoring***

Comment: Commenter (2333-LongPath) states that, where a VRU is used to route emissions to a process, continuous, quantitative emissions monitoring data is extraordinarily useful to operators for keeping VRU settings at the appropriate levels, and requests that EPA consider incentivizing operators to use continuous monitoring to monitor VRU set points and efficiency, and to make continuous monitoring an allowable solution for monitoring of VRUs.

Response II-7-90: Continuous emissions monitoring may provide owners/operators with useful operations information, and they may choose to use such a system to inform their processes. However, VRUs which route recovered gas and vapor back to the process are not considered to be control devices<sup>54</sup>, and are not subject to performance testing, emissions monitoring, or parameter monitoring requirements. As the EPA's requirements in the NSPS and EG are aimed at achieving the CAA mandate that the best systems of emissions reductions are used and to ensure systems that reduce emissions are performing properly to achieve the intended emissions reductions, devices that may improve operating performance are outside the scope of this action.

---

<sup>54</sup> See 78 FR 58241 and Letter from Peter Tsirigotis to Matthew Todd, American Petroleum Institute. September 28, 2012. Docket Item No. EPA-HQ-OAR-2010-0505-4595.

### ***7.7.5 Combine with Pneumatic Pumps***

Comment: Commenter (2294-OOGA) requests that EPA align the requirements for pneumatic controllers with the requirements for pneumatic pumps including, specifically: allowing emissions to be routed to a control device if it is technically infeasible to route to a process; and excluding natural gas pneumatic controllers that operate for less than 90 days per calendar year from the affected facility.

Commenter (2428-API) states EPA has proposed a completely distinct set of requirements for natural gas-driven controllers separate from natural gas-driven pneumatic pumps with sometimes conflicting statements made to justify EPA's decisions. The commenter requests that the requirements for both pneumatic controllers and pumps be streamlined for consistency with neutral technology standards that do not require additional certifications and allow for emissions to be routed to a control device.

Response II-7-91: The EPA has considered these comments and streamlined the requirements for process controllers and pumps to include the same technical feasibility and cost assumptions for components that would be common to both types of zero-emitting equipment, such as the costs and feasibility of the use of solar panels, compressed air systems, and generators. The result of this has largely been changes to the assumptions and costs for pumps, as well as changes to the final rule requirements to more closely align with the requirements for process controllers. For both process controllers and pumps, the EPA has determined the technical feasibility of the available emissions control types along with the costs and other factors associated with the control options, and as such, additional site-specific infeasibility determinations are not necessary. In the final rule for both process controllers and pumps, the requirements are technology-neutral. No additional certifications are required for process controllers or pumps complying with the zero-emissions standards. For pumps at a limited subset of sites for which zero-emissions pumps are not required, certifications are only required to verify the lack of certain emissions control equipment present at the site. For controllers, as technically feasible, cost-effective zero-emissions options were found to be available for all sites, the EPA determined that zero-emissions options represent the BSER, and this is reflected in the NSPS and EG. Therefore, control devices achieving less than 100% emissions reductions do not reflect the BSER and are not allowed for process controllers. For pumps, the EPA determined there are technically feasible, cost-effective zero-emissions options available for sites with access to electrical power and for sites without access to electrical power that have three or more natural gas-driven diaphragm pumps. Therefore, control devices achieving less than 100% emissions reductions do not reflect the BSER and are not allowed for pumps at these sites. For sites without access to electrical power that have fewer than three natural gas-driven diaphragm pumps, the EPA determined that the costs associated with the control of emissions from pumps was only reasonable if there was an existing VRU available onsite to enable emissions to be routed to a process or if an existing control device was otherwise already onsite. The EPA determined that the BSER for these sites is to use a VRU already onsite to route emissions to a process or to route emissions to an already onsite control device if a VRU is not present. The NSPS and EG reflect this BSER finding.

The EPA acknowledged in the December 2022 Supplemental Proposal that the focus of the BSER analysis has been on process controllers that are part of the routine operation of oil and natural gas facilities. We noted that we did not have sufficient information to include an exemption or an alternative standard for process controllers associated with temporary equipment, and we requested more information about these situations. The EPA requested information regarding when temporary equipment is used, the function of the controllers during this time, how they are powered, and the typical duration of their usage. The EPA also requested information explaining in detail why the zero-emission solutions that are used for the permanent equipment at the site cannot be also used for this temporary equipment. As the EPA did not receive this information or further explanation, the EPA has insufficient support for an exemption or alternative standard. Therefore, the final rule has not been revised to separately address process controllers on temporary equipment.

### **7.7.6 Backup Systems**

Comment: Commenter (2383-BH) states pneumatic controllers/positioners should be allowed on backup/monitor systems, provided the controllers bleed only when the backup system is engaged (e.g., in the event of a power failure to a primary electric actuator).

Conversely, commenter (2433-EDF et al) states allowing these backup systems would result in a potential loophole that would enable owners or operators to continue to use natural gas-driven controllers in routine situations. In this way, the commenter suggests that the allowance would amount to a broad exemption from the standard, which, as discussed above, is not necessary given the wide array of available technologies – including natural gas-driven controllers – that operators will be able to use to comply. Moreover, they note that the industry’s analysis regarding the need for such systems is flawed. Carbon Limits interviewed several zero-emission controller technology providers and operators using such controllers at their facilities, and none of these companies indicated a need for a natural gas system backup.<sup>55</sup> Furthermore, the commenter states that none of the rules in Colorado, New Mexico, or British Columbia – all of which prohibit venting natural gas-driven controllers at new sites and require significant retrofits of such devices at existing facilities – allow operators to use venting gas-driven controllers as a back-up. Clearly, according to the commenter, such back-up systems are not necessary.

The commenter (2433-EDF et al) also points out that such an exemption would also be extremely difficult to monitor. Operators would need to show the need to use emitting devices arose due to a system failure, which would require confirmation from EPA in each instance and necessitate personnel and continuous monitoring. The commenter believes that, if EPA is unable to monitor the use of these natural gas back-ups, this exemption would swallow the rule, effectively displacing the zero-emission standard that EPA has demonstrated is cost-effective and feasible.

Response II-7-92: The information regarding zero-emission process controller technologies available to the EPA do not suggest that a natural gas-driven back-up system is necessary. For compressed air systems used to power pneumatic process controllers, the systems are designed with two compressors to ensure one is always available in the case of a malfunction of the other.

---

<sup>55</sup> Carbon Limits, 2023 Memo, supra note 257.

If the system uses power from the grid, the system could be designed to have an alternate power source, such as a generator, to ensure the compressed air system does not lose power. If electrical process controllers are used, an alternate power source could also be used to ensure the process controllers continue to function, such as a generator or a battery system. Therefore, the use of natural gas-driven process controllers are not necessary to provide an alternative in the case of a power failure.

Comment: Commenter (1609-Qnergy) states that there is no need for backup systems. Operators can use proven cost-effective instrument air packages that have compressor redundancy i.e., if one compressor is malfunctioning the other will still operate. The built-in redundancy eliminates the need for backup systems.

Response II-7-93: The EPA agrees that backup systems are generally not necessary for compressor systems and that the systems are designed with two compressors so that one is always available to operate in the case of a malfunction in the other. This is the type of system included in the EPA's BSER analyses.

### ***7.7.7 Technology to Abate Methane Emissions***

Comment: Commenter (1609-Qnergy) asserts that the industry<sup>56</sup> can adopt a proven technology to abate methane emissions at minimal to no cost. The difference between 'low-cost' to 'no-cost' depends on the value assigned to the saved natural gas. The commenter notes that its position is based on field experience with respect to cost and per unit abatement capacity.

The commenter (1609-Qnergy) expresses pride in being the only company with a low-maintenance commercial power generator based on a linear 'Free Piston' Stirling Engine with no rotating parts, meaning no need for lubrication and maintenance. The commenter explains that the engine is designed to operate on unrefined methane from natural gas fields and biogas. The technology was developed and is manufactured in the U.S. It has already deployed more instrument air packages in the U.S. natural gas sector than any other company and is considered to be the market leader in off-grid solutions in the 1- 12 scfm range. [The commenter provides a map (Figure 2) in their comment letter of their installations across North America.] The commenter supports the EPA's efforts to eliminate methane and VOCs emissions in a cost-effective manner that reflects the significant technological advancements while providing the industry with clarity and consistency.

Commenter (1609-Qnergy) reports that the nationwide impact of using their technology would amount to abating about 1.2 million (M) tpy of methane at a cost of about \$300M per year across the U.S. industry. This result assumes zero value of natural gas. When the value of natural gas is considered, the abatement cost to the industry ranges from about \$190M at \$2 per million British thermal units (MMBtu) of natural gas to a net gain at \$6 per MMBtu with a crossover at \$5 per MMBtu. [The detailed derivation and sources of data are provided in Appendix B (of the commenter's letter)]. The overwhelming conclusion is that the industry can abate methane

---

<sup>56</sup> The commenter refers to 'industry' as gas production sites of two wells and above. Small (1 well per site) installations are not included in our current scope of supply and thus we do not have installation data to share with respect to these sites.

through pneumatic controller at a significantly lower cost than published, based on actual experience across the U.S. The commenter notes that their data is based on successful installations across all U.S. climate zones.

The commenter (1609-Qnergy) states in the broader perspective of instrument air, the industry has long passed the pilot stage. The commenter confirms that it has already installed hundreds of their zero-emission units. According to the commenter, this fact alone should remove any remaining doubt with respect to adequate demonstration of the technology, application, and its cost effectiveness. The commenter also reports emission reductions close to 99.6 percent. The commenter goes on and states EPA's values on instrument air system reductions are too conservative.

Response II-7-94: The EPA agrees that the use of generators to power electrical process controllers or to power compressed air systems is a mature technology, and owner/operators may choose to use such technology for compliance with the process controller requirements of the rule. We note that in our refreshed BSER analysis conducted for the final rule, the most up-to-date emissions factors were used, which included those used in the final GHGRP revisions. However, the final GHGRP does not include an emission factor for intermittent vent controllers, and instead requires that sites calculate emissions for each site based on site-specific measurements. Therefore, to estimate emissions from intermittent vents, the EPA used an average emission factor of intermittent vent emissions from a recent study that includes both properly functioning and malfunctioning intermittent vent process controllers.<sup>57</sup> As these emission factors have been updated recently and are based on data from field studies of emissions from process controllers, these emission factors are the best data available to estimate nationwide emissions from process controllers. The EPA does not anticipate that the use of these emission factors significantly overstate or understate process controller emissions.

---

<sup>57</sup> Luck, B., D. Zimmerle, T. Vaughn, T. Lauderdale, K. Keen, M. Harrison, A. Marchese, L. Williams, and D. Allen. 2019. "Multi-Day Measurements of Pneumatic Controller Emissions Reveal Frequency of Abnormal Emissions Behavior at Natural Gas Gathering Stations."

## Chapter 8. Pumps

### 8.1 NSPS OOOOb and EG OOOOc Affected Facility

#### 8.1.1 Proposed Pneumatic Pump Affected Facility Definition

Comment: Commenter (2410-California Office of the Attorney General (CA AG) *et al.*) supports the EPA’s proposed definition of the pneumatic pump affected facility to include the collection of natural gas-driven pneumatic pumps at a site instead of each individual natural gas-driven pump. The commenter also supports the EPA’s proposal to determine that zero-emission pneumatic pumps in all segments—specifically diaphragm and piston pneumatic pumps in the production segment and diaphragm pneumatic pumps in the transmission and storage segment—are the best system of emission reduction (BSER) for new and existing sources.

Response II-8-1: This comment is a supportive comment on an aspect of the December 2022 Supplemental Proposal that has remained unchanged in the final rule; as such, no response is required.

Comment: Commenter (2326-American Exploration and Production Council (AXPC)) requests that the EPA define the pneumatic pump new source performance standards (NSPS) OOOOb affected facility as, “the collection of natural gas-driven diaphragm and piston pumps at a well site, centralized production facility, onshore natural gas processing plant, or a compressor station that emits or has the potential to emit methane or VOC to atmosphere,” and similarly define the emission guidelines (EG) OOOOc designated facility with respect to only methane.

Response II-8-2: The EPA disagrees that adding the phrase “that emits or has the potential to emit methane or VOC to the atmosphere” should be added to the definition of the affected pump facility. As any natural gas-driven pump would have the potential to emit methane and VOC to the atmosphere, this phrase is redundant and could be confusing as to whether the affected facility includes pumps that have emissions routed to a process or control device. The EPA intends that any natural gas-driven pump be included in the affected facility, and therefore, the definition of affected facility was not changed as suggested by the commenter.

#### 8.1.2 Expansion of Affected Facilities and Proposed Control Options

Comment: Commenter (2428-American Petroleum Institute (API)) states that the expansion of affected facilities and proposed control options are unexpected based on the 2021 proposal. The commenter contends that operators have had no way of knowing:

- Piston pumps would be affected facilities under 40 CFR 60.5365b(h).
- The collection of both piston pump and diaphragm pumps would constitute an affected facility under 40 CFR 60.5365b(h).
- The control standard would require a zero emissions control or a suite of ongoing certifications to demonstrate feasibility or infeasibility in 40 CFR 60.5393b.
- Modification and reconstruction have never applied to such small ancillary equipment such as a single piston pump or diaphragm pump.

Therefore, the commenter asserts that the applicability date for pneumatic pumps under NSPS OOOOb should be the date of promulgation of the December 2022 supplemental proposal.

Response II-8-3: The EPA agrees that the appropriate applicability date for NSPS OOOOb is the date of promulgation of the December 2022 supplemental proposal, and we have revised the applicability date accordingly. This is discussed further in the preamble in section IX.

Comment: Commenter (2428-API) states that while EPA expanded the applicability to include piston pumps, EPA did not include a definition for what a piston pump is or how it is beyond the definition for natural gas diaphragm pump currently provided. The commenter provides the following recommendations on the definition of diaphragm pump (underlined text indicates new text and struck out text indicates deleted text):

*Natural gas-driven diaphragm pump* means a positive displacement pump powered by pressurized natural gas that uses the reciprocating action of flexible diaphragms in conjunction with check valves to pump a fluid. A pump in which a fluid is displaced by a piston driven by a diaphragm is not considered a diaphragm pump for purposes of this subpart. A lean glycol circulation pump that relies on energy exchange with the rich glycol from the contactor is not considered a ~~diaphragm~~ pneumatic pump.

Response II-8-4: The EPA acknowledges that the December 2022 Supplemental Proposal did not include a definition for piston pumps; however, rather than revising the definition of diaphragm pumps, we have added a definition for piston pumps. The added definition reads as follows, “*Natural gas-driven piston pump* means a positive displacement pump powered by pressurized natural gas that moves and pressurizes fluid by using one or more reciprocating pistons. A pump in which a fluid is displaced by a piston driven by a diaphragm is considered a piston pump for purposes of this subpart. A lean glycol circulation pump that relies on energy exchange with the rich glycol from the contactor is not considered a piston pump.”

### **8.1.3 Emission Threshold Recommendation**

Comment: Commenter (2180-Pennsylvania Department of Environmental Protection) recommends that the EPA replace the practice of installing emissions controls based on the number of pumps at a facility with an emissions threshold that governs the installation of emissions controls. Since 2018, the commenter states that natural gas-fired pneumatic pumps in Pennsylvania have been required to control emissions by 95 percent or greater if the potential or actual emissions from the pumps exceed 200 tons per year (tpy) of methane or 2.7 tpy of VOC.

Response II-8-5: While the EPA agrees that the determination of when to require emissions controls could be made based on the potential or actual emissions from an emissions source, the EPA has not revised the regulatory text for pumps in the final rule to require emissions controls based on an explicit emissions threshold. The use of such a regulatory emissions threshold implies that emissions at that level are high enough to justify emissions control requirements based on the emissions reductions that could be realized and the associated costs and other impacts of the controls. To simplify the applicability determination process for the final rule, we determined the emissions levels that would be necessary to justify emissions control

requirements and the conditions under which those emissions levels would occur. Thus, we determined in our BSER analysis the site conditions for which control of pumps is reasonable based on the emissions reductions that would be achieved and the costs and other impacts associated with emissions controls. This up-front determination simplifies the applicability process by not requiring owners or operators to determine potential or actual emissions and by not requiring an air quality agency to review that information.

#### ***8.1.4 Request for Exemption of Low-Pressure/Low-Emitting Pumps***

Comment: Commenters (2403-Petroleum Alliance of Oklahoma, 2305-Williams Companies, Inc. (Williams)) request that the EPA allow operators an exemption for low pressure, minimal emission pumps (e.g., chemical injection pumps) or provide an option where technical information could be provided to justify why they should be exempt for replacement and/or retrofitting. Additionally, commenter (2305-Williams) notes chemical injection natural gas-driven pneumatic pumps, such as those used to inject methanol, antifreeze, or defoamer, have generally low emissions and low pressure of emissions when they do occur. According to the commenter, this low-pressure scenario would make it difficult to capture and route the emissions back to a process or a flare with current capture technology.

Commenter (2391-Chesapeake Energy Corporation (CEC)) recommends EPA exempt pneumatic piston pumps with emissions below an appropriate emission threshold in mcf of gas vented per calendar year based on the emission factor of 13.3 standard cubic feet (scf)/hour (hr) in the Subpart W Greenhouse Gas Reporting Program (GHGRP) regulations.

Response II-8-6: The EPA has conducted an analysis of emissions control options for pumps, considering the emissions reduction potential of those options, along with the costs and other impacts associated with the emissions controls. We included pumps with low emissions in this analysis, and we determined that control of such pumps is reasonable under certain conditions. These conditions include having access to electrical power at a site, having three or more natural gas-driven diaphragm pumps at a site, and having existing emissions control devices or a vapor recovery unit at a site. Under these conditions, we determined that the costs and other impacts associated with controlling emissions from pumps are reasonable in consideration of the emissions reductions that would be achieved. For instances in which it is technically infeasible to control emissions from pumps at sites without access to electricity and fewer than three natural gas-driven diaphragm pumps, the final rule also retains the provisions included in the December 2022 Supplemental Proposal that allow owners or operators to demonstrate that it is technically infeasible to control emissions from pumps.

#### ***8.1.5 Zero-Emitting Pumps***

Comment: Commenter (2177-Southern Ute Indian Tribe (Southern Ute)) states that 40 CFR 60.5410b(g)(1) requires owners and operators to submit the identification of all your pneumatic pumps that are not powered by natural gas in your initial annual report as required by 40 CFR 60.5420b(b)(10)(i). The commenter recommends pneumatic pumps that are not powered by natural gas be exempt from the rule, and not included in an initial compliance demonstration.

The commenter suggests that operators only be required to maintain records sufficient to determine applicability with the regulations.

Commenter (2227-Western Energy Alliance (WEA)) contends that treating zero-emitting pneumatic pumps as affected facilities will have very little effect on reducing emissions. The commenter explains that zero-emitting pneumatics are an example of industry innovation to solve the problem of methane leaks. By treating them as affected facilities, the commenter states that the EPA is disincentivizing technical innovation and subjecting zero-emitting equipment to unnecessary recordkeeping and reporting. The commenter provides that, if there were to be a malfunction of a zero-emission pneumatic controller or the gas capture system connected to a pump, the malfunction would be found and subsequently repaired through leak detection and repair (LDAR). The commenter asserts that there is no need to include zero-emissions equipment as affected facilities.

Commenter (2326-AXPC) states EPA proposes best system of emission reduction (BSER) that would result in no VOC or methane emissions from pneumatic controllers, pneumatic pumps, or gas well liquids operations. Thus, compliance with EPA's proposed BSER ensures that pneumatic controllers, pneumatic pumps, and gas well liquids operations are not "stationary sources" because compliance will not, and could not, result in emissions. According to the commenter, this exceeds EPA's authority granted under Clean Air Act (CAA) section 111. The commenter requests that EPA define the NSPS OOOOb pneumatic controller and pneumatic pump affected facilities as equipment designed to emit VOC and/or methane and similarly define the EG OOOOc designated facility to include equipment designed to emit methane.

Commenter (2391-CEC) states pneumatic pumps relying on supplied air do not meet this definition because they are not natural gas driven. Furthermore, the commenter adds that there is no environmental benefit to keeping or submitting this information. The commenter recommends that the EPA delete any reporting or recordkeeping requirements for these pumps from the final regulations.

Response II-8-7: It appears some commenters mistakenly thought the EPA included all pumps in the affected facility definition. The December 2022 Supplemental Proposal only included pumps driven by natural gas in the affected facility definition in §60.5365b(h); however, it did require that records be kept of the pumps that were not driven by natural gas and not included in the affected facility definition. The pump affected facility was defined as follows in the December 2022 Supplemental Proposal:

Each pneumatic pump affected facility, which is the collection of natural gas-driven diaphragm and piston pneumatic pumps at a well site, centralized production facility, onshore natural gas processing plant, or a compressor station. Pneumatic pumps that are not driven by natural gas are not included in the pneumatic pump affected facility, provided the records in §60.5420b(c)(15)(i) are maintained.

The EPA agrees that pumps with no potential to emit methane or VOC to the atmosphere should not be included in the affected facility and is finalizing this affected facility definition. After considering these comments regarding the recordkeeping and reporting requirements for pumps

with zero emissions, we have determined that it is appropriate in this instance to require identification of the equipment that is included in the affected facility, rather than the equipment that is not part of the affected facility. The pumps included in the affected facility are those that are subject to the emissions standards in the rule, whereas pumps not included in the affected facility are not subject to the emissions standards in the rule, and also have no potential to emit methane or VOCs. Therefore, we have revised the recordkeeping and reporting requirements to require identification only of pumps that meet the finalized definition of an affected facility, which are those pumps that are driven by natural gas and that are in operation for 90 days or more in a calendar year.

### ***8.1.6 Modification/Reconstruction***

Comment: Commenter (2428-API) states NSPS OOOOa requires certain diaphragm natural gas driven pumps to be routed to a control device or process. As such, the commenter explains that these pumps are already controlled by at least 95 percent. The commenter suggests that the EPA has not adequately considered or accounted for how to handle these existing controlled pneumatic pumps within the proposed rules. Specifically, they state that these pumps should meet the requirements of EG OOOOc by continuing to comply with NSPS OOOOa. They add that they believe that these pumps should also be excluded from modification and reconstruction under NSPS OOOOa.

Response II-8-8: NSPS OOOOa at §60.5393a(b) requires that natural gas-driven diaphragm pumps at well sites must reduce natural gas emissions by 95% if a control device is onsite and must route those pump emissions to another control device if the only control device(s) at the site achieve less than 95% emissions reductions. If no control device is onsite, OOOOa does not require emissions reductions from pumps. For the December 2022 Supplemental Proposal, we re-evaluated pump options that would result in zero emissions of methane and VOC, and we also evaluated the use of new and existing control devices in our analysis. For the final rule, we have updated the analysis performed for the December 2022 Supplemental Proposal to include more recent cost information for pump zero-emissions options. For both the supplemental proposal and the final rule, our analyses showed that zero emissions represents the BSER at sites with certain characteristics, including having access to electricity at the site and having a certain number of diaphragm pumps at the site. While the analysis conducted for the December 2022 Supplemental proposal showed that the costs to achieve zero emissions from pumps were reasonable when the site has access to electricity and when there were four or more diaphragm pumps at a site without electricity, the analysis conducted for the final rule using the updated information shows that costs to achieve zero emissions from pumps are reasonable when there is access to electricity and when there are three or more diaphragm pumps at a site without electricity. For sites with access to electricity and for sites without electricity that have three or more natural gas-driven diaphragm pumps, 95% control was not determined to be the BSER and was not used to develop the pump standards for the NSPS or the presumptive standards for the EG. Zero emissions from pumps was shown in our analyses to be technically achievable and cost-effective through several available options, including the use of electrical pumps powered by electricity from the grid or solar power systems, pumps powered by compressed air using electricity from the grid, and by routing emissions to a process. Since these options achieve a rate of zero methane and VOC emissions, compared to an emission rate of up to 5 percent of the

baseline emissions through the use of a control device, we have not changed our determination that a zero-emissions option is the BSER at these site types. For sites without electricity and with fewer than three natural gas-driven diaphragm pumps, our analysis for the final rule shows that control of emissions through a control device otherwise onsite represents the BSER. At these sites, requiring zero emissions from pumps, requiring the use of a new control device, and requiring the routing of pump emissions to a process through a new vapor recovery unit (VRU) (which is usually required to attain the necessary pressure for the gas to enter a process onsite) does not represent the BSER due to the costs associated with the equipment needed for these options. The NSPS and the EG for these sites reflect the BSER determination by requiring that emissions be routed to a process through a VRU if a VRU is onsite; if a VRU is not onsite, pump emissions are required to be routed to a control device onsite that achieves 95% emissions reductions; if no control device that achieves 95% emissions reduction is onsite, another onsite control device may be used; and if no VRU or control device is onsite, pump emissions are not required to be controlled. For existing sites that have access to electrical power or that have three or more diaphragm pumps, owners/operators currently complying with OOOOa by routing emissions to a control device achieving 95% control will be required to switch to a zero-emissions option for pumps to comply with OOOOc. For existing sites that do not have access to electrical power or that have fewer than three natural gas-driven diaphragm pumps, owners/operators currently complying with OOOOa by routing emissions to a control device achieving 95% control will be required to switch to routing emissions to a process if a VRU is onsite, otherwise, they may continue to route emissions to a control device achieving 95% control for compliance with OOOOc.

Comment: Commenter (2177-Southern Ute) states that the theory that owners and operators will implement zero-emission pumps across a site when a modification occurs because converting a single zero-emitting device typically requires a conversion of all devices at the facility is accurate. The commenter argues the infeasibility of implementing zero-emission pumps. The commenter notes that, due to lack of power in many remote locations, the installation of power may be cost prohibitive, and installation of combustion-generated power may create more emissions than are being reduced. They add that construction projects on Tribal lands require permitting through the National Environmental Policy Act (NEPA) program, which can be extensive and burdensome.

Response II-8-9: As explained above in Response II-8-8, the EPA conducted an analysis of pump control options for the December 2022 Supplemental Proposal and a revised analysis for the final rule. Both analyses showed that there are zero-emissions options for pumps at remote locations that do not have access to electrical power. The analysis for the final rule showed that zero emissions options at sites without electricity that have three or more natural gas-driven diaphragm pumps are reasonable, considering the emissions reductions, costs, and other impacts associated with those options.

As we assumed some sites would choose to install an electric generator to power compressed air-driven pumps, we estimated the emissions that would be created by such generators. We found that those emissions are relatively small and are outweighed by the emissions reductions that would be reduced from the pumps. Generators, which produce power by burning a fuel, such as natural gas or diesel, will generate a small amount of emissions from this process. As we

assumed some sites would choose to install an electric generator to power compressed air-driven or electrical pumps, we estimated the emissions that would be created by such generators. For this analysis, we included natural gas generators of 5 to 10 horsepower, which should be sufficient sizes to accommodate approximately 5 to 50 pumps. We estimate that a natural gas-powered generator would produce between 0.006 and 0.012 tons of VOC and between 0.15 and 0.3 tons of NOx per year, depending on the number of pumps and the size of the generator needed to power them. However, the emissions reduced through the use of zero-emission pumps powered by such generators would range from 4.8 to 48 tons of VOC and 17 and 170 tons of methane per year. Therefore, we found the emissions created by generators to be relatively small and are outweighed by the emissions reductions that would be reduced from the pumps. Therefore, consideration of these impacts did not change the BSER determination or the requirements of the NSPS or EG.

Regarding administrative burdens related to permitting, the EPA understands that permitting actions may be required when adding or changing equipment at a facility. However, such permitting is not directly required by this rulemaking and is outside the scope of this action.

Comment: Commenter (2433-Environmental Defense Fund (EDF) *et al.*) supports EPA's interpretation of "modification". The commenter explains that the addition of routed natural gas-driven pumps should trigger a modification. As with controllers, the commenter notes that the fact that most mitigation solutions are site-wide supports that the appropriate affected facility definition should include the collection of pumps at a site. Because both zero-emission and natural gas-driven mitigation technologies (including control devices and systems that route to process) are typically site-wide solutions, EPA's affected facility and modification definitions in this context are reasonable. The commenter also supports EPA's proposal to interpret "reconstruction" of a site as whenever greater than 50 percent of the existing onsite pumps are replaced over a two-year period. Just as with pneumatic controllers, the commenter states that this definition for pneumatic pumps aligns with the statutory definition that reconstructed sources are those where the "fixed capital cost of the new components exceeds 50 percent of the fixed capital cost that would be required to construct a comparable entirely new facility." Thus, the commenter believes that the EPA's interpretation is appropriate, and they encourage the agency to clarify, as it should with controllers, that pumps that are part of replacement programs that commenced within the two-year period are included in the threshold determination.

Response II-8-10: This comment is largely supportive of an aspect of the December 2022 Supplemental Proposal that has remained unchanged in the final rule; as such, no response is required for those supportive remarks. Regarding the request for clarification about the period of time included in the threshold determination for modifications and reconstructions, we note that the proposed NSPS OOOOb and EG OOOOc already included provisions that those threshold determinations must include all natural gas-driven pneumatic pumps which are or will be replaced within any 2-year rolling period. To provide further clarification on the replacement period time period, the final rule specifies that all replacement programs that commence in a 24-month rolling period are included in the threshold determinations for modifications and reconstructions.

Comment: Commenters (2254-Permian Basin Petroleum Association, 2305-Williams, 2283-Endeavor Energy Resources, L.P. (Endeavor)) note one of EPA’s rationales is the assumption that the addition of a controller or a pump would “represent a physical change to the site” and, by default, “would result in an increase in emissions.” However, they suggest that support for EPA’s rationale—that the addition of a controller or pump would result in an increase in emissions—is not reflected in the proposed rule text. To conform the rule text to EPA’s rationale and historic practice, commenters request that EPA should at the least clarify in the rule text that, for purposes of the collection of controllers or pumps at a site, a modification occurs only when a natural gas-driven pneumatic controller is added. Commenter (2305-Williams) notes that the proposed definition would result in a facility being “modified” even if it adds a non-natural gas pneumatic pump to an affected facility. The commenter explains that, having now undergone a “modification”, the owner or operator must now transition all its pneumatic pumps to non-natural gas driven pumps. The commenter contends that this is an unreasonable and impermissible result under the CAA and conflicts with EPA’s own regulations. The commenter (2305-Williams) requests that EPA modify proposed 40 CFR 60.5365b(h)(1) as follows:

...a modification occurs when an owner or operator increases the number of natural gas-driven pneumatic pumps at the pneumatic pump affected facility that it owns or operates at a site is increased by one or more which results in a net emissions increase from the affected facility.

Response II-8-11: While it was our intention in the December 2022 Supplemental Proposal to only include the addition of natural gas-driven pumps in the conditions that would constitute a modification, as only those pumps could increase emissions, we agree that the proposed regulatory text did not specify this. We therefore have revised the regulatory language to clarify that the addition of one or more natural gas-driven pumps to a site constitutes a modification. We also are clarifying in the final rule that reconstruction would be considered to occur whenever greater than 50 of the number of existing onsite natural gas-driven pumps are replaced.

Comment: Commenter (2202-Texas Oil & Gas Association (TXOGA)) states that the December 2022 supplemental proposes to “include a second, simplified method of determining whether a pump replacement project constitutes reconstruction under 40 CFR 60.15(b)(1) whereby reconstruction may be considered to occur whenever greater than 50 [sic] of the number of existing onsite pumps are replaced.”<sup>1</sup> The commenter believes EPA accidentally omitted the word “percent” after “50” in the preceding paragraph because elsewhere in the supplemental notice, it is proposed that “the standard in 40 CFR 60.15(b)(1) specifying that the ‘fixed capital cost of the new components exceeds 50 percent of the fixed capital cost that would be required to construct a comparable entirely new facility’ can [now] be met through a showing that 50 percent or more of the number of existing onsite pumps are replaced.”<sup>2</sup> The commenter requests that the EPA clarify this language before publishing a final rule.

Response II-8-12: We agree the word “percent” was inadvertently omitted from the preamble in this sentence; however, the regulatory text of the December 2022 supplementary proposal correctly included “percent” in each instance where it should have been written. The regulatory

---

<sup>1</sup> 87 Fed. Reg. at 74,773.

<sup>2</sup> Id.

text of the final rule includes “percent” where it should be included, and the requirements related to the conditions that constitute a reconstruction for pumps should be clear to readers.

Comment: Commenters (2326-AXPC, 2391-CEC) request that EPA specifically exclude temporary pumps from the affected facility definition.

Commenter (2326-AXPC) provides that NSPS OOOOb excludes from the pneumatic pump affected facility definition “[a] single natural gas-driven diaphragm pump that is in operation less than 90 days per calendar year.” The commenter reports that EG OOOOc contains no such exclusion; however, EG OOOOc requires that operators maintain records of “[i]dentification of each pneumatic pump that is not driven by natural gas or single natural gas-driven diaphragm pump that is in operation less than 90 days per calendar year and is not a pneumatic pump designated facility as specified in §60.5386c(g).” Given the language of the recordkeeping requirements, the commenter requests that the EPA clarify that limited-use (less than 90 days) natural gas-driven diaphragm pneumatic pumps are excluded from the EG OOOOc pneumatic pump affected facility definition. The commenter (2326-AXPC) requests that EPA add the following subparagraph to 40 CFR 60.5386c(g):

(1) A single natural gas-driven diaphragm pump that is in operation less than 90 days per calendar year is not part of a designated facility under this subpart provided the owner/operator keeps records of the days of operation each calendar year in accordance with §60.5420c(c)(14)(i). For the purposes of this section, any period of operation during a calendar day counts toward the 90-calendar day threshold.

Commenter (2391-CEC) states EPA should exempt pneumatic controllers and pumps located on temporary or portable equipment from the proposed zero emission standard if the temporary pneumatic device remains onsite for less than 180 days. Feasibility and cost-effectiveness are not justified for its type of pumps to be connected to the grid. The commenter also states EPA should also exempt temporary pneumatic diaphragm pumps. The commenter notes that an example of the temporary use of such devices is for circulating glycol for heat trace as part of winterization efforts to prevent freezing. The commenter suggests that EPA could do so by amending the proposed NSPS OOOOb and EG OOOOc regulations to incorporate language like that in 40 CFR 60.5430a.

Commenter (2428-API) suggests that 40 CFR 60.5365b(h)(3) should also include an exemption for piston pumps. The commenter explains that temporarily used piston pumps emit very little, which is why they have historically been exempt from the control standards. According to the commenter, such an exemption would be analogous to what also already been granted for temporary natural gas-driven diaphragm pneumatic pumps, and we believe it was EPA’s intent to also include piston pumps in this provision.

Response II-8-13: As proposed in the NSPS OOOOb, the EPA is finalizing the definition of an affected facility that includes only natural gas-driven pumps that are in operation for 90 days or more in a calendar year. This definition of the affected facility already excludes equipment that is used temporarily (i.e., those used for less than 90 days). Commenters did not provide any rationale for the use of a different understanding of what is “temporary” for a pump, and a

review of state regulations for oil and gas operations, including those of Colorado and New Mexico, revealed that these rules also include a 90-day threshold for “temporary” pumps. Therefore, we have retained the 90-day threshold for the natural gas-driven pumps that need to be included in the affected facility.

Regarding the application of this 90-day threshold to both piston and diaphragm pumps, we agree that this is appropriate, and we note that piston pumps were inadvertently excluded in the December 2022 Supplemental Proposal regulatory language. We have revised the regulatory language accordingly to include both pump types.

Regarding the inclusion of the 90-day threshold in the EG of OOOOc, similar to the exclusion of piston pumps, we agree that including the 90-day threshold in OOOOc is appropriate, and we note that this provision was inadvertently excluded from the affected facility definition in the OOOOc December 2022 Supplemental Proposal regulatory language. We have revised the regulatory language of OOOOc accordingly to include this 90-day threshold.

Comment: Commenter (2428-API) states it is unclear how the notifications from 40 CFR 60.15 apply to the reconstruction provision proposed. Similar to natural gas-driven pneumatic controllers, the proposed language in 40 CFR 60.5365b(d)(2)(ii) suggests that reconstructed natural gas-driven pneumatic pumps would be subject to some of the requirements included in 40 CFR 60.15, which include 60-day notification and Administrator approval. According to the commenter, this directly conflicts with information presented in Table 5 that states 40 CFR 60.15(d) does not apply to pneumatic pumps. The commenter believes it was EPA’s intent to not apply the additional notification and approval, given the number of facilities that will trigger reconstruction over time.

Response II-8-14: We agree that we did not intend for facilities to be required to notify the Administrator of upcoming pump replacements that would constitute a reconstruction or for the Administrator to be required to review the notification and determine whether the replacements constitute a reconstruction. We have revised the final regulatory text to not refer to the requirements of 40 CFR 60.15(d) and have kept the information presented in Table 5 of the proposed regulatory text, which states that 40 CFR 60.15(d) does not apply to pumps.

## **8.2 NSPS OOOOb and EG OOOOc Control Options**

### ***8.2.1 General Support for Proposed Standards***

#### **8.2.1.1 Overall Support for Proposed Standards**

Comment: Commenters (1611-East Liberty Presbyterian Church, 1649-Sisters of St. Francis of Philadelphia, 2152-California State Teachers' Retirement System, 2156-Catholic Charities of Gallup Diocese, 2163-Federated Hermes Limited, 2164-Nordea Asset Management, 2184-Physicians for Social Responsibility Climate Ambassador, 2185-New York State Comptroller, 2190-Miller/Howard Investments, Inc., 2191-Boston Trust Walden Company, 2199-Rocky Mountain Farmers Union *et al.*, 2203-Ceres, Inc., 2206-Legal & General Investment Management America, Inc., 2209-Public Land Solutions, 2212-Union of Concerned Scientists,

2236-Physicians for Social Responsibility Pennsylvania, 2242-Seventh Generation Interfaith, Inc., 2249-NACAA, 2285-Bailard, Inc., 2287-Interfaith Center on Corporate Responsibility, 2299-NEI Investments, 2303-NTAA, , 2347-Clarke, 2348-Energy Workforce & Technology Council, 2352-Environment Texas Research and Policy Center, 2388-ExxonMobil, 2394-Earthworks, 2410-CA AG *et al.*, 2424-As You Sow, 2433-EDF *et al.*, 2441-Breathe Utah *et al.*, 2459-BMO Global Asset Management, 2461-Conservatives for Responsible Stewardship and Vet Voice Foundation, 2766-1000 Grandmothers for Future Generations) express support for phasing out of polluting pneumatic pumps in favor of zero-emitting alternatives. Commenter (2388-ExxonMobil) supports devices being granted limited exemptions where technical or safety limitations exist.

Commenter (2627-British Columbia Investment Management Corporation (BCI)) supports the expansion of the November 2021 proposed standards for pneumatic pumps/controllers. The commenter states that the stronger standards address one of the largest sources of methane pollution. In addition to requiring the phaseout of polluting pneumatic controllers and pumps in favor of zero-emitting alternatives, they believe that prohibiting the use of natural gas to power pumps and controllers will contribute to decreasing GHG emissions without requiring large investments, as non-emitting pneumatic controllers and pumps are inexpensive and readily available. The commenter commends the EPA for providing some flexibility for remote sites without electricity, if it has been demonstrated that it is not technically feasible to forego from using natural gas, as long as the installation of solar-powered controllers with batteries remains unreliable.

Response II-8-15: These comments are supportive comments on aspects of the December 2022 Supplemental Proposal that have remained unchanged in the final rule; as such, no response is required.

#### 8.2.1.2 Support Proposed Standards (Without Technical Infeasibility Exemption)

Comment: Commenter (2433-EDF *et al.*) states that Analysis Group Report<sup>3</sup> shows that for sites without electricity, solar pneumatic controller and pump systems are cost-effective at sites across the U.S., even in states with colder temperatures. They note that there is also evidence that zero-emission pumps are readily available and already being deployed in numbers. British Columbia and Alberta do not allow new emitting pumps. Additionally, the commenter adds that the Datu report<sup>4</sup> identified 13 suppliers of solar-based systems that can be used in remote locations or at sites without electricity, including nine providers of instrument air solar compressors and four providers of solar-driven electric actuators. As EPA itself notes, this equipment can be used for pumps in addition to controllers,<sup>5</sup> demonstrating the availability of suppliers of this type of

<sup>4</sup> Datu Research, Zero-emission Alternatives to Pneumatic Control: How Ready are Technology Providers to Meet Increased Demand? (Jan. 2023). (Included as Attachment P of the commenter’s submitted comments.).

<sup>5</sup> See 87 Fed. Reg. at 74770 (“In addition, some of the means of powering a pneumatic pump without the use of natural gas can also be used to power pneumatic controllers. While our updated BSER analyses for pneumatic

technology. Further, the commenter notes that Pump Projects provides solar electric pumps with compressed air instrumentation,<sup>6</sup> and EPA cited several vendors who confirmed during the rulemaking process the successful implementation of pumps not driven by natural gas at remote locations, including locations with very harsh winter weather.<sup>7,8</sup>

The commenter (2433-EDF *et al.*) also notes that EPA has determined that routed pumps are cost-effective and has included them as an option in the proposed NSPS OOOOb. As with the controller standard, the zero-emission pump standard that allows these types of pumps would provide the flexibility needed to remove a technical infeasibility exemption for sites without electricity. The commenter contends that the comments that EPA cites in the December 2022 proposal maintaining that “zero-emission pneumatic pumps are technically infeasible at sites without electricity” are not compelling. The commenter provides that one of the two cited comments simply states that “[z]ero-emissions pneumatic pumps are technically infeasible for our sites,” due to lack of electricity, and that “[s]olar-powered pumps are not reliable for 24/7 operation in geographic locations that receive extended periods of cloud cover or snowfall,” without providing any documentation or further arguments to support these claims. However, the evidence record shows that solar pumps have been shown to operate successfully in areas with harsh winter conditions, including the Wamsutter Basin in Wyoming, and that zero emissions pumps are required for new pumps province-wide in Alberta and British Columbia, where snowfall, cloud cover, and winter insolation conditions are all more challenging for solar than in the contiguous U.S. The commenter notes that the second of the two cited comments does not make any specific claim about solar-powered pumps per se, but rather claims that onsite solar/battery systems designed to serve both non-emitting pumps and non-emitting pneumatic controllers are “uncommon [and] unreliable.” However, according to the commenter, the evidence clearly shows that these systems are reliable, as the EPA has found for controllers. The commenter recommends that, since the solar/battery technology that serves non-emitting pumps is the same as that which serves non-emitting controllers, the EPA should recognize that concerns about the performance of these systems for non-emitting pumps are unfounded.

Commenter (2433-EDF *et al.*) asserts that an exemption for sites without electricity would be incredibly difficult to monitor and could negate the EPA’s otherwise strong pump standard. As it stands, the commenter states that the exemption allows the venting of gas from up to three pumps at sites without electricity and allows operators to self-certify with written statements that non-emitting options (solar-powered pneumatic pumps and generators for compressed air systems) and routing to capture and control are infeasible at a given location. Fraudulent

---

pumps and pneumatic controllers evaluated the cost effectiveness of these sources independently, the shared usage of solutions for the two sources, such as compressed air systems, solar-powered systems, or generators, will result in even lower overall site-wide cost effectiveness values.”).

statements will be subject to civil and potentially criminal penalties. However, the commenter suggests that, because the EPA provides no definition for “technical infeasibility” here or any guidance on how it would evaluate such claims, operators will have plenty of leeway to craft their own exemption from the standard in a way that may not be considered fraudulent. In this way, the commenter believes that the self-certified exemptions will swallow the rule that EPA has determined is the BSER for sites with up to three pumps, but which do not have electricity, and the cumulative emissions resulting from pumps at these sites will continue to be significant and detrimental to the environment and people’s health.

Response II-8-16: We agree with the commenters that the use of solar-powered pumps appears to be a cost-effective option for use at sites without access to electricity and that solar-powered pumps can be used in some situations. However, due to the high power needs of some pumps, the EPA acknowledges industry concerns about their technical feasibility in many common situations experienced at oil and gas sites. Due to uncertainty about whether they have been adequately demonstrated for these applications, the EPA concluded that it is not appropriate to establish BSER based solely on solar-powered pumps. At sites with fewer than three natural gas-driven pumps and without access to electrical power, solar-powered pumps are the only cost-effective zero-emissions option available. For these sites, the NSPS and the EG reflect the determination that BSER is the use of emissions reduction equipment that is already onsite. For these sites, pump emissions must be routed to a process through a VRU if a VRU is onsite; if a VRU is not onsite, pump emissions are required to be routed to a control device onsite that achieves 95% emissions reductions; if no control device that achieves 95% emissions reduction is onsite, another onsite control device may be used; and if no VRU or control device is onsite, pump emissions are not required to be controlled. Since these requirements are based on the use of existing equipment, it may not be feasible in all situations to use that equipment to control a site’s pump emissions. To account for this in the final rule, the EPA is retaining the proposed infeasibility demonstration requirements for this limited subset of pump sites. For these sites, which do not have access to electrical power and that have fewer than three natural gas-driven diaphragm pumps, the rule allows owners/operators to demonstrate infeasibility of the compliance methods according to the hierarchy of methods specified in the rule. For example, if a VRU is onsite, the owner/operator could demonstrate that it is technically infeasible to route pump emissions through the VRU to a process, and then proceed to route emissions to a control device that achieves a 95% reduction in emissions.

### ***8.2.2 Access to Electricity***

Comment: Commenter (2483-Interstate Natural Gas Association of America (INGAA)) states that they appreciate that EPA provided an alternative non-zero emission standard for pneumatic pumps where certain conditions exist at sites without electric supply (*i.e.*, it is technically infeasible to use a solar powered pneumatic pump and technically infeasible to install a compressed air system powered by either a natural gas-driven generator or a solar power generator).

Commenter (2321-Apollo Exploration and Development, Inc. (AED)) states EPA’s new requirement that equipment must be powered by electricity poses serious challenges to rural oil and natural gas fields that will not have easy access to electric power.

Commenter (2283-Endeavor) provides that many well sites in the Midland Basin are located in remote locations without access to an existing grid. Even if a grid is theoretically accessible, the commenter notes that it is not always logistically feasible to connect to that grid due to issues outside of an owner or operator's control. The commenter explains that these challenges include right-of-way issues for placement of power lines, a landowner's right to not install power lines on their property, and/or distance from an available power line that contains sufficient power and capacity to connect the facility. For those well sites that happen to be in proximity to a grid, or where it might be technically feasible to connect them to a grid, current electricity generation in many producing regions (such as the Midland Basin) will not be adequate to accommodate EPA's proposed requirements while also balancing competing load demands.

Commenter (2283-Endeavor) states alternative on-site power systems-at the scale necessary to power a site's myriad operations-may not be feasible as a meaningful and reliable replacement for a traditional power grid. Well site operations require power during all hours of operations, including for safety reasons, not just when there is sunlight. Accordingly, incorporation of intermittent renewable power sources into operations may not be practicable.

Commenter (2301-U.S. Chamber of Commerce (USCC)) expresses concern that the proposed requirements do not recognize the practical reality that many of these sites are unmanned and located in isolated regions with limited onsite or surrounding infrastructure.

Commenter (2202-Texas Oil & Gas Association) notes that the December 2022 Supplemental Proposal (see section IV.E.1 of the December 2022 Supplemental Proposal preamble)<sup>9</sup> for pneumatic pumps states that “all natural gas processing plants have access to electrical power,” however, it also states that “at sites without access to electricity” a “tiered structure” that accounts for “flexibility based on site-specific conditions” is prudent. To the extent that these statements are inconsistent, the commenter requests that EPA remedy these inconsistencies and any underlying analysis affected by such statements before publishing a final rule.

Response II-8-17: The EPA understands that sites with pumps may not have access to electrical power. There are several options available to such sites to meet the NSPS and EG. These include the use of solar-powered pumps, the use of compressed air-driven pumps powered by a generator, and routing emissions to a process. For sites without access to electricity and fewer than three natural gas-driven diaphragm pumps, existing control devices may also be used to comply with the rule requirements, if a VRU is not onsite to route emissions through to a process. The EPA also notes that solar-powered pump systems include batteries that are typically sized to contain a 10-day power supply, and this battery power ensures continuous pump operations. With regards to the commenter (2202-Texas Oil & Gas Association) that requests that EPA remedy inconsistencies, there are no inconsistencies as written. It is EPA's understanding that all natural gas processing plants have access to electrical power, which is why the preamble also states that “[s]ince all natural gas processing plants have access to electrical power, we only evaluated compressed air systems for this segment.” The flexibility for sites without access to “electricity” and analyses correctly included the tiered structure for other segments.

### 8.2.3 Solar

Comment: Commenter (2252-Petroleum Association of Wyoming, 2391-CEC) states solar panels can be covered with snow and ice, or there could be several days of cloudy weather where solar power generation is not sufficient to keep batteries charged enough to supply the amount of power necessary to run operations. The commenters stress that reliability is incredibly important as failure of devices may lead to serious safety and environmental incidents.

Commenter (2301-USCC) states onsite solar-power systems with battery storage may only be able to provide intermittent power that presents inherent reliability risks. For example, the commenter notes that power reliability at large-scale solar applications during the winter months are of considerable concern, when there is less sunlight, more cloud coverage, and increased snow cover. The add that battery capacity drops drastically at below the freezing point.

Commenter (2321-AED) states that solar alternatives are not reliable in Michigan weather conditions, which could cause a serious problem at a well site if equipment goes down. The commenter notes that the proposed rules need to reflect this reality and offer exceptions to this requirement when reliable electricity is not viable.

The commenter (2321-AED) is also concerned that the necessary resources for potential work to achieve compliance will not be available in terms of manpower and battery equipment additions. It has been a struggle to get work accomplished in the field and the commenter is afraid of how much work they will need to do and who is going to do it when it needs to be done.

Response II-8-18: The EPA maintains that solar-powered pumps can be used in many situations. Solar-powered pump systems are designed and sized with consideration of geographic location and the requirements for the pump, such as the amount of chemical to be injected and the injection pressure for a chemical injection pump. For systems located in less sunny locations, the configuration of solar panels and battery capacity may be different from that used in an area with high solar irradiance. In addition, batteries are typically sized to contain a power supply of several days, which ensures continuous pump operations.

Due to the high power needs of some pumps, the EPA acknowledges industry concerns about their technical feasibility in many common situations experienced at oil and gas sites. Considering the uncertainty about whether solar-powered pumps have been adequately demonstrated for these applications, the EPA concluded that it is not appropriate to establish BSER based solely on solar-powered pumps. At sites with electrical power or with three or more natural gas-driven diaphragm pumps, other compliance methods are available, including the use of grid-powered electrical pumps, compressed air-driven pumps, and routing pump emissions to a process. At sites with fewer than three natural gas-driven diaphragm pumps and without access to electrical power, a hierarchy of emissions control methods is required, and the NSPS and the EG reflect the determination that BSER is the use of emissions reduction equipment that is already onsite. Therefore, solar-powered pumps and other zero-emissions pump options are not required to be used at these sites.

#### **8.2.4 Generators**

Comment: Commenter (2220-Wyoming Department of Environmental Quality (WDEQ)) states the use of gas-powered generators as a substitute to power pneumatic pumps poses a concern because, even though the gas-powered generators would have to undertake their state's New Source Review (NSR) permitting process, their operation nevertheless could result in increased cumulative nitrogen oxide (NOx) and VOC emissions from sites implementing them; gas-powered generators or other approaches like air compressors or micro-turbines would run at all times as opposed to the intermittent function of pneumatics that periodically vent emissions. According to the commenter, this is particularly problematic in the Upper Green River Basin (UGRB) marginal ozone nonattainment area, where reducing NOx emissions has been a key area of their state's policy focus for over a decade to reduce the potential for wintertime ozone formation. Put simply, they note that there are emissions trade-offs that will occur when using gas-powered generators or air compressors to power pneumatics. Additionally, they add that using generators or other related alternative approaches is simply not cost-effective for operators.

Response II-8-19: As we assumed some sites would choose to install an electric generator to power compressed air-driven pumps, we estimated the emissions that would be created by such generators. We found that those emissions are relatively small and are outweighed by the emissions reductions that would be reduced from the pumps. See Response II-8-9 for further details.

#### **8.2.5 Route to Control**

Comment: Commenter (2177-Southern Ute) states that routing vapors to a process would likely require some kind of compression to increase the pressure of the vapors from near atmospheric, to something higher than the pressure of the process they are being introduced into. In many instances, they note that this will require additional equipment to be installed, resulting in an increase in facility emissions, and should be taken into consideration when requiring these types of controls.

Response II-8-20: As we assumed some sites would choose to install an electric generator to power a VRU to route emissions to a process, we estimated the emissions that would be created by such generators. We found that those emissions are relatively small and are outweighed by the emissions reductions that would be reduced from the pumps. For a VRU, it is assumed that the larger size of generator analyzed would be needed. See Response II-8-9 for further details.

Comment: Commenter (2220-WDEQ) states their state's compliance staff repeatedly raised concerns that owners/operators of sites with older equipment often run into technical problems as they attempt to retrofit and make changes to process equipment. According to the commenter, this practice often creates a cascading effect on other equipment on site, resulting in more unrelated compliance issues arising in other parts of the process and, as an unintended consequence of the rule, potentially higher emissions. Put simply, the commenter contends that re-routing to a process on site is not a practical or economically feasible solution for many existing sources and can result in unanticipated emissions increases due to other consequential compliance issues. This, in turn, results in an increased workload for their state's compliance

staff who will already face a significantly increased burden in site visits and reports due to the increased number of affected facilities because of the supplemental proposal.

Response II-8-21: While the EPA recognizes the possibility that changes made to processes or equipment at a facility may initially create unintentional issues or problems at the site. However, as the NSPS and EG requirements reduce emissions by 95% to 100% from all pump affected facilities, the guaranteed benefits of these long-term emissions reductions outweigh any potential initial issues that might arise as process or equipment modifications are made.

Comment: Commenter (2391-CEC) provides that the EPA proposes to allow operators to route to a control device, but only if they can demonstrate that routing to a process is technically infeasible. Thus, only after making both infeasibility demonstrations can the operator route the pumps to an existing control device. The commenter urges the Agency to recognize the substantial investments that operators have already made to route emissions from pneumatic pumps to control devices by allowing any natural gas-driven pneumatic device to be routed to controls—not only in situations where non-natural gas technology and routing to a process are each technically infeasible.

The commenter (2391-CEC) requests that, if the final rule requires operators to demonstrate the technical infeasibility of non-natural gas pumps, EPA expand the remaining analysis for routing an existing pneumatic pump to a control device to weigh the potential emission reduction benefits with the costs. The commenter explains that retrofitting existing diaphragm pumps is likely to be very expensive compared to routing these devices to existing controls. As a result, the commenter states that few emission reductions could be achieved over routing to controls are not going to be cost-effective. According to the commenter, to ignore economic viability would result in a rule that does not provide “achievable, cost-effective measures to significantly reduce methane and VOC emissions, consistent with the requirements of section 111 of the CAA.” See 87 Fed. Reg. at 74705.

Response II-8-22: The final rule allows for owners/operators at sites without electricity and fewer than three diaphragm pumps to route pump emissions to a process if a vapor recovery unit is onsite, or to an onsite control device if there is no vapor recovery unit onsite. No demonstration of the technical infeasibility of non-natural gas pumps is required. As routing pump emissions to a process would achieve 100% control of emissions and control devices would achieve less than this reduction, the final rule requires that emissions be routed to a process if a VRU is onsite before routing emissions to an onsite control device could be considered.

For the final rule, the EPA conducted an analysis of the emissions reductions, costs, and other impacts of the options available to achieve zero emissions from pumps and found that for sites with electricity and for sites without electricity and three or more natural gas-driven diaphragm pumps, there were at least two options available to achieve zero emissions at a reasonable cost. Therefore, the EPA concluded that zero-emissions represented the BSER, and the NSPS and EG reflect this determination by requiring zero emissions from pumps at these sites. For sites that route emissions from pumps to a process, no demonstration of infeasibility of using non-natural gas pumps is required. For sites without electricity and fewer than three natural gas-driven

diaphragm pumps, the EPA found the only zero-emissions option that could be implemented at a reasonable cost was solar-powered pumps. Due to the potential technical infeasibility of using solar-powered pumps for all site applications, the EPA determined that zero-emissions did not represent the BSER for these sites. The EPA further determined that costs for controlling emissions by routing the emissions to a control device or to a process through a VRU were only reasonable for these sites if there was a VRU or control device already or otherwise present. Therefore, considering the emissions reductions and the associated costs, the EPA determined that the BSER for these sites is the use of existing equipment to route emissions to a process or to a control device.

### ***8.2.6 Nitrogen Systems***

Comment: Commenter (1581-Kathairos Solutions US, Inc.) provides the following information regarding EPA nitrogen systems:

- Information describing specific situations where owners have captured gas from pneumatic pumps and routed it to a beneficial use: Nitrogen systems do not require gas to be captured or rerouted to eliminate methane venting without power. Natural gas is conserved for future sale.
- Information on the specific processes and types of equipment needed to capture and route the emissions, along with the costs: Nitrogen systems eliminate methane venting at an affordable rate, and no power is needed. There are no changes to existing devices, and no need to capture or route methane emissions. A nitrogen system is simply installed and tied into existing systems and the fuel line is turned off, keeping the natural gas for future sale.
- Information related to the Agency's understanding that routing emissions to a process reduces emissions by 100 percent: There is no need to capture or route emissions at remote wellsites with no power access. Using nitrogen eliminates emissions from pneumatics 100%; the commenter cannot speak to the efficacy of routing processes. However, the commenter does agree with EPA that steps must be taken to ensure emissions are eliminated from pneumatics at remote locations without electricity.
- Information about situations where a vapor recovery unit would be needed to enable the use of emissions from a pneumatic pump, along with the costs of those units: No vapor recovery units are needed to eliminate methane emissions from pneumatic pumps at remote wellsites when nitrogen systems are used. Nitrogen can be deployed reliably and economically at wellsites of all sizes and pressure requirements.

Response II-8-23: The EPA recognizes that compressed nitrogen could be used to power pneumatic pumps and that there are benefits to its use, such as having no secondary emissions at the site. The final rule is technology-neutral and allows for owners/operators to use this or other methods to meet the zero-emissions standard for pumps.

### ***8.2.7 Pneumatic Pumps Control Option Regional Considerations***

Comment: Commenter (2335-Private Citizen) states that recent studies have shown that climate warming in arctic regions is not twice that of the rest of the globe but about four times. The arctic

well sites might often be excused from some of the emissions standards due to their distance from electric supplies. The strictest of standards should be applied to all existing and any future oil and gas development projects northern Alaska. The commenter asserts that requiring all pneumatic pumps to have zero emissions is a step in the right direction.

Commenter (2483-INGAA) recommends that the alternative standard for areas in Alaska that lack electric supply and where it is technically infeasible to use a solar powered pneumatic pump and technically infeasible to install a compressed air system powered by either a natural gas-driven generator or solar powered generator should be available throughout the U.S.

Similarly, commenter (2220-WDEQ) requests, if EPA moves forward with the supplemental proposal's requirements for pneumatics, the same exemption as provided to pneumatic controller designated facilities located at a site in Alaska (see 40 CFR 60.5390b(b) in the proposed regulatory text for NSPS OOOOb and 40 CFR 60.5394c(b) in the proposed regulatory text for EG OOOOc). The commenter notes that the EPA's rationale for providing such an exemption is that there are facilities in Alaska that do not have access to electrical power due to Alaska's remote geography and the infeasibility of solar or other options. They explain that Wyoming's geography and climate are similarly remote in many parts of the state and operators run into the same infeasibilities as in Alaska. They contend that it is unfair for EPA to provide such an exemption specifically for sites in one state when there are other states that face essentially the exact same challenges. Furthermore, the commenter requests that EPA consider the harsh winter conditions in Wyoming with regards to how it poses compliance timing challenges in certain instances. They explain that there are potential situations where the frigid winter temperatures might not allow certain sites to perform required compliance duties within a 30-day period because the temperatures are so cold that it would require an operator to shut in a well to undertake compliance activities. Put simply, the commenter asserts that a "one-size-fits-all" rule does not account for these meteorological or geographical challenges and EPA should take this into consideration when revising the supplemental proposal.

Response II-8-24: The EPA notes that for pumps, the BSER determination was based on site conditions and reflects access to electricity and the number of natural gas-driven diaphragm pumps at the site but does not have an exemption for sites located in Alaska. The NSPS and EG requirements are based on the BSER determination, which requires zero emissions from pumps at sites with access to electrical power and at sites with three or more natural gas-driven diaphragm pumps. For sites without access to electrical power and fewer than three natural gas-driven diaphragm pumps, owners/operators are required to control emissions by using equipment or control devices already onsite.

### ***8.2.8 Pumps Should be Subject to LDAR***

Comment: Commenter (2248-North Dakota Petroleum Council) suggests that pneumatic pumps that do not bleed continuously and if found to do so during an optical gas imaging (OGI) camera inspection, should be considered as a fugitive leak subject to the repair timeframes in the LDAR requirements of the rule. Therefore, according to the commenter, the supplemental proposal requirements are prescriptive and will have negligible effect on emissions.

Response II-8-25: Diaphragm and piston pneumatic pumps, unlike controllers, are not designed for intermittent vent operation, but emit gas whenever they are pumping. While it is possible that there could be problems with pumps or their seals that result in additional emissions from leaks, such leaks are not the target of the NSPS and EG requirements for pumps. These requirements eliminate or greatly reduce the emissions that occur from the operation of the pump itself. In addition, where pumps not driven by natural gas are used, there would also be no potential for leaks of methane and VOC.

### **8.2.9 Technical Infeasibility**

Comment: Commenter (2433-EDF *et al.*) states because zero-emitting pumps are also feasible for operators at sites without electricity we urge EPA to finalize pump standards that mirror the proposed controller standards (including an allowance for routed natural gas-driven pumps in the baseline) and remove the tiered flexibility exemption. Critically, the commenter states that the EPA has determined that the BSER for pumps at both sites with and without electricity is zero-emitting pumps but permits the exemption for sites without electricity because it argues that there may be circumstances where the standard is infeasible. The commenter believes that installation of zero-emission pumps is feasible in all instances and that a feasibility exemption will create a significant loophole in a standard that the EPA has determined is the BSER. The commenter asserts that, even if EPA retains the exemption for sites without electricity, it must narrowly tailor the exemption. The commenter provides the following support for their position:

First, exemptions should not be available to operators that are converting a certain number of natural gas-driven controllers, and certainly all these controllers, or who have installed a number of site-wide systems that power non-natural gas-driven pneumatics. Limiting the exemption based on the percent of controllers converted or the number of site-wide systems installed is practical. Zero-emission controllers and pumps can share the same equipment (such as air compressors, solar panels, batteries, etc.). When operators install instrument air compressors or install solar arrays, those technologies can be used to power both controllers and pumps. Additionally, EPA's proposal discusses the cost-effectiveness of applying solutions site-wide and acknowledges that pump cost-effectiveness increases when controllers are on-site, due to the usage of shared equipment and our independent analysis demonstrates the cost effectiveness of site-wide zero-emitting solutions as well. As a result, zero-emission pumps should be required at facilities that already have the necessary infrastructure in place, since doing so would both result in greater emissions reductions and would be feasible and cost-effective.

Second, EPA must also strengthen the technical infeasibility showing. Specifically, to qualify, operators should have to show that they cannot use any of the many zero-emission pump options – including electric, solar, instrument air, and routed pumps. The commenter supports EPA's proposed requirements for the feasibility showing for solar and instrument air, but additionally would recommend the following: to demonstrate that use of electricity is infeasible, the operator must show that the relevant facility is in a remote location greater than 0.5 miles from the grid, as analyses show it is cost-effective to connect to the grid within that distance. To demonstrate that the use of solar is infeasible, operators must show why certain technical issues exist, such as those

associated with weather or temperature conditions. As EPA has proposed, operators should also need to show with specificity why routed pumps that achieve 100 percent capture are infeasible, and the commenter supports EPA's proposal for how operators would make that showing, including safety considerations, distance from a process, pressure losses, and other technical reasons.

Finally, upon an infeasibility showing, EPA should require operators to use a control device at all sites, even at sites with fewer than four pumps. As EPA notes, control devices are site-wide technologies that would usually—if not always—be used to avoid venting from just four pumps.

Commenter (2326-AXPC) expresses that the EPA does not provide any information within the rule on how an affected facility is expected to demonstrate that the regulatory provision in question is “technically infeasible”, other than a requirement that a professional engineer or other qualified individual so certify.

Because there is no explanation of technical infeasibility within the rulemaking, the commenter (2326-AXPC) reports that they evaluated what EPA has done in other CAA programs. For example, EPA's regulations related to best available retrofit technology (BART) determinations under the regional haze program include some insight into how EPA might evaluate technical feasibility considerations. According to EPA's BART regulations:

Control technologies are technically feasible if either (1) they have been installed and operated successfully for the type of source under review under similar conditions, or (2) the technology could be applied to the source under review. Two key concepts are important in determining whether a technology could be applied: “availability” and “applicability.” As explained in more detail below, a technology is considered “available” if the source owner may obtain it through commercial channels, or it is otherwise available within the common sense meaning of the term. An available technology is “applicable” if it can reasonably be installed and operated on the source type under consideration. A technology that is available and applicable is technically feasible.

While the commenter (2326-AXPC) notes that these regulations provide more context than EPA's proposed NSPS OOOOb/EG OOOOc regulations, the BART regulation conflates economic factors and technical feasibility and does not specifically account for other factors related to potential implementation that may be critical to compliance. The “available” concept is inherently an economic concept as it relates to whether the item is commercially available – i.e., that the price is at such a level that it can be produced commercially. According to the commenter, if EPA was truly looking at considering technical feasibility without regard to economic viability, whether a technology is commercially available would be irrelevant. And to do so here, would be inappropriate, particularly given the definition of standard of performance. Under CAA section§ 111(a)(1), standard of performance means-

a standard for emissions of air pollutants which reflects the degree of emission limitation achievable through the application of the best system of emission reduction (taking into

account the cost of achieving such reduction and any nonair quality health and environmental impact and energy requirements) the Administrator deems has been adequately demonstrated.

By providing an opt-out, the commenter (2326-AXPC) notes that the EPA inherently recognizes that BSER cannot be met at every facility. Thus, in making the demonstration that use of the opt out is appropriate, the costs of achieving such emissions reduction should be considered. Further, because EPA may only include standards that are determined to be adequately demonstrated, technical feasibility for the opt-out provisions in NSPS OOOOb/EG OOOOc, technical feasibility must include considerations such as: ability to access electrical power; landowner access; other local or state regulatory requirements; and other considerations that limit the ability to comply with the standard of performance. In other words, technical feasibility must include considerations beyond just physical impossibility. Anything that would preclude, or hinder implementation of the regulations should be included in a consideration of feasibility – whether technical, economic, or some other appropriate consideration. However, the commenter requests that the EPA be explicit that economics is to be considered in the feasibility analysis – as technical feasibility alone is insufficient.

Commenter (2221-TPA) suggests that the rules should allow in-house engineers, and non-professional engineer (PE) outside personnel, to make required certifications and determinations. With respect to certification requirements regarding determinations described in the proposed rules, the commenter supports the current proposal to allow certification by an in-house engineer instead of an outside engineer because in-house engineers are often the most experienced and knowledgeable personnel with respect to site design and control as well as specific design and feasibility questions. As such they are often the most qualified personnel to make the assessments for which certifications are required.

The commenter (2221-TPA) also believes that the EPA should expand the universe of persons who could make required certifications and determinations to include non-PE outside personnel. The commenter explains that companies on occasion can experience shortages or temporary unavailability of personnel and in those instances rely on outside personnel. The commenter suggests that such outside personnel can be as knowledgeable of and familiar with design and operations as in-house employees. The commenter believes that company-hired contractors or consultants should also be allowed to sign off on certifications if they have appropriate expertise, (e.g., if they have designed the system in question). The commenter contends that this would provide additional flexibility without sacrificing any environmental protections because such third parties would have to have appropriate expertise on design and operation of the system in order to complete a certification or to make a required technical determination.

Response II-8-26: The final rule requirements for pumps have been revised from the December 2022 Supplemental Proposal. The EPA determined it was possible to specify the conditions under which the different pump requirements apply in the NSPS and EG that reflect the BSER and that eliminate the need for demonstrations of technical infeasibility. The analyses for BSER show there are technically feasible zero-emission options, which can be implemented at costs the EPA considers reasonable at sites with access to electricity and at sites without electricity that have three or more natural gas-driven diaphragm pumps. Routing emissions to a process is

included as a zero-emissions option, as the EPA recognizes that with proper equipment operation, this option will result in zero emissions from pumps. Sites without electricity and with fewer than three natural gas-driven diaphragm pumps may use zero emissions options or may reduce emissions using existing control devices. At these sites, if a VRU is not onsite to route emissions through to a process, or if no emissions control device is onsite, pump emissions are not required to be reduced. These requirements reflect the BSER determinations regarding emissions reductions, costs, and other impacts.

Comment: Commenter (2326-AXPC) states that existing well sites, centralized production facilities, or compressor stations may not have adequate surface space for the proper placement of instrument air control systems – *e.g.*, due to safety and other permitting constraints. Where this is the case, the commenter provides that it would be technically infeasible to utilize a pneumatic pump not driven by natural gas. Accordingly, the commenter requests that EPA clarify in the final rule text that spacing constraints may pose technical infeasibility.

Response II-8-27: The technical infeasibility provisions of the final rule are limited to sites with fewer than three natural gas-driven diaphragm pumps, do not have access to electrical power, and that are trying to use existing control equipment or devices to reduce pump emissions. These provisions are intended to account for situations where it is technically infeasible for the existing equipment to handle pump emissions, which the equipment was likely not designed for. For other sites, considering the small footprint of the equipment necessary to power pumps, it is unlikely that space for the equipment will be an issue. However, the EPA notes that there are several options besides instrument air systems that are available to owners/operators for compliance with the rule if space is a constraint for such a system.

Comment: Commenter (2428-API) states that one of the legal flaws in EPA’s technical infeasibility opt-out scheme is that technical feasibility is the only governing criterion. The commenter provides that the cost of implementing the default zero-emitting standard is not a consideration. As a result, the commenter asserts that the proposed opt-out approach unlawfully evades the obligation that cost must be considered in prescribing CAA section 111 standards of performance. The commenter suggests that this flaw is easily cured by including cost as a consideration in implementing the opt-out provisions.

Response II-8-28: The final rule requirements for pumps have been revised from the December 2022 Supplemental Proposal. The EPA determined it was possible to specify the conditions under which the different pump requirements apply in the NSPS and EG that reflect the BSER and that eliminate the need for demonstrations of technical infeasibility. The BSER determinations included consideration of technical feasibility, emissions reduction potential, costs, and other impacts of emissions controls. The technical infeasibility provisions of the final rule are limited to those sites without access to electrical power, with fewer than three natural gas-driven diaphragm pumps, and that are trying to use existing control equipment or devices to reduce pump emissions. While control equipment can often accept additional emissions streams routed to them, existing equipment not already handling pump emissions would likely not have been designed with these emissions in mind. These provisions are intended to provide only for situations in which it is technically infeasible for the existing equipment to handle pump emissions.

### 8.3 NSPS OOOOb BSER Analysis/Emissions/Costs

Comment: Commenter (2446-Independent Petroleum Association of America (IPAA)) notes that the EPA acknowledges that historical GHG inventories, including those from the 2021 Greenhouse Gas Inventory (GHGI) for 2019 emissions, are significantly overstated. The commenter states that emissions are overstated by approximately 35 percent at least and over 90 percent or more at most for intermittent-bleed pneumatic devices, which represent a majority of the pneumatic devices in operation within the petroleum and natural gas system segments today. As such, the commenter states that a 5 percent difference in emissions reduction by allowing the use of existing or new control devices is hardly a "significant increase" and they believe should be an acceptable alternative BSER.

Response II-8-29: As explained in response II-8-22, the NSPS and EG reflect the EPA's BSER determinations. For sites with electricity and for sites without electricity and three or more natural gas-driven diaphragm pumps, the EPA concluded that zero-emissions represented the BSER, and the NSPS and EG reflect this determination by requiring zero emissions from pumps at these sites. For sites without electricity and fewer than three natural gas-driven diaphragm pumps, the EPA determined that the BSER for these sites is the use of existing equipment to route emissions to a process or to a control device. The NSPS and EG reflect this determination by requiring emissions from pumps at these sites to be routed to a process or control device, if a VRU or control device is onsite.

Comment: Commenter (2283-Endeavor) estimates that it would cost about \$85,500 per well site to convert pneumatic equipment to instrument air. If multiplied across just the commenter's approximately 2,000 existing well sites likely subject to EPA's proposed requirements, the cost would be astronomical. When all existing well sites across the industry are considered, the costs cannot be justified and are likely to significantly increase the prices that consumers pay for gas. According to the commenter, the complete retrofit of a low-producing facility with pneumatic equipment is likely cost prohibitive based on well economics, which may result in many low production or stripper well sites shutting in production. While EPA should revisit whether to include such requirements in its proposed EGs at all, the commenter believes that the EPA should at the very least exempt low-producing wells from the pneumatic equipment requirements to ensure the rule properly considers costs and remaining useful end of life as required by the CAA. If EPA does include any such requirements in its final rules, the commenter believes it must revise its economic analysis to reflect these higher costs.

The commenter (2283-Endeavor) adds that the incorporation of intermittent renewable power sources into operations may not be practicable. The commenter estimates that for its existing well sites, solar panels, and batteries necessary to power the site 24 hours per day would cost approximately \$140,000 per well site. Further, this equipment would likely require at least 300 square feet of space—a significant concern considering the limited footprint of many well sites and one which would also necessitate additional land disturbances and impacts to the local environment. Beyond costs figures, the commenter reports that large-scale solar applications have not been sufficiently tested in winter months when there is more cloud coverage, increased snow cover, and less sunlight. And solar generation systems with on-site battery storage raise

additional concerns regarding supply chain constraints (*e.g.*, availability of rare earth metals) and environmental concerns (*e.g.*, battery end-of-life disposal).

Commenter (2202-TXOGA) states that throughout the December 2022 supplemental proposal, technical feasibility is discussed in its relation to what compliance options are available depending on the source.<sup>10</sup> The proposal solicits comment regarding pneumatic pumps, and it appears to imply that technical viability is related to cost:

Instrument air systems can also be utilized at sites without access to the electricity grid, but these would require the installation and operation of a generator. These generators could be powered by engines fueled by solar energy, natural gas, or diesel. [...] While this is a technically viable option at these remote sites, we did not have detailed cost information available to include these systems in our analysis.

[...] The EPA is specifically requesting more detailed information on the use of generators at sites without access to the grid to power pneumatic controllers, primarily to power instrument air systems. The EPA is also interested in receiving more information on the costs associated with this equipment.<sup>11</sup>

The commenter (2202-TXOGA) expresses that they do not believe it was EPA's intent to link technical feasibility to cost.

Response II-8-30: The EPA's determination of BSER considers the emissions reduction methods that have been demonstrated, along with their efficacy, costs, and other impacts. In the analyses conducted for the BSER determination for pumps, the EPA included estimates of the costs of the systems that would be used for the affected equipment, which is the natural gas-driven pumps at the site, but not all equipment at the site. Where there are more pumps to be controlled, the costs of the system may be higher, but greater emissions reductions will also result from the control system. The EPA determined the BSER considering both the emissions reductions and the impacts, including the associated costs. The BSER determinations are reflected in the requirements of the NSPS and EG.

Comment: Commenter (2220-WDEQ) suggests that, for smaller operators who only have one or two pneumatic pumps on a site, performing process re-routing or putting on emissions controls may not be cost-effective.

---

<sup>10</sup> See 87 Fed. Reg. at 74,819 (Similarly, in making the BSER determination, the EPA must evaluate whether a system of emission reduction is "adequately demonstrated" for the source category based on the physical possibility and technical feasibility of control.); see also 87 Fed. Reg. at 74,820 (The EPA proposes in EG OOOOc to require that, in order to demonstrate that a designated facility cannot reasonably meet the presumptive level of stringency based on one of these three criteria, the state must show that implementing the BSER is not reasonable for the designated facility due to fundamental differences between the factors the EPA considered in determining the BSER, such as cost and technical feasibility of control, and circumstances at the designated facility.").

<sup>11</sup> EPA Issues Supplemental Proposal to Reduce Methane and Other Harmful Pollution from Oil and Natural Gas Operations, EPA's Supplemental Proposal for Oil and Natural Gas Operations - Comment Solicitation Spreadsheet, available at [https://www.epa.gov/system/files/documents/2022-11/MEMO\\_Supplemental%20Rule\\_Comment%20Solicitations\\_October%202022%20%281%29.pdf](https://www.epa.gov/system/files/documents/2022-11/MEMO_Supplemental%20Rule_Comment%20Solicitations_October%202022%20%281%29.pdf).

Response II-8-31: In determining the BSER, the EPA conducted analyses of the potential emissions reductions, costs of emissions control, and other impacts associated with various pump emissions control strategies. The EPA found that for sites without access to electrical power and with only one or two natural gas-driven diaphragm pumps, the costs are reasonable, considering the emissions reductions that would be achieved, for the affected pumps at the site to be routed to a process through an existing VRU or to an existing control device. The EPA found that the costs for routing emissions through a new VRU to a process or to a new control device at these sites would not be reasonable, considering the emissions reductions that would be achieved. The EPA determined that the BSER for these sites is to use a VRU already onsite to route emissions to a process or to route emissions to an already onsite control device. The NSPS and EG reflect this BSER finding.

Comment: Commenter (2399-GPA Midstream Association) requests that EPA include the cost of a vapor recovery unit (VRU), because a pneumatic pump requires a VRU to capture and route emissions. The statement in the Technical Support Document (TSD) misunderstands the purpose of a VRU at an oil and gas facility, including facilities in the midstream sector. The commenter explains that a VRU captures low pressure vapors (atmospheric, in the case of pneumatic pump emissions) and increases the pressure so that the vapor stream can be routed into the sales or process stream. It is not used to change gas composition, as the TSD suggests. Aside from the need to include the cost of installing and maintaining a VRU, the commenter states that the TSD underestimates other costs. For instance, the commenter's member companies' engineers when surveyed estimate that the costs for routing pneumatic pumps to an existing control device range from \$150,000 to \$300,000. The commenter states that this is far more than the \$6,102 EPA estimated in Tables 4-7 and 4-10 of the TSD based on oil and gas production well costs. Using the estimated lowest capital costs (\$150,000) for gathering and boosting compressor stations, the commenter states that the cost effectiveness numbers are significantly different than what EPA has estimated for this rulemaking.

Response II-8-32: In our revised analyses of control options for pumps, we considered the costs of a VRU for pump emissions to be routed to a process. The results of the analysis for this control option show that the costs of routing emissions to a process through a new VRU are reasonable for sites with access to electrical power and can use electricity from the grid to power the VRU. For sites without access to electrical power and fewer than three natural gas-driven diaphragm pumps, a generator would likely be needed to power the VRU, and the costs of routing emissions to a process would include the costs of both a new VRU and a new generator. The EPA determined that the costs associated with this equipment are not reasonable considering the emissions reductions that would be realized from the affected pumps at these sites.

Regarding the costs of routing emissions through a closed vent system to a process, the cost value used in our analyses includes information provided by commenters on the 2015 NSPS proposal. We note that the estimate of \$6,102 is the cost to route each pump, so a site with many pumps could have higher overall costs for routing all affected pumps to a process. In this instance, there would also be many pumps that have emissions reduced to zero, such that the costs of the closed vent system used to route the emissions to a process are reasonable considering the emissions reductions that would be realized.

Comment: Commenter (2446-IPAA) states that based on EPA's projected cost estimates, retrofitting a "medium model plant" would require an initial total capital investment (TCI) in the range of \$57,661,500 to \$180,000,000 to reduce 887 megatonne (mt) of methane emissions per year. Using the EPA's total annual cost (TAC) projections and a 15-year equipment life span, the cost per ton of methane reduced would be in the range of \$4,681 to \$23,819, which is well outside of EPA's reasonableness threshold of \$1,970/ton of methane reduced.

The commenter (2446-IPAA) adds that the EPA largely utilized historical data from its GHGRP as the basis for policy development, such as the requirements in NSPS OOOOb and EG OOOOc, which will require the oil and gas industry, amongst other things, to transition to zero-emitting pneumatic devices as the BSER. The commenter recommends replacing "one-size fits all" BSER for pneumatic pumps with the following alternatives:

*NSPS OOOOb:*

- Require pumps to be zero-emitting, consistent with current proposed BSER, if the BSER is determined to be "reasonable" based on a cost-effectiveness analysis performed by the operator of affected facilities. Reasonableness threshold of \$1970/ton methane emissions reduced or less; or
- If zero-emitting BSER is determined to be unreasonable/not cost effective, emissions must be routed to a control device with a destruction efficiency of at least 95 percent. All existing and proposed requirements for destruction devices would apply.

*EG OOOOc:*

- Require to be managed as part of proposed fugitive emissions requirements in EG Subpart OOOOc, including leak detection surveys, timely repairs, verifications, etc.; or
- Emissions routed to a control device with a destruction efficiency of at least 95 percent. All existing and proposed requirements for destruction devices would apply; or
- Zero-emitting, consistent with current proposed BSER.

Commenter (2294-Ohio Oil & Gas Association) states routing to process is unreasonable from a cost-effectiveness perspective. The commenter refers to Independent Petroleum Association of America (IPAA) and American Petroleum Institute (API) comment letter calculations.

Response II-8-33: The EPA has updated its BSER analysis to include more recent cost information for emissions control technologies as well as updated emissions factors now used for the Greenhouse Gas Reporting Program. Based on this analysis, the EPA finds that there are technically feasible emissions reduction options that are implementable at costs that are reasonable, considering the emissions reductions that would be achieved. The final standards reflect the BSER findings, which differ depending on site conditions. For sites with access to electrical power and sites that have three or more natural gas-driven diaphragm pumps, zero emissions from pumps is required. For sites without access to electrical power that have fewer than three diaphragm pumps (two or one), the standards require that GHG and VOC emissions

from all natural gas-driven pumps in the affected facility be routed to a process if a VRU is onsite. If a VRU is not onsite, emissions must be reduced by 95 percent if a control device with at least this emissions reduction capability is already available onsite or be reduced by less than 95 percent if a control device is onsite but is not capable of reducing GHG and VOC emissions by 95 percent or more.

Comment: Commenter (2428-API) states that the EPA relied on costs from the 2016 and 2021 Carbon Limits report for pneumatic controllers,<sup>12</sup> EPA uses different costs and assumptions as it pertains to converting to electric (assumed to be grid power) and solar pumps, which are not well documented and appear based on old information dating back to 2012.

Response II-8-34: The EPA acknowledges that the analysis for the 2022 supplemental proposal relied on older information. In the analyses for the supplemental proposal, updated costs from previous analyses were included for pumps to reflect changes in prices due to inflation. However, these cost updates do not necessarily reflect changes that have occurred in the production of alternative technologies to the standard natural gas-driven equipment, such as the drop in costs for solar panels and batteries. Therefore, the EPA updated its analysis for pumps to use the more recent information for non-natural gas-driven pump options. This included information from the Carbon Limits reports, which addressed pump options as well as controllers.

Comment: Commenter (2433-EDF *et al.*) states EPA's analysis shows that zero-emitting pneumatic pumps are cost-effective across all segments. The commenter notes that the EPA's cost analysis for pneumatic pumps remained largely unchanged between its 2021 and 2022 proposals. The adjustments EPA made have rendered the analysis more robust and further supports the cost-effectiveness of conversion to zero-emitting pumps. Notably, the commenter provides that the EPA's analysis now shows that conversion to electric pumps (either with access to grid electricity or solar-powered) or instrument air pumps is cost-effective, even if only a single diaphragm or piston pump is located at the site. And costs decrease as the number of pumps increase. The commenter recommends, however, that EPA further improve its cost analysis by considering whether controllers exist on-site. EPA's cost analysis noted that pneumatic pumps and controllers often use the same equipment. The commenter believes that its cost analysis should reflect that reality. The commenter states that such a change would result in increased cost-effectiveness for a zero-emission pneumatic pump standard. For example, they add that although EPA's analysis demonstrates cost-effectiveness, as EPA notes it is still likely underestimating costs as it does not account for the fact that certain sources, like compressed air systems and control devices, can be used for both controllers and pumps.

Response II-8-35: The EPA acknowledges that some sites may use common equipment for the control of emissions from both pumps and process controllers, such as a compressed air system. However, sites may also use a different compliance method for these types of equipment, such as using solar-powered electric pumps but a compressed air system for its controllers. As it is not necessary for sites to choose the same method of compliance for both equipment types, the EPA

---

<sup>12</sup> Carbon Limits. Zero Emission Technologies for Pneumatic Controllers in the USA. Applicability and Cost Effectiveness. August 1, 2016. and Carbon Limits. Zero Emission Technologies for Pneumatic Controllers in the USA. Updated Applicability and Cost Effectiveness. November 2021.

determined that it would not be reasonable to assess the BSER on the basis of both equipment types together. However, the EPA notes that even when assessed individually, the analyses show that there are zero-emissions options that are cost-effective for most sites.

## 8.4 Applicability and Compliance Date Considerations

Comment: Commenter (2428-API) notes that the EPA includes reference to [INSERT DATE OF PUBLICATION OF THE PROPOSED RULE IN THE FEDERAL REGISTER]. However, the regulatory text was not included in the *Federal Register* for neither the December 2022 proposal nor the November 2021 preamble description of requirements. As a result, the commenter states that it is unclear what date these provisions should be based. The commenter believes this should be based on the December 2022 proposal.

Commenter (2428-API) states the applicability date for pneumatic pumps under NSPS OOOOb should be the date of the publication of the December 2022 supplemental proposal. The commenter notes that, as the EPA acknowledges, the December 2022 proposed rule varies significantly from what was described in the November 2021 description for pneumatic pumps.

Response II-8-36: The applicability date for pumps under NSPS OOOOb is the date of publication of the December 2022 supplemental proposal, December 6, 2022.

Comment: Commenter (2326-AXPC) requests that the EPA extend implementation timelines – particularly for sources that became NSPS OOOOb affected facilities prior to the date of final rule publication. Until the effective date of NSPS OOOOb, some of these facilities would be unregulated under an existing NSPS or would begin operating as NSPS OOOOa affected facilities and may then need to complete retrofits to comply with newly applicable NSPS OOOOb standards. For example, the commenter states that NSPS OOOOa pneumatic pumps are not subject to a zero emissions standard but would be subject to zero emissions standards under NSPS OOOOb, requiring retrofit within 60 days of the final rule’s publication in the *Federal Register*. According to the commenter, this is not enough time to acquire retrofit equipment that will be in high demand, and likely short supply, as operators across the country place orders for equipment to meet the zero emissions standard. In addition, the commenter reports that operators must acquire engineering resources to engineer the installation of zero emissions pneumatic systems. They report that these engineering resources, too, are likely to be in high demand and short supply. The commenter asserts that the timing of compliance obligations is particularly pronounced for pneumatic pumps. For this equipment, EPA now proposes that operators may no longer utilize pneumatic pumps that are driven by natural gas, subject to limited exceptions. The commenter notes that the November 2021 proposal did not go so far as to eliminate the use of natural gas-driven pneumatic pumps entirely. This means operators may need to completely replace natural gas-driven pneumatic pumps that would have complied with the standards described in November 2021 proposal.

The commenter (2326-AXPC) proposes that EPA extend the initial compliance deadline for pneumatic controllers, pneumatic pumps, and storage vessels at least one year for those affected facilities that became NSPS OOOOb affected facilities between the “new” trigger date and the date the final rule is published in the *Federal Register*. Alternatively, if EPA is unwilling to

provide extended initial compliance deadlines, the commenter requests that EPA provide extensions where good cause exists, as it did under the recently promulgated Uintah and Ouray Indian Reservation Federal Implementation Plan (FIP) for oil and natural gas sources.

Response II-8-37: Based on these comments and supplemental information submitted by one commenter providing information regarding current equipment lead time and market conditions, it appears that some equipment necessary for the installation of zero-emitting pumps may not be available to enable new facilities or those that have started up or were modified or reconstructed since December 6, 2022, to comply with the zero-emissions pumps requirements within 60 days of the publication of the final NSPS.<sup>13</sup> According to this information, some of the operators surveyed report that they are experiencing delays in the availability of pumps, electrical transformers, generator skids, and compressor skids of up to 12 months.

Considering that the equipment types discussed in the information provided by these commenters are essential to the institution of zero-emitting pumps at a site and the estimated timeframes for the availability of equipment, the EPA is providing a compliance extension of one year for the zero-emissions pump requirements. Until the date of compliance of the zero-emissions requirements for pumps, owner/operators must be in compliance with the requirements for sites with fewer than three natural gas-driven diaphragm pump that do not have access to electrical power. The standards for these sites require that GHG and VOC emissions from all natural gas-driven pumps in the affected facility be routed to a process if a VRU is onsite. If a VRU is not onsite, emissions must be reduced by 95 percent if a control device with at least this emissions reduction capability is already available onsite or be reduced by less than 95 percent if a control device is onsite but is not capable of reducing GHG and VOC emissions by 95 percent or more. As these requirements are largely the same as the current NSPS OOOOa requirements for pumps at well sites, owners/operators of new and recently modified or reconstructed sites would already be routing emissions to a process or control device (if they have not installed zero-emitting pumps). The only difference is that NSPS OOOOb requires emissions to be routed to a process if a VRU is onsite before routing emissions to a control device would be allowed as a compliance method. Although the EPA expects this to be a rare circumstance, in some cases, it may be possible that pumps currently routed to a control device would be required to re-route those emissions to an onsite VRU to comply with these requirements. The information available to the EPA and provided by commenters does not suggest any equipment backlogs for additional common piping that may be needed to re-route emissions from a control device to a process through a VRU. Therefore, the EPA expects sites to be able to comply with these interim requirements within 60 days of publication of the final rule.

<sup>13</sup> API. Operator Survey of Supply Chain Delays for Equipment Needed for EPA Proposed NSPS OOOOb Methane Rule.

## 8.5 Miscellaneous Other Comments

### 8.5.1 Recommended Regulatory Text Changes

Comment: Commenter (2177-Southern Ute) points out that 40 CFR 60.5420c(d) is mistakenly included in paragraph 40 CFR 60.5420c(c)(14)(x) and should instead be formatted as its own paragraph [return needed].

Response II-8-38: We have revised the formatting of the paragraph formerly numbered as §60.5420c(c)(14)(x) and now numbered as §60.5420c(c)(14)(viii) to correct the missing separation between it and paragraph §60.5420c(d).

Comment: Commenter (2428-API) suggests that the following citation be checked for correct cross-referencing: 40 CFR 60.5420b(b)(10)(vi).

Response II-8-39: After review, we have found that the December 2022 Supplemental Proposal paragraph §60.5420b(b)(10)(vi) had an incorrect cross-reference to another paragraph in the proposed rule. For the final rule, we have revised and reorganized the regulatory text of §60.5420b(b)(10) such that paragraph §60.5420b(b)(10)(vi) no longer contains the same content that was included in that paragraph at proposal. We have ensured that this incorrect cross-reference is no longer in any paragraph of the final regulatory text.

### 8.5.2 Certifications

Comment: Commenter (2227-WEA) states that to the extent an engineer will be held responsible for a certification and be subject to potential civil and criminal penalties, it should be limited to fraudulent activity. The commenter believes it should not be related to unintentional errors or oversight that may have resulted in a flaw in the assessment. According to the commenter, these sorts of certifications will necessarily include a mix of objective and more subjective criteria, and engineers should be granted the deference to make determinations within their best professional knowledge and experience. The commenter recommends limiting subjecting an engineer's certifications liability and subjecting them to civil and criminal penalties to scenarios that involve fraudulent activity and not include unintentional errors or oversight.

Commenter (2428-API) states EPA should remove the additional certifications associated with the hierarchy (routing emissions to process being at a lower tier than that of implementing instrument air systems using solar or natural gas). The commenter provides that the CAA already has provisions for knowing criminal violations related to false statements, which includes reference to false material statement, representation, or certification in/omits material information from/alters, conceals, or fails to file or maintain a document filed or required to be maintained under the CAA.

The commenter (2428-API) also notes the proposed certification requirements are unreasonably onerous because, in each case, the certifying individual must essentially prove a negative – that the otherwise applicable zero-emissions approaches are “technically infeasible.” The commenter states that there is no definition of technical infeasibility in the proposed rules, but the words

could be construed as setting an exceedingly high bar, such that a given non-emitting technique is “infeasible” based solely on a technical assessment of whether it can theoretically be physically applied in the given situation. For example, that might require a non-emitting technology to be applied because it is technically theoretically possible, even though it would be inordinately expensive. According to the commenter, this outcome would not be lawful because it would violate the statutory requirement that BSER and the corresponding standard of performance must be cost effective.

And, in any event, the commenter (2428-API) believes that a “technical infeasibility” standard allows for second guessing by regulators or citizen enforcers, which invites a “battle of the experts” in potential enforcement actions. All of this diminishes the possibility that the opts outs can be implemented with reasonable certainty.

Lastly, the commenter (2428-API) reports that the express threat of possible personal liability on the part of certifiers surely will limit the number of individuals willing to make the needed certifications, particularly considering the uncertainties described above about what will be needed as a practical matter to demonstrate “technical infeasibility.” The commenter states that the clear opportunity and possibility of second guessing will be further material disincentives.

If EPA retains the requirement for case-specific certifications, the commenter (2428-API) recommends that EPA revise the required certification. The proposed regulatory text of each certification includes the following sentence:

Based on my professional knowledge and experience, and inquiry of personnel involved in the assessment, the certification submitted herein is true, accurate, and complete. [See, e.g., 40 CFR 60.5377b(b)(2).]

The commenter (2428-API) suggests that this should be revised to specify that the certification is based on “reasonable inquiry,” as is required for certifications under the Title V operating permit program. The commenter suggested the following revised certification language in lieu of the above language:

Based on reasonable inquiry, including application of my professional knowledge and experience and inquiry of personnel involved in the assessment, ....

The commenter (2428-API) provides that a “reasonable inquiry” standard would not shield a certifier from outright fraud but would provide more latitude for reasonable differences of opinion as to technical infeasibility.

Response II-8-40: In consideration of these comments, the EPA reviewed the proposed certification of infeasibility requirements. The EPA augmented the structure of the final standards for pumps based on comments received on the December 2022 Supplemental Proposal and determined that they could be revised to include the criteria for which certain emissions standards would apply without requiring the need for demonstrations of technical infeasibility. We have revised the proposed rule to incorporate the conditions that reflect our BSER determinations, which incorporate our understanding of technical feasibility, emissions

reductions, costs, and other impacts. The final rule now clarifies which emissions standards for pumps must be met based on the site conditions and does not require demonstrations of infeasibility.

Comment: Commenter (2221-Texas Pipeline Association) states the rules should allow in-house engineers, and non-PE outside personnel, to make required certifications and determinations. The commenter also states EPA should expand the universe of persons who could make required certifications and determinations to include non-PE outside personnel. Companies on occasion can experience shortages or temporary unavailability of personnel and in those instances rely on outside personnel. Such outside personnel can be as knowledgeable of and familiar with design and operations as in-house employees. Company-hired contractors or consultants should also be allowed to sign off on certifications if they have appropriate expertise, *e.g.*, if they have designed the system in question. According to the commenter, this would provide additional flexibility without sacrificing any environmental protections because such third parties would have to have appropriate expertise on design and operation of the system to complete a certification or to make a required technical determination.

Response II-8-41: The final rule now clarifies which emissions standards for pumps must be met based on the site conditions and does not require demonstrations of the infeasibility of the use of non-natural gas-driven pumps. However, for sites without access to electrical power and that have fewer than three natural gas-driven diaphragm pumps, owners/operators may demonstrate that it is technically infeasible to use existing equipment to control pump emissions. These demonstrations may be conducted by a qualified professional engineer or an in-house engineer. The EPA has not expanded the universe of persons permitted to make these demonstrations since owners/operators of this small subset of sites should be able to obtain the necessary in-house or hired contractors with these qualifications to perform these demonstrations.8.5.3 Interaction of the Pneumatic Pump Proposed Standards with Pneumatic Controller Proposed Standards

Comment: Commenters (2028-Westmoreland Marcellus Citizens' Group, 2039-Citizens to Preserve Ligonier Valley, Inc.) state that the requirement for air driven zero emitting pneumatic devices on controllers should be expanded to include pneumatic pumps.

Response II-8-42: For the final rule, the EPA has revised the NSPS and EG requirements for pumps to allow any zero-emitting option to be used at sites with access to electrical power and at sites without access to electrical power that have three or more natural gas-driven diaphragm pumps. One option available to owners/operators in achieving zero emissions from pumps is the use of pneumatic pumps driven by compressed air. For sites without access to electricity and with fewer than three natural gas-driven pumps, owner/operators may choose to employ a zero-emitting option for pumps or they may use a control device already onsite to reduce emissions. If no VRU is onsite for routing emissions through to a process or no control device is onsite, pump emissions at these sites are not required to be reduced.

Comment: Commenter (2428-API) has concerns regarding the practical and logistical aspects of how EPA has outlined control standards between the controllers and pumps. The commenter notes that the EPA has proposed a completely distinct set of requirements for natural gas-driven controllers separate from natural gas-driven pneumatic pumps with sometimes conflicting

statements made to justify EPA's decisions. The commenter requests that the requirements for both pneumatic controllers and pumps be streamlined for consistency with neutral technology standards that do not require additional certifications and allow for emissions to be routed to a control device.

Commenter (2433-EDF *et al.*) urges EPA to mirror the proposed pump standard with the proposed controller standard by including routed pumps as a compliance option and eliminating the tiered feasibility exemption at sites without electricity.

Response II-8-43: In consideration of these comments, the EPA reviewed the proposed certification of infeasibility requirements. The EPA augmented the structure of the final standards for pumps based on comments received on the December 2022 Supplemental Proposal and determined that they could be revised to include the criteria for which certain emissions standards would apply without requiring the need for demonstrations of technical infeasibility. We have revised the proposed rule to incorporate the conditions that reflect our BSER determinations, which incorporate our understanding of technical feasibility, emissions reductions, costs, and other impacts. The final rule now clarifies which emissions standards for pumps must be met based on the site conditions and does not require demonstrations of infeasibility. In addition, we also have restructured the requirements to be technology-neutral. Further, as routing pump emissions to a process results in zero emissions from the pumps, the EPA allows this as a zero-emissions compliance option and does not require that non-natural gas-driven pumps be used to meet the zero-emissions requirements.

## **Chapter 9. Inflation Reduction Act (IRA) and Methane Emissions and Waste Reduction Incentive Program (MERP)**

Chapter 9 Response: In the preamble to the December 2022 Supplemental Proposal, the EPA noted that implementation of CAA section 136 was outside the scope of the supplemental proposed rule, and that the EPA intended to take one or more separate actions to implement CAA section 136. The EPA requested comment on the criteria and approaches that the Administrator should consider in making the CAA section 136(f)(6)(A)(ii) “equivalency determination.” Consistent with our statements in the December 2022 Supplemental Proposal, these comments are outside the scope of this final rule. Summaries of comments received on these issues are provided below for reference, but substantive responses are not provided.

### **9.1 Administrator’s Equivalency Determination**

#### ***9.1.1 Temporal Elements of the IRA and MERP***

##### **9.1.1.1 Time Period for the Determination**

Comment: Commenter (2433-Environmental Defense Fund (EDF) *et al.*) states that EPA should require that equivalent reductions be achieved in each year that the CAA section 136(f)(6)(A) exemption may be in effect as well as in the aggregate across a multi-year period through 2035, as analyzed in the November 2021 Proposal. First, the commenter asserts that the equivalency determination must apply in each year that any exemption from the waste charge is available. By way of example, the commenter explains that if final standards and plans have been approved, are in effect, and have been fully implemented in all states in 2028, EPA should evaluate whether those standards and plans will achieve equivalent or greater reductions to what the November 2021 Proposal would have achieved in 2028 if it had been fully implemented. Evaluating equivalency on a year-by-year basis is necessary to account for the fact that final CAA section 111 standards and plans may take effect on different timelines than projected in the November 2021 Proposal, states the commenter.

Second, the commenter (2433-EDF *et al.*) states that the equivalency must apply over the multi-year period through 2035 evaluated in the November 2021 Proposal. The commenter explains that Congress was aware of the estimated impact of the November 2021 Proposal’s presumptive standards and incorporated an expectation of equivalent effectiveness into CAA section 136(f)(6)(A)(ii)<sup>1</sup>. Final standards and plans should therefore be compared to this timeline and deliver equivalent or greater reductions in the multi-year period through 2035, in addition to equivalent or greater reductions in each year that they are fully in effect and implemented, states the commenter. The commenter believes this will help ensure that final standards and plans will achieve equivalency to the November 2021 Proposal, even if those final standards and plans are implemented on a later timeline.

---

<sup>1</sup> See Greg Dotson and Dustin Maghamfar, The Clean Air Act Amendments of 2022: Clean Air, Climate Change, and the Inflation Reduction Act, 53 Env’t L. Reporter 10017, 10032 (Jan. 2023), <https://www.eli.org/sites/default/files/files-pdf/53.10017.pdf>.

Comment: Commenter (2326-American Exploration and Production Council (AXPC)) suggests that it may be possible that states could submit plans pursuant to CAA section 111(d) in a phased fashion (as long as each plan is submitted prior to the deadline). The commenter believes that if the states have adopted plans that implement emission guidelines (EG) OOOOc in part, then the exemption should apply for those sources covered by the state plans that have been adopted. The commenter states that such phasing could allow states to begin implementing the requirements from EG OOOOc faster, which would reduce emissions faster. According to the commenter, if the MERP exemption eligibility were deferred until a state has adopted all provisions of the state plan, that would disincentivize expeditious adoption of provisions with respect to many of the most prominent emissions sources, delaying reductions and resulting in considerable foregone emissions reductions.

Comment: Commenters (2283-Endeavor Energy Resources, L.P. (Endeavor), 2301-U.S. Chamber of Commerce (USCC)) encourage EPA to evaluate equivalence based on a multi-year evaluation of emission reductions (for requirements phased in over a multi-year period), rather than, as EPA proposes to do, considering emission reductions only upon full implementation of phased-in requirements (i.e., if a state phases in installation of zero-emitting pneumatic controllers over more than one year, the comparison should be made at the point that the EGs require full use of zero-emitting controllers). The commenter (2301-USCC) believes that EPA's proposed approach is inappropriately rigid and would ignore real world emissions reductions.

Conversely, commenter (2410-California Office of the Attorney General (CA AG) *et al.*) agrees with EPA that the appropriate comparison should be based on when the new source performance standards (NSPS) or state plan requirements are fully implemented by the sources. The commenter states that such an interpretation is consistent with the prefatory language in CAA section 136(f)(6)(A), which provides that a methane charge will not be imposed only when an affected facility is "subject to and in compliance with" methane standards under CAA section 111(b) or (d). The commenter states it is also consistent with CAA section 136(f)(6)(A)(i), which requires the standards and plans to have been approved and be in effect before the methane charge will no longer be imposed.

#### 9.1.1.2 Timing of the Determination for New Sources

Comment: Commenters (2326-AXPC, 2399-GPA Midstream Association (GPA)) state that new source eligibility for the exemption should not be tied to the status of implementation of existing source regulations. Commenter (2326-AXPC) states that EPA has significant latitude to interpret the scope of the exemption for regulatory compliance, due to the ambiguous language of the IRA and lack of legislative history. The commenter urges EPA to frame the determination by the overarching goal of reducing emissions which the commenter believes is the objective policy outcome in keeping with the title of this section of the IRA. For NSPS OOOOb, the commenter states the determination can be made when the regulation goes into effect and EPA could determine that all such sources subject to NSPS OOOOb are meeting the requirements under 42 U.S.C. Ch. 85 section 7436(f)(6)(A) (and exempt emissions associated with such sources from the methane fee).

Commenter (2326-AXPC) states that assuming that the final rule is “equivalent” to the November 2021 Proposal within the meaning of the IRA, the EPA Administrator should make the determination of this equivalency with respect to new sources at the same time of the final rule or before reporting and recordkeeping requirements go into effect, whichever is earlier. Further, the commenter states, this provision can only be reasonably interpreted such that the determination of whether new source standards “are in effect” should be made separately from any determination of whether existing source standards “have been approved and are in effect.” The commenter contends that it would be unreasonable to tie new-source eligibility for the exemption to the status of existing-source regulation. The commenter believes that Congress’s goal in the MERP is to ensure emissions reductions in keeping with the text and structure of CAA section 111, and the MERP provision should be read in harmony with that (in keeping with the fundamental axiom that all statutory provisions are to be read in harmony with one another to the greatest extent possible).

Commenter (2399-GPA) states that for purposes of determining that the waste emission charge exemption applies, EPA should use the NSPS OOOOb effective compliance date and make the necessary evaluation of equivalency at the time it issues a final rule. The commenter explains that this will ensure a reasonable application of the regulatory compliance exemption from the waste charge. The commenter believes there is no reason for a new source subject to CAA section 111(b) to wait for any state to choose to incorporate new source emission standards. As states are not obligated to adopt such standards for the standards to be “in effect” in a state<sup>2</sup> the commenter explains, such an interpretation could render the exemption a nullity, even if only temporarily, for those sources within states that delay or choose not to adopt their own new source standards. Likewise, the commenter states, it would be illogical to wait for a state to propose and implement a plan for existing sources that would not apply to the new source subject to CAA section 111(b) standards. The commenter warns that they believe that such an interpretation would accomplish the opposite of Congress’s intent in creating the exemption, by punishing complying facilities rather than incentivize continued compliance.

Comment: Commenters (2326-AXPC, 2410-CA AG *et al.*, 2433-EDF *et al.*) state that the IRA equivalency determination should be done once the standards of performance pursuant to CAA section 111(b) are fully promulgated. Commenter (2410-CA AG *et al.*) contends that this is consistent with the language at CAA section 136(f)(6)(A)(i) that standards “have been approved and are in effect.”

Commenter (2433-EDF *et al.*) states that the plain language of CAA section 136 indicates that EPA must evaluate final standards for equivalency. The commenter cites to CAA section 136(f)(6)(A)(i), which requires “methane emissions standards...pursuant to subsections (b)...of section 111 [to] have been approved and . . . in effect in all States.” In turn, the commenter explains, CAA section 136(f)(6)(A)(ii) requires EPA to determine that “compliance with the requirements described in clause (i)” will achieve equivalent reductions to the November 2021 proposed rule. The “requirements” for new sources evaluated for equivalency in section (ii) are referring to “emissions standards” that “have been approved” and are “in effect in all States” states the commenter.

---

<sup>2</sup> See 42 U.S.C. section 7411(c).

Commenter (2326-AXPC) recommends that the date of the final NSPS OOOOb be deemed the approval date for sources regulated under NSPS OOOOb and the effective date be sixty days following EPA's final NSPS OOOOb. The commenter suggests that the provision at CAA section 136(f)(6)(A)(i) can only be reasonably interpreted such that the determination of whether new source standards "are in effect" is to be made separately from any determination of whether existing source standards "have been approved and are in effect." The commenter adds that it would be unreasonable to tie new source eligibility for the exemption to the status of existing source regulation. The commenter believes that Congress's goal in the MERP is to ensure emissions reductions in keeping with the text and structure of CAA section 111, and the MERP provision should be read in harmony with that CAA section 111 (in keeping with the fundamental axiom that all statutory provisions are to be read in harmony with one another to the greatest extent possible).

#### 9.1.1.3 Timing of the Determination for Existing Sources

Comment: Commenter (2399-GPA) states that EPA should adopt a reasonable interpretation of the IRA requirement for standards and plans to be in effect "with respect to" the applicable facilities. Accordingly, the commenter recommends that EPA allow sources that comply with the EG OOOOc, establishing the minimum "standards and plans" for the facility, to be able to show compliance and thereby establish coverage for the exemption. The commenter believes this would incentivize sources to comply early—even before a state goes through what can be an often long planning and adoption process. At a minimum the commenter recommends that EPA confirm that the reference to "all states" does not mean a facility must wait for other states to act. The commenter warns that waiting for each and every state to adopt an EPA-approved plan would otherwise unfairly restrict a facility's ability to utilize the exemption, contrary to what they believe was Congress' intent.

Comment: Commenters (2283-Endeavor, 2326-AXPC, 2410-CA AG *et al.*) recommend that EPA make an evaluation as soon as possible. Commenter (2326-AXPC) states that EPA has significant latitude to interpret the scope of the exemption for regulatory compliance, due to the ambiguous language of the IRA and lack of legislative history. The commenter urges EPA to frame the determination by the overarching goal of reducing emissions which the commenter believes is the objective policy outcome in keeping with the title of this section of the IRA. The commenter states that the most efficient approach would be for the Administrator to make determinations when each state adopts as a matter of state law a state plan pursuant to CAA section 111(d) and EG OOOOc as this will encourage states to move faster in development of their state plans and thus reduce emissions faster. The commenter explains that due to the difference in resources available across different state agencies, and to the unique nature and distribution of each state's fleet of existing sources, it is highly likely that states will submit their state plans at different times and that these state plans will feature different levels of detail, which will require varying and unpredictable devotion of EPA resources to plan review.

Furthermore, the commenter (2326-AXPC) expresses, it would not be reasonable to interpret the term "in all states" to require that all states have approved state plans (or promulgated federal plans) in order for the facilities in any one state to be eligible for the exemption. The commenter notes that if there are delays or other obstacles to approving state plans or promulgating federal

plans in one or a handful of states, Congress showed no sign that it wanted to penalize facilities in other states where a state or federal plan is in effect. Instead, the commenter believes that by using the phrase “in all states *with respect to the applicable facilities*” (emphasis added) Congress recognized that facilities may reside in multiple states. According to the commenter, the best, perhaps the only permissible, reading of this provision is that, for an existing source facility to qualify for the exemption, a state (or federal) plan must be in effect in all states within whose territory the facility extends.

By way of example, the commenter (2326-AXPC) provides the following scenario:

States A, B, and C with just midstream operations (*e.g.*, natural gas processing plants) adopt (as a matter of state law) state regulations or plans pursuant to EG OOOOc, and the adopted state regulations or plans have become legally effective as a matter of state law (irrespective of submission to and timing of EPA approval). At the same time, some states (States E, F and G) have not adopted (as a matter of state law) state regulations or plans.

- EPA can determine that midstream operations that are regulated under state regulations adopted as a matter of state law pursuant to EG OOOOc in States A, B, and C meet the requirements under CAA section 136(f)(6)(A) and are exempt from the methane fee.
- To the extent that an operator’s assets span multiple states, then the operator should be exempt from the methane fee for emissions associated with any assets in a state that has adopted (as a matter of state law) regulations that are in effect (*i.e.*, States A, B, and C above) pursuant to EG OOOOc.

Regarding federal plans, the commenter (2326-AXPC) states that it is reasonable for EPA to interpret the IRA’s language such that a federal plan being “in effect” in the state (or multiple states in the case of facilities extending across state lines) satisfies the prerequisite for the exemption at CAA section 136(f)(6)(A)(i). Conversely, the commenter adds that it would be unreasonable to interpret this language such that a federal plan will not satisfy this prerequisite. According to the commenter, the purpose of the MERP is to ensure emissions reductions and they believe there is no sign that Congress wished to disregard reductions effected by federal plans for existing sources.

Commenter (2283-Endeavor) suggests that the equivalency be done by assuming designated facilities would be subject to their corresponding EG presumptive standards once state plans are implemented, given that that the start date for the methane fee will come before fully approved state EG plans are in place. Commenter (2410-CA AG *et al.*) asserts that, consistent with the language in CAA section 136(f)(6)(A)(i), EPA should make the evaluation once the EPA has approved state plans and/or developed a Federal Plan (*i.e.*, plans “have been approved and are in effect.”)

Comment: Commenter (2433-EDF *et al.*) states that EPA should make the evaluation and equivalency determination once standards of performance pursuant to CAA sections 111(d) are fully promulgated nationwide by comparing the November 2021 Proposal to final, approved state plans (and any Federal Plan if applicable). The commenter adds that the plain language of

CAA section 136 indicates that EPA must evaluate final plans for equivalency. The commenter cites to CAA section 136(f)(6)(A)(i) which requires “methane emissions...plans pursuant to subsection...(d) of section 111 [to] have been approved and . . . in effect in all States.” In turn, the commenter provides that CAA section 136(f)(6)(A)(ii) requires EPA to determine that “compliance with the requirements described in clause (i)” will achieve equivalent reductions to the November 2021 Proposal. The “requirements” for existing sources, evaluated for equivalency in CAA section 136(f)(6)(A)(ii) are referring to “plans” that “have been approved” and are “in effect in all States.”

#### 9.1.1.4 Remaining Useful Life and Other Factors (RULOF)

Comment: Commenters (2326-AXPC, 2410-CA AG *et al.*, 2433-EDF *et al.*) provide comments on addressing RULOF. Commenter (2433-EDF *et al.*) states that because CAA section 136(f)(6)(A)(ii) directs EPA to determine that “compliance” with plans will achieve equivalent reductions to the November 2021 Proposal, EPA must consider how facilities will comply with final plans. This necessarily entails an evaluation of whether fully implemented state plans—including any less stringent standards adopted based on an invocation of RULOF—achieve equivalent reductions to the November 2021 Proposal, states the commenter. The commenter suggests that, because that proposal did not indicate if or how variances might have been approved, and instead only contained presumptive standards in the proposed EGs, EPA cannot hypothesize states’ invocation of RULOF under the November 2021 Proposal but must instead assume each state fully implemented the proposed November 2021 EGs when estimating reductions. The commenter believes this is consistent with EPA’s emissions reductions estimates in the regulatory analysis for the November 2021 Proposal, where the agency did not assume any variances and instead assumed that state plans would fully reflect the emission reductions projected under the proposed guidelines. Lastly, the commenter states that evaluating final, approved state plans for equivalency will both incentivize expeditious submission of state plans and disincentivize overbroad invocation of RULOF to justify less stringent standards in state plans.

Commenter (2410-CA AG *et al.*) states that with respect to RULOF, CAA section 136 does not by its terms compel any consideration of RULOF in making an IRA equivalency determination. Therefore, the commenter believes that it would be appropriate for EPA to conduct an equivalency evaluation with respect to an applicable facility without consideration of the application of these factors.

Commenter (2326-AXPC) states that the November 2021 Proposal did not provide much, if any, detail on how states can apply RULOF, but acknowledges that its application is within the authority of the CAA and the states. Therefore, the commenter states, the use of RULOF is inherent within the stringency of the November 2021 Proposal, even if EPA does not quantify or monetize those provisions.

Comment: Commenter (2442-Wyoming Coalition of Local Governments (WYCLG)) appreciates EPA’s questions regarding how the proposed supplemental rule and the waste emissions charge (WEC) will interact. However, the commenter is concerned with the fact that the IRA equivalence determination is based on emissions reductions under the November 15, 2021,

proposed rule, which has now been substantially amended by the December 2022 Supplemental Rule. Further, the commenter adds that, under the December 2022 Supplemental Rule, there is the ability for states to apply a less stringent standard to a designated facility, based on RULOF. The commenter is concerned that it is unclear how less stringent RULOF standards would affect the IRA equivalency determination, and whether adopting the less stringent standards would then subject facilities to the WEC. The commenter believes this would ultimately conflict with the purpose of adopting a less stringent RULOF standard, which is to help avoid unnecessary and unreasonable costs when a facility is aging and towards the end of its useful life.

#### 9.1.1.5 Other Related Comments Regarding Timing for Both New and Existing Sources

Comment: Commenters (2301-USCC, 2326-AXPC, 2409-BP America Incorporated (BP)) recommend that the determination be made as soon as possible. Commenter (2326-AXPC) states that even if the determination is made only for a subset of sources, the earliest determination will maintain the purpose of the MERP and minimize administrative burden, states the commenter. Commenter (2301-USCC) states that given that the methane fee will take effect in 2025, the commenter notes that it is critical that EPA make the equivalence determination as soon as practicable and should not wait for all states to submit their plans, as doing so would unduly delay the determination and force operators in states that already have “equivalent” programs to pay potentially significant fees. Further, the commenter states that given that the start date for the methane fee will come before fully approved state EG plans are in place, EPA should make an evaluation by assuming designated facilities would be subject to their corresponding EG presumptive standards once state plans are implemented.

Commenter (2409-BP) asserts that it is imperative not only for EPA to finalize the CAA section 111(b) and (d) rules in a timely manner, but also for EPA to put in place a process and timeline for reviewing and approving state plans as efficiently as possible to ensure that the WEC exemption is available to compliant facilities. In particular, the commenter recommends that EPA ensure that state plans submitted pursuant to the proposed EG OOOOc (after the 18-month period allotted for states to develop those plans) are approved and effective by 2025 at the latest, so that there will be only one year (*i.e.*, 2024) in which the IRA fee is applicable without any safe harbor for facilities actively complying with the CAA section 111(b) and (d) standards. In consideration of the aforementioned, the commenter supports EPA’s efforts to finalize the supplemental proposal and implement a process for the expeditious approval of state plans.

Comment: Commenters (2254-Permian Basin Petroleum Association (PBPA), 2283-Endeavor) provide comments on the criteria and approaches that EPA should use in making the equivalence determination. Commenter (2254-PBPA) states that EPA should not unnecessarily delay making an equivalency determination. Commenters (2254-PBPA, 2283-Endeavor) state that EPA should assume that designated facilities would be subject to their corresponding EG presumptive standards once state plans are implemented.

Comment: Commenter (2292-West Virginia Office of the Attorney General *et al.*) states that the December 2022 Supplemental Proposal openly refuses to engage with the complications that result from the interplay between the provisions in the proposed rule and the MERP. The commenter is concerned that this could produce still more costs for the energy industry. They

add that they are also concerned that EPA has not explained how it will make the equivalency determination; nor has it explained how it will address the time gap between implementation of any new standards and the start date for the fee program. The commenter notes that they shared similar concerns, that a methane fee is ill-advised, more than a year ago.<sup>3</sup> The commenters believe that Congress created the “safe harbor” (*i.e.*, if the source complies with methane standards that produce emission reductions that are equivalent to or greater than the reductions the Proposed Rule) from fees, to address these concerns. Yet the commenter believes that EPA seems willing to undermine the safe harbor’s usefulness by keeping standards for meeting it vague (*e.g.*, EPA has done only a “purely qualitative” comparison between reductions achieved by the December 2022 Supplemental Proposal and reductions that would have been achieved by the November 2021 Proposed Rule).

Comment: Commenter (2399-GPA) states that EPA should apply a common sense definition of “applicable facility” to harmonize the different requirements in the WEC.<sup>4</sup> The commenter recommends that EPA view a “facility” using the common sense notion of an operating site – not the equipment-level “affected facility” used in NSPS OOOOb/EG OOOOc, nor the basin-level “facility” used in Subpart W. They add that they believe throughput should similarly be based on discrete sites (*i.e.*, each gathering and boosting compressor station). According to the commenter, any other interpretation would result in arbitrary treatment among industry segments and would lead to significant uncertainty as operators attempt to parse out what exactly is and is not a “facility” and how to correctly assess facility throughput. The commenter recommends that to address this potential confusion, EPA should revise Subpart W throughput reporting elements for gathering and boosting to allow reporters to reflect true facility throughput.

If EPA utilizes existing regulatory definitions to define a “facility,” the commenter (2399-GPA) cautions that implementation of the IRA’s language will be particularly challenging in that the terms “facility” and “facilities” have vastly different meanings in Subpart W and NSPS OOOOb/EG OOOOc, and those meanings themselves do not necessarily align with the public’s understanding of what these words mean. The commenter explains that, in NSPS OOOOb/EG OOOOc, the “affected facility” is an individual piece of equipment (or group of equipment, like all the natural gas-driven pneumatic controllers at a gas plant), while on the opposite side of the spectrum, under Subpart W, a gathering and boosting “facility” includes all gathering and boosting emission sources within a basin, which is usually a large geographic area spanning many counties and sometimes many states. The commenter adds that neither the NSPS OOOOb/EG OOOOc nor the Subpart W gathering and boosting facilities definitions are consistent with a general understanding of the word “facility.” Accordingly, the commenter suggests that EPA use the simplest interpretation of the term, which is that “a facility” is a single site, and not specific pieces of equipment within that site, nor the aggregation of hundreds of sites within a geographic area. The commenter believes this approach is straightforward and “bridges the gap” between NSPS OOOOb/EG OOOOc and Subpart W.

<sup>4</sup> See Docket ID Nos. EPA-HQ-OAR-2022-0875, EPA-HQ-OAR-2022-0875-0002 (submitted January 18, 2023) (“GPA Midstream Comments to MERP Docket”). See Exhibit F.

### ***9.1.2 Geographical Elements of Administrator’s Equivalence Determination***

Comment: Commenter (2177-Southern Ute Indian Tribe (Southern Ute)) provides comment on EPA’s request regarding the geographical elements of the requirements in CAA section 136(f)(6)(A)(i). The commenter states that EPA should consider a basin or depositional environment consideration for different oil and gas fields, as each field has unique elements that make blanket regulations not applicable or overly stringent in cases of low volatile organic compound (VOC) carrying capacity.

Comment: Commenters (2254-PBPA, 2283-Endeavor, 2301-USCC) state that EPA’s evaluation should make this evaluation on both a national level and state-by-state level, and that a finding of equivalence under either approach should be sufficient to trigger the methane fee exemption.

Comment: Commenter (2410-CA AG *et al.*) states that the geographical elements of the evaluation depend on EPA’s interpretation of the statutory language CAA section 136(f)(6)(A)(i), which provides that, before an applicable facility can no longer be subject to the charge, the Administrator must determine that emission standards “have been approved and are in effect in all States with respect to the applicable facilities.” The commenter believes it would be reasonable for EPA to interpret CAA section 136(f)(6)(A)(ii) as allowing a national evaluation of equivalency only if EPA interprets CAA section 136(f)(6)(A)(i) to mean that no affected facility in any state can avoid the charge until all states have approved state plans that are in effect. If, however, EPA interprets CAA section 136(f)(6)(A)(i) to allow an applicable facility to avoid the charge if a state plan is in effect in any state in which the applicable facility operates, then correspondingly EPA should interpret CAA section 136(f)(6)(A)(ii) to require a state-by-state equivalency evaluation. Otherwise, the commenter cautions, affected facilities in a state that is not achieving emission reductions equivalent to the November 2021 Proposal would unfairly benefit from greater emission reductions required under more stringent requirements in another state.

Comment: Commenter (2433-EDF *et al.*) states that EPA should conduct a state-by-state analysis across all states nationwide to determine equivalency. As part of this analysis, the commenter believes that EPA must first evaluate the standards and plan in effect in each state to ensure that reductions equivalent those under the November 2021 Proposal are being achieved. The commenter explains that evaluating the standards and plans in every state aligns with CAA section 136(f)(6)(A)(i)’s directive to evaluate “standards and *plans* . . . in effect in all States” (emphasis added) for equivalency under section 136(f)(6)(A)(ii).

The commenter (2433-EDF *et al.*) further states that EPA should compare emissions reductions expected under each state’s final CAA section 111(d) plan to the emissions reductions that would have been achieved under the November 2021 EGs, if finalized in that state. The commenter explains that this follows from CAA section 136(f)(6)(A)(ii)’s directive that the comparison is to the proposed November 2021 emissions guidelines “if *such rule* had been finalized and implemented” (emphasis added), which contemplates a full implementation of the November 2021 proposed standards and emissions guidelines in each state. The commenter notes that, if a state’s final CAA section 111(d) plan achieves fewer reductions than the November 2021

Proposal's EGs, including due to variances granted pursuant to RULOF considerations, then EPA could not make the equivalency determination.

The commenter (2433-EDF *et al.*) states that evaluating equivalency with regard to each state incentivizes the greatest reductions in emissions under both the waste charge program and CAA section 111, whereas solely considering aggregated nationwide emissions (which could allow for lower emissions reductions in one state to be offset by higher emissions reductions in another state) does not. The commenter explains that, evaluating whether stronger standards in one state offset less stringent standards in another state would also be technically difficult, given that many section 111 standards are non-numerical design, equipment, work practice, and/or operational standards that do not quantify emissions.<sup>5</sup> However, according to the commenter, while a nationwide analysis in and of itself is insufficient in the absence of a parallel state-by-state analysis, EPA must still ensure that aggregated nationwide emissions reductions are equivalent or greater than those under the November 2021 Proposal. The commenter notes that, by ensuring that each state is achieving equivalent reductions under the CAA section 111(b) standards and its CAA section 111(d) plan, a nationwide determination of equivalency across all states should necessarily follow.

### ***9.1.3 Meaning of "Equivalent" Emissions Reductions***

Comment: Commenter (2458-MiQ) states that EPA should encourage states that share basins (*i.e.*, New Mexico and Texas with regards to the Permian Basin, and Pennsylvania, New York, and West Virginia for the Marcellus Basin) to work in conjunction with each other on equivalence evaluations.

Comment: Commenter (2326-AXPC) believes that that it is not appropriate to quantitatively compare the November 2021 Proposal with the December 2022 Supplemental Proposal, nor would it be appropriate to quantitatively compare the final rule with the November 2021 Proposal. The commenter notes that the November 2021 Proposal did not provide any regulatory text for proposed NSPS OOOOb or EG OOOOc, and certain proposed requirements were not technically feasible. The commenter states that EPA has understood that some of the requirements were not possible as EPA modified them in the December 2022 Supplemental Proposal. Therefore, the commenter provides that the emissions reductions expected within the November 2021 Proposal would not have been realized as estimated within the rule. That said, the commenter believes that the December 2022 Supplemental Proposal is at least as stringent as the November 2021 Proposal, due to the significant changes to the November 2021 Proposal in the December 2022 Supplemental Proposal, and states that if industry's comments and recommendations are implemented in full by EPA, the final rule would still be as stringent as the November 2021 Proposal. By way of example, the commenter points to Table 5-5 of EPA's 2022 Regulatory Impact Analysis (RIA), where it is apparent that fugitive emissions, pneumatic devices, and reciprocating compressors make up a large portion of the emissions reductions. That commenter adds that, with respect to fugitive emissions, the inclusion of additional ways to do aerial monitoring as well as the potential for continuous monitoring will result in increased

---

<sup>5</sup> EPA discussed similar challenges in the supplemental proposal in the context of declining to conduct a total program evaluation for purposes of determining equivalency of a state plan with the OOOOc presumptive standards. See 87 Fed. Reg. at 74813.

emissions reductions from the November 2021 Proposal. Also, the commenter notes that the November 2021 Proposal exempted certain types of sources that are no longer exempted, resulting in additional emissions reductions. For pneumatic devices and reciprocating compressors, the commenter provides that the requirements for the supplemental proposal achieve significantly greater emissions reductions than the November 2021 Proposal.

Comment: Commenter (2326-AXPC) provides that, as long as the EGs established by EPA in the final rule are at least as stringent as the November 2021 Proposal, any approved state plan will inherently achieve equivalent or greater emissions reductions as compared to the November 2021 Proposal. The commenter believes that Congress enacted the MERP in full awareness of the long-standing text and structure of CAA section 111(d), and the MERP does not repeal by implication or in any other way detract from this other statutory provision, therefore, the only way to read these two statutory provisions (the MERP and CAA section 111(d)) in harmony is for EPA to deem any “satisfactory” state plan that it approves as equivalent to its own new regulations under CAA section 111(d). According to the commenter, to do otherwise would conflict with Congress’s earlier choice to establish an existing source regulation program mediated through a state-planning process. The commenter adds that for any state plans that EPA deems to be inadequate, the federal plan will act to replace the state plan and would serve as an equivalent plan.

Comment: Commenter (2433-EDF *et al.*) states that EPA should develop an updated analysis of the emissions reductions that would have been achieved by the November 2021 Proposal, if finalized and implemented. While EPA estimated emissions reductions in an RIA and Technical Support Document (TSD) for that proposal, the commenter believes that those emissions reductions were underestimated. Further, the commenter explains that the agency updated its methodologies and assumptions for calculating emissions impacts in the supplemental proposal. Thus, the commenter suggests that when EPA updates subpart W to ensure that reporting is based on empirical data pursuant to CAA section 136(h), it should also utilize that data to develop an updated analysis of the emissions reductions that would have been achieved under the November 2021 Proposal.

Comment: Commenter (2343-Institute for Policy Integrity at New York University School of Law) requests that EPA quantitatively compare the total emissions reductions of the November 2021 Proposal and December 2022 Supplemental Proposal, taking into account their stringencies in each year. Whether EPA adopts this approach for the final rule or not, they state it should explain that a quantitative review represents a best practice for future equivalency determinations. The comment further states that if EPA chooses not to apply a quantitative approach here, EPA should explain why this case is the exception because the December 2022 Supplemental Proposal tracks so closely with the November 2021 Proposal, as they are part of the same rulemaking.

#### ***9.1.4 Calculation of Waste Emissions Charge***

Comment: Commenter (2251-National Association of Manufacturers) is concerned about the effectiveness of the rule because the cost of the rule will affect the price of natural gas to manufacturers as fuel and as commodities. The commenter states that where the rule is not

correctly addressed, such as in Subpart W reporting, the reporting calculations might inadvertently affect the methane fee (tax) under the IRA. The commenter suggests technical corrections to ensure the IRA is implemented in a way that the calculation of the fee is more accurate, as follows:

- Correct subpart W reporting for the oil and gas sector.
- Declare that the emissions reductions under the final rule are greater than or equal to the emissions reductions that would have been achieved by the November 2021 Proposal had it been implemented.

### ***9.1.5 Compliance Determination***

Comment: Commenter (2326-AXPC) states that EPA has broad enforcement discretion on how to treat compliance, and EPA should interpret non-compliance for purposes of the WEC as long-term, knowing, and malicious states of noncompliance with the methane regulations. The commenter believes that Congress did not intend the MERP to as “double punishment” in the case of any potential for, or allegation of, any compliance violation.

Comment: Commenter (2399-GPA) supports EPA’s request to consider public input and provide stakeholders direction on the implementation of the IRA framework, which the commenter states could present an undue impact on the midstream sector. In particular, the commenter states that EPA should include direction on how to fairly apply the “exemption for regulatory compliance” provided in this new law, which encourages compliance as a way to minimize the financial charges that may result from the law. Moreover, the commenter supports EPA’s intention to provide a separate draft proposal on this topic to allow stakeholders to comment on specific regulatory text before issuing any final regulations.

Comment: Commenter (2399-GPA) recommends that EPA reasonably interpret the phrase “in compliance.” The commenter states that they previously provided suggestions regarding the application of the exemption for regulatory compliance<sup>6</sup> which they also incorporate in these comments. The commenter urges EPA to recognize the challenges with real world compliance with complex and detailed regulatory requirements and interpret the exemption reasonably to allow some measure of flexibility in determining whether a facility is “in compliance.” In the real world, the commenter states it is unreasonable to expect, if not impossible, for an individual affected facility to establish strict 100 percent “compliance” with all aspects of complex rules. Non-compliance can arise from minor technical or paperwork deviations or other process-related issues leading to brief emissions exceedances, explains the commenter. According to the commenter, it would be unreasonable for EPA to determine that a facility loses its regulatory compliance exemption for an entire year where it submits a late report or barely exceeds a threshold for a few minutes on one day, while reporting compliance the rest of the year. The commenter is concerned that such a narrow and strict approach would be unduly punitive and contrary to the basic notions of due process. Therefore, the commenter urges EPA to consider a reasonable “substantial compliance” standard for EPA’s chosen interpretation of “applicable facility,” allowing an appropriately flexible approach to avoid the harshness of what could

---

<sup>6</sup> See GPA Midstream Comments to MERP Docket at 7- 8.

otherwise be a significant financial burden. The commenter states that EPA and states could provide further guidance on reasonable limits for this approach.

In addition, the commenter (2399-GPA) states that “in compliance” should allow for a broad safe harbor for a facility to promptly correct instances of non-compliance, consistent with routine monitoring, a compliance assessment or other auditing function. There is a well-worn path for regulated parties to follow, such as that laid out in EPA and state audit disclosure policies, that would provide an established mechanism for prompt correction of any non-compliance, states the commenter. The commenter believes that allowing this as a way to qualify for the exemption would incentivize sources to conduct additional compliance assessments and to timely correct any issues identified.

To the extent that a facility is not in substantial compliance with the applicable CAA section 111(b) or 111(d) standard, the commenter (2399-GPA) suggests that EPA incorporate a “notice and cure” process into its implementation of the waste emission exemption process. First, the commenter explains that EPA is authorized to revise its reporting regulations to ensure the emissions data reporting is accurate. The commenter believes that as part of those regulations, EPA should provide that applicable facilities would not be subject to a charge that may otherwise be owed unless and until EPA, or the relevant state permitting agency, issue a notification that the facility is not in substantial compliance with applicable CAA section 111(b) or (d) emission standards or requirements and that, if not promptly cured, a WEC will be assessed. The commenter believes that this would provide a financial incentive for the facility so notified to correct any issues to be in compliance. A notice and cure process would also ensure the waste emission charge is applied only where a facility has in fact failed to qualify for the regulatory exemption, states the commenter. The commenter maintains that a facility should not lose its regulatory compliance exemption for an entire year for non-material compliance concerns, such as a late report or minor exceedance of a threshold for a few minutes on one day. Similarly, the commenter states, a facility should not lose its regulatory compliance exemption where there is disagreement between a facility and EPA, or the governing state, regarding the application of a standard or the relevant state plan.

Determining whether a facility is “in compliance” is highly fact-specific and could be highly subjective without adequate safeguards, warns the commenter (2399-GPA). Here, a notice and cure process will better serve both EPA and regulated entities in fairly applying the charge to the correct facilities states the commenter. To accomplish that, the commenter explains that the notice and cure process should provide a facility with the option to confer promptly with EPA or the relevant state regarding the notice in the event the facility disputes the regulator’s findings. According to the commenter, that will allow a reasonable opportunity to resolve potential disagreements prior to a final WEC assessment. The commenter states there should also be an opportunity for the facility to exercise its rights to question the charge through a form of administrative or judicial review under the CAA. The commenter adds that applying the WEC without notice and cure opportunities would be unduly punitive and contrary to the basic notions of due process.

The commenter (2399-GPA) believes that this type of procedure would be consistent with the framework EPA has created. The commenter explains, that in CAA section 136(f)(6)(B),

Congress provided EPA with authority to resume charging a facility after first applying the compliance exemption where EPA later determines that either of the two conditions at CAA section 136(f)(6)(A)(i)–(ii) were no longer met (*e.g.*, methane emission standards not approved or not in effect in an applicable state). It stands to reason, the commenter explains, that prior to determining whether these two conditions have been met to have applied the exemption, EPA should first determine whether the facility is “in compliance” with applicable methane emission requirements, consistent with CAA section 136(f)(6)(A). The commenter states that having EPA provide the requisite notice fits seamlessly with this framework.

### ***9.1.6 Duration of the WEC***

Comment: Commenter (2326-AXPC) states that if EPA believes the language of the MERP requires a source to be in compliance at all times or the MERP would go back in place, it is unclear for how long the methane fee would be reinstated; *e.g.*, for only the applicable reporting year? The commenter notes that this interpretation would require the facility to collect information even if the fee does not apply, which would undermine the purpose of the regulatory exemption. The commenter believes that this additional unnecessary burden on the regulated entity and the administrative burden on the EPA, without providing any additional methane reduction, is a strong policy reason for why small compliance issues should not be treated as an initial triggering or a retriggering of the methane fee.

## **9.2 Funding and Technical Assistance for Emissions Reductions Programs**

### ***9.2.1 Assistance for Industry***

Comment: Commenter (2247-Ohio Environmental Protection Agency) notes that while the IRA has allocated significant monies to assist the owners of oil and gas wells with emission reduction programs, it is not possible at this time to estimate whether these funds are adequate to fulfill the immediate needs of the marginal well operators to comply with these proposed rules. Also, the commenter notes that IRA funding is a one-time allocation and although having funding from the federal government to assist with compliance costs is appreciated, it is unknown how much more funding would be needed to ensure compliance on an ongoing widescale basis.

Comment: Commenter (2224-Zero Emission Vacuum and Compressor (ZEVAC)) states that EPA should consider providing grants, rebates, and loans to fund company purchases of methane capture and recovery technology that can be used to mitigate and prevent emissions during downstream operations. The commenter contends that technology, and the framework for proper use, is an existing, proven way to avoid and reduce emissions and funding would support the purchase of necessary equipment, improve operator compliance with emission reduction goals, and support the integration of technologies with proven performance. Further, the commenter states that EPA should develop a list of “shovel ready” technology demonstration programs and include examples of current or recent technology and mitigation projects in downstream operations to provide guidance and direction for companies looking to improve their emissions reporting and compliance. The commenter explains that leveraging existing technology and projects can help speed up the implementation of new emissions regulations and improve their

effectiveness. Finally, the commenter suggests that the RACT/BACT/LAER clearinghouse<sup>7</sup> should be updated so that companies can become aware of technology that has been implemented and successfully achieved compliance.

### ***9.2.2 Assistance for Regulators (State/Local)***

Comment: Commenter (2249-National Association of Clean Air Agencies) asserts that EPA should use the funding resources provided by the IRA to augment its own capabilities and to support the capabilities of state and local air pollution control agencies that will implement and enforce the rule. The commenter notes that state and local air pollution control agencies already face a great variety of challenges, and if finalized, the proposed rule will require agencies to increase their investments in personnel and technical capabilities, and to incur other costs. The commenter notes that while federal grants support these state and local programs, the funding essentially has been flat since 2004 and in any event, developing new capabilities related to the rulemaking should not come at the expense of resources allocated to existing air programs. Further, the commenter urges EPA to consider funding beyond equipment procurement, as underinvesting in human resources, training, and technical assistance will yield challenges for planning, permitting, community engagement and enforcement by state and local agencies.

Comment: Commenter (2458-MiQ) states that EPA (in conjunction with Department of Energy) should assist states in making equivalency determinations, through technical assistance.

## **9.3 Target Setting and Tracking**

Comment: Commenter (2224-ZEVAC) states that EPA could provide value to corporate target setting and tracking by providing resources and technical support to standardize commitments and help companies implement voluntary climate action plans, including funding for research and development of new technologies and approaches. The commenter notes that implementation will run more smoothly if the revisions require the use of empirical data to account for company-specific methane emissions and reductions. Enhanced standardization of corporate climate commitments could provide a common framework and set of criteria for companies to use in setting and reporting on their commitments, according to the commenter. The commenter believes that this could help ensure that commitments are consistent and comparable across different sectors and industries and make it easier for investors and other stakeholders to understand and evaluate companies' progress.

## **9.4 Synergy with other programs**

Comment: Commenter (2166-Ohio Department of Natural Resources) states that it will be valuable, for the programs that result from the IRA funds, to require methane measurements to be collected as a rate measured in grams per hour rather than a concentration (ppm) so that the work completed under the IRA can be utilized when plugging results with Infrastructure, Investment, and Jobs Act (IIJA) future grants funds.

---

<sup>7</sup> See <https://www.epa.gov/catc/ractbactlaer-clearinghouse-rblc-basic-information>.

Comment: Commenter (2350-Cheniere Energy, Inc.) reports that several regulatory initiatives related to the oil and natural gas sector are in development in addition to this proposed rulemaking, including the requirements for the greenhouse gas reporting program (GHGRP) under Subpart W and the implementation of the IRA methane fee and MERP. The commenter notes that evolving measurement technologies offer EPA the opportunity to harmonize the methodologies used to satisfy both GHGRP and NSPS OOOO requirements, along with upcoming requirements for the implementation of the methane fee. The commenter recommends that approved technologies, and the conditions around their deployment such as survey frequency and probability of detection be consistent between the different regulatory programs. The commenter also recommends that EPA use modeling tools and public empirical datasets compiled by credible third-party experts, because creating a like-to-like comparison between facilities or operators in an evolving environment of measurement technologies is challenging. The commenter states that measurements from advanced technologies must be carefully interpreted so that their spatial and temporal scales align with those of the reporting program, noting that different technologies have different spatial and temporal characteristics, along with varying probabilities of detection and uncertainty. The commenter emphasizes that it is essential to use qualified experts familiar with how to accurately measure and quantify GHG emissions from oil and gas facilities when developing empirical data.

Commenter (2350-Cheniere Energy, Inc.) notes the Energy Emissions Modeling and Data Lab (“EEMDL”) is developing transparent models and datasets for accurate greenhouse gas emissions accounting across global oil and gas supply chains. EEMDL has three strategic approaches: (1) develop community models and tools for greenhouse gas emissions assessments, (2) make timely and high-resolution emissions datasets that are publicly available, and (3) create educational and training materials to enable the widespread use of EEMDL’s models and data. Modeling tools, such as those EEMDL is developing, may help EPA account for the different spatial and temporal scales of available measurement technologies, and support operators as they prepare annual GHGRP inventories based on empirical data. EEMDL’s datasets may be robust enough to help EPA conduct a robustness check on its bottom-up inventory, and even be used to prepare dynamic, empirical emission factors based on the previous year’s measurement data from industry.

Comment: Commenter (2442-WYCLG) states that EPA should address the Bureau of Land Management’s (BLM) Proposed Rule: Waste Prevention, Production Subject to Royalties, and Resource Conservation.<sup>8</sup> The commenter suggests that EPA address whether the BLM has encroached upon its authority to protect and regulate air quality<sup>9</sup> through its proposed rule and address any areas of inconsistency or duplication. By way of example, the commenter states that BLM recognizes that the EPA has “promulgated emissions limitations for pneumatic equipment and storage tanks as well as LDAR requirements for new and modified sources in the oil and gas production sector.”<sup>10</sup> Therefore, the commenter summarizes, the proposed Waste Prevention Rules allows “operators to comply with analogous EPA regulations as an alternative means of compliance with the BLM’s requirements.”

<sup>10</sup> See 87 Fed. Reg. at 73595.

## 9.5 Miscellaneous

Comment: Commenter (2433-EDF *et al.*) states that Congress’s passage of the IRA, including provisions like the MERP, further cements EPA’s authority to regulate methane under CAA section 111 by recognizing and affirming its support. The commenter asserts that EPA’s authority and obligation to address methane pollution from oil and gas sources under CAA section 111 is expressly affirmed through CAA section 136(f)(6) in the MERP, which references EPA’s proposed regulations. Specifically, explains the commenter, CAA section 136(f)(6) provides for a potential exemption from the waste emissions charge under CAA section 136(c) for “compliance with methane emissions requirements pursuant to subsections (b) and (d) of section 111[.]”

Comment: Commenter (2333-LongPath Technologies, Inc.) suggests that EPA explore incentives, such as limited statutory exemptions from the methane waste program, for sites that employ continuous site-wide measurements of methane emissions with valid mass emission rate as per the EPA’s final rule standards. The commenter points to the emerging science showing that the most accurate means of determining total site-wide emissions is via measurement with 1) valid mass emission rate quantification and 2) continuous monitoring. By way of example, the commenter references one new study which demonstrates that high-frequency monitoring is essentially a prerequisite for accurate closure of top-down and bottom-up emissions estimation techniques.<sup>11</sup> The commenter notes that daily to sub-daily coverage is critical, given the high variability in emissions.<sup>12</sup>

Comment: Commenter (2393-Oklahoma Office of the Secretary of Energy and Environment) states that the fees collected by EPA under the MERP conflict with state’s own Emissions Fees. The commenter explains that emission fees have historically been collected at the state level, where the emissions are occurring, and where the inventory, permit, inspection, and enforcement programs are located. The commenter states that it is an unacceptable overreach by EPA to begin collecting fees on methane emissions, while simultaneously expecting states to greatly expand their current programs to cover existing sources under EG OOOOc. The commenter requests that EPA ensure in its “IRA equivalence determination” that any state that implements EG OOOOc through the submission of a state 111(d) plan is considered equivalent to reductions under EPA’s November 2021 Proposal, ensuring the state’s facilities are not subject to the federal methane fee.

Comment: Commenter (2425-Taxpayers for Common Sense) states that while EPA estimated the net compliance costs to industry, not all of the compliance costs will be shouldered by industry. The commenter points to the IRA, which will provide funds through the end of FY 2028 to the EPA in the way of grants, rebates, contracts, loans and other activities for methane mitigation and monitoring.<sup>13</sup> The commenter notes that Department of Energy also has been funding methane mitigation research. Finally, the commenter notes that taxpayers have also been

---

<sup>11</sup> Daniels et al., Towards multi-scale measurement-informed methane inventories: reconciling bottom-up inventories with top-down measurements using continuous monitoring systems, in preprint: <https://doi.org/10.26434/chemrxiv2023-jp5nt>.

<sup>12</sup> See EPA Docket No. EPA-HQ-OAR-2020-0317.

<sup>13</sup> See CAA section 136(a)(1)-(4) and section 136(b).

shouldering some of the costs of operational and equipment improvement through various incentivizes to increased capture.

Comment: Commenter (2326-AXPC) recommends that EPA establish procedural regulations as soon as possible for how states and operators can petition the EPA for a determination (if EPA has not acted) and timeframes for when EPA will make the determination. The commenter states that EPA should allow owners or operators subject to the MERP; states where operators subject to the MERP operate; and trade association representing owners or operators subject to the MERP to petition EPA individually or jointly for a determination. The commenter recommends that EPA commit to reviewing and approving/disapproving petitions within three months of receiving a petition. The commenter further recommends that if EPA takes longer than three months to dispose of a petition, the methane fee payments made by operators (that would have been exempted if EPA had granted the petition) be held in abeyance or placed into a separate fund such that they can be refunded if the determination is made.

Comment: Commenter (2177-Southern Ute) asserts that the proposed methane fee does not address the environmental justice concerns, the driving force behind these regulations. The commenter requests that operations on tribal lands be excluded from the methane fee, or alternately, the funds be redistributed directly back to the Tribe. The commenter notes that all monies collected under this fee will not be distributed to their Tribe nor returned to the community to address the environmental impact of these emissions. Rather, the fee is being collected at the expense of their Tribe and goes directly into the EPA's funds. Thus, the commenter states that not only will the Tribe be hurt from a financial perspective overall, but the fees taken will in no way directly benefit their Tribe and Tribal members.

Comment: Commenter (3380-Douglas Elenbaas) states Michigan's Oil and Gas Industry does not warrant the new regulations on Existing Emission Sources that are covered under the EPA's proposed Subpart OOOOc. During 2021, Michigan had 15,748 active oil and gas wells (10,362 gas and 5,386 oil). The total annual production was 4,400,000 barrels oil and 71,800,000 mcf natural gas. Therefore, the average production for oil wells was 2.24 BOPD and for gas wells 20 Mcfd. Furthermore, there were only 25 producing properties making over 100 BOPD and 32 gas production properties delivering over 1,000 Mcfd.

Commenter (3380-Douglas Elenbaas) continues, assessing fees for natural gas emissions on pumping oil wells that are only active for a couple hours per day is excessive and fees associated would likely make a significant number of wells uneconomic. Likewise for gas wells, a significant number are operated on vacuum compression, so emissions are not feasible on wellheads and gathering lines. The commenter understands the need to reduce natural gas emissions but assessing fees must focus on large emitters. EPA should have production rate minimums similar to marginal wells such as a minimum of 10 BOPD or of 50 Mcfd.

## Chapter 10. Centrifugal Compressors

### 10.1 New Source Performance Standard (NSPS) OOOOb Affected Facility/Definitions

#### 10.1.1 Affected facility

Comment: Commenter (2428-American Petroleum Institute (API)) states that conducting annual measurements on temporary compressors is logistically impractical and temporary compressors should be exempt from 40 CFR 60.5365b(b). The commenter suggests that temporary compressors should be exempt from the monitoring requirements as it would be infeasible to conduct monitoring on a compressor that will be removed from a site after less than a year. Equipment that is intended for temporary use and is not a stationary source should not be subject to either NSPS OOOOb. The commenter requests that EPA make the following clarifications to address this concern (underlined text is new text) for centrifugal compressors [similar changes would apply to 40 CFR 60.5386c(b)]:

*40 CFR 60.5365b(b)-*

(b) Each centrifugal compressor affected facility, which is a single centrifugal compressor. A centrifugal compressor located at a well site is not an affected facility under this subpart. A centrifugal compressor located at a centralized production facility is an affected facility under this subpart. A centrifugal compressor that is skid mounted or permanently attached to something that is mobile (such as trucks, railcars, barges, or ships) and intended to be located at a site for less than 12 consecutive months is not an affected facility under this subpart.

Response II-10-1: With regards to the commenters' request that the applicability of the rule not apply to temporary, portable and emergency compressors because conducting measurements on temporary compressors is logistically impractical, the EPA disagrees.

The EPA considered similar comments on the November 2021 Proposal, see discussion in section IV.G.1.b of the December Supplemental Proposal preamble,<sup>1</sup> and maintains that basing reciprocating compressor flow rate monitoring on the hours of operation (*i.e.*, 8,760 hours) in lieu of requiring monitoring based on a calendar year addresses limited-use reciprocating compressors and allows owners and operators flexibility when planning maintenance.

Comment: Commenter (2257-Michigan Oil and Gas Association (MOGA)) recommends the EPA continue the exemption of both centrifugal and reciprocal compressors "located at a well site, or an adjacent well site and servicing more than one well site, is not an affected facility" as provided in both NSPS OOOO and NSPS OOOOa. Well operators visit and service these wells and associated compressors daily to inspect for proper operation, leaks and to conduct maintenance and repair activities. Any necessary repairs are repaired as soon as possible to avoid product loss and to maximize profit returns. If the EPA wishes to propose monitoring for well

---

<sup>1</sup> 87 FR 74796, December 6, 2022.

site compressors, the commenter recommends the EPA allow the more feasible and cost-effective monthly auditory, visual & olfactory (AVO) inspection and documentation, similar to the requirements allowed under 40 CFR 60.5416a.

Response II-10-2: The final rule and emission guidelines retain the concept that centrifugal and reciprocating compressors located at a well site are not affected or designated facilities. However, compressors located at centralized production facilities are affected or designated facilities. Section XI.G.5 of the preamble to the final rule details EPA’s rationale and reasoning regarding the applicability of requirements to compressors located at centralized production facilities. Centrifugal compressors located at well sites are not subject to requirements. However, centrifugal compressors located at centralized production facilities that consist of equipment at a single surface site used to gather, for the purpose of sale or processing to sell, crude oil, condensate, produced water, or intermediate hydrocarbon liquid from one or more offsite natural gas or oil production wells (including centrifugal compressors) are subject to centrifugal compressor requirements.

Comment: With respect to emissions standards on dry seal centrifugal compressors as part of NSPS OOOOb and [Emission Guidelines (EG) OOOOc]<sup>2</sup>, commenter (2301-U.S. Chamber of Commerce (USCC)) is concerned that the EPA has not followed the necessary process to demonstrate a legitimate nexus between the proposed additional sources—dry seal centrifugal compressors—and the existing sources within the category to be regulated, nor undertaken a process to expand the source category (or create a new one), consistent with the requirements of Clean Air Act (CAA) section 111(b)(1)(A).<sup>3</sup> The commenter notes that they provided a similar comment on the November 2021 Notice.<sup>4</sup> According to the commenter, the EPA must make the necessary findings under the CAA before expanding its regulations under section 111.

Specifically, to regulate greenhouse gas (GHG) emissions in the oil and natural gas sector under CAA section 111, the commenter (2301-USCC) asserts that the EPA must determine through rulemaking that (1) such “air pollution” endangers public health or welfare and (2) the pollutant-specific emissions from each of these sectors “contributes significantly” to that air pollution.<sup>5</sup> Requiring such a finding helps ensure that the imposition of new rules will have a meaningful effect on a meaningful problem. The EPA failed to comply with these statutory requirements in 2012 when transmission and storage sources were improperly brought into the production and processing segments without making the requisite findings.<sup>6</sup> As the original expansion of the source category to transmission and storage did not include the requisite statutory findings, if the EPA now adds dry seal centrifugal compressors to the transmission and storage segment, it would continue to improperly expand the source category in violation of the statute.

As it presently stands, the commenter (2301-USCC) states that the Methane Proposal would create standards for dry seal centrifugal compressors that were previously not regulated under

---

<sup>2</sup> See 87 Fed. Reg. at 74,716 (“In this rulemaking, the EPA is proposing standards for dry seal centrifugal compressor and intermittent bleed pneumatic controllers for the first time in NSPS OOOOb and EG OOOOc.”); see also id. at 74,788–92 (outlining the proposed standards).

<sup>3</sup> See 42 U.S.C. § 7411(b)(1)(A).

<sup>4</sup> See Chamber January 2022 Comment Letter, at 10–11.

<sup>5</sup> Id.

<sup>6</sup> See 77 Fed. Reg. 49,490, 49,496–99 (Aug. 16, 2012).

NSPS and that are not described in the November 2021 Notice. And it would do so without any analysis of whether the operations share a proper commonality with the activities under the production and processing and transmission and storage segments. The commenter suggests that the EPA should therefore take this opportunity to help ensure the legal durability of these important proposed regulations by making all requisite findings for the transmission and storage segment, including those for dry seal centrifugal compressors.

Response II-10-3: The commenter is correct that NSPS OOOOa does not regulate dry seal compressors and that regulation of dry seal compressors was not proposed in November 2021 Proposal. However, this is not relevant as it was proposed in the December 2022 supplemental proposal and commenters had the opportunity to review EPA's proposal, as well as the analysis supporting the proposal. Therefore, the EPA feels that the rulemaking has followed all Administrative Procedure Act requirements and is therefore, finalizing standards and presumptive standards for dry seal compressors.

Comment: Commenter (2433-Environmental Defense Fund (EDF) et al) reaffirms their support for extending centrifugal compressor standards to centrifugal compressors at centralized production facilities.

Response II-10-4: This is a supportive comment on an aspect of the December 2022 Proposal that has remained unchanged in the final rule; as such, no response is required.

### ***10.1.2 Definitions***

Comment: Several commenters (2282-Kinder Morgan, Inc, 2305-Williams Companies, Inc (Williams), 2399-GPA Midstream Association (GPA), 2428-API)<sup>7</sup> support the EPA's development of a new "self-contained wet seal centrifugal compressor" category in its proposed Rule and suggests that the EPA provide further definition on what industrial segments are included and excluded in the definition of "centrifugal compressor affected facility" at proposed 40 CFR 60.5365b(2)(b) [assumed to mean 40 CFR 60.5365b(b)]. According to one commenter (2305-Williams) the EPA makes no mention of compressor stations or processing plants: it is not clear if centrifugal compressors located in these industrial segments are subject to the proposed rule.

Response II-10-5: With regards to support for EPA's development of an alternative compliance option for "self-contained wet seal centrifugal compressor[s]", this is a supportive comment on an aspect of the December 2022 Proposal that has remained unchanged in the final rule; as such, no response is required.

Regarding clarification of the industrial segments included and excluded in the definition of "centrifugal compressor affected facility", centrifugal compressor requirements apply to all oil and natural gas industry segments (which would include compressor stations and processing plants), which is why there was and is no specific industry segments specified as being included or excluded. 40 CFR 60.5365b(b) has therefore not been revised in the final rule.

---

<sup>7</sup> 2428-API and 2282-KM support all 2399-GPA comments

Comment: Commenter (2428-API) states that clarification is requested to the definition of centrifugal compressor. Within the definition “centrifugal compressor” in 40 CFR 60.5430b [and §60.5430c], the EPA describes the compressor as “discharging significantly higher-pressure natural gas by means of mechanical rotating vanes or impellers.” The commenter requests that the phrasing of “significantly higher-pressure” should be further delineated to eliminate ambiguity. If left undefined the regulated operator does not have a clear understanding of what is affected and what is not affected.

The commenter (2428-API) explains that the definition of centrifugal compressor as it was used in the initial NSPS OOOO rulemaking only affected wet-seal centrifugal compressors, which includes a relatively small population of affected facilities that were generally considered to discharge significantly higher-pressure natural gas. With the expansion of the NSPS OOOOb [and Emissions Guideline (EG) OOOOc] to also include dry seal compressors, which are more widely utilized, additional clarity is warranted.

In the oil and natural gas industry, the commenter (2428-API) provides that compressors that boost natural gas pressures are normally designed to discharge natural gas greater than 300 pounds per square inch differential (psid). The original intent of the EPA including this language was to exclude smaller compressors with low differential pressure (e.g., process compressors, vapor recovery units, and other low pressure service units). With this consideration, the commenter recommends that EPA update 40 CFR 60.5430b to include a definition of significantly higher-pressure and includes the following language [a similar comment would also apply to EG OOOOc definition] (underlined text indicates new text):

*Centrifugal compressor* means any machine for raising the pressure of a natural gas by drawing in low pressure natural gas and discharging significantly higher-pressure natural gas by means of mechanical rotating vanes or impellers. Screw, sliding vane, and liquid ring compressors are not centrifugal compressors for the purposes of this subpart. For the purposes of §60.5380b, significantly higher-pressure means having a design pressure differential greater than 300 pounds per square inch differential (psid).

Response II-10-6: According to the commenter, with the expansion of the NSPS OOOOb [and EG OOOOc] to also include dry seal compressors, which are more widely utilized, clarifying changes are needed in the definition for centrifugal compressors to indicate what is meant by significantly higher-pressure to more-narrowly define applicability for dry seal centrifugal compressors, which would exclude a subset of dry seal centrifugal compressors from rule requirements. The EPA disagrees with the recommended change. Insufficient information/basis has been provided by the commenter to support making their suggested change which would limit applicability of the dry seal compressor requirements.

Also, in response to comments received on the December 2022 Supplemental Proposal, EPA has finalized a different regulatory approach for dry seal centrifugal compressor affected/designated facilities. For details, please see discussion in section XI.G.1 (Redefining the affected facility to include centrifugal compressors with dry seals and the proposed standard) of the final rule preamble. The December 2022 Supplemental Proposal regulatory text for centrifugal compressors under NSPS OOOOb and EG OOOOc does not require volumetric flow rate

monitoring if screening for emissions or leaks from the centrifugal compressor seal vent using optical gas imaging (OGI) or Method 21 does not indicate a leak. For dry seal centrifugal compressors that have a design pressure differential less than or equal to 300 psid that are screened as not having a leak, minimal recordkeeping and reporting is required. This has been maintained in the final NSPS OOOOb and EG OOOOc requirements. See final test methods and procedures for centrifugal compressors at 40 CFR 60.5385b and 40 CFR 60.5405c.

Comment: Commenter (2428-API) states that the proposed requirements for wet seal Centrifugal compressors do not consider our previous comments regarding the unique equipment design in the Alaskan North Slope (ANS).

The commenter (2428-API) explains that, on the ANS there is not a market for natural gas sales. Most of the gas that is produced with the oil is separated and either used as a fuel or is compressed (using large wet seal compressors) to be reinjected back down hole for gas lift or enhanced oil recovery. The wet seal compressors on the ANS were installed from the mid-1970s to the mid-1980s, when the oil fields there began to be produced.

The commenter (2428-API) continues by noting that wet seal centrifugal compressors located on the ANS were originally designed and installed with a seal oil degassing system that captures most of the gas by volume then routes that gas to a flare, as described in their January 31, 2022, comment letter.<sup>8</sup> The ANS system design is simple. Rather than routing the sour seal oil directly to a degassing drum/tank (which vents to atmosphere), the sour seal oil is first routed to the sour seal oil traps. In these traps, most of the gas breaks out of the oil while remaining at a high enough pressure that it can enter the low-pressure flare header line. The gas that breaks out in these traps is routed to the flare, not vented. The sour seal oil is only then sent to the degassing drum/tank, where any remaining entrained gas breaks out and is vented to atmosphere. In 2010, the EPA's Natural Gas Star<sup>9,10</sup> program, in conjunction with British Petroleum (BP), conducted an analysis of this wet seal degassing system design on the ANS at the Central Compressor Station. This analysis concluded that the sour seal oil degassing design employed on the ANS has greater than 99.0 percent emission control by volume. The commenter reports that this same study is also cited by the California Air Resources Board (CARB) regulation references. It would stand to reason that this system of gas capture and control should be allowable to use the volumetric standard.

In summary, the commenter (2428-API) states that wet seal compressors with the sour seal oil traps in Alaska as described above, route the gas to the flare, not to the "compressor suction." Because of this, these compressors would seemingly not meet the definition of "self-contained wet seal compressor." However, there is language in that definition which suggests that the purpose of that definition is that degassed emissions do not route to atmosphere as proposed in 40 CFR 60.5430b [and 40 CFR 60.5430c]. Therefore, the commenter offers the following redline

---

<sup>8</sup> EPA-HQ-OAR-2021-0317-0808.

<sup>9</sup> <https://www.epa.gov/sites/production/files/2016-04/documents/smith.pdf>.

<sup>10</sup> <https://www.epa.gov/sites/default/files/2016-06/documents/capturemethanefromcentrifugalcompressionsealoiddegassing.pdf>.

for the definition of self-contained wet seal centrifugal compressor (underlined text indicates new text and text struck out indicates deleted text):

*Self-contained wet seal centrifugal compressor* means a wet seal centrifugal compressor system which has an intermediate closed process that degasses most of the gas entrained in the seal oil and sends that gas to either another process or combustion device ~~that is a closed process that ports the degassing emissions to the natural gas line at the compressor suction~~ (i.e., degassed emissions are recovered). The de-gas emissions are routed back to ~~suction~~ a process or combustion device directly from the intermediate closed degassing process degassing/sparging chambers; ~~after the intermediate closed process~~ the oil is ultimately recycled for recirculation in the seals to the lube oil tank where any small amount of residual gas is released through a vent.

Alternatively, the commenter (2428-API) suggests that EPA could allow all centrifugal compressors the option to comply with the volumetric standard thereby obviating the need for a special definition for a “self-contained wet seal compressor.”

Response II-10-7: The EPA appreciates the information and suggestion provided by the commenter. The EPA has not revised the definition of “self-contained wet seal centrifugal compressor” to include centrifugal compressors equipped with a sour seal oil separator where the seal oil degassing system captures most of the gas by volume then routes that gas to a flare. However, the EPA has made some of the clarifications to the definition suggested by the commenter and added a separate definition in the final NSPS OOOOb and EG OOOOc rules for “centrifugal compressor[s] equipped with sour seal oil separator and capture system” to address other comments provided on these compressors (see Responses II-10-28, 29 and 30 of this Chapter). The final definition for “self-contained wet seal compressor” included in NSPS OOOOb and EG OOOOc reads as follows:

*Self-contained wet seal centrifugal compressor* means:

(1) A wet seal centrifugal compressor system that is a closed process that ports the degassing emissions into the natural gas line at the compressor suction (*i.e.*, degassed emissions are recovered) or which has an intermediate closed process that degasses most of the gas entrained in the seal oil and sends that gas to another process. The de-gas emissions are routed back to suction or process directly from the closed or intermediate closed degassing process; after the closed or intermediate closed degassing process the oil is ultimately recycled for recirculation in the seals to the lube oil tank where any small amount of residual gas is released through a vent.

(2) A wet seal centrifugal compressor equipped with mechanical wet seals, where (1) a differential pressure is maintained on the system and there is no off gassing of the lube oil, and (2) the mechanical seal is integrated into the compressor housing.

The EPA has also established alternative standards/presumptive standards for wet seal centrifugal compressors equipped with sour seal oil separator and capture system that are located in Alaska. See XI.G.6 (Wet seal compressors equipped with a seal oil gas separation system utilized on the Alaska North Slope (ANS)) of the final rule preamble for EPA's rationale for these changes.

Comment: Commenter (2348-Energy Workforce & Technology Council (EWTC)) requests that EPA add the following to the definition of centrifugal compressor:

The process of directing pressurized fluids containing any combination of water, proppant, and any added chemicals to penetrate tight formations, such as shale or coal formations, that subsequently require high rate, extended flowback to expel fracture fluids and solids during completions for the purpose of production, NOT intervention.

Response II-10-8: The commenter does not provide any reasoning or support for the need for their suggested change to the centrifugal compressor definition. This requested definition is ambiguous and to an extent misleading. The definition seems to align more with a high-pressure pump (frac pump) than a centrifugal compressor. These are distinct types of equipment that are utilized differently in the oil and gas industry. The former is used for hydraulic fracturing operations for generating high pressure to inject fluids (water, proppant and added chemicals) into formation. The latter is utilized in the industry as well as others to handle continuous flow of gases and provide relatively constant pressure ratio. These equipment's differ in function, design operation and application. Therefore, the EPA has not made the requested change. Note also that the centrifugal compressor definition included in the NSPS OOOOb and EG OOOOc rules is also included in NSPS OOOOa.

## **10.2 NSPS OOOOb Proposed Best System of Emission Reduction (BSER)**

[**Note:** Many of the comments provided in this section also apply to EG OOOOc. For BSER-related comments that were only provided on EG OOOOc for centrifugal compressors, see section 10.4.]

### ***10.2.1 Wet Seal Compressors***

Comment: Commenters (2282-Kinder Morgan, Inc, 2258-Marcellus Shale Coalition (MSC)) support the EPA's recognition that [self-contained] wet seal systems have low seal emissions and additional controls should not be required. The commenters note that a volumetric flow rate requirement is appropriate. One commenter (2258-MSC) adds that the EPA should allow additional flexibility in reducing or controlling seal emissions to meet the flow requirement. The commenter notes that technology to reduce emissions, such as seal gas recovery, is relatively new and emerging and the regulation should not discourage these options.

Response II-10-9: With regards to support for EPA's recognition that [self-contained] wet seal systems have low seal emissions, where a volumetric flow rate requirement is appropriate, this is

a supportive comment on an aspect of the December 2022 Proposal that has remained unchanged in the final rule; as such, no response is required.

In response to request that the EPA allow addition flexibility in reducing or controlling seal emissions to meet flow requirements, the final NSPS OOOOb standard and EG OOOOc presumptive standard requirements do not limit owners and operators from employing technologies that reduce emissions to meet performance-based volumetric flow rate requirements.

Comment: Commenter (2282-Kinder Morgan, Inc) states that the standard for wet seals in NSPS OOOOb should also be an emissions rate limit. The commenter appreciates that the Supplemental Proposed NSPS adjusted the approach for existing wet seals, finding a BSER based on preventative maintenance and repair to maintain a specified volumetric flow rate for wet seals on existing units in EG OOOOc. However, the commenter states that the Supplemental Proposed NSPS does not take this approach for new wet seals, despite many of the same considerations applying to new wet seals. Rather, the proposed BSER for new wet seals under NSPS OOOOb is to capture and route emissions to a control device.<sup>11</sup> Because the same considerations for existing wet seals apply to new wet seals, the commenter asserts that the EPA should also incorporate the emissions flow rate approach for wet seals in NSPS OOOOb.

The commenter (2282-Kinder Morgan, Inc) cites the their 2022 comments, which are attached as Exhibit B in their comment letter, were not limited to just EG OOOOc but were on proposals related to wet seals in both NSPS OOOOb/EG OOOOc,<sup>12</sup> and many of its arguments apply with equal force to new wet seal centrifugal compressors because replacing a compressor at an existing compressor station would not affect the footprint of that compressor station. Thus, the arguments regarding existing flaring capabilities, compressor station layout, and risk of explosion, which the EPA credited with respect to existing wet seal centrifugal compressors,<sup>13</sup> apply equally to new wet seal centrifugal compressors.

Further, the commenter (2282-Kinder Morgan, Inc) adds that Supplemental Proposed NSPS's conclusion that routing wet seal emissions to a control device is cost-effective in the natural gas transmission and storage industry segment is flawed, even using the EPA's own cost data. The Supplemental Proposed NSPS states that "the costs of routing the captured gas from the centrifugal compressor wet seal degassing system to a control device are reasonable for the control of methane for the gathering and boosting, processing and transmission, and storage segments using both the single and multipollutant approaches."<sup>14</sup> However, an inspection of Table 32 in the Supplemental Proposed NSPS reveals this conclusion to be false for the transmission and storage segment. Table 32 states that the cost of routing emissions to a control device in the transmission and storage segment under the single-pollutant approach is \$1,973 for

---

<sup>11</sup> See 87 Fed. Reg. at 74,787. Kinder Morgan notes that this is different than the proposed BSER in the Original Proposal, which included routing to a process. See 86 Fed. Reg. at 63,119. Kinder Morgan appreciates that EPA recognized "that this option may not be available in situations where downstream equipment capable of handling a low-pressure fuel source is unavailable." 87 Fed. Reg. at 74,785.

<sup>12</sup> See Kinder Morgan 2022 Comments, at 2 (defining "Wet Seal Proposal" as the proposal found at pages 63,220–24, which set forth proposed standards for both Subparts OOOOb and OOOOc).

<sup>13</sup> See 87 Fed. Reg. at 74,791 (crediting such concerns with respect to the Subpart OOOOc wet seal proposal).

<sup>14</sup> Id. at 74,784.

methane and \$71,240 for volatile organic compounds (VOC).<sup>15</sup> Both costs exceed the reasonableness thresholds for methane and VOC in the Supplemental Proposed NSPS.<sup>16</sup> Regarding the multipollutant approach, the Supplemental Proposed NSPS states that both pollutants must be found cost effective to pass the multipollutant test,<sup>17</sup> but Table 32 reveals that only methane is cost-effective on a multipollutant basis.<sup>18</sup> In short, even based on the EPA's own analysis and reasonableness thresholds, routing to a control device in the transmission and storage segment is not cost-effective under either the single pollutant or multipollutant basis.

Similarly, commenter (2428-API) states that the wet seal centrifugal compressor requirements must be clarified between NSPS OOOOb and EG OOOOc. The commenter notes that it is unclear why the standards between NSPS OOOOb and EG OOOOc for centrifugal compressor standards are different:

- NSPS OOOOb – Dry seal compressors and “self-contained wet seal compressors” can only comply with volumetric standard. All other wet seal compressors can only comply with the 95.0 percent capture and control requirement.
- EG OOOOc – Any wet seal compressor can either comply with volumetric standard or reduce emissions by 95.0 percent through a control standard.

The commenter (2428-API) suggests that the implications of the NSPS OOOOb regulations seem to be that the 3 standard cubic feet per minute (scfm) volumetric standard is equivalent to the 95.0 percent capture and control requirement. If this is the case, then it stands to reason, according to the commenter, that all centrifugal compressors should be able to choose to comply with either the volumetric standard or the 95.0 percent capture and control practice.

If owners of centrifugal compressors had the option to comply with either standard, the commenter (2428-API) states that it obviates the need for a specially defined class of compressors: “self-contained wet seal compressors.” Removing this definition from the rule would result in a more simple and straightforward understanding of the rule requirements. The commenter states that the NSPS OOOOb standards would mimic the EG OOOOc standards.

Response II-10-10: The EPA maintains, as it did in the December 2022 Supplemental Proposal, that, for all segments, the costs in relation to the emission reductions were reasonable for all options evaluated as BSER for wet seal compressors under the NSPS OOOOb.<sup>19</sup> However, the options to route captured gas to a control device or to a process achieve greater emission reductions than conducting maintenance and repair to maintain the volumetric flow rate at or below 3 scfm per seal and was not and has not been adopted as BSER under the final NSPS OOOOb requirements. Under the EG OOOOc, BSER was determined to be maintenance and repair to maintain the volumetric flow rate at or below 3 scfm because of particular concerns and challenges that would be associated with retrofitting existing wet seal centrifugal compressors to

---

<sup>15</sup> Id. at 74,787.

<sup>16</sup> See id. at 74,718 (The proposed thresholds are \$1,970/ton for methane and \$5,540 for VOC.).

<sup>17</sup> See id. at 74,787 tbl.32 n.b (For multipollutant approach, “the cost effectiveness of both methane and VOC . . . must be within the ranges considered reasonable by EPA.”).

<sup>18</sup> Id. at 74,787 tbl.32.

<sup>19</sup> 87 FR 74787.

accommodate reducing methane emissions from each centrifugal compressor wet seal fluid degassing system by 95 percent or greater.<sup>20</sup> Although the EPA has not included the emissions flow rate approach for wet seals in NSPS OOOOb, the EPA has made revisions to the NSPS OOOOb requirements for wet seal compressors to allow owners and operators added flexibility in meeting the NSPS OOOOb standards for specified centrifugal compressors in the final rule. The EPA has also revised, but not removed the definition of self-contained centrifugal compressors in the NSPS OOOOb final rule. See section X.G.1 of the final rule preamble for a summary of the final rule requirements for centrifugal compressors.

Comment: Commenters (2282-Kinder Morgan, Inc, 2483-Interstate Natural Gas Association of America (INGAA)) appreciate and support the EPA acknowledging self-contained wet seal compressors as BSER. However, the commenters note there are flaws in the provision as proposed. With respect to self-contained wet seal compressors, the EPA not only specified that self-contained wet seal compressors are BSER due to their inherently very low emission rate; the EPA also adopted an emission rate of 3 scfm for the lube oil tank vent from which a small amount of residual gas is released because, according to the EPA, “there could be increased emissions due to leaks and malfunctions.” This is speculation. According to the commenters, there is nothing in the record indicating that this ever has occurred at a self-contained compressor, and the commenter is not aware of any occurrences. According to the commenters, manufacturer recommended maintenance is more than adequate to ensure a very low emission rate from self-contained wet seal compressors.

Response II-10-11: With regards to support for EPA’s recognition that [self-contained] wet seal systems have low seal emissions, this is a supportive comment on an aspect of the December 2022 Proposal that has remained unchanged in the final rule; as such, no response is required. The EPA, however, has maintained the requirement to conduct performance-based volumetric flow rate monitoring for self-contained centrifugal compressors in both the final NSPS OOOOb standards and final EG OOOOc presumptive standards.

The EPA disagrees, however, that manufacturer recommended maintenance is more than adequate to ensure a very low emission rate from self-contained wet seal compressors. In order to allow for an alternative standard to the NSPS OOOOb BSER for self-contained wet seal compressors (which was included based on information provided by industry), the EPA needs to be assured that any potential leaks are identified and repaired. Based on the December 2022 Supplemental Proposal and final NSPS OOOOb rule requirements. The December 2022 Supplemental Proposal and final rule requirements for self-contained wet seal compressors do not require volumetric flow rate monitoring if screening for emissions or leaks from the centrifugal compressor using optical gas imaging (OGI) or Method 21 does not indicate a leak.

---

<sup>20</sup> The cost of routing emissions to a control device in the transmission and storage segment under the single-pollutant approach of \$1,973/ton of methane is considered reasonable. The cited \$1,970/ton of methane was based on rounding and not considered a hard threshold of reasonableness, just illustrative of \$/ton (rounded) that were considered reasonable under the proposal BSER analyses evaluated. In fact, the EPA stated in the December 2022 Supplemental Proposal that the cost-effectiveness value of \$1,970/ton of methane reduction considered reasonable for controls identified as BSER in the November 2021 proposal and the supplemental proposal were well below the \$2,185/ton of methane reduction that EPA has previously found to be reasonable for the industry. 87 FR 74719.

See final test methods and procedures for centrifugal compressors at 40 CFR 60.5385b and 40 CFR 60.5405c.

Comment: Several commenters (2258 MSC, 2282-Kinder Morgan, Inc, 2305-Williams, 2399-GPA, 2428-API, 2483-INGAA) request clarification that the volumetric standard applies to each seal and not each compressor and that the rule text clearly addresses manifolded vents on a combined basis. The commenters cite the precedent set by the California Air Resources Board (CARB) where wet seal compressors in California are restricted to 3 scfm per seal, and not per compressor as set forth in 17 CCR § 95668, Greenhouse Gas Emission Standards for Crude Oil and Natural Gas Facilities (underlined text reflects new text):

§ 95668 Standards

(d) Centrifugal Natural Gas Compressors

(6) A compressor with a wet seal emission flow rate greater than three (3) scfm, or a combined flow rate greater than the number of wet seals multiplied by three (3) scfm, shall be successfully repaired....

Commenter (2282-Kinder Morgan, Inc) further notes that the California program and the Gas STAR document cited by the EPA use a per-seal approach and that Solar Turbines' Product Information Letter (PIL) is also on a per-seal basis, clarifying that many centrifugal compressor models have two or more seals per compressor.

Commenters (2305-Williams, 2399-GPA) cite that their actual annual compressor measurements collected pursuant to the EPA's Greenhouse Gas Reporting Program indicate that a 3 scfm per seal threshold is a reasonable indicator of a self-contained wet seal compressor not operating properly.

According to commenter (2282-Kinder Morgan, Inc), the EPA's preamble discussion, and at least some of the proposed rule text, imply that the emissions rate would be on a per-seal basis, and the commenter understands this to be the EPA's intent. The commenter provides that it is important that the EPA's final rule more clearly reflect this intent. Specifically, according to commenter (2428-API) the proposed text provided in 40 CFR 60.5380b or 40 CFR 60.5385b(a), does not provide the distinction that the limits are per seal. According to the commenter, it would be impractical for a compressor with multiple seals (centrifugal) to operate the same as compressor with only a single seal.

Commenters (2282-Kinder Morgan, Inc, 2428-API) request that the rule language more clearly address manifolded vents on a combined basis. The commenters state that the Supplemental Proposed NSPS preamble provides that the manifolded wet and dry seal flow rate must be "less than or equal to the number of compressors multiplied by 3 scfm (in operating or standby pressurized mode)."<sup>21</sup> The commenters support this approach, as it reflects the practicalities of measuring emissions from manifolded seals. The commenters also note that the approach is

---

<sup>21</sup> 87 Fed. Reg. at 74,790, 74,792.

supported by the 2006 Natural Gas STAR report, which states that emissions rates from two seal systems would be double the emissions from a single seal system.<sup>22</sup>

Commenter (2282-Kinder Morgan, Inc) states that it appears that this concept of multiple seals manifolded to one vent is intended to be captured in the proposed regulations at 40 CFR 60.5380b(a)(5)(i)–(ii), 60.5415b(d)(2), 60.5392c(a)(2)(i)–(ii), and 60.5415c(c)(1). However, the proposed regulatory sections addressing the actual volumetric flow rate requirement do not clearly incorporate the preamble concept of multiplying the emissions rate by the number of manifolded seals. Proposed 40 CFR 60.5380b(a)(4)(i) and 60.5392c(a)(1) provide that the volumetric flow rate must not exceed 3 scfm, but they do not mention manifolded seals. Likewise, proposed 40 CFR 60.5415b(d)(2) and 60.5415c(c)(1), pertaining to demonstrating compliance, do not mention manifolded seals either. The commenter provides that this lack of regulatory text on manifolded seals makes it difficult for operators to rely on the preamble text alone. Moreover, for internal compliance processes, operators do not always cross-reference the preamble pertaining to each regulatory provision.

Several commenters (2282-Kinder Morgan, Inc, 2305-Williams, 2428-API, 2483-INGAA) provide suggested regulation text changes that would clarify the intent of the Supplemental Proposed NSPS preamble to allow for grouping of manifolded wet and dry seal vents where an emissions rate limit is applicable to such seals and that the emissions rate standard is on a per-seal basis. The commenters note that their suggested changes align with the CARB rule, and how it describes manifolded, or combined, seals.<sup>23</sup> and §95668 (c)(4)(D) of the 2017 California’s GHG Emissions Regulations, which this proposed standard was based.

Commenter (2305-Williams) recommends that EPA revise 40 CFR 60.5380b(4)(i) as follows:

- i. The volumetric flow rate must not exceed 3 standard cubic feet per minute (scfm) per seal.

Commenter (2428-API) recommends the following regulation text changes to 40 CFR 60.5380b(a)(4)(i) and 40 CFR 60.5392c(a)(1) (underlined text reflects new text):

*40 CFR 60.5380b(a)(4)(i):* The volumetric flow rate must not exceed 3 standard cubic feet per minute (scfm) per seal. If the individual seals are manifolded to a single open-ended vent line, the volumetric flow rate must not exceed the sum of the individual seals multiplied by 3 scfm. You must conduct measurements of the volumetric flow rate in accordance with the schedule specified in paragraphs (a)(4)(ii) and (iii) of this section and determine the volumetric flow rate in accordance with paragraph (a)(5) of this section.

---

<sup>22</sup> EPA, *Lessons Learned: Replacing Wet Seals with Dry Seals in Centrifugal Compressors*, at 2 (Oct. 2006), [https://www.epa.gov/sites/default/files/2016-06/documents/ll\\_wetseals.pdf](https://www.epa.gov/sites/default/files/2016-06/documents/ll_wetseals.pdf) (stating that “dry seals leak at a rate of 0.5 to 3 scfm across each seal (1 to 6 scfm for a two-seal system)”).

<sup>23</sup> See 17 Cal. Code Regs. § 95668(c)(4)(D), (d)(6) (provisions for centrifugal compressors and reciprocating compressor rod packing both specify “a combined flow rate” based on the number of seals or compression cylinders multiplied by the applicable emissions standard for a single seal or rod packing unit).

*40 CFR 60.5392c(a)(1)*: You must conduct volumetric flow rate measurements from each centrifugal compressor wet and dry seal vent using the methods specified in paragraph (a)(2) of this section and in accordance with the schedule specified in paragraphs (a)(1)(i) and (ii) of this section. The volumetric flow rate, measured in accordance with paragraph (a)(2) of this section, must not exceed 3 standard cubic feet per minute (scfm) per seal. If the individual seals are manifolded to a single open-ended vent line, the volumetric flow rate must not exceed the sum of the individual seals multiplied by 3 scfm.

Commenter (2282-Kinder Morgan, Inc) requests that the EPA incorporate modest changes to 40 CFR 60.5392c(a)(1), (a)(2)(i), 60.5410c(c)(1), and 60.5415c(c)(1), as well as the respective NSPS OOOOb provisions.<sup>24</sup> [Note: This comment also refers to the respective NSPS OOOOb provisions, however the redline provided is only noted for EG OOOOc provisions.] These proposed changes would align the regulatory language with the fact that it is not possible to determine the vent rate value for each individual seal in a manifolded seal arrangement.

*40 CFR 60.5392c(a)(1)*, proposed changes (underlined text reflects new text):

(1) You must conduct volumetric flow rate measurements from each centrifugal compressor wet and dry seal vent using the methods specified in paragraph (a)(2) of this section and in accordance with the schedule specified in paragraphs (a)(1)(i) and (ii) of this section. The volumetric flow rate, measured in accordance with paragraph (a)(2) of this section, must not exceed 3 standard cubic feet per minute (scfm) per wet or dry seal, or in the case of manifolded groups of dry or wet seals, 3 scfm multiplied by the number of seals.

The commenter (2282-Kinder Morgan, Inc) also suggests two changes globally in the centrifugal compressor affected facility section to ensure consistent use of terms, with the proper meaning as is intended to apply in practice. First, when referring to the volumetric flow rate of 3 scfm, this rule should be referring to an individual wet seal or dry seal. The rule should not refer to the centrifugal compressor itself, or the seal vent, when referring to the required volumetric flow rate (i.e., the BSER threshold). Notably, a single centrifugal compressor can have more than one wet or dry seal, and thus, more than one wet or dry seal vent. Second, and in contrast to the above, when the rule refers to the point where the volumetric flow rate is measured, the rule should be referring to the seal vent or stack. In cases where multiple seals are manifolded together, the combination of seals would be measured as one vent/stack. The commenter recommends specific regulatory text changes to address their concerns.

*40 CFR 60.5392c(a)(1)(i)*, proposed changes (underlined text reflects new text):

(i) You must conduct your first volumetric flow rate measurement from your centrifugal compressor dry or wet seal vent on or before 8,760 hours of operation [Insert Date 36 months after state plan submittal deadline] or on or before 8,760 hours of operation after startup, whichever is later.

---

<sup>24</sup> The commensurate sections in Subpart OOOOb would be §§60.5380b(a)(4)(i), (a)(5)(i), 60.5410b(d)(6), and 60.5415b(d)(2).

As an example, the commenter (2282-Kinder Morgan, Inc) notes that, relevant to the above comment, because 40 CFR 60.5392c(a)(1)(i) and (ii) are discussing when to take the measurement, the commenter refers here to the seal vent, and not the seal itself. Here the centrifugal compressor is what will be in “operating-mode or in standby-pressurized mode”, so we propose to re-order the text to reflect that fact. The second sentence is not necessary. The commenter has proposed changes to 40 CFR 60.5392c(a)(1) to address the required volumetric flow rate (i.e., BSER) for more than one seal, which clarifies that when you have more than one seal manifolded to one vent, the required volumetric flow rate threshold is 3 scfm multiplied by the number of seals. Then, the commenter adds that the EPA’s proposed 40 CFR 60.5392c(a)(2)(ii) already addresses the appropriate measurement methodology when more than one wet or dry seal is manifolded together to a single vent/stack. So, it is unclear to the commenter what this second sentence offers that is not already addressed by other rule language. Furthermore, as the EPA addressed in the preamble to the Supplemental NSPS Proposal, when more than one seal is routed to the same vent, the operator cannot determine individual seal flow rates and “sum” them. Thus, this language, as drafted creates confusion as to how an operator would “sum” multiple measured rates from each seal. The commenter provides suggested regulation text changes below [suggested changes would also apply to parallel provisions in the proposed NSPS OOOOb].

*40 CFR 60.5392c(a)(2)(i)* proposed changes (underlined text reflects new text and struck out text reflects deleted text):

(i) For each dry or wet seal centrifugal compressor ~~vents~~ in operating-mode or in standby-pressurized-mode, determine volumetric flow rate at standard conditions from each dry or wet seal vent using one of the methods specified in paragraphs (a)(2)(i)(A) through (C) of this section. ~~If there is more than one dry seal compressor or wet seal compressor seal vent, determine the aggregate centrifugal compressor dry or wet seal vent volumetric flow rate for the compressor as the sum of the volumetric flow rates determined for each dry seal compressor or wet seal compressor vent on the compressor.~~

*40 CFR 60.5392c(a)(2)(ii)* proposed changes (underlined text indicates new text and struck out text indicates deletions):

(ii) For conducting measurements on manifolded groups of dry or wet seals centrifugal compressors, you must determine the volumetric flow rate from the ~~compressor~~ dry or wet seal vent as specified in paragraph (a)(2)(ii)(A) or (B) of this section.

(A) Measure at a single point in the manifold downstream of all dry or wet seal compressor inputs and, if practical, prior to comingling with other non-~~compressor~~-seal emission sources.

(B) Determine the volumetric flow rate at standard conditions from the common stack using one of the methods specified in paragraph (a)(2)(i)(A) through (~~E~~) of this section.

Changes recommended for *40 CFR 60.5392c(a)(2)(ii)* reflect the recommended paragraph additions to *40 CFR 60.5392c(a)(2)(i)* (see section 10.5.3 for this commenter’s

requested additions) and recommended monitoring changes based on the measurement of manifolded wet and dry seal vent inputs to meet a per seal standard.

*40 CFR 60.5410c(c)(1)* proposed changes (underlined text reflects new text and struck out text reflects deleted text):

(1) You must maintain the volumetric flow rate at or below 3 scfm for your wet ~~and or~~ dry seal ~~centrifugal compressors~~ (or in the case of manifolded groups of wet or dry seals, 3 scfm multiplied by the number of seals) and you must conduct your initial annual volumetric measurement as required by §60.5392c(a)(1)(i).

*40 CFR 60.5415c(c)(1)* proposed changes (underlined text reflects new text and struck out text reflects deleted text):

(1) You must maintain volumetric flow rate of each dry or wet seal below 3 scfm (or in the case of manifolded groups of dry seal or wet seals, 3 scfm multiplied by the number of seals) and you must conduct the required volumetric flow rate measurement ~~of~~ at your dry or wet seal vent ~~centrifugal compressor~~ in accordance with §60.5392c(a)(1) and (2) on or before 8,760 hours of operation after your last volumetric flow rate measurement which demonstrates compliance with the ~~3 scfm~~ applicable volumetric flow rate.

Commenter (2483-INGAA) also suggests regulatory language [assuming standard changed from an emission limit standard to a work practice standard] to address the same per seal volumetric flow rate clarification and measurement issues as follows (underlined text reflects new text and struck out text reflects deleted text):

Proposed regulatory text changes for *40 CFR 60.5392c(a)* and *60.5380b(a)*: A new paragraph 40 CFR 60.5392c(a)(1)(iii) should be added as follows (underlined text reflects new text and struck out text reflects deleted text):

(1) You must conduct volumetric flow rate measurements from each centrifugal compressor wet and dry seal vent using the methods specified in paragraph (a)(2) of this section and in accordance with the schedule specified in paragraphs (a)(1)(i) and (ii) of this section. If the ~~The~~ volumetric flow rate, measured in accordance with paragraph (a)(2) of this section, ~~must not exceeds~~ 3 standard cubic feet per minute (scfm) multiplied by the number of wet seals connected to the vent, the wet and dry seals connected to the measured vent must be repaired as provided in paragraph (a)(1)(iii) of this section.

[...]

(iii) The seal repair must be conducted no later than the next scheduled compressor station shutdown for maintenance. Delay of repair beyond the next compressor station shutdown for maintenance is allowed for a centrifugal compressor wet and dry seal, if seal replacement is necessary during the compressor station shutdown for maintenance, seal supplies have been depleted, and seal supplies had been sufficiently stocked before the supplies were depleted. Delay of repair beyond the next compressor station shutdown

for maintenance will not be allowed unless the next compressor station shutdown for maintenance occurs sooner than 6 months after the first compressor station shutdown for maintenance. You must conduct volumetric flow rate measurements from each centrifugal compressor wet and dry seal vent using the methods specified in paragraph (a)(2) of this section within 15 days after the repair to document that the rate has been reduced to less than 3 scfm per seal.

*Proposed 40 CFR 60.5392c(a)(2)(i)* suggested regulation text changes as indicated in the language below (struck out text reflects deleted text):

(i) For centrifugal compressor dry or wet seal vents in operating-mode or in standby-pressurized-mode, determine volumetric flow rate at standard conditions from each dry or wet seal vent using one of the methods specified in paragraphs (a)(2)(i)(A) through (C) of this section. ~~If there is more than one dry seal compressor or wet seal compressor seal vent, determine the aggregate centrifugal compressor dry or wet seal vent volumetric flow rate for the compressor as the sum of the volumetric flow rates determined for each dry seal compressor or wet seal compressor vent on the compressor.~~

*Proposed 40 CFR 60.5380b(a)(4)(i)* suggested regulation text changes as indicated in the language below (underlined text reflects new text and struck out text reflects deleted text):

(i) ~~The volumetric flow rate must not exceed 3 standard cubic feet per minute (scfm).~~ You must conduct measurements of the volumetric flow rate in accordance with the schedule specified in paragraphs (a)(4)(ii) and (iii) of this section and determine the volumetric flow rate in accordance with paragraph (a)(5) of this section. If the volumetric flow rate, measured in accordance with paragraph (a)(2) of this section, exceeds 3 standard cubic feet per minute (scfm) multiplied by the number of wet seals connected to the vent, the seals connected to the measured vent must be repaired as provided in paragraph (a)(6) of this section.

*Proposed 40 CFR 60.5380b(a)(5)(i)* suggested regulation text changes as indicated in the language below (struck out text reflects deleted text):

(i) For centrifugal compressor dry seal vents or self-contained wet seal centrifugal compressor in operating-mode or in standby-pressurized-mode, determine volumetric flow rate at standard conditions from each dry seal vent or self-contained wet seal centrifugal compressor using one of the methods specified in paragraphs (a)(5)(i)(A) through (C) of this section. ~~If there is more than one dry seal vent or self-contained wet seal centrifugal compressor, determine the aggregate dry seal vent or self-contained wet seal centrifugal compressor volumetric flow rate for the compressor as the sum of the volumetric flow rates determined for each centrifugal compressor dry seal vent or self-contained wet seal centrifugal compressor.~~

Response II-10-12: Section XI.G.3 (Clarification that the standard is based on a per-seal basis) of the preamble to the final rule responds to these comments. The EPA agrees that the basis and

intent of the performance-based volumetric flow rate standard is that it be applied on a per-seal basis and that clarity was needed in both the NSPS OOOOb and EG OOOOc regulatory text. EPA considered the comments/suggested edits and made the necessary clarifying changes to the final NSPS OOOOb and EG OOOOc regulatory text to address commenter's concerns.

Comment: Commenters (2282-Kinder Morgan, Inc, 2483-INGAA)<sup>25</sup> note that EPA stated that it is also considering other types of inherently low-emitting wet seals. Commenter (2483-INGAA) has previously submitted information on mechanical wet seals that it believes is sufficient to designate such designs as BSER for compressors that use them.<sup>26</sup> The commenter submits additional information on mechanical wet seals in Attachment D to their comments. With respect to mechanical wet seals, the commenters add that when a differential pressure maintained on the system, there is no off gassing of the lube oil. The commenter attaches an example to their comment letter that shows that the oil is pumped via the seal oil pump to the seal gas bottle, when the seal oil pressure is maintained at 32 psi above discharge gas pressure. With the differential pressure applied, the oil follows the (yellow) line down to the seals to maintain mechanical contact between the carbon ring and the seal collar. The reference line serves 2 purposes: (1) as a reference for seal oil pressure and (2) to push sour oil through to processing. The green line is the sour oil drain to the Armstrong dump valves. The Armstrong dumps are regulated via a float/needle & seat valve. The only way to lift the float off its seat in the dump is to introduce a liquid (sour oil) to the pot. Another unique feature of this type of mechanical seal is that it is integrated into the compressor housing. It has pins holding it in place. It is more expensive to convert one of these units to dry seals because the housing would need to be machined out to remove it. Then a mechanical seal with limited venting is replaced with a dry seal that has continuous venting.<sup>27</sup>

Response II-10-13: Section XI.G.3 (Other inherently low-emitting compressor with wet seal configurations) of the preamble to the final rule responds to these comments.

Comment: Commenter (2433-EDF et al.) states that the EPA should further strengthen the wet seal compressor standards by prioritizing control methods that route captured gas to a process rather than a completion device. [This comment applies to both NSPS OOOOb and EG OOOOc.]

Response II-10-14: The EPA does not have information that would support requiring an owner or operator to route to a process over routing captured gas to a combustion control device. However, the EPA encourages owners and operators choose that option (where technically feasible) and the December 2022 Supplemental Proposal and the final regulatory requirements for demonstrating compliance with the routing to a process option are less than what is required

---

<sup>25</sup> 2282-Kinder Morgan noted in their comments that they support all 2483-INGAA comments.

<sup>26</sup> INGAA Comments on 2021 Partial Proposal at 24.

<sup>27</sup> The cost difference to convert a mechanical wet seal to a dry seal is about \$150K-\$400K more than converting a clearance wet seal to a dry seal. The range depends on overhung (1 seal) vs beam (2 seals). Significant engineering is involved for mechanical wet seals manufactured by Delaval because the mechanical wet seal is locked in place using the bearing housing and there is no removable barrel. Therefore, machining the compressor case would be required.

if an owner or operator reduces emissions by routing to a combustion control device under both NSPS OOOOb standards and EG OOOOc presumptive standards.

Comment: The EPA solicited comment on its assumption that the emissions reduced by requiring the capture of gas and routing to a process is 95 percent or greater. The EPA also solicited comment on the prevalence of owners and operators complying with NSPS OOOO and NSPS OOOOa or other rules by routing emissions from the wet seal fluid degassing system to a process and the need for a vapor recovery unit (VRU) in order to be able to route emissions from the wet seal fluid degassing system to a process.

In response, commenter (2333-LongPath) states that their experience with continuous monitoring shows that continuous quantitative (emission rate) monitoring data is extremely effective at aiding operators in properly maintaining set points of VRUs. The commenter suggests that the EPA allow for quantitative continuous monitors with full site coverage to be usable as a form of VRU efficiency monitoring.

Response II-10-15: The EPA appreciates the commenter's input. While the EPA is not requiring continuous monitoring of VRU "set points" at this time as a form of VRU efficiency monitoring due to insufficient information, owners or operators would be allowed to employ continuous monitoring of "set points" of their VRUs as a form of VRU efficiency monitoring under the final NSPS OOOOb and EG OOOOc rule requirements.

### ***10.2.2 Dry Seal Compressors***

Comment: Commenter (2218-Texas Commission on Environmental Quality (TCEQ )) states that EPA's Oil and Gas Control Techniques Guidelines (CTG) model rule and current TCEQ rules do not require additional controls for centrifugal compressors with dual dry seals, which are already assumed to be 95.0 percent more effective than centrifugal compressors with wet seals. The model rule's additional centrifugal compressor dry seal control requirements are both economically unreasonable and unduly burdensome.

Response II-10-16: In response to comments received on the December 2022 Supplemental Proposal, EPA has finalized a different regulatory approach for dry seal centrifugal compressor affected/designated facilities. For details, please see discussion in section XI.G.1 (Redefining the affected facility to include centrifugal compressors with dry seals and the proposed standard) of the final rule preamble.

Comment: Commenter (2258-Marcellus Shale Coalition (MSC)) contends that the EPA should allow additional flexibility in means for reducing or controlling dry gas seal emissions. Technology to reduce emissions, such as seal gas recovery, is relatively new and emerging and the regulation should not discourage these options. In addition, the use of proven add-on controls, such as a combustor, should be allowed. Such options may be key for modified or reconstructed units.

Response II-10-17: In response to comments received on the December 2022 Supplemental Proposal, EPA has finalized a different regulatory approach for dry seal centrifugal compressor

affected/designated facilities. For details, please see discussion in section XI.G.1 (Redefining the affected facility to include centrifugal compressors with dry seals and the proposed standard) of the final rule preamble. As an alternative to meet the dry seal performance-based volumetric NSPS OOOOb standards and EG OOOOc presumptive standards, the EPA has revised the requirements for centrifugal compressors equipped with dry seals to allow owners and operators to comply with the VOC and GHG standards for compressors with dry seals by reducing VOC and methane emissions from each centrifugal compressor dry seal system by 95.0 percent, or by comply with the option to route the emissions from each centrifugal compressor dry seal system to a process.

Based on the final requirements, seal gas recovery would be allowed, however, the compressor would need to be able to comply with the final NSPS OOOOb standards and EG OOOOc presumptive standards (*e.g.*, by complying with either the performance-based volumetric flow rate standard or the route to process alternative option). Additionally, states can consider RULOF to support the need for alternative compliance options under EG OOOOc in their state plans. See section XIII.C.3 (Remaining useful life and other factors (RULOF)) of the final rule preamble for a summary of the RULOF provisions that have been finalized in the subpart Ba rulemaking (codified at 40 CFR part 60, subpart Ba).

Comment: Commenters (2282- Kinder Morgan, Inc, 2483-INGAA) request that the EPA not adopt the currently proposed standard of 3 scfm because that standard is unsupported. The BSER determination upon which this standard is based contains no data whatsoever to support this purported standard or the cost that would be required to maintain it. If the EPA continues to believe that dry seal centrifugal compressors should be subjected to a standard, it must first obtain data – both on cost and, more importantly, feasibility and reasonableness of the standard itself – to support a proper BSER analysis. Any other approach would be arbitrary and capricious. The commenters add that any requirements adopted should be a work practice standard, where emissions exceeding a defined threshold trigger maintenance or seal replacement, and not an emission rate limitation.

Commenter (2258-MSC) states that the EPA’s volumetric flow rate of 3 scfm is not consistent with manufacturer’s data and further evaluation is needed. The commenter reports that the volumetric flow rate will vary per compressor model and suction pressure. Assuming a suction pressure of 500 to 1,000 pounds per square inch gauge (psig), manufacturer’s maximum seal gas leakage will be at least three-plus times this rate.

Several commenters (2282-Kinder Morgan, Inc, 2305-Williams, 2399-GPA, 2428-API)<sup>28</sup> recommend that EPA wait for more accurate data. However, if the EPA is intent on establishing a dry seal emissions threshold before receiving the Subpart W reports, commenters recommend relying upon the manufacturer’s specified maximum leak rate for a particular unit. A recent review of dry seal leak curves from a major supplier of centrifugal compressors to the natural gas industry indicates that dry seal leakage rates can vary from 2 to 20 scfm per compressor (with 2 seals per compressor), depending on the make, model, and operating suction pressure of the

---

<sup>28</sup> 2428-API and 2282-KM support all 2399-GPA comments.

compressor.<sup>29</sup> If the EPA wishes to set one threshold applicable to all dry seal centrifugal compressors within the next year, the commenters recommend that the EPA set the threshold at 10 scfm per primary dry seal in order to allow for sufficient variability among existing dry seal leak rates. One commenter (2305-Williams) adds that since both dry seals on a dry seal compressor are commonly vented to a single vent stack, companies should be permitted to measure the combined flow rate from the common vent stack and divide by two to obtain the flowrate (scfm) vented per dry seal. Commenter (2428-API) adds that, as the Natural Gas STAR report documents, it is also impractical to expect the same level of emissions from dry seals for various sized units.

Response II-10-18: In response to comments received on the December 2022 Supplemental Proposal, EPA has finalized a different regulatory approach and performance-based volumetric flow rate per seal standard/presumptive standard for dry seal centrifugal compressor affected/designated facilities. For details, please see discussion in section XI.G.1 (Redefining the affected facility to include centrifugal compressors with dry seals and the proposed standard) of the final rule preamble.

The EPA has also made clarifying changes to the final NSPS OOOOb and EG OOOOc regulatory text to clearly indicate that the standard is on a per seal basis. For details, please see discussion in section XI.G.3 (Clarification that the standard is based on a per-seal basis) of the final rule preamble.

Comment: Several commenters (2258 MSC, 2282-Kinder Morgan, Inc, 2305-Williams, 2366-Berkshire Hathaway Energy Company (BHE), 2399-GPA, 2428-API, 2483-INGAA)<sup>30</sup> request clarification that the volumetric standard applies to each seal and not each compressor and that the rule text clearly address manifolded vents on a combined basis to reflect this. The commenters cite the precedent set by the CARB where wet seal compressors in California are restricted to 3 scfm per seal, and not per compressor as set forth in 17 CCR § 95668 (as discussed for wet seal compressors under section 10.2.1 of this Chapter).

Commenter (2282-Kinder Morgan, Inc) notes that the EPA's preamble discussion, and at least some of the proposed rule text, imply that the emissions rate would be on a per-seal basis, and the commenter understands this to be the EPA's intent. The commenter asserts that it is important (as discussed for wet seal compressors under section 10.2.1 of this Chapter) that the EPA's final rule more clearly reflect this intent. Specifically, according to commenter (2428-API), the proposed text provided in 40 CFR 60.5380b or 40 CFR 60.5385b(a), does not provide the distinction that the limits are per seal. It would be impractical for a compressor with multiple seals (centrifugal) to operate the same as compressor with only a single seal. Further, the commenter adds that, as the Natural Gas star report documents, it is also impractical to expect the same level of emissions from dry seals for various sized units.

Commenter (2282-Kinder Morgan, Inc) (and supported by commenter 2428-API) states that the rule language must more clearly address manifolded vents on a combined basis. The commenter

---

<sup>29</sup> Solar Turbines, Emissions from Centrifugal Compressor Dry Gas Seal System, PIL 251 Revision 1 (May 22, 2020).

<sup>30</sup> 2428-API and 2282-KM support all 2399-GPA comments.

states that the Supplemental Proposed NSPS preamble provides that the manifolded wet and dry seal flow rate must be “less than or equal to the number of compressors multiplied by 3 scfm (in operating or standby pressurized mode).”<sup>31</sup> The commenters support this approach, as it reflects the practicalities of measuring emissions from manifolded seals. The commenters also note that the approach is supported by the 2006 Natural Gas STAR report, which states that emissions rates from two seal systems would be double the emissions from a single seal system.<sup>32</sup>

Commenter (2282-Kinder Morgan, Inc) states that it appears that this concept of multiple seals manifolded to one vent is intended to be captured in the proposed regulations at 40 CFR 60.5380b(a)(5)(i)–(ii), 60.5415b(d)(2), 60.5392c(a)(2)(i)–(ii) and 60.5415c(c)(1). However, the proposed regulatory sections addressing the actual volumetric flow rate requirement do not clearly incorporate the preamble concept of multiplying the emissions rate by the number of manifolded seals. Proposed 40 CFR 60.5380b(a)(4)(i) and 60.5392c(a)(1) provide that the volumetric flow rate must not exceed 3 scfm, but they do not mention manifolded seals. Likewise, proposed 40 CFR 60.5415b(d)(2) and 60.5415c(c)(1), pertaining to demonstrating compliance, do not mention manifolded seals either. The commenter notes that the lack of regulatory text on manifolded seals makes it difficult for operators to rely on the preamble text alone. Moreover, they note that, for internal compliance processes, operators do not always cross-reference the preamble pertaining to each regulatory provision.

Several commenters (2282-Kinder Morgan, Inc, 2305-Williams, 2428 API, 2483-INGAA) provide suggested regulation text changes that would clarify the intent of the Supplemental Proposed NSPS preamble to allow for grouping of manifolded wet and dry seal vents where an emissions rate limit is applicable to such seals and that the emissions rate standard is on a per-seal basis. The commenters provide suggested changes that parallel what was provided for similar comments on wet seal compressors (that would also apply for dry seal compressors) under section 10.2.1 of this Chapter. The recommended changes that are detailed under section 10.2.1 of this Chapter would clarify the allowance for grouping of manifolded wet and dry seal vents where an emissions rate limit is applicable to such seals, and make clear that the emissions rate standard is on a per-seal basis.

Response II-10-19: In response to comments received on the December 2022 Supplemental Proposal, the EPA has made clarifying changes to the final NSPS OOOOb and EG OOOOc regulatory text to clearly indicate that the standard is on a per seal basis. For details, please see discussion in section XI.G.3 (Clarification that the standard is based on a per-seal basis) of the final rule preamble.

Comment: Several commenters (2212-Union of Concerned Scientists (UCS), 2249-National Association of Clean Air Agencies (NACAA), 2256-Mille Lacs Band of Ojibwe, 2433-EDF et al) support setting methane and VOC standards for dry seal centrifugal compressors.

---

<sup>31</sup> 87 Fed. Reg. at 74,790, 74,792.

<sup>32</sup> EPA, *Lessons Learned: Replacing Wet Seals with Dry Seals in Centrifugal Compressors*, at 2 (Oct. 2006), [https://www.epa.gov/sites/default/files/2016-06/documents/11\\_wetseals.pdf](https://www.epa.gov/sites/default/files/2016-06/documents/11_wetseals.pdf) (stating that “dry seals leak at a rate of 0.5 to 3 scfm across each seal (1 to 6 scfm for a two-seal system)”).

Response II-10-20: This is a supportive comment on an aspect of the December 2022 Proposal that has remained unchanged in the final rule; as such, no response is required.

Comment: Commenter (2258-MSC) states that dry seal centrifugal compressors typically consist of a primary and secondary seal which use natural gas. In addition, the assembly has a buffer seal which uses air. The commenter requests that the EPA verify/clarify that measurement of air from the buffer seal is not required.

Response II-10-21: The commenter is correct that the intent of the rule is to not include the measurement of air from the buffer seal.

Comment: Commenter (2258-MSC) states that the EPA needs to expand its cost analysis. Estimated cost for repair is noted as \$15,000 per year. Parts and labor for a seal repair can range from \$100,000 to \$150,000. The commenter adds that an aggressive volumetric flow rate requirement may significantly increase the frequency of required repairs. In addition, the regulatory supplement assumes a typical repair will correct the volumetric flow rate. The commenter recommends that other options be available.

Response II-10-22: In response to comments received on the December 2022 Supplemental Proposal, EPA has finalized a different regulatory approach and performance-based volumetric flow rate per seal standard/presumptive standard for dry seal centrifugal compressor affected/designated facilities. For details, please see discussion in section XI.G.1 (Redefining the affected facility to include centrifugal compressors with dry seals and the proposed standard) of the final rule preamble. In direct response to the comment, the EPA believes that if a repair is needed where the cost is in the range cited by the commenter, there are likely issues well beyond a seal leak that need to be addressed to ensure proper operation of the compressors. Such necessary repairs cannot be attributed to the regulation, even if the testing is what identifies the major issue.

Comment: Several commenters (2282-Kinder Morgan, Inc, 2366-BHE, 2399-GPA, 2428-API, 2483-INGAA)<sup>33</sup> state that the EPA should not adopt the currently proposed dry seal standard of 3 scfm (per seal) because that standard is unsupported and not adequately justified. Specifically, two commenters (2282-Kinder Morgan, Inc, 2483-INGAA)<sup>34</sup> state that the EPA must first obtain data – both on cost and, more importantly, feasibility and reasonableness of the standard itself – to support a proper BSER analysis.<sup>35</sup> Any other approach would be arbitrary and capricious. The commenters cite three main concerns with the BSER determination:

- 1) The BSER determination contains no data whatsoever to support this purported standard or the cost that would be required to maintain it. The commenters dispute the appropriateness of reliance on §95668(d)(4-9), California’s Regulations<sup>36</sup> for Greenhouse Gas Emission

---

<sup>33</sup> 2282-KM noted in their comments that they support all 2483-INGAA comments.

<sup>34</sup> 2282-KM noted in their comments that they support all 2483-INGAA comments.

<sup>35</sup> For example, EPA has recently proposed to require measurements for dry seal compressors under the GHGRP, proposed “Revisions and Confidentiality Determinations for Data Elements Under the Greenhouse Gas Reporting Rule,” 87 Fed. Reg. 36,920, 36,974 (June 21, 2022). If EPA finalizes that requirement, it would start collecting data for dry seal emissions.

<sup>36</sup> [https://ww2.arb.ca.gov/sites/default/files/2020-03/2017 Final Reg Orders GHG Emission Standards.pdf](https://ww2.arb.ca.gov/sites/default/files/2020-03/2017%20Final%20Reg%20Orders%20GHG%20Emission%20Standards.pdf).

Standards for Crude Oil and Natural Gas Facilities to support the standard. Research into the underlying sources of the CARB regulation does not yield supporting information for the development of the 3 scfm standard. According to the commenters, there are no data in the California rulemaking supporting any numeric standard for dry seals, much less a specific rate of 3 scfm. The commenters note both issues with the information/data (outdated or lack of data) used, and the record as provided in the Supplemental Proposal.

- 2) The BSER determination does not consider data that seal emission rate is a function of compressor size and suction pressure, and consequently, the standard should does not properly account for compressor size; and
- 3) The record is also devoid of any information (or data) indicating that proper maintenance and repair could reduce such compressors' dry seal emissions rate to 3 scfm or less, or any information regarding the associated costs of doing so.

The commenters (2282-Kinder Morgan, Inc, 2483-INGAA) state that there is better data available which should be reviewed and analyzed prior to setting a standard.

Several commenters (2282-Kinder Morgan, Inc, 2366-BHE, 2399-GPA, 2428-API)<sup>37</sup> note that the emission threshold appears to be based on §95668(d)(4-9), California's Regulations<sup>38</sup> for Greenhouse Gas Emission Standards for Crude Oil and Natural Gas Facilities which uses a severely limited number of outdated dry seal measurements. This data is referenced in the EPA's Natural Gas Star report, "Lessons Learned: Replacing Wet Seals with Dry Seals in Centrifugal Compressors" (2006), and in Annex Tables 3.6-2 and 3.6-6 supporting the EPA's, "Inventory of U.S. Greenhouse Gas Emissions and Sinks: 1990–2020." This underlying data dates back to 1996 (EPA/GRI study<sup>39</sup>) with few studies being performed since 2000. The commenters assert that the EPA should not rely on such stale data to establish an emission threshold as it is neither accurate nor representative of dry seal centrifugal compressors.

Several commenters (2282-Kinder Morgan, Inc, 2366-BHE, 2483-INGAA)<sup>40</sup> state that the record of the California rulemaking includes no measured data at all. The basis of the California statement that dry seals have an average emission rate of 3 scfm is merely an EPA natural gas STAR document,<sup>41</sup> but that document is also devoid of any information providing adequate support for the 3 scfm rate cited by CARB staff. Further, the California regulation, which chose not to regulate dry seal units, but reported a typical dry seal emission rate as the basis for an alternative, optional standard for centrifugal compressors with wet seals. In identifying 3 scfm as the alternative limit for wet seal units, the California regulation cited an EPA Natural Gas STAR Lessons Learned document that provided limited information from a European company not representative of the prevalent centrifugal compressors in U.S. natural gas operations. In

<sup>39</sup> Methane Emissions From the Natural Gas Industry, Volume 2: Technical Report EPA-600 /R-96-C80b (June 1996).

<sup>40</sup> 2282-KM noted in their comments that they support all 2483-INGAA comments.

<sup>41</sup> EPA: Lessons Learned from Natural Gas STAR Partners, "Replacing Wet Seals with Dry Seals in Centrifugal Compressors" (Oct. 2006), [https://www.epa.gov/sites/default/files/2016-06/documents/ll\\_wetseals.pdf](https://www.epa.gov/sites/default/files/2016-06/documents/ll_wetseals.pdf) (hereinafter "Lessons Learned from Natural Gas STAR Partners").

addition, the natural gas STAR program did not include quality control elements to verify emissions estimates, so use of such data as the sole basis for an NSPS standard is not adequate.

According to the commenters (2282-Kinder Morgan, Inc, 2366-BHE, 2483-INGAA)<sup>42</sup>, the [Natural Gas STAR] document only provides, as a basis for this purported “average” rate for dry seals, a chart of estimated dry seal emission rates from a vendor that generally does not serve U.S. markets and is primarily associated with liquid pump products – not the natural gas compressor drivers that serve the U.S. transmission and storage markets. In short, the dry seal emission estimate in the 2006 natural gas STAR document is not based on any actual measured rates; just supposition upon supposition based on inapplicable data from a foreign manufacturer.

Commenters (2282-Kinder Morgan, Inc, 2483-INGAA)<sup>43</sup> add that California presumes the 3 scfm rate would be the average emission rate for well-maintained dry seals, as the EPA seems to acknowledge.<sup>44</sup> Therefore, some well-maintained dry seals will have an inherently higher rate than 3 scfm, and there is no evidence or even a suggestion in the record that proper maintenance would be sufficient to bring such a rate down to 3 scfm. Identifying an “average” rate as the basis for a standard is flawed, especially when data ranges associated with the average are not discussed nor their relevance analyzed. The commenter suggests that an average value should not serve as the basis for the standard unless its validity is clearly supported.

Commenters (2366-BHE, 2428-API) state that the dry seal emission standard does not properly account for compressor size and has not considered data that seal emission rate is a function of compressor size and suction pressure. According to commenter (2428-API), larger compressors usually have larger shaft diameters, higher operating speeds, and greater operating pressures. These three variables all contribute factors to the amount of gas that might ultimately slip through the seals. The combination of these three factors will usually yield higher leak rates from seals as measured on a volumetric basis, thus larger compressors will have a higher baseline for normal operations. According to commenter (2366-BHE), information available from the primary manufacturer of transmission and storage segment turbines in the U.S. shows that dry seal emission rates are a function of compressor type (e.g., size) and operating (suction) pressure. For the transmission and storage segment, the majority of turbines are manufactured by Solar Turbines, and a Solar PIL presents emissions as a function of compressor suction pressure for different units. The PIL also explains dry seal technology. The U.S. manufacturer data clearly shows that 3 scfm will be exceeded during standard operations for many units and/or at many suction pressures that are common on transmission systems.

Several commenters (2282-Kinder Morgan, Inc, 2366-BHE, 2483-INGAA)<sup>45</sup> state that the EPA has erroneously concluded that maintenance alone can ensure that a 3 scfm flow rate can be met. The commenters state that the record is devoid of any information whatsoever indicating that proper maintenance and repair could reduce such compressors’ dry seal emissions rate to 3 scfm or less, or any information regarding the associated costs. Commenter (2366-BHE) states that in the Technical Support Document (TSD), the EPA assesses maintenance costs (without support

---

<sup>42</sup> 2282-KM noted in their comments that they support all 2483-INGAA comments.

<sup>43</sup> 2282-KM noted in their comments that they support all 2483-INGAA comments.

<sup>44</sup> [Id.]

<sup>45</sup> 2282-KM noted in their comments that they support all 2483-INGAA comments.

for the assumed value) but provides no evidence or documentation to support a conclusion that dry seal emissions exceed 3 scfm when poorly maintained units or due to anomalous operations. In simple terms, the EPA makes assumptions with no technical support. The commenter adds that the EPA provides no information or data to support its assertion that maintenance or repair will lower emissions below that threshold for larger units and/or higher-pressure applications. This assertion is false based on available information (e.g., Solar PIL).

Commenters (2282-Kinder Morgan, Inc, 2483-INGAA)<sup>46</sup> states that there is no evidence anywhere – and certainly not in the California rulemaking – supporting the assumption that the emission rate of a dry seal fluctuates much or is susceptible to increasing because of lack of maintenance or repair. Because of the inherent design of a dry seal, the emission rate of a dry seal “is what it is” and it is much less than the very high emission rates (more than 50 scfm) that purportedly have been measured in the past for some wet seal compressors. The incentives for proper maintenance (or, more likely, replacement) exist regardless of whether these compressors are subject to a numeric standard or not. For example, Solar Turbines, the primary manufacturer of transmission and storage compressors used in the U.S., includes in some of its models an onboard operational control system to track seal health (primarily through pressure measurements). Owners have a strong incentive to follow Solar’s recommendations to replace the dry seal when measurements indicate a necessity to do so. The commenter states that where a dry seal has failed and is emitting at a rate materially higher than its inherent, design rate, the only maintenance and repair action available is to replace the seal, likely at a cost of \$100,000 or more.<sup>47</sup> Moreover, depending on the size of the compressor and the line pressure, no amount of maintenance, repair, or replacement will be sufficient to reduce the emissions rate of some dry seal compressors to 3 scfm (or any other unsupported level, unless that level was high enough to cover all well-functioning dry seals).

Several commenters (2282-Kinder Morgan, Inc, 2366-BHE, 2428-API, 2483-INGAA)<sup>48</sup> note that more reliable information and data are available that could be used in developing a dry seal emission standard. Commenter (2428-API) states that based on data submitted to the EPA pursuant to 40 CFR Part 98, Subpart W for the 2021 calendar year, dry seal compressor driver power output ranged between 5 – 42,000 horsepower and for wet seals the compressor driver power output ranged between 40 – 53,665 horsepower.<sup>49</sup> The commenter does not believe compressors associated with the higher end of this range should be expected to operate the same as compressors closer to the lower end of this range. Table 2 of the commenter’s letter provides more details on their short analysis showing variable sizes of both dry and wet seal compressors as reference. [Table 2. Variation in Compressor Driver Output as Reported under the EPA’s greenhouse Gas Reporting Program for Calendar Year 2021]

Several commenters (2282-Kinder Morgan, Inc, 2366-BHE, 2483-INGAA)<sup>50</sup> state that for transmission and storage, the majority of turbines are manufactured by Solar Turbines. The

---

<sup>46</sup> 2282-KM noted in their comments that they support all 2483-INGAA comments.

<sup>47</sup> A recompression system, which may be needed in some instances, would cost in excess of \$500,000.

<sup>48</sup> 2282-KM noted in their comments that they support all 2483-INGAA comments.

<sup>49</sup> Information was extracted from EPA’s Envirofacts database using the GHG query builder: <https://enviro.epa.gov/query-builder/ghg>.

<sup>50</sup> 2282-KM noted in their comments that they support all 2483-INGAA comments.

commenters suggest that the Solar Turbine PIL<sup>51</sup> be considered as a superior reference compared to the Gas STAR document. Information available from Solar shows that dry seal emission rates are a function of compressor type (e.g., size) and operating (suction) pressure. The PIL also explains dry seal technology. The PIL provides data plots for a range of compressor sizes and suction pressures. The U.S. manufacturer data clearly shows that 3 scfm will be exceeded during standard operations for many units and/or at many suction pressures that are common on transmission systems. Since that data shows higher emission rates for many applications, it alone refutes the basis of the EPA's proposed 3 scfm emission rate. According to the commenters, if the EPA insists on proceeding with a standard for dry seal compressors at this time, that standard may have to be variable and a function of the operating conditions for the seal (i.e., unit size and suction pressure); or, if the standard is a single emission rate, it must be high enough to address the largest units and highest suction pressures in natural gas operations.

As a result of these concerns, several commenters provided recommendations to the EPA for development of a dry seal emission standard. Commenter (2366-BHE) offers their support to assist the EPA in developing a reasonable work practice standard for dry seal centrifugal compressors.

- Commenter (2428-API) states that the EPA should supplement the docket with information to support why the proposed value is representative of the population of dry seal compressors across the nation (taking into consideration compressor size variability).
- Commenters (2282-Kinder Morgan, Inc, 2399-GPA, 2428-API)<sup>52</sup> recommend that the EPA postpone establishing any type of quantitative threshold for dry seal centrifugal compressors until after it finalizes amendments to the Subpart W reporting rule. See 87 Fed. Reg. 36,920 (June 21, 2022) (proposed rule). Once implemented, the commenters contend that the EPA will have thousands of data points to give a more accurate dry seal centrifugal compressor measurements that can be used for a subsequent emissions threshold.
- Commenters (2282-Kinder Morgan, Inc, 2399-GPA, 2428-API)<sup>53</sup> state that if the EPA decides to re-propose a numeric emission standard for dry seal compressors, it must first identify reliable information about emission rates that are actually achieved by well-maintained dry seal compressors and the maintenance/replacement activity needed to achieve them. Because of the functional dependence on unit size and suction pressure, it is likely that a single emissions rate is not sufficient, unless that rate is high enough to address the largest units and highest suction pressures in natural gas operations.<sup>54</sup> Second, any emission rate standard must be expressed as a per seal standard.<sup>55</sup> If a compressor has more than one dry seal, it cannot possibly meet a standard developed on the basis of data from individual dry

<sup>52</sup> 2428-API and 2282-KM support all 2399-GPA comments.

<sup>53</sup> 2428-API and 2282-KM support all 2399-GPA comments.

<sup>54</sup> INGAA also believes EPA should investigate whether the types of onboard sensors that Solar Turbines provides with some of its models are prevalent in the industry. If that is the case, these sensors – even if they do not measure emission rates specifically, may be adequate to provide information about the health of the dry seals, possibly supporting a standard requiring seal replacement as recommended by the manufacturer.

<sup>55</sup> The source information cited by EPA (the California regulation and EPA natural gas STAR document) clearly indicate this is an emission rate per seal, as does the Solar Turbines PIL. If a dry seal emission rate threshold is retained in the final rule, it should be clearly indicated that the rate applies on a per seal basis.

seals. Finally, if the standard would require yearly measurements and monitoring of these compressors for the first time, as the current proposal does, the cost of monitoring<sup>56</sup> would be part of the proposed standard and should be accounted for in the BSER analysis.

- Commenter (2366-BHE) notes that, in principle, they do not object to a standard for dry seal compressors. The commenter states the EPA should: (1) recognize that 3 scfm is an approximate average rate for some dry seal compressors, but it is not characteristic of units that may have an emission rate several times higher – e.g., large compressors with relatively high suction pressure); (2) consider the upper end range or tiered emission rates in the standard; (3) conduct analysis and consider cost effectiveness of installing a seal vent recovery / control system if the emission rate cannot be met; (4) account for the cost of additional monitoring a numeric standard would require; (5) clarify that the selected standard applies for each dry seal, not for the entire compressor; and (6) if a standard is retained (considering the factors above), propose a work practice standard and define the schedule for operators to resolve the issue when a unit exceeds its defined emission rate threshold.

Response II-10-23: In response to comments received on the December 2022 Supplemental Proposal, EPA has finalized a different regulatory approach and performance-based volumetric flow rate per seal standard/presumptive standard for dry seal centrifugal compressor affected/designated facilities. For details, please see discussion in section XI.G.1 (Redefining the affected facility to include centrifugal compressors with dry seals and the proposed standard) and section XI.G.2 (Numeric standard versus work practice standard) of the final rule preamble.

### **10.3 Emission Guidelines OOOOc Designated Facility/Definitions**

[**Note:** Comments provided in section 10.1 of this Chapter on NSPS OOOOb affected facility/definitions also apply to EG OOOOc designated facilities/definitions.]

### **10.4 EG OOOOc Proposed BSER**

[**Note:** BSER comments (and EPA's response to comments) that apply to both the proposal for NSPS OOOOb and EG OOOOc are presented in section 10.2 of this Chapter. Below are comments and EPA's responses to comments that were specifically provided for EG OOOOc.]

Comment: Commenter (2282-Kinder Morgan, Inc) supports the December 2022 EG OOOOc proposed approach for establishing a defined emissions flow rate rather than the 95.0 percent reduction of methane emissions that was based on the impractical and potentially dangerous BSER of routing emissions to a control device or process. The commenter supports the change in approach based on the feasibility and safety concerns discussed in the December 2022 Supplemental Proposal.

Response II-10-24: With regards to support for EPA's December 2022 EG OOOOc proposed approach for establishing a defined emissions flow rate rather than the 95.0 percent reduction of

---

<sup>56</sup> For example, a flow meter is estimated to cost upwards of \$10,000 and installation also costs upwards of \$10,000.

methane, this is a supportive comment on an aspect of the December 2022 Proposal that has remained unchanged in the final rule; as such, no response is required.

Comment: Commenter (2218-TCEQ) states that the proposed requirements for several types of designated facilities are economically unreasonable and should be revised. They state as an example that the model rule requires a capture and 95.0 percent effective control system for centrifugal compressors to “central production sites” regardless of their seal configuration.

Response II-10-25: The final EG OOOOc model rule includes capture and 95 percent control of emissions for centrifugal compressors to provide owners and operators an alternative compliance option in lieu of meeting the performance-based volumetric flow rate standards and is not required. Additionally, states can consider RULOF to support the need for alternative compliance options under EG OOOOc in their state plans. See section XIII.C.3 (Remaining useful life and other factors (RULOF)) of the final rule preamble for a summary of the RULOF provisions that have been finalized in the subpart Ba rulemaking (codified at 40 CFR part 60, subpart Ba).

Comment: Commenter (2258-MSD) states that the compliance alternative of EG OOOOc, the requirement to reduce emissions, should note a reduction of 95 percent or less than the presumptive standard. The commenter recommends incorporating the following language (underlined text is new text and struck out text is deleted text):

an owner or operator of a centrifugal compressor equipped with wet seals can comply with EG OOOOc by reducing methane emissions from each centrifugal compressor wet seal fluid degassing system by 95 percent, which or achieves emission reductions resulting in emissions less than ~~greater than~~ or equal to the 3 scfm proposed presumptive standard.

Response II-10-26: While the EPA appreciates the concept put forth by the commenter, the implementation of such an alternative is problematic. For instance, in order to establish the reduction achieved by the 3 scfm standard, it would be necessary for the owner or operator to establish the baseline from which the reduction would be measured. The commenter did not recommend a process for the establishment of a baseline, but the EPA would anticipate that such a process would be burdensome and fraught with complications and issues. Therefore, the commenter’s suggestion was not incorporated in the final rule.

Comment: With regards to 40 CFR 60.5392c(a)(3) which includes the option to reduce methane emissions by 95.0 percent by routing to a control device or process, commenter (2282-Kinder Morgan, Inc) requests that EPA refer to their November 2021 proposal comments, dated January 31, 2022 (included as Exhibit B in their December 2022 proposal comment letter), where they express concerns regarding the safety, feasibility, and cost as it relates to routing a seal to control or process. The commenter supports a volumetric flow rate BSER. For the reasons discussed in the comments they submitted on the November 2021 proposal, the commenter opposes a BSER for wet and dry seals that would require reducing emissions from the seal by 95.0 percent reduction by routing to control or process. The commenter states that they recognize that the EPA presents this as an alternative to the volumetric flow rate, however, the commenter does not

believe these are feasible, or cost-effective, alternatives that should be reasonably drafted into a rule.

Response II-10-27: In response to the comment that EPA should not, even as an alternative to the performance-based volumetric flow rate standard, include the option to reduce emissions from seals by 95.0 percent by routing to control or a process, we disagree. Although the commenter may not opt to comply with this option because of feasibility or cost-effectiveness, that is not a reason to not provide these alternative options to other owners or operators that may find these options more attractive.

Comment: Commenter (2317-Alaska Oil and Gas Association (AOGA)) requests that the EPA revise the proposed EGs for existing wet seal centrifugal compressors to address the characteristics of the wet seal compressors deployed in Alaska oil production operations.

Commenter (2317-AOGA) reports that their members use wet seal compressors at their ANS and Cook Inlet production fields to increase the pressure of residual gas captured in production operations to enable delivery to gas processing plants and/or re-injection into well fields. There are about 40 compressor trains on the ANS installed for this purpose. The compressors in use on the ANS were installed in the late 1970s through mid-1980s and have not been modified or reconstructed. They range in size from 15,140 hp to 53,665 hp. None are currently subject to NSPS OOOO or NSPS OOOOa.

The commenter (2317-AOGA) states that all the wet seal centrifugal compressors in Alaska are equipped with a seal oil gas separation system that separates gas from the sour seal oil exiting the compressor seal assembly, upstream from the degassing drum. On the ANS the gas captured in the seal oil trap is routed to various outlets for use as turbine fuel, low pressure fuel gas, compressor suction, flare purge or to flare (for destruction). In Cook Inlet the gas is processed for delivery to market. The commenter notes that the EPA described this technology enthusiastically in the 2014 Natural Gas STAR Report. Sour seal oil passes through a “seal oil trap,” a type of separator, prior to routing to the seal oil degassing drum. The commenter notes that they described the seal oil traps in their comments on EPA’s 2021 proposal.<sup>57</sup> Attachment B<sup>58</sup> of the commenter’s letter resubmits that information, including a process flow diagram of the seal oil recovery system on an ANS wet seal compressor. The commenter notes that the EPA’s 2014 Natural Gas STAR report praises the seal gas recovery system deployed on the ANS as “highly effective at capturing degassing emissions from wet seal centrifugal compressors . . .”<sup>59</sup>

<sup>58</sup> Attachment B - Re-submittal of Alaska Oil and Gas Association comments "Proposed New Source Performance Standards and Emissions Guidelines for Control of GHG Emissions from the Oil and Natural Gas Sector, Docket ID No. EPA-HQ-OAR-2021-0317", dated January 31, 2022. (Attachment B).

<sup>59</sup> 2014 Natural Gas Star Report at 5. Page 5 of 11.

The commenter (2317-AOGA) also provides the following:

- Careful review of the CARB support document sources provides no support for the EPA’s proposed finding that preventive maintenance and repair will enable compliance with a 3 scfm flow limit at wet seal compressor seal vents.<sup>60</sup>
- The current NSPS Subpart OOOO and Subpart OOOOa require 95.0 percent control efficiency for VOCs (not methane) from new and modified wet seal compressors,<sup>61</sup> but neither standard includes a volumetric flow limit. Neither standard provides support for a 3 scfm flow limit as a “demonstrated” system of emission reduction for control of VOC and methane emissions from existing wet seal compressor vents.
- One document CARB cited is a 2014 EPA report on the use of seal oil traps to capture and recycle seal oil and entrained gas.<sup>62</sup> The 2014 EPA report contains no data supporting the feasibility of meeting a 3 scfm flow limit per seal from the degassing system vents. To the contrary it finds that gas volume from degassing centrifugal compressor seal oil varies due to site-specific features of each compressor.<sup>63</sup>
- A 2006 Natural Gas STAR report recommended the replacement of wet seals with dry seals. That report estimated that wet seals emit 50 scfm per seal, but dry seals emit only 3 scfm.<sup>64</sup> CARB based its 3 scfm wet seal flow limit on the estimated dry seal emission rate, explaining that the 3 scfm limit is “similar to” the NSPS 95.0 percent control efficiency requirement for new wet seal compressors.<sup>65</sup>
- The CARB Staff Report cites data collected in the 2007 CARB Oil and Gas Survey as support for its 3 scfm flow limit. That survey included 47 centrifugal compressors, but CARB did not request data on the size of the compressor, and the report does not differentiate between wet and dry seal designs.<sup>66</sup> The CARB Staff Report noted that there was only one uncontrolled wet seal centrifugal compressor operating in California at the time of the 2007 CARB survey.<sup>67</sup> The feasibility of meeting the 3 scfm flow limit at that one compressor may not have carried much weight in the development of the 3 scfm flow limit. CARB proposed as a compliance option to give the owner of the last uncontrolled compressor in California extra time to replace wet seals with dry seals by the compliance deadline, “if controlling the emissions with the use of a vapor collection system is not possible.”<sup>68</sup>
- Information provided to the EPA during the comment period on the 2021 proposal suggests that no wet seal compressor currently meets Subpart OOOOa capture and control requirements. Kinder Morgan explained that none of its 197 wet seals have been modified to trigger the 95.0 percent control standard, that Kinder Morgan’s practice for new compressors is to install dry seal units, and that at least one compressor

<sup>68</sup> Id. at 100.

manufacturer questioned the safety of capturing and flaring emissions from a wet seal compressor degassing vent.<sup>69</sup>

- The experience of the commenter's members echoes the Kinder Morgan's comments. No ANS wet seal compressors have been installed or modified since adoption of the Subpart OOOO control requirements. The practice of ANS operators has been to install dry seal compressors when a new compressor is necessary. The EPA cited Kinder Morgan's comments to support its decision in the current proposal to shift its presumptive BSER recommendation for existing wet seal compressors from 95.0 percent control to a flow limit.<sup>70</sup> But the 3 scfm limit in the CARB standard assumes the same 95.0 percent control efficiency assumption that is unproven in practice for wet seal compressors.

In summary, the commenter (2317-AOGA) states that:

- The EPA candidly acknowledges that CARB developed the 3 scfm emission standard for wet seal compressor vents "because this was the equivalent to an average dry seal emission rate."<sup>71</sup>
- The three resources that CARB staff considered in developing the 3 scfm flow limit provide no support for the feasibility of meeting that limit at wet seal compressor vents.
- The EPA offers no other data supporting the viability of meeting a 3 scfm flow limit on a wet seal compressor vent through preventive maintenance and repair.
- The EPA offers no evidence that any wet seal compressor vent currently complies with CARB's 3 scfm flow limit. Even if one such compressor could be found, it would not support the 3 scfm flow limit because the flow rate from a wet seal compressor degassing drum varies broadly based on site-specific factors.
- The EPA concedes that it lacks "specific costs" for the maintenance and repair activities needed to meet 3 scfm.<sup>72</sup> But these acknowledgments understate the challenge of demonstrating that a well-maintained wet seal compressor can meet a 3 scfm flow limit per seal vent.

The commenter (2317-AOGA) supports the concept of adopting a volumetric limit based on diligent maintenance and repair as BSER for control of emissions from wet seal compressor vents. But the 3 scfm limit in the proposal is not based on data from wet seal compressors, and that limit.

The comment (2317-AOGA) supports the concept of adopting a flow limit based on maintenance and repair as BSER for control of emissions from wet seal compressor vents. That option avoids the safety risks, engineering challenges and extravagant cost of capturing and flaring low volume, low pressure vent streams. The problem with the EG OOOOc proposal is that the 3 scfm proposed limit does not account for variability in the size and configuration of wet seal compressors within the source category and is not demonstrated or achievable for wet seal

---

<sup>69</sup> Comments of Kinder Morgan Inc. on EPA Proposed Standards and Emissions Guidelines for the Oil and Natural Gas Sector at 8, 13-14, Docket ID No. EPA-HQ-OAR-2021-0317-1375 ("Kinder Morgan Comments").

<sup>70</sup> 87 Fed. Reg. at 74791.

<sup>72</sup> 87 Fed. Reg. at 74785-86.

compressors of the size and configuration of those deployed in oil and gas production operations in Alaska.

Response II-10-28: The EPA has made revisions to the final rule to address some of the commenter's concerns regarding their particular centrifugal compressors equipped with wet seals in the final rule (see below). While the EPA notes that it does not have sufficient information to establish separate performance-based volumetric flow rate work practice standards based on every size and configuration of centrifugal compressor equipped with wet seals, the EPA has received a lot of support from industry for proposing the 3 scfm per seal performance-based volumetric flow rate work practice standard as a compliance option in lieu of having to reduce methane emissions from each centrifugal compressor wet seal fluid degassing system by 95 percent by routing emissions via a closed vent system (CVS) to a control device, or by routing emissions via a CVS to a process for existing sources. Nonetheless, the compliance options to route emissions to a control device or process are maintained in the final EG OOOOc presumptive standards. In addition, states can consider remaining useful life and other factors (RULOF) to support the need for an alternative performance-based volumetric standard for wet seal centrifugal compressors in their state plans. See section XIII.C.3 (Remaining useful life and other factors (RULOF)) of the final rule preamble for a summary of the RULOF provisions that have been finalized in the subpart Ba rulemaking (codified at 40 CFR part 60, subpart Ba).<sup>73</sup>

See Section XI.G.6 (Wet seal compressors equipped with a seal oil gas separation system utilized on the Alaska North Slope (ANS)) of the preamble to the final rule responds to comments on the commenter's concerns that their centrifugal compressors cannot meet a 3 scfm per seal performance-based volumetric flow rate.

See also section XI.G.2 (Numeric standard versus work practice standard) of the final rule preamble that discusses EPA's decision to revise the format of the volumetric flow rate per seal performance standard for compressors equipped with wet seals to be implemented as a work practice standard and not a numeric limit where an exceedance would be considered a violation.

Comment: Commenter (2317-AOGA) would support the designation of seal oil traps as an EG OOOOc compliance option for Alaska wet seal compressors. For several reasons, however, Alaska wet seal compressors equipped with seal oil traps do not uniformly meet the proposed 3 scfm limit. The volume of seal oil slip from a wet seal compressor correlates with compressor shaft size, pressure and speed. Alaska wet seal compressors span a broad range of capacities, and the degassing drums serving the larger units vent higher volumes of seal gas. Attachment C <sup>74</sup>to their comments provides a table showing flow rate data from 27 wet seal compressor degassing vents sampled by AOGA member Hilcorp for the EPA GHG emissions reporting. The table shows the flow rate per seal, but a single degassing drum can discharge gas from up to four seal oil traps. The variability in the data reflects the variability in size and configuration of the

---

<sup>73</sup> The D.C. Circuit vacated certain timing provisions within subpart Ba. *Am. Lung Assoc. v. EPA*, 985 F.3d 914 (D.C. Cir. 2021), petition for cert. pending, No. 20-1778 (filed June 23, 2021) (*Am. Lung Assoc.*). However, the court did not vacate the applicability provision. Therefore, 40 CFR part 60, subpart Ba, applies to the final EG. In addition, on November 17, 2023, the EPA finalized amendments to subpart Ba that address the provisions that were vacated in 2021 and make other updates to the implementing regulations applicable to this EG.

<sup>74</sup> Attachment C - Table of data titled "Hilcorp Alaska Wet Seal Combustion Turbines, Volumetric Flow Rate Per Seal (2016-2011). (Attachment C).

compressors and the fact that each seal oil trap operates on a discharge cycle, and a degassing drum may receive sour seal oil from up to four different seal oil traps at any moment. Depending on when in the cycle the sample is taken, the per seal flow rate can exceed 3 scfm.

Based on the degassing drum flow rate data summarized in Table 1 (of Attachment C to their comment letter) the commenter (2317-AOGA) proposes a volumetric flow limit for Alaska wet seal compressor vents of 9 scfm of methane and VOCs per seal, multiplied by the number of compressor seals venting through a common stack. For example, they note that a two-stage compressor has four seals (two per stage), all of which are manifolded into one vent to atmosphere. If the per seal flow limit was 9 scfm, the flow limit for the common vent should be 36 scfm.

Response II-10-29: Section XI.G.6 (Wet seal compressors equipped with a seal oil gas separation system utilized on the Alaska North Slope (ANS)) of the preamble to the final rule responds to these comments.

Comment: Commenter (2317-AOGA) states that the NSPS OOOOb capture and control requirements for new wet seal compressors are not reasonably achievable for existing compressors in Alaska. The commenter notes that the December 2022 proposed EG OOOOc offers the NSPS OOOOb control options as a fallback for wet seal compressors that cannot meet the presumptive 3 scfm flow limit.<sup>75</sup> But these options would require a cover on the degassing drums, connected through a closed vent system to process or to a control device that achieves a 95.0 percent reduction in emissions, should an existing compressor ever be modified or reconstructed.<sup>76</sup> The commenter states that in Alaska oil and gas production operations there is no cost-effective option to recover degassing drum emissions. Degassing drums vent small volumes of methane and VOCs at atmospheric pressure. They refer to flow rates reported in Attachment C of their comment letter. The volumes are small because the seal oil traps capture and recycle most of the seal gas upstream of the degassing drum. They report that operators would need to install new compression devices to boost degassing drum vent gas pressure to the approximately 20 psi that would enable delivery of those streams to the flare header line. The commenter states that larger new compression devices would be required to boost vent gas to a much higher pressure that would enable delivery to a process line for injection into sub-surface reservoirs.

According to the commenter (2317-AOGA), the combination of low methane and VOC recoveries with high capture costs makes the capture and control alternative very expensive on a cost per ton basis. They note that Kinder Morgan's comments on the 2021 EPA proposal, where they provide that the 95.0 percent reduction requirement is technically infeasible and cost-prohibitive even for wet seal compressors located on natural gas pipelines in the lower 48.<sup>77</sup> For wet seal compressors deployed in Alaska production operations with seal oil traps the cost per ton of covering the degassing drum vents and reducing emissions from those vents by 95.0 percent would be prohibitive.

---

<sup>75</sup> 87 Fed. Reg. at 74791.

<sup>76</sup> 87 Fed. Reg. at 74787; proposed § 60.5392c(3)-(4). Page 7 of 11.

<sup>77</sup> Kinder Morgan Comments 8-20.

Response II-10-30: Section XI.G.6 (Wet seal compressors equipped with a seal oil gas separation system utilized on the Alaska North Slope (ANS)) of the preamble to the final rule responds to these comments.

Comment: Commenter (2433-EDF et al) states that the EPA should further strengthen the wet seal compressor standards by prioritizing control methods that route captured gas to a process rather than a completion device.

Response II-10-31: While the EPA agrees that routing to a process is a preferred option to routing to a combustion device, there is insufficient evidence to support a hierarchy that prioritizes routing to a process over routing to control. See Response II-10-14 for a response to this comment.

## **10.5 NSPS OOOOb and EG OOOOc Compliance Issues**

### ***10.5.1 Subpart KKK Wet Seal Compressor Requirements***

Comment: Commenter (2222-Wisconsin Department of Natural Resources (WDNR)) recommends that EPA incorporate all compliance options provided in NSPS KKK for wet seal centrifugal compressors at natural gas processing plants. The commenter states incorporating all the compliance options provided in NSPS KKK for wet seal centrifugal compressors at natural gas processing plants would provide significant clarity and consistency to both state regulators and affected facilities. In addition, the EPA should consider taking this approach for other categories of affected facilities that will be covered by the new NSPS and EG as well as the existing NSPS.

Response II-10-32: The EPA evaluated this option and determined that incorporating compliance options provided in NSPS KKK for wet seal centrifugal compressors at natural gas processing plants in NSPS OOOOb or EG OOOOc was unnecessary. The EPA is instead clarifying applicability of requirements in the final rule preamble and NSPS KKK regulatory text. See discussion in section IX.C (How will the final EG OOOOc impact sources already subject to NSPS KKK, NSPS OOOO, or NSPS OOOOa?) of the final rule preamble.

### ***10.5.2 Recommended Work Practice Standard Provisions (Apply to All Centrifugal Compressors)***

Comment: Several commenters (2258-MS, 2282-Kinder Morgan, Inc, 2305-Williams, 2326-American Exploration and Production Council (AXPC), 2399-GPA, 2428-API, 2483-INGAA) assert that the rule should clarify the required compliance obligations, include a repair or replacement timeline, and eliminate avoidable emissions from repair to wet and dry seals. According to the commenters, the proposed NSPS rule is drafted to require an emissions flow rate limit for wet and dry seals. If the individual seal exceeds the 3 scfm (or a group of seals exceeds the applicable threshold), the EPA expects the operator to repair, or replace, that seal, as appropriate.<sup>78</sup> The rule does not describe what is required if the measurement at the seal vent

---

<sup>78</sup> See, e.g., 87 Fed. Reg. at 74,711-12 (Table 3).

exceeds the applicable flow rate. The commenters recommend that dry seal centrifugal compressors and self-contained wet seal compressors be regulated through work practice standards. And that the rule provide a proposed timeline for repair or replacements, as well as delay of repair provisions, consistent with nearly all other NSPS drafted by the EPA.

According to commenter (2483-INGAA), the EPA, without any explanation or analysis of the consequences, summarily turned California's work practice standard into an emission rate limitation. There is nothing in the record about what it would technically take, and the associated cost, to meet such a limitation. The commenter states that a delay of repair provision in such a regulatory scheme appropriately recognizes that the unit must be shut down to affect any such repair and replacement and that parts availability and supply chain disruptions may be relevant to how quickly the repair or replacement can be made. In addition, there is nothing in the record to indicate that it is feasible for the source to anticipate that a well-functioning wet seal that meets the 3 scfm limitation one year will exceed it before the next year's test, or the cost of doing so (if possible).

Several commenters (2282-Kinder Morgan, Inc, 2428-API, 2305-Williams, 2399-GPA) suggest that the EPA allow one of the following corrective actions by an operator within two years if the applicable emission threshold is exceeded:

- (1) repair or replace the dry seal, wet seal or internal seal gas recovery system; and
- (2) route emissions from the dry seal vent through a closed vent system or from the degassing vent using a cover and closed vent system a control device; or
- (3) route emissions from the primary dry seal vent through a closed vent system or route the degassing vent using a cover and closed vent system to a process.

The commenters (2282-Kinder Morgan, Inc, 2305-Williams, 2399-GPA, 2428-API) recommend that if an operator cannot complete the corrective action within two years, then a corrective action plan with work scope and alternate schedule be submitted to the EPA under a work-practice-based framework. According to the commenters, two years is a reasonable corrective action period since the corrective actions listed above can require significant planning, scheduling, engineering, and construction. Exceedance of the emissions threshold after two years (in the absence of a corrective action plan), or after the time stated in the corrective action plan, would result in a deviation subject to recordkeeping and reporting requirements similar to other types of compressors.

Commenters (2282-Kinder Morgan, Inc, 2399-GPA) the delay of repair provision is consistent with delay of repair requirements under 40 CFR 60.5397a(h)(3), requiring repair within two years, or the next scheduled shutdown (whichever is earlier) where repairs are technically infeasible, would require a vent blowdown, a compressor station shutdown, a well shutdown or well shut-in, or would be unsafe to repair. Further, the EPA has taken this approach before in

most if its NSPS regulations.<sup>79</sup> In fact, the EPA has also proposed a delay of repair approach in other contexts of the Proposed NSPS Rule where emissions caused by the repair would exceed the existing leak rate.<sup>80</sup>

Commenter (2282-Kinder Morgan, Inc) proposes 90 days as a reasonable timeframe given the significant variety of repair methods (including replacement) that may be appropriate for these units, as the EPA recognizes in its preamble.

Commenters (2282-Kinder Morgan, Inc, 2483-INGAA) propose revisions to regulatory language to implement the requested work practice approach and delay of repair provision.

The following revised rule language is proposed by commenter (2282-Kinder Morgan, Inc) for dry and wet seals in the proposed new 40 CFR 60.5392c(d) and redesignating the existing paragraph (d) as paragraph (e) (underlined text is new text and struck out text is deleted text):

(d) If the results of the initial (§60.5410c(c)) or continuous (§60.5415c(c)) compliance measurement demonstrate that the wet or dry seal emissions flow rate is greater than 3 scfm, you must repair or replace the wet or dry seal within 90 days from the date of the initial or continuous flow rate measurement.

(1) If the repair or replacement is technically infeasible, would require a vent blowdown, a process unit or facility requires shutdown, parts or materials are unavailable, or it would be unsafe to repair during operation of the unit, the repair must be completed during the next scheduled process unit or facility shutdown for maintenance, after a scheduled vent blowdown, or within 2 years, whichever is earliest. For purposes of this paragraph (d)(1), a vent blowdown is the opening of one or more blowdown valves to depressurize major production and processing equipment, other than a storage vessel.

~~(e)~~ You must perform the reporting as required by §60.5420c(b)(1) and (4) and (b)(10) through (12), as applicable, and the recordkeeping as required by §60.5420c(c)(3) and (c)(7) through (12), as applicable. The following revised rule language is proposed by commenter (2483-INGAA) for dry and wet seal compressors:

*40 CFR 60.5392c(a) and 60.5380b(a):*

*Recommended 40 CFR 60.5392c(a)(1) and (a)(1)(iii) changes (underlined text is new text and struck out text is deleted text):*

---

<sup>79</sup> See, e.g., 40 C.F.R. §§ 60.482-9(c)(1) (delay of repair allowed if emissions of purged material resulting from immediate repair are greater than the fugitive emissions likely to result from delay of repair), 60.5416(b)(10) (delay of repair permitted if emissions resulting from immediate repair would be greater than the fugitive emissions likely to result from delay of repair).

<sup>80</sup> See, e.g., proposed § 60.5400b(h)(6)(ii)(A) (Delay of repair showing requires in part “that emissions of purged material resulting from immediate repair are greater than the fugitive emissions likely to result from delay of repair.”).

(1) You must conduct volumetric flow rate measurements from each centrifugal compressor wet and dry seal vent using the methods specified in paragraph (a)(2) of this section and in accordance with the schedule specified in paragraphs (a)(1)(i) and (ii) of this section. If the volumetric flow rate, measured in accordance with paragraph (a)(2) of this section, must not exceeds 3 standard cubic feet per minute (scfm) multiplied by the number of wet seals connected to the vent, the wet and dry seals connected to the measured vent must be repaired as provided in paragraph (a)(1)(iii) of this section.

[...]

(iii) The seal repair must be conducted no later than the next scheduled compressor station shutdown for maintenance. Delay of repair beyond the next compressor station shutdown for maintenance is allowed for a centrifugal compressor wet and dry seal, if seal replacement is necessary during the compressor station shutdown for maintenance, seal supplies have been depleted, and seal supplies had been sufficiently stocked before the supplies were depleted. Delay of repair beyond the next compressor station shutdown for maintenance will not be allowed unless the next compressor station shutdown for maintenance occurs sooner than 6 months after the first compressor station shutdown for maintenance. You must conduct volumetric flow rate measurements from each centrifugal compressor wet and dry seal vent using the methods specified in paragraph (a)(2) of this section within 15 days after the repair to document that the rate has been reduced to less than 3 scfm per seal.

Recommended *40 CFR 60.5392c(a)(2)(i)* changes (struck out text is deleted text):

(i) For centrifugal compressor dry or wet seal vents in operating-mode or in standby-pressurized-mode, determine volumetric flow rate at standard conditions from each dry or wet seal vent using one of the methods specified in paragraphs (a)(2)(i)(A) through (C) of this section. ~~If there is more than one dry seal compressor or wet seal compressor seal vent, determine the aggregate centrifugal compressor dry or wet seal vent volumetric flow rate for the compressor as the sum of the volumetric flow rates determined for each dry seal compressor or wet seal compressor vent on the compressor.~~

Recommended *40 CFR 60.5380b(a)(4)(i)* changes (underlined text is new text and struck out text is deleted text):

(i) ~~The volumetric flow rate must not exceed 3 standard cubic feet per minute (scfm).~~ You must conduct measurements of the volumetric flow rate in accordance with the schedule specified in paragraphs (a)(4)(ii) and (iii) of this section and determine the volumetric flow rate in accordance with paragraph (a)(5) of this section. If the volumetric flow rate, measured in accordance with paragraph (a)(2) of this section, exceeds 3 standard cubic feet per minute (scfm) multiplied by the number of wet seals connected to the vent, the seals connected to the measured vent must be repaired as provided in paragraph (a)(6) of this section.

Recommended new paragraph *40 CFR 60.5380b(a)(6)* (underlined text is new text):

(6) The seal repair must be conducted no later than the next scheduled compressor station shutdown for maintenance. Delay of repair beyond the next compressor station shutdown for maintenance is allowed for a centrifugal compressor wet and dry seal, if seal replacement is necessary during the compressor station shutdown for maintenance, seal supplies have been depleted, and seal supplies had been sufficiently stocked before the supplies were depleted. Delay of repair beyond the next compressor station shutdown for maintenance will not be allowed unless the next compressor station shutdown for maintenance occurs sooner than 6 months after the first compressor station shutdown for maintenance. You must conduct volumetric flow rate measurements from each centrifugal compressor wet and dry seal vent using the methods specified in paragraph (a)(2) of this section within 15 days after the repair to document that the rate has been reduced to less than 3 scfm per seal.

Recommended changes to *40 CFR 60.5380b(a)(5)(i)* (struck out text is deleted text):

(i) For centrifugal compressor dry seal vents or self-contained wet seal centrifugal compressor in operating-mode or in standby-pressurized-mode, determine volumetric flow rate at standard conditions from each dry seal vent or self-contained wet seal centrifugal compressor using one of the methods specified in paragraphs (a)(5)(i)(A) through (C) of this section. ~~If there is more than one dry seal vent or self-contained wet seal centrifugal compressor, determine the aggregate dry seal vent or self-contained wet seal centrifugal compressor volumetric flow rate for the compressor as the sum of the volumetric flow rates determined for xv each centrifugal compressor dry seal vent or self-contained wet seal centrifugal compressor.~~

Response II-10-33: In response to comments on the December 2022 Supplemental Proposal, the EPA reconsidered establishing the performance based volumetric flow rate standard as a numeric standard.

The EPA evaluated the comments provided and have finalized the performance-based volumetric flow rate standards and presumptive standards as work practice standards (including adding repair and delay of repair provisions) and has clarified in both the preamble to the final rule and in edits to the final NSPS OOOOb and EG OOOOc regulatory text that the performance-based volumetric flow rate standards for centrifugal compressors are on a per-seal basis. Under the final NSPS OOOOb and EG OOOOc seal repair requirements, seal repair must be conducted within 90 calendar days from the date of the volumetric emissions measurement. If the repair of the wet or dry seal is technically infeasible, would require a vent blowdown, a compressor station shutdown, or would be unsafe to repair during operation of the unit, the repair can be delayed but must be completed during the next scheduled compressor station shutdown for maintenance, after a scheduled vent blowdown, or within 2 years, whichever is earliest. In addition, if the repair requires replacement of the compressor seal or a part thereof, but the necessary replacement seals or parts cannot be acquired and installed within the repair timelines specified due to supplies being unavailable (where previously sufficiently-stocked), a delay of repair is allowed. However, in order to qualify for a delay of repair, the required seal or parts replacement must be ordered no later than 10 calendar days after the centrifugal compressor seal is added to the delay of repair list due to parts unavailability. The repair must then be completed

as soon as practicable, but no later than 30 calendar days after receipt of the replacement seal or part.

For details, please see discussion in section XI.G.2 (Numeric standard versus work practice standard), and section XI.G.3 (Clarification that the standard is based on a per-seal basis) of the final rule preamble. See also a summary of the final requirements for centrifugal compressors in section X.G of the final rule preamble.

Comment: Commenter (2258-MS) states that clarification is needed on the timing of the repair. Repair of the seal will require the compressor to be taken out of service resulting in a significant reduction in facility capacity. The commenter notes that the availability of parts is also a concern. The commenter recommends that the timing of repair be similar to fugitive emissions where parts availability and performing repairs during the next equipment outage are relevant.

Response II-10-34: As noted in response II-10-33, in response to comments on the December 2022 Supplemental Proposal, the EPA reconsidered establishing the performance based volumetric flow rate standard as a numeric standard. The EPA evaluated the comments provided and have finalized the performance-based volumetric flow rate standards as work practice standards (including adding repair and delay of repair provisions). For details, please see discussion in section XI.G.2 (Numeric standard versus work practice standard). See also a summary of the final requirements for centrifugal compressors in section X.G of the final rule preamble.

Comment: Commenters (2282-Kinder Morgan, Inc, 2305-Williams, 2399-GPA, 2428-API) request that EPA clarify in the final rule that if a defective primary dry seal or a wet seal or internal gas recovery system is repaired or replaced, or if vented emissions from a wet or dry seal compressor are routed to a process; that volumetric flow rate monitoring is not required. If vented emissions from a dry seal compressor or self-contained wet seal compressor are routed to a control device, then volumetric flow rate monitoring should be required every 26,000 hours (or three years) of operation. The commenters add that recordkeeping and reporting requirements be the same as those currently in place for other types of compressors.

Response II-10-35: For centrifugal compressors equipped with wet seals, an owner or operator that complies with the routing to a process or control device options to meet the final standards would not need to comply with the performance-based volumetric flow rate work practice standards.

Under the NSPS OOOOb, centrifugal compressor affected facilities with wet seals must comply with the GHG and VOC standards by reducing methane and VOC emissions from each centrifugal compressor wet seal fluid degassing system by 95 percent by routing emissions via a CVS to a control device. As an alternative to routing the CVS to a control device, an owner or operator may also route the CVS to a process. For specified centrifugal compressors (*i.e.*, self-contained wet seal compressor, wet seal compressor equipped with a mechanical seal, centrifugal compressors equipped with sour seal oil separator and capture system, centrifugal compressors equipped with dry seals), an owner or operator has the option to comply with the rule by meeting

the work practice performance-based volumetric flow rate standards in lieu of them being required to meet emissions be routed to a control device or process.

Thus, the EPA disagrees that there is a need to make changes to the rule for self-contained wet seal compressors that route emissions to a control device or process as those wet seal compressors are already allowed to comply with those rule requirements in lieu of the performance-based volumetric flow rate monitoring requirements under the final NSPS OOOOb standards and EG OOOOc presumptive standards.

Under the NSPS EG OOOOc, each centrifugal compressor designated facility that is a wet seal centrifugal compressor, each self-contained wet seal centrifugal compressor, and each Alaska North Slope centrifugal compressor equipped with sour seal oil separator and capture system, must comply with the GHG standards, using volumetric flow rate as a surrogate. Alternatively, owners or operators have the option of complying with the GHG standards for compressors with wet seals by reducing methane emissions from each centrifugal compressor wet seal fluid degassing system by 95.0 percent by meeting the requirements, or the option of routing the emissions from each centrifugal compressor wet seal fluid degassing system to a process.

For centrifugal compressors equipped with dry seals, in response to comments received on the December 2022 Supplemental Proposal, EPA has finalized a different regulatory approach for dry seal centrifugal compressor affected/designated facilities. For details, please see discussion in section XI.G.1 (Redefining the affected facility to include centrifugal compressors with dry seals and the proposed standard) of the final rule preamble. While not required, the EPA has revised the requirements for centrifugal compressors equipped with dry seals to allow owners and operators to comply with the VOC and GHG standards for compressors with dry seals by reducing VOC and methane emissions from each centrifugal compressor dry seal system by 95.0 percent, or by comply with the option to route the emissions from each centrifugal compressor dry seal system to a process.

See also a summary of the final requirements for centrifugal compressors in section X.G of the final rule preamble.

### ***10.5.3 Recommended Monitoring Provisions (Apply to All Centrifugal Compressors)***

Comment: Commenters (2282-Kinder Morgan, Inc, 2399-GPA, 2428-API)<sup>81</sup> suggest that the EPA's detailed calibration requirements for high-volume samplers, in proposed 40 CFR 60.5386b(c)(5)(i)(B), use a more general requirement that samplers be calibrated in accordance with the manufacturer's specifications. Daily field calibration of methane concentrations and volumetric flow rate vary by manufacturer such that one set of calibration instructions is not appropriate for all high-volume samplers and should not be subject to a universal rule or standard.

Response II-10-36: EPA disagrees with the commenters and is maintaining the calibration requirements from the proposed rule. The approach we are finalizing is performance-based and designed to verify the measurement system for its application in the rulemaking. EPA also notes

---

<sup>81</sup> 2428-API and 2282-KM support all 2399-GPA comments.

that if a manufacturer design is not compatible with the requirements in the final rule, the owner or operator may petition the Administrator for an alternative test method under §60.8(b).

Comment: Commenter (2282-Kinder Morgan, Inc) states that the EPA should allow the use of anemometers, calibrated bags, and other suitable methodologies approved by the EPA for measuring emission rates from dry and wet seals, consistent with Subpart W.

The commenter (2282-Kinder Morgan, Inc) states that the EPA's proposed emissions rate limit applicable to new dry seals requires flow rate measurement every 8,760 hours of operation.<sup>82</sup> To perform such flow rate measurements, the December 2022 proposed NSPS requires specific testing methods.<sup>83</sup> These testing methods require operators to incur significant costs and would not be as practical to implement as the use of anemometers, calibrated bags, and other suitable testing methods approved by the Administrator. For this reason, the commenter request that the EPA allow additional testing methods, including the use of either a hotwire or vane anemometer or calibrated bags, consistent with the measurement methodologies allowed by Subpart W.<sup>84</sup> The commenter does not suggest replacing the currently proposed measurement methods with the use of anemometers; rather, requests the use of additional compliance approaches for more flexibility, as proposed below.

The commenter (2282-Kinder Morgan, Inc) explains that the December 2022 proposed NSPS OOOOb requires that testing of volumetric flow rates using one of two methods: (1) use of a temporary or permanent flow meter according to Method 2D in Appendix A-1 of 40 C.F.R. Part 60; or (2) use of a high-volume sampler according to the methods set forth in 40 CFR 60.5386b(c).<sup>85</sup>

Beginning with the high-volume sampler method, the commenter (2282-Kinder Morgan, Inc) reports that they requested quotes from a vendor for the costs of high-volume samplers, and an individual high-volume sampler would cost \$43,100. In order to have enough high-volume samplers on hand for performing testing, the commenter would need to have approximately 32 samplers across its subsidiaries and affiliates, making the total cost to procure high-volume samplers approximately \$1,380,000. The commenter notes that this is just the capital cost for the equipment necessary to conduct testing with high-volume sampling. Additional operational costs would also result from implementing testing protocols specified in proposed 40 CFR 60.5386b(c), as well as the on-site testing. Notably, the commenter states that these costs have not been factored into the EPA's analysis of cost-effectiveness.<sup>86</sup>

---

<sup>82</sup> See Proposed 40 CFR 60.5380b(a)(4)(iii). Additionally, proposed § 60.5392c(a)(1) includes the same requirements for Subpart OOOOc.

<sup>83</sup> See Proposed 40 CFR 60.5380b(a)(5)(i)(B) (providing for use of a temporary or permanent flow meter pursuant to methods in 40 CFR 60.5386b(b)), 60.5380b(a)(5)(i)(C) (providing for use of a high-volume sampler according to the method set forth in 40 CFR 60.5386b(c)). See also proposed 40 CFR 60.5392c(a)(2)(i) (same requirements, applicable in proposed EG OOOOc).

<sup>84</sup> 40 C.F.R. 98.233(o)(2)(ii), (o)(4)(ii)(B).

<sup>85</sup> See Proposed 40 CFR 60.5380b(a)(5)(i), 60.5386b(b)–(c).

<sup>86</sup> See, e.g., 87 Fed. Reg. at 74,785–86 (only considering costs of maintenance and repairs required to achieve 3 scfm emissions rate without considering testing costs).

Turning to the second method, the commenter (2282-Kinder Morgan, Inc) notes that using a temporary or permanent flow meter pursuant to Method 2D in Appendix A-1, is a less costly option than a high-volume sampler, but it is more invasive and requires physical modification to a system. Method 2D provides for measurement in a pipe or duct “through a rotameter, orifice plate, or similar device to measure flow rate or pressure drop.”<sup>87</sup> According to the commenter, this would require installing a three-way block and bleed valve on the vent system, which would cost an estimated \$2,500.00 per vent for both temporary and permanent setups. For permanent meters, the commenter reports it would cost an additional approximately \$7,400.00 for the meter to be installed permanently. These costs assume no automation.

The commenter (2282-Kinder Morgan, Inc) suggests that a flexible approach would be to also allow the use of hotwire or vane anemometers to measure flow rates, consistent with Subpart W’s approach for measuring emissions from wet seal degassing vents.<sup>88</sup> This methodology would streamline compliance activities for operators by remaining consistent with the approach under Subpart W. In the commenter’s experience, hotwire anemometers are particularly well suited to detecting small gas flows and have strong resolution at low gas flows. Additionally, to ensure accuracy, the commenter has its hotwire anemometers checked and calibrated annually by the manufacturer. Finally, they state that this approach would avoid the unnecessarily high cost of the high-volume samplers. The costs for the anemometer would involve the \$2,500 for the three-way block and bleed valve. Typically, the commenter adds that the anemometer could be used at multiple sites and would not be permanently installed.

Another approach suggested by the commenter (2282-Kinder Morgan, Inc) would be to allow the use of calibrated bags for measuring volumetric flow rates. The commenter reports that they have been successfully utilizing calibrated bags to quantify leaks on various units, including but not limited to vents and flanges, for at least the last seventeen years. This method has proven effective, reliable, and economically feasible. The commenter explains that calibrated bags are a simple concept—the volume of the bag is known, meaning the flow rate can be determined based on the amount of time needed to fill the bag. This measurement method is allowed by the EPA in Subpart W and, notably, by California’s regulations addressing methane emissions from combined seals.<sup>89</sup> Thus, in addition to anemometers, the commenter requests the EPA allow the use of calibrated bags for measuring emissions from wet and dry seals (centrifugal compressors) and rod packing (for reciprocating compressors).

In addition to these validated technologies, and recognizing that technologies continue to evolve and improve, the commenter (2282-Kinder Morgan, Inc) recommends that EPA also allow the use of any other Administrator-approved measuring method, either already approved pursuant to Subpart W, or independently approved by the Administrator pursuant to application of any final version of the Proposed NSPS Rule. They note that this is already contemplated by the EPA’s

---

<sup>87</sup> 40 C.F.R. Part 60, Appendix A-1, Method 2D, § 2.0.

<sup>88</sup> Id. § 98.233(o)(2)(ii).

<sup>89</sup> See, e.g., id. §98.233(o)(2)(i)(A), (o)(4)(ii)(B), (p)(2)(ii)(A), (p)(4)(ii)(B); 17 Cal. Code Regs. §95668(c)(4)(B), (d)(4).

proposed 40 CFR 60.5405c(d), addressing “What test methods and procedures must I use for my centrifugal compressor and reciprocating compressor designated facility.”<sup>90</sup>

The commenter (2282-Kinder Morgan, Inc) states that the concept of new (undefined), alternative proposals, however, is not consistently drafted into the rule. The commenter proposes specific rule changes reflected below, and in the attached Exhibit A of their comment letter [included here], to address this concern.

Recommended *40 CFR 60.5392c(a)(2)(i)(A)* proposed changes (underlined text reflects new text and struck out text reflects deleted text):

(A) You may choose to use any of the methods set forth in §60.5405c(a) to screen for leaks/emissions. For the purposes of this paragraph, when using any of the methods in §60.5405c(a), emissions are detected whenever a leak is detected according to the method. If emissions are detected using the methods set forth in §60.5405c(a), then you must use one of the methods specified in paragraph (a)(2)(i)(B) ~~or through (F)~~ or through (F) of this section to determine the volumetric flow rate. If emissions are not detected using the methods in §60.5405c(a), then you may assume that the volumetric ~~emissions~~ flow rate is ~~are~~ zero.

Recommended *40 CFR 60.5392c(a)(2)(i)(D) through (F)* additions (underlined text indicates new text):

(D) Use a hotwire or vane anemometer according to the methods set forth in §98.234(b).

Hotwire or vane anemometers are a common measurement method that provides reliable data, and it is more cost-effective than a flow meter or high-volume sampler. Hotwire or vane anemometers are also authorized under Subpart W, and it is a method operators are familiar with. The commenter notes that this 40 CFR 98.234(b) is a reference to the methods for use of this technology, as referenced in 40 CFR 98.233(o)(4)(ii)(B).

(E) Use a calibrated bag according to the methods set forth in §98.234(b).

40 CFR 98.234(b) notes that this is a reference to the methods for use of this technology, as referenced in 40 CFR 98.233(o)(2)(ii). The commenter states that they would be open to re-locating the same/similar methodology description into §60.5405c if that is preferred by the EPA.

(F) Use of an alternative method, as set forth in §60.5405c(d).

---

<sup>90</sup> Proposed § 60.5405c(d) (“As an alternative to a high-volume sampler, you may use any other method that has been validated in accordance with the procedures specified in Method 301 in appendix A in 40 CFR part 63, subject to Administrator approval, as specified in §60.8(b).”).

Technologies continue to advance and improve. The commenter states that the EPA recognizes this in §60.5405c(d) and should explicitly state it here.

Response II-10-37: EPA disagrees with the commenter. While we acknowledge that the methods suggested by the commenter are allowed in 40 CFR part 98 subpart W and are adequate for estimating emission inventories, as noted in the December 2022 Supplemental Proposal, these types of measurements are not as well defined or prescriptive as the methods EPA generally requires for demonstrating compliance with a standard. As such, we are not updating the final rule to include these additional types of measurements.

Comment: Commenters (2366-BHE, 2428-API) recommend that for both wet and dry seal compressors, the EPA more clearly explain and define requirements for measuring seal methane emission rates. The commenters recommend that measurements include both flowrate and the methane content of the stream (measured at operators' discretion) so that scfm of methane can be determined. For wet seals with closed systems, commenter (2366-BHE) recommends that the units not require measurement or monitoring because the inherent design limits emissions. For cases where measurement is conducted, the commenter suggests that requirements be more clearly defined such that the emission threshold should be 3 scfm of methane, not a flowrate of 3 scfm.

According to commenter (2428-API), both wet seal and dry seal systems often use an inert gas, such as nitrogen, for system blankets at positive pressure. That nitrogen vents through the same vent as the seal gas. So measured total vent rates may be overestimating the amount of methane or VOC being vented to atmosphere. The commenter recommends that the EPA make clear that the standard could be interpreted as either total volumetric flow or methane and VOC flow depending on which method of monitoring is employed. The commenter specifically suggests that the EPA expand the volumetric flow measurement options to allow for alternative ways to obtain the methane and VOC flow such as:

- Use of thermal mass meter or ultrasonic meter readings in conjunction with gas composition samples to calculate methane and VOC flow, or
- Flow balance equations (i.e., if the amount of inert gas into the system is metered, then that volume could be subtracted from the total flow measurement, thus yielding the methane and VOC only flow.)

Response II-10-38: EPA notes that when measurement of flow rate is required, owners and operators may use a high-volume sampler. When using a high-volume sampler, the high-volume sampler must have a methane sensor. As such, the measurement is taken in terms of methane and a separate method for methane determination is not needed.

Comment: Commenter (2258-MSC) states that the EPA should allow flexibility regarding methods for identifying the need for a seal repair. The commenter notes that centrifugal compressors can be monitored for many parameters to ensure proper operation and to prevent damage to the unit. This includes monitoring and regulating gas pressure to the seals. The

commenter requests that this type of monitoring be allowed as an alternative to annual volumetric flow monitoring.

Response II-10-39: EPA notes that it has provided some flexibility in monitoring centrifugal compressor seals. For example, OGI or EPA Method 21 may be used to screen for leaks in lieu of measuring the volumetric flowrate.

#### ***10.5.4 Performance-Based Monitoring Alternative for Measurement of VOC and Methane Flow Rate***

Comment: Commenter (2317-AOGA) requests that EPA add a performance-based monitoring alternative for measurement of VOC and methane flow rate from seal gas vents. The commenter explains that wet seal compressors deployed in the natural gas transportation sector process pipeline quality natural gas which is 95.0 to 98.0 percent methane.<sup>91</sup> Compressors installed in upstream oil and gas production operations process gas that includes other constituents, such as carbon dioxide and ethane, and that exhibits sharp variations in flow volume over short intervals. A volumetric flow limit for VOCs and methane from seal gas vents in oil and gas production must be supported by a monitoring method that is capable of screening out other constituents in the vent gas stream. The two methods proposed in EG OOOOc to monitor the seal gas vent flow rate, Method 2D and a high-flow sampler,<sup>92</sup> lack that capability [same two methods included in NSPS OOOOb].

Commenter (2317-AOGA) notes that Method 2D – Measurement of Gas Volume Flow Rates in Small Pipes and Ducts, requires that all the gas flow in the pipe or duct is directed through a rotameter, orifice plate or similar device to measure volume flow rate or pressure drop. The method also requires that the device has been previously calibrated in a manner that ensures its proper calibration for the gas being measured. Absolute temperature and pressure measurements are made to allow correction of volumetric flow rates to standard conditions. The method also provides general specifications for the gas meter. “A rotameter, orifice plate, or other volume rate or pressure drop measuring device capable of measuring the stack flow rate to within  $\pm 5$  percent. The metering device shall be equipped with a temperature gauge accurate to within  $\pm 2$  percent of the minimum absolute stack temperature and a pressure gauge (accurate to within  $\pm 5$  mm Hg). The capacity of the metering device shall be sufficient for the expected maximum and minimum flow rates at the stack gas conditions.”

Commenter (2317-AOGA) notes that gas flow rates from centrifugal compressor vents may be very low and non-continuous. Volumetric flow meter technologies prescribed by Method 2D may not be able to accurately measure these low volume flow rates. Other technologies, e.g., thermal mass flow meters (TMFMs), are capable of accurately measuring very low gas flow rates. TMFMs measure mass flow, which can easily be converted to volume flow based on engineering knowledge of the gas being measured. In fact, the EPA has evaluated TMFMs and determined that the technology can measure flow as accurately or more accurately than volume

---

<sup>91</sup> <https://www.epa.gov/natural-gas-star-program/overview-oil-and-natural-gas-industry>.

<sup>92</sup> Proposed § 60.5405c(b). 28 Proposed § 60.5405c.

flow meters. TMFMs can meet or exceed the  $\pm 5$  percent accuracy requirements in Method 2D, but they do not meet the requirement in that method to measure volume flow rate.

Commenter (2317-AOGA) recommends that the proposal be revised to set performance-based flow measurement criteria, as an alternative to Method 2D. Any commercially available technology that is suitable and capable of accurately measuring gas flow to within  $\pm 5$  percent should be authorized to monitor compliance with the volumetric flow limit for centrifugal compressor seal gas vent flow. Thermal mass flow meters should be authorized, even though they do not directly measure volumetric flow rate. They added that other current or future commercially available technologies should also be allowed, if they meet minimum performance specifications. Importantly, the accuracy specifications should accommodate variability resulting from low flow conditions.

Commenter (2317-AOGA) states that the proposal allows parties to apply to the EPA for validation of alternate test methods following the procedures of Method 301, subject to Administrator approval as specified in 40 CFR 60.8(b). However, the commenters contend that this option is unnecessarily burdensome and time-consuming, where a performance-based set of measurement criteria can ensure accuracy while providing flexibility to adapt measurement techniques to the challenges of low flow volumes, variability in the composition, density and molecular weight of vent gas and variability in the flow rate. The commenter requests that the rules allow flow rate measurement (volume or mass) approaches using any instrument appropriate for the vent stream being measured, properly calibrated and meeting  $\pm 5$  percent accuracy requirements. With these refinements, the commenter would support a volumetric de minimis limit as a vehicle to establish BSER for wet seal compressors deployed in Alaska production operations.

This commenter (3839-AOGA) also provided additional information on their concerns related to being able to account for non-methane and non-VOC gas accounting when conducting volumetric flow rate monitoring methods. They reiterated that the two methods proposed by EPA to monitor the seal gas vent flow rate, Method 2D and a high-flow sampler, lack that capability.” The commenter notes that upstream field gas compressed by centrifugal wet seal compressor (and dry seal compressors) likely has significant volumes of non-methane/non-VOC constituents in the gas (ethane, carbon dioxide, etc.). The state that these constituents should be able to be subtracted from the volumetric measurement using engineering knowledge and calculations. Then the resulting flow measurement can be compared against the propose volumetric standard. They add that TMFMs should be allowable to derive a volumetric flow in low pressure/low flow situations like those on the ANS for wet seal compressor vents. They contend that they are also more precise than the technologies described in Method 2D for low pressure/low flow circumstances. As written, they state that the precision requirements ( $\pm 5\%$ ) of Method 2D will likely not be able to be achieved for these low pressure/low flow situations, which necessitates a compliance option that is feasible. The commenter believes that would be the allowance of a TMFM, but a different proposal would be to change the precision requirements for these applications to allow a wider range of precision that what is in Method 2D. AOGA suggests an allowance of up to  $\pm 10\%$  for low pressure/low flow situations.

Response II-10-40: Mass thermal flowmeters rely on knowledge of the gas stream in order to provide accurate measurements. EPA is concerned that due to the variability in the gas that may leak from the compressor a mass thermal flowmeter may not be able to provide accurate measurements. Without further information to demonstrate that the variability of the gas stream is unimportant to the precision of the measurement, EPA considers the more direct measurement techniques of EPA Method 2D to be more appropriate for measuring the volumetric flowrate from the compressor.

EPA Method 2D describes how to conduct the measurement of flow through direct measurement or by using pressure drop measurements to calculate flow. The method allows for many different types of measurement devices, including but not limited to rotameters and orifice plates, to accomplish the measurement, as long as the device measures the gas flow (volume rate or pressure drop) accurately. Because EPA Method 2D is not limiting in the types of measurement devices that can be used, we believe the method provide owners and operators with enough flexibility to choose the type of measurement device that works best for the situation.

EPA notes that when measurement of flow rate is required, owners and operators may use a high-volume sampler. When using a high-volume sampler, the high-volume sampler must have a methane sensor. As such, the measurement is taken in terms of methane and a separate method for methane determination is not needed.

## Chapter 11. Reciprocating Compressors

### 11.1 New Source Performance Standard (NSPS) OOOOb Affected Facility/Definitions

[**Note:** Many of the comments provided for reciprocating compressors would also apply to designated facilities under EG OOOOc. For comments that were provided with the specific focus on EG OOOOc, see section 11.4 of this Chapter.]

Comment: Commenter (2227-Western Energy Alliance (WEA)) states that the EPA should not be regulating reciprocating compressors that are non-emitting. The commenter notes that rod packings routed to a closed vent system (CVS) provide a solution for eliminating emissions, yet EPA is treating them as affected facilities with unnecessary regulation. If any leaks were to occur in the CVS, the emissions would be detected and repaired through leak detection and repair (LDAR) inspection requirements.

Response II-11-1: The final NSPS OOOOb standards and EG OOOOc presumptive standards both allow for owners and operators, as an alternative to meeting a performance-based volumetric flow rate standard, to collect emissions (methane and/or VOC) from their reciprocating compressor rod packing using a rod packing emissions collection system that is operated to route the rod packing emissions to a process through a closed vent system. In order to comply with this option, the owner or operator must equip the reciprocating compressor with a closed vent system that meets design requirements and operates with no identifiable emissions, which consists of using procedures for conducting OGI as specified under the CVS requirements. The EPA disagrees that these affected facility/designated facility requirements constitute unnecessary regulation as there is a need to ensure the integrity of the CVS, and EPA has included the minimum requirements necessary to ensure compliance.

See section X.I. of the final rule preamble for a summary of the final standards/presumptive standards for reciprocating compressors. See final standards/presumptive standards at 40 CFR 60.5385b and 40 CFR 60.5393c.

Comment: Commenters (2257-Michigan Oil and Gas Association (MOGA), 2326-American Exploration and Production Council (AXPC)) support the EPA's exemption of reciprocal compressors "located at a well site, or an adjacent well site and servicing more than one well site, is not an affected facility" as provided in both new source performance standards (NSPS) OOOO and NSPS OOOOa. According to commenter (2257-MOGA), well operators visit and service these wells and associated compressors daily to inspect for proper operation, leaks and to conduct maintenance and repair activities. Any necessary repairs are repaired as soon as possible to avoid product loss and to maximize profit returns. Further, the commenter suggests that if the EPA wishes to propose monitoring for well site compressors, the commenter recommends the EPA allow the more feasible and cost-effective monthly Auditory, Visual & Olfactory (AVO) inspection and documentation, similar to the requirements allowed under 40 CFR 60.5416a.

Response II-11-2: Section XI.I.5 of the preamble to the final rule details EPA's rationale and reasoning regarding the applicability of requirements to compressors located at centralized

production facilities. Reciprocating compressors located at well sites are not subject to requirements. However, reciprocating compressors located at centralized production facilities that consist of equipment at a single surface site used to gather, for the purpose of sale or processing to sell, crude oil, condensate, produced water, or intermediate hydrocarbon liquid from one or more offsite natural gas or oil production wells (including reciprocating compressors) are subject to reciprocating compressor requirements.

Comment: Commenters (2305-Williams, 2428-American Petroleum Institute (API)) state that the rule does not address conducting annual measurements on temporary, portable and emergency compressors. The commenters contend that these compressors should be exempt from 40 CFR 60.5365b(c) because, according to commenter (2428-API) conducting these measurements is logistically impractical and that equipment that is intended for temporary use and is not a stationary source should not be subject to either NSPS OOOOb or emission guidelines (EG) OOOOc.

According to commenter (2305-Williams), these compressors are on-site typically less than 12 calendar months and/or operate for 10-20% of normal annual operating schedule. They add that many states provide for this operating flexibility within existing permits or the current structure of air regulations.

Commenter (2428-API) requests the EPA make the following clarifications to address this concern (underlined text reflects new text):

*40 CFR 60.5365b(c):*

(c) Each reciprocating compressor affected facility, which is a single reciprocating compressor. A reciprocating compressor located at a well site is not an affected facility under this subpart. A reciprocating compressor located at a centralized production facility is an affected facility under this subpart. A reciprocating compressor that is skid mounted or permanently attached to something that is mobile (such as trucks, railcars, barges, or ships) and intended to be located at a site for less than 12 consecutive months is not an affected facility under this subpart.

Response II-11-3: With regards to the commenters' request that the applicability of the rule not apply to temporary, portable and emergency compressors because conducting measurements is logistically impractical, the EPA disagrees. The EPA considered similar comments on the November 2021 Proposal, see discussion in section IV.I.1.b of the December Supplemental Proposal preamble,<sup>1</sup> and maintains that basing reciprocating compressor flow rate monitoring on the hours of operation (*i.e.*, 8,760 hours) in lieu of requiring monitoring based on a calendar year addresses limited-use reciprocating compressors and allows owners and operators flexibility when planning maintenance and an exemption is not warranted.

Comment: Commenter (2172-Kentucky Oil and Gas Association (KOGA)) suggests that the EPA's proposal to define an additional group of well affected facilities (*i.e.*, the "small well

---

<sup>1</sup> 87 FR 74796, December 6, 2022.

site”) and allowing a single well with a single piece of production equipment (such as a small compressor) to perform fugitive emission surveys as in what is required for a single well, should also be extended to cover reciprocating compressors.

Response II-11-4: Section XI.I.5 of the preamble to the final rule details EPA’s intent regarding the applicability of requirements to compressors located at centralized production facilities. That intent is that reciprocating compressors located at well sites are not subject to reciprocating compressor requirements. This is included in the final rule. However, reciprocating compressors located at centralized production facilities that consist of equipment at a single surface site used to gather, for the purpose of sale or processing to sell, crude oil, condensate, produced water, or intermediate hydrocarbon liquid from one or more offsite natural gas or oil production wells (including reciprocating compressors) are subject to reciprocating compressor requirements.

## **11.2 NSPS OOOOb Proposed Best System of Emission Reduction (BSER)**

[*Note:* Most of the comments provided on the BSER for NSPS OOOOb also apply to EG OOOOc. For specific comments that apply to EG OOOOc, see section 11.4 of this Chapter).]

### ***11.2.1 Work Practice Standard vs Emission Limitation Standard***

Comment: Several Commenters (2305-Williams, 2326-AXPC, 2399-GPA Midstream Association (GPA), 2428-API, 2483-Interstate Natural Gas Association of America (INGAA)) state that reciprocating compressor rod packing requirements should be considered a work practice standard instead of an emission standard. The commenters state that under a work practice standard, the operator would screen the compressor to determine the volumetric leak rate from each cylinder and replace the rod packing where the volumetric leak rate exceeds the applicable threshold. So long as the operator timely replaces rod packing, there is no deviation. Therefore, the volumetric flow rate would serve as a trigger for repair activity under a work practice standard instead of a numeric emission standard.

Commenter (2483-INGAA) states that in the November 2021 proposal, the EPA described a work practice standard that would require yearly monitoring and replacement of the rod packing when the measured emissions exceed 2 standard cubic feet per minute (scfm). The EPA cited the Natural Gas STAR document in the November 2021 proposal that described a work practice approach for rod packing replacement. The commenter further states that the work practice approach, including a 2 scfm threshold for triggering rod packing replacement, was further demonstrated at the EPA’s November 2019 Natural Gas STAR and Methane Challenge Workshop.<sup>2</sup> The commenter adds that the California regulation<sup>3</sup> cited by the EPA in the Technical Support Document (TSD) is also a work practice standard with a 2 scfm threshold. However, the commenter notes that the EPA appears to have proposed an emission limitation standard in the December 2022 proposal. The 2022 Supplemental Background TSD does not

---

<sup>2</sup> “DTE Energy Rod Packing Evaluation and Replacement Program,” U.S. EPA 2019 Natural Gas STAR & Methane Challenge Workshop (November 2019).

<sup>3</sup> CARB. “[Regulation for Greenhouse Gas Emission Standards for Crude Oil and Natural Gas Facilities.]” Oil and Gas Final Regulation Order (ca.gov).

include any information to support an emission standard rather than a work practice – and the October 2021 original Background Technical Support Document<sup>4</sup> envisioned a work practice. Thus, if EPA intended to propose an emission limitation standard, it gave no justification for, or analysis of, the change, which the commenter states is arbitrary and capricious. The commenter continues that based on the two TSDs; it appears that EPA intended to propose a work practice standard that triggers rod packing maintenance when the threshold is exceeded. The extensive and case-by-case nature of rod packing replacement makes it particularly unsuitable for an emission limitation standard.

Commenter (2399-GPA, 2428-API)<sup>5</sup> states that similar to the LDAR program, owners and operators would have to monitor the rod packing to determine if fugitive emissions have reached a threshold level and, if the threshold is reached, repair or replace the rod packing. Such a situation accords with the statute’s determination of when using a work practice standard is appropriate: where “a pollutant or pollutants cannot be emitted through a conveyance designed and constructed to emit or capture such pollutant.” 42 U.S.C. § 7411(h)(2).

Commenters (2305-Williams, 2399-GPA, 2428-API)<sup>6</sup> state that as an emission standard, the proposed rod packing requirements are unworkable. Operators would be forced to decide between continuing to operate out of compliance until a maintenance shutdown can be scheduled or shutting down the compressor immediately to conduct the repair and venting or flaring gas that can no longer be compressed and transported during the unscheduled shutdown. A forced shutdown will likely result in significantly more emissions than continuing to operate until the next scheduled maintenance shutdown. For systems that are at capacity, shifting the incoming gas to another station is not a feasible or reliable option, resulting in additional flaring and venting, which is magnified given the time it takes to have producers shut-in wells. According to commenter (2305-Williams), the December 2022 proposal also makes an incorrect assumption that the gas can simply be rerouted to other natural gas compression facilities, but often that is not a possibility as piping is not in place to bypass a facility, or there may not be an alternative facility available. Commenter (2428-API) adds that while it is true that flow can be measured, it is not technically or economically practicable to install measurement systems that would assure compliance with a numeric emissions limitation. See CAA § 111(h)(2)(B).

Commenters (2305-Williams, 2399-GPA) suggest that under a work practice framework (which they say is the only supported option), companies would be required to complete a corrective action within 720 hours of operation (equivalent to 30 days) and allow for delay of repair, similar to leak monitoring programs, of up to two years if repair goes beyond the replacement of rod packing. The commenters note that exceeding the vent rate threshold after the time for corrective action would be a deviation, but exceeding the vent rate within the time allotted to correct would not.

<sup>4</sup> EPA, Oil and Natural Gas Sector: Emission Standards for New, Reconstructed, and Modified Sources and Emissions Guidelines for Existing Sources: Oil and Natural Gas Sector Climate Review, Background Technical Support Document for the Proposed New Source Performance Standards (NSPS) and Emissions Guidelines (EG) (Oct. 2021), Docket ID No. EPA-HQ-OAR-2021-0317-0166 (hereinafter “2021 Background TSD”).

<sup>5</sup> API endorses GPA’s comments.

<sup>6</sup> API endorses GPA’s comments.

Response II-11-5: Section XI.I.1 (Numeric standard versus work practice standard) of the preamble to the final rule details EPA's rationale and reasoning that responds to the numeric standard versus work practice standard comments and establishes final standards/presumptive standards related to reciprocating compressors as work practice standards.

Comment: Commenter (2428-API) states the EPA proposes to establish the 2 scfm flowrate as a not-to-exceed standard of performance, such that a violation occurs if flow rate exceeds that value (87 FR 74797). In doing so, the commenter suggests that the EPA fundamentally misconstrues the manufacturers recommendations. In practice, exceeding a manufacturer-recommended flow rate is an indication that a repair should be made. Exceeding that rate does not necessarily compromise operability of the unit and, in fact, the values are selected to allow continued operation for the period necessary to arrange for needed repairs to be made. According to the commenter, the EPA without explanation proposes to transform what in practice constitutes an action level into a regulatory cap that cannot be exceeded without the prospect of incurring a violation. The commenter states that the EPA's proposal is at odds with the facts and is an unreasonable reinterpretation of standard maintenance practices.

Therefore, the commenter (2428-API) argues that, if the EPA is intent on setting a numeric standard of performance, the value must be well above the 2 scfm that the EPA believes to be the standard manufacturer recommendations. The value must accommodate operations for a reasonable and potentially significant period of time that may be needed to accomplish needed repairs. If the EPA takes this path, a re-proposal is necessary so that commenters can know the newly proposed value, understand EPA's rationale, and have an opportunity to submit comments on the record.

Response II-11-6: Section X.I.1 (Numeric standard versus work practice standard) of the preamble to the final rule details EPA's rationale and reasoning that responds to the numeric standard versus work practice standard comments and establishes final standards/presumptive standards related to reciprocating compressors as work practice standards.

### ***11.2.2 Clarification that Emissions Threshold is on a Per Cylinder Basis***

Comment: Several commenters (2258-Marcellus Shale Coalition (MSC), 2282-Kinder Morgan, Inc., 2305-Williams, 2326-AXPC, 2366-Berkshire Hathaway Energy Company (BHE), 2391-Chesapeake Energy Corporation (CEC), 2399-GPA, 2428-API, 2483-INGAA) request clarification that the volumetric standard applies to each rod packing (or throw) or set of packing and not the entire compressor and that the rule text clearly addresses manifolded vents on a combined basis. The commenters cite the precedent set by the California Air Resources Board (CARB) where reciprocating compressors in California are restricted to 2 scfm per rod packing, and not per compressor as set forth in 17 CCR § 95668(c)(4)(D), Greenhouse Gas Emission Standards for Crude Oil and Natural Gas Facilities) (allowing for "a combined rod packing or seal emission flow rate greater than the number of compression cylinders multiplied by two (2) scfm") which states:

(6) with a rod packing or seal with a measured emission flow rate greater than two (2) standard cubic feet per minute (scfm), or a combined rod packing or seal emission flow

rate greater than the number of compression cylinders multiplied by two (2) scfm...

The commenters (2258-MSA, 2282-Kinder Morgan, Inc., 2305-Williams, 2326-AXPC, 2366-BHE, 2391-CEC, 2399-GPA, 2428-API, 2483-INGAA) state that this approach makes sense and is consistent with the proposed BSER from the November 2021 proposal. In addition, the EPA based its proposal to measure the flow rate of each cylinder on volumetric emission factors used in the 1996 EPA/GRI report quantifying methane emissions from the U.S. natural gas industry—which EPA notes are per cylinder. See 86 Fed. Reg. at 63216 & n.277.

Commenter (2399-GPA, 2428-API)<sup>7</sup> states that combining is appropriate because a single reciprocating compressor may have multiple cylinders (also referred to as compression cylinders, throws, or packing case vents) routed to a common vent stack, making rod packing-specific measurements impractical and unreasonable.

According to commenter (2282-Kinder Morgan, Inc.), the EPA’s preamble discussion, and at least some of the proposed rule text, imply that the emissions rate would be on a per-rod packing basis, and the commenter understands this to be the EPA’s intent. It is important that the EPA’s final rule more clearly reflect this intent. Specifically, according to commenter (2428-API), the proposed text provided in 40 CFR 60.5380b or 40 CFR 60.5385b(a), does not provide the distinction that the limits are per cylinder. It would be impractical for a compressor with multiple cylinders to operate the same as a compressor with only a single cylinder.

Commenter (2282-Kinder Morgan, Inc.) states that the rule language must more clearly address manifolded vents (of multiple rod packing units) on a combined basis. The commenter supports the approach to determine the required leak rate for the manifolded units, whereby the operator would multiply the required flow rate by the number of units flowing to that single vent. It appears that this concept of multiple seals manifolded to one vent is intended to be captured in the proposed regulations at 40 CFR 60.5380b(a)(5)(i)–(ii), 60.5415b(d)(2), 60.5392c(a)(2)(i)–(ii), and 60.5415c(c)(1). However, the proposed regulatory sections addressing the actual volumetric flow rate requirement do not clearly incorporate the preamble concept of multiplying the emissions rate by the number of manifolded cylinders or throws. The commenter asserts that this lack of regulatory text on manifolded vents makes it difficult for operators to rely on the preamble text alone.

Several commenters (2282-Kinder Morgan, Inc., 2305-Williams, 2391-CEC, 2399-GPA, 2428-API, 2483-INGAA) provide suggested changes to regulation language to address concerns. The commenters urge the EPA to adopt their proposed revisions. They explain that their suggested changes will clarify the regulatory text to align with the intent of the December 2022 proposal preamble to allow for grouping of manifolded vents where an emissions rate limit is applicable to such rod packing or throw.

- Commenter (2305-Williams) recommends that 40 CFR 60.5385b(a) be revised as follows (underlined text reflects new text):

---

<sup>7</sup> GPA comments endorsed by API.

*40 CFR 60.5385b-*

(a) The volumetric flow rate, measured in accordance with paragraphs (b) or (c) of this section, must not exceed 2 standard cubic feet per minute (scfm) per cylinder or a combined rod packing emission flow rate greater than the number of compression cylinders multiplied by 2 scfm. You must conduct measurements of the volumetric flow rate in accordance with the schedule specified in paragraphs (a)(1) and (2) of this section.

- Commenter (2391-CEC) suggests adding “of each compressor cylinder” or similar language as appropriate in proposed 40 CFR 60.5385b and 60.5393c. They also request that EPA also make conforming edits to other provisions in both NSPS OOOOb and EG OOOOc, as necessary. Example language follows:

§60.5385b What GHG and VOC standards apply to reciprocating compressor affected facilities?

Each reciprocating compressor affected facility must comply with the GHG and VOC standards, using volumetric flow rate of each compressor cylinder as a surrogate, in paragraphs (a) through (c) of this section, or the GHG and VOC standards in paragraph (d) of this section. You must also comply with the requirements in paragraphs (e) through (g) of this section.

(a) The volumetric flow rate of each compressor cylinder, measured in accordance with paragraphs (b) of this section, must not exceed 2 standard cubic feet per minute (scfm). You must conduct measurements of the volumetric flow rate in accordance with the schedule specified in paragraphs (a)(1) and (2) of this section.\*\*\*

- Commenter (2399-GPA) suggests the following edits to 40 CFR 60.5385b(a) (underlined text reflects new text):

*40 CFR 60.5385b(a)-*

The volumetric flow rate, measured in accordance with paragraphs (b) or (c) of this section, must not exceed 2 standard cubic feet per minute (scfm) per cylinder, or a combined rod packing emission flow rate greater than the number of compression cylinders multiplied by 2 scfm. You must conduct measurements of the volumetric flow rate in accordance with the schedule specified in paragraphs (a)(1) and (2) of this section.

- Commenter (2483-INGAA) suggests the following edits to 40 CFR 60.5385b(a) and 60.5393c(a) (underlined text reflects new text and struck out text reflects deleted text):

*40 CFR 60.5385b(a)/40 CFR 60.5393c-*

~~(a) The volumetric flow rate, measured in accordance with paragraphs (b) of this section, must not exceed 2 standard cubic feet per minute (scfm). You must conduct measurements of the volumetric flow rate in accordance with the schedule specified in paragraphs (a)(1) and (2) of this section and determine the volumetric flow rate in accordance with paragraph (b) of this section. If the volumetric flow rate, measured in accordance with paragraph (b) of this section, for a rod packing exceeds 2 standard cubic feet per minute (scfm), or if the combined volumetric flow rate, measured in accordance with paragraph (b) of this section, for multiple rod packings that are manifolded together exceeds 2 scfm multiplied by the number of rod packings, the rod packing or packings must be repaired as provided in paragraph (a)(3) of this section.~~

- Commenter (2428-API) suggests the following edits to 40 CFR 60.5385b(a) and 60.5393c(a) (underlined text reflects new text):

*40 CFR 60.5385b(a)/40 CFR 60.5393c(a)-*

(a) The volumetric flow rate, measured in accordance with paragraphs (b) of this section, must not exceed 2 standard cubic feet per minute (scfm) per individual cylinder. If the individual cylinders are manifolded to a single open-ended vent line, the volumetric flow rate must not exceed the sum of the individual cylinders multiplied by 2 scfm. You must conduct measurements of the volumetric flow rate in accordance with the schedule specified in paragraphs (a)(1) and (2) of this section.

- Commenter (2282-Kinder Morgan, Inc.) requests that the EPA incorporate modest changes to 40 CFR 60.5393c(a), 60.5410c(d)(1), and 60.5415c(f)(1), as well as the respective NSPS OOOOb provisions.<sup>8</sup> The commenter notes that their proposed changes would align the regulatory language with the intent that the required flow rate for more than one rod packing unit that are manifolded to one vent would be the rate limit for an individual rod packing unit, multiplied by the number of units and to clarify the standards' applicability to individual rod packing units rather than an entire compressor. Recommended changes are provided below (underlined text reflects new text and struck out text reflects deleted text). [This comment applies to both NSPS OOOOb and EG OOOOc, although change recommendations were only provided for EG OOOOc regulation.]

---

<sup>8</sup> The commensurate sections in Subpart OOOOb would be §§60.5385b(a), and 60.5410b(e)(1).

*40 CFR 60.5393c(a)-*

(a) The volumetric flow rate, measured in accordance with paragraphs (b) of this section, must not exceed 2 standard cubic feet per minute (scfm), or in the case of manifolded groups of reciprocating compressor rod packing vents, 2 scfm multiplied by the number of individual reciprocating compressor rod packing units. You must conduct measurements of the volumetric flow rate in accordance with the schedule specified in paragraphs (a)(1) and (2) of this section.

*40 CFR 60.5393c(a)(1) suggested changes (underlined text reflects new text)-<sup>9</sup>*

(1) You must conduct your first volumetric flow rate measurements from your reciprocating compressor rod packing vent on or before 8,760 hours of operation after the effective date of an approved state or tribal plan or on or before 8,760 hours of operation after startup, whichever is later.

The commenter (2282-Kinder Morgan, Inc.) proposes to use “applicable” here given their suggested revisions above which clarify that if there is more than one rod packing unit, the target threshold is 2 scfm multiplied by the number of units.

*40 CFR 60.5393c(a)(2) suggested changes (underlined text reflects new text and struck out text reflects deleted text) -<sup>10</sup>*

(2) You must conduct subsequent volumetric flow rate measurements from your reciprocating compressor rod packing vent on or before 8,760 hours of operation after the previous measurement which demonstrates compliance with the 2-scfm-applicable volumetric flow rate.

*40 CFR 60.5410c(d)(1) suggested language (underlined text reflects new text and struck out text reflects deleted text) -*

(1) If you comply with §60.5393c(a) by maintaining volumetric flow rate ~~below 2 scfm~~, you must maintain the volumetric flow rate for each rod packing unit below 2 scfm (or in the case of manifolded groups of reciprocating compressor rod packing vents, 2 scfm multiplied by the number of individual reciprocating compressor rod packing units), and you must conduct your initial annual volumetric flow rate measurement as required by §60.5393c(a)(1).

*40 CFR 60.5415c(f)(1) suggested language (underlined text reflects new text and struck out text reflects deleted text) -*

(1) You must maintain the volumetric flow rate at or below 2 scfm (or in the case of manifolded groups of reciprocating compressor rod packing vents, 2 scfm multiplied

---

<sup>9</sup> The Subpart OOOOb section to which these changes should also apply is 40 CFR 60.5410b(e)(1).

<sup>10</sup> The Subpart OOOOb section to which these changes should also apply is 40 CFR 60.5410b(e)(2).

by the number of individual reciprocating compressor rod packing units) and you must conduct the required volumetric flow rate measurement of your reciprocating compressor rod packing in accordance with §60.5393c(b) on or before 8,760 hours of operation after your last volumetric flow rate measurement which demonstrated compliance with the ~~2-scfm~~applicable volumetric flow rate.

Response II-11-7: Section XI.I.3 (Clarification that the standard is based on a per-cylinder basis) of the preamble to the final rule responds to these comments. The EPA agrees that the basis and intent of the performance-based volumetric flow rate standard is that it be applied on a per-cylinder basis and that clarity was needed in both the NSPS OOOOb and EG OOOOc regulatory text. EPA considered the comments/suggested edits and made the necessary clarifying changes to the final NSPS OOOOb and EG OOOOc regulatory text to address commenter's concerns.

### ***11.2.3 Other Comments on Proposed Standards***

Comment: Several commenters (2282-Kinder Morgan, Inc., 2410-California Office of the Attorney General (CA AG) et al, 2433-Environmental Defense Fund (EDF) et al, 2483-INGAA) express general support for the EPA's proposed standard for all reciprocating compressors, except those located at well sites.

However, while commenter (2433-EDF et al) expresses support for key aspects of the EPA's proposed standards for reciprocating compressors, including extending requirements to existing sources and to centralized production facilities in the production segment, the commenter urges the EPA to lower the emissions threshold for rod packing replacement based on annual monitoring and to consider measures to reduce the significant emissions from compressor exhaust.

Response II-11-8: For comments that are supportive comments on reciprocating compressor requirements as of the December 2022 Proposal, the proposed requirements have not changed and no response is required.

In response to the comment urging EPA to lower the emissions threshold for rod packing replacement, there is insufficient information at this time to support the establishment of a standard based on a lower volumetric flow rate.

In response to the commenter's request that EPA consider measures to reduce emissions from compressor exhaust, see Response II-11-20.

Comment: Commenter (2180-Pennsylvania Department of Environmental Protection (PADEP)) disagrees with the proposed rule requirements for reciprocating compressors. Since 2018, the commenter reports that the State of Pennsylvania has required similar reciprocating compressors to replace the rod end packing after every 26,000 hours of operation or every 36 months. The commenter also disagrees with the EPA's proposal mandating that oil and gas operators must monitor and quantify emissions from the rod end packing and replace the packing if the volumetric flow rate exceeds 2 standard cubic feet per minute (scfm). The commenter recognizes that the proposed emission limit of 2 scfm is equivalent to a flow rate of 120 standard cubic feet

per hour (scfh), which is approximately double the maximum emission rate of reciprocating compressors found in Table 7-2 of the technical support document (TSD) (EPA-HQ-OAR-2021-0317-0166). The commenter suggests that the EPA either reconsider the 2 scfm emission rate and reduce the emission rate to 1 scfm or less to be consistent with the emission rates in Table 7-2; or, maintain the 26,000 operating hour or 36-month replacement schedule.

Response II-11-9: In response to the comment requesting that EPA lower the emissions threshold for rod packing replacement, there is insufficient information at this time to support the establishment of a standard based on a lower volumetric flow rate.

With regards to the comment noting that the 2 scfm performance-based volumetric flow rate standard is more than double the maximum emission rate of reciprocating compressors found in Table 7-2 of the November 2021 TSD, and that the emission rates in Table 7-2 support requiring a lower performance-based volumetric flow rate standard for reciprocating compressors, we disagree. The baseline estimates in Table 7-2 represent an average and individual reciprocating compressor volumetric flow rates would be expected to be both higher and lower than the rates included in Table 7-2. As noted in the November 2021 TSD, the emissions after the replacement of the rod packing were calculated using an emission rate of 11.5 scfh/cylinder, which is the emission factor identified by EPA's Natural Gas Star program as representing emissions from newly installed rod packing.<sup>11</sup> Emissions would be expected to increase (and emission reductions decrease) in subsequent years until the next time the annual measurements require that the rod packing be replaced. As for the request that the EPA maintain the 26,000 operating hour or 36-month replacement schedule, see section XI.I.2 (Rod packing changeout schedule-based approach) of the preamble to the final rule for EPA's response to that comment.

Comment: Commenter (2248-North Dakota Petroleum Council (NDPC)) states that they believe the requirements [for reciprocating compressors] are onerous and costly. The commenter contends that any benefits that could potentially come from requiring replacement will be outweighed by these significant costs.

Response II-11-10: The EPA maintains, as it did in sections XII.E.1.d and 2 of the November 2021 Proposal preamble, that BSER under the NSPS OOOOb standards and EG OOOOc presumptive standards is annual rod pack flow rate monitoring and replacement of the packing where flow rate monitoring indicates a measurement that exceeds 2 scfm for all segments. The commenter's inference is that the requirement to repair or replace rod packing to maintain the performance-based volumetric standard will require that owners or operators will need to replace the rod packing more frequently than under the NSPS OOOOa fixed-schedule requirement to replace rod packing. The EPA contends that, based on the performance-based flow rate monitoring standard, while there will be some reciprocating compressors that will be required to change out rod packing more frequently, there will also be some reciprocating compressors that will be required to change out rod packing less frequently.

Comment: Several commenters (2258-MS, 2305-Williams, 2399-GPA, 2428-API) request that they have the option to use proven add-on controls, such as an existing combustor or flare, be

---

<sup>11</sup> 2011 TSD, pg. 6-13.

allowed in addition to routing to a process. The commenter explain that such options may be key for existing units and units that are modified or reconstructed.

Commenters (2305-Williams, 2399-GPA, 2428-API)<sup>12</sup> provide several reasons for why it may not always be feasible to route rod packing vents back to the process:

- Depending on the pressure differential between nearly ambient rod packing vents and pressurized piping, substantial horsepower may be required to achieve capture.
- Recompression designs require substantial horsepower and could require gas engines of variable horsepower to achieve the recompression, negating some of the emissions reductions this rule seeks to achieve.
- Currently available rod packing capture systems attempted by Williams and others in the industry have performed poorly or are ineffective in certain applications or configurations.
- Rod packing vents are essentially at ambient pressure, creating a situation where oxygen could be introduced into the process gas leading to safety concerns.
- The gas quality in the rod packing vents may not be compatible with the only technically feasible location in the process, based on pressure differentials, for the gas to be routed. For example, if the gas in the compressor is sour gas, but the only technically feasible place for the gas to be absorbed in the process is the fuel gas system, the sour gas is often not a good candidate for fuel gas use due to the detrimental effect on components.

According to commenter (2399-GPA), currently available rod packing capture systems that have been attempted by the commenter and their members have not performed as intended and, in some applications, have not worked at all. They explain that even if these systems were as effective as advertised, timing is a significant concern as the supply is not currently available to meet demand. The commenter recommends that where rod packing vents are routed to a control device, they recommend that the flow be measured every 26,000 hours of operation. The commenter provides that this would ensure that rod packing is appropriately maintained while overall emissions are greatly reduced.

Commenter (2428-API) suggests that the emissions from reciprocating rod packing vents that are routed to a process or flare should be considered an adequate alternative in reducing emissions. The incremental benefit achieved between monitoring and subsequent repair (if applicable) versus capturing the vent to control device that achieves 95 percent destruction efficiency has not been substantiated by EPA within their cost benefit analysis. This, according to the commenter, is especially true for any compressor that already is designed and configured to route rod packing to a flare or other combustion device.

Response II-11-11: Section X.I.4 (Routing to process or control device) of the preamble to the final rule responds to these comments. The EPA has revised the final reciprocating compressor requirements under NSPS OOOOb and EG OOOOc to allow owners or operators of

---

<sup>12</sup> Comments provided by GPA are endorsed by API.

reciprocating compressors the option of routing emissions to a control device that achieves 95 percent control to meet the final rule standards and presumptive standards.

Comment: Several commenters (2227-WEA, 2258-MSO, 2282-Kinder Morgan, Inc., 2298-Pioneer Natural Resources USA, Inc. (Pioneer), 2326-AXPC, 2366-BHE, 2399-GPA, 2428-API, 2483-INGAA) note that given the uncertainties of the assumptions underlying the BSER evaluations for the two options, and that the cost effectiveness of the two options are very close, they urge the EPA to provide flexibility to affected facilities by adopting both standards as BSER alternatives with the operator selecting their preferred approach.

According to commenter (2366-BHE), retaining the schedule-based approach is warranted because that compliance option has not only been implemented at NSPS OOOOa facilities, but also through state regulations and voluntary actions by companies. The prescribed maintenance schedule is also an EPA-approved best management practice for the voluntary Methane Challenge program. Due to these EPA decisions, the commenter reports that many companies have “built out” reciprocating compressors rod packing maintenance programs using schedule maintenance, including existing compressors not subject to the federal mandate or state rules. According to the commenter, it is critical that these existing and successful company programs not be supplanted by different requirements in NSPS OOOOb and EG OOOOc.

Several commenters note specific suggestions with respect to a fixed schedule:

- Several commenters (2258-MSO, 2298-Pioneer, 2326-AXPC) request that the EPA allow rod packing replacement every 8,760 operating hours.
- Commenter (2428-API) requests that the EPA allow replacement annually or 8,760 hours (whichever comes first), which is similar in approach but more frequent than the current requirements in NSPS OOOO and NSPS OOOOa.
- Commenter (2366-BHE) requests retaining the NSPS OOOOa approach, requiring the replacement of rod packing every 3 years or 26,000 hours of operation (if operating hours are monitored).

Several commenters (2227-WEA, 2298-Pioneer, 2326-AXPC, 2399-GPA, 2428-API) request that the EPA specify that where operators choose to replace rod packing on a fixed schedule, that they not be required to measure volumetric flow rates.

Response II-11-12: Section X.I.2 (Rod packing changeout schedule-based approach) of the preamble to the final rule responds to these comments.

Comment: Commenter (2366-BHE) requests that EPA provide data to support the 2 scfm emission rate threshold for higher pressure scenarios. They note, for example, that compressors at natural gas storage facilities may warrant a higher threshold for operations with significantly higher operating pressures.

Response II-11-13: Available information does not include flow rate/emissions data by operating pressures and the commenter did not provide any information to support their claim or to establish a different standard.

Comment: Commenter (2172-KOGA) states that the proposal for operators to monitor rod packing emissions to determine when the rod packing needs to be repaired or replaced is appropriate for large compressors or compressor stations. However, the commenter states that this type of monitoring of the typical small compressors used in the Appalachian Basin to deliver gas to intermediate gathering systems from fields of low volume/low pressure wells for sale, is problematic. The commenter explains that most small reciprocating compressors, compressors that may have pistons as small as 2", may not be equipped with crank case ports from which to measure blowby. There is a concern as to what would happen to the lubricant in the crankcase when pressure is added to be able to measure the packing emission volume.

The commenter (2172-KOGA) adds that the EPA's previously proposed requirement of replacing rod packing on a schedule is still a viable option to measuring packing blow by for a small operator. However, the commenter believes that the 36-month requirement for the typical small compressor of the Appalachian Basin is too short of a time frame. The commenter states that rod packing compressors that run at a low RPM and pressure can typically exceed 36 months.

Commenter (2172-KOGA) recommends that the EPA adopt a two-tiered approach to emissions control from reciprocating compressors. Production facilities with more than one compressor would be required to have rod packing repaired or replaced in the case of measurable blowby of 2 cubic feet per hour. For production facilities with a single compressor, rod packing repairs or replacement is not to exceed every 48 months or 35,040 hours of run time. This two-tiered approach differentiates requirements because small operators rarely operate facilities with more than one compressor at a time. Production facilities with more than one compressor are more typical of large-company and transmission pipeline operations who would be more apt to have the technical ability to measure crankcase blow by.

Response II-11-14: Section X.I.1 (Numeric standard versus work practice standard) of the preamble to the final rule details EPA's rationale and reasoning that responds to the numeric standard versus work practice standard comments and establishes final standards/presumptive standards related to reciprocating compressors as work practice standards, including repair and delay of repair requirements. These requirements apply to both large and small operators. Where an owner or operator is complying with the performance-based volumetric flow rate standard, if the measured volumetric flow rate 2 scfm or below, an owner or operator would not be required to change out the rod packing, which could be the case for a small reciprocating compressor, even after 26,000 hours of operation.

In response to comment that small compressors may not be equipped with crank case ports from which to measure blowby, the final rule allows owners or operators to conduct leak detection of emissions from the rod packing case into an open distance piece, or, for compressors with a closed distance piece, they would be allowed to conduct annual leak detection of emissions from the rod packing vent, distance piece vent, compressor crank case breather cap, or other vent emitting gas from the rod packing.

The final requirements for reciprocating compressors under NSPS OOOOb and EG OOOOc also include several alternative compliance options to the performance-based volumetric flow rate

standard that an owner or operator can comply with to meet the standards. See section X.I. of the final rule preamble for a summary of the final standards/presumptive standards for reciprocating compressors. See final standards/presumptive standards at 40 CFR 60.5385b and 40 CFR 60.5393c.

Comment: Commenter (2202-Texas Oil & Gas Association (TXOGA)) states that the reciprocating compressor rod-packing measurement standard announced in the December 2022 proposal should be abandoned, and if any standard is issued, it should be consistent with the limits in the November 2021 Notice. The November 2021 Notice explained that the EPA was planning to find that the BSER for reciprocating compressors is to “replace the rod packing” when, “based on annual flow rate measurements,” there are “indications that the rod packing is beginning to wear to the point where there is an increased rate of natural gas escaping around the packing to unacceptable levels.”<sup>13</sup> Now, in the December 2022 proposal, the EPA states that the BSER is “replacement of the rod packing and/or other necessary repair and maintenance activities to maintain emissions at or below 2 scfm.”<sup>14</sup>

The commenter (2202-TXOGA) notes that the EPA states that its “BSER analysis is unchanged from what was presented in the November 2021 [Notice],” and describes as a “clarification” its introduction of a numeric standard of 2 scfm.<sup>15</sup> Be it a “clarification” or an actual change, the “major difference” between this standard and what the EPA explained in November 2021 is that, “under this supplemental proposal, owners and operators would be required to maintain emissions at or below the emission limit (emission flow rate of 2 scfm);” whereas, “under the November [Notice], owners or operators would have been required to change out the rod packing only after discovering an exceedance of 2 scfm.”<sup>16</sup> According to the commenter, this is no minor difference.

Upon finalization of this standard of performance, the commenter (2202-TXOGA) states regulated community would be required to actively monitor all reciprocating compressors for a leak flow rate of less than 2 scfm. The commenter provides that it is reasonably anticipated that this will result in significantly increased monitoring costs for owners and operators, yet these costs are not accounted for in the proposal, nor is the analysis of the statutory factors for BSER addressed. Further, additional repair to and replacement of reciprocating compressors would also increase owners and operators’ costs, providing, at best, a de minimis benefit. According to the commenter, this is especially true, when, as the EPA states in its December 2022 proposal, 2 scfm is considered only “indicative” of rod packing failure and does not necessarily mean that such failure has in fact taken place or even that it will likely occur in the near future.<sup>17</sup> Exacerbating the burden is that many companies rent, and do not own, such equipment. The proposal to make exceeding the 2 scfm rate a violation, even though the packing may be perfectly fine and even though emissions would not exceed expected levels that served as basis for the BSER analysis, does not constitute reasoned decision-making. The commenter asserts

---

<sup>13</sup> 86 Fed. Reg. at 63,215.

<sup>14</sup> 87 Fed. Reg. at 74,797.

<sup>15</sup> Id.

<sup>16</sup> Id. (emphasis added).

<sup>17</sup> See id. at 74,796 (emphasis added).

that the EPA should return to the BSER for reciprocating compressors as originally described in the November 2021 Notice.

Response II-11-15: Section X.I.1 (Numeric standard versus work practice standard) of the preamble to the final rule details EPA's rationale and reasoning that responds to the numeric standard versus work practice standard comments and establishes final standards/presumptive standards related to reciprocating compressors as work practice standards, including repair and delay of repair requirements.

The EPA maintains as set out in sections XII.E.1.d and 2 of the November 2021 proposal preamble,<sup>18</sup> that annual rod pack flow rate monitoring and replacement of the packing where flow rate monitoring indicates a measurement that exceeds 2 scfm represents BSER for NSPS OOOOb and EG OOOOc for all segments including reciprocating compressors located at centralized productions facilities (with the exception of compressors at stand-alone well sites). Monitoring costs were included in the November 2021 proposed BSER analyses.<sup>19</sup> The analyses assumed the same reciprocating compressor monitoring costs used under Part 98 subpart W information collection request (ICR).<sup>20</sup>

Comment: Commenter (2383-Baker Hughes) recommends against the proposal to trigger rod packing replacement or repair based on a one-size-fits-all leak rate of 2 scfm, because frequent replacement of rod packing will lead to unnecessary compressor blowdowns and emissions. Rather, the commenter recommends tuning the leakage threshold based on the operating parameters of the compressor, mainly flow and pressure. The commenter explains that packing seals always leak some amount of the compressed media, even when newly installed. For larger applications, such as transmission compressors, historical data shows that newly installed packing leaks at a rate of approximately 1 scfm. According to the commenter, the proposed actionable leak rate of 2 scfm will lead to a significant increase in packing replacement for large, transmission sector, compressors. This in turn will lead to a significant increase in compressor blowdowns with associated large volumes of emitted blowdown methane. Before adopting such a proposal, the commenter recommends that EPA analyze the increased volume of methane emissions from more frequent blowdowns compared to increasing the actionable leak rate, especially for the larger transmission compressors.

Response II-11-16: In response to comments received on the December 2022 Proposal, EPA has finalized the performance-based volumetric flow rate standard as a work practice standard under both the NSPS OOOOb and EG OOOOc, including repair and delay of repair provisions (including if there would be a need for a blowdown to conduct repairs). See section XI.I.1 of the preamble to the final rule which provides EPA's rationale and reasoning for finalizing the performance-based volumetric flow rate standard as a work practice standard.

<sup>18</sup> 86 FR 86 63215-63219, November 15, 2021.

<sup>19</sup> November 2021 TSD. Pgs. 7-12 to 7-14.

<sup>20</sup> Greenhouse Gas Reporting Program (EPA ICR No. 2300.18, OMB Control No. 2060-0629) to the Office of Management and Budget (OMB).

Comment: Commenter (2433-EDF et al) does not support the EPA's proposed change to allow monitoring of reciprocating compressors only every 8,760 operational hours as opposed to annually. The commenter states that an annual monitoring requirement is reasonable and does not impose an undue burden on operators. They note that, while it is true that compressors may not be continuously operated all year at all facilities, the risk of malfunction from compressors that are only operated intermittently is high because nonuse can cause components to shift or corrode while unobserved. Compressors that operate for even 1,000 hours a year have an equally high, if not higher, risk of malfunction or deterioration as compared to compressors that operate continuously. The commenter contends that only requiring compressors to be monitored just once every nine years is unreasonable. According to the commenter, such a monitoring schedule would likely allow for emissions well above the threshold to go unchecked.

Response II-11-17: The EPA acknowledges the commenter's concern, however, the EPA proposed and is finalizing its allowance that performance-based volumetric flow rate monitoring be done based on operational hours as opposed to annually. With regards to the comment that the risk of malfunction from compressors that are only operated intermittently is high because non-use can cause components to shift or corrode while unobserved, the commenter did not provide evidence to support their hypothetical claim. The EPA reiterates its position, as outlined in Section IV.I.1.b of the December 2022 Supplemental Proposal preamble, that it makes sense to require periodic reciprocating compressor flow rate monitoring based on the hours of operation (*i.e.*, 8,760 hours) to allow owners and operators the needed flexibility to plan maintenance for limited-use reciprocating compressors.<sup>21</sup>

Comment: Commenter (2433-EDF et al) states that the EPA should lower the emissions threshold for rod packing replacement in reciprocating compressors. The commenter notes that the EPA has proposed requiring replacement when emissions exceed 2 scfm, which the agency estimates will achieve a 92 percent reduction in emissions for reciprocating compressors in all segments.<sup>22</sup> However, as explained in the Clean Air Task Force's (CATF's) Reciprocating Compressor Cost Memo and Spreadsheet,<sup>23</sup> the EPA likely overestimates the emissions reductions associated with replacement at the 2 scfm threshold, because only compressors with emissions that exceed that threshold will replace rod packing and thus reduce emissions. For compressors with emissions below that threshold, there will be no such reductions.

To ensure emissions are meaningfully reduced based on an annual monitoring program, the commenter (2433-EDF et al) requests that the EPA lower the threshold for replacement to 0.5 scfm, which we estimate will reduce approximately 80 percent of compressor station emissions while remaining highly cost-effective. While the EPA did not estimate the cost-effectiveness of replacement at lower thresholds, the CATF estimates that imposing a 0.5 scfm threshold would entail a cost of \$270/ton of methane not accounting for gas savings, and \$89/ton of methane after accounting for gas savings, at gathering and boosting compressors, which is the highest cost

---

<sup>21</sup> 87 FR 74797, December 6, 2022.

<sup>22</sup> Initial TSD, *supra* note 413, at 7-1 through 7-33.

<sup>23</sup> See Lesley Fleischman, Reciprocating Compressor Cost Memo (Jan. 24, 2022) (included as Attachment U to 2022 Joint Environmental Comments, *supra* note 1); Clean Air Task Force, Reciprocating Compressor Cost Spreadsheet (Jan. 24, 2022) (included as Attachment V to 2022 Joint Environmental Comments, *supra* note 1).

segment. Table 19 of their comment letter shows the CATF cost summary for all segments; these abatement costs are very similar to costs for the current NSPS OOOOa requirement for new sources.<sup>24</sup> [Table 19 VOC and Methane Cost of Control (\$/ton) for all Segments (Gathering and Boosting, Processing, Transmission, Storage).] The commenter provides that a detailed description of the cost calculation methodology is an attachment to their comment letter (Reciprocating Compressor Cost Memo and Spreadsheet). The commenter reports that a lower threshold is also in line with standards adopted in Canadian jurisdictions, which, as EPA notes, require rod packing replacement at vent volume thresholds ranging from 0.49 to 0.81 scfm/cylinder.<sup>25</sup>

Response II-11-18: In response to comment requesting that EPA lower the emissions threshold for rod packing replacement, there is insufficient information at this time to support the establishment of a standard based on a lower volumetric flow rate. While EPA can apply costs and emissions based on a lower volumetric flow rate as provided by the commenter, the commenter did not provide evidence that 0.5 scfm represents deterioration of the rod packings, or that it is even achievable with newly replaced rod packings.

Comment: Commenter (2433-EDF et al) states that the EPA should not allow for repair instead of replacement of rod packing unless the emissions threshold is lowered to at least 0.5 scfm. If the EPA maintains the currently proposed emission threshold of 2 scfm, the agency must require replacement of rod packing (as opposed to also allowing for repair). Conversely, if the EPA were to adopt an emissions threshold of 0.5 scfm, then repair of rod packing would offer emissions abatement that is comparable to that of replacing the rod packing. Table 20 of their comment letter shows the projected emissions reductions from rod packing replacement versus repair at both 2 scfm and 0.5 scfm. At a threshold of 2 scfm, merely repairing rod packing offers significantly less emissions reductions than would be possible with replacement.

Response II-11-19: See Response II-11-18 of this Chapter.

Comment: Commenter (2433-EDF et al) requests that EPA develop standards to reduce emissions from compressor exhaust. The commenter states that these emissions are substantial: The commenter estimates 393,355 tons of methane emissions resulting from gathering and boosting compressor exhaust in 2019. The commenter has recommended to EPA in the past, the agency should consider requiring that compressors be driven by turbines or electric motors, since according to emissions factors in the Greenhouse Gas Inventory (GHGI), turbines produce less methane per horsepower-hour than reciprocating internal combustion engines (RICE) by about a factor of 25.<sup>26</sup>

Response II-11-20: The EPA acknowledges the commenter's input. However, the scope of the oil and natural gas industry sources that are subject to NSPS OOOOb standards and EG OOOOc

---

<sup>24</sup> Initial TSD, *supra* note 413, at Table 7-9 and 7-10.

<sup>25</sup> 86 Fed. Reg. at 63218.

<sup>26</sup> Sierra Club et al., Comment Letter on New Source Performance Standards: Oil and Natural Gas Sector; Review and Proposed Rule for Subpart OOOO, at 48 (Nov. 30, 2011), <https://www.regulations.gov/comment/EPA-HQ-OAR-2010-0505-4240>.

presumptive standards excludes the regulation of RICE and was therefore not evaluated under the NSPS OOOOb and EG OOOOc rules.

#### ***11.2.4 Alternative Compliance Option***

Comment: Commenter (2383-Baker Hughes) states that they support the proposed alternative compliance option, 40 CFR 60.5411b(d), of allowing operators to collect the methane and VOC emissions from a reciprocating compressor rod packing using collection system (a closed vent system that meets the requirements of the final emission standard) and to route the rod packing emissions to a process. The commenter recommends that in addition, the EPA allow operators to adjust compressor performance to bring the leak rate down below an established threshold. If performance of the compressor at a lower flowrate or lower pressure meets the needs of the operator, and by adjusting those performance parameters, the leak rate can be held down, this should be a viable mitigating action that allows the operator time to make repairs once seal wear leads to unacceptable performance.

Response II-11-21: The final NSPS OOOOb and EG OOOOc rules require that the volumetric flow rate of each cylinder not exceed 2 standard cubic feet per minute (scfm). If the individual cylinders are manifolded to a single open-ended vent line, the volumetric flow rate must not exceed the sum of the individual cylinders multiplied by 2 scfm. Adjusting the performance of the compressor to decrease the cylinder leak rate below 2 scfm per cylinder would be allowed.

With regards to the comment that requests that, if a packing leakage system is in place that captures all packing leakage in a closed loop that routes the leakage away for re-use or sales, then the packing leak rate should not be the trigger for abatement action as there are no emissions connected with the leak rate. As an alternative to having to meet the 2 scfm performance-based emissions standard per cylinder, the final rule allows owners and operators to route emissions from the rod packing via a CVS to a process or to a control device achieving 95 percent control. See sections X.I.1 and 2 of the final rule preamble for a summary of the final reciprocating compressor standards included in NSPS OOOOb and EG OOOOc.

Comment: Commenter (2258-MS) supports the removal of the language “under negative pressure” as part of the requirement of routing rod packing emissions to a process. The commenter requests that additional flexibility be allowed in the regulatory requirements for reducing or controlling rod packing emissions. The commenter states that technology to reduce emissions, such as seal gas recovery, is relatively new and emerging and the regulation should not discourage these options. The commenter explains that these systems will be monitored as fugitive emission sources and the additional requirements of them being closed vent systems does not provide additional value. They note that simply requiring a reduction of 95 percent of emissions and fugitive emissions monitoring should be adequate to verify compliance.

Response II-11-22: With regards to the comment supporting the removal of the language “under negative pressure” from the routing rod packing emissions to a process requirement, this is a supportive comment on an aspect of the December 2022 Proposal that has remained unchanged in the final rule; as such, no response is required.

With regards to the commenter's suggestion that the EPA should allow the option of routing rod packing emissions to a process without the need for owners and operators having to comply with closed vent system requirements, see Response II-11-21 of this Chapter.

See section X.I. of the final rule preamble for a summary of the final standards/presumptive standards for reciprocating compressors. See final standards/presumptive standards at 40 CFR 60.5386b and 40 CFR 60.5393c.

Comment: Commenter (2177-Ute Tribe) responds to the EPA solicitation for comment regarding its assumption that the emissions reduced by requiring the capture of gas and routing to a process are greater than the requirement to maintain the flow rate from the reciprocating compressor rod packing at or below 2 scfm; and on the prevalence of owners and operators complying with NSPS OOOO and NSPS OOOOa by capturing and routing emissions from the reciprocating compressor rod packing to a process.

The commenter (2177-Southern Ute) states that capturing these emissions and routing them to a process may require installation of additional compression equipment. This needs to be assessed on a site-by-site basis and should not just be assumed that it will result in a reduction in emissions. The commenter continues that other regulations (NESHAP ZZZZ, NSPS OOOOa) require the replacement of rod packing, and not the monitoring for rod packing leaks. The commenter notes that this provision has the potential for a source to be required to conduct both rod packing replacement and monitoring, creating unnecessary requirements. The commenter requests that requirements be aligned with other subparts to prevent an unnecessary burden on operators.

Response II-11-23: The commenter suggests that a fixed rod packing replacement schedule under other regulations (specifically, NESHAP ZZZZ and NSPS OOOOa) means that an owner or operator might be required to conduct both rod packing fixed-schedule replacement and monitoring requirements.

While the commenter is correct that there may be overlapping regulations, overlapping of requirements would not occur under NSPS OOOOa and NSPS OOOOb or NESHAP ZZZZ and NSPS OOOOb. If you are a new or modified source subject to NSPS OOOOb, you would not be subject to NSPS OOOOa. And NESHAP ZZZZ establishes national emission limitations and operating limitations for hazardous air pollutants emitted from stationary reciprocating internal combustion engines (RICE) located at major and area sources of HAP emissions and not reciprocating compressors regulated under NSPS OOOOb standards/EG OOOOc presumptive standards. Nonetheless, if an owner or operator is required to change out packing every three years (or every 26,000 hours of operation) on a fixed schedule and must also meet the requirements of NSPS OOOOb, an owner or operator would be required to do monitoring under NSPS OOOOb, but would only be required to conduct more frequent repair or rod packing change-outs if the performance-based volumetric flow rate standard is exceeded.

Comment: In response to EPA no longer including option under the alternative compliance option to route emissions to a control device, commenter (2305-Williams) states that there is a timing concern for facilities that would need to retrofit existing design to accommodate EPA's

proposed rule changes. The commenter notes that supply of these systems is not sufficient to meet current demand even absent this regulatory driver. They add that additional delay in application is also reasonably likely due to the need for reengineering of facility processes. Assuming a facility can be redesigned to route rod packing vents back to process, the capture and return to process is an engineering modification requiring adequate time for a facility to undergo the necessary design and review process to ensure any changes to safety mechanisms and process programs are understood and mitigated.

Response II-11-24: See section XI.I.5 of the final rule preamble for EPA's decision to allow routing of vented emissions to a control device achieving a 95 percent reduction in VOC and methane emissions as an acceptable alternative compliance option under the final NSPS OOOOb standards and EG OOOOc presumptive standards for reciprocating compressors.

### ***11.2.5 BSER Analysis/Emissions/Costs***

Comment: Commenter (2483-INGAA) states that the EPA's BSER analysis did not consider that in some circumstances, rod packing replacement is not sufficient to reduce the emission rate to 2 scfm. In these situations, it may be necessary to conduct a complete "tear down" or to replace the rod also. It is often necessary to replace both a rod and the surrounding rod packing at the same time to ensure there are no differences in the metallurgy of the components that could render them incompatible. Separately, even if replacement of rod packing sufficiently reduces the emissions rate, installation of newer types of lower-emissions packing requires pulling out the rod, which requires additional time.

Commenter (2483-INGAA) notes that these activities have a much higher cost than replacing the rod packing, potentially making their cost effectiveness unreasonable or at a minimum affecting repair schedule. Such a scenario cannot be predicted or planned for in advance, as there are multiple factors that affect the type of repair that is appropriate in each instance. In those instances where rod packing replacement does not sufficiently reduce the emission rate, an operator may have to remove the rod assembly and piston, and potentially replace the rod as well as components like the piston rings, rider bands, and the compressor liner. The costs of such a replacement project could approach \$100,000. The commenter suggests that the EPA analyze these situations to determine whether they are cost effective and, if not, the EPA should adopt provisions to either exempt these situations from the limitation requirements or that otherwise address them in a cost-effective manner, with an appropriate schedule allowed.

Response II-11-25: In situations where it might be necessary to complete a "tear down" or to replace the rod (and not just the rod packing), that would not be considered an added emissions control cost, but an indication of equipment failure/age/malfunction that impacts emissions. Owners and operators would need to address these major issues without regard to the NSPS.

Comment: Commenter (2383-Baker Hughes) suggests condition monitoring as BSER. According to the commenter, there are commercially available condition monitoring solutions for reciprocating compressors, considering performance parameters, that can be used to predict the need for seal replacement in a timelier manner than annual seal leak monitoring, and should be considered as a BSER for minimizing compressor seal leakage for new and existing

reciprocating compressors. As one of the oldest compressor designs, reciprocating compressors enjoy unique capabilities such as broad capacity control ranges, interstage cooling, the flexibility to efficiently compress gas regardless of mole weight or k value, and extremely high compression ratios. Consequently, the commenter reports that they are an ideal fit for selected applications such as hydrogen compression. However, reciprocating compressors suffer from one very serious drawback: higher maintenance costs. In fact, compared to similarly sized centrifugal compressors, reciprocating compressors can consume as much as five times the amount of maintenance dollars. Smart compression condition monitoring technology monitors performance and other analytics of the compressor to ascertain if maintenance is required and can adjust performance of the compressor to optimize performance when degradation has been sensed. Operators can optimize performance while operating below a prescribed emission threshold rather than relying on annual detection to signal the need to corrective action.

Response II-11-26: Smart compression condition monitoring technology that monitors the performance of the compressor and optimizes performance when degradation has been sensed is certainly allowed, but not required under the final NSPS OOOOb standards or EG OOOOc presumptive standards. Owners and operators can use this option as an internal operational and maintenance procedure to constantly check the status of integrity of the rod packings to ensure that, when the periodic measurement is made that the flow rate is below 2 scfm. The EPA has insufficient information to evaluate condition monitoring technology as BSER.

Comment: Commenter (2196-Massengale) provides the following analysis:

A failed rod packing @ 2 scfm is (~56.63 l/m) or 1,051,188 standard cubic feet (scf)/year (yr) or 5.36 pounds (lbs)/hour (hr) or 46,953.6 lbs/yr CH<sub>4</sub>.

- EPA “Natural Gas Star Circular 2006: Reducing Methane Emissions From Compressor Rod Packing Systems” published data on Rod packing venting and NG compression infrastructure said there are about 51,000 compressors in natural gas industry. For example, purposes, let’s assume there are 60,000 compressors as of now.
- If we assume (for example purposes) 4 rod packing vents per compressor. That is 240,000 rod packing vents.
- 240,000 “Vents” x 5.36 lbs/hr (vent failure) x 8760 hrs/yr = 11,268,864,000 lbs per year if they all failed @ 2 scfm all year - worst-case scenario (i.e., failed for a year before being found).
- NSPS OOOO required Rod packing be replaced every “3 years” ... assume 33% fail per year and assume that they are found halfway thru a yearly cycle.
- 11,268,864,000 lbs x 33% failure rate x 0.5 (failure found half-way thru 1 yr fail cycle) = 1,859,362,560 lbs or 929,681 tons/yr CH<sub>4</sub> from rod packings.

The commenter (2196-Massengale) contends that leaks can be found 4 times faster due to 40 CFR 60.5397 quarterly optical gas imaging (OGI) frequency (with little or no additional costs) by requiring that the rod packings be checked at the associated 40 CFR 60.5397 frequency and if no leak “nothing is done” as far as volumetric flow rate requirement as indicated in 40 CFR 60.5385b(c)(2)(iv). We can argue mass numbers and validity of assumptions above, but the

benefit of finding and stopping rod packing leaks faster with very little to NO additional or associated cost should be considered. The commenter recommends that rod packing vents be inspected with OGI at the frequency (and most times same time as) required in 40 CFR 60.5397b (which will be quarterly in majority of the cases).

Using the same assumption scenario above:

- A leak (averaging) could be found half-way thru a quarterly cycle or 45 days.
- As opposed to ~182.5 days (1/2 yearly cycle), which is approximately 25% of the emissions above (all else being equal). Or 232,420 tons per year (tpy) instead of 929,681 tpy. Or a reduction in emissions of 697,261 tpy. Or, a 75 percent reduction.

Thus, the commenter (2196-Massengale) adds that whatever numbers we choose in our modeling of emissions above, finding leaks sooner with little or no additional costs (excluding recordkeeping) could reduce rod packing venting by percent over proposal.

Response II-11-27: The EPA acknowledges the commenter's illustrative analysis. While the EPA agrees that more frequent monitoring could identify leaks sooner in some cases, we believe that the monitoring frequency based on 8,760 hours of operation is sufficient.

### **11.3 NSPS OOOOb and EG OOOOc Compliance Issues**

[*Note:* Most of the comments provided on the BSER for NSPS OOOOb also apply to EG OOOOc. For specific comments that just apply to EG OOOOc, see section 11.4 of this Chapter).]

#### ***11.3.1 Test Methods and Procedures (Apply to Both NSPS OOOOb and EG OOOOc)***

Comment: Commenter (2227-WEA) states that volumetric flow measurements must be conducted using rate meters conforming to EPA Method 2D. However, they note that Method 2D does not list specific rate meters or technologies that could be used and there are few meter technologies commercially available to measure low volumetric flow rates from very small vents. The commenter notes that annual flow measurements present many complexities and costs.

Commenter (2326-AXPC) proposes an alternative to conducting the annual inspection via Method 2D. The commenter proposes, that in lieu of annual Method 2D test, an operator can utilize an OGI camera as a screening tool to scan the rod packing vent during the required fugitive emission surveys – e.g., quarterly for compressor stations subject to NSPS OOOOb or EG OOOOc. Under this alternative, the commenter notes that, if the operator detects no emissions with an OGI camera during a routine fugitive emissions survey, no action is required because the volumetric flow rate from the compressor cylinder is assumed to be well below the proposed 2 scfm limit, given that OGI cameras are capable of detecting hydrocarbon emissions well below a 2 scfm flowrate. However, if the operator observes emissions with the OGI camera, the operator would confirm within 30 days that the emissions are below the 2 scfm limit via a high-volume flow sampler using Method 2D. The commenter believes this proposal is very

conservative given that OGI cameras can detect emissions much lower than the proposed 2 scfm. The commenter believes this is a cost-effective alternative because it allows operators to take advantage of staff already onsite to conduct the fugitive emission survey, and the OGI camera can detect emissions well below the proposed threshold. Further, this approach may alleviate high volume flow sampler supply issues noted just below.

Response II-11-28: EPA Method 2D describes how to conduct the measurement of flow through direct measurement or by using pressure drop measurements to calculate flow. The method allows for many different types of measurement devices, including but not limited to rotameters and orifice plates, to accomplish the measurement, as long as the device measures the gas flow (volume rate or pressure drop) accurately. Because EPA Method 2D is not limiting in the types of measurement devices that can be used, we believe the method provide owners and operators with enough flexibility to choose the type of measurement device that works best for the situation.

In response to commenter requesting an alternative approach to conducting inspection via Method 2D, the December 2022 Supplemental Proposal regulatory text for reciprocating compressors under NSPS OOOOb and EG OOOOc does not require volumetric flow rate monitoring if screening for emissions or leaks from the reciprocating compressor rod packing using optical gas imaging (OGI) or Method 21 does not indicate a leak. This has been maintained in the final NSPS OOOOb and EG OOOOc requirements. See final test methods and procedures for reciprocating compressors at 40 CFR 60.5385b and 40 CFR 60.5405c.

Comment: Commenter (2282-Kinder Morgan, Inc.) states that the EPA should allow the use of calibrated bags, anemometers, as well as any other suitable measurement methods for measuring emission rates from rod packing. They add that EPA should also allow the use of anemometers and calibrated bags for flow rate measurement from rod packing. Allowing the use of anemometers and calibrated bags would be more straightforward for operators to implement and would be lower cost, while still providing reliable and robust data. As they noted on their comments on centrifugal compressor monitoring, they note that anemometers are a cost-effective and accurate measurement tool that the EPA should allow for measurements from rod packing. The commenter incorporates the same arguments that they provided for centrifugal compressor monitoring with respect to measurements from rod packing.

In addition, the commenter (2282-Kinder Morgan, Inc.) reports that they have successfully utilized calibrated bags for measuring emissions from rod packing for reporting under Subpart W. This measurement method is allowed by the EPA in Subpart W,<sup>27</sup> and has been successful implemented by the commenter for nearly two decades. Thus, in addition to anemometers, the commenter requests the EPA allow the use of calibrated bags for measuring emissions from rod packing.

The commenter (2282-Kinder Morgan, Inc.) requests that the EPA expressly allow the use of any other Administrator-approved measurement method, either already approved pursuant to Subpart W, or independently approved by the Administrator pursuant to application of any final version of the NSPS Rule. The commenter proposes the following specific rule changes below and in the

---

<sup>27</sup> See, e.g., 40 CFR 98.233(p)(2)(i)(A), (p)(2)(ii)(A), (p)(2)(iii)(B).

Exhibit A of their comment letter to address their concerns (underlined text reflects new text and struck out text reflects deleted text) [Track change versions of regulatory language and reasoning four suggested changes included with their comment letter.]:

- *40 CFR 60.5393c(b)(1)*<sup>-28</sup>

(b) You must determine the volumetric flow rate from your reciprocating compressor rod packing as specified in paragraph (b)(1) or (2) of this section.

(1) For reciprocating compressor rod packing equipped with an open-ended vent line on compressors in operating or standby pressurized mode, determine the volumetric flow rate of the rod packing using one of the methods specified in paragraphs (b)(1)(i) through ~~(viii)~~ of this section.

(i) Determine the volumetric flow rate at standard conditions from the open-ended vent line using a high-volume sampler according to methods set forth in §60.5405c(c).

(ii) Determine the volumetric flow rate at standard conditions from the open-ended vent line using a temporary or permanent meter, according to methods set forth in §60.5405c(b).

(iii) Determine the volumetric flow rate at standard conditions from the open-ended vent line using a hotwire or vane anemometer according to the methods set forth in §98.234(b).

(iv) Determine the volumetric flow rate at standard conditions from the open-ended vent line using a calibrated bag according to the methods set forth in §98.234(b).

(iv) Determine the volumetric flow rate at standard conditions from the open-ended vent line using an alternative method, as set forth in §60.5405c(d).

~~(viii)~~ Any of the methods set forth in §60.5405c(a) to screen for leaks and emissions. For the purposes of this paragraph, emissions are detected whenever a leak is detected according to any of the methods in §60.5405c(a). If emissions are detected using the methods set forth in §60.5405c(a), then you must use one of the methods specified in paragraph (b)(1)(i) and (b)(1)(ii) of this section to determine the volumetric flow rate. If emissions are not detected using the methods in §60.5405c(a), then you may assume that the volumetric ~~emissions~~ flow rate ~~are~~ is zero.

- *40 CFR 60.5393c(b)(2)*<sup>-29</sup>

(2) For reciprocating compressor rod packing not equipped with an open-ended vent line on compressors in operating or standby pressurized mode, you must determine the

---

<sup>28</sup> The NSPS OOOOb section to which this change should also apply is 40 CFR 60.5385b(b)(1).

<sup>29</sup> The NSPS OOOOb section to which this change should also apply is 40 CFR 60.5385b(b)(2).

volumetric flow rate of the rod packing using the methods specified in paragraphs (b)(2)(i) and (iiv) of this section.

(i) You must use the methods described in §60.5405c(a) to conduct leak detection of emissions from the rod packing case into an open distance piece, or, for compressors with a closed distance piece, you must conduct annual leak detection of emissions from the rod packing vent, distance piece vent, compressor crank case breather cap, or other vent emitting gas from the rod packing. You must measure emissions found in paragraph (b)(2)(i) of this section using:

(ii) ~~You must measure emissions found in paragraph (b)(2)(i) of this section using a~~ A meter or high-volume sampler according to methods set forth in §60.5405c(b) or (c).

(iii) A hotwire or vane anemometer according to the methods set forth in §98.234(b).

(iv) A calibrated bag according to the methods set forth in §98.234(b).

(v) An alternative method, as set forth in §60.5405c(d).

- *40 CFR 60.5393c(c)* (underlined text reflects new text and struck out text reflects deleted text)-<sup>30</sup>

(c) For conducting measurements on manifolded groups of reciprocating compressor designated facilities rod packing, you must determine the volumetric flow rate from ~~reciprocating compressor~~ the rod packing vent as specified in paragraph (c)(1) and (2) of this section.

(1) Measure at a single point in the manifold downstream of all ~~compressor~~ rod packing inputs and, if practical, prior to comingling with other non-~~compressor~~ rod packing emission sources.

(2) Determine the volumetric flow rate of the rod packing at standard conditions from the common stack using one of the methods specified in paragraph (c)(2)(i) through (iv) of this section.

(i) A temporary or permanent flow meter according to the methods set forth in §60.5405c(b).

(ii) A high-volume sampler according to methods set forth §60.5405c(c).

(iii) A hotwire or vane anemometer according to the methods set forth in §98.234(b).

(iv) A calibrated bag according to the methods set forth in §98.234(b).

---

<sup>30</sup> The NSPS OOOOb section to which this change should also apply is 40 CFR 60.5385b(c)(2).

(iiiiv) An alternative method, as set forth in §60.5405c(d).

(ivi) Any of the methods set forth in §60.5405c(a) to screen for emissions. For the purposes of this paragraph, emissions are detected whenever a leak is detected when using any of the methods in §60.5405c(a). If emissions are detected using the methods set forth in §60.5405c(a), then you must use one of the methods specified in paragraph (c)(2)(i) through (iiiv) of this section to determine the volumetric flow rate. If emissions are not detected using the methods in §60.5405c(a), then you may assume that the volumetric ~~emissions-flow rate are~~ is zero.

Response II-11-29: EPA disagrees with the commenter. While we acknowledge that the methods suggested by the commenter are allowed in 40 CFR part 98 subpart W and are adequate for estimating emission inventories, as noted in the December 2022 Supplemental Proposal, these types of measurements are not as well defined or prescriptive as the methods EPA generally requires for demonstrating compliance with a standard. As such, we are not updating the final rule to include these additional types of measurements.

Comment: Commenter (2399-GPA, 2428-API)<sup>31</sup> states that high-volume samplers should be calibrated according to manufacturer specifications. The commenter suggests that the EPA's detailed calibration requirements for high-volume samplers be removed and replaced with a more general requirement that samplers be calibrated in accordance with the manufacturer's specifications. The commenters note that daily field calibration of methane concentrations and volumetric flow rate vary by manufacturer such that one set of calibration instructions is not appropriate for all high-volume samplers and should not be subject to a universal rule or standard.

Response II-11-30: EPA disagrees with the commenters and is maintaining the calibration requirements from the proposed rule. The approach we are finalizing is performance-based and designed to verify the measurement system for its application in the rulemaking. EPA also notes that if a manufacturer design is not compatible with the requirements in the final rule, the owner or operator may petition the Administrator for an alternative test method under §60.8(b).

Comment: Commenter (2196-Massengale) states that the oil and gas rule states in every "standard citation for each affected facility" that it is a "GHG and VOC" standard. Then we go to the 40 CFR 60.5386b which is "the test methods and procedures I must use for my centrifugal compressor and reciprocating compressor affected facilities" .... which is regulated by 40 CFR 60.5385b - What GHG and VOC standards apply to reciprocating compressor affected facilities ..... it becomes a methane (or GHG) only test method. The commenter suggests that the EPA strive not to limit or choose specific instrument manufacturers when specifying equipment requirements for test methods and procedures. They state that this is a GHG and VOC rule. As such, the commenter notes that specifying that the sensor should be methane only is counter to the rule itself. Historically, the commenter notes that sensors have been VOC sensors, though they always have been calibrated to methane in the same fashion that the legacy Method 21 VOC analyzers have always been and more recently required (to be calibrated to methane).

---

<sup>31</sup> API endorsed comments submitted by GPA.

Manufacturers have recently begun making methane only sensors due to recent focus on “GHG’s/Global warming”. A VOC sensor that is calibrated to methane that is reading a natural gas or field gas line should be acceptable if it meets the other criteria in this section. According to the commenter, by codifying a “methane selective or specific sensor” the EPA is “choosing a winner”, or limiting or eliminating competition that will ultimately drive technology prices down. Legacy GHG programs have allowed VOC sensors for the GHG rod packing testing programs and have come up with calculation procedures to account for the mixed streams that are inevitably present in our industry. The commenter contends that methane specific sensors will underestimate emissions when used for field gas. Methane concentrations (percent) in field gas can be in the high 70’s (percent) with remainder being mostly C2 and C3 [hydrocarbons] with much lower amounts of C4 thru C6 or C7 [hydrocarbons].

The commenter (2196-Massengale) recommends that the EPA allow the use of a methane specific or VOC sensor calibrated to methane in High volume sampler, and recommends the following rule text changes to address this issue:

*40 CFR 60.5386b(c)(3)*: Replace “Methane” with “VOC or Methane”

*40 CFR 60.5386b*: [What test methods and procedures must I use for my reciprocating compressor affected facilities?]

*40 CFR 60.5386b (c)(3)(i)*: Deals with a methane specific sensor, if using a methane specific sensor. *NOTE*: A methane specific sensor will underestimate emissions from field gas. Though the amount of underestimation from field gas compressors would vary based on actual field gas composition.

*40 CFR 60.5386b(c)(3)(ii)*: Replace “Methane” with “VOC or Methane”

*40 CFR 60.5386b(c)(3)(iii)*: Replace “Methane” with “VOC or Methane”

*40 CFR 60.5386b(c)(5)*: Replace “Methane” with “VOC or Methane”

*40 CFR 60.5386b(c)(5)(i)*: Replace “Methane” with “VOC or Methane”

*40 CFR 60.5386b(c)(6)(iii)*: Replace “Methane” with “VOC or Methane”

*40 CFR 60.5386b(c)(6)(iv)*: In the calculation, when using a “VOC sensor” that is calibrated to methane all readings are referenced as methane for the purposes of determining 2 scfm compliance level. The VOC sensor reading can be input directly into this equation and result would be a total VOC reading as methane which would be more representative of leak rate (when testing field gas compressor rod packing vents). It is “my opinion” that we not try to over-calculate (or over-think) this calculation procedure. Input the value ... keeping in mind all the of the high-volume samplers being developed take the flow rate and concentration and give leak rate (i.e., Q) using the procedure referenced in this citation. Thus, the equipment manufacturer’s give “Q” in units that can be selected from a menu setting. *NOTE*: 2 of the 3 or 4 Hi volume samplers tested at

METEC [Methane Emissions Technology Evaluation Center] are Methane only sensors. The other was a VOC detector.

Response II-11-31: EPA disagrees with the commenter. We are finalizing the requirement, as proposed that the high-volume sampler must have a sensor that is selective to methane. As the commenter notes, methane is the predominant constituent of the gas stream, and as such, it is appropriate to use methane emissions as a surrogate when determining emissions from the compressor. Additionally, the methane sensors used with the high-volume samplers are generally more reliable than other sensors that would be used for VOC measurement.

### ***11.3.2 Clarification of Compliance Deadlines***

Comment: Commenters (2399-GPA, 2428-API)<sup>32</sup> state that there are certain conflicting compliance deadlines which require clarification. Specifically, the commenters note that there are portions of the proposed regulatory text that include compliance dates that are inconsistent with other portions of the text that they cross-reference. The commenters urge the EPA to resolve these conflicting dates before issuing any final rule.

- Proposed 40 CFR 60.5370b(a)(1)(i) requires compliance with 40 CFR 60.5385b(a)(1) on or before 12 months after publication of the final rule or 12 months after the source's initial startup, whichever is later. This is inconsistent with proposed 40 CFR 60.5385b(a)(1) which requires owners and operators to "conduct your first volumetric flow rate measurements from your reciprocating compressor on or before 8,760 hours of operation after" the final rule publication date "or on or before 8,760 hours of operation after startup, whichever is later." The EPA should clarify that the compliance timeline referenced in proposed 40 CFR 60.5370b(a)(1)(i) should be on or before 8,760 hours of operation after either the final rule publication date or the startup date, whichever is appropriate.
- Proposed 40 CFR 60.5370b(a)(1)(ii) requires compliance with proposed 40 CFR 60.5385b(a)(2) within 30 days after compliance with proposed 40 CFR 60.5385b(a)(1) (referenced above). This 30-day compliance date, however, is inconsistent with proposed 40 CFR 60.5385b(a)(2). That requires owners and operators to "conduct subsequent volumetric flow rate measurements from your reciprocating compressor on or before 8,760 hours of operation after the previous measurement which demonstrates compliance with the 2 scfm volumetric flow rate." The EPA should clarify that the compliance date referenced in proposed 40 CFR 60.5370b(a)(1)(ii) should be 8,760 hours of operation, as identified in proposed 40 CFR 60.5385b(a)(2).
- Proposed 40 CFR 60.5370b(a)(1)(iii) requires compliance with proposed 40 CFR 60.5385b(a)(3) upon initial startup. However, there is no 40 CFR 60.5370b(a)(3) in the proposed regulatory text. The EPA should clarify whether 40 CFR 60.5370b(a)(3) is missing or if proposed 40 CFR 60.5370b(a)(1)(iii) should be deleted. This would impact 40 CFR 60.5370b(a)(1) as well, which requires compliance with 40 CFR

---

<sup>32</sup> API endorsed GPA comments.

60.5370b(a)(1)(iii). If proposed 40 CFR 60.5370b(a)(1)(iii) is deleted, that should be noted in proposed 40 CFR 60.5370b(a)(1) by deleting the reference.

- Proposed 40 CFR 60.5415b(g) requires that reciprocating compressors complying with proposed 40 CFR 60.5385b(d) must demonstrate continuous compliance with 40 CFR 60.5415b(g)(4) through (g)(6). However, there are no paragraphs (g)(5) or (g)(6) in the proposed regulatory text. The EPA needs to clarify if paragraphs (g)(5) and (6) are real requirements that are missing from the regulatory text or if the text should be changed to only list paragraph (g)(4).

Response II-11-32: The EPA agrees that clarification of compliance deadlines is needed. The EPA has made the following clarifications:

- The EPA has made clarifying revisions to the language of 40 CFR 60.5370b(a)(1)(i) as follows:

(i) You must comply with the requirements of §60.5385b(a)(1) and (d)(3) on or before 8,760 hours of operation after [INSERT DATE 60 DAYS AFTER PUBLICATION OF FINAL RULE IN THE FEDERAL REGISTER], on or before 8,760 hours of operation after last rod packing replacement, or on or before 8,760 hours of operation after startup, whichever is later; and
- The EPA has made clarifying revisions to the language of 40 CFR 60.5370b(a)(1)(ii) as follows:

(ii) You must comply with the requirements of §60.5385b(a)(2) within 8,760 hours after compliance with §60.5385b(a)(1) and (d)(3).
- The EPA has made clarifying revisions to the language of 40 CFR 60.5370b(a)(1)(iii) as follows:

(iii) You must comply with the requirements of §60.5385b(d)(1) and (2) for your reciprocating compressor upon initial startup.
- Several revisions were made to 40 CFR 60.5415b(g) in the final rule and the referencing issue identified by the commenter is no longer an issue.

### ***11.3.3 Timeline for Repair or Replacements (Apply to Both NSPS 0000b and EG 0000c)***

Comment: Several commenters (2258-MSA, 2282-Kinder Morgan, Inc., 2305-Williams, 2366-BHE, 2399-GPA, 2428-API, 2483-INGAA) state that the rule should clarify the required compliance obligations, specifically, what is required when annual monitoring yields a measured flow rate for an individual cylinder that exceeds 2 scfm. The commenters recommend the rule provide a proposed timeline for repair or replacements, as well as delay of repair provisions, consistent with nearly all other NSPS drafted by the EPA.

According to commenter (2483-INGAA), because rod packing replacement is a major

maintenance activity that can be undertaken only during a shutdown, the EPA should make clear in the regulatory language that rod packing replacement would be required at the next planned shutdown for maintenance after such a measurement. The EPA should revert to a work practice that requires timely replacement of rod packing after the emission rate is measured to exceed 2 scfm and provide a suitable delay of repair provision.

According to commenters (2282-Kinder Morgan, Inc., 2399-GPA, 2428-API),<sup>33</sup> a delay of repair provision in such a regulatory scheme appropriately recognizes potential issues with obtaining necessary parts or equipment in the time required to make repairs or where weather makes compressors in remote areas inaccessible. This would be consistent with multiple federal fugitive monitoring programs (specifically NSPS VVa, and NSPS OOOOa) and California regulations. See also 87 Fed. Reg. at 74,798 (acknowledging the need for a delay of repair option for “scenarios beyond the owner or operator’s control”). Thus, the commenters note that a delay of repair option is a commonly used and well understood compliance option for certain scenarios. The commenters had diverse recommendations as to the length of delay as noted below:

- Commenter (2282-Kinder Morgan, Inc.) suggests that the EPA allow an operator to repair or replace the rod packing measuring above the volumetric flow rate threshold within 90 days from the date of the applicable measurement. However, such a requirement would only be triggered after a measurement required every 8,760 hours of operation. Additionally, and as an exception to the 90-calendar day timeframe, the agency must provide a delay of repair provision if the repair or replacement would require a vent blowdown, or otherwise be infeasible or unsafe, until the next process unit shutdown.
- Commenter (2428-API) recommends that 40 CFR 60.5380b and 60.5385b be amended to accommodate a work practice standard that includes clear provisions for repair or replacement and delay of repair or replacement that is consistent with 40 CFR 60.5397b(h)(3).
- Commenter (2483-INGAA) recommends that repair be required no later than the next scheduled compressor station shutdown for maintenance.
- Commenter (2399-GPA) suggests repair within 720 operating hours which would be more consistent with the hours of operation limitations in proposed 40 CFR 60.5385b(a)(1) and (2).
- Commenter (2305-Williams) requests a two-year delay of repair timeline that matches the leak monitoring program for streamlining. Additionally, the time to repair rod packing has all similar repair timing constraints as fugitive components.

Commenters (2282-Kinder Morgan, Inc. I, 2483-INGAA) propose specific regulatory language revisions to implement the requested work practice approach and delay of repair provision.

The following revised rule language is proposed by one commenter (2483-INGAA) for the proposed new section 40 CFR 60.5385b(a) and 60.5393c(a) (underlined text reflects new text and struck out text reflects deleted text):

---

<sup>33</sup> API endorsed GPA comments.

~~(a) The volumetric flow rate, measured in accordance with paragraphs (b) of this section, must not exceed 2 standard cubic feet per minute (scfm). You must conduct measurements of the volumetric flow rate in accordance with the schedule specified in paragraphs (a)(1) and (2) of this section and determine the volumetric flow rate in accordance with paragraph (b) of this section. If the volumetric flow rate, measured in accordance with paragraph (b) of this section, for a rod packing exceeds 2 standard cubic feet per minute (scfm), or if the combined volumetric flow rate, measured in accordance with paragraph (b) of this section, for multiple rod packings that are manifolded together exceeds 2 scfm multiplied by the number of rod packings, the rod packing or packings must be repaired as provided in paragraph (a)(3) of this section.~~

A new paragraph 40 CFR 60.5393c(a)(3) and 60.5385b(a)(3) should be added as follows (underlined text reflects new text):

(3) The rod packing repair must be conducted no later than the next scheduled compressor station shutdown for maintenance. Delay of repair beyond the next compressor station shutdown for maintenance is allowed for a reciprocating compressor rod packing, if rod packing replacement is necessary during the compressor station shutdown for maintenance, rod packing supplies have been depleted, and rod packing supplies had been sufficiently stocked before the supplies were depleted. Delay of repair beyond the next compressor station shutdown for maintenance will not be allowed unless the next compressor station shutdown for maintenance occurs sooner than 6 months after the first compressor station shutdown for maintenance. You must conduct volumetric flow rate measurements from each repaired rod packing using the methods specified in paragraph (b) of this section within 15 days after the repair to document that the rate has been reduced to less than 2 scfm per rod packing.

The following revised rule language is proposed by commenter (2282-Kinder Morgan, Inc.) for reciprocating compressors to address their concerns:

40 CFR 60.5393c(g) and 60.5393c(g)(1)<sup>34</sup> suggested additions include (underlined text reflects new text):

(g) If the results of the initial (§60.5410c(d)) or continuous (§60.5415c(f)) compliance measurement demonstrate that the rod packing flow rate is greater than 2 scfm, you must repair or replace the rod packing within 90 days from the date of the initial or continuous flow rate measurement.

(1) If the repair or replacement is technically infeasible, would require a vent blowdown, a process unit or facility requires shutdown, parts or materials are unavailable, or it would be unsafe to repair during operation of the unit, the repair must be completed during the next scheduled process unit or facility shutdown for maintenance, after a scheduled vent blowdown, or within 2 years, whichever is earliest. For purposes of this paragraph (d)(1),

---

<sup>34</sup> The Subpart OOOOb section to which this change should also apply is §60.5385b.

a vent blowdown is the opening of one or more blowdown valves to depressurize major production and processing equipment, other than a storage vessel.

Response II-11-33: In response to comments received on the December 2022 Proposal, EPA has finalized the performance-based volumetric flow rate standard as a work practice standard under both the NSPS OOOOb and EG OOOOc, including repair and delay of repair provisions. See section XI.I.1 of the preamble to the final rule which provides EPA's rationale and reasoning for finalizing the performance-based volumetric flow rate standard as a work practice standard.

As such, and in consideration of the comments above, the EPA has included the following repair and delay of repair requirements in 40 CFR 60.5385b(a)(3) and 40 CFR 60.5393c(a)(3):

(3) The rod packing must be repaired or replaced within 90 calendar days after the date of the volumetric emissions measurement that exceeded 2 scfm per cylinder. You must conduct follow-up volumetric flow rate measurements from compressor vents using the methods specified in paragraph (b) of this section within 15 days after the repair (or rod packing replacement) to document that the rate has been reduced to less than 2 scfm per cylinder. Delay of repair will be allowed if the conditions in paragraphs (a)(3)(i) or (ii) of this section are met.

(i) If the repair (or rod packing replacement) is technically infeasible, would require a vent blowdown, a compressor station shutdown, or would be unsafe to repair during operation of the unit, the repair must be completed during the next scheduled compressor station shutdown for maintenance, after a scheduled vent blowdown, or within 2 years of the date of the volumetric emissions measurement that exceeds the applicable required flow rate per cylinder, whichever is earliest. A vent blowdown is the opening of one or more blowdown valves to depressurize major production and processing equipment, other than a storage vessel.

(ii) If the repair requires replacement of the rod packing or part, but the replacement cannot be acquired and installed within the repair timelines specified under this section due to the condition specified in paragraph (a)(3)(ii)(A) of this section, the repair must be completed in accordance with paragraph (a)(3)(ii)(B) of this section and documented in accordance with §60.5420b(c)(5)(viii) through (x).

(A) Rod packing or part supplies had been sufficiently stocked but are depleted at the time of the required repair.

(B) The required rod packing or part replacement must be ordered no later than 10 calendar days after the reciprocating compressor is added to the delay of repair list. The repair must be completed as soon as practicable, but no later than 30 calendar days after receipt of the replacement rod packing or part, unless the repair requires a compressor station shutdown. If the repair requires a compressor station shutdown, the repair must be completed in accordance with the timeframe specified in paragraph (a)(3)(i) of this section.

## 11.4 EG OOOOc Proposed BSER

[**Note:** Many of the comments provided for reciprocating compressors included in sections 11.1 through 11.3 of this Chapter would also apply to the reciprocating compressor requirements proposed to be regulated under EG OOOOc. This section provides comments that were submitted on the proposed reciprocating compressor requirements that focused on EG OOOOc.]

### 11.4.1 Applicability

Comment: Commenter (2173-Northeast Natural Energy LLC (NNE)) states that for existing RICE engines under EG OOOOc the operator must determine if vent emissions exceed 2 scfm w/8,760 hours of the effective date of the approved state plan. The commenter suggests that this seems to conflict with the "up to three years compliance date" language found elsewhere in the proposal. The commenter asserts that the EPA needs to clarify why they do not defer to whatever compliance date is in the approved state plan.

Response II-11-34: The EG OOOOc presumptive standards (nor the NSPS OOOOb standards) for reciprocating compressors do not apply to Reciprocating Internal Combustion Engines (RICE) engines. See Compliance Requirements for Stationary Engines (including RICE) at <https://www.epa.gov/stationary-engines/compliance-requirements-stationary-engines>.

Owners or operators of reciprocating compressor designated facilities under the final rule must conduct their first volumetric flow rate measurements from their reciprocating compressor cylinder vents on or before 8,760 hours of operation after the effective date of an approved state or tribal plan, or on or before 8,760 hours of operation after last rod packing replacement, or on or before 8,760 hours of operation after startup, whichever is later. Owners or operators must conduct subsequent volumetric flow rate measurements from their reciprocating compressor cylinder vents on or before 8,760 hours of operation after the previous measurement which demonstrates compliance with a volumetric flow rate of 2 scfm per cylinder (or a combined cylinder emission flow rate greater than the number of compression cylinders multiplied by 2 scfm), or on or before 8,760 hours of operation after last rod packing replacement, whichever is later.

### 11.4.2 Proposed Standards

Comment: Commenters (2305-Williams, 2399-GPA, 2428-API)<sup>35</sup> state that the proposed rules for reciprocating compressors need to consider the full costs and technical challenges with retrofitting each existing reciprocating compressor cylinder for monitoring ports. Each cylinder does not necessarily have its own vent. There would need to be alterations made to the piping to allow for monitoring to be conducted on a per-cylinder basis. The costs required to add new piping so each cylinder has its own vent and install monitoring ports have not been considered. Should the EPA choose to move forward with a proposed rule, the commenter assert that the

---

<sup>35</sup> API endorses GPA comments.

EPA should issue guidelines allowing a phased approach to adequately account for port installation.

Response II-11-35: The final rule does not require that each cylinder be equipped with a monitoring port. Individual cylinders can be manifolded to a single open-ended vent line/vent, where the volumetric flow rate must not exceed the sum of the individual cylinders multiplied by 2 scfm. Further, EPA proposed in the December 2022 Supplemental Proposal (and is maintaining in the final rule) that an owner or operator does not have to conduct volumetric flow rate monitoring if screening for emissions or leaks from the reciprocating compressor rod packing using OGI or Method 21 does not indicate a leak. See final standards/presumptive standards at 40 CFR 60.5386b(a) and 40 CFR 60.5405c(a) test methods and procedures for reciprocating compressors.

In addition, as an alternative to the reciprocating compressor performance-based volumetric flow rate per cylinder presumptive standard, the final EG OOOOc reciprocating compressor requirements allow owners or operators to meet several other compliance options to meet the final NSPS OOOOb standards and EG OOOOc presumptive standards.

Comment: Commenter (2218-Texas Commission on Environmental Quality (TCEQ)) states that the proposed requirements for several types of designated facilities are economically unreasonable and should be revised. The EPA's Oil and Gas Control Techniques Guidelines (CTG) model rule and current TCEQ rules have three control options for reciprocating compressors, including two that simply impose time limits on packing change-outs. The commenter states that the proposed 40 CFR 60.5393c requires packing volumetric flow rate measurements for all affected reciprocating compressors, regardless of when the packing change-outs last occurred. This is unnecessarily burdensome for sources with recently changed packing.

Response II-11-36: The EPA evaluated this and other similar comments. It was not the EPA's intent for affected reciprocating compressors to be required to conduct volumetric flow rate measurements where sources recently changed rod packing. The final EG OOOOc presumptive standards have been revised to clarify that an owner or operator must conduct their first volumetric flow rate measurements from their reciprocating compressor cylinder vents on or before 8,760 hours of operation after the effective date of an approved state or tribal plan, on or before 8,760 hours of operation after last cylinder rod packing replacement, or on or before 8,760 hours of operation after startup, whichever is later. Similarly, owners or operators are required to conduct subsequent volumetric flow rate measurements from reciprocating compressor cylinder vents on or before 8,760 hours of operation after the previous measurement which demonstrates compliance with a volumetric flow rate of 2 scfm per cylinder (or a combined cylinder emission flow rate greater than the number of compression cylinders multiplied by 2 scfm), or on or before 8,760 hours of operation after last rod packing replacement, whichever is later.

## **11.5 Regulation Text Correction**

Comment: Commenter (2298-Pioneer, 2326-AXPC, 2428-API) seeks clarification on a missing cross-referenced section in the reciprocating compressor proposed requirements. Specifically,

they requested that EPA clarify the rule text of 40 CFR 60.5370b(a)(1)(iii), which cross-references a non-existent 40 CFR 60.5385b(a)(3).

Response II-11-37: The EPA evaluated the cross-reference issue identified by the commenters. The EPA has revised 40 CFR 60.5370b(a)(1)(iii) to correctly reference 40 CFR 60.5385b(d) and not 40 CFR 60.5385b(a)(3) in the final rule.

## Chapter 12. Equipment Leaks at Natural Gas Processing Plants

### 12.1 Monitoring Requirements

#### *12.1.1 Inspection Frequency*

Comment: Commenter (2211-Lambda Energy Resources LLC) urges EPA to consider semi-annual monitoring, rather than the proposed bi-monthly surveys for greenhouse gas (GHG) emissions, which would impose significant and unnecessary additional costs on plant operations. The commenter states that they currently employ leak detection and repair (LDAR) monitoring and monitor most components quarterly using EPA Method 21, as well as monitoring for GHG annually with optical gas imaging (OGI) technology. The commenter believes that these existing monitoring programs have proven to be effective and have resulted in minimal emissions. The commenter also urges the EPA to consider delay of repair (DOR) leniency in the event GHG components are found leaking and cannot be repaired or replaced without a process unit shutdown.

Response II-12-1: Regarding the monitoring frequency for OGI monitoring, the EPA has found that bimonthly OGI monitoring is the best system of emission reduction (BSER) for monitoring equipment leaks at onshore natural gas processing plants for both components “in VOC service” (traditional applicability) and components in GHG service that are not in VOC service. We disagree that annual monitoring of components that are not in VOC service but in GHG service is BSER. The commenter did not provide information showing that EPA’s BSER analysis is incorrect in any aspect or supporting its claim that bimonthly OGI monitoring imposes significant and unnecessary additional cost. In addition, the EPA has also finalized an alternative LDAR program that allows the owner/operator to comply with an EPA Method 21 program like that required for onshore natural gas processing plants in New Source Performance Standards (NSPS) OOOOa and OOOO, which has been implemented at onshore natural gas processing plants subject to these subparts for many years. This alternative allows quarterly monitoring for valves and annual monitoring for connectors. The EPA did not find this long standing LDAR program based on Method 21 as the BSER because it is not as cost effective as OGI, but our modeling indicated that the Method 21 alternative applied to all components with a potential to emit methane or VOC provided equivalent emission reductions as bimonthly OGI. <sup>1</sup>This EPA Method 21 alternative is also like the requirements that Lambda Energy Resources described in their comments.

Regarding DOR leniency in the event GHG components are found leaking and cannot be repaired or replaced without a process unit shutdown, the final NSPS OOOOb and the model rule implementing EG OOOOc allow for the DOR for equipment that cannot be repaired or replaced without a process unit shutdown.

Comment: Commenter (2240-Rose Rock Environmental Services, LLC) suggests that while bimonthly OGI is an excellent method for manually monitoring for leaks, low-cost continuous monitoring solutions provide a more cost-effective means of further reducing emissions by

---

<sup>1</sup> See 86 FR 63232, November 15, 2021.

providing immediate detection of leaks down to 3 standard cubic feet per hour (scfh). The commenter encourages EPA to also allow continuous monitoring technology solutions as a BSER for natural gas processing plants to minimize methane emissions.

Commenter (2333-LongPath Technologies, Inc. (LongPath)) suggests that continuous methane emissions monitoring technologies with the ability to provide valid quantification (emission rate) should be allowable to meet the proposed standard.

Response II-12-2: The EPA agrees with the commenters that employing continuous monitoring technology to detect VOC and methane leaks from equipment at onshore natural gas processing plants can be used to achieve emission reductions equivalent to those achieved by bimonthly OGI. The use of a continuous monitoring technology is not directly specified in this final rule because the application of a continuous monitoring network that achieves equivalent emission reduction to bimonthly OGI (BSER) is very site-specific, dependent on the plant layout and prevailing meteorological conditions, to assess proper number and placement of continuous monitors based on the sensitivity of the monitoring sensors. Because a site-specific approach is needed, this final rule provides a pathway for allowing the use of continuous monitoring technology as an alternative on a site-specific basis.

Comment: Commenter (2433-Environmental Defense Fund (EDF) *et al.*) supports EPA's proposal to require bimonthly OGI monitoring in accordance with Appendix K for all pumps, valves, and connectors located within affected process units at onshore natural gas processing plants. The commenter states this is an appropriate BSER for both new and existing processing plants that is cost-effective and can significantly reduce emissions.

Response II-12-3: Comment is a supportive comment on an aspect of the November 2021 Proposal that has remained unchanged in the final rule; as such, no response is required.

Comment: Commenter (2180-Pennsylvania Department of Environmental Protection) recommends that for natural gas processing plants, audio, visual, and olfactory (AVO) be conducted monthly, and instrument-based inspections should be conducted quarterly. The commenter states that Pennsylvania has required this inspection frequency since 2013.

Response II-12-4: A combined monitoring of quarterly OGI and monthly AVO was not evaluated as BSER for natural gas processing plants because, unlike well sites and compressor station sites, natural gas processing plants typically are manned and because AVO is not expected to be effective for identifying leaks from all potential methane leak source, such as leaks of treated natural gas. The rule provides AVO requirements based on the fact that some equipment leaks can be identified via AVO methods as part of daily operational duties. For example, pumps in light liquid service must be visually monitored weekly for indications of liquids dripping. Open-ended valves and lines, pumps, valves, and connectors in heavy liquid service, and pressure relief devices in light liquid or heavy liquid service are subject to leak repair anytime there is evidence of a leak by AVO. As discussed in Response II-12-1, the EPA has found that bimonthly OGI monitoring using Appendix K is the BSER for equipment leaks at onshore natural gas processing plants, and the commenter did not provide information showing that EPA's BSER analysis is incorrect in any aspect.

Comment: Commenter (2193-California Air Resources Board) believes the application of LDAR requirements should be uniformly applied to all facilities. The commenter notes that the proposed structure creates different LDAR requirements for every different type of facility, which the commenter believes is likely to result in extreme difficulty with respect to enforcement and compliance due to the different rules for nearly every type of facility, as well as a great deal of regulatory complexity in implementation. The commenter cites to California's Greenhouse Gas Emissions Standards for Crude Oil and Natural Gas Facilities<sup>2</sup> which the commenter states have the same LDAR requirements regardless of the facility type. The commenter believes that amending this portion of the proposed rule to require quarterly EPA Method 21 inspections, or alternatively, bimonthly advanced technology inspections with annual OGI monitoring, regardless of the type of facility, would ensure a streamlined process for states to implement and enforce in their plans.

Response II-12-5: The EPA is required by CAA section 111 to establish the best system of emission reduction (BSER) for each type of affected facility. The EPA has found that bimonthly OGI monitoring using Appendix K is BSER for monitoring VOC and methane leaks from equipment at onshore natural gas processing plants. EPA has also finalized an alternative LDAR program that allows the owner/operator to comply with an EPA Method 21 program like that required in NSPS OOOOa. EPA has found that BSER at single wellhead only sites and small well sites is quarterly AVO, BSER at multi-wellhead only sites is quarterly AVO and semiannual monitoring using OGI, BSER at well sites with major production and processing equipment and centralized production facilities is bimonthly AVO and quarterly monitoring using OGI, and BSER at compressor stations is monthly AVO and quarterly monitoring using OGI. BSER at well sites and compressor station sites in Alaska North Slope was determined to be annual monitoring using OGI. The commenter did not provide information that EPA's BSER analysis is incorrect in any aspect.

### ***12.1.2 Use of OGI vs. EPA Method 21***

Comment: Commenter (2214-BlueCrest Alaska Operating, LLC) requests that EPA allow EPA Method 21 as an alternative to OGI in all instances, as EPA Method 21 can be conducted anytime and allows prompt monitoring and repair, whereas OGI requires advanced scheduling with a contractor.

Response II-12-6: EPA has finalized an alternative LDAR program that allows the owner/operator to comply with an EPA Method 21 program like that required in New Source Performance Standards (NSPS) OOOOa.

Comment: Commenter (2362-Environmental Integrity Project (EIP) *et al.*) states that EPA's proposed requirements related to OGI are arbitrary and capricious and do not constitute BSER for several reasons. First, the commenter states that while OGI can indeed be a useful way to respond to large leaks more rapidly, EPA has not adequately or rationally explained - or explained at all - why it is not requiring sources to also use EPA Method 21 in tandem with OGI. Nor, according to the commenter, has the agency rationally explained, or explained at all, why it would be more cost-effective, in terms of the dollars spent per ton of volatile organic compounds

---

<sup>2</sup> See California Code of Regulations, Title 17, Sections 95665-95677.

(VOC) and methane emissions reduced, to eliminate the requirement to conduct full LDAR surveys that identify leaks at or above 500 parts per million (ppm) in return for OGI surveys that are limited to finding leaks that exceed 100,000 ppm, according to the commenter. In the proposed rule, the commenter states that EPA recognizes that LDAR can detect leaks at 500 ppm and although the proposed rule requires OGI equipment to be capable of imaging gas at a concentration of 10,000 ppm, EPA elsewhere recognizes that OGI cannot reliably detect leaks smaller than 100,000 ppm.<sup>3</sup> Thus, by eliminating any requirement to use EPA Method 21, the commenter states that EPA's proposal allows oil and gas sources to ignore leaks that range from 500 to 100,000 ppm. The commenter believes that requiring OGI in combination with regular Method 21 monitoring would detect leaks in the 500 to 100,000 ppm range, would better reduce fugitive emissions of VOCs and methane, and is cost-effective. As part of its cost-effectiveness analysis and rationale, the commenter asserts that the EPA must make available any relevant studies or data that compare the percentage of leaks, and mass and volume of VOCs and methane released during such leaks, as detected by OGI versus Method 21.

Second, the commenter (2362-EIP *et al.*) states, as noted above, while the proposed rule requires OGI equipment to detect leaks at 10,000 ppm, EPA elsewhere suggests that OGI cannot reliably detect leaks smaller than 100,000 ppm. The commenter asserts that EPA must resolve and rationally explain this conflict in the record. If EPA maintains that OGI can detect leaks below 100,000 ppm, they state that the Agency must provide evidence that this is the case.

Response II-12-7: The EPA has found that bimonthly OGI monitoring conducted according to Appendix K is the BSER for equipment leaks at onshore natural gas processing plants and that it achieves equivalent emission reduction to the "quarterly" EPA Method 21 historically required for natural gas plants as provided in NSPS OOOO/OOOOa without the need for an annual EPA Method 21 monitoring requirement. We attribute this to two factors: more effective OGI monitoring based on the requirements of Appendix K and the ability of OGI to readily detect methane and other light hydrocarbons in process streams at natural gas processing sites. These two factors allow a work practice of bimonthly OGI surveys to achieve equivalent emissions reductions to the current EPA Method 21-based work practice in NSPS OOOOa. We assessed including an annual EPA Method 21 requirement in addition to bimonthly OGI surveys but determined that the additional emission reductions achieved by the annual EPA Method 21 monitoring was not cost effective for natural gas plants. Therefore, we did not include an annual EPA Method 21 monitoring as part of the BSER.

We also note that the commenter is misinterpreting the model inputs when they suggest that OGI does not detect leaks below a concentration of 100,000 ppmv. That is not the case. The model assumption that the commenter is referencing is related to the probability of detection - we assumed OGI would detect 100% of leaks with a concentration above a 100,000 ppmv EPA Method 21 concentration; that does not mean that an OGI camera will not detect leaks below 100,000 ppmv. The OGI camera required for surveys of fugitive emissions components in NSPS OOOOa requires a demonstration that it can image a gas mixture of propane and methane with a concentration of 10,000 ppmv. As EPA stated in the preamble to the final rule for NSPS OOOOa, "Available data show that OGI can detect fugitive emissions at a concentration of at

---

<sup>3</sup> See EPA-HQ-OAR-2021-0317-0166, Attachment 6 [Excel sheet] at "Introduction" Tab (assuming an OGI concentration sensitivity of 100,000 ppm).

least 10,000 ppm when restricting its use during certain environmental conditions such as high wind speeds. Due to the dynamic nature for the OGI detection capabilities, OGI may also image emissions at a lower concentration when environmental conditions are ideal.”<sup>4</sup> Studies performed in support of the final TSD for Appendix K show that in the right conditions, a cooled, midwave infrared camera can easily see leaks at a concentration below 10,000 ppmv.

The primary factor used to determine OGI detection was the projected mass emission rate of the leak, not the concentration of the leak. It is possible to have high emission rate leaks at both low and high concentrations. Across a large number of Monte Carlo simulations where EPA Method 21 concentration leaks were randomly assigned a mass emission rate consistent with EPA correlation equations<sup>5</sup> and the variability therein, we determined that bimonthly OGI conducted following methods in Appendix K is BSER and achieves equivalent emission reductions as “quarterly” Method 21 included in NSPS OOOOa at natural gas plants without an annual Method 21 monitoring survey.

Comment: Commenter (2362-EIP *et al.*) believes that EPA should require oil and gas sources to keep records of all OGI images and not just a subset of those images. The commenter notes, for example, if EPA is allowing sources to retain only those images that capture leaks as determined by the owner or operator, this would leave EPA and state agencies with no independent ability to assess whether sources are accurately interpreting OGI data. The commenter states that relying on independent contractors for such an assessment will not suffice.

Response II-12-8: EPA disagrees with the commenter. EPA determined that bi-monthly OGI monitoring in accordance with Appendix K is the BSER for equipment leaks at on-shore natural gas processing plants. At these facilities, EPA expects that the effectiveness of the OGI program will be assessed through reviewing facility reports and EPA inspections. Additionally, for sites conducting OGI surveys with Appendix K, EPA and state agencies will be able to review training records, semiannual audits, and daily quality assurance videos for OGI camera operators to assess the ability of an OGI camera operator, as well as facility monitoring plans and records of OGI surveys. These records include information on the meteorological conditions at the site and the length of time surveying was conducted. Reviewing all of this information together will provide EPA and state agencies with information necessary to assess the quality of the OGI survey.

EPA notes that facilities utilizing OGI for leak detection under the alternative work practices at 40 CFR 60.18 and 63.11 must continue to keep video records of the leak survey results, including a time and date stamp for each monitoring event. Whether Appendix K and its recordkeeping requirements is BSER for other industry sectors and should be incorporated into other subparts will be considered in rulemaking for the subparts specifically applicable to those sectors.

<sup>5</sup> Protocol for Equipment Leak Emission Estimates. November 1995. EPA-453/R-95-017. Available here: [https://www.epa.gov/sites/default/files/2020-09/documents/protocol\\_for\\_equipment\\_leak\\_emission\\_estimates.pdf](https://www.epa.gov/sites/default/files/2020-09/documents/protocol_for_equipment_leak_emission_estimates.pdf).

### 12.1.3 Use of Appendix K

Comment: Commenter (2248-North Dakota Petroleum Council (NDPC)) believes that the OGI camera is an effective tool for finding leaks. In many ways superior to EPA Method 21; however, the commenter notes that Appendix K as written, will discourage use of OGI in the natural gas processing sector.

Response II-12-9: Regarding OGI, this comment is a supportive comment on an aspect of the November 2021 Proposal that has remained unchanged in the final rule; as such, no response is required.

Regarding Appendix K, see responses to relevant comments in this chapter, as well as Volume I, Chapters 15 and 22, and Volume II, Chapter 22.

Comment: Commenter (2196-Private Citizen) states that if Appendix K is finalized as proposed, the current trend to use the alternative work practice (AWP) at gas plants (which has been allowed for years) will revert back to the use Method 21. As written, the commenter is concerned there are too many compliance traps due to the recordkeeping burden. The commenter believes the protocol and the time spent on response factors etc., is designed with chemical species other than light alkanes in mind. The commenter provides a sample hydrocarbon analysis of field gas and sales gas and states that due to the consistency of feed (*i.e.*, field gas) to a natural gas processing plant being essentially 96-98 percent methane and ethane, requiring the use of Appendix K to establish a program to use OGI for the suite of light hydrocarbons (which the commenter states has been established is valid using the methods in 40 CFR 60.5397b) is an unnecessary burden on the industry. The commenter recommends that natural gas facilities be allowed to use the OGI camera as specified 40 CFR 60.5397b or Appendix K. The commenter provides the following recommended changes to the regulatory text at *40 CFR 60.5400b(b)* [introductory text] (suggested additions are underlined):

(b) *Monitoring surveys.* You must monitor for leaks using optical gas imaging in accordance with appendix K of this subpart or as specified in §60.5397b, unless otherwise specified in paragraphs (c) or (d) of this section. [...]

The commenter (2196-Private Citizen) states that Appendix K becomes relevant when other industries with chemicals species that fall outside of the well-established light hydrocarbon range (C<sub>5</sub> and less), where there is about a decade of data showing that the OGI camera adequately images these hydrocarbons. These other industries, such as refining and synthetic organic chemical manufacturing industry (SOCMI), can incorporate Appendix K by reference, states the commenter.

Response II-12-10: We disagree with the commenter that the compliance provisions in the final Appendix K are too burdensome and will force facilities to revert back to using EPA Method 21. The commenter did not specify which recordkeeping provisions are problematic from a compliance standpoint, The EPA carefully balanced recordkeeping burden with the minimum records needed to ensure that the requirements of Appendix K are followed. We also disagree that we should allow the OGI method for fugitive emission components as specified in

§60.5397b for gas plants. The detection limit requirements in Appendix K are lower than those specified in §60.5397b. The lower detection limits in Appendix K were critical in our determination that OGI provided equivalent emission reductions to EPA Method 21 for gas processing plants.

Regarding Appendix K, see responses to relevant comments in this chapter, as well as Volume I, Chapters 15 and 22, and Volume II, Chapter 22.

Comment: Commenter (2286-Colorado Department of Public Health and Environment (CDPHE)) agrees that LDAR is a necessary program to reduce emissions at natural gas processing plants, but the commenter is concerned about the potential shortage of expertise to conduct necessary inspections for Colorado’s approximately 60 natural gas processing gas plants, due to the level of credentials and experience required to be an Appendix K LDAR technician. The commenter notes the state has long required the owners or operators of natural gas processing plants located in Colorado’s ozone nonattainment area to comply with LDAR requirements, beginning in 2003 with EPA’s LDAR program in NSPS KKK, and currently requires the owners or operators of natural gas processing plants to comply with the LDAR requirements in EPA’s NSPS OOOO or NSPS OOOOa on a state-wide basis. According to the commenter, these facilities may have to revise their LDAR programs to comply with EPA’s presumptive standards for natural gas processing plants within 36 months after the specified state plan submittal date. Should there be a shortage of credentialed Appendix K technicians, the commenter is concerned that Colorado’s gas plants may be unable to complete the initial and ongoing LDAR inspections.

Response II-12-11: See Response II-22-15 and II-22-28 of Volume II, Chapter 22 of this RTC.

Comment: Commenter (2305-Williams Companies, Inc.) appreciates revisions made in response to comments between the November 2021 Proposal and December 2022 Supplemental Proposal. However, the commenter still has concerns as it relates to gas processing plants. Specifically, the commenter recommends:

- Instead of requiring a dwell time of 2 seconds per component at multiple angles, a minimum of 3 seconds per scene would be more appropriate. When looking for fugitive emissions the actual component is not looked at but instead around the component to see movement of “smoke” that indicates an emission.
- The development of the operating envelope is overly complicated and could inadvertently introduce more issues. Instead, daily field checks would be adequate. These field checks would ensure the camera operator is able to identify fugitive emissions and set a maximum viewing distance. These daily field checks would be completed utilizing a known gas concentration and flow rate at actual metrological conditions prior to conducting monitoring surveys. Field conditions can change throughout the day so any time there are weather changes that could significantly alter the viewing distance (*e.g.*, large temperature changes of 10 degrees or significant wind changes) a new check would be completed and documented to ensure the viewing distance set point is still adequate to identify fugitive emissions.

- Prescriptive breaks should not be required. When a fugitive emissions survey is being completed the camera operator is not looking through the camera lens for periods longer than 1-2 minutes at a time before the camera is put down so the operator can see their surroundings and walk to the next viewing location. Additionally, when a fugitive emission is identified a more prolonged break is completed while the leak record is being made giving the operator many opportunities to rest their eyes.

Response II-12-12: See Responses II-22-30 and II-22-38 of Volume II, Chapter 22 of this RTC, and section XIV.B.1 (Dwell Time) of the preamble to the final rule for a response to these comments.

## 12.2 Equipment Classification

Comment: Commenters (2399-GPA, 2428-American Petroleum Institute (API)) believe that EPA should retain the “in VOC service” requirement and 10 percent VOC by weight threshold, as well as establish a methane threshold, as the current thresholds for VOC and methane are essentially zero. Both commenters suggest a 1 percent threshold for equipment in methane service. Commenter (2399-GPA) explains that gas plants contain many streams, such as acid gas, wastewater, and recycled water, where VOCs and methane are present but so low that they would not be detected by flame ionization detectors (FIDs). The commenter includes data from acid and amine gas samples by way of example. The commenter is concerned, that because the VOC or methane content of these streams are not zero, and presumably have a theoretical potential to emit, owners and operators would waste substantial resources to conduct LDAR monitoring on components that will always result in non-detects. The commenter states that the December 2022 Supplemental Proposal offered no actual data to the contrary. Thus, they contend that the proposed regulatory language would wastefully impose costs and burdens on owners and operators with no potential benefit.

Commenter (2428-API) points out that some streams at gas processing plants contain methane or VOC but in such low concentrations that monitoring would be meaningless as it would likely always result in no detected emissions and would add costs and use personnel resources with minimal, if any, environmental benefit. Examples of such streams, provided by the commenter, include but are not limited to purity ethane, acid gas, ancillary chemicals, wastewater, and recycled water. The commenter states that in existing LDAR regulations, EPA has recognized and reaffirmed the need for concentration thresholds to achieve cost-effective emission reductions, but that in this rulemaking, the agency has not provided sufficient justification for deviating from this longstanding practice.

The commenter (2428-API) questions EPA’s analysis in the November 2021 Proposal, where the commenter states that EPA appears to consider only components in VOC service (defined as 10 percent by VOC by weight or in wet gas service) or in non-VOC service (defined as a component in methane service with at least 10 percent methane that is not also in VOC service). The commenter states that EPA then estimates VOC and methane emissions, reductions and

cost-effectiveness using a limited set of composition ratios,<sup>6</sup> then appears to treat the “potential to emit methane” as equivalent to “in non-VOC service” in evaluating control options. Therefore, the commenter states, EPA does not appear to fully consider the cost-effectiveness of a potential to emit applicability threshold. The commenter reiterates that EPA should retain the current 10 percent by weight threshold for VOC and establish a similar concentration threshold for methane (suggested as 1 percent by weight). To address this the commenter offers the following recommended edits to the definitions in 40 CFR 60.5430b (suggested additions are underlined; suggested deletions are shown in strike-through):

*Equipment*, as used in the standards and requirements of this subpart relative to the process unit equipment affected facility at onshore natural gas processing plants, means each pump, pressure relief device, open-ended valve or line, valve, and flange or other connector ~~that has the potential to emit in methane or VOC service~~ and any device or system required by those same standards and requirements of this subpart.

In methane service means that the piece of equipment contains or contacts a process fluid that is at least 1 percent methane by weight. (The provisions of § 60.5400b(a)(2) specify how to determine that a piece of equipment is not in methane service.)

In VOC service means that the piece of equipment contains or contacts a process fluid that is at least 10 percent VOC by weight. (The provisions of § 60.5400b(a)(2) specify how to determine that a piece of equipment is not in VOC service.)

Regarding how to determine when a piece of equipment is not subject to monitoring, the commenter (2428-API) suggests that the language in 40 CFR 60.5400b(a)(2) should also be revised, as appropriate.

Conversely, commenter (2433-EDF *et al.*) supports EPA’s proposal to eliminate the “in VOC service” distinction for purposes of LDAR inspections and instead require bimonthly OGI (in accordance with Appendix K) at all pumps, valves, and connectors located within affected process units at processing plants. The commenter believes that EPA is correct that “a VOC concentration threshold bears no relationship to the LDAR for methane and is therefore not an appropriate threshold for determining whether LDAR for methane applies.” They add that they also believe EPA is correct that “since there would be no threshold for requiring LDAR for methane, any equipment not in VOC service would still be required to conduct LDAR for methane even if not for VOC.”

Response II-12-13: The EPA is not including a VOC or methane threshold in the final rule. See discussion in section XI.L.1 (Potential to emit methane and VOC) of the final rule preamble.

---

<sup>6</sup> The commenter (2428-API) refers to Table 10-8 of the Technical Support Document (TSD). See EPA-HQ-OAR-2021-0317-0166.

## 12.3 Overlapping NSPS Applicability

Comment: Commenter (2286-CDPHE) requests that EPA put forth a singular standard for gas plant LDAR to streamline oversight and reduce uncertainty in the various applications of portions of federal rules. The commenter notes that EPA thoroughly discusses in the proposal that some sources may already be subject to similar requirements under EPA's NSPS KKK, NSPS OOOO, or NSPS OOOOa, which may vary in stringency as compared to EPA's proposed standards. The commenter notes that the November 2021 Proposal and the December 2022 Supplemental Proposal identify specific sections of several existing NSPS which oil and gas plants are subject to; namely, the proposal combines select requirements found in NSPSs KKK, VV, VVa, OOOO, and OOOOa. While the commenter appreciates EPA's narrative discussion comparing the older NSPS to the proposed presumptive standards, the commenter requests that EPA include the described more stringent provisions in the proposed presumptive standards directly or by reference, should EPA prefer those requirements continue to be implemented instead of the proposed presumptive standards once finalized.

Response II-12-14: The EPA is finalizing the regulatory structure as proposed. The EPA notes that Method 21 may be used as an alternative to OGI at gas plants, so sources have the option to streamline to one detection methodology should they choose. Regarding the standards for compressors subject to NSPS KKK which will become subject to a state or Federal plan implementing the presumptive standards of EG OOOOc, see the discussion in section IX.C of the preamble to the final rule.

Comment: Commenter (2222-Wisconsin Department of Natural Resources (WI DNR)) states that it would provide significant clarity and consistency to both state regulators and affected sources if NSPS OOOOb and emission guidelines (EG) OOOOc were to incorporate all compliance options provided in NSPS KKK for wet seal centrifugal compressors at natural gas processing plants. Further, the commenter states that EPA should consider taking this approach for other categories of affected sources that will be covered by the new NSPS and EG as well as the existing NSPS.

Response II-12-15: The EPA evaluated this option and determined that incorporating compliance options provided in NSPS KKK for wet seal centrifugal compressors at natural gas processing plants in NSPS OOOOb or EG OOOOc was unnecessary. The EPA is instead clarifying applicability of requirements in the final rule preamble and NSPS KKK regulatory text. See discussion in section IX.C (How will the final EG OOOOc impact sources already subject to NSPS KKK, NSPS OOOO, or NSPS OOOOa?) of the final rule preamble.

## 12.4 Request for Exemption

Comment: Commenter (2248-NDPC) requests that temporary portable natural gas liquid processing skids ( $\leq 10$  million standard cubic feet per day (MMscfd)) in the oil and natural gas production segment be exempt from requirements applicable to natural gas processing plants in the natural gas processing sector.

Response II-12-16: The EPA cannot tell from the information provided if the commenter means that all temporary/portable units are  $\leq 10$  million standard cubic feet per day (MMscfd) or whether the commenter is asking for two types of exclusions from the definition of natural gas processing plant (i.e., temporary/portable and size). With respect to exemptions for natural gas processing plants which do not have the design capacity to process 10 MMscfd or more of field gas, see the discussion in Response II-12-21. Regarding temporary units, the EPA is not finalizing an exclusion from the definition of natural gas processing plants for temporary/portable units, beyond the exclusion for standalone Joule-Thompson skids which currently exists in the definition of natural gas processing plant in NSPS OOOO and OOOOa and is being finalized for NSPS OOOOb and EG OOOOc. The commenter did not provide any information on why the temporary/portable status is relevant to whether an operation meets the definition of natural gas processing plant. Further, if the exclusion also is tied to a size cutoff, the commenter did not provide a basis for how the size would be (re)determined as the temporary/portable natural gas processing skid is moved from site to site. The EPA therefore is not making the changes suggested by the commenter.

## **12.5 Closed Vent Systems and Equipment Designated as No Identifiable Emissions**

Comment: Commenter (2399-GPA) states that EPA has provided no rationale for either increasing closed vent system monitoring frequencies from the current initial EPA Method 21 monitoring and annual AVO inspections under NSPS VVa or requiring optical gas imaging inspections instead of EPA Method 21 monitoring. The commenter explains that closed vent systems have extremely low leak rates, largely owing to the small number of components and the lack of constantly moving parts, such as valves. The commenter explains that hard piping or duct work will not suffer the type of deterioration, and potential leaks, as moving parts that endure friction. The commenter believes that EPA should either withdraw this proposed requirement or provide some explanation regarding the basis for increasing the monitoring frequency, including a description of what environmental benefit could be expected by more frequent monitoring of equipment that rarely leak.

Response II-12-17: Contrary to the commenter's assertion, the EPA did explain the basis for requiring bimonthly OGI monitoring. Specifically, in section IV.L.1.b. of the December 2022 Supplemental Proposal,<sup>7</sup> The EPA stated "[w]e believe it is most efficient and cost effective to monitor the CVS at the same frequency and according to the same methodology as other equipment in the process unit equipment affected facility," which is bimonthly monitoring. The commenter did not mention, much less provide substantive comment disputing, this rationale.

Comment: Commenter (2433-EDF *et al.*) requests that EPA extend bimonthly OGI monitoring to any equipment or components designated as having no detectable emissions. As bimonthly monitoring will already be required, surveying additional components and equipment will add very little cost, according to the commenter, and is an inexpensive solution for ensuring compliance that will also help operators detect any anomalous sources at the processing plant.

---

<sup>7</sup> 87 FR 74807.

Response II-12-18: The EPA is not requiring OGI monitoring for equipment which is designated as having no detectable emissions; instead, the EPA is finalizing a standard of “no identifiable emissions” when using OGI, where a numerical limitation is relevant. See discussion in Section XI.K. of the preamble to the final rule for the rationale for this change.

Regarding extending bimonthly OGI monitoring to equipment or components, which under NSPS OOOOa are designated as “no detectable emissions” (e.g., pressure relief devices (PRDs), open-ended valves and lines, and closed vent systems) the EPA explained in the 2022 Supplemental Proposal<sup>8</sup> that a review of the NSPS KKK record found that the basis for the standards for PRDs was a routine LDAR program, not a “no detectable emissions” standard. Therefore, in the final rule, PRDs must be monitored bimonthly using OGI (or periodic monitoring using Method 21, as an alternative) and repaired. Similarly, EPA discussed in the 2022 Supplemental Proposal that it is not cost effective to require the BSER LDAR program (i.e., bimonthly OGI) for open-ended valves or lines. Finally, for closed vent systems, bimonthly OGI monitoring is finalized with a standard of “no identifiable emissions” as discussed in Section XI.K of the preamble to the final rule.

## 12.6 Leak Repair Timeline

Comment: Commenter (2433-EDF *et al.*) supports the proposed repair timeframe, which would require leaks detected by OGI to be repaired within 5 days of detection and final repairs completed no later than 15 days of detection. The commenters also urge EPA to require repair within 5 days of detection without exception for technical infeasibility.

Response II-12-19: Due to the nature of OGI monitoring (i.e., surveying from a distance), the proper equipment needed for physically reaching a component may not be in place at the time of monitoring and may take longer than 5 days to put in place. Therefore, we believe that a technical infeasibility exemption for the first attempt at repair within 5 days is reasonable, when the repair would require elevating the repair personnel more than 2 meters above a support surface. In all cases, the final NSPS OOOOb requires that final repairs be completed no later than 15 days of detection, unless there is a qualified delay of repair.

## 12.7 Leaking Valve Replacement

Comment: Commenter (2433-EDF *et al.*) urges EPA to require replacement of leaking equipment with low-E valves, despite the agency’s previous determination not to require their use because the agency believes such a replacement is not appropriate for all valve repairs. The commenter points to a recent rulemaking, where Colorado found these options to be similar in cost to non-low-E valves and packing and directed operators to consider them.<sup>9</sup> Some manufacturers claim their low-E packing can reduce emissions of harmful gases by up to 95

---

<sup>8</sup> See 87 FR 74807.

<sup>9</sup> See Colorado Air Pollution Control Division, Rebuttal Prehearing Statement, Proposed Revisions to Regulation Numbers 7 and 22 (Dec. 14–17, 2021).

percent versus valves with traditional packing, with minimal cost impacts, according to the commenter.<sup>10</sup>

Response II-12-20: See discussion in section XI.L.2 (Low-E technology for repair) of the preamble to the final rule for EPA's response to this comment.

## **12.8 Regulation Definitions**

### ***12.8.1 Definition of Natural Gas Processing Plant***

Comment: Commenters (2248-NDPC, 2326-American Exploration and Production Council (AXPC)) state that the definition of natural gas processing plant should be amended, to incentivize development of a broader range of potential beneficial uses.

Commenter (2248-NDPC) states that there are technologies that can be used to shrink the volume of wet natural gas that would otherwise be flared, or to process and compress the produced gas to be used as fuel for drill rigs or other nearby sources, but due to confusion about what NSPS standards would be applicable, producers have avoided these technologies. The commenter requests that the EPA clarify the definition of a Natural Gas Processing Plant as follows:

A natural gas processing plant consists of equipment used to separating certain hydrocarbons and fluids from the natural gas to produce "pipeline quality" dry natural gas for the Transmission Sector. The natural gas processing plant is in the Processing Segment. While some processing of natural gas can be accomplished in the production segment, processing equipment with the capacity of less than or equal to 10 MMscfd would not be considered a natural gas processing plant for the purposes of NSPS.

The commenter (2248-NDPC) believes that this definition is consistent with the NSPS OOOOa Technical Support Document (TSD), would clarify the application of any NSPS standards that are different between production, and processing segments, and would allow for more options to create beneficial uses of stranded natural gas.

Commenter (2326-AXPC) states that under the proposed definition, equipment used to put associated gas to beneficial use (as required by EPA's proposed oil well associated gas requirements) would be a natural gas processing plant if the equipment extracts natural gas liquids from field gas. Indeed, one of EPA's enumerated beneficial uses is the production of liquified natural gas, which requires the extraction of natural gas liquids from field gas, according to the commenter. In some regions, the commenter explains, operators utilize small natural gas liquids extraction skids, and EPA has recognized this fact in its exclusion of certain types of equipment from the natural gas processing plant definition. However, to further incentivize the beneficial use of associated gas through use of technologies or processes not explicitly excluded from the definition (e.g., a mobile refrigeration skid) EPA should exclude equipment with a design processing capacity of less than 10 MMscf/day according to the

---

<sup>10</sup> Id.

commenter. The commenter suggests the following definition of natural gas processing plant (underlined text indicates new text and struck through text indicates deleted text):

*Natural gas processing plant* means any processing site engaged in the extraction of natural gas liquids from field gas, fractionation of mixed natural gas liquids to natural gas products, or both. The following are not a natural gas processing plant: A Joule-Thompson valve, a dew point depression valve, or an isolated or standalone Joule-Thompson skid, or any combination of equipment having a design natural gas processing capacity of 10 MMscf per day or less is not a natural gas processing plant.

Response II-12-21: The EPA is not finalizing the suggested changes to the definition of natural gas processing plant. Please see the discussion in Response II-12-16.

However, EPA proposed specific exceptions to the requirements for process unit equipment affected facilities at §60.5402b of NSPS OOOOb and §60.5402c of the model rule in EG OOOOc. Specifically, §§60.5402b(b)(1) and 60.5402c(b)(1) allows for quarterly OGI monitoring (instead of bimonthly OGI monitoring) of pumps in light liquid service, pressure relief devices in gas/vapor service, valves in gas/vapor and light liquid service, and connectors in gas/vapor service and light liquid service that are located at a nonfractionating plant that does not have the design capacity to process 283,200 standard cubic meters per day (scmd) (10 million standard cubic feet per day) or more of field gas. Further, §§60.5402b(b)(2) and 60.5402c(b)(2) exempts this same equipment from routine monitoring if complying with the EPA Method 21 alternative standards of §§60.5401b and 60.5401c. There is an historical basis for reduced Method 21 monitoring requirements at these facilities going back to NSPS KKK and they are exempt from certain monitoring requirements as specified in §§60.5401(d) and 60.5401a(d) of NSPS OOOO and OOOOa, respectively. The EPA did not re-analyze the exemption for Method 21 in the 2021 Proposal or the 2022 Supplemental Proposal nor did we analyze it for OGI. The EPA did not intend that there would be an exemption from the standards when using one methodology (i.e., Method 21) versus another (i.e., OGI), in light of the fact that EPA has determined that the Method 21 standards are an equivalent alternative to OGI. Therefore, the EPA is finalizing an exemption from routine monitoring for pumps in light liquid service, PRDs in gas/vapor service, and valves and connectors in gas/vapor or light liquid service at nonfractionating plants that do not have the design capacity to process 10 MMscfd or more of field gas, whether using OGI or Method 21, to maintain consistency as well as to maintain the historical treatment of nonfractionating plants of this size.

### ***12.8.2 Definition of Equipment***

Comment: Commenter (2428-API) states that definition of equipment is unclear on which equipment is considered when evaluating whether a capital expenditure occurred, because capital expenditure is a definition, not a standard or requirement. The commenter is concerned that this lack of clarity could lead to varying interpretations and uncertainty on whether a capital expenditure occurred. By way of example, the commenter notes that for other regulations, EPA has clarified the scope of equipment considered for the affected facility<sup>11</sup>. For leak detection and

---

<sup>11</sup> See U.S. EPA Applicability Determination Index Control Number: 0600027, Modification and Capital Expenditure Calculations, dated February 9, 2001.

repair, the commenter suggests that an appropriate scope would be to apply the same definition of equipment to the capital expenditure evaluation as the standards and requirements. Therefore, the commenter asserts that the definition of equipment should clearly specify it also applies to capital expenditure. The commenter offers the following recommended edits to definitions in 40 CFR 60.5430b (underlined text indicates new text and struck out text reflects deleted text)<sup>12</sup>:

Equipment, as used in the standards and requirements and for purposes of evaluating capital expenditure in section 60.5365b(f)(1) of this subpart relative to the process unit equipment affected facility at onshore natural gas processing plants, means each pump, pressure relief device, open-ended valve or line, valve, and flange or other connector ~~that has the potential to emit~~ in methane or VOC service and any device or system required by those same standards and requirements of this subpart.

In methane service means that the piece of equipment contains or contacts a process fluid that is at least 1 percent methane by weight. (The provisions of § 60.5400b(a)(2) specify how to determine that a piece of equipment is not in methane service.)

In VOC service means that the piece of equipment contains or contacts a process fluid that is at least 10 percent VOC by weight. (The provisions of § 60.5400b(a)(2) specify how to determine that a piece of equipment is not in VOC service.)

Response II-12-22: The EPA is not making the change regarding the definition of equipment. The EPA disagrees that there is a need to revise the definition of equipment to specify it also applies to capital expenditure when cited at 40 CFR 60.5365b(f)(1). 40 CFR 60.5365b(f) clearly establishes the scope of equipment to which the following paragraphs apply (i.e., the group of all equipment within a process unit) and the proposed definition of equipment specifies that the definition applies to all standards and requirements relative to the process unit affected facility (which includes the modification and capital expenditure provisions). Further, EPA notes that the definition of equipment finalized in NSPS OOOOb and EG OOOOc is consistent with the existing NSPS OOOO and OOOOa “equipment” definitions, which have been used since 2012 and 2016, respectively.

In response to edits recommended related to “in methane service” and “in VOC service”, EPA is not including a VOC or methane threshold in the final rule. See discussion in section XI.L.1 (Potential to emit methane and VOC) of the final rule preamble.

## **12.9 Miscellaneous Other Comments**

Comment: Commenter (2196-Private Citizen) believes there may be a citation error in the text at 40 CFR 60.5400b(h). The commenter notes that there is no (h)(7) as referenced in that paragraph of the proposed regulatory text. The commenter offers the following suggested edits (underlined text indicates new text and struck through text indicates deleted text):

---

<sup>12</sup> The commenter (2428-API) also provided comments on defining “in VOC service” and “in methane service” in a prior comment. The edits suggested in this paragraph also include edits suggested to address that prior comment.

40 CFR 60.5400b(h)-

(h) *Repair requirements.* When a leak is detected, you must comply with the requirements of paragraphs (h)(1) through (65) of this section, except as provided in paragraph (h)(76) of this section.

Response II-12-23: EPA has modified the regulatory text accordingly.

Comment: Commenter (2428-API) states that 40 CFR 60.5401c(i)(6)(iii) cites 40 CFR 60.5401c(i)(4)(iii)(A) and (B), however, the commenter states that those citations do not exist. The commenter suggests that perhaps the citation should be 40 CFR 60.5401c(i)(6)(iii)(A) and (B).

Response II-12-24: EPA has modified the regulatory text accordingly.

Comment: Commenter (2222-WI DNR) states that the December 2022 Supplemental Proposal includes a requirement to repair open-ended valves or lines whenever emissions are identified in order to comply with the general duty provisions. However, these requirements are not accompanied by any specific monitoring requirements for open ended valves or lines that would result in identification of emissions.

Response II-12-25: AVO monitoring is required for open-ended valves and lines, but the commenter is correct that the final rule does not specify a frequency. The EPA discussed the rationale for the standards for open-ended valves and lines in the 2022 Supplemental Proposal.<sup>13</sup> The EPA is finalizing, as proposed, that the primary control requirement for open-ended valves and lines is the closure device, which can achieve nearly 100 percent emissions reductions. In the case that there may be a leak past a closure device, which is detected as part of daily operating duties using AVO or required OGI surveys for other equipment, the final rule requires that leaks detected by any method (and at any frequency) must be repaired.

---

<sup>13</sup> See 87 FR 74087.

## Chapter 13. Storage Vessels

### 13.1 General Support/Opposition for Proposed Requirements

Comment: Commenters (1611-East Liberty Presbyterian Church, 1620-Evangelical Environmental Network, 1644-Young Evangelicals for Climate Action, 1651-Creation Justice Ministries, 1658-Physicians for Social Responsibility, 2028-Westmoreland Marcellus Citizens' Group (WMCG), 2039-Citizens to Preserve Ligonier Valley, Inc., 2174-Progress Michigan, 2217-Religious Action Center of Reform Judaism (RACRJ), 2236-Physicians for Social Responsibility Pennsylvania, 2352-Environment Texas Research and Policy Center, 2356-Earthworks *et al.*, 2364-CleanEarth4Kids, 2394-Earthworks, 2404-Dakota Resource Council, 2422-Western Leaders Network, 2466-Pennsylvania State Senator Katie Muth, 2502-Rio Grande International Study Center) request that all storage tanks be covered under the rule with no exemptions. The commenters state that these tanks continue to pollute after the drilling process is completed and people have reported illness due to exposure to fumes emitted.

Commenters (2028-WMCG, 2195-Environmental Health Project (EHP), 2212-Union of Concerned Scientists (UCS), 2217-RACRJ, 2303-National Tribal Air Association (NTAA), 2394-Earthworks, 2407-Methane Action *et al.*, 2433-Environmental Defense Fund (EDF) *et al.*, 2462-Private Citizen) suggest that the rule does not go far enough in scope or stringency. Commenter (2462-Private Citizen) requests that EPA expand the rules to include all tanks (*e.g.*, tanks to store outflows with gas emissions) and enhance standards for construction, capture of fugitive emissions, and monitoring. Commenters (2195-EHP, 2212-UCS, 2217-RACRJ) also request that EPA expand the categories of tanks covered by the emissions standards. Commenters (2303-NTAA, 2394-Earthworks, 2433-EDF *et al.*) request that EPA lower the threshold which determines which tanks are covered by the rule. Commenter (2407-Methane Action *et al.*) recommends strengthening standards that address emissions from oil and gas storage tanks by making them applicable to more tanks. The commenter suggests that by lowering the threshold that determines which tanks are covered by the rule, EPA could address the pollution from more tanks, thereby better protecting communities.

Commenter (2394-Earthworks) believes that the proposed rule leaves a significant loophole for storage tank emissions at small wells sites, which must be addressed. The commenter states that these small wells account for over 50 percent of Pennsylvania's oil and gas methane pollution, are decades old (often in neglected or poor condition), but are owned by companies who profit from operation of these small wells – in Pennsylvania, just ten operators generated 60 percent of production<sup>1</sup> from small wells in 2019, each of them earning between \$5 million and \$48 million in revenue, according to the commenter. The commenter explains that at their surveys of produced water storage tanks at smaller well sites in Pennsylvania often are the source of some of the worst emissions<sup>2</sup> and that these tanks often are located not only near homes and schools, but in the middle of backyards and playgrounds. The commenter states that these tanks are designed such that they continuously release benzene and other health hazardous pollutants into

---

<sup>1</sup> Earthworks, "Gov Wolf: Despite its claims, oil and gas industry can afford to cut pollution," September 2020, <https://earthworks.org/blog/gov-wolf-despite-its-claims-oil-and-gas-industry-can-afford-to-cut-pollution/>.

<sup>2</sup> YouTube, "Low-producing well storage tank emissions, Forest County, PA (June 2021)," June 2021, <https://www.youtube.com/watch?v=BwX6LTBWijc&list=PL9BS7nDf-8trQ91EHSnuL7Gtzrv9S0be6&index=127>.

the air and the problem with these smaller sized tanks must be taken seriously. The commenter also provided results of fieldwork they conducted in Pennsylvania. Finally, the commenter believes the applicability should include brine tanks.

Response II-13-1: EPA points out several key factors to address the concerns of the commenters. EPA is finalizing the November 2021 Proposal and December 2022 Supplemental Proposals which modified the applicability criteria to remove averaging across storage vessels in the same tank battery. “Tank battery” has been defined to include tanks with common liquid piping, such that more tanks are to be regulated and direct their emissions through a closed vent system to a control device. EPA has revised the criteria for tanks that adopt legally and practicably enforceable emissions limitations, to better assure reductions in emissions are achieved. The final rule, consistent with NSPS OOOO, OOOOa, and the December 2022 supplemental proposal, applies to storage vessels which contain crude oil, condensate, intermediate hydrocarbon liquids, and produced water.

EPA disagrees that the 6 tpy threshold is a loophole. Contrary to commenter’s implication, the proposed OOOOb and OOOOc did not exempt single storage vessels not located at a well site, centralized production facility, compressor station, or a natural gas processing plant, nor does EPA have any such intent. EPA has set the threshold for tanks emitting 6 tpy VOC and 20 tpy methane based on reductions that can be obtained under the BSER analysis which includes the factor of cost effectiveness. Tank batteries which emit less than 6 tons per year (tpy) VOC or 20 tpy methane are not storage vessel affected facilities and do not have to be controlled under the NSPS or EG. EPA cannot discern from the comment what the potential for VOC and methane emissions are for the “small” tanks in referenced by the comment. EPA considered lowering the threshold of applicability for volatile organic compounds (VOC) emissions and contemplated a series of applicability thresholds for methane. EPA chose to retain the 6 tons per year (tpy) threshold for VOC because a lower threshold was not cost effective and chose the 20 tpy threshold for methane for the same reason. The 20 tpy threshold for methane applies to existing sources. See EPA’s cost analysis for tanks cost memo in the TSD to the proposed rule in the docket, EPA-HQ-OAR-2021-0317-0039.

EPA recognizes that some tanks which take legally and practicably enforceable limits to remain below the applicability thresholds, may experience excess emissions episodes for various reasons (e.g., unintended gas carryover or open thief hatch). In those cases, any excess emissions episodes would be addressed through enforcement of the emission limits by the respective permitting or enforcement agency, including EPA. EPA is also finalizing a Super-Emitter Response Program that will address emissions for storage vessel affected facilities that experience a super emitter event.

Comment: Commenters (2199-Rocky Mountain Farmers Union (RFU) *et al.*, 2362-EIP, 2458-MiQ) request an increase in the stringency of controls. Commenter (2458-MiQ) supports the provision to increase combustion efficiency to 98 percent control and to require additional monitoring of the control device. Commenter (2199-RMFU *et al.*) suggests that EPA look to states in the east and west which have strengthened controls regarding leaks from storage tanks.

Commenter (2362-EIP) believes EPA should be aware that the state agencies that regulate oil and gas emissions already require that these combustion devices at tank batteries, gas processing units, compressors and other oil and gas sources achieve a 98 percent DRE. These requirements apply to storage tanks and other units where pre-control VOC emissions are well below 90 tons per year, i.e., where pre-control methane emissions are likely to be less than the 20 tons that EPA has identified as the threshold for the 95 percent DRE standard it proposes for storage tanks. The commenter provides several attachments to their comments, as follows:

- Attachment C (of the commenter's public submission) includes 6 permit applications and other records for six permitted tank batteries in Reeves County, Texas, and each one represents that flares or VCUs will achieve 98 percent DRE (permit representations in Texas are enforceable).
- Attachment D (of the commenter's public submission) identifies condensate or produced water tanks at five West Virginia well pads or compressors. Each of these sources has a potential to emit that is less than 90 tons of VOCs per year. The flares or VCUs at each site are required to destroy 98 percent of the tank vapors.
- Tank batteries and other oil and gas sources in Texas that report VOC emissions from flares or VCUs during malfunctions, maintenance, startup, and shutdown have reported achieving 98 percent DRE for many years. Attachment E (of the commenter's public submission) identifies 45 tank batteries or other oil and gas units that reported VOC or sulfur dioxide emissions from flares with links to the online reports that calculate reported emissions based on a DRE of 98 percent. The table includes more than 2,000 reports between 2002 and 2022.
- Attachment F (of the commenter's public submission) summarizes information from four manufacturers (Zeeco, MRW Technologies, Encore Combustion, and Mission Flares & Combustion) that claim that the flares or VCUs they install will achieve destruction efficiencies of 98 percent or greater and indicate such devices are available to upstream and downstream oil and gas operations. [Attachments included in the Comment Letter File.]

Commenter (2362-EIP) believes that these examples show that 98 percent DRE is BSER and is cost-effective. According to the commenter, the EPA's failure to consider such examples means its requirement for a 95 percent DRE is unlawful, arbitrary, and capricious.

Response II-13-2: The EPA has declined to increase the required control efficiency from 95 percent to 98 percent. See EPA's cost analysis for tanks in docket at EPA-HQ-OAR-2021-0317-0039. EPA considered the same comment in our supplemental proposal. Commenters asserted in comments to our proposal, and again here, that 98 percent destruction efficiency was technically possible, and to our supplemental proposal, included documentation that flares can achieve 98 percent destruction efficiency and in some cases that level of destruction efficiency is enforceable. EPA agrees that flares can achieve 98 percent destruction efficiency, but the commenter fails to address EPA's rationale for not adopting 98 percent as BSER. As explained in our supplemental proposal (see 87 FR 74794) EPA did not find it cost effective to increase destruction efficiency. Specifically, EPA stated, and the commenter did not address that a higher destruction rate would require additional monitoring and commensurate operational costs. EPA determined that a 98 percent destruction efficiency would compel EPA to raise the threshold for

affected facility to 12 tpy VOC and 40 tpy methane for 98 percent to be considered the BSER. EPA further pointed out that raising the threshold for affected facility status would result in more emissions to atmosphere than could be obtained by increasing destruction efficiency by 3 percent.

Comment: Commenter (2383-Baker Hughes) supports EPA's proposed standard that all storage vessel affected facilities reduce methane and VOC emissions by 95 percent and the proposed 6 tpy VOC and 20 tpy methane thresholds for a single storage vessel or a tank battery affected facility at completely new well sites, centralized production facilities, and compressor stations. The commenter also supports EPA's retention of the current alternate control standard to maintain the uncontrolled actual VOC emissions from a single storage vessel or a tank battery affected facility at less than 4 tpy VOC and 14 tpy methane.

Commenter (2258-Marcellus Shale Coalition (MSC)) acknowledges the incorporation of the uncontrolled methane emission rate (14 tpy) for affected facilities as requested in their comments on the November 2021 Proposal and expresses its appreciation for this incorporation.

Response II-13-3: The comment is a supportive comment on an aspect of the December 2022 Supplemental Proposal that has remained unchanged in the final rule; as such, no response is required.

Comment: Commenter (2254-Permian Basin Petroleum Association (PBPA)) states that the application of the VOC and methane thresholds to tank batteries, instead of individual storage tanks will subject a staggering number of facilities to additional regulation. The commenter is concerned that the impact on upstream sources, both in terms of increased storage tank applicability and costs, will increase exponentially. The commenter also is concerned the proposed rule applies uncontrolled potential to emit (PTE) and limits states' ability to consider legally and practicably emissions controls in the PTE calculation, which the commenter says will result in practically every storage tank becoming an affected facility under the proposed NSPS.

Response II-13-4: EPA discusses the rationale for selecting the tank battery framework to determine applicability for storage vessels in section IV.J. of the supplemental proposal. See 87 FR 74800. EPA is finalizing, as proposed, that a storage vessel affected facility is a tank battery with the potential for VOC or methane emissions above 6 tpy or 20 tpy, respectively.

With respect to costs incurred by the industry, the New Source Performance Standard (NSPS) technology review is a statutory mandate that requires EPA to review the NSPS rule every 8 years to determine whether the standards continue to reflect the best system of emission reduction. The timeframe for implementation for existing sources is extended over several years as states adopt plans to implement the EG for existing sources. For further information on the anticipated cost with respect to storage vessels, see EPA's cost analysis for storage vessels at EPA-HQ-OAR-2021-0317-0039. Regarding the use of legally and practicably enforceable limits when determining the potential for VOC and methane emissions from tank batteries, the final rule allows that a source may take into account legally and practicably enforceable limits in such determinations. The final rule also specifies the criteria for legally and practicably enforceable limits. See RTC section 13.2.6. and Section XI.J.1.a of the preamble to the final rule for EPA's

rationale for finalizing the criteria for legally and practicably enforceable emissions limitations specifically for determining storage vessel affected facility/designated facility status under subpart OOOOb/OOOOc.

## 13.2 Applicability

### 13.2.1 Definition of Storage Vessel

Comment: Commenter (2428-American Petroleum Institute (API)) states that a storage vessel located at a well site, central production facility, compressor station, or natural gas processing plant used to alleviate dangerous, or emergency events must clearly be excluded from the definition of storage vessel. The commenter explains that at some facilities, storage vessels may be installed for the sole purpose of providing relief from pressure vessels during emergencies. Previously, these storage vessels would not trigger applicability as a single emergency use vessel was unlikely to exceed 6 tpy VOC threshold under NSPS OOOO or NSPS OOOOa, according to the commenter. Now, the commenter states, these tanks present a challenge with the new applicability threshold proposed in NSPS OOOOb and EG OOOOc for the tank battery. At the state level, the commenter explains, emergency use tanks are exempt from control requirements from state and local regulations because state agencies such as California's Air Resources Board (CARB) or San Joaquin Valley Air Pollution Control Board (SJVAPCD) have recognized that these tanks are used in rare and extreme situations for the safety of people and nearby infrastructure.<sup>3 4</sup>

The commenter (2428-API) requests that EPA provide an exclusion for emergency use tanks from the definition of storage vessel as follows (suggested additions are underlined):

*Storage vessel* means a tank or other vessel that contains an accumulation of crude oil, condensate, intermediate hydrocarbon liquids, or produced water, and that is constructed primarily of nonearthen materials (such as wood, concrete, steel, fiberglass, or plastic) which provide structural support. A well completion vessel that receives recovered liquids from a well after startup of production following flowback for a period which exceeds 60 days is considered a storage vessel under this subpart. A tank or other vessel shall not be considered a storage vessel if it has been removed from service in accordance with the requirements of 40 CFR 60.5395b(c)(1) until such time as such tank or other vessel has been returned to service. For the purposes of this subpart, the following are not considered storage vessels:

Vessels that are skid-mounted or permanently attached to something that is mobile (such as trucks, railcars, barges or ships), and are intended to be located at a site for less than

---

<sup>3</sup> CARB O&G Regulation, 17 CCR 95668(a)(2)(E): Separators, tanks, and sumps that have contained crude oil, condensate, or produced water for 45 calendar days or fewer per calendar year provided that the owner or operator maintains and can make available at the request of the ARB Executive Officer, a record of the number of days per year in which the separators, tanks, or sumps have contained liquid.

<sup>4</sup> The SJVAPCD has defined an emergency in some permits as: an unforeseeable failure or malfunction of operating equipment that: (1) is not due to neglect or disregard of air pollution laws or rules; (2) is not intentional or the result of negligence; (3) is not due to improper maintenance; and (4) is necessary to prevent or control an unsafe situation.

180 consecutive days. If you do not keep or are not able to produce records, as required by 60.5420b(c)(5)(iv), showing that the vessel has been located at a site for less than 180 consecutive days, the vessel described herein is considered to be a storage vessel from the date the original vessel was first located at the site. This exclusion does not apply to a well completion vessel as described above.

Process vessels such as surge control vessels, bottoms receivers or knockout vessels.

Pressure vessels designed to operate in excess of 204.9 kilopascals and without emissions to the atmosphere.

Vessels that only receive crude oil, condensate, intermediate hydrocarbon liquids, or produced water due to an unforeseeable failure or malfunction of operating equipment that is necessary to prevent or control an unsafe situation and contains the crude oil, condensate, or produced water for 45 days or less per calendar year.

Response II-13-5: EPA disagrees that emergency use tanks should be exempted from the definition of storage vessel. These tanks have the potential to emit large quantities of VOC and methane if uncontrolled. EPA notes, that if the storage vessel is not connected by liquid line to other tanks in the tank battery, then it is not part of a tank battery affected facility and may determine its potential for VOC and methane emissions separately from the tank battery. This determination may take into account legally and practicably enforceable limits, which may include limits on throughput received. Allowing a tank that is connected by liquid line to the remaining tanks to be uncontrolled with respect to air emissions would undermine the standard, because emissions could bypass the control device through the uncontrolled tank. Finally, the commenter did not explain why they cannot be controlled (e.g., safety reasons, technical infeasibility, or cost) and did not explain why the states referenced do not regulate these types of tanks.

### ***13.2.2 Definition of Tank Battery***

Comment: Commenters (2305-Williams Companies, Inc. (Williams), 2399-GPA Midstream Association (GPA)) support the regulatory text defining “tank battery.” Commenter (2399-GPA) states that it is greatly improved from the description EPA included in the November 2021 Proposal preamble (*i.e.*, the term “adjacent” is not included). Commenter (2305-Williams) states that the removal of the terms “adjacent,” “fluids from the same source,” and “vapor transfer” are improvements to the previous definition of “tanks battery.”

Response II-13-6: The comment is a supportive comment on an aspect of the December 2022 supplemental proposal that has remained unchanged in the final rule; as such, no response is required.

Comment: Commenters (2305-Williams, 2399-GPA) do not believe that storage vessels should be required to be manifolded together with piping such that all vapors are shared among the headspace of the storage vessel comprising the tank battery. Commenter (2399-GPA) states that EPA’s proposed requirement to manifold the vapor space for tank batteries, found at 40 CFR

60.5395b(b)(1), unnecessarily dictates how storage vessels are routed to controls. The commenter cites to the December 2022 Supplemental Proposal which states, “that these changes reflect our intent that a group of storage vessels which are manifolded together by liquid line operate as a system and, as such, share the same control device.” 87 Fed. Reg. at 74,800. However, the commenter states that the December 2022 Supplemental Proposal provides no explanation, and cites no record support, for requiring all of the tanks in a tank battery to share the same control device. The commenter goes on to explain that while it is not unusual for all storage vessels in a tank battery to be routed to the same control device, this will not always be possible, such as when vessels store different contents. The commenter states that this means that, under certain circumstances, more than one control device and closed vent system would be required to control storage vessels across a tank battery, especially for storage vessels at existing sites. The commenter is concerned that an owner or operator could find itself unable to comply with conflicting requirements. By way of example, the commenter explains that where steel and fiberglass vessels are forced to share a common vapor space manifold, static buildup and grounding deficiencies will result in a severe safety issue, including the risk of an explosion. Additionally, the commenter describes a scenario where, if storage vessels are not located near each other, it may be better to install two separate control devices. The commenter states that using multiple control devices for storage vessels does not significantly affect emission rates and will result in the same total emissions from the tank battery. The commenter provides the following suggested edits to the regulatory text at 40 CFR 60.5395b(b)(1) (suggested additions are underlined; suggested deletions are shown in strike-through):

(b) Control requirements.

(1) Except as required in paragraph (b)(2) of this section, if you use a control device to reduce methane and VOC emissions from your storage vessel affected facility, you all storage vessels within the tank battery must meet all of the design and operational criteria specified in paragraphs (b)(1)(i) through ~~(iii)~~ of this section.

(i) Each storage vessel in the tank battery must be equipped with a cover that meets the requirements of §60.5411b(b);

~~(ii) The storage vessels must be manifolded together with piping such that all vapors are shared among the headspaces of the storage vessels in the tank battery;~~

(iii) The tank battery must be equipped with a closed vent system that meets the requirements of §60.5411b(a) and (c); and

~~(iii)~~ The vapors collected in paragraphs (b)(1)(ii) ~~and (iii)~~ of this section must be routed to a control device that meets the conditions specified in §60.5412b(a) or (c). As an alternative to routing the closed vent system to a control device, you may route the closed vent system to a process.

Commenter (2305-Williams) also recommends that EPA delete 40 CFR 60.5395b(b)(1)(ii). The commenter states that storage vessels should not be required to be manifolded together with piping such that all vapors are shared among the headspaces of the storage vessels comprising

the tank battery, as is supported by EPA removing “vapor transfer” from its previous definition of “tank battery” so that tank batteries are now defined as a single storage vessel or storage vessels that are manifolded together by liquid transfer only. The commenter believes that EPA’s current closed vent system requirements in 40 CFR 60.5411(b) and control device requirements in 40 CFR 60.5412(b) sufficiently assure proper conveyance and control of storage vessel VOC and methane emissions.

Response II-13-7: EPA agrees with the commenter that it is not necessary to specify that the vapor spaces of the tanks within a tank battery be manifolded for control purposes, because the control criteria of a cover, closed vent system, and control device provide sufficient regulatory certainty that each tank in a storage vessel affected facility must be controlled to 95 percent.

On the issue of whether all tanks should be routed to a single control device, EPA does not interpret “a control device” as “a single control device” for the purpose of controlling a tank battery. By maintaining the text as “a control device” an operator can use redundant or multiple control devices within a single tank battery and still meet the requirements of the standard, because the collection of tanks in a tank battery manifolded by liquid line is an affected facility (where the potential for VOC and methane emissions is met) and each tank in the storage vessel affected facility must be controlled to 95 percent, when the battery as a whole must be controlled to 95 percent.

Comment: Commenters (2428-API, 2483-Interstate Natural Gas Association of America (INGAA)) recommend that the definition of tank battery be clarified with respect to the clause that the tanks are manifolded for liquid transfer. Commenter (2438-INGAA) is concerned of an extreme interpretation where two tanks that are very distant are connected via a pipe and be considered manifolded for liquid transfer. The commenter provides three suggested edits to the regulatory test at 40 CFR 60.5430b and 60.5425c:

**Proposed Regulatory Text** (suggested additions are underlined):

*Tank battery* means a group of all adjacent storage vessels that are manifolded together for liquid transfer. A tank battery may consist of a single storage vessel if only one storage vessel is present.

**Alternative Proposed Regulatory Text** (suggested additions are underlined):

*Tank battery* means a group of all storage vessels located at a well site, central production facility, compressor station, or natural gas processing plant that are manifolded together for liquid transfer. A tank battery may consist of a single storage vessel if only one storage vessel is present.

**Alternative Proposed Regulatory Text** (suggested additions are underlined):

*Tank battery* means a group of all storage vessels that are manifolded together for liquid transfer, where the liquid free flows between the vessels without assistance from an

external source of energy. A tank battery may consist of a single storage vessel if only one storage vessel is present.

Commenter (2428-API) supports EPA's proposed definition for tank battery based on storage vessels that are manifolded together for liquid transfer, but offers a clarification regarding its location as follows (suggested additions are underlined):

*Tank battery* means a group of all storage vessels that are manifolded together for liquid transfer. A tank battery may consist of a single storage vessel located at a well site, central production facility, compressor station, or natural gas processing plant if only one storage vessel is present.

The commenter (2428-API) states that this clarification addresses the situation of a single storage vessel not located at a well site, central production facility, compressor station, or natural gas processing plant (e.g., drip station along a pipeline). The commenter explains that these storage vessels typically have low throughput and methane and VOC emissions. Because EPA does not describe how to determine potential to emit (PTE) for tank batteries at locations other than a well site, centralized production facility, compressor station, or natural gas processing plant in 40 CFR 60.5365b(e)(2)(ii) and 60.5365b(e)(2)(iii), the commenter believes that the agency did not intend to regulate these low-emitting tanks with these proposed rules.

Response II-13-8: Contrary to commenter's belief, the proposed OOOOb and OOOOc did not exempt single storage vessels not located at a well site, centralized production facility, compressor station, or a natural gas processing plant, nor does EPA have any such intent. The commenter points out that storage vessels not located at a well site, centralized production facility, compressor station, or natural gas processing plant typically have low throughput, methane, and VOC emissions. The EPA acknowledges that such single storage vessel may have emissions below the rule's applicability thresholds and therefore not subject to the standards; however, OOOOb and OOOOc apply to those above the threshold(s).

In the commenters' example that a tank could be part of a battery, at distance to the other tanks in the battery, EPA has removed the requirement for manifolding vapor spaces for all tanks in a battery, thereby simplifying compliance in such cases. Tanks manifolded together for liquid transfer and which are storage vessel affected facilities are no longer required to have their vapor spaces manifolded together under the control criteria. This means such a storage vessel, in the commenters example, could be controlled at the distant tank battery of which it is a part, without the need to manifold the vapor space to the other storage vessels in the battery. Therefore, tanks in a tank battery need not be adjacent to each other. The EPA also notes that in the 2022 Supplemental Proposal, it declined to use the term "adjacent" in the definition of tank battery in response to comment on the 2021 proposal. EPA expressed its agreement with commenters to the November 2021 proposal that this term was not needed. See 87 FR 74800.

### ***13.2.3 Definition of Centralized Production Facility***

Comment: Commenters (2399-GPA, 2428-API) believe that the definition of "compressor station," as proposed at 40 CFR 60.5430b, must be clarified with respect to the storage vessel

applicability provisions. Commenter (2399-GPA) believes EPA should revise the definition of “centralized production facility,” because it does not clearly exclude compressor stations that are not part of producing operations. The commenter suggests that the last sentence of the definition be revised as follows (suggested additions are underlined):

A centralized production facility is located upstream of the compressor station, the natural gas processing plant, or the crude oil pipeline breakout station and is a part of producing operations.

The commenter (2399-GPA) is concerned that the proposed definition does not clearly distinguish between a compressor station, which will have associated storage vessels, and a centralized production facility which may have associated compression. The commenter explains that storage vessels located at compressor stations would provide a function similar to a centralized production facility, but they are not “part of producing operations” and without the proposed revision provided above, there would be significant confusion as to how applicability determinations would be performed for storage vessels and which leak detection and repair (LDAR) monitoring program would apply. Further, the commenter suggests that the definition exclude independent centralized production facilities that are not part of producing operations, such as where the centralized production facility is owned by a midstream company separately from production assets. The commenter explains that where a centralized production facility is owned and operated by a midstream company, that company cannot know whether a well site added equipment or fractured a well because there is no obligation for the production company to inform downstream processing companies. The commenter states that EPA should clarify that a centralized production facility that is not part of producing operations is not included in the definition.

Commenter (2428-API) explains that with the introduction of the newly defined central production facility, an additional clarification is needed for when and how to calculate the tank battery PTE at well sites and central production facilities that may have compression versus at a compressor station. The commenter believes that EPA makes this distinction clearly for how to consider the fugitive emission monitoring, by referencing 40 CFR 60.5397b in the definition of compressor station. By way of example, the commenter examines the scenario of a reciprocating compressor at an oil processing facility. The commenter states that the facility would be a “*tank battery at a well site or centralized production facility*” under 40 CFR 60.5365b(e)(2)(ii) and yet also a “*tank battery located at a compressor station*” as used in 40 CFR 60.5365b(e)(2)(iii). The commenter requests that EPA also clarify the storage vessel requirements in a similar way by the referencing of 40 CFR 60.5365b(e) in the definition of compressor station as follows (suggested additions are underlined):

*Compressor station means* any permanent combination of one or more compressors that move natural gas at increased pressure through gathering or transmission pipelines, or into or out of storage. This includes, but is not limited to, gathering and boosting stations and transmission compressor stations. The combination of one or more compressors located at a well site, centralized production facility, or an onshore natural gas processing plant, is not a compressor station for purposes of §60.5365b(e) and §60.5397b.

Response II-13-9: EPA agrees with the commenters additional clarity is needed to better distinguish centralized production facilities from compressor stations. Although we think either suggestion may work, we think modifying the definition of compressor station is sufficient. As such the last sentence of the definition will read as follows:

The combination of one or more compressors located at a well site, centralized production facility, or an onshore natural gas processing plant, is not a compressor station for purposes of §60.5365b(e) and §60.5397b.

#### ***13.2.4 Emissions Threshold for Tank Battery Applicability - General***

Comment: Commenters (2296-New Mexico Environment Department (NMED), 2410-California Office of the Attorney General (CA AG) *et al.*) recommend that the applicability threshold be set lower. Commenter (2296-NMED) explains that their state's applicability thresholds for new and existing storage vessels are lower than what EPA is currently proposing in NSPS OOOOb and EG OOOOc. The commenter notes that NMED's Part 50 requires controls for new storage vessels with a PTE  $\geq 2$  tpy of VOC, existing storage vessels in multi-tank batteries with a PTE  $\geq 3$  tpy of VOC, and existing storage vessels in single tank batteries with a PTE  $\geq 4$  tpy of VOC, according to the commenter. Commenter (2410-CA AG *et al.*) requests that for existing storage vessels, EPA consider lowering the applicable threshold. By way of example, the commenter states that Colorado requires the control of all new and existing storage tanks emitting 2 tpy of VOC or more;<sup>5</sup> Pennsylvania requires controls if VOC emissions exceed 2.7 tpy; and New Mexico has adopted a threshold of 2 tpy of VOC for new tanks, 3 tpy of VOC for existing tanks in multi-tank batteries, and 4 tpy for existing tanks in single tank batteries.<sup>6</sup>

Commenter (2180-Pennsylvania Department of Environmental Protection (PADEP)) recommends that the VOC emissions threshold should be 2.7 tpy and notes that they have required 95 percent control of VOC emissions from storage vessels since 2013.

Response II-13-10: EPA discussed the results of the analysis which was used to establish emissions thresholds for storage vessel applicability in section XII.B.1.e of the November 2021 Proposal and used this same analysis in the December 2022 Supplemental Proposal. The EPA evaluated lower emissions thresholds, including 3 tpy from a tank battery, and as discussed in the same section of the November 2021 Proposal was determined not to be cost effective. EPA also notes that Section 111(d), which requires regulation of existing sources, excludes from such regulation pollutants regulated under CAA section 108(a) (*i.e.*, criteria pollutants such as ground-level ozone and particulate matter, and their precursors, like VOC); therefore none of the VOC limits suggested by the commenters are germane to OOOOc, which contains presumptive standards for reducing methane emissions only. Finally, the commenters did not identify flaws with EPA's analysis and EPA is finalizing the emissions thresholds for storage vessel applicability as proposed.

---

<sup>5</sup> 5 Colo. Code Regs. § 1001-9:D.II.C.1.c.

<sup>6</sup> New Mexico Administrative Code 20.2.50, at 20.2.50.123(A), available at <https://www.env.nm.gov/air-quality/wp-content/uploads/sites/2/2022/07/Oil-and-Gas-SectorOzone-Precursor-Pollutants-Final-rule-20.2.50-NMAC-06Jul22.pdf>.

Comment: Commenter (2356-Earthworks *et al.*) requests that EPA expand the threshold for storage tanks. The commenter states that the December 2022 Supplemental Proposal did not expand the applicability threshold for storage vessels, which are prevalent throughout communities impacted by oil and gas development. They suggest that EPA strengthen the standards to address emissions from storage tanks by making the standards applicable to more tanks.

Response II-13-11: See response II-13-10.

Comment: Commenter (2305-Williams) believes that the proposed emissions threshold of 20 tpy methane is too low and lacks justification. The commenter suggests that EPA review methane emissions for other emissions sources at oil and natural gas facilities and establish a more reasonable emissions threshold and corresponding emission standard for storage vessels. For comparison, the commenter provides the following currently permissible methane emissions in California:

- 80 tpy for a 4-throw reciprocating compressor's rod packing emissions<sup>7</sup>
- 60 tpy for a wet seal centrifugal compressor's degassing vent emissions<sup>8</sup>

For added context, the commenter also provides that the methane emissions from a dry seal centrifugal compressor with a leak rate of 3 scfm/primary seal is 60 tpy, assuming continuous operation and 90 mol percent methane gas composition.

Response II-13-12: EPA disagrees that methane emissions for other sources at oil and gas facilities are relevant to the analysis of cost-effective control of storage vessels. EPA set the threshold for methane control for storage vessels corresponding to the anticipated representative emissions of VOC and methane together, because the current VOC threshold was found to be cost effective. Since the controls used to control VOC are the same controls for methane, it was reasonable for EPA to analyze and select a threshold value for VOC that corresponds to a representative methane level. See the EPA memo describing the BSER analysis [Docket Item No. EPA-HQ-OAR-2021-0317-0039, Attachment 21; based on worst-case ratio of VOC to methane; see "Oil" tab, row 33, data for "Sample Tank No. 52"] and how EPA selected the methane level of 20 tpy as representing the most likely threshold corresponding to 6 tpy VOC.

Comment: Commenter (2168-Indiana Oil and Gas Association) notes that Table 2 of the December 2022 Supplemental Proposal does not provide best system of emission reduction (BSER) for tanks with a PTE of less than 6 tpy and inquires whether those tanks still are not regulated under the proposed rule.

Response II-13-13: In the 2021 proposal, the EPA described its BSER analysis for tank batteries, in which the EPA evaluated routing emissions to a VRU and combustion control device and at different potential emission levels (3 tpy and 6 tpy VOC and 1.3 tpy, 5.3 tpy, 20 tpy, and 50 tpy

---

<sup>7</sup> Based on California Air Resources Board's 2 scfm/throw emissions limit, 8760 hours per year operation, and 90 mol percent methane gas composition).

<sup>8</sup> Based on California Air Resources Board's 3 scfm/wet seal emissions limit, 8760 hours per year operation, and 90 mol percent methane gas composition.

methane from a tank battery) (86 FR 63199). The EPA did not find the costs of these control options to be reasonable at the lower thresholds considered. The EPA did not identify any other control options for tank batteries, nor did the commenter suggest any other control for EPA to consider as the BSER for tank batteries with potential VOC and methane emissions below 6 tpy and 20 tpy respectively. Therefore, there is no BSER for tank batteries with potential emissions below these applicability thresholds.

Comment: Commenters (2254-PBPA, 2305-Williams) do not agree with EPA's proposal that when a storage vessel affected facility reduces its emissions below the applicable threshold, it remains an affected facility. The commenter (2254-PBPA) points out this "once in, always in" policy requires facilities to meet regulatory obligations when actual emissions are below the regulatory trigger. The commenter believes that such a policy directly disincentivizes operators from reducing emissions and is unwarranted. The commenter points out that EPA previously had a similar policy for its National Emission Standard for Hazardous Air Pollutants (NESHAPs) but revoked this policy in 2020, in part, based on its study of emission impacts from 34 different facilities. The commenter summarizes that EPA concluded that of the 34 facilities that were reclassified from major sources to area sources, emissions from all facilities either remained the same or were reduced.

Commenter (2305-Williams) reports that natural gas gathering rates and associated condensate production rates in maturing fields can and do decrease as production rates decrease over time. The commenter believes a compressor station operator should be allowed to re-evaluate these changing throughput conditions and potential emissions. The commenter suggests that if the new throughput conditions lead to maximum potential emissions estimates that do not exceed 6 tpy VOC (or the annual methane emissions limit), then the affected storage vessel status should no longer apply.

Response II-13-14: See 78 FR 58415 at 58430, where the EPA explained our position on the need for storage vessels that have experienced a decline in emissions to remain affected facilities. In that notice EPA stated "In the context of once in always in, the EPA has not extended this policy by providing that storage vessel affected facilities that subsequently reduce PTE to below 6 tpy remain affected facilities. The EPA historically has never let facilities in and out of affected facility status and is consistent in subpart OOOO. Having storage vessels remain affected facilities when emissions decline allows regulatory agencies to track emissions of these storage vessels and to monitor compliance if they increase."

### ***13.2.5 Emissions Threshold for Tank Battery Applicability – Methane Permits***

Comment: Commenters (2202-TXOGA, 2428-API, 2483-INGAA) are concerned about basing applicability on methane emissions. Commenters (2202-TXOGA, 2221-Texas Pipeline Association (TPA), 2227-Western Energy Alliance (WEA), 2428-API) also are concerned with the timing of issuing state permits. Commenter (2483-INGAA) states that it is problematic because many permitting programs do not include provisions for methane emissions, and/or the related methane emissions in the transmission and storage segment are below *de minimis* levels in state minor source permit programs. The commenter describes where members have experienced instances in which the member requested from a state permitting authority a permit

limit for methane, and the permitting authority would not issue a permit because the emissions or emission levels were not covered in the state permitting program. Therefore, the commenter recommends retaining the 6 tpy VOC basis for storage vessel/tank battery applicability.

Commenter (2202-TXOGA) recommends that EPA recognize permit limits set for VOC as a surrogate for methane-specific limits. The commenter explains that the Texas Commission on Environmental Quality (TCEQ) does not set and issue to individual sources permit limits specifically for methane<sup>9</sup>. Further, the commenter states, EPA has always recognized that VOC limits also limit volatile organic hazardous air pollutants (VOHAP), and as the Clean Air Act (CAA) section 112 program was being developed, states and sources relied on VOC limits as effective ways to create synthetic minor sources for purposes of Title V where VOHAP were the only HAP emitted. The commenter believes the same result applies with the oil and gas rule under CAA section 111.

Further, commenter (2202-TXOGA) states that they have serious concerns regarding the new definition of “storage vessel affected facility,” given the interrelationship between the new definition and EPA’s earlier proposal to adopt a new definition of “legally and practicably enforceable.”<sup>10</sup> The commenter states that EPA’s proposal to define a “storage vessel affected facility” as a “tank battery” which has the “potential for methane emissions equal to or greater than 20 tpy” is very problematic. The commenter explains that some of their larger members have many hundreds, and in some cases over a thousand tank batteries with VOC limits in place, limits that they spent considerable effort obtaining through minor New Source Review (NSR) permit processes. The commenter believes that EPA is aware that obtaining permit limits in most states requires preparation and submittal of a permit application, review by the state permitting authority, preparation of a draft permit, publication for a 30-day notice and comment period, review of any comments submitted, and finalization of the permit. For Title V facilities, the commenter explains that these terms then needed to be incorporated into the Title V operating permit, which can involve a separate permit amendment process, depending on the state’s regulations. The commenter states that the proposal to require separate methane permit limits, will lead to requiring that same process to be repeated, and even if it turns out that for some of these sources, the VOC limit is effective to limit methane emissions below 20 tpy for the battery, the evaluation by the source and likely confirmation process with the permitting authority will be resource and time consuming. The commenter is concerned that the logistical and administrative burdens have not been adequately considered by the Agency. The commenter states that the December 2022 Supplemental Proposal lacks an adequate analysis of these burdens, which is essential to determining if a transition program is needed. By way of example, the commenter reminds EPA of problems that were confronted as sources sought to obtain minor NSR permits to avoid Title V or so-called federally enforceable state operating (FESOP) permits to obtain PTE limits to be classified as area sources under CAA section 112. The commenter stated that in the 1990s, EPA issued a policy establishing transition rules recognizing that states could not possibly issue the permits needed to create minor Title V sources and section 112 area sources,

---

<sup>9</sup> Texas does have under its “permit by rule” program provisions that establish a facility-wide VOC limit of 25 tpy for those sources in the oil and gas industry that choose to opt in to that program.

<sup>10</sup> TxOGA provided comments on “legally and practicably enforceable” in their January 2022 comments in response to the November 2021 proposal. TxOGA did not provide new comments on “legally and practicably enforceable” in response to the December 2022 proposal.

allowing for reliance on actual emissions while permits were processed.<sup>11</sup> This policy was initially set to expire after two years, but the Agency ended up extending it so that it lasted over five years.

The commenter (2202-TXOGA) states that accordingly, one effect of this shift will be to necessitate tank-by-tank and battery-by-battery PTE calculations for methane for these many hundreds of potentially affected facilities. For companies in this situation, the commenter states that this will be a monumental undertaking that, as a practical matter, will take an extraordinary amount of time and that there is no question that transition rules will be essential. The commenter urges the Agency to establish common sense transition rules for any new requirements (1) for legally and practicably enforceability and (2) to phase in the methane 20 tpy applicability limit. The commenter believes that EPA has the ability to place these transition provisions directly into the regulations to provide regulatory certainty to companies and to avoid drastically overburdening state agencies, which are already behind in processing Title V renewals. In particular, the commenter states, EPA should provide that 6 tpy VOC permit limits will (1) be deemed to satisfy any new legal and practical enforceability requirements and (2) be deemed an acceptable surrogate for the 20 tpy methane limit. The commenter states that EPA should provide the revisions be conducted either during the next Title V renewal for the source (provided such renewal is at least one year after rule issuance) or at the next significant permit modification under Title V. For non-Title V sources, the commenter recommends that the transition rules should provide a five-year period to allow sources to obtain necessary permits, recognizing that overburdened states will typically allocate resources to major sources first. This commenter believes that this transition period recommendation makes sense for several reasons:

- First, the VOC limit has been acting as a surrogate limit on methane already.
- Second, many of these tanks qualifying for the less than 6 tpy cut point have vapor recovery units (VRUs) or flares ensuring emissions below the 6 tpy VOC and 20 tpy methane cut points.
- Third, forcing an enormous effort on permitting authorities to create new limits meeting these two new requirements (without emission reduction benefits) is simply an unwise use of resources by the both the regulated industry and permitting authorities.

Commenter (2428-API) states that few existing sources have express emissions limitations for methane or greenhouse gases (GHGs), yet, EPA has proposed a 20 tpy methane applicability trigger for the NSPS OOOOb and EG OOOOc storage vessel standards (in addition to the 6 tpy VOC trigger). As a result, the commenter believes that many potentially affected/designated facilities likely will seek to rely on VOC emissions limitations as a surrogate for methane emissions. The commenter believes the use of surrogates in establishing effective PTE limits is a cross-cutting issue for which EPA should establish a unitary CAA approach rather than the proposed piecemeal, rule-by-rule approach.

Commenter (2428-API) notes that for permitting, methane is typically regulated as a GHG for major sources under the Prevention of Significant Deterioration (PSD) program. The commenter

---

<sup>11</sup> EPA, Options for Limiting the Potential to Emit of a Stationary Source Under Section 112 and Title V of the Clean Air Act, Memorandum from John S. Seitz, Office of Air Quality Planning and Standards, and Robert I. Van Heuvelen, Office of Regulatory Enforcement, to Regional Air Directors (Jan. 25, 1995).

is concerned that states may not be able to permit a methane limit under their minor NSR programs. As such, the commenter believes that EPA should clarify that a methane emission limit is not required to be explicitly listed in the permit provided the control device and/or production limits are included that would limit the PTE from a storage vessel or tank battery to less than 20 tpy of methane. Another approach the commenter recommends is to allow a VOC limit of less than 6 tpy to serve as a surrogate for the methane emission limit. A potential consequence of requiring an explicit methane emission limit is that existing tanks may have a permit that does not make them an affected facility under NSPS OOOO or NSPS OOOOa but will not be able to obtain an updated permit for the purposes of EG OOOOc applicability, warns the commenter.

Another issue the commenter (2428-API) points out is the permitting effort for the hundreds of thousands of existing storage vessel designated facilities potentially subject to EG OOOOc will take years and be an administrative burden on operators and the state permitting authorities with no environmental benefit. According to the commenter, one member has estimated that it will take ten (10) years to obtain updated permits at the current preparation and agency review timelines. This estimated effort will likely take longer as other operators also seek to update permits at the same time, the commenter warns. Given the potential enormous re-permitting burden for existing storage vessels/tank batteries, the commenter recommends that EPA should allow operators to rely on VOC limits as a surrogate for methane in existing permits that have previously been understood to be legally and practicably enforceable.

Commenter (2221-TPA) states that their understanding is that some state agencies with jurisdiction over air permits believe that these requirements would pose significant problems and that it would take a substantial amount of time and resources to address and incorporate this proposal into their permitting structures, given that their new source review programs do not have minor source permitting programs allowing for inclusion of GHG emissions.

Commenter (2227-WEA) states that the new methane applicability threshold creates an issue with state permits as it is a new criterion for which state permits would not have a direct limitation. The commenter states that the administrative process to modify these permits to address these new criteria is a very significant and unnecessary burden on owners, operators and permitting authorities without emissions reduction benefit. The commenter states that assuming the typical pace to process permits and depending on the number of permits that need to be modified, the process to modify permits can take upwards of ten years.

Response II-13-15: EPA agrees with the commenter that low levels of VOC are a reliable indicator of limited methane emissions. Reviewing the data in the docket, EPA estimated that 4 tons per year of VOC would likely be an appropriate level at which it can be assumed that a source would emit under 20 tpy methane [Docket Item No. EPA-HQ-OAR-2021-0317-0039, Attachment 21; based on worst-case ratio of VOC to methane; see “Oil” tab, row 33, data for “Sample Tank No. 52”]. While we agree in principle that some level of VOC may be an appropriate surrogate for applicability of a methane threshold, EPA did not propose the surrogate relationship of VOC emissions that can be reviewed by commenters.

The addition of methane as a regulated pollutant may require revision to state permit programs

generally, but such changes will not affect existing sources until a federal or state plan has been promulgated and such a limit in a permit is not a prerequisite for determining the potential for methane emissions. Responses to comments regarding legally and practicably enforceable limits may be found in Section 13.2.6. EPA stated in the supplemental proposal (87 FR 74832) that 18 months from final promulgation of this rule should adequately accommodate the differences in state processes necessary for the development of a state plan that meets applicable requirements. Those state plans would have up to a 36-month period from the final adoption of state rules to come into full compliance (87 FR 74836).

The applicability threshold for methane emissions applies to affected facilities that are new, modified, or reconstructed after December 6, 2022 (87 FR 74702). For existing sources, states have the opportunity to review EG OOOOc and adapt their state programs to the requirements of the final rules, a period which would be no less than a year and could extend up to 36 months for state 111(d) plans.

### ***13.2.6 Legally and Practicably Enforceable Limits***

Comment: Commenters (2298-Pioneer Natural Resources USA, Inc. (Pioneer); 2301- U.S. Chamber of Commerce (USCC), 2326-American Exploration and Production Council (AXPC), 2428-API) urge EPA to defer final action on the proposed definition of legally and practicably enforceable limits until such time as the Agency undertakes a national rulemaking. Commenter (2428-API) believes such a broad-based rule would prevent potential inconsistencies among the various CAA programs (*e.g.*, an effective emissions limit used to avoid major NSR permitting might, at the same time, not be effective for purposes of the NSPS OOOOb and/or EG OOOOc storage vessel standards); would avoid the possible implication that the “effectiveness” criteria established under EG OOOOc should be applied under other CAA programs (*i.e.*, how can an emission limit be both effective and not effective at the same time); and would allow EPA to establish reasonable transition rules so that affected sources and states have time to revise existing emissions limitations as needed to meet the new effectiveness criteria. The commenter states they raised similar issues in the November 2021 Proposal and are raising them again, because EPA recently announced its intention to issue national guidance on establishing effective limits on PTE.<sup>12</sup> The commenter believes that effort appears to be driven by a July 2021 report from the EPA Inspector General that criticized the Office of Air and Radiation for not responding to a series of 1990’s era D.C. Circuit decision that vacated or remanded the then “federal enforceability” criteria that applied across EPA’s CAA regulatory programs.<sup>13</sup> The commenter states that EPA’s announced plan to establish national rules for effective limits on PTE and to do so in the relative near future<sup>14</sup> lends strong additional support that EPA should not address these issues in a premature and piecemeal fashion in the EG OOOOc rule.

Commenter (2326-AXPC) recommends that EPA set aside the definition of “legally and practicably enforceable” limit unless and until EPA completes a national rulemaking. The

---

<sup>12</sup> NAAQS, Regional Haze & Permit Program Implementation Updates, Presentation by Scott Mathias, Director Air Quality Policy Division, OAQPS, to AAPCA Fall Meeting (Sept. 29, 2022).

<sup>13</sup> EPA Should Conduct More Oversight of Synthetic-Minor-Source Permitting to Assure Permits Adhere to EPA Guidance, Report No. 21-P-0175, memorandum from Sean W. O’Donnell to Joseph Goffman (July 8, 2021) at 17.

<sup>14</sup> The commenter states that EPA intends to issue national guidance by October 2023.

commenter states that while the definition is within the context of determining storage vessel applicability under NSPS OOOOb and EG OOOOc, the concept of a legally and practicably enforceable limit is not limited to NSPS OOOOb/EG OOOOc storage vessels though, and its finalization will create much uncertainty across CAA programs, as other sources wonder whether EPA's newfound definition will apply in other contexts – *e.g.*, NSR permitting or section 111 performance standards for other source categories. The commenter states that a national rulemaking would avoid many potential inconsistencies and uncertainties across CAA programs and would allow EPA to establish reasonable transition rules so that affected sources and states have time to revise existing emissions limitations as needed to meet the new effectiveness criteria.

Commenter (2298-Pioneer) states that EPA should not define and impose practicably enforceability requirements without first developing a coherent approach for all EPA programs. The commenter believes that the question of what constitutes an acceptable and effective “legally and practicably enforceable limit” goes well beyond the four corners of this regulation and has implications far beyond this narrow regulatory provision. The commenter believes that this question is relevant across EPA's CAA stationary source programs: from major source permitting under New Source Review (NSR)/PSD, to the Title V operating permit program, to all manner of federal and state emissions control programs (of which CAA section 111 is just one). The commenter opines that what constitutes an acceptable and effective “legally and practicably enforceable limit” has been an open question since the mid-1990s, when the prior “federal enforceability” requirement was remanded or vacated across EPA's programs.<sup>15</sup> The commenter notes that EPA announced its intent to conduct a comprehensive rulemaking to address the holdings in these cases but has not yet taken action almost 30 years after the decisions were handed down. Addressing it in a piecemeal, rule-by-rule fashion will ultimately cause confusion and potential inconsistency across the relevant programs, the commenter states. Moreover, the commenter states, affected facilities and states now have years of experience implementing the NSPS OOOO and NSPS OOOOa storage vessel standards, including substantial experience in crafting appropriate emissions limitations to govern applicability of these standards. Creating new mandatory procedural requirements is unnecessary according to the commenter, given that no systemic problem has emerged during this long implementation period. The commenter believes that such requirements would add to the cost and burden of implementing these standards without delivering any commensurate benefit. The commenter recommends that EPA defer final action on the proposed definition until such time as the EPA undertakes a broad-based rule that would provide a single, consistent approach across all affected CAA programs.

Response II-13-16: See discussion in Section XI.J.1. of the preamble to the final rule which details EPA's final standards for legally and practicably enforceable emissions limitations.

Comment: Commenter (2298-Pioneer) is concerned that the legally and practicably enforceable criteria could inadvertently call into question existing permitting and regulatory regimes that do not specifically include the parameters proposed by EPA.

---

<sup>15</sup> *National Mining Ass'n v. EPA*, 59 F. 3d 1351 (D. C. Cir. 1995); *Chemical Mfrs. Ass'n v. EPA*, 70 F. 3d 637 (D.C. Cir. 1995); *Clean Air Implementation Project v. EPA*, 1996 WL 393118 (1995).

Response II-13-17: The EPA agrees the final requirements will result in coverage for the first time for numerous existing storage vessels, but not under OOOOb. Instead, the requirements that EPA is finalizing do not apply to existing sources before states have the opportunity to submit 111(d) implementation plans after state rulemaking takes place to reflect the emission guidelines. EPA has allowed states 18 months to carry out state rulemaking activity to adopt the appropriate emission guidelines and standards. In addition to the 18 months, EPA has recommended that states adopt compliance deadlines within 36 months, providing over 4 years for existing sources to adapt their systems to new federal and state standards.

Comment: Commenter (2301-USCC) is concerned with the proposed definition for the term “legally and practicably enforceable” as it relates to state emissions limits for “storage vessel affected facilities” that limit their potential for VOC emissions below 6 tpy. The commenter believes that in effect, if EPA deems applicable state standards not “legally and practically enforceable,” it would disregard the state limits and treat the storage vessels as uncontrolled for purposes of federal regulation.<sup>16</sup> The commenter is concerned that this proposal thus has the potential to create substantial friction between EPA and the states, and could result in many more facilities becoming subject to federal emission standards. The commenter believes that EPA’s proposed enforceability indicia put form over substance by ignoring how states *actually enforce* emissions limits in favor of a series of checkboxes. Based on these indicia, many state limits that states *actively enforce* could be deemed not “legally and practically enforceable,” despite states having years of experience implementing storage vessel standards and enforcing these standards, according to the commenter. The commenter recommends that EPA defer final action on any proposed definition of “legally and practicably enforceable” until such time as the agency elects to undertake a comprehensive, broad-based rulemaking to ensure consistency across CAA programs. The commenter is concerned that to otherwise proceed risks creating a piecemeal, rule-by-rule regime that would ultimately create confusion among regulated parties and state regulators and inconsistencies across CAA programs.

Response II-13-18: EPA disagrees with the contention of the commenter that the EPA is placing form over function with the legally and practicably enforceable criteria. As a legal matter, the revised criteria apply to OOOOb sources and would not apply to OOOOc EG sources until states act to designate sources and adopt their own plans under 111(d), meaning the number of existing sources subject to the OOOOc EG criteria will not increase until that time. As discussed in the November 2021 Proposal, EPA has reviewed some state limits, and believes they are too general to require a reduction in emissions. See 86 FR 63201. See also the examples provided in Section XI.J.1. of the preamble to the final rule. With respect to verifying compliance, EPA has not asserted that states are not enforcing limits, but EPA does believe that in some cases, the limits which are being enforced are not capable of achieving the required emissions reductions to stay below the potential for VOC emissions under the NSPS. EPA believes that establishing legally and practicably enforceable criteria for the oil and gas industry will create a level of certainty as to what EPA considers legally and practicably enforceable for the next generation of sources. This level of specificity and certainty will serve to guide states as they consider how to apply

---

<sup>16</sup> See 86 Fed. Reg. at 63,202 (“Only those limits that include the elements described [in the proposed definition] will be considered ‘legally and practicably enforceable’ for purposes of determining the potential for VOC emissions from a single storage vessel or tank battery, and thus applicability (or nonapplicability) of each single storage vessel or tank battery as an affected facility under the rule.”).

these criteria through state requirements promulgated under OOOOc EG and through permits issued for OOOOb and OOOOc sources.

Comment: Commenter (2221-TPA) states that EPA should not add unduly prescriptive requirements associated with claiming emissions limits for storage vessels. The commenter urges EPA not to adopt the proposed new definition of what is considered a legally and practicably enforceable limit for storage vessels.<sup>17</sup> The commenter is concerned that EPA's proposed revisions to the concept of legally and practicably enforceable emissions limits in the context of storage vessel applicability thresholds are unduly prescriptive and that the proposal casts aside the traditional means of assessing PTE limits for threshold applicability purposes and replaces it with a highly prescriptive scheme that would constitute regulatory overkill and add uncertainty to whether and how limits could be claimed going forward. The commenter explains their understanding, that where a rule contains an emissions threshold under which a given piece of equipment is not subject to the rule's requirements, it is fair and logical that the equipment be considered outside of rule coverage where emission controls or limitations are in place to keep emissions below the threshold, even though in an uncontrolled state the equipment is capable of producing emissions above threshold levels. The commenter states that this concept has been embodied in EPA rules for decades<sup>18</sup> and was incorporated into NSPS OOOOa in 2016.<sup>19</sup> The commenter states that they are not aware that it has caused any significant problems or compliance issues in the context of NSPS OOOOa or more generally.

The commenter (2221-TPA) is concerned that EPA continues to take the position that an owner or operator would have to coordinate with the applicable permit authority to work out specific limits, monitoring requirements and recordkeeping that will ensure any permitted emission limit is achieved, whatever this might entail in a given circumstance. If all this does not occur, the commenter is concerned that presumably the result would be that an owner or operator would be unable to claim the existence of legally and practicably enforceable limits or throughput limitations keeping a storage vessel below the applicability threshold. The commenter states that this all is unnecessary regulatory overkill and would add significant burden and uncertainty to what should be a straightforward process. The commenter points out burden and complications that they say would be felt both by companies seeking enforceable limits and state regulatory agencies which might have to revisit permit terms in order to align permit conditions with the new requirements. The commenter is concerned that if that alignment could not be achieved, then EPA 's proposed new requirements would have the effect of placing numerous storage vessels into NSPS coverage for the first time, even if there had been no indication that the vessels had been circumventing controls that had kept PTE below threshold levels. In addition, it is the commenter's understanding that some state agencies with jurisdiction over air permits believe that these requirements would pose significant problems and that it would take a substantial amount of time and resources to address and incorporate this proposal into their permitting structures, given that their NSPS programs do not have minor source permitting programs allowing for inclusion of GHG emissions. The commenter also states that even if an

---

<sup>17</sup> Our comments on this point are not limited to emission limits for storage vessels; any rule provisions that allow owners and operators to claim legally and practicably enforceable emissions limits should be free from the additional restrictions being proposed by EPA here, regardless of type of operation at issue.

<sup>18</sup> See, e.g., 40 CFR § 5 I. I 65(a)(I)(iii); 40 CFR § 5 I. I 66(b)(4); 40 CFR § 52.21 (b)(4).

<sup>19</sup> 81 Fed. Reg. 31500 (June 3, 2016).

owner or operator could satisfy every item required by the proposed criteria for “legally and practicably enforceable,” there would be the additional burden of translating compliance with those requirements into an arrangement with the permitting authority that may require rewriting existing permit authorization terms so that the permit would meet the criteria EPA has in mind. The commenter states that application of these new criteria would only work to hinder or eliminate the use of a concept that EPA (rightly) considered to be advisable in its 2016 promulgation of NSPS OOOOa and that EPA has employed for decades, in each case free from the restrictions EPA is now contemplating. In the context of relying on permit limits to claim reductions in PTE, the commenter believes it has long been EPA's position that “[w]hen permits contain production or operational limits, they should also have recordkeeping requirements that allow a permitting agency to verify a source's compliance with its limits.”<sup>20</sup> The commenter believes the requirement of an enforceable limit has always been and continues to be in place, per storage vessel applicability requirements at 40 CFR 60.5365a(e) that cognizable PTE limits must take the shape of “requirements under a legally and practicably enforceable limit in an operating permit or other requirement established under a Federal, state, local, or tribal authority.” The commenter summarizes that a permit limit is a permit limit, and it is inconceivable that there is any federal, state, or local permit that does not carry with it the ability of the issuing authority to ensure and enforce compliance if permit limits are exceeded. The commenter states that they recognize that reporting, recordkeeping, monitoring requirements will vary from permit to permit, but that all permits ultimately must be complied with or enforcement consequences from the issuing authority may follow. To the commenter’s knowledge, they state there is no permit that does not contain consequences for violations.

Response II-13-19: See discussion in Section XI.J.1. of the preamble to the final rule which details EPA’s final standards for legally and practicably enforceable emissions limitations.

Comment: Commenter (2221-TPA) states that it is inaccurate to suggest (as they said that EPA did in the November 2021 Proposal), that a permitted emissions limit that does not contain one or more mechanisms to ensure or monitor compliance (*e.g.*, performance testing requirements, continuous or other monitoring requirements, recordkeeping and reporting provisions) is somehow less than enforceable or merely constitutes a “voluntary” limit that EPA should simply disregard. The commenter states that in no sense is an emissions limit memorialized in a permit voluntary; it is a legal requirement that must be followed, even if the particular monitoring or recordkeeping provisions contained in the permit do not reflect EPA's proposed new requirements.

The commenter (2221-TPA) recognizes that it is inappropriate to claim an enforceable limit if the limit is actually unenforceable in practice, but states that this issue has been present ever since the first time EPA implemented the concept of claiming limits on PTE and they do not think that circumstances surrounding claimed PTE limits have changed dramatically such that all the new requirements, burdens, and attendant uncertainty in EPA's proposal are justified.

Response II-13-20: EPA agrees with the commenter that an emissions limit memorialized in a permit is not a voluntary limit. EPA disagrees with the commenter that a limit in a permit is self-

---

<sup>20</sup> EPA Memorandum, "Limiting Potential to Emit in New Source Permitting," Terrell E. Hunt and John S. Seitz (June 13, 1989) at 6.

evidently enforceable without more specific requirements that allow EPA or the state to determine ongoing compliance using field-gathered data summarizing ongoing compliance with the terms in the permit.

Comment: Commenter (2222-Wisconsin Department of Natural Resources (WIDNR)) states that the requirements for legally and practicably limiting the “potential for methane emissions” are unclear and conflict with the definition of “potential to emit.” Specifically, the commenter states:

- It is unclear why EPA has proposed that production limits must be accompanied by operational limits in order to be legally and practicably enforceable. (40 CFR 60.5386c(e)(2)(i)(A))
- It is unclear how a source would establish parametric limits for production and/or operational limits. (40 CFR 60.5386c(e)(2)(i)(C))
- It is unclear how a source would use a control device to meet an operational limit. (40 CFR 60.5386c(e)(2)(i)(C))

The commenter (2222-WIDNR) states that EPA should refer to the available case law and guidance on limiting “potential to emit” to ensure the use of terms such as “production limit,” “operational limit,” and “parametric limit” in the proposed rules are consistent with the widely accepted use of those terms in air permitting programs.

Response II-13-21: See discussion in section at Section X.J.1. of the preamble to the final rule which details EPA’s final standards for legally and practicably enforceable emissions limitations.

Comment: Commenter (2258-MSA) suggests revisions or clarifications to the regulatory text regarding legally and practicably enforceable. At 40 CFR 60.5365b(e)(2)(i), the commenter asks EPA to clarify that a legally and practically enforceable limit applies to both; 1) an operating permit and, 2) other requirement established under a Federal, state, local, or tribal authority. At 40 CFR 60.5365b(e)(2)(i)(A), the commenter requests clarification that both a quantitative production limit, meeting criterion of 40 CFR 60.5365b(e)(2)(i)(B) and a quantitative operational limit are required. The commenter also asks that EPA confirm that more than one operational limit (*e.g.*, 95 percent control) that does not qualify as a parametric limit is required.

Response II-13-22: The EPA disagrees that the current references to “enforceable limit in an operating permit or other requirement established under a Federal, state, local, or tribal authority” in 40 CFR 60.5365b(e)(2)(i) requires further clarification. The EPA disagrees with the need to specify that an operational limit of 95 percent control is not a parametric limit. Examples of parametric limits for control devices are typically flow rate, residence time, combustion zone temperature, visible emissions, or similar metrics of the control reaction or oxidation.

Comment: Commenter (2423-Coterra Energy, Co.) states that they support the proposed VOC and methane thresholds (*i.e.*, 6 tpy VOCs and 20 tpy methane) for a single storage vessel or a tank battery affected facility at new well sites, centralized production facilities, and compressor stations, but are concerned that the proposed criteria for establishing legally and practically enforceable limits will create confusion and burdensome compliance issues. The commenter explains that in administering the CAA, states establish limits that allow operators to keep below

permitting thresholds for both Title V and PSD thresholds. The commenter states that the oil and gas industry, as well as other industries, have come to rely on that practice. In turn, according to the commenter, states have adopted monitoring, recordkeeping, and reporting requirements as part of permits. Nevertheless, the commenter is concerned that existing permits in many states may not meet the criteria that EPA is proposing for legally and practically enforceable permit terms. The commenter believes that the proposed changes will require states to review and revise countless permits and also may require states to engage in rulemakings over and above the efforts states will be required to initiate to implement these rules. The commenter states that EPA has neither explained nor justified this policy change, as it must, and should retract it.

Response II-13-23: See discussion in section at Section X.J.1. of the preamble to the final rule which details EPA's final standards for legally and practicably enforceable emissions limitations.

Comment: Commenter (2399-GPA) states that they provided comments on the definition of legally and practicably enforceable in their comments in response to the November 2021 Proposal and that for the purposes of the December 2022 Supplemental Proposal, they reassert and adopt those previous comments and objections as if fully stated here. In summary, the commenter states the following:

- Contrary to EPA's suggestion that this is codification of previous policy, EPA previously defined and used the term differently.<sup>21</sup> Therefore, regardless of EPA's intent, providing a new and different definition does not provide "clarity to owners and operators claiming the storage vessel is not an affected facility in NSPS OOOOb, due to legally and practicably enforceable limits that limit their potential for VOC emissions below 6 tpy."
- Rather than provide clarity, EPA's proposed definition—including quantitative production and operational limits, averaging time, parametric limits on performance testing, continuous monitoring, and recordkeeping and reporting thereof - is inconsistent with the long-standing definition, overly restrictive, excludes work practices and other control options, and effectively prohibits the use of permits by rule and general permits. EPA has not provided any reasonable justification for this shift from its previous position.
- EPA should not upend the state permitting process, which has long relied on the current understanding of legally and practically enforceable. Indeed, EPA has approved the state minor source permitting programs, which are part of the states' implementation plans. Based on those programs, sources have obtained permits and relied on the presence and operation of its controls to meet its regulatory requirements, such as the limit on VOC emissions from storage vessels. By substantially revising this definition - and apparently effectively assuming that controls are not in place - EPA would dramatically change the permitting landscape. Moreover, it is really putting the cart before the horse. If EPA believes state minor source programs generally require revision, there is a process for that and EPA should follow that process of generally revising state SIPs, as opposed to attempting to make changes in this regulation.
- Adoption of this legally deficient proposed definition would prove unworkable in practice and would require significant time and resources to implement, for which EPA

---

<sup>21</sup> See 40 CFR 49.152, 49.167; 76 Fed. Reg. 38,748 (July 1, 2011); see also Prevention of Significant Deterioration and Nonattainment New Source Review: Debottlenecking, Aggregation, and Project Netting, 71 Fed. Reg. 54,235, 54,240 n. 13 (Sept. 14, 2006).

has not provided in its proposal. Among other concerns, these sources do not have methane limits in permits now. EPA's new approach offers no guidance on how to assess whether a particular set of parameters is legally and practically enforceable to achieve a methane limit in that case. Further, prohibiting the use of permits by rule and general permits would impose enormous burdens on sources and state permitting authorities, for which the proposal makes no provision. This would have a cascading effect on Title V determinations across numerous sources, imposing substantial additional burdens and complexities on sources and states.

The commenter (2399-GPA) states that if EPA decides to finalize the text, EPA should recognize that sources in good faith went to the regulator and obtained a permit under the applicable state minor source program. Thus, at a minimum, the commenter states that EPA should provide flexibility by phasing in the requirement and applying the new definition only when a source needs to apply for a new or revised permit or a permit renewal. Moreover, crucially, for all existing sources, the commenter states that EPA should be clear that existing permits authorizing a source to operate remain fully effective, pending state processing of new permits.

Response II-13-24: EPA disagrees that the criteria finalized in OOOOb is inconsistent with prior guidance. The language adopted reflects the tenets of guidance applicable to OOOO and OOOOa sources that remains applicable today. Such prior guidance includes the January 25<sup>th</sup>, 1995 memo from John Seitz to the Air Directors of all ten EPA regions titled "Options for Limiting the Potential to Emit (PTE) of a Stationary Source Under Section 112 and Title V of the Clean Air Act (Act)" and the January 25<sup>th</sup> 1995 memo from the Office of Enforcement and Compliance assurance from Kathie A. Stein, Director of the Air Enforcement. Division to all ten EPA regions titled "Guidance an Enforceability Requirements for Limiting Potential to Emit through SIP and §112 Rules and General Permits."

EPA is not adding regulatory language for legally and practicably enforceable limits in an effort to correct state permit programs. EPA enforces the NSPS as written and has chosen to add regulatory language for new affected sources under OOOOb to facilitate compliance on the part of owners and operators. EPA has obtained consent decrees for sources that failed to show compliance with the NSPS from owners and operators. The EPA did not obtain those consent decrees with state agencies.

With regard to the comment that existing sources do not have methane limits in permits now, see the discussion in the Final Preamble in Section XI.J.1.,

EPA's promulgation of these criteria is the basis of how the EPA will evaluate whether a facility is subject to legally and practicably enforceable emission limits for new and modified facilities under new and modified sources under OOOOb and existing sources under OOOOc EG. These criteria will apply going forward and will not be used to determine whether prior determination of OOOO/OOOOa applicability were accurate. As the EPA stated in our proposal and supplemental proposal, the enforcement record shows that there is a need for EPA to further specify what legally and practicably enforceable emissions limitation means in the oil and gas sector because we have found through enforcement actions that sources have relied on inadequate limitations to support their status as not subject to the storage vessel provisions of the

NSPS. However, the EPA disagrees with the comment that our action results in the need for all storage tank owners and operators to obtain site-specific permits. A permit-by-rule or general permit system that creates legally and practicably enforceable limits that meet the criteria would not require a site-specific permit. Further, no owner or operator is required under this provision to obtain any minor source permit. The owner or operator could instead comply with storage vessel requirements under OOOOb.

We also point out that the provisions finalized in this action are applicable to new, modified, and reconstructed sources under the NSPS OOOOb generation of sources, and existing source designated facilities under OOOOc, and are not retroactively applicable to OOOO or OOOOa sources. The EPA enforcement cases to date have relied on EPA guidance and the provisions of OOOO and OOOOa, and will continue to do so.

Comment: Commenter (2254-PBPA) states that the definition of legally and practicably enforceable usurps state authority, and directly conflicts with how that term is used in other CAA programs. The commenter states that as a matter of practice, states have exercised their right to promulgate their own regulations that operators could take into account when determining PTE. The commenter believes individual states are much better equipped to determine the appropriate methods for the specific circumstances facing industries within their state and that process is required under EPA's regulations (when the states meet certain conditions). The commenter is concerned that the proposed requirements conflict with the approach used in both the Title V and NSR/PSD permitting programs. Under these programs, the commenter explains, operators may rely on control requirements to limit their PTE that would no longer be available under the Proposed Rule. In effect, the commenter is concerned that the Proposed Rule would arbitrarily require operators to have two different PTE calculations – one for Title V and NSR permitting and another for NSPS/EGs under the Methane Rule.

The commenter (2254-PBPA) states that the definitions of “potential to emit” and “federally enforceable” show that EPA's own regulations provide states with substantial latitude to establish “legally enforceable procedures.” The commenter cites to 40 CFR Part 51 for the definition of “potential to emit”<sup>22</sup> and “federally enforceable.”<sup>23</sup> Thus, the commenter states, the TCEQ emissions limits, established under its EPA-approved State Implementation Plan (SIP), are by EPA's own definition federally enforceable. The commenter also states that EPA previously determined that the regulations and permits issued by both the TCEQ and NMED were legally and practicably enforceable. The commenter states that in the preamble to the proposed 2013 amendments to NSPS OOOO, EPA reviewed the regulations in several states to determine which states already had storage tank control requirements for calculating PTE. Based on its evaluation of these regulations, the commenter states that EPA determined that several states already had sufficient regulations, including both Texas and New Mexico, such that EPA could subtract the storage vessels in these states “from the overall count of storage vessels that

---

<sup>22</sup> “Potential to emit is the maximum capacity of a stationary source to emit a pollutant under its physical and operational design. Any physical or operational limitation on the capacity of the source to emit a pollutant, including air pollution control equipment and restrictions on hours of operation or on the type or amount of material combusted, stored, or processed, shall be treated as part of its design only if the limitation or the effect it would have on emissions is federally enforceable.” See, e.g., 40 CFR 51.165(a)(1)(iii).

<sup>23</sup> “...all limitations and conditions which are enforceable by the Administrator...[and] requirements within any applicable State implementation plan...”. Id. at 40 CFR 51.165(a)(1)(xiv).

would be subject to the final rule.” The commenter believes that EPA’s proposal to require a new definition of “legally and practicably enforceable” substitutes its own judgment as to what is legally and practicably enforceable when its own regulations say that determination should be left to the states, subject to EPA review. The commenter reminds EPA of its ability to weigh in on whether a state’s regulations are legally and practicably enforceable through the SIP review process. The commenter believes that when given the opportunity to review the regulations of Texas and New Mexico with regard to calculating PTE, EPA already has determined those regulations were federally enforceable.

Response II-13-25: EPA disagrees with the commenter that the legal basis for federal enforceability of SIP provisions addresses the criteria that EPA is promulgating for legally and practicably enforceable limits. EPA is promulgating the requirements that allow field data to be compared to operational and production limitations for the purpose of verifying compliance. This is fundamentally different than establishing the legal underpinning that make SIP provisions federally enforceable in general. EPA also disagrees that the definition of “potential to emit” cited by the commenter is relevant in this instance. The final rule provides that production limits must be accompanied by operational limits to be legally and practicably enforceable because potential VOC and methane emissions from a storage vessel are a function of the facility operational conditions and production rates. Consequently, both are inputs to the storage vessel emission calculations and changes in either may result in an increase in vessel emissions. Compliance with any emissions limit should be demonstrated by monitoring the operational conditions and production rates used to establish emissions from the storage vessel.

EPA disagrees that adopting regulatory language governing how the EPA will evaluate legally and practicably enforceable limitations usurps state authority to issue minor source permits. The NSPS applies to emissions from affected sources and does not serve as the legal basis upon which any source operates.

The EPA also disagrees that the criteria EPA is promulgating conflicts with other Clean Air Act programs. The commenter states in their comment letter that “Operators currently rely on the same regulations and permit conditions to comply with minor source permitting requirements under the Title V and NSR programs.” The EPA cannot understand how more specific criteria within the NSPS OOOOb that supports an ongoing demonstration of compliance can undermine compliance with Title V and NSR permits. The EPA repeats that existing sources subject to OOOO and OOOOa are not affected by the standards of OOOOb until they are modified or reconstructed, or until they become designated facilities under OOOOc EG in coming years. Even in the event that a conflict were to arise that EPA has not foreseen for existing sources, EPA contends that the time period to adopt state plans, designate facilities, and implement an existing source program is sufficient for sources and states to revise applicable requirements.

EPA rejects the view of the commenter that EPA substitutes its own judgement for that of states on what constitutes legally and practicably enforceable limitations, because EPA has been issuing guidance on that concept to states since 1995. EPA regularly enforces its own cases on the provisions of legally and practicably enforceable limitations, and EPA points out that our decision to adopt regulatory criteria for legally and practicably enforceable limitations in this rule is based on review of actual permits, which were not revealed by (or apparent from)

reviewing the state regulations. In summary, it is EPA's responsibility to ensure that NSPS is effectively implemented.

EPA agrees that in promulgating OOOOb and OOOOc EG that thousands of sources may become subject to additional emission control regulations, since the purpose of section 111(b) and (d) is to reduce emissions for new, modified, reconstructed, and existing sources, some of which pre-date subpart OOOO standards promulgated in 2012. EPA disagrees that the emissions from these sources do not warrant regulation, which can be reviewed in the RIA.

Comment: Commenter (2298-Pioneer) believes that permits obtained from the TCEQ would show all of the legally and practicably enforceable requirements, however the commenter believes the proposed requirements are vague and they seek clarification. The commenter points to the first requirement, “quantitative production limit and quantitative operational limit” and they believe these requirements are shown in the state TCEQ permit, however, the commenter asks if operators need to obtain a federal permit on top of the state permit. Because the air permitting SIP was approved by EPA, and TCEQ has received delegation to run their permitting program, the commenter strongly recommends that EPA specify that the certified state permit suffices in demonstrating that tank batteries are under the required threshold limit of 6 tpy VOCs. Generally, the commenter believes that the SIP approval and delegation should provide the assurances EPA needs to rely on the state agency.

Response II-13-26: See discussion in section at Section X.J.1. of the preamble to the final rule which details EPA’s final standards for legally and practicably enforceable emissions limitations. EPA cannot provide the permit shield suggested by the commenter, because EPA has found through enforcement actions that certain state permits do not contain the provisions necessary under EPA guidance to constitute a legally and practicably enforceable limitation. We also point out that the provisions finalized in this action are applicable to new, modified, and reconstructed sources under the NSPS OOOOb generation of sources, and existing source designated facilities under OOOOc EG, and are not retroactively applicable to OOOO or OOOOa sources. The EPA enforcement cases to date have relied on EPA guidance and the provisions of OOOO and OOOOa and will continue to do so. On the issue of requesting a federal permit, this would only be possible for a source located on federal land where the Administrator is the permitting authority, or where a state or local permitting authority does not have delegated authority to issue permits. A list of states and other jurisdictions with delegated authority can be accessed under 40 CFR Part 70, Appendix A to Part 70—Approval Status of State and Local Operating Permits Programs.<sup>24</sup>

Comment: Commenter (2298-Pioneer) requests that EPA define “parametric limits” to mean the ongoing monitoring of production and operational limits.

Response II-13-27: See response I-9-14 and discussion in in section at Section X.J.1. of the preamble to the final rule which details EPA’s final standards for legally and practicably enforceable emissions limitations.

Comment: Commenter (2483-INGAA) states that the elements that a legally and practicably

---

<sup>24</sup> See <https://www.ecfr.gov/current/title-40/chapter-I/subchapter-C/part-70#Appendix-A-to-Part-70>.

enforceable limit must include under proposed 40 CFR 60.5365b(e)(2)(i)(A)-(F) are too prescriptive, and indeed wholly inappropriate. The commenter points out that states (and EPA) have been establishing federally and practically enforceable limits for decades under Title V, the NSR programs, and the hazardous air pollutants (HAP) provisions of the CAA. The commenter believes that there is no reason for EPA to require in this rulemaking a prescriptive approach such as that proposed here. In addition, the commenter states that the elements that EPA requires in the December 2022 Supplemental Proposal are wholly inappropriate – as they unduly restrict the discretion of permitting authorities and go well beyond what is typically needed for federally and practically enforceable limitations.

By way of example, the commenter (2483-INGAA) states that proposed 40 CFR 60.5365b(e)(2)(i)(A) requires a “quantitative production limit and quantitative operational limit(s) for the equipment, or quantitative operational limits for the equipment.” The commenter is concerned that if EPA intends this proposed provision to require a standalone production limit or operational limit, that is inconsistent with long-standing EPA policy. The commenter believes that production and/or operational factors can be used as part of a parametric calculation of emissions, but they need not be standalone.<sup>25</sup> Finally, the commenter takes issue with proposed 40 CFR 60.5365b(e)(2)(i)(C) which requires that “where a control device is used to achieve an operational limit, an initial compliance demonstration (*i.e.*, performance test) for the control device that establishes the parametric limits.” While the commenter agrees that the regulations should certainly allow the use of a compliance demonstration, presumably in the form of a test, there is no reason for EPA to preclude other means of estimating the control device efficiency, such as AP-42 factors or vendor-provided factors, especially when these factors are known to be conservative.

Response II-13-28: EPA disagrees with the characterization by the commenter that specifying what EPA requires for the next generation of sources to comply with OOOOb and OOOOc EG restricts the discretion of state permit authorities. The Administrator retains the authority to enforce the NSPS, and promulgate the requirements to which sources must adhere to be in compliance. A source is not required to avail themselves of a legally and practicably enforceable limitation, but in the event that they do, such limitations must meet the criteria in OOOOb, and designated sources will be required to meet OOOOc EG. States are not required to issue legally and practicably enforceable emissions limitations, but in the event that they do, it is in the interest of the permittee, the permit authority, and EPA that EPA specify upon promulgation the metrics and standards that EPA will require of sources to show ongoing compliance.

The commenter expressed concern that the legally and practicably enforceable limit criteria somehow required a “standalone” production limit or operational limit. EPA replies that the production and operational limits may rely on several factors including parametric measurements that show compliance.

---

<sup>25</sup> See, e.g., In re. Salt River Project Agua Fria Generating Station], Petition No. IX-2022-4, at 12-13 (Adm’r July 28, 2022), available at [https://www.epa.gov/system/files/documents/2022-08/SRP%20Agua%20Fria%20Order\\_7-28-22.pdf](https://www.epa.gov/system/files/documents/2022-08/SRP%20Agua%20Fria%20Order_7-28-22.pdf),

(“EPA does not interpret the federal regulations to require production and/or operating limits in all situations.”).

The EPA disagrees that using only emission factors for control devices as a demonstration of compliance with a legally and practicably enforceable limitation is sufficient to show compliance for a controlled source in the oil and gas category. See discussion in section at Section X.J.1. of the preamble to the final rule which details EPA's final standards for legally and practicably enforceable emissions limitations.

Comment: Commenter (2483-INGAA) states that proposed 40 CFR 60.5365b(e)(2)(i)(B) requires an averaging period of less than 30 days when a production-based limit is used, but the commenter believes that is arbitrary and capricious, as well as inconsistent with EPA policy, where the overall standard that the limit is intended to enforce is a tons per year (*i.e.*, annual) standard. In such a case, as here, a 12-month rolling limit, as long as it is well defined in how it is calculated, is more than adequate, according to the commenter<sup>26</sup>.

Response II-13-29: See discussion in section at Section X.J.1. of the preamble to the final rule which details EPA's final standards for legally and practicably enforceable emissions limitations.

Comment: Commenter (2292-West Virginia Office of the Attorney General *et al.*) believes that EPA's proposed definition of "legally and practically enforceable" in the specific context of storage vessels, which would push aside state regulation of emissions from this sector. The commenter believes that this shows that EPA will disregard the state limits and treat the storage vessels as uncontrolled, and rather than respect state rules limiting emissions, EPA starts from a place of skepticism, effectively assuming it can supplant any state regulation that EPA considers inadequate based solely on its own disagreement. The commenter is concerned that this presumption of federal control destroys the cooperative federalism that the CAA prescribes. The commenter is concerned that EPA is ignoring the State's expertise, even though States have extensive and useful experience regulating emissions for decades.

Response II-13-30: See discussion in section at Section X.J.1. of the preamble to the final rule which details EPA's final standards for legally and practicably enforceable emissions limitations.

Comment: Commenter (2428-API) believes that the proposed legally and practicably enforceable criteria and the additional methane emissions threshold may be impossible to obtain under existing permitting mechanisms. The commenter states that EPA should continue to defer to the states on sufficient monitoring, recordkeeping, and reporting requirements to include in permits to establish legally and practicably enforceable limits. The commenter is concerned that EPA's proposed criteria for legally and practicably enforceable limits have legal implications beyond this rulemaking and pose permitting challenges.

The commenter (2428-API) believes that the proposed revisions are inconsistent with EPA's reliance on states to administer the CAA with regard to Title V and PSD. That is, the commenter states, EPA allows states to establish emission limits on sites that keep sites below Title V and

---

<sup>26</sup> [See, e.g.,] Memorandum from John S. Seitz, Director, EPA Office of Air Quality Planning and Standards, to EPA Regional Air Division Directors, [Options for Limiting the PTE of a Stationary Source Under Section 112 and Title V of the Clean Air Act], at 6 (Jan. 25, 1995), available at <https://www.epa.gov/sites/default/files/documents/limit-pt-rpt.pdf> (explaining that "annual limits such as rolling annual limits" are appropriate to practically enforce an annual emission limitation).

PSD permitting thresholds. The commenter believes that EPA should continue to defer to states to determine the appropriate level of monitoring, recordkeeping, and reporting requirements to include in permits rather than imposing a list of strict criteria, which according to the commenter, has long been an effective approach to reduce recordkeeping burden while reducing potential emissions. The commenter states that the proposed criteria for legally and practicably enforceable limits provide no additional benefit and pose several permitting challenges. The commenter is concerned that existing permits and associated state programs and rules likely do not meet all the required criteria since EPA has historically deferred to the states on the sufficient monitoring, recordkeeping, and reporting requirements to include in the various levels of permits. By way of example, the commenter states that permits have proposed annual or rolling 12-month limits on emissions and production since the tank PTE thresholds and NSR permitting thresholds are based on annual emissions. The commenter believes that EPA should clarify that such annual limits meet the proposed 30-day averaging time for production limits especially since facilities are typically permitted for a worst-case scenario. Another criterion likely not in existing permits is “*periodic reporting that demonstrates continuous compliance*,” according to the commenter. Historically, the commenter points out, periodic reporting has applied to major sources under Title V and affected facilities regulated under a NSPS or National NESHAP, which the commenter states is a small fraction of the sites that will be regulated under NSPS OOOOb and EG OOOOc. Monitoring, recordkeeping, and reporting requirements in a permit should be tailored to align with the level of authorization with minor sources having less requirements than major sources, according to the commenter. The commenter recommends that for streamlined permitting mechanisms, such as Permits by Rule in Texas, the state agency would have to engage in rulemaking before operators could rely on such permits for determining storage vessel and tank battery PTE. Such rulemaking could take months to years, meaning that operators cannot rely on legally and practicably enforceable limits until those rule updates are finalized and effective, according to the commenter.

The commenter (2428-API) does believe that improving the clarity of the storage vessel applicability criteria is a worthwhile effort and offers the following redline for 40 CFR 60.5365b(e)(2)(i) (suggested deletions are shown in strike-through):

For purposes of determining the applicability of a storage vessel tank battery as an affected facility, a legally and practicably enforceable limit ~~must~~ may include the elements such as those provided in paragraphs (e)(2)(i)(A) through (F) of this section.

Response II-13-31: No owner or operator is required under this provision to obtain any permit meeting the legally and practicably enforceable criteria. The owner or operator could instead comply with storage vessel requirements under OOOOb. See also the discussion in section at Section X.J.1. of the preamble to the final rule which details EPA’s final standards for legally and practicably enforceable emissions limitations.

Comment: Commenter (2227-WEA) believes that the proposed provisions for legally and practicably enforceable would render many state permits ineligible for determining storage tank applicability. The commenter urges EPA not to codify the requirements for meeting the definition of legally and practicably enforceability, and instead continue to defer to states for regulations and permitting. Further, the commenter states that the new methane applicability

threshold creates an issue with state permits as it is a new criterion for which state permits would not have a direct limitation. The commenter states that the administrative process to modify these permits to address these new criteria is a very significant and unnecessary burden on owners, operators and permitting authorities without emissions reduction benefit. The commenter states that assuming the typical pace to process permits and depending on the number of permits that need to be modified, the process to modify permits can take upwards of ten years. Because of these concerns, the commenter believes that EPA should continue to defer to states for establishing appropriate monitoring, recordkeeping, and reporting.

Response II-13-32: See discussion in section at Section X.J.1. of the preamble to the final rule which details EPA's final standards for legally and practicably enforceable emissions limitations.

Comment: Commenter (2202-TXOGA) urges the Agency to establish common sense transition rules for any new requirements legally and practically enforceability. The commenter believes that EPA has the ability to place these transition provisions directly into the regulations to provide regulatory certainty to companies and to avoid drastically overburdening state agencies, which are already behind in processing Title V renewals. In particular, the commenter states, EPA should provide that 6 tpy VOC permit limits will be deemed to satisfy any new legal and practical enforceability requirements. The commenter states that EPA should provide the revisions be conducted either during the next Title V renewal for the source (provided such renewal is at least one year after rule issuance) or at the next significant permit modification under Title V. For non-Title V sources, the commenter recommends that the transition rules should provide a five-year period to allow sources to obtain necessary permits, recognizing that overburdened states will typically allocate resources to major sources first.

Response II-13-33: See discussion in section at Section X.J.1. of the preamble to the final rule which details EPA's final standards for legally and practicably enforceable emissions limitations.

### ***13.2.7 Potential to Emit***

Comment: Commenter (2254-PBPA) states that the proposal to use uncontrolled PTE would conflict with both existing state permitting programs and conflict with other CAA programs that allow for and account for "legally and practicably enforceable" limits. The commenter states that not allowing the use of controls in the PTE evaluation for storage tanks and tank batteries results in practically every storage tank becoming an affected facility under the proposed NSPS. Further, the commenter states it is their understanding that under the proposed rule, emissions events and upset conditions are considered as part of the PTE calculations. According to the commenter, emissions events and upset conditions are unauthorized emissions under TCEQ rules, thus, including emissions events or other upset events in the methane PTE representations assumes noncompliance. The commenter suggests that instead of assuming such noncompliance, these types of events should be addressed through enforcement procedures, not NSPS. Similarly, the commenter believes that instances when the vessels are not operating as designed should not be included in an NSR authorization. Consistency between PTE evaluation for the NSR program and this NSPS is critical, according to the commenter. The commenter states that if EPA does not intend to include emission events and upset conditions in calculating PTE, it should make that clear in its PTE calculation methodology.

Response II-13-34: EPA believes the commenter is conflating the November 2021 proposal for fugitives monitoring frequency based on total site-level baseline methane emissions, with the requirement to determine the potential for VOC and methane emissions for storage vessel applicability. In the November 2021 proposal, EPA requested comment on whether, for purposes of determining which proposed monitoring frequency would apply, sites should use the uncontrolled PTE calculation for their storage vessels in their site-level baseline estimate to account for times when these vessels are not operating as designed. See 86 FR 63171. However, as explained in the December 2022 supplemental proposal [and is reference to RTC chapter on fugitives needed?] EPA did not propose to establish fugitive emissions monitoring frequency on total site-level baseline emissions, so the comment is moot. See 87 FR 74722.

When determining storage vessel applicability, the final rule continues to allow legally and practicably enforceable limits to be included in the determination of whether a storage vessel is an affected facility. Further, upset conditions and their resulting emissions are not included in the determination. Under 40 CFR 60.5365b(e)(2)(ii), the provisions do not require that upset conditions be included in the maximum average daily throughput, which forms the basis for determining the potential for VOC and methane emissions from storage vessels.

The commenter expressed that the criteria for legally and practicably enforceable emissions limitations in the NSPS raises their concerns about how this new interpretation/approach would apply in the Title V and New Source Review (“NSR”)/Prevention of Significant Deterioration (“PSD”) context where operators are relying on the same control requirements to limit their PTE. EPA points out that promulgation of standards under a specific rule are not applicable to other categories. EPA is promulgating these criteria to address a specific type of source within this category that EPA intends to address proactively by applying the criteria going forward. Any change to the criteria for legally and practicably enforceable emissions limitations proposed under Title V, NSR, or any other rule would be subject to notice and comment rulemaking where the commenter would have the opportunity to comment.

Comment: Commenter (2353-CrownQuest Operating, LLC (CrownQuest)) has concerns with the tank battery applicability when determining the potential for emissions. The commenter is concerned that EPA is stretching past the limit of what an atmospheric tank is used for and treating it like a pressured vessel. Regarding the potential for emissions, the commenter points out that NSPS OOOOa, which has been in place for 12 years, determined each tank should be 6 tpy. The commenter states that proposed rule has not identified any instances of how the existing per-tank interpretation has affected emission reductions, but instead made a new BSER for what the EPA prefers to say. The commenter is concerned that this change will only make the industry adjust how they have been calculating the PTE for the past several years, and it is unlikely that there will be any significant number of instances where this change would affect anything other than to increase costs on the industry and require more work for the EPA. All facilities, according to the commenter, including the combination of tanks, must be below 25 tpy, hence if a facility has five tanks, it would already have to limit the emission as the combination of tanks at 6 tpy per tank would be above the statutory limit. The commenter states that other emissions calculations, such as fugitive, must be factored in that limit that number even further. Therefore, according to the commenter, the industry’s common practice of putting controls in place on all

tanks is necessary as there is not an easy or cost-effective way to isolate the tanks to put controls on some and not on others.

Response II-13-35: The commenter may be considering that a formerly uncontrolled atmospheric storage vessel that is connected by a liquid line will now be considered part of a battery subject to a 6 tpy VOC limit for the entire battery, and therefore have to be modified or replaced to be controlled. In such a scenario, the facility would not be subject to OOOOb, unless modified or reconstructed. The facility may be a designated facility by OOOOc EG, and may in fact become an affected facility if it was not already. Under our BSER analysis the EPA asserts that control of such vessels will reduce emissions and that the reduction is cost-effective. This is why EPA disagrees with the premise of the comment that regulating tanks on a per-tank basis is as effective as regulating tanks on a battery-basis given the many tank configurations that exist. In discussion with industry across multiple rulemakings to modify OOOO and OOOOa, and through EPA's own field work, EPA learned that the critical factor for determining whether a series or group of tanks was operated as a single system was whether they were linked by liquid line. While many tank batteries may be manifolded together by vapor lines and headspace, both that requirement and the requirement the tanks in the tank battery be adjacent has been discarded for OOOOb and OOOOc EG. The EPA further disagrees that requiring that a tank battery be subject to control at 6 tpy VOC and 20 TPY methane, regardless of the number of tanks, is less protective of the environment because each tank in the tank battery must achieve the emissions reduction. Lastly, the EPA points out that a tank battery subject to control must control all of the tanks in the battery and there will not a scenario where some tanks are controlled and others are not. Other commenters have specifically asked for the flexibility to use multiple closed vent systems and controls within a single tank battery, in contrast to this comment. The EPA agreed with the other commenter in that a situation could arise that multiple control devices used for a single battery could be an effective control strategy under the standard, as long as each tank in the tank battery is equipped with a cover, closed vent system and routed to a control device which achieves a 95% reduction in emissions.

Comment: Commenter (2483-INGAA) recommends flexibility for owners/operators to document their potential for emissions, especially if EPA retains methane as an applicability basis. The commenter request that reasonable assumptions for transmission and storage compressor station operations (e.g., frequency of tank turnover) be deemed sufficient to demonstrate that emissions are less than 20 tpy, because permit programs may not always provide an avenue for documenting methane emissions PTE in a permit limit. The commenter believes that when adding a methane emissions threshold to NSPS OOOOb and EG OOOOc, EPA did not consider whether current permitting programs include methane emissions and/or whether tank emissions would be below permitting *de minimis* thresholds. The commenter explains that some states, such as West Virginia and North Dakota, do not include tanks with low emissions in their permits. The commenter states that as proposed, owners/operators may not have a pathway to document that a storage vessel or tank battery is exempt, so it is imperative that EPA address this issue. The commenter is concerned that while EPA may determine that state program updates are warranted, that could take time to implement, and EPA should not ignore the current status. Thus, owner/operator records documenting PTE emissions less than the applicability threshold, where the emissions calculations are based on operations characteristics of transmission and storage compressor stations, should suffice (with recordkeeping), and a legal, federally

enforceable permit condition should not be required, according to the commenter. Further, the commenter states that the determination that applicability thresholds are not exceeded should be on a 12-month rolling basis.

The commenter (2483-INGAA) cautions that is a reasonable pathway to document emissions less than the threshold is not provided, operators must undertake onerous and costly actions to otherwise prove status. For example, the commenter states that 40 CFR 60.5396c(a)(3) allows an operator to comply with a 14 tpy uncontrolled methane emissions rate, but only after demonstrating a 95 percent methane emission reduction for twelve months. Thus, the commenter states, if reasonable and documented emission estimates (in lieu of a federally enforceable permit limit) are not allowed to confirm emissions less than the threshold, a transmission and storage tank with emissions well less than 14 tpy would first have to install and demonstrate 95 percent control for a year before being allowed to comply with the “uncontrolled” emission limit. The commenter believes that EPA developed these provisions with higher emitting upstream operations in mind (*i.e.*, high flashing losses and much more frequent tank turnover) and did not consider the implications for tanks at transmission and storage compressor stations.

Commenter (2483-INGAA) also believes the language at 40 CFR 60.5386c(e)(2), “[t]he determination *may* take into account requirements under a legally and practicably enforceable limit in an operating permit or other requirement established under a Federal, state, local, or tribal authority” (emphasis added) allows that a legally and practicably enforceable limit is needed only when the owner relies on an operating limit or other requirement to establish the PTE; conversely, if a straightforward calculation demonstrates methane emissions are less than 20 tpy based on operations associated with the transmission and storage compressor station, the tank is exempt without the need for a permit limitation. Further, the commenter believes the two methodologies in subparagraphs (A) and (B) of 40 CFR 60.5386c(e)(2)(iii) are clear that subsection (A) requires a permit limitation, while subsection (B) does not. Because the legally enforceable limit required in subparagraph (A) can be problematic for transmission and storage operators (because permits are not accessible for a low emitting tank), operator documentation of the associated emission calculation assumption can provide assurance that the exclusion is appropriate. The commenter requests that EPA confirm the intent of this provision. With respect to legally and practicably enforceable limits, the commenter recommends that EPA revise the elements to make them consistent with current, long-standing policy - for example allowing but not requiring standalone production and operational limitations and acknowledging that a rolling 12-month limitation is more than adequate to ensure conformance with an annual applicability threshold.

Response II-13-36: To address the commenters’ concern that certain states do not have permit programs that allow operators to avail themselves of a limitation under the NSPS, EPA included the provisions for legally and practicably emission limitations in the promulgation of OOOO and OOOOa, and did not condition the use of this mechanism to state permitting programs. Rather states were able to use permits by rule or general permits to issue such limitations, so long as they met the prior guidance. EPA’s promulgation of new criteria under OOOOb and OOOOc EG did not change in this respect for sources subject to NSPS OOOO and OOOOa and EPA is not making any determination that states must update their programs, beyond the necessity to respond to our proposal of OOOOc EG.

EPA notes that the long-standing premise of storage vessel applicability is based the potential for VOC, which may take into account legally and practicably enforceable limits. In this rulemaking, EPA is not departing from that premise (except to include methane), but is establishing specific criteria which are considered legally and practicably enforceable. As discussed elsewhere (see I-9-22), EPA is choosing to add regulatory certainty to describe legally and practicably enforceable emissions limitations now, because of the issues discussed in the November 2021 proposal, namely that when reviewing the limits considered by these facilities as legally and practicably enforceable, EPA believes the limits do not require a reduction in emissions as they are often of such a general nature as to be unenforceable or otherwise lack measures to assure the required emission reduction. See also examples of such limits in Section I-9-15. If the EPA were to choose to issue another round of guidance, states and sources would not have the same level of certainty as to what EPA considers legally and practicably enforceable for the next generation of sources. This level of specificity and certainty will serve to guide states as they consider how to apply these criteria through state requirements promulgated under OOOOc EG and through permits issued for OOOOb sources. A calculation demonstration alone is not legally and practicably enforceable under these criteria.

Regarding the language at section 60.5465b(e)(2), the commenter is correct that the application of legally and practicably enforceable requirements is an option available to owners and operators when determining the potential for VOC and methane emissions. As the commenter notes, subparagraph (A) of section 60.5365b(e)(2)(ii) specifies that throughput must be established as a legally and practicably enforceable limit. Subparagraph (B) of section 60.5365b(e)(2)(ii) does not require a legally and practicably enforceable limit, because the potential for emissions is determined using the maximum design capacity of the facility, which by definition is not limited. The provisions of section 60.5365b(e)(2)(ii) are the same as the provisions in 60.5365a(e)(2)(ii), which were added in September 2020<sup>27</sup> to address comments from midstream operators that the “first 30-days” of production was not meaningful in many cases for storage vessels downstream of well sites. The commenters stated that:

Compressor stations (including gathering and boosting compressor stations) and onshore natural gas processing plants typically utilize process simulations based on representative or actual liquid analysis to determine potential VOC emissions and volumetric condensate rates from the storage vessels based on the maximum gas throughput capacity of each facility. These generally accepted engineering models and calculation methodologies are then utilized to obtain Federal, state, local, or tribal authority issued permits to set legally and practicably enforceable limits to maintain potential VOC emissions from storage vessels at less than 6 tpy. 85 FR 57427.

EPA agreed and stated:

Based on the above reasons, the EPA is amending the 2016 NSPS subpart OOOOa to specifically provide the following two options for determining the potential for VOC emissions from storage vessels at facilities downstream of well sites. The first option, which is already allowed in the 2016 NSPS subpart OOOOa, allows owners or operators to take into account throughput and/or emission limits incorporated as legally and practicably enforceable limits in a

---

<sup>27</sup> See 85 FR 57427.

permit or other requirement established under a Federal, state, local, or tribal authority. The second option allows the use of generally accepted engineering models (*e.g.*, volumetric condensate rates from the storage vessels based on the maximum gas throughput capacity of each producing facility) to project the maximum throughput used to calculate the potential for VOC emissions. 85 FR 57427.

Because the commenter to this rulemaking asks the question regarding the difference between subparagraph (A) and subparagraph (B) of 60.5365b(e)(2)(ii) regarding the need for a legally and practicably enforceable limit, EPA is adding the term “design” to subparagraph (B) to make clear the calculation is based on the unlimited design capacity of the site. Subparagraph (B) is finalized as follows (additions underlined):

(B) Determine the potential for VOC and methane emissions using a generally accepted model or calculation methodology that accounts for flashing, working and breathing losses and based on projected maximum average daily throughput. Maximum average daily throughput is determined using a generally accepted engineering model (*e.g.*, volumetric condensate rates from the tank battery based on the maximum design gas throughput capacity of each producing facility) to project the maximum average daily throughput for the tank battery based on design conditions.

Finally, EPA agrees that a 12-month rolling average is an acceptable averaging period to determine compliance with a 30 -day limit where the rolling 12-month average is supported by 30-day subtotals, beginning in the first 30-days and redetermined every month.

Comment: Commenter (2483-INGAA) states that the proposed requirements for establishing the PTE of storage vessels, which heavily emphasize that any limitations must be made legally and practicably enforceable in a state-issued permit, ignore the practical reality that many state agencies do not process permits for low emitting tanks in transmission and storage service because the actual emissions of these tanks are far below the states’ permitting thresholds. The commenter states that these provisions are unworkable and urges EPA instead to adopt provisions exempting storage vessel affected facilities for which the owner documents that emissions from the affected facility will not exceed the applicability thresholds under any expected operations of the facility, and in fact do not exceed the thresholds on a 12-month rolling basis.

Response II-13-37: EPA disagrees that provisions of legally and practicably enforceable are unworkable, because they are based on prior guidance that has been applied in OOOO and OOOOa dating back to 2012. EPA also points out that obtaining a site-specific permit is not the only way to approach such a limit. States have used permits by rule or general permits to regulate storage vessels with low levels of emissions, and these types of permits may apply automatically to specified sources without further processing by States. Subparts OOOOb and OOOOc that the EPA finalized today do not necessarily require a site-specific permit. Other mechanisms may be used, as long as the LPE definition is met.

### ***13.2.8 Determination of Potential Emissions***

Comment: Commenter (2172-Kentucky Oil and Gas Association (KYOGA)) states that accurately determining emissions from a tank or tank battery that is used to store crude oil produced from a single source, well or lease, is very difficult and potentially very expensive for a small operator. The commenter believes it may be EPA's intention to force operators to engage engineering firms to plan tank and tank battery construction and operation, to capture a few new previously uncontrolled vessels. The commenter states that sampling an uncontrolled storage tank is very difficult, both technically and physically. For older tanks, potentially subject to EG OOOOc, the commenter states that they have estimated that there are over 12,000 active tank batteries in Kentucky, the vast majority operated by small operators. The commenter points out that many small operators rely on the "TANKS" software to simply, quickly, and inexpensively generate expected VOC working and breathing emissions. The commenter states that while the emission estimates that the Tanks program generates may not be 100 percent accurate, it is consistent with historic practices. However, according to the commenter, EPA's inclusion of flashing emissions and methane eliminates an operator's ability to use the TANKS program and changes will be required to TANKS to address methane emissions, as the current version only accounts for VOC emissions. The commenter points to an EPA statement in the proposed rule, that EPA is including "regulatory text which instructs the owner or operator on how to determine the potential for VOC or methane emissions as the cumulative emissions from all storage vessels within the tank battery according to certain timelines." The commenter interprets this as if there is a published guide to calculating tank emissions based on EPA's proposed new emission standards. However, the commenter states they have been unable to find it and provide comments to EPA. The commenter recommends that EPA update the TANKS software so that small operators can estimate emissions in a low-cost way.

Response II-13-38: Because flashing emissions are often the largest contributor to storage vessel emissions in the production sector, a generally accepted model or calculation methodology must account for flashing, as well as working and breathing losses. Because the basic "TANKS" software does not calculate emissions from flashing, it should not be used to assess the potential to emit from the storage of fluids that were previously stored under pressure, including oil and condensate from producing wells. It is not the EPA's intention to force operators to engage engineering firms to plan tank and tank battery construction and operation, but it is necessary for operators to accurately assess the potential emissions from the well's tank battery. There are a number of software systems that account for flash emissions from the tank battery, including WinSim, Designer II, HYSIM, HYSIS, VMG, PROMAX, and E&P Tanks (API Publication 4697). While the EPA is currently working to update the TANKS software model based on the equations in Chapter 7 of AP-42, Section 7.1.3.5 of AP-42 specifically notes that "The equations in Section 7.1.3.1 for estimating routine emissions from fixed roof tanks do not address the scenario of a tank storing a liquid which contains gases that have the potential to flash out of solution... There are numerous methodologies available for estimating flashing losses and specific guidance regarding their application and use. However, discussion of such methodologies is beyond the scope of this section." Consequently, even when updated, the TANKS software model will not be capable of estimating flashing losses.

Comment: Commenter (2399-GPA) states that the applicability determination methodology for compressor stations and natural gas processing plants should be revised, given the new interpretation of “legally and practicably enforceable limits,” and the lack of certainty regarding the enforcement of state-issued permits that renders the prior NSPS OOOOa and proposed NSPS OOOOb text and approach no longer appropriate. The commenter understands that under the proposal, emission calculations for these sources would be based upon the projected maximum daily average vessel throughput derived from the maximum gas throughput capacity of each facility. In most cases, the commenter states, this would significantly overstate actual tank battery emissions and the effect would be to premise applicability determinations on the site’s design capacity, not actual emissions or even engineering estimates of throughput used for NSR permit authorizations of the site (*i.e.*, a methodology based upon the maximum gas throughput capacity is used to calculate PTE thresholds for NSR permits). However, the commenter cautions, condensate production is not easily estimated as it is a combination of liquid that drops out of field gas during compression and condensate that drops out of the gas along the pipeline to the station or plant and is dependent on several factors, including weather conditions that change throughout the year. The commenter states that EPA’s methodology will ensure that many storage tank batteries would be deemed subject to NSPS OOOOb, even though they would be exempt based upon actual throughput data. As such, the commenter urges EPA to allow for qualified engineering estimates, instead of design capacity. For new compressor station sites, the commenter explains that permit calculations are generally submitted prior to construction, based upon engineering estimates of liquid throughput based on expected gas design capacity. The commenter states that this is not the same as storage vessel design capacity, which may be much higher. For existing sites that are modified, the commenter explains that existing throughput data is used in combination with engineering estimates of any expected throughput increase. The commenter cautions that in neither case would the maximum design capacity be used to estimate VOC or methane emissions from the storage tank battery. Instead, the commenter states, engineering estimates based upon expected throughput are much more accurate than assumptions of maximum throughput capacity for the site. Additionally, in permitting hourly and annual emission limits, frequently the maximum hourly emission limit does not match the annual limit due to issues with variability in storage vessel throughput across an entire year, according to the commenter. The commenter explains that owners or operators must obtain a permit for any new tank battery, the reconstruction of a tank battery, or the modification of a tank battery (where a tank is added, total capacity will increase, or the actual throughput will exceed the current permit or most recent NSPS OOOOb determination). In each instance, according to the commenter, owners or operators must submit an emissions estimate prior to startup. The commenter suggests that engineering estimates, signed by a qualified individual or professional engineer involved with the project, should be used in lieu of maximum design capacity. The commenter states that they understand that these estimates infrequently may underestimate the actual throughput once the site comes online, but to account for this, the commenter suggests that the throughput estimates be compared to actual operating data within 30 days of startup to ensure accuracy. The commenter believes this approach is consistent with current requirements under NSPS OOOOa and the definition of “maximum daily throughput.”

Response II-13-39: As discussed in Response II-13-36, EPA provided two options to determine the potential for emissions from storage vessels at facilities downstream of well sites in September 2020. In short, the provisions allowed for a legally and practicably enforceable limit

on throughput, or an engineering determination of maximum average daily throughput based on maximum design capacity (typically gas throughput) of the site. These provisions were added in response to comment from midstream operators that the first 30-days of production might not be accurate for certain scenarios. EPA proposed these same options in December 2022 in OOOOb and OOOOc.

EPA understands from the comment, that because of the legally and practicably enforceable criteria which EPA proposed and is finalizing, the limits which midstream operators have relied on to limit the emissions through a permit may not be “legally and practicably” enforceable under the finalized criteria, leaving only the option to determine maximum average daily throughput based on design capacity. According to the commenter, this would significantly overstate actual tank battery emissions and the effect would be to premise applicability determinations on the site’s design capacity, not actual emissions or even engineering estimates of throughput, which are used for NSR permit authorizations of the site. The commenter asserts that actual emissions would better estimate emissions to determine whether the tank is greater than 6 tpy VOC or 20 tpy methane and is asking that EPA provide a third means to determine applicability for tanks applicable to these instances. Their comment suggests that engineering estimates, signed by a qualified individual, should be used in lieu of maximum design capacity. The commenter further states that they understand that these estimates may underestimate the actual throughput once the site comes online, but to account for this, the commenter then suggests that the throughput estimates be compared to actual operating data within 30 days of startup to ensure accuracy.

First, EPA notes that the final legally and practicably enforceable criteria applies to storage vessel affected facilities subject to NSPS OOOOb and the presumptive standards for storage vessel affected facilities under the EG and does not apply retroactively to sources subject to NSPS OOOO or OOOOa. Regarding an alternative to the proposed criteria, the EPA disagrees that a determination based on “qualified” engineering estimates and/or actual throughput is a workable approach, absent memorializing such a determination in a permit, which under the final rule, must meet the legally and practicably enforceable criteria. Any “qualified” or actual limit which is less than design capacity would have to be verified against the engineering estimate, or actual production would have to be measured (among other criteria as specified by the final legally and practicably enforceable limits) to assure ongoing compliance. We do not think that the commenter envisioned a system that required on-going verification, because the commenter suggested only one verification 30 days after startup and expressed concerns with acquiring permits with the legally and practicably enforceable criteria. Further, the commenter explained that condensate production is not easily estimated as it is a combination of liquid that drops out of field gas during compression and condensate that drops out of the gas along the pipeline to the station or plant and is dependent on several factors, including weather conditions that change throughout the year. For the EPA, this calls into the question the representativeness of one month of condensate production to verify applicability. The final rule does allow for an actual uncontrolled mass emissions limit of 4/14 tpy, after one year of compliance with the 95% reduction and records demonstrating that emissions have remained below those limits for 12 consecutive months.

Comment: Commenter (2428-API) believes that in terms of the PTE calculations, centralized

production facilities should be considered like compressor stations and natural gas process plants because the storage capacity is typically based on “a projected maximum average daily throughput.” Therefore, the commenter offers the suggested redlines for 40 CFR 60.5365b(e)(2)(ii) and 60.5365b(e)(2)(iii) (suggested additions are underlined; suggested deletions are shown in strike-through):

(ii) For each tank battery located at a well site ~~or centralized production facility~~, you must determine the potential for VOC and methane emissions within 30 days after startup of production, or within 30 days after an action specified in paragraphs (e)(3)(i) and (ii) of this section, except as provided in paragraph (e)(5)(iv) of this section. The potential for VOC and methane emissions must be calculated using a generally accepted model or calculation methodology that accounts for flashing, working and breathing losses, based on the maximum average daily throughput to the tank battery determined for a 30-day period of production.

(iii) For each tank battery located at a centralized production facility, compressor station or onshore natural gas processing plant, you must determine the potential for VOC and methane emissions prior to startup of the compressor station or onshore natural gas processing plant or within 30 days after an action specified in paragraphs (e)(3)(i) and (ii) of this section, using either method described in paragraph (e)(2)(iii)(A) or (B) of this section.

As an alternative, the commenter suggests another solution is to harmonize the PTE calculation requirements for all sites based on the requirements proposed for compressor stations and gas plants.

Response II-13-40: EPA disagrees that centralized production facilities are more akin to compressor stations and gas plants than well sites. As discussed at 86 FR 63184, EPA understands that the activities at centralized production sites are the same types of operations as would be conducted at the individual well sites. The commenter did not provide sufficient information to understand why this premise is not correct. Therefore, the EPA is not making the changes suggested by the commenter.

Comment: Commenter (2177-Ute Indian Tribe) suggests the following change to OOOOc: “The potential for methane emissions must be calculated using a generally accepted model or calculation methodology that accounts for flashing, working, and breathing losses, based on the projected maximum average daily throughput to the tank battery determined for a 30-day period of production.””(suggested additions are underlined; suggested deletions are shown in strike-through).

Response II-13-41: In reconsideration of the 2011 rule for NSPS OOOO<sup>28</sup> EPA determined that 30 days was the appropriate timeframe for determining the potential for emissions from a storage vessel affected facility. In further amendments to NSPS OOOO<sup>29</sup> the EPA explained that because “we believe it is important to achieve control of storage vessel affected facilities as soon

---

<sup>28</sup> See 78 FR 58416.

<sup>29</sup> See 79 FR 79018.

as practicable, we believe it is important to begin the 30-day period for estimating storage vessel VOC PTE as soon as this estimation can be achieved and will provide a representative estimate of the storage vessel's PTE during production.”<sup>30</sup> In September 2020<sup>31</sup>, the EPA finalized an alternative determination process for storage vessels not located at well sites, because the first 30-days of production at these types of sites (e.g., natural gas processing plants and compressor stations) may not be representative of the maximum throughput for which they are designed.

We do not believe that existing tank batteries at well sites will not be able to determine the maximum average daily throughput during a 30-day production period after the effective date of an approved state or tribal plan. These sites have been producing for some period of time, and the 30-day production period should be representative of the potential for methane emissions. The commenter did not explain why “projected” maximum average daily throughput would provide a more accurate representation of the potential for methane emissions than a determination based on a 30-day period of production, therefore, the EPA is not making this change.

### ***13.2.9 Modification of Storage Vessel Affected Facility***

Comment: Commenter (2218-Texas Commission on Environmental Quality and Railroad Commission to Texas) states that the modification definitions between NSPS OOOOa and NSPS OOOOb are different and that for a well site applicable to NSPS OOOOa, any changes to the well that increase throughput will have to be evaluated differently under both rules. The commenter provides by way of example that NSPS OOOOb proposes that a storage vessel modification can be triggered if there is a throughput increase and if the resulting VOC or methane emissions are greater than the specified thresholds, but under NSPS OOOOa, the modification definition is tied to a new well, or changes to an existing well. The commenter is concerned that the differences in applicability criteria may cause confusion with both regulators and regulated entities, which again will lead to longer review times for permit applications and compliance evaluations.

Response II-13-42: EPA does not agree that the differences in modification provisions between OOOOa and OOOOb sources are significant. Upon promulgation of OOOOb the modification provisions of OOOOa are moot. Other changes to the storage vessel provisions are intended in part to simplify applicability for tanks in general, whether they are part of a battery of multiple tanks or a single tank. With respect to tank modification as a function of a well modification, the EPA has opted to change tank modification to better address the concern of midstream tank operators that receive product from assets they have little control over or even knowledge of daily activity that could affected their facility status. See response II-13-47 for additional discussion.

Comment: Commenters (2172-KYOGA; 2298-Pioneer; 2248-NDPC) are concerned about the modification provisions related to replacement of a storage tank. Commenter (2248-NDPC) also is concerned about the modification provisions related to relocation of a storage vessel. Commenter (2172-KYOGA) states that an operator of an unregulated tank or tank in a battery

---

<sup>30</sup> See 79 FR 79026.

<sup>31</sup> See 85 FR 57405.

that reaches the end of its safe operational life and must be replaced should not be required to have to prove the tank or tank battery should still be unregulated. The commenter explains that many oil and gas wells typical of legacy production are limited only in their productive life by the life of the tubulars in them (as exhibited by the many 100+ year old wells still producing in the Appalachian Basin of east Kentucky). The commenter believes that operators should be permitted to replace equipment in kind (e.g., akin to a “standard set” for the Refining industry) and should not be burdened with potentially expensive compliance activities for replacing equipment that has reached the end of its useful life. The commenter believes that if EPA finalizes the modification provisions as proposed, many operators will not replace equipment and it will result in more emissions from equipment not being replaced to avoid EPA’s compliance requirements.

Commenter (2298-Pioneer) recommends that replacement of a tank that only increases battery capacity should not trigger a modification because an increase in tank capacity does NOT equal an increase in emissions and, therefore, should not be considered a modification under any rule.

Commenter (2248-NDPC) states that certain activities which EPA is proposing which potentially trigger a modification include activities that are not a “physical change in, or change in the method of operation of, a stationary source” as required by CAA section 111(a)(3). By way of example, the commenter points out that the definition of modification in the proposed rule could include the relocation or replacement of a storage vessel. The commenter also states that EPA has not demonstrated the necessity of this change nor how its implementation will benefit the environment.

Response II-13-43: See discussion in section at section X.J.2. of the preamble to the final rule which details EPA’s final standards for modification.

Comment: Commenter (2326-AXPC) is concerned that EPA has departed from the definition of modification found at 40 CFR 60.14 and recommends that EPA limit modifications to where the operator increases emissions from the tank battery by increasing the capacity of the tank battery. The commenter explains that as proposed, subparagraphs (A) and (B) of 60 CFR 60.5365b(e)(3)(ii) would trigger a potential modification even where the increase in capacity of the tank battery is not accompanied by an increase in the tank battery’s emission rate. By contrast, the commenter says that their proposal would ensure consistency with 40 CFR 60.14 by requiring a capital expenditure on the potential affected facility accompanied by an increase in emissions. The commenter states that operators may readily track and document the addition or replacement of storage vessels within a tank battery. The commenter cautions that if EPA does not define modification to require an increase in the emissions rate of the tank battery, that perverse outcomes may occur. By way of example, the commenter explains that an operator may increase the size of tank battery without increasing the emissions from the tank battery, and if the emissions (which have not changed) exceed the applicability threshold, the tank battery would become an affected facility. The commenter explains that this possibility is real given that EPA now proposes to apply the 6 tpy VOC and 20 tpy methane applicability thresholds to the entire tank battery, where it previously under NSPS OOOO and NSPS OOOOa used the same VOC threshold but on an individual storage vessel basis, which effectively reduces the NSPS applicability threshold proportionally by the number of individual storage vessels in a tank

battery. Regarding subparagraphs (C) and (D) of 40 CFR 60.5365b(e)(3)(ii), the commenter states that the proposed criteria regarding increases in liquid throughput are too broad and are inconsistent with 40 CFR 60.14(e)(2) and should be removed. The commenter explains that per 40 CFR 60.14(e)(2), an increase in throughput for a storage vessel, accomplished without a capital expenditure on that storage vessel, is not considered a modification and EPA has not fully explained why it is proposing to deviate from the historical legal understanding of modification which requires both an increase in throughput and a capital expenditure on the storage vessel or tank battery. Also, the commenter states, increases in liquid throughput at well sites, central production facilities, and compressor stations are difficult to track as operators typically track liquid throughput using tank gauging rather than flow meters. Further, the commenter explains, the modification criteria for tank batteries at well sites and centralized production sites serves as a disincentive to the centralization of facilities, as the addition of production from a new well to an existing centralized production facility would trigger a modification under 40 CFR 60.5395b(e)(3)(ii)(C). If EPA does not remove the criteria at 40 CFR 60.5395b(e)(3)(ii)(C), the increase in liquid throughput also must be accompanied by a capital expenditure to the tank battery itself. The commenter explains that some actions, such as drilling a new well or fracturing or refracturing an existing well, could increase liquid throughput and require capital expenditure but not necessarily on the tank battery itself. The commenter recommends other clarifications to subparagraph (C). First, the commenter believes that EPA should remove the reference to “process unit” in subparagraph (C), because “process unit” is defined in the rule within the context of facilities that process natural gas, not well sites and centralized production facilities and the reference to process unit in the context of well sites and centralized production facilities is confusing and misplaced. Second, the commenter states that EPA should limit the scope of subparagraph (C) to “actions taken with respect to equipment that directly, or through a series of equipment, provides crude oil, condensate, intermediate hydrocarbons, or produced water throughput to the tank battery, including the addition of, or change to, a production well (including hydraulic fracturing or refracturing of the well).” By way of example, the commenter explains that hydraulic fracturing activities occurring in the vicinity of a well that delivers produced liquids to a storage tank battery may temporarily increase production of the well, which would, in turn, increase throughput of the tank battery, but as drafted, it is unclear whether this increase in production is an “action” that modified the tank battery if it resulted in exceedance of the potential for emissions threshold. The commenter believes it should not as operators cannot plan for or anticipate increases in production from activities occurring off-site that are outside the scope of operations associated with the tank battery. Further, in this example, the commenter explains that the cause of a temporary increase in production may be unknown to the operator and considering “actions” having no direct relationship to equipment in the definition of modification would be a far and extreme departure from longstanding NSPS modification principles. If EPA retains these modification triggers, the commenter requests that well sites and centralized production facilities should also be allowed to compare liquid throughputs to limits in a legally and practicably enforceable permit as is allowed for compressor stations and natural gas processing plants. The commenter believes this recommendation would also make modification criteria consistent for all sites and clearly define what an increase in liquid throughput is.

Response II-13-44: See discussion in section at section X.J.2. of the preamble to the final rule which details EPA’s final standards for modification.

EPA must defer to a case-by-case determination on the comment asking that EPA determine that an action "...from activities occurring off-site that are outside the scope of operations associated with the tank battery" is not an action that results in a modification because of the seemingly site-specific circumstances of the example. The commenter seems to be citing an example of hydraulic fracturing at a nearby well that induces a change in throughput to tanks at another unrelated well site or centralized production facility. EPA cannot draft rules that account for every eventuality such as changes in well production as a result of nearby well drilling activity. Regarding temporary increases in throughput, the modification actions do not have a temporal element. For the reasons discussed in the November 2021 proposal, EPA believes the actions will result in emissions increase to the atmosphere. See 86 FR 63198. Limitations on throughput may be accounted for in a legally and practicably enforceable limit when determining the potential for VOC and methane emissions, which is conducted after one of the actions occurs.

Regarding the term "process unit", see discussion in section at Section X.J.2. of the preamble to the final rule which details EPA's final standards for modification, including the term "process unit."

To the request that EPA clarify that 40 CFR 60.14 does not apply to storage vessels, the EPA instead states in Table 7 of the NSPS that to the extent any provision in §60.14 conflicts with specific provisions in subpart OOOOb, it is superseded by subpart OOOOb provisions.

Comment: Commenter (2326-AXPC) requests that EPA clarify that it does not intend for operators to maintain records of potential emissions calculations for any of the actions in 40 CFR 60.5365b(e)(3)(ii)(A) through (D) that do not result in the potential for VOC or methane emissions to meet or exceed either of the thresholds specified in 40 CFR 60.5365b(e)(1)(i) or (ii). The commenter explains that if one of these actions does not result in the potential for VOC or methane emissions to exceed the storage vessel applicability threshold, then a modification did not occur, and NSPS OOOOb would not apply, including recordkeeping requirements, but that this is not clear in the December 2022 Supplemental Proposal. Lastly, the commenter requests that EPA clarify that the storage vessel "modification" definition in 40 CFR 60.5365b(e)(3)(ii) is the singular controlling "modification" definition for NSPS OOOOb storage vessel affected facility determinations and that the modification definition in 40 CFR 60.14 does not apply.

Response II-13-45: We disagree with commenters that they are not required to maintain records of these evaluations. The evaluation is required under the rule. This record is needed to verify the rule does not apply. We have authority under CAA section 114(a) to require owners/operators of emission sources (not just regulated sources) to establish and keep records necessary for, among other purposes, determining whether anyone is in violation of the standard or for carrying out any provision of the CAA. Here the record is necessary to show that the NSPS is effectively implemented and that any claim of non-applicability status is accurate. Such record keeping requirement is common. See, e.g., 40 CFR 63.10(b)(3).

Comment: Commenter (2403-PAO) requests that in order to determine if a modification occurs, the rule should allow that operators can provide information that shows that emissions are not increasing and if emissions are not increasing, a modification has not been triggered.

Response II-13-46: The definition of modification included in the final rule at section 60.5365b(e)(3)(ii) does not provide that an owner or operator can show that emissions are not increasing (after conducting one of the actions specified in that section) to determine that a modification did not occur. In section IV.J.1.b of the December 2022 Supplemental Proposal,<sup>32</sup> EPA explained the rationale as to why we believe these specific actions lead to an increase in the VOC and methane emissions from a tank battery and therefore constitute a modification of an existing tank battery. Therefore, under the final rule, an existing tank battery or single storage vessel will become subject to the NSPS if one of the actions in this definition of modification occur and the potential VOC or methane emissions are greater than or equal to the 6 tpy VOC/20 tpy methane emissions threshold as determined in accordance with section 60.5365b(e)(2). An existing storage vessel that undertakes one of those actions, but does not surpass the applicability threshold remains an unaffected facility. A storage vessel that undertakes one of the actions can accept a legally and practicably enforceable emission limitation such that emissions will remain below the applicability threshold and will not be subject to the NSPS.

The commenter does not dispute EPA's rationales for the two-part test of modification. Rather the commenter suggests a case-by-case determination of no emission increase, which we believe to be unlikely. Further, since sources claiming non-applicability do not need to report to EPA, in light of the potential universe of thousands of tanks cited by the commenter, not including future new and modified tanks, it would be impossible for EPA to investigate each potentially incorrect claim of non-applicability.

Comment: Commenter (2399-GPA) is concerned that the proposed definition of modification includes the mere receipt of “additional fluids which cumulatively exceed the throughput used in the most recent ... determination of the potential for VOC or methane emissions.” The commenter states that these modification requirements are not feasible, as the midstream owner/operator is not the producer. The commenter explains that the owner or operator of midstream tank batteries at compressor stations or natural gas processing plants have no control over the receipt of fluids from upstream production facilities owned by third parties - midstream companies take possession of liquids at the custody transfer point and lack information regarding the upstream exploration and production company’s production volume prior to that point.

Commenter (2399-GPA) also states that attempting to define a change in throughput as a modification is contrary to law because under the CAA, a mere increase in throughput without any capital expenditure, other physical change to the equipment, or change in the method of operation is not a “modification.” See 42 U.S.C. § 7411(a)(3). The commenter states that the December 2022 Supplemental Proposal is not only inconsistent with the statutory definition of “modification,” but it is inconsistent with EPA’s prior interpretation that a “modification” requires some physical change to a tank. See Letter from Valdus Adamkus, EPA Region 5, to Bradley Miller, Hamilton County Environmental Services (Mar. 25, 1996) (increase in vapor pressure resulting in increased tank emissions was not a “modification” under 40 C.F.R., Part 60, Subpart Kb because there were no physical changes to the tank). The commenter is concerned that, unless the proposed definition of “modification” is revised to require a physical change or change in the method of operations, midstream owners and operators could find their equipment

---

<sup>32</sup> 87 FR 74801 (December 6, 2022).

“modified” solely based on the decisions of upstream third parties and without taking any action themselves.

Response II-13-47: See discussion in section at Section X.J.2. of the preamble to the final rule which details EPA’s final standards for modification. Regarding the comment that the owner or operator of midstream tank batteries at compressor stations or natural gas processing plants have no control over the receipt of fluids from upstream production facilities owned by third parties, EPA previously finalized a different framework for estimating emissions at compressor stations and natural gas processing plants. See 85 FR 57404. Also, the commenter explained in response to the November 2021 proposal, that for midstream facilities, an upstream facility adding or refracturing a well simply means receiving a relatively minor volume of additional product, which is part of routine operations and is evaluated in potential to emit calculations during permitting activities and that the receipt of additional product is not a change to the regulated facility itself and the routine changes in product volume are already accounted for by permitting agencies as part of the facility design. See Comment and Response I-9-35. In response to this comment, in the December 2022 Supplemental Proposal, EPA agreed that as long as the additional throughput is accounted for in the design capacity of the tank battery and included in a legally and practicably enforceable limit for the tank battery, the additional throughput does not result in emissions increase from the tank battery because those emissions have already been accounted for in the permit. See 87 FR 74802. EPA proposed language to that effect at §60.5365b(e)(3)(ii)(D). The commenter did not explain why this proposed regulatory language does not resolve the issues raised by the commenter nor did the commenter provide alternative regulatory language for EPA’s consideration. EPA therefore is finalizing, as proposed, the requirements regarding modification actions at natural gas processing plants and compressor stations. In summary, a tank battery at a natural gas processing plant and compressor station is modified if one of the actions (adding a storage vessel to an existing tank battery, replacing one or more storage vessels such that the cumulative capacity of the tank battery increases, or the existing tank battery receives additional fluids which cumulatively exceed the throughput used in most recent determination of the potential for VOC or methane emissions) occur and the potential for VOC or methane emissions meet or exceed the thresholds.

Regarding the comment that a modification must include a capital expenditure see discussion in section at section X.J.2. of the preamble to the final rule.. With respect to the comment that a modification must include a physical change or change in the method of operation, EPA believes that the addition of a storage vessel to an existing tank battery and the replacement of one or more tanks such that the cumulative storage capacity of the existing tank battery increases are physical changes. As explained in the November 2021 proposal, EPA believes that the receipt of additional fluids is an operational change, unless for natural gas processing plants and compressor stations, the throughput has been accounted for in a legally and practicably enforceable permit.) See 86 FR 63199.

Comment: Commenter (2298-Pioneer) recommends that the addition of a tank(s) to an existing battery should not trigger a modification. The commenter explains that adding a tank to an existing battery which is already controlled under existing rules/regulations does not increase emissions. Because the commenters tank storage systems are all manifolded, the addition of one or more tanks without a corresponding increase in production would not increase emissions,

according to the commenter. The commenter suggests either (1) removal of this from the definition or (2) change the language to include a corresponding increase in production at the tank battery.

Response II-13-48: With regard to the general definition of modification of tank batteries, see discussion in section IV.J.1.b of the December 2022 Supplemental Proposal.<sup>33</sup> The definition of tank battery no longer includes the requirement that a tank vapor space be manifolded to the other tank vapor spaces in the battery to be part of the battery. Rather, a tank is part of a battery if it is connected by liquid line to other tanks.

The commenter's scenario of adding a tank to a tank battery already controlled under existing rules/regulations appears to mean connecting a tank by liquid line at a tank battery which contains one or more storage vessel affected facilities which are subject to either subpart OOOO or OOOOa. As explained in section XII.B.1.c of the November 2021 proposal<sup>34</sup>, EPA believes that even if the type and quantity of fluids processed remains the same, the increased storage capacity from an added tank will lead to higher breathing losses and therefore an increase in emissions. The EPA also explained the outcome with respect to applicability from such a scenario (Scenario 3), in the December 2022 Supplemental Proposal.<sup>35</sup> The commenter did not explain why this assumption is incorrect. Even if emissions are controlled, absent installation of a control device capable of achieving greater than 95% control, an increase in gas throughput to the control device will result in a corresponding increase in controlled emissions to the atmosphere.

Comment: Commenter (2298-Pioneer) recommends that increasing throughput to an existing tank should only trigger a "modification" if the increase in the PTE exceeds permitted levels. The commenter recommends that EPA define "increasing throughput" in accordance with how tanks are managed through the state permitting process. By way of example, the commenter states that these facilities typically are permitted at maximum design production throughput based on equipment at the site and then a limit is set. The commenter states that if they operated under that limit (regardless of decreases or increases in throughput), the commenter is in compliance with the permits. The commenter suggests including language that specifies an increase in production above permitted PTE would be considered a "modification."

Response II-13-49: See discussion in section XII.B.1.c. of the December 6, 2022, Supplemental Proposal<sup>36</sup> for special provisions for modifications related to increases in throughput at compressor stations and natural gas processing plants which account for increases above permitted limits. See also Response II-13-46.

In the November 2021 Proposal, EPA described that an event like hydraulically fracturing or refracturing a well increases the volumetric throughput of the tank battery and will increase working losses and potentially increase flashing losses. See 86 FR 63198. Under the modification provisions of the final rule, the action triggers the need to determine applicability against the VOC and methane potential for emissions thresholds. There is nothing to preclude the

---

<sup>33</sup> 87 FR 74801 (December 6, 2022).

<sup>34</sup> 86 FR 63198 (November 15, 2021).

<sup>35</sup> 87 FR 74803 (December 6, 2022).

<sup>36</sup> 87 FR 74802 (December 6, 2022).

owner or operator from using previous legally and practicably enforceable limits, including limitations on throughput, when determining the potential for VOC and methane emissions after a modification action.

Comment: Commenter (2428-API) believes that the proposed definition of modification requires clarification. The commenter supports the first two proposed criteria for modification found in 40 CFR 60.5365b(e)(3)(ii)(A) and (B): “*A storage vessel is added to an existing tank battery*” and “*One or more storage vessels are replaced such that the cumulative storage capacity of the existing tank battery increases*” because both of these changes require capital expenditure on the potential affected facility (i.e., the tank battery) and would increase emissions. However, the commenter states that the proposed criteria in 40 CFR 60.5365b(e)(3)(ii)(C) and (D) regarding increases in liquid throughput are too broad and inconsistent with 40 CFR §60.14(e)(2). The commenter cites to 40 CFR 60.14(e)(2), where an increase in throughput for a storage vessel, accomplished without a capital expenditure on that storage vessel, is not considered a modification. The commenter states that EPA has not fully explained why it is proposing to deviate from the historical legal understanding of modification which requires both an increase in throughput and a capital expenditure on the storage vessel or tank battery. Also, the commenter explains, increases in liquid throughput at well sites, central production facilities, and compressor stations are difficult to track as sites typically track liquid throughput using tank gauging rather than flow meters. Due to the historic understanding of modification and practical challenges of tracking liquid throughput, the commenter believes that 40 CFR 60.5365b(e)(3)(ii)(C) and (D) should be removed from the definition of modification.<sup>37</sup>

However, the commenter (2428-API) states, if EPA decides to include increases in liquid throughput as a criterion for modification, the following changes are recommended:

- **The increase in liquid throughput must also be accompanied by a capital expenditure on the tank battery itself.** Actions, such as drilling a new well or fracturing or refracturing an existing well, could increase liquid throughput and require capital expenditure but not necessarily on the tank battery itself. These actions would not be considered modifications to the tank battery unless there is capital expenditure on the tank battery itself. This recommendation would make NSPS OOOOb consistent with NSPS A.

---

<sup>37</sup> Please see Section 11.6 of our comments on the original proposal for overarching legal comments on the proposed modification definitions. We note that EPA appears to have responded in part to these comments by providing that a modification to a tank battery occurs only when specified actions “result in the potential for VOC or methane emissions to meet or exceed either of the thresholds specified in paragraphs (e)(1)(i) or (ii)” (the PTE-based applicability thresholds for storage vessels). But we note that EPA’s proposed PTE criteria apply to an annual PTE and not, as specified in § 60.14, a short-term measure of PTE (such as lb/hr). This is a significant change in how a potential emissions increase should be considered in determining the existence of a modification because the annual PTE basis in practice likely results in a more expansive modification definition because the short term PTE of storage vessels in almost all cases will be much higher than an annual value, which means that more variation in actual short term emissions can be accommodated without triggering a modification than under an annual metric. EPA fails to explain why it has shifted from a short-term to an annual basis for determining emissions increases associated with a change. As a result, we do not have a reasonable opportunity to understand EPA’s rationale and to provide meaningful comments.

- **Reference to process unit in 40 CFR 60.5365[b](e)(ii)(C) should be removed since process unit is defined such that they should not exist at well sites and centralized production facilities.** Process unit is a term specific to natural gas processing plants and does not apply to well sites and centralized production facilities.
- **Well sites and centralized production facilities should also be allowed to compare liquid throughputs to limits in a legally and practicably enforceable permit like compressor stations and natural gas processing plants.** EPA should be consistent and allow well sites and centralized production facilities to compare liquid throughputs to limits in a legally and practicably and enforceable permit since such a permit can be relied upon for the PTE determination for all sites.
- **In the absence of a legally and practicably enforceable limit, all sites should be allowed to compare liquid throughputs to those used to design the existing cover and closed vent system in operation when a potential modification action occurs.** These recommendations would also make modification criteria consistent for all sites and clearly define what an increase in liquid throughput is.

Based on these recommendations, the commenter offers the following suggested edits to 40 CFR 60.5365b(e)(3)(ii) (suggested additions are underlined; suggested deletions are shown in strike-through):

“Modification” of a tank battery occurs when any of the actions in paragraphs (e)(3)(ii)(A) through ~~(D)(C)~~ of this section result in the potential for VOC or methane emissions to meet or exceed either of the thresholds specified in paragraphs (e)(1)(i) or (ii) of this section.

(A) A storage vessel is added to an existing tank battery;

(B) One or more storage vessels are replaced such that the cumulative storage capacity of the existing tank battery increases; or

~~(C) For tank batteries at well sites or centralized production facilities, an existing tank battery receives additional crude oil, condensate, intermediate hydrocarbons, or produced water throughput from actions, including but not limited to, the addition of a process unit or production well, or changes to a process unit or production well (including hydraulic fracturing or refracturing of the well).~~

~~(D)(C)~~ For tank batteries at compressor stations or onshore natural gas processing plants, A capital expenditure occurs at an existing tank battery, when that existing tank battery receives additional fluids which cumulatively exceed the throughput used in the most recent (i.e., prior to an action in paragraphs (e)(3)(ii)(A), (B) or ~~(D)(C)~~ of this section) determination of the potential for VOC or methane emissions; or in the absence of a legally and practicably enforceable permit, a capital expenditure occurs at an existing tank battery, when that existing tank battery receives additional fluids which cumulatively exceed the throughput used in the most recent (i.e., prior to an action in paragraphs (e)(3)(ii)(A), (B) or (C) of this section) design of the storage vessel cover(s) and closed vent system.

Response II-13-50: See discussion in section at Section X.J.2. of the preamble to the final rule which details EPA’s final standards for modification, including capital expenditure and the term “process unit.”.

Regarding liquid throughput, the EPA notes that the action in paragraph (e)(3)(ii)(C) anticipates that the activities described will result in an increase in liquids throughput and a resulting emissions increase. At that point, the owner or operator of a tank battery at a well site or centralized production facilities must determine the potential for VOC and methane emissions. EPA agrees that a legally and practicably enforceable emission limitation could be applied in the context of determining the potential to emit resulting from a modification action. For example, an existing storage vessel that commenced construction before promulgation of 40 CFR 60 subpart OOOO that modifies under the conditions of OOOOb can apply a legally and practicably enforceable emission limitation when assessing the potential to emit to remain an existing (pre-OOOO) facility.

As a practical matter, however, the EPA is concerned with the statement that an owner or operator has difficulty tracking liquid throughput; if liquid throughput is expected to be used as a legally and practicably enforceable limit to maintain VOC and methane emission below the applicability threshold, then in accordance with the finalized criteria for legally and practicably enforceable, those limits must be tracked. The specific criteria for what constitute legally and practicably enforceable are discussed elsewhere in this chapter.

EPA interprets the last comment that all sites should be allowed to compare liquid throughputs to those used to design the existing cover and closed vent system in operation when a potential modification action occurs to refer to provision that a storage vessel at a well site is modified if the well is modified by hydraulic fracturing or refracturing of the well. The EPA disagrees because hydraulic fracturing or refracturing by its nature is to increase production and throughput such that an emissions increase is inevitable, unless a more stringent legally and practicably enforceable limit on the emissions reduction achieved by a control device is applied. Thus, we find it reasonable and necessary to require a re-evaluation of the potential to emit after any of the described modification actions.

#### ***13.2.10 Reconstruction of Storage Vessel Affected Facility***

Comment: Commenter (2403-PAO) provides responses to questions raised by EPA in the December 2022 Supplemental Proposal. With respect to EPA’s request for comment regarding the assumption that the cost to replace all depreciable components on a single storage vessel could exceed 50 percent of the cost of an entirely new storage vessel, the commenter states that typically, tank components such as tank hatches and pressure relief devices would not exceed 50 percent of the cost of an entirely new storage vessel. With respect to whether a specific timeframe for reconstruction is appropriate for determining reconstruction to a tank battery with more than a single storage vessel, and whether that time frame should be a 2-year time frame, the commenter agrees with this requirement and believes it will provide operators with a clear way to determine if reconstruction has been triggered.

Response II-13-51: See discussion in section at Section X.J.2. of the preamble to the final rule which details EPA’s final standards for reconstruction.

Comment: Commenter (2428-API) states that the proposed definition for reconstruction is internally inconsistent. The commenter cites EPA’s rationale in the proposal, that for a tank battery consisting of more than one storage vessel, reconstruction is based on replacing at least half of the storage vessels based on the assumption that “*the cost of replacing storage vessel components such as thief hatches and pressure relief devices, in comparison to the cost of constructing an entirely new storage vessel affected facility, will not exceed 50 percent of the cost of constructing a comparable new storage vessel affected facility.*” However, the commenter points out, for a tank battery consisting of a single storage vessel, the existing provisions of 40 CFR 60.15 apply on the chance that the cost of replacement storage vessel components could be 50 percent or more of the cost to construction a comparable new storage vessel. The commenter explains that either the cost of depreciable components on a storage vessel other than the tank itself could be 50 percent or more of the cost of a new comparable tank or not. The commenter is concerned that this inconsistency means that operators would have to track the cost of storage vessel component replacements for single storage vessel tank batteries, but not for multi-vessel tank batteries. For both single and multi-vessel tank batteries, the commenter believes that operators should have the option to track either storage vessel replacements or all depreciable components. Based on this recommendation, the commenter offers the following redline of 40 CFR 60.5365b(e)(3)(i) (suggested additions are underlined; suggested deletions are shown in strike-through):

“Reconstruction” of a tank battery occurs when the provisions of §60.15 are met for the existing tank battery ~~any of the actions in paragraphs (e)(3)(i)(A) or (B) of this section~~ and results in the potential for VOC or methane emissions to meet or exceed either of the thresholds specified in paragraphs (e)(1)(i) or (ii) of this section. As an alternative to the provisions of §60.15, an operator may determine reconstruction has occurred if at least half of the storage vessels are replaced in the existing tank battery that consists of more than one storage vessel and results in the potential for VOC or methane emissions to meet or exceed either of the thresholds specified in paragraphs (e)(1)(i) or (ii) of this section.

~~(A) The provisions of §60.15 are met for the existing tank battery ; as an alternative to the provisions of 60.15, At least half of the storage vessels are replaced in the existing tank battery that consists of more than one storage vessel; or~~

~~(B) The provisions of §60.15 are met for the existing tank battery that consists of a single storage vessel.~~

Response II-13-52: See discussion in section at Section X.J.2. of the preamble to the final rule which details EPA’s final standards for reconstruction.

Comment: Commenters (2305-Williams, 2433-EDF *et al.*) support EPA’s proposed definition of “reconstruction” for storage vessels. Commenter (2433-EDF *et al.*) believes it is reasonable for EPA to equate replacing 50 percent of tanks at a site with replacements where “the fixed capital cost of components exceeds 50 percent of the fixed capital cost that would be required to construct a comparably entirely new facility.” The commenter states that because individual tanks are likely to have comparable replacement costs, it is reasonable to assume that there would be a one-to-one correlation between the percentage of tanks being replaced at a site and

the percentage of the fixed capital cost that would be required to construct a comparable entirely new facility. Regarding the appropriate timeframe when determining if a reconstruction has occurred, the commenter supports mirroring the two-year rolling reconstruction time frame proposed for pneumatic controllers. The commenter believes that a two-year rolling period provides a reasonable method of determining whether an owner of an oil and natural gas site with storage tanks is actually pursuing an extensive tank replacement program, within the EPA's original intent in promulgating 40 CFR 60.15. The commenter believes the two-year timeframe also recognizes that it may be more cost-effective for operators to replace a larger portion of their tanks rather than initiate several, smaller replacement programs. Without a two-year window, the commenter is concerned that operators could create multiple replacement programs below the 50 percent threshold over the course of several years to avoid compliance with NSPS OOOOb. The commenter cautions that allowing this loophole would undermine Congress' intent that air quality be enhanced over the long term with the turnover of polluting equipment and with the intent of EPA's reconstruction provisions.

Commenter (2305-Williams) generally agrees with EPA's proposed regulations characterizing modification and reconstruction of storage vessels. The commenter believes that addition or replacement of a storage vessel that results in an exceedance of 6 tpy VOCs qualifies as a modification. The commenter also agrees that an increase in condensate or produced water throughput above a previous permit level that results in an exceedance of 6 tpy VOCs qualifies as a modification. The commenter believes the same holds true for methane, if EPA significantly increases its current methane threshold limit of 20 tpy. The commenter supports EPA's proposed reconstruction with respect to storage vessels and agrees with EPA that 2 years is a reasonable time during which activities potentially resulting in reconstruction should be evaluated.

Response II-13-53: See discussion in section at Section X.J.2. of the preamble to the final rule which details EPA's final standards for reconstruction.

## **13.3 BSER**

### ***13.3.1 General***

Comment: Commenter (2428-API) requests that EPA clarify that location is not a restriction on the use of a floating roof tank. The commenter notes that in 40 CFR 60.5395b(b)(2), EPA correctly prohibits the use of a floating roof if the storage vessel or tank battery has flashing emissions. However, the commenter points out that EPA also prohibits the use a floating roof at a well site or centralized production facility. Flashing emissions alone, regardless of location, should prohibit the use of a floating roof tank because flashing emissions, not location, could prevent proper operation of a floating roof, according to the commenter. The commenter offers a recommended redline to 40 CFR 60.5395b(b)(2) (suggested deletions are shown in strike-through):

For storage vessel affected facilities that do not have flashing emissions ~~and that are not located at well sites or centralized production facilities~~, you may use a floating roof to reduce emissions. If you use a floating roof to reduce emissions, you must meet the requirements of §60.112b(a)(1) or (2) and the relevant monitoring, inspection,

recordkeeping, and reporting requirements in 40 CFR part 60, subpart Kb. You must submit a statement that you are complying with §60.112b(a)(1) or (2) with the initial annual report specified in §60.5420b(b)(1) and (8).

Commenter (2248-NDPC) asks that EPA clarify what storage vessel types they propose to regulate under the oil and gas rules, as the BSER analysis only appears to address fixed roof tanks.

Response II-13-54: The EPA explained that production operators may not use floating roof tanks to meet the requirements of OOOOb, or OOOOc EG at well sites and centralized production facilities because floating roofs are not designed to handle flash emissions, which are prevalent in the production segment, a point that the commenter does not dispute. See 86 FR 63184. Storage vessels that do not have flashing emissions and that are not located at well sites or centralized production facilities may use floating roof controls following the provisions in subpart Kb.

### ***13.3.2 Technical Considerations***

Comment: Commenter (2362-EIP) states that current NSPS rules require new storage tanks with the potential to emit 6 tons or more of VOCs (without controls) to control tank vapors by installing flares or VCUs and operating them with a destruction removal efficiency (DRE) of 95 percent. The commenter notes that the proposed rule extends the same requirement to new and existing storage tanks with the potential to emit (PTE) 20 tons or more of methane per year. When calculating the cost-effectiveness, the commenter notes that the EPA assumes that a storage tank with a 20-ton PTE for uncontrolled methane would release about 91 tons of VOCs per year. As the commenter noted previously, they are concerned that the EPA has not obtained data from oil and gas sources to support its claim that 95 percent DRE represents the BSER for existing flares and vapor combustion units.

Response II-13-55: See response II-13-15 with respect to EPA's choice of 20 tpy as the applicability threshold for methane. See the EPA memo describing the BSER analysis [Docket Item No. EPA-HQ-OAR-2021-0317-0039].

Comment: Commenter (2353-CrownQuest) urges EPA to acknowledge the limitations of atmospheric tanks and their design to be at atmospheric pressure and understand that any additional pressure they hold to manage emissions is an improvement. The commenter states that EPA should not create new regulations that cause even more potential issues, including the potential for rupture and bodily harm from field personnel. The commenter believes that EPA's current rules are sufficient, and nothing in the new proposed rules will significantly affect emissions, although they will increase the cost of operating locations with tanks.

Response II-13-56: The EPA disagrees that the new NSPS OOOOb and EG OOOOc storage vessel requirements will not reduce emissions. See the RIA in the docket for the reductions that EPA estimates will be derived from the final storage vessel requirements. The EPA points out that the reductions quantified in the RIA are attributed to in part to the change in the definition of an affected facility tank battery will reduce emissions significantly as a result of more storage

vessels requiring control, as emissions averaging across tanks will no longer be the technique to determine the requirement to control emissions. With respect to atmospheric tanks, the NSPS exempts atmospheric tanks from controls if they demonstrate that uncontrolled emissions are below 4 tpy. For storage vessels with potential to emit greater than 6 tpy but that choose to accept legally and practicably enforceable emissions limitations, new criteria have been added to the NSPS to provide robust criteria to ensure such emissions limitations are met. We anticipate that these robust criteria applied by operators will decrease emissions from their storage vessels. Both the 4 tpy VOC threshold for uncontrolled tanks and the 6 tpy VOC threshold for controlling tank emissions are unchanged from OOOO and OOOOa, so we are not able to identify the commenter's concern regarding standards that could cause a rupture of storage vessels that present a risk to personnel.

Comment: Several comments provided feedback on EPA's proposed thief hatch monitoring provisions. Some of the specific comments are provided in the following paragraphs.

Commenter (2353-CrownQuest) has concerns with the thief hatch monitoring provisions. The commenter states that open or partially closed tank hatches is a human error issue that arises from the remote nature of oil and gas sites. The commenter points out that operators monitor most sites only minutes a day or every few days due to their remote locations and open tank hatches periodically to measure the contents of the tanks. The commenter notes that EPA already does not allow open tank hatches, and the industry has worked on limiting them over the years. The commenter urges EPA to revisit its 12 years of data to realize how little open hatches would be affected by this massive increase in paperwork and reporting. To the contrary, the commenter believes this has been an industry focus for years, and it is difficult to refute that instances have decreased without increased regulation. Further, the commenter believes that monitoring thief hatches with optical gas imaging (OGI) is a misuse of technology because it is easy to see if tank hatches are open, and the commenter states that OGI will not achieve that any better.

Commenter (2403-PAO) believes that EPA should not include a requirement to equip thief hatches with alarms, automated systems to monitor for pressure changes, or use of automatically closing thief hatches.

The commenter (2403-PAO) states that these requirements would be impractical as hatches are accessed to gauge tanks and conduct routine maintenance and repair. The commenter also states it would be difficult to monitor tanks that have low pressures. Additionally, the commenter is not aware where such equipment has been installed and operated successfully and requests that until such technology has been adequately designed, tested, and the costs and results are known, EPA should not finalize this requirement.

Commenter (2227-WEA) believes that it is not reasonable to include provisions in the regulations which require storage tank thief hatches to be equipped with preventive automated features such as alarms, pressure change monitors, or automatically closing thief hatches, because installing such automated features are not always feasible due to economic or technical limitations. In some circumstances the cost of equipment and labor can be too high for the benefit that would be seen for the resulting additional reduction in emissions, according to the commenter. The commenter believes that there are already preventative steps in place that focus

on maximizing the proper operation of thief hatches, including fugitive emissions programs, LDAR programs which identify leaking gaskets, and training for operations personnel. The commenter cautions that automated systems are also not always technologically feasible when power is necessary for actions at the storage tank and for communications that might be necessary to implement systems, especially in areas that bring challenges due to remoteness and geographical features. The commenter urges EPA not to finalize requirements for equipping storage tank thief hatches with automated features and instead should defer to LDAR regulations, existing inspection programs and focused operator training programs.

Conversely, commenter (2433-EDF *et al.*) supports EPA's proposal to require that thief hatches be equipped with alarms, automated systems to monitor for pressure changes, or automatically closing thief hatches. The commenter explains that thief hatches act as pressure safety devices and, when operated properly, prevent emissions from escaping into the atmosphere, but thief hatches can open and unintentionally emit either through improper latching after routine operations (checking tank levels, etc.) or, as a result of a pressure build-up within the tank.<sup>38</sup> The commenter points out that open or malfunctioning thief hatches, if not closed or repaired promptly, can be responsible for large amounts of methane and VOC emissions.<sup>39</sup> The commenter is concerned that because storage tanks are often located in remote locations with operating teams moving in and out, unsealed thief hatches could remain open for long stretches of time, freely emitting harmful methane and VOCs into the atmosphere.<sup>40</sup> According to the commenter, this issue could be significantly improved by installing monitoring technology on this equipment. The commenter states that requiring operators to choose to install at least one type of mitigation technique is reasonable and cost-effective. Various developers of automation technology and equipment have made viable options for thief hatch monitoring available to industry operators, according to the commenter.<sup>41</sup> When taking into account the lost revenue associated with wasted gas lost through open thief hatches, installing monitoring systems may ultimately benefit operators financially while also preventing harmful emissions, the commenter

believes<sup>42</sup> and will be an important step for EPA in promulgating effective, economical standards for these sources.

Response II-13-57: The EPA did request comment on thief hatch monitoring or alarm systems, recognizing the utility of such systems to reduce emissions from thief hatches and storage vessels generally. However, the EPA did not receive the type and scope of data and information in response to our request for comment that would be necessary to finalize any requirements in this respect. EPA reviewed the material referenced by footnote in the comment submitted. The report from the South Coast Air Quality Management District (SCAQMD)<sup>43</sup> provided some information but was insufficient for EPA to adopt without first submitting such a concept in proposal in notice and comment rulemaking. Specifically, the assumptions made in the SCAMD were not necessarily the same costs and assumptions EPA would need to make for a nation-wide rulemaking. We would also point out that the super-emitter program is anticipated to increase the level of vigilance that sources will need to address the events from storage vessels that could be observed and flagged for investigation. To that end, sources may find it prudent and cost effective to adopt such systems as a means to reduce the likelihood that a thief hatch could open and cause a super-emitter event that could be observed.

Comment: Commenter (2458-MiQ) recommends that because downstream emissions controls, like VRUs, are not an effective control for open thief hatches, specific regulation should be considered for thief hatches and other vent sources that are not routed directly into VRUs.

Response II-13-58: EPA did request comment on such systems, recognizing the utility of such systems to reduce emissions from thief hatches and storage vessels generally. However, the EPA did not receive the type and scope of data and information in response to our request for comment that would be necessary to finalize any requirements in this respect. See our response to comment II-13-56.

Comment: Commenters (2333-LongPath Technologies, Inc. (Longpath), 2440-Nevada Nanotech Systems, Inc. (NNS)) believe that storage vessels are excellent applications for continuous monitoring, especially thief hatches which represent one of the most problematic sources of emissions in the industry. The commenter (2440-NNS) suggests that continuous monitoring solutions such as “CP-CMS” systems provide immediate notification of emissions to operators, allowing rapid remediation of the emissions. For existing applications, the commenter states that these solutions can provide continuous methane detection for less than \$300 per year and five tank batteries can be monitored for less than \$900 per year. The commenter also encourages the EPA to also allow continuous monitoring technology solutions as a BSER for tanks and tank

<sup>42</sup> See, e.g., Jeff Voorhis, Best Practices for Vapor Recovery Systems to Reduce Venting and Flaring at 4, <https://www.epa.gov/sites/default/files/2016-04/documents/8voorhis.pdf> (positing that when subtracting the estimated cost of wasted gas from estimated project costs, industry operators would ultimately experience a net gain.); Ray, supra note 538 (One company’s costs for installing monitoring technology on an 8-tank battery totals \$8,300).

<sup>43</sup> SCAQMD; Preliminary Draft Staff Report. Proposed Amended Rule 1178 – Further Reductions of VOC Emissions from Storage Tanks at Petroleum Facilities; and Proposed Amended Rule 463 – Organic Liquid Storage. February 2023. (See Docket EPA-HQ-OAR-2021-0317).

batteries to minimize methane emissions and states that continuous monitoring for methane emissions is especially important for NSPS OOOOb (existing) applications.

Commenter (2333-LongPath) notes that they have systems which correctly alarms operators to the presence of emissions from open thief hatches and deteriorated seals and believe that any requirements to equip thief hatches with alarms or other automated systems should also allow the use of continuous emissions monitoring systems with valid quantification. The commenter believes that this will incentivize operators to use this more comprehensive form of coverage, which reliably detects and quantifies this emission source category.

Response II-13-59: The EPA did request comment on such systems, recognizing the utility of such systems to reduce emissions from thief hatches and storage vessels generally. However, the EPA did not receive the type and scope of data and information in response to our request for comment that would be necessary to finalize any requirements in this respect. See response II-13-56 of this Chapter.

Comment: Commenter (2362-Environmental Integrity Project (EIP) *et al.*) questions why EPA limits flaring for oil wells but not for storage vessels. The commenter states that EPA has not rationally explained (or explained at all) why it is not requiring storage vessel facilities to minimize flaring and use of other controls. The commenter states that EPA's differing treatment of oil wells and tank batteries regarding the use of controls and flaring is arbitrary and capricious.<sup>44</sup> The commenter believes that requiring storage vessel facilities to minimize their use of flares and other combustion devices is important because these facilities can emit very large amounts of VOCs and methane through their flares and other control devices in situations such as when downstream processing facilities are shut down for repair or other reasons. The commenter provides an exhibit which they say identifies the total annual sulfur dioxide emissions released by ten oil and gas sources between 2015 and 2019 during various emission events that range from an average of several hundred to more than a thousand hours per year. Emissions of VOC's or methane from other facilities can also be very high, according to the commenter. The commenter believes there are available, cost-effective options to reduce the use of flares and other control devices at tank batteries. By way of example, the commenter believes that EPA could require storage vessel facilities to minimize flaring and use of other controls by recycling excess gas, which will likely require compressors to hold the gas until it can be fed back into downstream processing units. These compressors could be required at the tank batteries themselves or at the downstream processing units, explains the commenter.

The commenter (2362-EIP *et al.*) believes it is "appropriate" under CAA section 111(b)(1)(B), 42 U.S.C. section 7411(b)(1)(B), to strengthen the NSPS (and EG) for tank batteries to reduce flaring and use of other controls in these ways. Further, these improvements constitute the "degree of emission limitation achievable through the application of the best system of emission reduction which (taking into account the cost of achieving such reduction and any nonair quality health and environmental impact and energy requirements) . . . has been adequately demonstrated" under CAA section 111(a)(1), *id.* section 7411(a)(1), according to the commenter.

---

<sup>44</sup> See *Transactive Corp. v. United States*, 91 F.3d 232, 237 (D.C. Cir. 1996) ("A long line of precedent has established that an agency action is arbitrary when the agency offered insufficient reasons for treating similar situations differently.").

At a minimum, the commenter states that EPA must strengthen the proposed standards and EG by requiring tank batteries with flares to develop flare management plans designed to minimize flaring and promote flare gas recovery, as EPA has required for refineries. The NSPS for refineries require owners and operators of flares to develop, implement, submit, and comply with a flare management plan that includes several detailed categories of information, including: a listing of units and systems connected to the flares; descriptions of the flares; an assessment of whether discharges to the flares can be minimized; and procedures to minimize or eliminate discharges to the flares during planned startup and shutdown of the units and systems connected to the flares, explains the commenter.

Similarly, states the commenter (2362-EIP *et al.*), although tied to certain unlawful loopholes (according to the commenter) for periods when flares operate above “smokeless capacity,” the NESHAP for refineries require owners and operators of flares that have the potential to operate above their smokeless capacity to develop, implement, submit, and comply with a flare management plan to minimize flaring during periods of startup, shutdown, or emergency releases. The commenter states that EPA has not rationally explained (or explained at all) why flare management plans should not be required here and that requiring refineries but not oil and gas tank batteries to develop and implement flare management plans would render EPA’s final rule arbitrary and capricious.

Response II-13-60: The standards for associated gas (gas from the first stage of separation during production) and for storage vessels differ because their BSER differ. While the BSER for associated gas is routing the gas to a sales line, section 60.5377b(a), the EPA has identified combustion (flaring) as the BSER for storage vessels affected facilities since the promulgation of the NSPS OOOO standards in 2012, and that continues to be the same in NSPS OOOOa and now OOOOb/OOOOC. The commenter has not claimed that our BSER analysis was flawed, or that any other control qualifies as the BSER for storage vessels. We further note that the standard is an emission limit and does not require flaring, and the EPA has expressly identified non-flaring options for meeting the standard, such as routing to a vapor recovery systems or a process.

EPA disagrees that flare management plans are necessary in the context of upstream oil and gas facilities. While flare management plans clearly enhance the effectiveness of flaring in the refinery setting, EPA disagrees that such an approach is necessary in this NSPS. EPA does not agree that a flare management plan would be reasonable for many affected facilities that constitute one flare, where assisted flares are less in use, and where the level of flaring is less overall. Moreover, EPA is finalizing a number of additional requirements with respect to flaring that will increase control effectiveness, such as additional monitoring of flaring operations.

Comment: Commenter (2428-API) believes that the requirement to manifold the vapor space of each storage vessel in the tank battery is unnecessary and restricts an operator’s flexibility in achieving compliance with the required 95 percent emissions reduction. The commenter states that an operator should be able to install any number of control devices and manifold the vapor space of the storage vessels from one or more tank batteries into one or more closed vent systems

so that each control device is properly sized for the expected vent gas flow rate.<sup>45</sup> The requirement to manifold the vapor space of a tank battery may also cause confusion with the proposed definition of tank battery which is based on storage vessels manifolded together for liquid transfer, according to the commenter. To address this issue, the commenter offers the following redline to the regulatory text at 40 CFR 60.5395b(b) (suggested deletions are shown in strike-through):

Control requirements.

(1) Except as required in paragraph (b)(2) of this section, if you use a control device to reduce methane and VOC emissions from your storage vessel affected facility, you must meet all of the design and operational criteria specified in paragraphs (b)(1)(i) through ~~(iv)~~ (iii) of this section.

(i) Each storage vessel in the tank battery must be equipped with a cover that meets the requirements of §60.5411b(b);

~~(ii) The storage vessels must be manifolded together with piping such that all vapors are shared among the headspaces of the storage vessels in the tank battery;~~

~~(iii)~~(ii) The tank battery must be equipped with a one or more closed vent systems that meets the requirements of §60.5411b(a) and (c); and

~~(iv)~~(iii) The vapors collected in paragraphs (b)(1)(ii) ~~and (iii)~~ of this section must be routed to a control device that meets the conditions specified in §60.5412b(a) or (c). As an alternative to routing the closed vent system to a control device, you may route the closed vent system to a process.

Response II-13-61: EPA agrees with the commenter that it is not necessary to specify that the vapor spaces of the tanks within a tank battery be manifolded for control purposes, because the control criteria of a cover, closed vent system, and control device provide sufficient regulatory certainty that each tank in a storage vessel affected facility must be controlled to 95 percent.

On the issue of whether all tanks should be routed to a single control device, EPA does not interpret “a control device” as “a single control device” for the purpose of controlling a tank battery. By maintaining the text as “a control device” an operator can use redundant or multiple control devices within a single tank battery and still meet the requirements of the standard, because the collection of tanks in a tank battery manifolded by liquid line is an affected facility (where the potential for VOC and methane emissions is met) and each tank in the storage vessel

---

<sup>45</sup> If not corrected, EPA’s failure to consider these obvious and important aspects of its proposed manifolding requirement would render such a requirement arbitrary and capricious. *Motor Vehicle Mfrs. Assn. v. State Farm Mut. Automobile Ins. Co.*, 463 U.S. 29, 43 (1983).

affected facility must be controlled to 95 percent, when the battery as a whole must be controlled to 95 percent.

Comment: Commenter (2428-API) states that EPA should provide an exemption from control requirements due to technical infeasibility if the control device or VRU would require supplemental fuel. The commenter explains that with the change in affected facility from a single storage vessel to a tank battery, control devices will be required for a longer time compared to NSPS OOOO and NSPS OOOOa - until the actual uncontrolled emissions from the tank battery (versus each individual storage vessel) are below 4 tpy VOC and 14 tpy of methane. The commenter believes that this longer period for the control requirement will increase the likelihood that some control devices or VRUs will require supplemental fuel to be technically feasible. Similar to comments the commenter provided with respect to control device pilot flames, operators may have to bring propane for supplemental fuel for sites without fuel gas or burn additional sour fuel gas. As such, the commenter recommends EPA consider an exemption from control requirements for a tank battery if use of a control device or VRU would be technically infeasible without supplemental fuel for pilot flame or other purposes. The commenter states that such exemptions currently existing in state regulations for storage vessels and tank batteries including Colorado. Based on the language for the Colorado exemption, the commenter offers the following recommended redlines to the control requirements in §60.5395b(b) (suggested additions are underlined; suggested deletions are shown in strike-through):

Control requirements.

(1) Except as required in paragraphs (b)(2) and (b)(3) of this section, if you use a control device to reduce methane and VOC emissions from your storage vessel affected facility, you must meet all of the design and operational criteria specified in paragraphs (b)(1)(i) through ~~(iv)~~(iii)<sup>46</sup> of this section.

\* \* \*

(3) You may apply to the Administrator for an exemption from the control requirements in paragraphs (b)(1) of this section if the use of a control device would be technically infeasible without supplemental fuel. Such request must include documentation demonstrating the infeasibility of the control device.

Response II-13-62: The EPA disagrees with the commenters that an exemption from controlling emissions from storage vessels is needed when supplemental fuel is required. All flares or combustors will require supplemental fuel, either by natural gas or propane, for use for pilot gas and for sweep or purge gas. While we assumed most facilities would have natural gas available, propane can also be used. We therefore do not consider control to be technically infeasible when it would require supplemental fuels.

---

<sup>46</sup> This citation includes other redlines suggested by the commenter regarding the requirement to manifold the vapor lines of storage vessels which are part of a tank battery.

Comment: Commenter (2383-Baker Hughes) agrees that open thief hatches and deteriorated seals around tank openings are significant emissions sources at tank batteries. The commenter believes that EPA is right to solicit comment on including a requirement to equip thief hatches with alarms, automated systems to monitor for pressure changes, or use of automatically closing thief hatches. The commenter supports such a requirement but notes that operators have traditionally been hesitant to deploy electronic monitoring equipment near thief hatches due to the risk associated with electrified sensing technologies in potentially flammable atmospheres that can be present at the thief hatch. A lower cost, less risky and more long-term abatement solution should be physical replacement of the thief hatch with a device that allows for capture of the emissions associated with pressure venting at the thief hatch port, according to the commenter. According to the commenter, there are technologies in late-stage development that will achieve significant reductions in storage vessel emissions associated with thief hatches. By way of example the commenter states that a thief hatch elimination device will eliminate the vent to atmosphere from thief hatches and would retrofit on to existing storage tanks and replace thief hatches on new storage tanks. The commenter states it would eliminate nearly 100 percent of the emissions resulting from thief hatches as it provides a pipe-away configuration to a vapor recovery system while still providing access to the tank contents for gauging and sampling purposes and has the added benefit of protecting the worker from being exposed to flammable atmosphere at the thief hatch port as well as toxic vapors from the storage tank head space. The commenter recommends that EPA include in both 40 CFR 60.5395b and 60.5396c allowance for solutions that eliminate or replace the thief hatch and provide a means of capturing emissions from thief hatch ports due to over pressure venting by piping those emissions to a flare or sales line.

Response II-13-63: EPA agrees with the comment with respect to the need for additional technology to address thief hatch emissions and is encouraged by the technology that is under development. The NSPS does not preclude the development and use of such technologies. EPA has attempted to address thief hatch emissions by other means, through revising the method to determine affected facility status for storage vessels, and the alternative technology component of the fugitive program, and the super-emitter program. With the commenter, EPA encourages further development of technology to address sources of emissions such as thief hatches.

### **13.4 Miscellaneous Other Storage Vessel-Related Comments**

Comment: Commenters (2326-AXPC, 2399-GPA) request that EPA extend the implementation deadlines; particularly for sources which become NSPS OOOOb affected facilities between proposal and promulgation. Commenter (2326-AXPC) explains that until NSPS OOOOb is a final rule, those storage vessels that commenced construction, modification, or reconstruction after November 15, 2021 (“NSPS OOOOa/b Vessels”), are subject to NSPS OOOOa, which has a different applicability threshold than NSPS OOOOb. The commenter explains that this switch to a storage tank battery approach effectively reduces the storage vessel affected source threshold, meaning the same storage may not be an NSPS OOOOa affected facility but will be an NSPS OOOOb affected facility if the applicability criteria remain the same in the final NSPS OOOOb. For these storage vessels, the commenter is concerned that a new suite of new requirements will become applicable 60 days after publication of the final rule, but operators will require more than 60 days’ time to implement these requirements. The commenter provides by

way of example, that certifying the design of each storage vessel closed vent system could take weeks, and operators will need to hire staff to implement control device monitoring requirements. Additionally, the commenter states, the proposed control device monitoring requirements require extensive capital investment in equipment that is likely to be in short supply (e.g., calorimeters). The commenter anticipates that EPA may argue that operators are on notice of the requirements, but notes that the rule is not final and may change in its final form and therefore it is inappropriate and poor policy for EPA to require operators to undertake significant capital investment and personnel hiring for a rule that is not, and may never become, final simply to be in position to comply suddenly with requirements that may be materially different in the final rule. The commenter reminds EPA that similar issues were encountered for storage vessels under NSPS OOOO, and in that rulemaking, EPA recognized the infeasibility of compliance for storage vessels constructed following proposal and before publication of the final rule and provided an additional year for those storage vessels to comply. Alternatively, the commenter requests that if EPA is unwilling to provide extended initial compliance deadlines as requested, that EPA provide extensions where good cause exists, as it did under the recently promulgated Uintah and Ouray Indian Reservation Federal Implementation Plan (FIP) for oil and natural gas sources.

Commenter (2399-GPA) states that the December 2022 Supplemental Proposal added monitoring requirements for storage vessel control devices that were not included in the November 2021 Proposal, as the November 2021 Proposal only provided general concepts for monitoring, recordkeeping, and reporting requirements but did not propose anything specific. The commenter explains that unlike large, capital-intensive equipment, storage vessels can be put into operation quickly and that in fact, a significant number of new storage tanks have been operating since EPA published the November 2021 Proposal. The commenter points out that these storage vessels are currently operating without the newly proposed monitoring requirements, and if application of the monitoring requirements were to relate back to the November 2021 Proposal, these sources would need to be retrofitted for compliance equivalent to an existing source as the equipment necessary for compliance with the new monitoring requirements could not have been incorporated into their initial design. Therefore, the commenter requests that any date for storage vessel compliance be at least one year after the effective date of any final rule as this time is needed to determine what type of monitoring devices could be used for each specific application and budget for the additional equipment purchasing and installation. Given the large number of storage vessels used in the midstream industry the commenter states, retrofitting will take a significant amount of time and resources.

Response II-13-64: The commenter seems to imply that the 1-year phase-in 2012 was to allow sources to allow sources time to see what the final rule requires and then begin to plan for compliance. That is incorrect. The prior phase-in was to address the concern at the time about not having enough control systems for the number of tanks that would need control. 77 FR 49525-6 (2012).

The commenters appear to be concerned with the potential change in status or operating requirements for storage vessels that were constructed, reconstructed or modified after the 2021 proposal and prior to the 2022 supplemental proposal. The EPA clarifies that OOOOb applies to storage vessel tank batteries that are new or modified after the date of the supplemental proposal,

December 6, 2022 (87 FR 74702). Therefore, storage vessels that commenced construction, modification, or reconstruction after November 15, 2021, and before December 6, 2022, continue to be subject NSPS OOOOa and not OOOOb. There is no change in affected facility status for these storage vessels. See the preamble section IX.A for a discussion of the dates when new requirements apply.

Comment: Commenter (2296-NMED) requests that EPA provide sufficient time for owners and operators to comply with the control requirements as part of a phased compliance timeline. The commenter explained that during the NMED Part 50 rulemaking hearing, affected owners and operators and industry stakeholders raised concerns about having sufficient numbers of control devices available to implement controls simultaneously. To address this, the commenter states that NMED Part 50 imposes a phased compliance deadline in order to ensure there are sufficient control devices available over the course of the compliance timeline.

Response II-13-65: The EPA disagrees with the comment that additional time is required for facilities to meet the requirements of the final rule. The proposed rule of November 15, 2021 (86 FR 63110) gave sources sufficient notice that additional requirements could require additional control systems. Furthermore, the EPA has determined that the effective date for implementation of the final rule will be determined based on the supplemental proposal, December 6, 2022 (87 FR 74702). Given these two factors, the EPA considers the final effective dates and compliance dates as sufficient to achieve compliances.

Comment: Commenter (3846-GPA) presented an example to illustrate an issue they identified regarding initial compliance demonstrations for storage vessel affected facilities. The commenter provides the following example:

A tank battery is controlled by a tank vapor recovery unit (VRU) with LPE limits and emissions over 6 tpy, so the tank battery is a storage vessel affected facility. According to the standards, the owner or operator is required to install a control device and is subject to **“60.5412b What additional requirements must I meet for determining initial compliance of my control device?”** It appears that §60.5412b(a)(2) would be the section for VRU controls, but that section then references testing procedure requirements in 60.5413b and there doesn’t appear to be any testing procedures in 60.5413b that apply to tank VRUs.

The commenter questions whether the rule considers tank VRUs to be control devices and if so, how do they comply with performance testing requirements? If not, the commenter is concerned that this could inadvertently require sites with tank VRUs to unnecessarily install a combustor to comply with the rule.

The commenter also noted a potential oversight at 40 CFR §60.5365b(e)(5). The commenter believes this cite should include methane in addition to VOC for sites without LPE limits. Without it, the commenter believes that no tanks under the prescribed circumstance would qualify for the exemption.

Response II-13-66: A storage vessel affected facility is subject to the control requirements of 40

CFR §60.5395b. 40 CFR §60.5395b(b) specifies that if the owner or operator uses a control device to reduce emissions from the storage vessel affected facility, it must meet the cover and closed vent system requirements. 40 CFR 60.5395b(b) also allows that emissions may be routed to a process, as an alternative to routing emissions to a control device, but the same cover and closed vent system requirements apply. As explained in the September 23, 2013, final rule<sup>47</sup> EPA previously clarified<sup>48</sup> that VRUs which route recovered gas and vapor back to the process are not control devices. Emissions which are routed to a process are not subject to control device performance testing procedures. To clarify that the performance test requirements of 40 CFR §60.5413b do not apply to emissions routed to a process, EPA has amended the initial compliance requirements at 40 CFR §60.5410b(j) to specify the initial compliance requirements when routing to a process (and which do not include a performance test).

The EPA notes that if the VRU is required as part of a legally and practicably enforceable permit limitation (as described in the example above), there may be requirements in the permit which apply.

Regarding the addition of “or methane” to 40 CFR §60.5365b(e)(5), the EPA agrees and has made that change.

---

<sup>47</sup> See 78 FR 58241.

<sup>48</sup> Letter from Peter Tsirigotis to Matthew Todd, American Petroleum Institute. September 28, 2012. Docket Item No. EPA-HQ-OAR-2010-0505-4595.

## Chapter 14. Super Emitter Program

In the December 2022 supplemental proposal, this program was proposed under the name Super-Emitter Response Program (SERP), in the final rule, this program has been rebranded as the Super-Emitter Program. The responses in this chapter will address this program, as the Super-Emitter Program or as “the program”.

### 14.1 General Support and Opposition

Comment: Commenters (2212-On behalf of the Union of Concerned Scientists, 2296-New Mexico Environment Department (NMED), 2360-Devon Energy (Devon), 2392-Earthjustice et al., 2408-Colorado Local Government Coalition, 2410-California Office of the Attorney General et al., 2414-Carbon Mapper and RMI, 2442-Wyoming Coalition of Local Governments, 2453-Carbon Mapper and RMI, 2626-Kayrros, 2627-British Columbia Investment Management Corp. (BCI), 3389-First Focus on Children) broadly support EPA’s proposed SERP aimed at addressing large emission events from oil and gas facilities that significantly harm nearby communities. This innovative, first-of-a-kind initiative will combine third-party observations and direct operator notification of super emitter events with requirements for operators to conduct follow-up assessment and repair action.

Response II-14-1: EPA acknowledges the commenters support.

Comment: Commenters (2296-NMED, 2414-Carbon Mapper and RMI, 2627-BCI) support the Proposed Rule to prevent, detect and mitigate super emitter emissions events, which are some of the largest and most difficult to identify and fix. Methane leaks have significant consequences on the mix of greenhouse gases in the atmosphere, and its warming potential.

Commenter (2414-Carbon Mapper and RMI) adds the SERP can also identify potential issues with self-reported methane leakage with implications for EPA’s Methane Emission Reduction Program introduced in the Inflation Reduction Act (IRA). Similarly, the SERP will have the ability to flag gaps in EPA’s Greenhouse Gas Reporting Program (GHGRP), particularly for intermittent super emitters that often go undetected by traditional site-level monitoring, enabling improvements in overall methane accounting. While the SERP as proposed is limited to the onshore oil and gas production equipment included in the scope of this rule, it establishes a framework that encourages the use of persistent wide-area, high-resolution methane monitoring by satellites and other remote methods. One benefit of such systems is the ability to precisely geolocate methane point source emissions at adjacent infrastructure such as gathering pipelines, downstream natural gas operations, landfills etc, thus reducing the potential for misattribution to oil and gas producers. Another benefit, particularly for satellites capable of detecting methane over the ocean, is the ability to detect leaks and malfunctioning equipment at coastal processing and export facilities and offshore oil and gas platforms - thus offering more complete methane intensity verification of the US natural gas value chain with implications on US competitiveness in global markets. SERP-enabled precise location, quantification and transparent reporting of methane super emitters will offer significant climate benefits and additional co-benefits, such as

enabling improved assessment and communication of local impacts (both for operators and nearby communities) resulting from potential co-emitted pollutants such as VOCs and other health-harming air pollutants. Finally, the SERP will contribute to improved public confidence in mitigation progress by industry and government.

Commenter (2296-NMED) states the proposed rules are likely to affect thousands of sources in New Mexico. Effective, efficient and innovative compliance and enforcement strategies will improve overall rates of compliance, reduce harmful air pollution, and improve overall air quality and impacts on public health and the environment. Strategies could include the preparation and submittal of annual compliance certifications identifying specific areas of compliance and noncompliance with rule provisions and third-party audits of an operator's compliance with the rule, including the effectiveness of the operator's LDAR program.

Response II-14-2: EPA acknowledges the commenter's support and suggestions.

Comment: Commenters (2409-BP America Inc., 2446-Independent Petroleum Association of America (IPAA)) encourage the safe, accurate, and rapid identification and mitigation of large methane emissions events. If there are reliable, high-quality data indicating a significant methane leak at their facility, the commenters want to know about it. The commenters therefore support EPA's effort to design a SERP, so long as EPA (or a state with delegated authority) maintains a meaningful oversight role, ensures data quality and reliability, and retains discretion and accountability relating to compliance and enforcement.<sup>1</sup>

Commenter (2409-BP America Inc.) appreciates the effort by EPA to consider and incorporate feedback on the November 2021 proposed community monitoring program to inform the currently proposed SERP. The commenter is encouraged that EPA appears to have begun addressing feedback on critical issues including: the role EPA should play in a third-party program; the importance of safety and minimizing incentives for untrained, non-industry personnel to be out in the field; and incorporating operational and technical requirements for validated third parties. The commenter urges EPA to revise the program so that it: (1) reconceptualizes the respective role of third-party monitors and EPA, so that EPA retains its oversight authority; (2) incentivizes operators to respond to validated third-party notifications by encouraging responsiveness and protecting corrective actions; and (3) fosters accountability and transparency from all parties involved.

Response II-14-3: EPA acknowledges the commenters' support and suggestions. EPA has revised the final rule to include EPA in a central role for approving technology used and certifying the third parties participating in the program. EPA has revised the final rule to require the third party to submit super-emitter data to the EPA and then EPA will review this data before providing the notification to the owner or operator.

---

<sup>1</sup> In its proposal for reviewing third-party monitoring and detection technologies, EPA recognizes the importance of ensuring that "data quality objectives" are met. 87 Fed. Reg. at 74746. EPA should apply that same principle in reviewing and validating third-party monitoring data before that data is publicly reported. EPA should define its "data quality objectives," be transparent in how it plans to implement.

Comment: Commenter (2389-American Chemistry Council (ACC)) states it is critical that new monitoring programs and associated requirements are well-supported with clear and definite environmental benefits. As proposed, it is unclear if EPA has identified an adequate basis of environmental benefits sufficient to support a program of this sweeping and precedential nature. In the proposal, EPA notes that the program's objective is to "provide a comprehensive and effective remedy for large emission events that disproportionately contribute to methane emissions from the Crude Oil and Natural Gas source category" and may potentially impact nearby communities. EPA proposes this program as a backstop to help monitor and respond to these types of emissions events while avoiding additional significant and unnecessary inspection costs.

While this overall goal is commendable, Commenter (2389-ACC) is concerned that the environmental benefit of the EPA's super emitter program as proposed is not well-defined, resulting in a program that could carry significantly onerous implications with minimal actual benefits. EPA itself acknowledges this reality and states that it is "not currently able to quantify the emissions reductions likely to result from preventing or more quickly mitigating super emitter emissions."<sup>2</sup> Despite this, the proposed program would result in the creation of serious regulatory obligations for facility owners and operators that may or may not result in any emissions reductions. Given the important nature of such a new program, the commenter believes that the Agency should provide a more accurate and detailed description of the precise environmental benefits to support it.

Response II-14-4: EPA acknowledges the commenters' support and suggestions. The super-emitter program is designed to provide actionable (*i.e.*, EPA verified) data of a super-emitter event that would trigger a response by an owner or operator. There are no additional obligations for owner or operators than the required investigations into the potential cause of a large emission event as detailed in Section X.C and XI.C of the preamble of the final rule. Any other requirements on an owner or operator to either repair the cause(s) of the emissions, are already required by the applicable regulations.

Comment: Commenters (2177-Ute Indian Tribe, 2202-Texas Oil and Gas Association (TXOGA), 2218-Texas Commission on Environmental Quality (TCEQ), 2399-GPA Midstream Association) argue the proposed super emitter program is overly burdensome for states and should be removed from the final rule.

Commenter (2177-Ute Indian Tribe) argues due to the greatly varying technologies currently available that could theoretically detect a super emitter event, there is too much uncertainty for this to be a regulatory requirement. Operators should address any potential leaks that are brought to their attention on a timely basis (which they will likely do anyway as there is an economic incentive to keeping gas in the pipelines).

Commenter (2177-Ute Indian Tribe) states due to the in-ability of EPA to regulate the accuracy of remote-sensing aircraft, mobile monitoring platforms, or satellites to identify super emitter

---

<sup>2</sup> 87 FR 74747.

emissions events, this should not be a regulated program. These provide useful information that can be passed along to operators, but their response should not be regulated in this way.

Response II-14-5: EPA acknowledges the commenters' support and suggestions. EPA disagrees the program is burdensome on the states and the design of the program in the final rule put the responsibilities on the EPA to certify the third parties and the underlying technology used in this program. These steps have been put in place in the final rule to assure the accuracy of the super-emitter data being provided to the owner or operator to aid in their follow-up investigations.

Comment: Commenters (2283-Endeavor Energy Resources, 2301-U.S. Chamber of Commerce, 2366-Berkshire Hathaway Energy Corporation (BHE)) recommend that EPA remove this proposed program in its entirety from any final rule or defer action on this program to avoid unnecessary violations of law that would risk the durability of the Methane Proposal more broadly. As proposed, the provisions to ensure third-party notices are credible are inadequate and risk distracting or detracting from addressing real or more pressing environmental, health, and safety concerns without providing an environmental benefit. As currently proposed, the program would also force operators to spend significant resources on defending against even erroneous reports, including reports identifying the wrong operator or misidentifying compliant emissions events as unlawful). According to the commenters, their suggested revisions would not suffice to make the proposed program lawful and workable, although they would at least mitigate some problematic aspects of the program.

Commenter (2202-TXOGA) believes that, in order to provide the regulated community adequate notice of the proposed parameters of the Super emitter Program, EPA should initiate a separate rulemaking, backed by additional analysis, and propose anew a program, the elements of which, to include its legal basis, specific form, and likely effectiveness, are more clearly identified at the outset. The commenter believes that EPA's current approach is likely to lead to problems of "logical outgrowth" whatever form the final rule may take.

Response II-14-6: EPA acknowledges the commenters' support and suggestions. EPA has revised the final rule to better address expectations regarding investigations conducted by the owner or operators when they receive a super-emitter notification as detailed in Section X.C.2 and XI.C.4 of the preamble of the final rule. EPA considers these investigations to be necessary and appropriate for identifying if a super-emitter emissions event has happened or are ongoing.

## **14.2 Definition Changes**

### ***14.2.1 Super-Emitter Definition***

Comment: Commenter (2202-TXOGA) states rather like Schrödinger's cat, a "super-emitter" affected facility (or designated facility) would spring into existence only when someone (be it EPA, a delegated authority, or a private party) actually detects an ongoing "super emitter event" (i.e., ongoing emissions beyond the 100 kg/hr threshold) and then informs the relevant owner/operator of the existence of that ongoing event. Until this point in time, the facility is not an "affected facility." Thus, the actions of private, third-party notifiers would not only compel an

owner/operator to take action, but such action would also operate to “create” the “super emitter affected facility” (or designated facility) when it could not be said to exist prior to notification being made. Assuming that Clean Air Act (CAA) Section 111 does authorize defining “affected facility” and “designated facility” on the basis of contingent events, in the situation where private, third-party actors are left responsible for triggering the regulatory response in the first instance, it is that much more important to establish that the CAA grants authority to adopt such a program.

Response II-14-7: EPA acknowledges the commenters’ suggestions; the final rule no longer includes a super-emitter affected facility definition. The final rule would require owner or operators to determine whether the source of emissions could have been through equipment subject to either NSPS OOOO, OOOOa, OOOOb, or potentially, EG OOOOc.

Comment: Commenter (2258-Marcellus Shale Coalition (MSC)) objects to the usage of the term “super-emitter” as it sensationalizes these events and has been used to describe events of varying magnitudes from various different sources.

Response II-14-8: EPA disagrees that the term super-emitter is “sensationalism” and super-emitter is a defined term meaning a methane emission event with an emission rate of >100 kg/hr of methane which would trigger an investigation of the oil and natural gas facility (e.g., individual well site, centralized production facility, natural gas processing plant, or compressor station).

Comment: Commenter (2305-The Williams Companies, Inc.) have significant concerns by the EPA’s use of the term “super emitter.” The term can invoke incorrect conclusions about an owner, operator, or a facility for emissions activities likely already contemplated or accounted for in a facility’s existing air permit. EPA should consider aligning the term “super emitter” in this draft rule with “other large, release events” proposed in the draft Subpart W Rule to ensure consistency and avoid confusion and over-exaggeration of events that are the result of abnormal operations or equipment malfunction, and that typically occur on an intermittent basis.

Response II-14-9: EPA recognizes the commenters’ concern; however, we are maintaining the term super-emitter in the final rule. The term is defined a methane emission event with an emission rate of >100 kg/hr of methane which would trigger an investigation of a site. For that reason, it is essential that we have term that are different than what is used in other rulemakings (i.e., Subpart W) in order to distinguish what the required actions should be.

Comment: Commenters (2172-Kentucky Oil and Gas Association, 2354-Business Roundtable) state the Super emitter threshold is not well defined. EPA is proposing to apply the super emitter definition to a large emission event at an individual well site, centralized production facility, compressor station or natural gas processing plant. It is unclear if the threshold is for all combined emissions, specific emission unit or other grouping, so it will be difficult to determine what emissions would be considered under the super emitter definition and therefore who might be the responsible party. This raises additional complications regarding third-party notifications and whether notifications are valid.

Response II-14-10: The super-emitter term is assumed to be an aggregate site-level emission event given many of the remote detection technology expected to be applied to this program would not be able to identify component level emissions.

Comment: Commenter (2453-Carbon Mapper and RMI) states EPA should clarify the definition of “owner/operator” and “site” and specify the interval for evaluation when reviewing claims that “more than three notifications were made in error”. In one instance the proposed rule applies to “the same site” and in another “to that same owner or operator”. While more than three verifiable errors at a single production site in one month might be reasonable grounds for review, three errors across a population of hundreds of facilities over the course of a year would not be excessive considering statistical fluctuations inherent in a large number of samples.

Response II-14-11: The EPA has revised and better-defined criteria for when an owner or operator may petition the Administrator to remove a third-parties certification in the final rule, including the requirements where an owner or operator may petition the Administrator to remove a certification. An owner or operator may petition the Administrator after an owner or operator that has received more than three erroneous notices of a super-emitter event at the same well site, centralized production facility, or compressor station from the EPA that were submitted to the EPA by the same third party may petition.

EPA has also expanded the criteria for grounds on which a third-party certification could be removed to include a certified third-party notifier making material changes to their procedures for identifying super-emitter events without seeking recertification and when an the administrator finds that the certified third-party notifier has submitted data with significant errors (e.g., misidentification of the owner or operator) or if the third-party notifier has engaged in illegal activity during the during the assessment of a super-emitter event (e.g., trespassing).

Comment: Commenter (2172-Kentucky Oil and Gas Association) states EPA’s use of Tons, pounds, kilograms, per hour, per year is confusing and does not include a consistent basis used by the oil and gas industry. The commenter’s calculation concludes that 100 kg is approximately equal to 4.2 Mcf of pure methane.

Commenter (2172-Kentucky Oil and Gas Association) states a 4 Mcf in an hour release (100 kg/hr) trigger point could result in many reportable occurrences that are insignificant, not to mention very difficult to determine if such a small volume has been emitted. Super Emitter reporting would become an excessive burden for small operators who operate most of the small wells that when opened for maintenance could possibly emit 4 Mcf quickly but then drop to an undetectable flow. A small gas well that produces less than 10 Mcf/day, shut in prior to being opened for maintenance, might release 4 Mcf in its first few minutes. Further, the well probably would not vent 8 Mcf (200 kg) total during a 10-hour period it is open maintenance.

Commenter (2172-Kentucky Oil and Gas Association) states total Emissions from this type of event during what would be considered normal operations could qualify as a Super Emitter event requiring the operator to generate an unnecessary report that would include “root cause” and “corrective action” which would be known before the well is opened. The commenter does not

believe this type of event is what the EPA is trying to identify, nor asking third parties to help identify.

Commenter (2172-Kentucky Oil and Gas Association) recommends that the EPA modify the definition of Super Emitter and adopt a significantly longer period over which the emission is to occur before it is considered a Super Emitter. The type of event described above could be excluded by extending the time frame of the event, i.e., “averaging 4 Mcf/hour over a 4-hour period”, or an event that releases an excess of 100 Mcf to the atmosphere in a 24-hour period.

Response II-14-12: EPA acknowledges the commenters’ suggestions. EPA is maintaining the >100 kg/hr of methane detection criteria and it represents a threshold and not a total mass of emissions.

Regarding the commenters to concern that maintenance events may trigger a super-emitter response; EPA acknowledges these events could have been caused by maintenance events. The final rule is intended to provide additional information to an owner or operators when large emission events are identified to ensure the emission event has ended, in the case of a maintenance, those emissions should end upon completion of those maintenance events.

Comment: Commenter (2458-MiQ) the supplemental preamble states “Super emitter emissions events could also be from intentional venting as part of normal operations or maintenance. The proposed SERP discussed in this section is not intended to address these events.”<sup>3</sup> Given the ultimate intention of the SERP – to limit large-scale methane release events – the commenter recommends that EPA define emission events that are part of normal operations or maintenance, and place regulatory parameters on these event types. This recommendation is made so that this provision does not become a regulatory loophole whereby super emitter and intentional events become effectively interchangeable – thereby obviating the value of the SERP.

Response II-14-13: EPA recognizes the comment and agrees that a super-emitter event could be the result of an allowable emission. The goal of the Super Emitter Program is intended to inform an owner or operator when these large events occur, so an owner or operator could investigate and repair if necessary. Where the event is an allowable emission, the owner or operator would indicate that as part of the reporting requirement in the final rule and in the instances where those emission events were known process releases due to maintenance events.

Comment: Commenter (2428-American Petroleum Institute (API)) points to just a few months ago, when addressing essentially the same issue under Subpart W of the GHGRP, EPA proposed to establish a new reporting requirement for “other large release events,” which EPA proposed to define as “events that release at least 250 mtCO<sub>2</sub>e per event.”<sup>4</sup> In explaining its rationale for setting this threshold, EPA explains that, “[w]hile some sources covered by subpart W methodologies, such as equipment leaks, may represent “malfunctioning” equipment, these

---

<sup>3</sup> 87 Fed. Reg. 74747, fn 101.

<sup>4</sup> 87 Fed. Reg. 36920, 36982 (June 21, 2022)

sources are ubiquitous across the oil and gas sector [and] are generally small.”<sup>5</sup> The proposed 250 mt reporting threshold is intended to capture “large emissions events.”<sup>6</sup> EPA derived the value by assessing “other emissions sources that [it] considered large.”<sup>7</sup> The threshold was expressly designed to be considerably lower than the emissions rates estimated for the largest release events (e.g., Aliso Canyon or Ohio well blowouts), and compares favorably to a similar reporting requirement under Subpart Y for petroleum refinery flares.<sup>8</sup>

Commenter (2428-API) continues, despite the obvious similarities between the proposed Subpart W large emissions event proposal and the proposed NSPS OOOOb and EG OOOOc super emitter proposal, EPA fails to mention the Subpart W proposal when explaining in the NSPS OOOOb and EG OOOOc proposal its rationale for establishing the emissions threshold for super-emitting events. The omission is particularly striking given the significant differences between the two proposals as to what EPA believes to be a large-emitting event. For example, EPA proposes to apply a kg/hr metric in NSPS OOOOb and EG OOOOc versus an event-based metric for Subpart W. Additionally, the proposed NSPS OOOOb and EG OOOOc threshold of 100 kg/hr is facially much lower than the 250 mt per event threshold in Subpart W. The Subpart OOOOb and OOOOc proposal would define events as “super-emitting” that EPA in the Subpart W proposal dismisses as “ubiquitous” and “generally small.”

Commenter (2428-API) argues the two proposed rules are contradictory in many relevant aspects. EPA has not provided any explanation in the NSPS OOOOb and EG OOOOc original or Supplemental Proposals as to why the proposed definition of “super emitter” makes sense in light of the proposed rules for large event release reporting under Subpart W. Lack of such an explanation would render this aspect of the final NSPS OOOOb and EG OOOOc rule arbitrary and capricious. Moreover, even if EPA provides an explanation in the final rule, the definition of “super emitter” is of central relevance to the SERP and, thus, failure to provide an opportunity for public notice and comment on its explanation would violate the CAA § 307(d) procedural rulemaking requirements.

Response II-14-14: EPA acknowledges the commenters’ comments and suggestions, and EPA has chosen not to finalize the super-emitter affected facility under OOOOb and has redefined the program to better identify which sites would be subject to the rule. EPA acknowledges there are similarities in the GHG reporting rule and the NSPS rulemaking how these emission events are defined however the NSPS is distinctly different, as the goal of the Super Emitter Program is to provide information to an owner or operator as these emissions happen, so they may be remedied, if necessary.

Commenter (2326-American Exploration and Production Council (AXPC)) argues EPA’s proposed rule language lacks clarity regarding whether super-emitter events can only be identified at affected facilities covered by NSPS OOOOb (or upon adoption by the states, from designated facilities covered by EG OOOOc). In its preamble, the EPA makes numerous

---

<sup>5</sup> Id.

<sup>6</sup> Id.

<sup>7</sup> Id.

<sup>8</sup> Id. at 36983.

statements that indicate it intends that super-emitter emissions events can come only from NSPS OOOOb/c sources, including:

- the EPA's conclusion that a super-emitter emissions event that requires mitigation is one "either due to a failure to comply with one of the standards in this rule or due to an upset or malfunction at a source covered by this rule."
- Owners and operators would have the opportunity to rebut information provided by the third party, including that "the emissions event did not occur at a regulated facility."
- "Where compliance is achieved with the applicable standards, the EPA does not expect unintentional releases at these very high levels to occur in normal operation."
- "Super-emitter emissions events could also be from intentional venting as part of normal operations or maintenance. The proposed super-emitter response program discussed in this section is not intended to address these events."
- "[T]he super-emitter response program can be justified as part of the standards and requirements that apply to individual affected/designated facilities under this rule."

Commenter (2326-AXPC) states, despite the language from the preambles, the EPA's draft proposed regulations do not specifically state that the super-emitter emission events only occur at NSPS OOOOb affected facilities (or designated facilities). Rather, the EPA simply defines a super-emitter emissions event to be any source of emissions over the threshold "located at an individual well site, centralized production facility, or compressor station." Nowhere does the EPA make clear that it must be located at one of those facility types that is subject to NSPS OOOOb and also associated with/emitted from an affected facility – an intent the preamble makes clear.<sup>17</sup> However, if the EPA does have the authority to adopt super-emitter emission events regulations in a performance standard, such requirements would need to be relevant to and only apply to NSPS OOOOb affected facilities.

Response II-14-15: Super-emitter events can originate from sources that are not affected/designated facilities under NSPS OOOOb and EG OOOOc. Accordingly, the final Super Emitter Program requires the owner/operator who has received an EPA notice of a super emitter event to conduct an investigation of an oil and natural gas facility which could be the cause of the super emitter event identified in the EPA notice, and whether or not such equipment is subject to regulation NSPS OOOO, OOOOa, OOOOb, or a state or Federal plan implementing EG OOOOc.

Therefore, Commenter (2326-AXPC) argues if the EPA retains the super-emitter emissions event affected facility, it must revise the definition of a super-emitter emissions event to refer to those emissions above the threshold and associated with an affected facility subject to NSPS OOOOb. Thus, if a third party provides notification of an event over 100 kg/hour of methane, then only those events associated with an NSPS OOOOb affected facility (e.g., if above the thresholds: an unlit flare or combustion device associated with an NSPS OOOOb affected tank battery facility, a malfunctioning natural gas pneumatic controller, etc.) could potentially constitute a super-emitter emissions event and require an operator's corrective action or recordkeeping under NSPS OOOOb. Revisions to reflect this intent would need to be made throughout the provisions.

Commenters (2298-Pioneer Natural Resources USA, Inc., 2326-AXPC) state often under the CAA, the term "source" refers to the entirety of the stationary source. However, the use of the term source or emissions source throughout the super emitter provisions makes clear that EPA intends for the term source to mean specific equipment located at one of the specific types of stationary sources. In particular, it is clear EPA intended to apply the super emitter emissions event program to affected facilities as defined in NSPS OOOOb.

Response II-14-16: EPA has chosen to finalize the Super-Emitter Program as primarily a compliance assurance program. EPA's authority to regulate sources under CAA section 111 and its authority under CAA section 114(a) to require "any person who owns or operates any emission source" (except mobile sources) to provide information necessary for purposes of carrying out the CAA. EPA has revised the final rule as detailed in Section X.C and XI.C of the preamble of the final rule and has defined the responsibilities of the owner or operator to investigate large emissions from sites to determine if the causes are from equipment subject to from regulation under NSPS OOOO, OOOOa, OOOOb, or a state or Federal plan implementing EG OOOOc.

Comment: Commenters (2298-Pioneer Natural Resources USA, Inc., 2326-AXPC) note EPA's rule defines a super emitter emissions event as "any source of emissions" located at an individual well site, centralized production facility, or compressor station, with emissions detected above a certain rate.

Commenters (2298-Pioneer Natural Resources USA, Inc., 2326-AXPC) ask EPA to clarify that "source," as used in this section, refers to emissions above the threshold at any individual (e.g., storage vessel, pneumatic controller, etc.) affected facility. This clarification is important, because if there is no individual piece of equipment or activity emitting over 100 kg/hr, then it should not be considered a super emitter event - even if the methane concentrations from the entire source are greater than 100 kg/hr.

Response II-14-17: EPA is maintaining the definition of a super-emitter event from the December 2022 proposal and has clarified the responsibilities of the owner or operator to investigate large emissions from an identified oil and natural gas facility to determine if the causes are from equipment subject to from regulation under NSPS OOOO, OOOOa, OOOOb, or a state or Federal plan implementing EG OOOOc.

#### ***14.2.2 "Normal Operation"***

Comment: Commenter (2483-Interstate Natural Gas Association of America (INGAA)) notes as EPA acknowledges, normal operations and maintenance from intentional venting might exceed the proposed threshold of 100 kg/hr of methane.<sup>9</sup> Although EPA says the program "is not intended to address these events," owners and operators will nonetheless likely receive notices that stem from normal operations that will require at a minimum investigation and the filing of a

---

<sup>9</sup> 87 Fed. Reg. at 74,747 n.101.

report “explaining ... that ... the emissions event was not the result of malfunctions or abnormal operation that could be mitigated.”<sup>10</sup> This is unduly burdensome.

Commenter (2483-INGAA) notes EPA has stated that it “does not expect unintentional releases at [the 100 kg/hr threshold level] to occur in normal operations” and says “the occurrence of an unintentional release at this emissions rate should be unusual...”<sup>11</sup> Unfortunately, the 100 kg/hr threshold is too low, and commenter members believe that the reporting of emissions from normal operations will not be an “unusual” occurrence. Typical operational releases will exceed the 100 kg/hr threshold in some cases. These intentional releases, which include blowdowns, are performed for important safety purposes. EPA should consider revising the program to take into account the difference between continuous leaks (which are problematic and should be addressed) and events-based emissions (such as venting emissions during normal operation and maintenance) that are permitted. In any event, any final rule must make clear that an intentional, permitted release cannot ever be considered a “super emitter event.”

Response II-14-18: EPA acknowledges the suggestions and revised the defined the owner or operators’ requirements for responding to super-emitter notifications in Section X.C.2 and XI.C.4 of the preamble of the final rule.

One of these investigations steps is to evaluate any maintenance events or operational events that had been conducted in the timeframe of the super-emitter event. The goal of this program is not to prevent allowable maintenance or operational events from being conducted, but to inform an owner or operator when these large events occur, so an owner or operator can investigate, correct, and repair if necessary. The goal of this program is not to prevent these maintenance or operational event from being conducted and only to make sure that they do not become persistent emissions in the event a close-out is not adequately performed.

Comment: Commenter (2306-Citizen's Climate Lobby, 2444-NAACP) argue “normal operations” should never involve emissions over 100 kg/hr, so the proposed rule should remove this framing in section (c)(8) except for emissions under 100 kg total.<sup>12</sup>

Commenter (2444-NAACP) states this would change the current language of “Documentation that emissions were the result of allowed venting of emissions as part of normal operations, including routine maintenance (if applicable)” to “Documentation that emissions under 100kg total were the result of allowed venting of emissions as part of normal operations, including routine maintenance (if applicable).” This change clarifies that corrections under this program do not constitute “compliance” to earn any exemptions from the methane charge for those excess emissions.

Commenter (2306-Citizen's Climate Lobby) recommends changing “...emissions were...” to “...emissions under 100 kg total were...” This also makes clear that corrections under this

---

<sup>10</sup> Id. at 74,750.

<sup>11</sup> Id. at 74,749.

<sup>12</sup> Proposed Rule P.24 - 40 CFR 60.5371b(c)(8).

program do not constitute “compliance” to earn any exemptions from the methane charge for those excess emissions.

Comment: Commenter (2444-NAACP) argues “normal operations” should never involve emissions over 100 kg/hr, so the proposed rule should remove this framing in section (c)(8) except for emissions under 100 kg total.<sup>13</sup> This would change the current language of “Documentation that emissions were the result of allowed venting of emissions as part of normal operations, including routine maintenance (if applicable)” to “Documentation that emissions under 100 kg total were the result of allowed venting of emissions as part of normal operations, including routine maintenance (if applicable).” This change clarifies that corrections under this program do not constitute “compliance” to earn any exemptions from the methane charge for those excess emissions.

Response II-14-19: EPA acknowledges the commenters’ support and suggestions. However, EPA is aware that certain maintenance events could result in emission rates in excess of 100 kg/hr of methane, however these events are infrequent. EPA has structured the required investigation steps to determine the cause of these emissions, including identification of these infrequent maintenance events, and that they are not ongoing.

Note: EPA has chosen to finalize the Super-Emitter Program as primarily a compliance assurance program. A notification of a super-emitter event by EPA is not an allegation of a violation and is there to trigger an obligation to investigate by the owner or operator of an applicable oil and gas facility.

### **14.3 Rationale for Proposed Program**

Comment: Commenter (2410-California Office of the Attorney General et al.) states as EPA notes, the SERP would largely require owners and operators to undertake actions already required by other standards and requirements of the proposed rule in order to mitigate super emitter emissions events; the SERP would merely require that these actions be taken sooner, rather than waiting until they are detected by periodic monitoring.<sup>14</sup>

Response II-14-20: EPA acknowledges the commenters’ support and agrees that beyond the requirement for investigations, the requirements to mitigate any found emissions are already included under either the NSPS OOOO, OOOOa, OOOOb, or a state or Federal plan implementing EG OOOOc.

Comment: Commenter (2249-National Association of Clean Air Agencies) states EPA’s efforts to create streamlined pathways for data to be actionable for these events is laudable. However, aspects of the proposal remain concerningly ambiguous and could render the proposed program unworkable, counterproductive, and/or superfluous. The SERP is a novel program without precedent, that lies outside the usual delegation of authority to state and local air agencies that

---

<sup>13</sup> Proposed Rule P.24 - 40 CFR 60.5371b(c)(8).

<sup>14</sup> 87 Fed. Reg. at 74,753–54.

the CAA is built on. EPA should be more explicit in citing its specific authority to implement if it proceeds or make the program legally severable to protect the remainder of the methane proposal from court challenges. If EPA determines that it will not proceed with the SERP as proposed, there are many options available for EPA to leverage its own remote sensing and other detection programs. The IRA offers significant resources for satellite and other programs that EPA can use to detect super emitter events and situations. EPA may wish to augment its own detection programs with a focus on improved data accessibility and transparency, making information more readily and easily available for the public to access and understand, in ways that productively enable their engagement.

Commenter (2249-National Association of Clean Air Agencies) states if EPA chooses to proceed, numerous clarifications will be important prior to finalization. Although EPA has articulated that only applications leveraging remote sensing platforms are approvable, the supplemental proposal offers little clarity about the approvable sensing methods borne on these platforms. The proposal also offers little clarity about the necessary demonstrated expertise for third parties. Among other clarifications, EPA should be explicit that state and local clean air agencies can be presumed as qualifying; EPA should also offer a high level of clarity about other approved third parties. In addition, if EPA proceeds with this program, the agency should make transparent and publicly disclose what other qualified parties have been certified and provide more robustly considered and detailed description of how submitted data would be disclosed.

Response II-14-21: EPA acknowledges the commenters' input and in the final rule, we have provided additional structure in the rule explaining the qualifications of third parties and what these parties must submit to the EPA as part of the certification processes in Section X.C.2 and XI.C.2 of the preamble of the final rule. EPA has also revised the criteria for the which remote sensing technologies could be applied, including the approval of the technology used through the advanced methane technology program in the final rule.

Comment: Commenter (2249-National Association of Clean Air Agencies) adds EPA should consider whether its SERP in fact marshals the resources to address the largest, most concerning sources. EPA's supplemental proposal cites research that holds that the top five percent of sources account for over fifty percent of emissions (with results that vary by production basin), and that many of the provisions included in EPA's 2021 proposal and 2022 supplemental proposal would prevent most of these events (by requiring improved equipment and facility performance and by improving monitoring that can detect malfunctioning or improperly operated equipment.) EPA may wish to consider if the backstop program to augment these other provisions that would make more sense focuses on basin-wide detection and reporting, rather than specific equipment or facility reporting. Backstopping with detection and actionable reporting at the basin level, that would address multiple sources, would involve different detection methods, thresholds, and other parameters, but may serve as a more appropriate backstop that would trigger effective compliance assurance efforts by the appropriate agencies.

Commenter (2283-Endeavor Energy Resources) adds while EPA emphasizes the need for the SERP as an additional "backstop" due to the "significant impact[s]" of super emitter events and

the possibility that operator inspection programs may miss some such events,<sup>15</sup> the agency does not explain the need to supplement EPA's existing monitoring and oversight authority with private parties. Nor does EPA explain why private parties must also possess enforcement authority-in the sense that operators will be required to investigate and respond to a report super emitter event-to effectuate the stated goal of serving as a backstop in detecting and reporting potential super emitter events. The absence of an explanation to justify additional, borderline redundant monitoring is arbitrary and capricious.<sup>16</sup>

Response II-14-22: EPA recognizes the commenters' concern, with EPA in centralized role in the Super Emitter Program in the final rule, we have addressed the commenters oversight and enforcement authority concerns. EPA disagrees the Super Emitter Program is redundant monitoring and instead in complementary monitoring, and the program is intended to provide actionable (*i.e.*, EPA verified super-emitter event) information regarding a sites' emissions outside of an owner or operators typical monitoring frequency.

Comment: Commenter (2343-Institute for Policy Integrity at New York University School of Law) states while there are significant uncertainties related to predicting specific super emitter events, EPA should work to better quantify the net benefits of the SERP to the extent possible. While it is fully appropriate for EPA to consider the benefits of the SERP even if it is unable to fully quantify them,<sup>17</sup> EPA should consider whether it can provide a range of possible emissions reductions based upon the modeling information in Appendix D or other information. EPA should also consider performing a breakeven analysis to identify the minimum number of emissions reductions necessary to justify the program.<sup>18</sup> EPA should then explain why it believes the emissions reductions exceed the breakeven point.

Commenter (2343-Institute for Policy Integrity at New York University School of Law) states given that super emitter events have such large mass emissions rates (100 kg/hr or greater) and the SERP could decrease the length of these events significantly, its potential benefits stand to be quite large. Further, EPA estimates that the additional cost to regulated entities of a program that would merely require owners to perform a root-cause analysis and take corrective action if they are notified of a super emitter emissions event<sup>19</sup> stands to be quite small. EPA already

<sup>17</sup> See Exec. Order No. 13,563 § 1, 76 Fed. Reg. 3821, 3821 (Jan. 18, 2011) (affirming Exec. Order No. 12,866); accord Exec. Order No. 12,866 § 1(a), 58 Fed. Reg. 51,735, 51,735 (Sept. 30, 1993) ("Costs and benefits shall be understood to include both quantifiable measures (to the fullest extent that these can be usefully estimated) and qualitative measures of costs and benefits that are difficult to quantify, but nevertheless essential to consider."). Circular A-4 (2003), which provides further guidance on conducting regulatory analysis from the Office of Management & Budget, further cautions agencies against ignoring the potential magnitude of direct unquantified benefits, because the most efficient alternative may not have the "largest quantified and monetized . . . estimate." Circular A-4 (2003), *supra* note 10; see also EPA, GUIDELINES FOR PREPARING ECONOMIC ANALYSIS 7-49 (2014), <https://perma.cc/9JZH-FKK5> [hereinafter EPA ECONOMIC ANALYSIS GUIDELINES].

<sup>18</sup> See Circular A-4 (2003), *supra* note 10, at 2 (instructing that if the agency determines that the non-quantified benefits or costs are important, agencies should carry out a threshold or break even analysis to evaluate their significance and to "indicate, where possible, which non-quantified effects are most important and why"); EPA ECONOMIC ANALYSIS GUIDELINES, *supra* note 37, at 7-50 (discussing the appropriateness of using break even analysis).

<sup>19</sup> Supplemental Proposal, *supra* note 2, at 74,712 tbl.3.

determined that there would be “no associated monitoring cost for owners and operators” because “owners and operators do not bear the cost of monitoring and detecting super emitter emissions events.”<sup>20</sup> EPA’s choice to not quantify the impacts of this program thus likely leads the agency to again undercount the net benefits of the Supplemental Proposal.

Response II-14-23: EPA acknowledges the commenters’ input and has removed the root cause and corrective action requirement in the final rule. EPA has designed the investigation criteria in the final rule to minimize time and effort in identifying these large emission events, as they should be relatively easy to distinguish if they are ongoing as opposed to a fugitive monitoring inspection designed to identify much smaller leaks.

#### **14.3.1 Studies Supporting SERP**

Comment: Commenter (2284-Kairos Aerospace) cites Cusworth et al. (2021) (“Cusworth”) and Chen et al. (2022) (“Chen”) as works cited by EPA that are major advancements in our understanding of the emission contribution and frequency of large emissions. The commenter agrees with EPA’s decision to cite and include these papers in its thought process for both the FEAST modeling work as well as the SERP.

Commenter (2284-Kairos Aerospace) acknowledges EPA’s efforts to reflect the latest peer-reviewed science on leak distributions within its modeling. Many historical studies that rely on bottom-up inventory measurements fail to account for super emitter events at all. As more recent studies have demonstrated<sup>21</sup>, super emitter events are rare but can dominate the total amount of methane being emitted at the basin scale. By incorporating these latest results into its modeling, EPA ensured that it was incorporating the best available information upon which to base its decisions.<sup>22,23</sup>

Additionally, commenter (2284-Kairos Aerospace) states Sherwin et al. (2023) is the most comprehensive summary to date of aerial remote sensing campaigns, based on a dataset of nearly one million site-level measurements. This dataset is over three orders of magnitude larger than the Zavala-Araiza et al. (2017) dataset (informed by several hundred ground-based, downwind measurements) which informed the leak generation rate of large emitters in EPA FEAST modeling.

Commenter (2284-Kairos Aerospace) states the current impact of EPA FEAST modeling underestimating the impact of large emitters is that alternative technologies with higher detection limits than the current BSER of OGI will have their real-world effectiveness underrepresented during modeling. This will unfairly favor routine OGI inspections during modeling and make it challenging for alternative technologies to achieve equivalency thresholds. By accurately

<sup>20</sup> Id. at 74,752, 74,755.

<sup>21</sup> Cusworth et al., 2021, Chen et al., 2022

<sup>22</sup> Cusworth, D.H., Duren, R.M., Thorpe, A.K., Olson-Duvall, W., Heckler, J., Chapman, J.W., Eastwood, M.L., Helmlinger, M.C., Green, R.O., Asner, G.P., Dennison, P.E., Miller, C.E., 2021. Intermittency of Large Methane Emitters in the Permian Basin. Environ. Sci. Technol. Lett. <https://doi.org/10.1021/acs.estlett.1c00173>

<sup>23</sup> Chen et al. 2022

accounting for the presence of these large emitters, the benefits of an alternative screening method with the ability to screen many sites rapidly will be more accurately described. In addition, modeled mitigation results will likely more accurately reflect what is commonly accepted regarding methane emissions in that the large emissions make up a disproportionate number of total emissions in a given basin / asset base.

Commenter (2284-Kairos Aerospace) continues, producing high quality studies such as these often requires some form of partnership between an agent capable of collecting measurements at scale (e.g., a company or government entity), and academic researchers positioned to produce transparent data-driven analysis and conclusions unbiased by commercial motivations.<sup>24</sup> This process is further backed by peer-review and publication in reputable scientific journals. The commenter strongly encourages EPA to continue to consider similar quality evidence of emission distributions to ensure policies are based upon the best available data and independently derived science. Studies that lack independent authors without a commercial interest are a fraught starting point for high quality, science-backed policy.

Commenter (2284-Kairos Aerospace) adds FEAST modeling results showed that due to their rarity, a single generated large-emitter had a marked impact on simulation results if it were to be generated. Introducing a higher probability of generating large emitters in FEAST modeling may alleviate some of the requirements for a high number of simulation rounds carried out by the EPA FEAST modeling.

Commenter (2284-Kairos Aerospace) also notes EPA modeling captures the full distribution of emissions by constructing model plant representations from three separate distributions (fugitive emissions components, tanks, and large emitters). Of particular interest is the emissions distribution for the large emitters, which was generated by augmenting the Cusworth et al. (2021) dataset with a lognormal distribution between 10 kg/hr and 70 kg/hr to account for deterioration of detection capabilities below 70 kg/hr.

Commenter (2284-Kairos Aerospace) continues, new evidence from Sherwin et al. suggests that 1.7%, 3.4% and 4.3% of site-level emissions are above 10 kg/hr, for the Appalachia, Denver-Julesburg and Permian basins respectively. With the probability of generating a large emitter in the FEAST modeling carried out by the EPA at 2% maximum, this suggests that the EPA FEAST modeling underestimates emissions from large emitters, especially in basins prone to larger emissions such as the Permian Basin.

Response II-14-24: EPA acknowledges the commenters' input.

Comment: Commenter (2284-Kairos Aerospace) states this supposition is driven by the possible intermittency of super emitters. Cusworth et al. (2022) find short-lived, large sources to contribute a significant amount (~40-50%) of basin-scale methane. Less frequent surveys (even ones using advanced screening technologies) could completely miss these short-duration

---

<sup>24</sup> e.g., Tyner & Johnson, 2021; Cusworth et al., 2021; Chen et al., 2022

emissions if they start and end between surveys. The probability of this happening grows as the survey frequency decreases, which in turn leads to an underestimate of total emissions.

Commenter (2284-Kairos Aerospace) adds less frequent surveys will still find large emissions, but they will also be less constrained in quantifying its duration (and thus the summed volume of methane emitted). At monthly frequency, there is a tighter window within which it is possible for a detected emission to be leaking. With decreasing survey frequency, the impact of the detected emission will not be as well understood. It could be emitting for a shorter or longer period than assumed, and thus be over OR underrepresented. In the words of the study authors themselves, “A revisit strategy with long revisit intervals (e.g., months) would not be able to easily distinguish between these timescale categories and could potentially miss a sizable contribution from short-lasting emission sources.” This points to an additional benefit from the high frequency survey programs (even when using fewer sensitive instruments) that are potentially underrepresented in EPA’s FEAST modeling.

Response II-14-25: EPA acknowledges the commenters’ feedback and agrees that more monitoring would increase the identification of these large emission events.

Comment: Commenter (2433-EDF et al.) states new studies published in the year since EPA issued its initial proposal have only further solidified the problem posed by super emitters, documenting the widespread existence of sources emitting at or well-above EPA’s proposed super emitter threshold of 100 kg/hr. A study by Chen et al. released in March 2022 found that just 118 out of 958 sources surveyed in the Permian Basin using an aerial monitoring program were responsible for 50% of total emissions from the region.<sup>25</sup> Another study released in July 2022 found that super-emitting sources were responsible for nearly 40% of total methane emissions between 2019 and 2021 across five major oil and gas basins: the San Joaquin Valley in California, the Uinta Basin in Utah, Denver-Julesburg Basin in Colorado, the Permian Basin in Texas and New Mexico, and the Marcellus Shale Basin in Pennsylvania.<sup>26</sup> The study included super-emitting sources from oil and gas production, wet manure from animal feedlots, large landfills, and coal mine venting, but found that oil and gas production sources made up the majority of super emitters in almost every basin except the Marcellus Shale, which was more heavily influenced by coal mine venting.<sup>27</sup>

Commenter (2433-EDF et al.) states recent measurement-based studies again confirm that total oil and gas emissions are much higher than official estimates.<sup>28</sup> This discrepancy is attributed to

---

<sup>25</sup> Chen et al., Quantifying Methane Emissions in New Mexico Permian Basin, *supra* note 196.

<sup>26</sup> Daniel H. Cusworth et al., Strong Methane Point Sources Contribute a Disproportionate Fraction of Total Emissions Across Multiple Basins in the United States, 119 *Proceedings of the Nat’l Acad. of Scis.* 1, 1–4, 6 (2022), <https://www.pnas.org/doi/10.1073/pnas.2202338119> [hereinafter “Cusworth et al., Strong Methane Point Sources “].

<sup>27</sup> *Id.* at 3–4.

<sup>28</sup> Sherwin et al., *supra* note 166 (combining Carbon Mapper and Kairos surveys with an expanded version of the emissions simulation tool from Rutherford et al. 2021 to “infer emissions inventories for six regions in the United States comprising 52% of onshore oil and 29% of gas production over fifteen aerial campaigns. Total estimated

“low-probability but high-consequence sources [that] can contribute the majority of methane emissions from an oil and gas producing region” but that are not well characterized in official inventories.<sup>29</sup> These studies underscore that addressing super emitters is centrally important in efforts to drive down total emissions.

Commenter (2433-EDF et al.) notes studies have also identified and quantified ultra-emitters.<sup>30</sup> These sources are responsible for some of the largest methane plumes ever observed. An international study released in July 2022 used global satellite monitoring data to identify multiple ultra-emitters in the Permian Basin with emission rates ranging from 700 kg/hr up to a whopping 24,000 kg/hr.<sup>31</sup> NASA satellite monitoring data from the Earth Surface Mineral Dust Source Investigation mission has also identified at least one ultra-emitting facility in the Permian Basin with a recorded emissions rate of 18,300 kg/hr of methane released.<sup>32</sup>

Commenter (2433-EDF et al.) notes despite the significant contribution of these sources to overall methane pollution, these emission events can be difficult to capture through periodic monitoring programs because they tend to be intermittent and unpredictable.<sup>33</sup> Indeed, we explained in our comments on EPA’s initial proposal that regular LDAR can fail to capture super emitters, especially within the timeframe required for mitigation.<sup>34</sup> For instance, if a super emitter source at a well site starts leaking after an inspection, it could continue to leak 100 kg/hr

---

emissions range from 9.63% of natural gas production, roughly nine times the US government estimate, to 0.75% in a high-productivity gas-rich region.”); William Kunkel et al., Extension of Methane Emission Rate Distribution for Permian Basin Oil and Gas Production Infrastructure By Aerial LiDAR, Earth ArXiv (2023) (preprint), <https://eartharxiv.org/repository/view/4895/> (Carbon Mapper and Bridger measurements in the Permian at 7,920 oil and gas production facilities increase the total emission rate for the survey region by a factor of 3.0 after controlling for scale factors such as survey area and number of scans per facility); Matthew Johnson et al., Creating Measurement-Based Oil and Gas Sector Methane Inventories Using Source-Resolved Aerial Surveys, Rsch. Square (2022) (preprint), <https://www.researchsquare.com/article/rs-2203868/v1>.

<sup>33</sup> 2022 Joint Environmental Comments, *supra* note 1, at 63. See also Cusworth et al., Strong Methane Point Sources, *supra* note 201, at 5; 87 Fed. Reg. at 74747.

<sup>34</sup> See, e.g., 2022 Joint Environmental Comments, *supra* note 1, at 68. See also Cusworth et al., Strong Methane Point Sources, *supra* note 201, at 6; 87 Fed. Reg. at 74747 (explaining that periodic LDAR can miss these emission events).

unabated for three months—the period of time between quarterly inspections. That would equate to over 17.5 million metric tons of CO<sub>2</sub>-e, or the annual emissions of 5,400 passenger cars.<sup>35</sup>

But, as noted above, many sources emit well above even EPA’s 100 kg/hr threshold. For example, a 2018 natural gas well blowout in Ohio was initially estimated to have a leak rate of 100 million cubic feet of natural gas per day—twice that of the Aliso Canyon leak. For the next twenty days, the well emitted an estimated 60,000 tons of methane.<sup>36</sup> From a climate standpoint, this amount is larger than some entire countries’ annual emissions and is equivalent to the emissions of one million passenger vehicles driven for a year.<sup>37</sup> Moreover, super emitters are widespread across the oil and gas sector, encompassing numerous sources scattered over broad geographic areas.<sup>38</sup> New studies from 2022 have identified large emission events at well sites, gas processing plants, compressor stations, storage tanks, and gathering pipelines.<sup>39</sup> As a result, there is a significant need for EPA’s standards to address super emitters.

Commenter (2433-EDF et al.) states there are a number of individuals and institutions that are already tracking super emitters, so it is efficient and practical for EPA to develop approaches that can leverage these independent data sources to quickly mitigate huge emission events. As discussed above, scientists have been studying super emitters for years and have gathered substantial amounts of data on the sources and locations of these emitters. Multiple organizations have also developed programs to identify super emitters, collecting information on the location, facility type, and emission rates of these sources across the oil and gas industry.<sup>40</sup> For instance both Carbon Mapper and EDF’s PermianMAP project provide interactive maps with the location and emission rate of methane emitting sources.<sup>41</sup> Satellites under development will also soon provide information on the location of super emitter events. Even other federal and international

Reg. at 74748 (stating that the most widely known sources of super emitter events are controlled tank batteries, flares, natural-gas driven pneumatic controllers, and fugitive emission components).

<sup>40</sup> See, e.g., Benjamin Hmiel et al., Empirical Quantification of Methane Emission Intensity from Oil and Gas Producers in the Permian Basin, 18 *Env’t Rsch. Letters* 024, 029 (2023), <https://iopscience.iop.org/article/10.1088/1748-9326/acb27e> [hereinafter “Hmiel et al., Empirical Quantification of Producers in the Permian Basin”].

<sup>41</sup> Carbon Mapper, Data Portal, *supra* note 214; EDF, Permian (MAP), *supra* note 214.

agencies have been collecting data on super emitters, including NASA’s Jet Propulsion Lab and the United Nations Environment Programme’s Methane Alert and Response (MARS) program.<sup>42</sup> States are also beginning to conduct monitoring for super emitters. California plans to deploy satellites, starting with two launches this year, to monitor for plumes of carbon dioxide and methane across the state.<sup>43</sup>

Commenter (2433-EDF et al.) states utilizing this kind of independent monitoring information to identify major emission events and help to ensure action to eliminate them also makes sense from a practical standpoint. As the industry faces increasing scrutiny for its emissions, owners and operators will have bigger incentives to avoid detecting and disclosing large emissions.<sup>44</sup> Independent, third-party monitoring data can help to build confidence that efforts to reduce emissions are working. These data can be an important addition to the current industry self-reporting systems, under which numerous studies show that actual emissions are far higher than official estimates and do not align with operators’ stated actions and goals.<sup>45</sup>

Commenter (2433-EDF et al.) states these types of independent checks and mandatory reporting and corrective action programs like SERP are well established and consistent with past EPA practice. For example, EPA, along with the U.S. Coast Guard, administers the National Response Center program, which houses a reporting hotline that allows members of the public to report spills and discharges of oil and other dangerous and hazardous material.<sup>46</sup> Reports to the hotline can trigger obligations on the part of EPA, the Coast Guard, and other federal agencies, as well as responsible facilities, to investigate and, where necessary or appropriate, take action to clean-up and mitigate the spill or discharge in accordance with the National Contingency Plan.<sup>47</sup> EPA also issued fenceline monitoring standards for petroleum refineries in 2015 that require refineries to set up systems around refinery fencelines to monitor for benzene as an indicator pollutant for other hazardous pollutants.<sup>48</sup> If monitoring shows that benzene levels exceed a certain threshold,

<sup>46</sup> U.S. Env’t Prot. Agency, National Oil and Hazardous Substances Pollution Contingency Plan (NCP) Overview (last updated Mar. 25, 2022), <https://www.epa.gov/emergency-response/national-oil-and-hazardous-substances-pollution-contingency-plan-ncp-overview> [hereinafter “EPA NCP Overview”]. See also 87 Fed. Reg. at 74749.

<sup>47</sup> *Id.*; See also 40 CFR, pt. 300, subparts D & E; *id.* § 300.185 (providing for non-governmental participation in response efforts).

<sup>48</sup> 40 CFR § 63.658; 87 Fed. Reg. at 74748 (citing 79 Fed. Reg. 36880, 36920 (Jun. 30, 2014)).

the refineries are then required to conduct a root cause analysis and take corrective action.<sup>49</sup> Refineries also must report their fenceline monitoring data to EPA, which makes the data publicly available on its Enforcement and Compliance History Online (ECHO) site.<sup>50</sup> Other federal agencies have also developed similar third-party programs to assess compliance with a wide variety of regulations, from food safety and labeling to energy and water efficiency standards.<sup>51</sup>

Commenter (2433-EDF et al.) states SERP, as well as the EPA programs noted above, all build on the longstanding and well-established role that independent parties have played in reporting potential violations of CAA standards to EPA. “Reports from the public have led to state and federal enforcement cases and ultimately served environmental protection well.”<sup>52</sup> To that end, EPA has long “invite[d]” independent third parties to assist the agency in carrying out its environmental protection duties under the CAA “by identifying and reporting environmental violations” via its online Report an Environmental Violation webpage or by contacting relevant regional staff.<sup>53</sup> EPA’s online reporting tool is housed in the agency’s ECHO database, which includes EPA, state, local, and tribal compliance and enforcement records that are reported to EPA national databases.<sup>54</sup>

Response II-14-26: EPA acknowledges the commenters’ input and support for the Super Emitter Program.

### ***14.3.2 Existing State Plans***

Comment: Commenter (2220-Wyoming Department of Environmental Quality (WDEQ)) questions the fundamental basis for the proposed SERP. In accordance with Wyoming’s Environmental Quality Act (W.S. §§ 35-11-101 et seq.), the commenter has a well-established, well-functioning complaint process through which third parties and members of the general

public can report any pollutant emission event of concern, regardless of whether it is a large-scale or small-scale event. The agency's compliance program promptly handles inspections and investigations, addressing any identified issues. Requiring that an EPA-approved third-party entity notifies operators of a potential super-emitting event convolutes the compliance process and diverts both WDEQ and operator resources from providing a more-immediate follow-up to correct the issue and also redirects resources away from other critical work.

Response II-14-27: EPA recognizes the commenter's concern and in the final rule, a third party must now submit notifications to the EPA, which has the obligation to review the data prior to submitting information to the owner or operator. The obligation to conduct investigation is on the owner or operator of an oil and gas natural facility and there isn't an expectation on a state, local, or tribal agency to investigate.

Comment: Commenters (2240-Rose Rock Environmental Services, LLC, 2292-West Virginia Attorney General et al.) note EPA proposes cutting States out of the process for dealing with super emitter events altogether.<sup>55</sup> Right now, when a large-emission event is detected, States are notified. States then review and respond to the event accordingly. But under EPA's Supplemental Proposal, third parties who identify large methane leaks would notify owners and operators directly. That notice then obligates the plant's operators to conduct a root-cause analysis and take corrective action. (Id) The States are effectively cut out of the process. Perhaps States may play some tag-along role in following up with the companies after they respond to a compulsory super emitter notice. But other than that minimal bit, States are effectively sidelined. Commenters (2292-West Virginia Attorney General et al.) further believes that EPA does not have authority to implement a SERP of this kind at all. But that fundamental problem aside, the agency's failure to consider the present role of States in performing these functions is emblematic of the Supplemental Proposal's lack of concern for the federalism principles built into the CAA.

Response II-14-28: In the December 2022 supplemental proposal, there was not an intent to "cut" the states out of the process and the program was designed to provide actionable data (*i.e.*, EPA verified super-emitter event data) to an owner or operator without delay. EPA has received many comments explaining how this approach is problematic, is finalizing the rule with EPA is a centralized position to take in notifications from third parties through a public facing Super Emitter Portal, built with transparency in mind. The goal of this program in the final rule is to inform owner or operators when these large emission events happen in a short time frame, and the Super Emitter Portal is the mechanism for informing them as well as the local authority and public at large.

Commenter (2240-Rose Rock Environmental Services, LLC) states there are no guidelines in the proposed rules for how third-party monitoring should be conducted and no process to verify findings before making them publicly available. States typically have programs in place for citizens to file complaints regarding emissions from a regulated facility. The States are in the best position to address such issues under their current rules and regulations. Commenter (2240-

---

<sup>55</sup> 87 Fed. Reg. at 74,747.

Rose Rock Environmental Services, LLC) argues states typically have programs in place for citizens to file complaints regarding emissions from a regulated facility. The States are in the best position to address such issues under their current rules and regulations. The SERP should be removed from the proposed rule.

Response II-14-29: EPA acknowledges the commenter's views, and in the final rule EPA has developed a mechanism to verify data submitted to the EPA through the Super Emitter Program. For awareness, this program is not designed for citizens to file "complaints". EPA has chosen to finalize the Super-Emitter Program as primarily a compliance assurance program. A notification of a super-emitter event by EPA is not an allegation of a violation and is there to trigger an obligation to investigate by the owner or operator of an applicable oil and gas facility.. Also, the Super Emitter Program is not intended to replace any state, local, or tribal authority address complaints received by the general public.

Comment: Commenter (2296-NMED) states New Mexico's Part 50 rules allows for agency-approved alternative monitoring plans to address equipment leak requirements through equally effective methods, incenting industry, spurring technology development, and reducing waste. The rules allow the commenter to terminate such a plan if it finds the owner or operator failed to comply with any of the plan's provisions and did not promptly notify NMED. Similarly, EPA should follow the commenter's rules embrace of fuel cells as an air pollution control device, a climate and air quality solution which also reduces waste. Like NMED's Part 50 rules, EPA should establish that violations of the proposal are prohibited activities and provide that credible evidence obtained by the agency or provided by a third-party may be used as a basis for establishing whether a violation occurred.

Response II-14-30: EPA recognizes the commenters take, however EPA has chosen to finalize the Super-Emitter Program as primarily a compliance assurance program. A notification of a super-emitter event by EPA is not an allegation of a violation and is there to trigger an obligation to investigate by the owner or operator of an applicable oil and gas facility. Receiving a Super Emitter Program notification from the EPA triggers a responsibility of the owner or operator to investigate the cause of the emission event, if the investigation identifies a deviation of a regulation, then they would be required to repair and report as required by the applicable federal regulation.

### ***14.3.3 Super Emitter Events are Predominantly Infrequent and Short-Duration***

Comment: Commenter (2315-New York State Department of Environmental Conservation (DEC)) does not believe that EPA has adequately addressed super emitters in this proposal. A range of studies published between 2013 and 2015 characterize super emitters as a small portion of sources emitting a larger portion of emissions.<sup>56</sup> This does not necessarily mean each of these sources emit at the level EPA has determined as the super emitter threshold. While the proposal

---

<sup>56</sup> Brandt, A.R., et al. 2014. Methane Leaks from North American Natural Gas Systems. Science. Vol. 343; Miller, S.M., et al. 2013. Anthropogenic Emissions of Methane in the United States. Proceedings of the National Academy of Sciences. December 10, 2013.

may identify large emission sources in areas where third-party entities may want to monitor, it does not account for the various smaller sources that may be hard to reach nor accessible by the public.

Response II-14-31: EPA acknowledges the commenters' input. EPA has developed this program in response recent studies, which indicate a small portion of sources contribute ~50 percent of the methane emission in the oil and gas sector, and on a global scale, the largest of these emissions sources globally, may represent as much as 12% of global methane emissions from oil and gas production and transmission. The goal of this program is to identify when these large emission events as they, so they can be identified and mitigated, if necessary.

Comment: Commenter (2258-MSD) states a sound program addressing the largest sources of methane emissions can have significant environmental benefits. However, as recent experience with flyovers in Pennsylvania has demonstrated, most of the large emission sources are not from oil and gas operations. If U.S. EPA believes that a SERP is warranted, it should be a stand-alone program addressing all such sources and should not be limited to the oil and gas sector.

Response II-14-32: EPA recognizes the commenters' thoughts, this rule is limited to the oil and gas sector, however EPA may choose to evaluate similar programs for other sectors later and through notice-and-comment rulemaking.

Comment: Commenter (2353-CrownQuest Operating, LLC.) argue the following studies lean on the tail-heavy site emission distribution to suggest that only a small number of "super emitter" sites are responsible for most of the oil and gas industry's emissions.

- Super emitters in Natural Gas Infrastructure are Caused by Abnormal Process Conditions
- Assessment of Methane Emissions from the US Oil and Gas Supply Chain
- Intermittency of Large Methane Emitters in the Permian Basin
- Closing the Methane Gap in US Oil and Natural Gas Production Emissions Inventories
- Quantifying Regional Methane Emissions in the New Mexico Permian Basin with a Comprehensive Aerial Survey

Commenter (2353-CrownQuest Operating, LLC) states however, the EPA assumes that the requirements in the OOOOb/c rule would reduce the number of super emitter events when none of the referenced studies show any research to indicate such a conclusion. The referenced studies gathered data on emissions but not on inspections. Essentially, the EPA hopes to avoid super emitter events by increasing inspection frequency. However, they present no research that would suggest such a correlation.

Commenter (2353-CrownQuest Operating, LLC.) notes in the rule's preamble, the EPA admits that "a cost-effective inspection program can therefore miss some of these super emitter events, even if implemented in accordance with the proposed standards."<sup>57</sup> The EPA's analysis of the proposed rules would not eliminate most super emitter events. Furthermore, the EPA states in the

---

<sup>57</sup> Preamble pg. 152.

preamble that many high-rate events are due to human error, such as the pumper accidentally leaving a valve or hatch open after maintenance. Most of the time, these events are unpredictable but quickly resolved when discovered shortly after by existing operating practices.

Commenter (2353-CrownQuest Operating, LLC.) states the oil and gas industry already has a financial incentive to prevent such accidental losses and voluntary industry initiatives to reduce the frequency of such events. Additionally, there is little evidence to show that more frequent inspection decreases the frequency of these events or increases discovery. As previously proposed, most events are due to human error and are discovered soon after the error happens by the person that caused it. To say that quarterly inspections at a well site would decrease the chances of a super emitter is not backed by research.

Response II-14-33: EPA acknowledges the commenters' input and EPA disagrees with the assumption that additional monitoring would not lead to more large emission events being identified. The goal of this program is to provide owners or operators with actionable information that a large emission event has been detected, so that an owner or operator can investigate the cause and if necessary, eliminate the emission.

Comment: Commenter (2336-Kuva Systems) is not aware of any study suggesting that all super emitters are persistent as currently modeled. Instead, plane-based studies have for several years concluded that super emitters are predominantly intermittent. A major shortcoming of these plane-based studies is that the duration of super emitters is poorly characterized as measurements are taken very infrequently, often several days apart. Moreover, it is not clear if emissions that are characterized as persistent by plane detections are really persistent or if they are intermittent and just happen to emit on a second overflight. More recently, continuous monitoring has been used to investigate the intermittency of super emitters more closely. Of particular interest is the study from Wang et al.<sup>58</sup> that published a table showing the duration of super emitters based on studies in two production basins, reproduced below:

[Figure 1]: Reproduction of Figure 5 of Wang et al. showing leak durations and wait times as observed by continuous monitoring devices in 2 N. American basins

Commenter (2336-Kuva Systems) states a shortcoming of this study was that the emissions were not attributed to equipment groups and that the study was limited to two production basins. In order to address these gaps Kuva Systems employees conducted an analysis of the intermittency of super emitters for Kuva cameras that are installed at Kuva customers in the USA oil and gas industry.

Commenter (2336-Kuva Systems) notes the evaluation included 25 Kuva cameras located at sites in five different oil and gas production basins in the United States (Permian Basin, Eagleford, East Texas, North Dakota, and Oklahoma). The sites were all complex upstream production sites, except for one gas processing facility and one compressor station. Each site had one or

---

<sup>58</sup> Wang et. al. "Multiscale Methane Measurements at Oil and Gas Facilities Reveal Necessary Frameworks for Improved Emissions Accounting", <https://pubs.acs.org/doi/full/10.1021/acs.est.2c06211> (Oct. 6, 2022).

more Kuva cameras installed for a period of 2 to 18 months. The camera took images of each field-of-view every 30 seconds to 3 minutes as long as environmental conditions were within the operating envelope. The objective of the study was to analyze the duration and frequency of sites that exhibit super emitters. The goal was not to analyze the frequency of occurrence of super emitters. Therefore, the selection criteria for cameras to be included in this study was that they had at least one super emitter event occur since their installation. A super emitter event was defined as an emission of approximately 10 kg/h or larger. The study was performed at the beginning of February 2023.<sup>59</sup> All super emitters from these sites were attributed by visual review of the images to the following four equipment types: compressors, controlled tanks, separators, and flares.

Commenter (2336-Kuva Systems) states Figure 2 below shows independent time series of representative monitoring cameras from their date of installation, showing emission signatures for flares, tanks, and one separator. The figure shows the irregular short- and long-term behavior of super emitters for all three equipment types.

Commenter (2336-Kuva Systems) states Figure 3 shows the temporal distribution of the super emitter events detected by Kuva cameras. Over 1,000 events were detected by the subset of 25 installed cameras. We find a mean super emitter duration of 21 minutes for all equipment types, and a standard deviation of 43 minutes. These values confirm the general distribution of super emitters as shown by Wang et.al. and they demonstrate that this distribution holds true for tanks, flares and separators and for five production basins.

Substantially all super emitters had a duration of less than one day. We therefore recommend for EPA to use a “duration” factor of one day as part of EPA’s FEAST simulations.

[Figure 2: Example timelines of emission events for a representative set of installed cameras, from date of installation (Day 0) through 3-4 months of continuous monitoring operations. Cumulative daily operations are shown as individual columns, with each event category shown as a different color, with a length equal to the percentage of a 24-hour for each category. Super emitter events are in almost all observed cases less than a day long and generally constitute 1%-10% of a day in cumulative duration (15 minutes to ~ 2 hours).]

[Figure 3: Histogram of super emitter event durations by equipment type. The distribution contains over 1,000 self-defined “super emitter” events from 25 individual cameras installed at a variety of upstream production facilities. The emitter distribution has a mean duration ( $\mu$ ) of 21 minutes and a standard deviation ( $\sigma$ ) of 43 minutes.]

Response II-14-34: EPA acknowledges the commenters’ input for the Super Emitter Program. EPA recognizes the intermittency of these events and increase monitoring through the program

---

<sup>59</sup> Commenter (2336-Kuva Systems) also compiled and anonymized multi-month time-series datasets for each camera and provided them for a statistical analysis conducted by Daniel Zimmerle and colleagues of Colorado State University (see separate comment by Daniel Zimmerle and Colorado State University for Docket No. EPA-HQ-OAR-2021-0317).

increases the probability of catching consecutive events and increases the likelihood of identifying the underlying cause(s).

Comment: Commenter (2399-GPA Midstream Association) argues the Proposed Rule introduces “super emitter” events as very rare and “typically caused by abnormal operating conditions or malfunctions.”<sup>60</sup> EPA then states that “the November 2021 Proposal and this supplemental proposal contain standards and requirements that, if implemented correctly, would prevent ... or detect and mitigate ... most of these large emissions events.”<sup>61</sup> Thus, EPA anticipates that implementing these new regulations would make “super emitter” events extremely rare.<sup>62</sup> That itself demonstrates that adopting this additional and extraordinary program is not justified by actual record-based evidence.

Commenter (2399-GPA Midstream Association) continues, regardless of how many larger emission events would remain, if any, a new quasi-enforcement program is not required to address them. EPA’s proposal is not intended to address intentional venting as part of normal operations or maintenance. *Id.* at 74,747, n. 101. Thus, a “super emitter” event would present an enforcement issue, not a new regulatory issue, as these events would only arise through violations of the regulations. *See id.* at 74,753 (“Where one of these facilities is determined to be the cause of a super emitter emissions event; it is reasonable to assume that the emissions source is out of compliance and to require corrective action to bring the facility back into compliance with the applicable standard or requirement”); *id.* (Where flares cause a super emitter event they are not in compliance with existing regulations).

Commenter (2399-GPA Midstream Association) recognizes that EPA claims this extraordinary program is necessary as “a backstop to address the large contribution of super emitters to the pollution from this sector.” *Id.* at 74,747. However, EPA offers no supporting data and provides no reason why traditional federal, state, and citizen suit enforcement mechanisms would be unable to fully address these events, if any occur under a new set regulation once finalized. EPA found additional monitoring would not be cost-effective, and thus, EPA’s proposed program would not increase the availability of monitoring capabilities or the likelihood that sources will be monitored. Instead, the SERP would only change how monitoring information may be handled if an alleged “super emitter” is discovered.

Commenter (2399-GPA Midstream Association) states the Supplemental Proposed Rule provides no actual data or any other credible explanation of why monitoring information cannot be used for traditional regulator responses, as may be appropriate under the CAA. The Supplemental Proposed Rule also infers that these events are somehow different than other

---

<sup>60</sup> 87 Fed. Reg. at 74,746-47; *see also id.* at 74,748 (the percentage of super-emitting sources is so small that “it is not cost-effective to impose additional inspection costs on every source”), *id.* at 74,749 (where a source is compliant with regulations “the EPA does not expect unintentional releases at these very high levels to occur in normal operations”).

<sup>61</sup> *Id.* at 74747.

<sup>62</sup> This is the best description in the record available to the public, given that EPA has not identified how many alleged “super emitters” there are under current conditions or estimated a reduction in “super emitters” if measures like the proposed rules were promulgated and implemented.

potential regulatory violations because they are intermittent. See, e.g., 87 Fed. Reg. at 74,747 (stating that “many such large emissions events are intermittent and can occur at different sites over time”). To the extent that EPA is claiming that the intermittent nature of these alleged events presents an unusual problem for traditional state, federal, or citizen enforcement, it provides no data or evidence to support such a claim. In fact, many types of alleged environmental violations occur on an intermittent basis, yet they have been addressed with existing enforcement tools – and without deputizing private parties well beyond the authority provided by the CAA. To the extent that a facility is out of compliance and truly causing significant methane emissions, traditional enforcement mechanisms are available.

Response II-14-35: EPA has chosen to finalize the Super-Emitter Program as primarily a compliance assurance program. A notification of a super-emitter event by EPA is not an allegation of a violation and is there to trigger an obligation to investigate by the owner or operator of an applicable oil and gas facility. If an owner or operator identifies any deviations to the applicable regulations identified as part of that investigations, it would be addressed through reporting provisions incorporated in the final rule.

## **14.4 Program Design**

### ***14.4.1 Reporting Requirements***

Comment: Commenters (2177-Ute Indian Tribe, 2222-Wisconsin Department of Natural Resources, 2227-Western Energy Alliance, 2410-California Office of the Attorney General et al.) request that reports for designated facilities covered by a state, tribal or local agency be sent to the responsible entity.

Commenter (2177-Ute Indian Tribe) responds to EPA’s solicitation of comment on requiring the submission of a written report within 15 days of completing the root cause and corrective action to the Agency and delegated state authority. Commenter believes if a designated facility is covered by a state or tribal plan, all notifications should be submitted to the state or tribe in question. An annual report to EPA would be sufficient.

Commenter (2227-Western Energy Alliance) states written reports required to be submitted to EPA within 15 days of conducting a root-cause analysis should also be sent to the state or local agency.

Commenter (2177-Ute Indian Tribe) states notifications should include a copy of the super emitter event notification received, and information regarding basic corrective actions taken. Detailed information should be submitted along with annual compliance reports. If an annual compliance report is not required for the facility, a single annual report for any super emitter actions should be submitted.

Commenters (2222-Wisconsin Department of Natural Resources, 2410-California Office of the Attorney General et al.) agrees with EPA that when a third-party notifier submits a notification to an owner or operator, the party should provide a complete copy to EPA and the appropriate state

authority. The commenter believes that all subsequent reports and submittals should also be copied to the state. This will allow states to monitor compliance efforts under the SERP and will provide valuable information that states can use in their own compliance and enforcement efforts. The commenter also suggests that EPA clarify that EPA will enforce the requirements of the super emitter program. While reports submitted pursuant to the program can assist state agencies in enforcement of state regulations, enforcement of the requirements of the SERP itself should be centralized with EPA.

Response II-14-36: EPA acknowledges the commenters' input regarding how best to structure the reporting requirements in the Super Emitter Program. Any notifications and reports for this program will come through the super-emitter program and available to state, local, and tribal authorities as well as the general public.

Comment: Commenter (2247-Ohio Environmental Protection Agency) asks should either the approved notifier or the owner/operator of the super-emitting facility be required to report the event to appropriate emergency response organizations?

Response II-14-37: EPA thanks the commenters for their comment and this program does not require super-emitter data to be reported to emergency response organizations.

Comment: Commenter (2248-North Dakota Petroleum Council (NDPC)) states the specific information that would be required to document a source of emissions may not be detailed enough for an operator to evaluate what the third-party monitoring entity is seeing. For example, four decimal points are not accurate enough when there are nearby potential sources outside the control of the operation that is notified. Aerial imagery, or ground-based photographs, must be taken on the exact day and time of the alleged emissions with enough resolution to determine what might be going on at that time on the ground (truck traffic, maintenance equipment, workover rig, etc.).

Response II-14-38: EPA acknowledges the commenters' input and has revised the final rule to account for some uncertainty in the identification of the location of these super-emitter events. We disagree that reporting the latitude and longitude to 4 decimals (11 m<sup>2</sup>) is not accurate enough, in fact due to the size of these emissions it may be difficult to identify the exact source, to account for this we are requiring an owner or operator to identify any regulated equipment within 50 m<sup>2</sup> for inspection in the final rule. We agree that imagery from the time of the monitoring is helpful to determine if any maintenance was conducted during the super-emitter event, but we don't consider it to be mandatory as the investigation into a super-emitter event is required to evaluate any maintenance records that occurred during the identified super-emitter event.

Comment: Commenter (2626-Kayros) states the six elements required in each super emitter notification (location, technology description, documentation, flow rate, timestamp and signed certification) are consistent with the services provided by commercial providers of remote sensing data and provide sufficient information for the relevant operator to act. For the avoidance

of doubt, the EPA should clearly state that notifications should always include the associated imagery (from satellite, aerial or mobile sensor).

Response II-14-39: EPA acknowledges the commenters' suggestion and in the final rule we have clearly defined that third-party notifications must include appropriate imagery of the super-emitter event or equivalent proof of the event.

Comment: Commenter (2345-GHGSat Inc.) agrees with EPA's proposed elements of specific information for a notification to operators. The commenter is providing commentary on each of the six elements of information required:

- 1) The location of emissions in latitude and longitude coordinates. Commenter believes that this information is of the utmost importance. It is also relevant to recognize that remote sensing technologies need to apply inverse reconstruction techniques to identify the source of the emission. In areas where the installation footprint is relatively large or is isolated from neighboring infrastructure, then source allocating an emission does not pose a major challenge. The challenge arises when the emission originated in an area where infrastructure is dense. In this scenario, remote sensing technologies with high spatial resolution (like the commenter's satellite and aircraft) offer an advantage to minimize the error in the source allocation reconstruction process.

In the case of the commenter every satellite and aircraft detection come with a geolocation of the emissions source.

- 2) Description of the detection technology and sampling protocols used to identify the emissions. Commenter believes that this element can be fully documented at the registration period and then referenced on each of the detections.
- 3) Documentation depicting the emission and the site (e.g., aerial imaging with emission plume depicted). Commenter believes that this element is relevant. The colorless nature of methane prompts the need for spectroscopy techniques to identify and characterize the plume. This imagery must be part of the delivery. It will permit the characterization of the plume behavior at the time of detection, identifying the effect of wind and emission rate on the direction and dispersion of the plume. In the case of the commenter, every satellite detection provides imagery of the plume overlaid over the most recent commercial visible imagery map. Every aircraft detection provides imagery of the plume utilizing its own visible imagery taken at the time of the detection.
- 4) Quantified emissions rate. Commenter believes that this information is relevant. Based on the proposed definition of super emitter event, if an emission is detected by employing satellites, it is already understood that in fact is a super emitter event. In addition to the quantified emission rate, it is important to report the uncertainty associated with the emission rate calculation. This one could be express as percentage or a numerical deviation from the calculated rate.

In the commenter's case, every satellite and aircraft detection provide the calculated emission rate in kilograms per hour (kg/hr) and the associated uncertainty in that calculation express as plus or minus the deviation rate in kg/hr.

- 5) Date(s) and time(s) of detection and confirmation after data analysis that a super emitter emission event was present. Commenter believes this is another important parameter to be included in the report. Date and time of each detection should be reported in Universal Time Coordinated (UTC). This parameter can help in creating the baseline for such detection, and if recurrent, it can help in the determination of persistent or transient behavior of a leak. One aspect to note is that with every remote sensing technology, there is always a time between the detection of the plume and the actual processing of the data. Hence, the EPA should consider starting any action or regulatory timeline at the time of notification to the operator and not at the time of the detection. In the case of the commenter, every satellite and aircraft detection provide the associated date and time in UTC when the emission was detected.
- 6) A signed certification that the notifier is an EPA-approved entity for providing the notification, and the information was collected and interpreted as described in the notification. Commenter agrees that this signed certification provides fidelity to the receiving end that the information is coming from a vetted source. Commenter believes that this can be in the form of a weblink that traces back to the EPA's website hosting the list of third-party notifiers.

In addition to these six steps, commenter (2345-GHGSat Inc.) recommends including a description of the wind speed and direction that was considered at the time of the detection and that consequently used to characterize the leak.

Response II-14-40: EPA acknowledges the commenters' suggestion and the requirement in the final rule are reflective of these suggestions.

Comment: Commenter (2409-BP America Inc.) suggests that, in lieu of the third-party reports called for by EPA's proposal, EPA consider preparing an annual report (potentially in coordination with an academic institution), that includes an aggregated overview of total, validated emissions events sent to EPA by third parties, consolidated at a localized level but not at the site level. We believe a consolidated, comprehensive annual report validated and published by EPA would better achieve EPA's goal of enhanced transparency by allowing operators, regulators, and community members to see – in the aggregate – how implementation of EPA's methane regulations and the SERP program have reduced the frequency of super emitter emissions events.

Commenter (2409-BP America Inc.) believes an annual report will allow time for data review/verification and quality assurance, consistent with other EPA annual reports whose purpose is to increase transparency and community access to environmental data. Furthermore, an annual report could also allow industry, communities, and other stakeholders to see regionalized trends over time. By contrast, publishing individualized, privately sourced reports about operators could have the opposite effect and be misleading to the public. This approach

could shift attention to particular operators (many of whom may have taken prompt action or determined that no action was needed under SERP) merely because they were the focus of, or targeted by, third parties whose decisions may reflect a variety of priorities not necessarily in line with the priorities of EPA or the statute.

Response II-14-41: EPA acknowledges the commenters' input. However, an annual report that is only regional in specificity holds does not meet the transparency goals of this program to provide timely super-emitter to the public.

Comment: Commenter (2394-Earthworks) urges the EPA to create a streamlined process for determining and notifying responsible operators so that emissions are quickly addressed. The EPA should not require multiple detections before owners and operators would be required to take responsive action.

Response II-14-42: EPA acknowledges the commenters' input, and the final rule requires notifications and owner, or operator reports to be submitted through the Super Emitter Portal, a website designed to take in and display timely super-emitter data. Also, while requiring multiple detections is not unreasonable and EPA believes this could be unnecessary of a single detection can be used to confirm a super emitter event.

Comment: Commenter (2453-Carbon Mapper and RMI) argue EPA should consider implementing an annual review of the GHGRP to evaluate consistency with SERP reports towards improving treatment of super emitter activity in the former.

Response II-14-43: EPA acknowledges the commenters' input; however, this effort only addresses the NSPS rulemaking.

Comment: Commenter (2453-Carbon Mapper and RMI) states EPA should encourage third-party reporters to expedite operator notification of super emitter detection. Notification timelines should account for robust quality control review that minimizes false alarms. EPA should be flexible on notification timelines in the interest of maximizing SERP participation from qualified nonprofit or research organizations whose quality control (QC) processes may be constrained by available workforce. Additionally, EPA should require that all super emitter reporting is conducted in a transparent and non-proprietary manner.

Response II-14-44: EPA acknowledges the commenters' input and in the final rule we are requiring third-party data to be provided to the EPA within 15 days of a confirmed super-emitter detection. This timeline was chosen to provide the maximum amount of time for confirmation of an event and identification of an owner or operator while being conscious that owner or operators need this information within a reasonable timeframe to conduct a successful investigation.

#### **14.4.2 Quantification**

Comment: Commenters (2184-Social Responsibility Climate Ambassador, 2345-GHGSat Inc., 2626-Kayrros) urge the EPA to leverage data from remote sensing technology to quickly identify and fix large methane leaks. The commenters applaud the EPA's strong interest in employing new tools for methane identification and quantification, particularly for super-emitters, and the EPA's creation of a regime to promote and accommodate their development and use.

Response II-14-45: EPA acknowledges the commenters' support of the Super-Emitter Program.

Commenter (2184-Social Responsibility Climate Ambassador) adds this must be required because in rural areas, 42" gas pipelines can be laid with shutoff valves that are up to 29 miles apart. By the time they are detected on the ground, they have leaked vast amounts of methane into the air, and groundwater.

Response II-14-46: EPA acknowledges the commenters' input; however, the scope of this program is limited to oil or natural gas facility subject to regulation under the NSPS OOOO, OOOOa, OOOOb, and/or under a state or Federal implementing plan of EG OOOOc.

Comment: Commenter (2410-California Office of the Attorney General et al.) suggests that EPA establish a procedure for communities to report super emitter emissions events that does not rely on the quantification of emissions. Many communities will not have access to the technologies required to quantify emissions on a kilograms-per-hour basis. The SERP should incorporate community experiences of super emitter emissions events. Communities may experience odors, health effects, and other impacts of high levels of methane and VOC emissions but may not have the resources or the ability to quantify the level of emissions. EPA should establish a pathway for community members to notify operators and the EPA of such health impacts. While notifications of odors and health impacts may not necessarily require an operator to take immediate corrective action, providing a mechanism for communities to report odor and health impacts would alert owners and operators of potential problems, and create a record of facilities that have frequent community impacts, allowing the EPA and states to identify facilities where compliance efforts should be focused.

Response II-14-47: EPA acknowledges the commenters' input. The scope of this rule is limited to approved remote sensing monitoring platforms capable of quantifying methane emissions of at least 100 kg/hr. For the purpose of this program, it is important there be some minimal quantification requirement for labeling a super emitter on part of a third-party, to trigger a response by the owner or operator.

Comment: Commenter (2458-MiQ) recommends that the report from the operator should include traceable quantification of the total emissions from super emitter event that have occurred. This will assist in recording the emissions from the super emitter event in required regulatory inventories.

Response II-14-48: EPA acknowledges the commenters' input. EPA has chosen to finalize the Super-Emitter Program as primarily a compliance assurance program. A notification of a super-emitter event by EPA is not an allegation of a violation and is there to trigger an obligation to investigate by the owner or operator of an applicable oil and gas facility." We recognize there is benefit for the owner or operator to quantify the potential emission from a super-emitter event, it is not a requirement in this final rule.

Comment: Commenter (2294-Ohio Oil and Gas Association) requests any technology used to identify a super emitter event must be capable of quantifying the methane emissions rate without reliance on an assumed gas composition.

Response II-14-49: EPA agrees with the commenter and any remote sensing technologies used in this program must verify the measurement technology can directly quantify methane emissions.

Comment: Commenters (2218-TCEQ) argue the EPA needs to clarify the qualifications for third-party reporters in the super emitter program. The commenters agree that the qualifications of third-party reporters are important and that approved third-party reporters should show proficiency and accuracy in identifying super emitter leaks. The EPA should provide clear guidance on the requirements to obtain approval as a third-party reporter for the super emitter program. The EPA should provide draft guidance on the approval requirements for public review and comment before finalization.

Response II-14-50: EPA agrees with the commenter that the rule should expand on the requirements for those third parties seeking certification as part of the Super Emitter Program. EPA and has revised the final rule to include expanded the existing criteria for those seeking certification, these criteria can be found in §60.5371b(b) of the final rule.

Comment: Commenter (2366-BHE) argues it is imperative that any technology approved for use in the program have scientifically validated levels of performance and standard test methods developed. Any methane detection and quantification program, whether community-based or not, must include three key program components: (1) proven technology to be used to not only detect methane but accurately quantify the emission rate; (2) validated method(s) that provide a standard approach for technology use; and (3) qualification requirements or certification for users. The proposed SERP lacks these fundamental criteria.

Commenter (2366-BHE), along with other natural gas industry operators, have long supported development of new technologies to detect methane emissions. Introduction and development of OGI technology for methane leak detection was championed by industry through a Gas Research Institute (GRI) research and development program over 20 years ago. The GRI program included initial application of infrared cameras for leak detection at compressor stations and gathering and boosting facilities, and laboratory projects that evaluated OGI and other technologies, such as laser-based leak detection and quantification.

Commenter (2366-BHE) notes while (1) satellite detection, (2) remote sensing equipment on an aircraft, and (3) mobile monitoring platforms are promising technologies, they are developmental

and/or have not been through peer-reviewed demonstration programs that validate accuracy and measurement uncertainty. Nor have test methods for their use been developed and standardized. While measurement accuracy and uncertainties may be provided by technology users, those claims have not been verified via performance testing and comparison to standardized methods or defined emission rates. The commenter supports advancing these technologies, but application in a regulatory program is premature.

Commenter (2366-BHE) notes relevant methane detection and quantification technologies require standardized methods for use. That is lacking in the Supplemental Notice, which simply states that a third-party must “demonstrate technical expertise” in the three remote detection technologies.<sup>63</sup>

Response II-14-51: EPA agrees that the remote sensing technology should be validated to ensure they are able to accurately detect methane emission events at or above 100 kg/hr of methane and therefore any remote sensing technology must be approved for use under the alternative technology program in this rule. This provision in the rule requires technology providers seeking approval to develop standard methods for the operations of their measurement solutions and provide sufficient information to the EPA on their performance of these solutions in the real-world environments.

### ***14.4.3 Super-Emitter Emissions Event Detection***

#### ***14.4.3.1 Detection Methods***

Comment: Mirroring the LDAR program, Commenter (2392-Earthjustice et al.) argues EPA should not require multiple detections before owners and operators would be required to take responsive action.

Response II-14-52: EPA agrees, and the Super-Emitter rule does not require multiple detections, however the final rule now requires that the measurement technology used in this program be approved for this use to safeguard against erroneous data being submitted to the EPA.

Comment: Commenters (2220-WDEQ, 2298-Pioneer Natural Resources USA, Inc., 2326-AXPC, 2366-BHE, 2483-INGAA) contend that EPA should maintain equivalency between third-party monitoring requirements and existing standards for owners, operators, and air agency compliance staff.

Commenter (2220-WDEQ) requests that EPA require similarly stringent requirements for third-party equipment operators as those in the proposed Appendix K regulatory text. Compliance staff at agencies like WDEQ and operators must conduct OGI surveys for a minimum of 1,400 hours over the entirety of his/her career under the proposed regulations. The commenter (2220-WDEQ)

---

<sup>63</sup> §60.5371b(a) and §60.5388c(a).

considers it inappropriate to allow “qualified” third parties to operate remote detection equipment under requirements that are less stringent than those that apply to states and operators.

Response II-14-53: EPA agrees with the commenters that the Super Emitter Program should include more stringent requirements for the third parties and has revised the final rule to expand the certification criteria to ensure third parties are sufficiently reviewing the super -emitter data and that the data presented to the EPA is accurate and reasonable. Likewise, the final rule requires that the measurement technology used in this program be approved for this use to safeguard against erroneous data being submitted to the EPA under the advancement alternative methane technology program, as described in §60.5398b(d).

Comment: Commenters (2298-Pioneer Natural Resources USA, Inc., 2326-AXPC) request EPA require the same level of rigor that EPA determines is required for alternative fugitive emissions monitoring and only authorize technologies that provide enough granularity to enable the third-party to identify the correct site, specific equipment or activity from which 100 kg/hr of methane is emitting. If a technology can only identify the total kg/hr of methane from the entirety of the site (*e.g.*, 25-meter x 25-meter area), the third-party would not be providing the requisite information necessary for an operator to understand whether a super emitter emissions event from an affected facility in fact exists.

Commenter (2366-BHE) is very concerned with the lack of standard methods for the example technologies EPA identifies (*e.g.*, remote or fence line monitoring technologies using laser or infrared sensors) as compared to test method requirements (*i.e.*, validated test methods) that underpin compliance determinations for NSPS or NESHAP standards. As EPA knows, an established programmatic approach has been in place for validation of compliance test methods; the SERP should be conducted with the same level of quality assurance and follow the same validation procedures.

Commenter (2483-INGAA) is very concerned with the lack of standard methods for the identified EPA technologies as compared to test method standards that have always been required by EPA for assessing compliance with a NSPS or national emission standard for hazardous air pollutants (NESHAP). A well-established programmatic approach has been in place for validation of compliance test methods, and the methods to be used in the SERP should be conducted with the same rigor to ensure the same level of quality assurance. For example, EPA has published pollutant-specific reference methods<sup>64</sup> and requirements for pollutant-specific continuous emissions monitoring specifications<sup>65</sup> for assessing compliance with NSPS and NESHAPs. EPA has also included rule-specific methods<sup>66</sup> for NSPS and NESHAPs that have undergone peer review and method validation. In this rulemaking, EPA has proposed a very

---

<sup>64</sup> [See, *e.g.*,] 40 CFR pt. 60, Appendix A Reference Methods. Other EPA-approved methods include the methods promulgated or proposed by EPA’s Air Emission Monitoring Center (EMC). <https://www.epa.gov/emc/emc-promulgated-test-methods>.

<sup>65</sup> 40 CFR pt. 60, Appendix B Performance Specifications and Appendix F Quality Assurance Procedures.

<sup>66</sup> For example, a portable analyzer method for measuring carbon monoxide (CO) from natural gas-fired reciprocating internal combustion engines was adopted as Appendix A to 40 CFR pt. 63, Subpart ZZZZ (*i.e.*, the NESHAP governing Reciprocating Internal Combustion Engines).

rigorous procedure, Appendix K, for operator or service provider use of OGI technology to detect leaks at onshore natural gas processing plants.<sup>67</sup> Similar rigor must be required for methods used by third parties under the SERP, especially because those methods not only detect leaks (i.e., Appendix K is a leak detection method) but also quantify the emission rate.

Commenter (2366-BHE) provides the example, EPA has published pollutant specific reference methods<sup>68</sup> and requirements for pollutant specific continuous emissions monitoring specifications<sup>69</sup> for assessing NSPS and NESHAP compliance. EPA has also included rule-specific methods<sup>70</sup> for NSPS and NESHAPs that have undergone peer review and method validation. For this rulemaking, EPA has proposed a very rigorous procedure, Appendix K, for operator or service provider use of OGI technology for detecting leaks for a compressor station LDAR program. Similar rigor should be required for methods used by third parties under the SERP, especially because those methods not only detect leaks (i.e., Appendix K is a leak detection method) but also quantify the emission rate.

EPA also has a published procedure for validating measurement protocols: Method 301, entitled “Field Validation of Pollutant Measurement Methods from Various Waste Media.”<sup>71</sup> Section 1.0 of Method 301 defines its purpose:

Method 301 provides a set of procedures for the owner or operator of an affected source to validate a candidate test method as an alternative to a required test method based on established precision and bias criteria. These validation procedures are applicable under 40 CFR part 63 or 65 when a test method is proposed as an alternative test method to meet an applicable requirement or in the absence of a validated method. Additionally, the validation procedures of Method 301 are appropriate for demonstration of the suitability of alternative test methods under 40 CFR parts 59, 60, and 61. If, under 40 CFR part 63 or 60, you choose to propose a validation method other than Method 301, you must submit and obtain the Administrator's approval for the candidate validation method.<sup>72</sup>

The standards required for operators to validate a method should also apply to methods used for the SERP because compliance obligations for source owners and operators are contingent upon the third-party measurements. In addition, EPA had a historical process for “conditionally” approving test methods (CTMs) through the EMC<sup>73</sup> that has more recently evolved into listings of “other test methods” (OTMs)<sup>74</sup> that have been reviewed by EPA but not yet been subjected to

---

<sup>67</sup> [See, e.g.,] Proposed 40 CFR §§ 60.5386b(a)(1)(i), 60.5400b(b), 60.5416b(b)(1)(B), 60.5400c(b), 60.5405c(a)(1)(i), 60.5416c(b)(1)(B).

the federal rulemaking process. Through the GRI and Pipeline Research Council International (PRCI), commenter (2483-INGAA) members have participated in projects to develop and validate CTMs and OTMs for measurement of pollutants such as NO<sub>x</sub>, CO, and formaldehyde from natural gas-fired sources. These projects were typically multi-year projects that included experimental design, field (and sometimes laboratory) testing to gather data to validate performance, and method review and approval or acceptance by EPA.<sup>75</sup> While the commenter (2483-INGAA) encourages a more expedient process and schedule for validating methane sensing and quantification test methods, similar rigor is imperative for the SERP to ensure the efficacy of third-party measurements. Because of this, it is premature at this time to implement the proposed SERP. Instead, programmatic integrity should be ensured by embarking on an effort to build the necessary “infrastructure” to confirm technology performance and develop validated test procedures. Funding available from the IRA<sup>76</sup> could be used as a resource to support development and implementation of the needed methane measurement programs.

Commenter (2366-BHE) notes EPA also has a published procedure for validating measurement protocols, i.e., Method 301, “Field Validation of Pollutant Measurement Methods for Various Waste Media.”<sup>77</sup> The introductory section of Method 301 defines its purpose:

“Method 301 provides a set of procedures for the owner or operator of an affected source to validate a candidate test method as an alternative to a required test method based on established precision and bias criteria. These validation procedures are applicable under 40 CFR part 63 or 65 when a test method is proposed as an alternative test method to meet an applicable requirement or in the absence of a validated method. Additionally, the validation procedures of Method 301 are appropriate for demonstration of the suitability of alternative test methods under 40 CFR parts 59, 60, and 61. If, under 40 CFR part 63 or 60, you choose to propose a validation method other than Method 301, you must submit and obtain the Administrator’s approval for the candidate validation method.”

Commenter (2366-BHE) states the standards required for operators to validate a method should also apply to methods used for the SERP because compliance obligations for owners and operators are contingent upon the third-party measurements. In addition, EPA had a historical process for “conditionally” approving test methods (CTMs)<sup>78</sup> through its Emission Measurement Center, which more recently evolved into listings of “other test methods” (OTMs)<sup>79</sup> that have been reviewed by EPA but not yet subjected to the federal rulemaking process. Through the GRI and Pipeline Research Council International (PRCI), INGAA members have participated in projects to develop and validate CTMs and OTMs for measurement of pollutants such as NO<sub>x</sub>,

<sup>76</sup> The IRA includes various funding sources, including the Section 60113 methane emissions reductions program, which includes \$850 million in funds through 2028 to support facility methane reporting under the GHGRP (40 CFR pt. 98, Subpart W), methane emissions monitoring, and methane mitigation from natural gas systems. IRA of 2022, 136 Stat. 2305, Pub. Law No. 117-169 § 60113 (Aug. 16, 2022).

<sup>77</sup> [https://www.epa.gov/sites/default/files/2020-12/documents/method\\_301\\_0.pdf](https://www.epa.gov/sites/default/files/2020-12/documents/method_301_0.pdf).

<sup>78</sup> <https://www.epa.gov/emc/emc-conditional-test-methods>.

<sup>79</sup> <https://www.epa.gov/emc/emc-other-test-methods>.

CO and formaldehyde from natural gas-fired sources. These projects were typically multi-year projects that included experimental design, field (and sometimes laboratory) testing to gather data to validate performance, and method review and approval or acceptance by EPA. While INGAA encourages a more expedient process and schedule for validating methane sensing and quantification test methods, similar rigor is imperative for the super emitter technological program to ensure the efficacy of third-party measurements. Because of this, it is premature to implement the proposed program at this time. Instead, programmatic integrity should be ensured by embarking on an effort to build the necessary “infrastructure” to confirm technology performance and develop validated test procedures. Funding available from the IRA<sup>80</sup> could be used as a resource to support development and implementation of the needed methane measurement programs.

Commenters (2222-Wisconsin Department of Natural Resources 2238-Southeastern Ohio Oil and Gas Association (SOOGA), 2294-Ohio Oil and Gas Association, 2399-GPA Midstream Association) request EPA provide methods and guidance for detecting super emitter emissions events.

Commenter (2222-Wisconsin Department of Natural Resources) states that EPA proposes to allow the use of remote-sensing aircraft, mobile monitoring platforms, or satellites to identify super emitter emissions events. Commenter recommends EPA test and recommend monitoring methods, guidance and standards for states to use to define super emitter emissions events.

Response II-14-54: EPA agrees with the commenters and the final rule now requires that the measurement technology used in this program be approved for this use to safeguard against erroneous data being submitted to the EPA. The requirements for this approval are the same requirements in the alternative technology program in this rule which is consistent if not more demanding than EPA’s existing alternative test method programs.<sup>81,82</sup>

Comment: Commenter (2483-INGAA) states that once a methane detection program has identified the relevant technologies, guidance then needs to be given regarding how that technology must be deployed. The proposed regulatory text provides no information on how these technologies should be used. It simply specifies that a third-party must “demonstrate [] technical expertise” in the three remote detection technologies.<sup>83</sup>

Response II-14-55: EPA agrees with the commenters and the final rule now requires that the measurement technology used in this program be approved for this use through the advancement

---

<sup>80</sup> IRA includes various funding sources, including the Section 60113 methane emissions reductions program, which includes \$850 million in funds through 2028 to support facility methane reporting under the GHG Reporting Program (40 CFR, Part 98, Subpart W), methane emissions monitoring, and methane mitigation from natural gas systems.

<sup>81</sup> 40 CFR 60.8(b).

<sup>82</sup> 40 CFR 63.7(e).

<sup>83</sup> Proposed 40 CFR §§ 60.5371b(a), 60.5388c(a).

alternative methane technology program, as described in §60.5398b(d), to safeguard against erroneous data being submitted to the EPA.

Comment: Commenter (2483-INGAA) notes that the proposed program, as written, defines a super emitter based on an hourly rate but does not specify that the technology must measure a statistically significant period to determine that an emissions event exceeds the hourly rate. For example, a third-party could measure an emission rate of 1.7 kg/min for 3 minutes and draw the conclusion that the source exceeds 100 kg/hr (i.e., 1.7 kg/min x 60 mins = 102 kg/hr). In reality, however, this source could be a single, short-term blowdown event (e.g., a compressor blowdown) lasting several minutes with total emissions far less than 100 kg/hr and not constitute a “super emitter” event. These short-term blowdown events can be associated with necessary and regular operational practices and/or emergency shutdown procedures. It is imperative that this program include proof that the emission source is persistent (e.g., an ongoing large leak), and the time element and/or cumulative emission total should be defined before a third-party can issue a notice to the owner or operator of a source.

Response II-14-56: EPA disagrees with the commenter that super emitter events must be proven as persistent. EPA recognizes that these events are infrequent and may be intermittent, however the intent of this additional monitoring effort is to identify this emission when they happen so the cause can be investigated.

Comment: Commenter (2238-SOOGA, 2294-Ohio Oil and Gas Association) states that notwithstanding U.S. EPA’s questionable legal authority for establishing the SERP, the regulatory framework for the program needs further development. The commenter (2294-Ohio Oil and Gas Association) suggests that U.S. EPA initiate the rulemaking process to approve each technology used by the third-party detectors so that industry has an opportunity to comment on the merit of each technology. The Supplemental Proposal does not provide adequate detail for stakeholders to provide comments as it only identifies the technology by name with no information about the technology and its limitation. Similarly, U.S. EPA should develop detailed criteria for the certification of qualified third-party detectors for public review and comment.

Commenter (2399-GPA Midstream Association) urges EPA to develop and impose criteria on the third-party detection technologies that may be used under any SERP. At present, the proposal offers no criteria, leaving room for third-party detection equipment that is not reliable, and thus, could be used to compel another private party to invest substantial time and resources unnecessarily, as well as to create a public perception regarding an industry entity that is unfair and unjustified. Before finalizing these new criteria, EPA should make the proposed criteria available for public comment, as required by the APA.

Response II-14-57: EPA thanks the commenter for their input and has expanded that criterion in the final rule. EPA does not consider it necessary that these expanded criteria are subject to additional public comment because the final rule no longer includes the third-party contacting the owner or operator. Instead, with the super-emitter notifications being sent to EPA, these criteria are to improve the quality of the information being provided to the EPA and EPA has the final decision on whether this super-emitter data is actionable.

Comment: Commenter (2399-GPA Midstream Association) recommends EPA require approved third parties to implement and document protocols established by equipment manufacturers for how they calibrate, use and regularly maintain detection equipment in a fashion similar to proposed Appendix K, which includes exceptionally detailed proposed mandates for OGI use (from maximum wind speeds to operator break times). Yet, as framed in the proposal, EPA appears to allow for approval of third-party detection equipment upon the barest showing of theoretical functionality – a standard that EPA does not follow for monitoring or compliance monitoring generally. New test methods or monitoring techniques must go through rigorous review by technical experts and public scrutiny before EPA allows their use – and often not until the technology or the technique has first gone through lengthy testing and review by knowledgeable standards setting bodies, such as ASTM and others. This type of rigor should be applied to any technology that would be used for a proposed program, along with a public process for review and comment on the technology. Any less rigorous approach would, again, not only lack credibility – but would arbitrarily impose requirements on industry that it would not impose on those bringing quasi-enforcement actions against industry.<sup>84</sup>

Additionally, the commenter (2399-GPA Midstream Association) notes that where EPA has provided general descriptions of technologies that would be allowed under this proposed program, the draft regulatory text - specifically the categories of “Satellite detection of methane emissions,” “Remote-sensing equipment on aircraft,” and “Mobile monitoring platforms” – highlights the need for EPA to consider these technologies and their use further, offer a more detailed regulatory proposal, and allow for public input. Proposed §§ 60.5371b(a)(1)-(3).

First, commenter (2399-GPA Midstream Association) provides that the proposed text conflates the concepts of detection and quantification. All of the listed categories of technologies involve remote sensing technologies that detect methane emissions – but they do not directly measure emissions. At most, these technologies may rely on proprietary algorithms to estimate remotely sensed concentrations (commonly expressed in ppm-m) and convert those into a mass emissions rate (such as kg/hour). EPA should recognize that these technologies can only provide a rough estimated emissions rate. They do not provide a “quantified emission rate” as the proposed text asserts. See Proposed §§ 60.5365b(j), 60.5371b, 60.5371b(b)(4), 60.5371b(e)(ii)(D).

Second, commenter (2399-GPA Midstream Association) states that while these technologies (if properly calibrated, operated, and maintained) may be able to detect methane emissions, each of

---

<sup>84</sup> Although the commenter (2399-GPA Midstream Association) views the SERP as unlawful under both Section 111(b) and 111(d), EPA appears to believe that the program also will be applied to existing sources through Section 111(d) state plans. See 87 Fed. Reg. at 74,753 (stating that most super emitters would be violating “the proposed NSPS OOOOb/EG OOOOc.”). The Supplemental Proposed Rule never addresses how EPA will evaluate state plans implementing the SERP and the discretion state agencies may have in approving third-party notifiers and the detection technologies they use. EPA should not apply this program to existing sources unless and until it addresses these and other issues regarding extending this program in a separate proposal subject to public comment.

these technologies have documented accuracy limitations.<sup>85</sup> EPA has provided no independent evaluation or other rationale for accepting the listed technologies as accurately detecting methane to a degree that they may be used as tools to compel investigations and corrective actions by affected facility owners and operators. Further, as noted above, it does not appear that EPA plans to impose any protocols on how these technologies are used or their results interpreted. For example, if the technology's field study data shows an error in emission estimates that ranged from -50% to 100%, a measurement should only be valid as it relates to this program if it is still over the 100 kg/hr threshold assuming the potential error. These types of nuances in data interpretation need to be thoughtfully considered and explained. OGI cameras are comparatively mature technologies, yet EPA would use proposed Appendix K to impose restrictive mandates on how they are used, and who may use them. The absence of any similar protocols for the technologies in Proposed §§ 60.5371b(a)(1)-(3) not only undermines confidence in their use, but effectively implements an arbitrary “no rules” policy for these technologies.

Accordingly, to improve the confidence in use of these technologies, the commenter (2399-GPA Midstream Association) recommends EPA create a detailed protocol through which these technologies prove their accuracy (including maintenance and calibration requirements) and provide assurance that changes made to proprietary algorithms are not made without agency approval. Further, in view of inherent limitations with certain technologies (e.g., satellite/aerial detection capability is limited due to weather conditions), EPA should specify conditions under which these technologies are suitable for emissions detection.

Third, the commenter (2399-GPA Midstream Association) considers the term “mobile monitoring platform” vague. EPA should provide the public with fair notice of exactly what platforms may be qualified for use by third-party notifiers and proffer specific guidelines on how each of the defined set of platforms may be used to support a notice under this program.

Response II-14-58: EPA acknowledges the commenters' input. A detailed process by which EPA will approve the use of specific technologies and approaches is included in the final rule. Similarly, the final rule includes requirements on the user of these technologies to develop performance criteria and data quality requirements to be met as part of the operation of these approaches, which will be evaluated and approved by the EPA.

Comment: Commenters (2258-MS, 2391-Chesapeake Energy Corporation (CEC)) provide that EPA should ensure that any technology used by third parties to monitor affected facilities under this proposed program meets the same requirements EPA has proposed for alternative technologies for periodic screening of fugitive emissions.

Response II-14-59: EPA agrees with the commenter and the final rule now includes the requirement that any remote sensing technology used in the super-emitter program must be

---

<sup>85</sup> The tools used to evaluate an emissions event have error bars for a single “measurement” ranging from +/- 17% at the most accurate end to +/- 70% for the types of events that occur in the field. Heltzel, R., et al., Understanding the Accuracy Limitations of Quantifying Methane Emissions Using Other Test Method 33A, *Environments* 2022, 9, 47, <https://doi.org/10.3390/environments9040047>; Halley L., et al., Assessment of Methane from Oil and Gas Production Pads Using Mobile Measurement, *Env't'l Sci. & Techn.* 2014 48 (24), 14508-14515.

approved under the alternative test method provision in the rule as found in § 60.5398b(d) in the final rule.

Comment: Commenter (2284-Kairos Aerospace) highlights a recently released preprint publication, “Quantifying oil and natural gas system emissions using one million aerial site measurements” by Sherwin et al. (Under review at Nature) establishes basin-scale emission estimates from fifteen survey campaigns (including the two campaigns described by Cusworth and Chen) across six producing basins.<sup>86</sup> Although still undergoing peer review, this study is unparalleled in its scope, making use of 1 million aerial measurements— a factor of ten greater than the previously mentioned studies. This study examines six basins: Permian (several surveys), San Joaquin, Denver-Julesburg, Marcellus (partial Appalachia focused on a high production region of Pennsylvania), Uinta, and Barnett. It leverages data from two airborne survey providers, Kairos Aerospace and Carbon Mapper, covering 15 airborne campaigns. Critically, the study’s methodology merges top-down airborne surveys with bottom-up emissions modeling specific to asset inventories and surveyed area production of each basin (based on the model of Rutherford et al., 2021) to develop a full emissions distribution for each basin (site-level).<sup>87</sup> This includes modeled emissions below the minimum detection limit of the airborne technologies. The resulting distributions can be used to quantify full basin loss and assess the effectiveness of airborne detection strategies at the basin scale.

The study presents several key findings:

- Sites with aerially-detectable emissions are rare but even more impactful than previously understood— “Aerially measured emissions at 0.05%-1.4% of well sites contribute 51%-81% of total emissions in twelve of fifteen campaigns.”
- Surveyed regions in this study contribute an estimated 6.3 million t/yr of methane emissions, equivalent to total greenhouse gas emissions from France.
- Basin-level methane loss rates vary significantly, but all campaigns with greater than 80% basin coverage (n=11) quantified a loss rate greater than the EPA GHG inventory estimated loss rate.
- Basin-level loss rates can vary over time.

Commenter (2284-Kairos Aerospace) argues this study further strengthens EPA’s footing for using advanced leak screening techniques as a part of its proposed matrix and as part of the scientific underpinning for the SERP. It also provides some of the very first, basin-scale evidence that these large sources of emissions are not a Permian-only phenomenon. It also raises the question of why, through its FEAST modeling, EPA would disadvantage these same advanced screening technologies by biasing model outputs in favor of OGI. As Dr. Robert Kleinberg of Columbia University observed, EPA’s own greenhouse gas inventory shows “[M]ethane emissions have changed little over the years following promulgation of the OOOO rules,

---

<sup>86</sup> Sherwin et al. “Quantifying oil and natural gas system emissions using one million aerial site measurements” <https://www.researchsquare.com/article/rs-2406848/v1> 2023 In Revision.

<sup>87</sup> Rutherford, J.S., Sherwin, E.D., Ravikumar, A.P., Heath, G.A., Englander, J., Cooley, D., Lyon, D., Omara, M., Langfitt, Q., Brandt, A.R., 2021. Closing the methane gap in US oil and natural gas production emissions inventories. Nat Commun 12, 4715. <https://doi.org/10.1038/s41467-021-25017-4>

consistent with a long-term annual decline rate of about 0.3 percent.”<sup>88</sup> Clearly, the traditional OGI-based leak detection program being established as BSER leaves opportunity for improvement. Advanced leak screening technology has been instrumental in shaping our understanding of methane emissions, and ought to be instrumental in our plans to reduce methane emissions.

Response II-14-60: EPA acknowledges the commenters’ input.

Comment: Commenter (2333-LongPath Technologies, Inc.) contends that there is no inherent reason to limit the use of any type of technology for applying to be a super emitter program participant. The limitation of technology types in the final rule will only risk stifling future technology improvements and innovations. For example, there is no fundamental reason to exclude fixed or ground-based technologies by providing a prescriptive and limited list, provided the approval requirements clearly ensure the safety of all participants. Commenter requests more information justifying this level of technology-specificity or for this requirement to be removed.

Response II-14-61: EPA acknowledges the commenters’ input. Ground-based remote sensing is an option in the rule, our intent in limiting the technology to remote sensing technology was to ensure the public was not seeking to access to well-sites out of a concern for security and safety.

Comment: Commenter (2389-ACC) notes EPA solicits comment on its proposed technology types for conducting monitoring on the program, i.e., “remote-sensing aircraft, mobile monitoring platforms, or satellites” to identify potentially relevant events.<sup>89</sup> Commenter (2389-ACC) believes that the reliability of monitoring programs depends on the quality and accuracy of the collected data and the knowledge and expertise of the persons operating the program.

As such, the commenter (2389-ACC) states it is critically important that EPA ensure that the new programs’ emissions data is accurate, reflective of current conditions, and relevant to the overall program’s purpose. As a technical matter, the Agency should also ensure that the monitoring instruments and equipment that collect the data are of high scientific and technical integrity. That is, EPA should require that the instruments are in good working order and are properly calibrated and maintained according to the manufacturer’s specifications.

Additionally, the commenter (2389-ACC) recommends EPA ensure that any personnel involved in the collection, analysis, and ongoing maintenance of the super emitter monitoring program is appropriately qualified and trained to execute these types of technical programs. Specifically, the commenter (2389-ACC) recommends that EPA ensures that staff from approved third parties that may be involved in the operation of monitoring equipment (e.g., citing, calibration, standard maintenance, etc.) or in the handling of monitoring data (e.g., collection, interpretation, communication, etc.) who have relevant experience in monitoring programs, as well as some

<sup>88</sup> Kleinberg, Robert L., “Methane Emission Controls: Redesigning EPA Regulations for Greater Efficacy,” Columbia University Center on Global Energy Policy, October 4, 2021, <https://www.energypolicy.columbia.edu/research/commentary/methane-emission-controls-redesigning-epa-regulations-greater-efficacy>

<sup>89</sup> 87 FR 74749.

level of practical experience and training against applicable technical, procedural, and quality assurance standards. Without properly trained personnel using operational equipment to collect accurate emissions information, EPA risks the creation of monitoring programs that generate and present flawed information and conclusions.

Commenter (2389-ACC) also notes that EPA's proposed technology types for monitoring under this program appears to signal that the Agency is requiring that qualifying technologies meet at least some level of QA/QC requirements associated with air monitors (rather than air sensors). The commenter (2389-ACC) supports this approach since more scientifically sound monitoring technologies are more likely to provide reliable, actionable information for both facilities and the communities in which they operate. The commenter (2389-ACC) further recommends that EPA carries forward a similar approach for criteria and qualifications for its proposed and future programs that will be administered with funding provided by the IRA. Many IRA programs would launch air monitoring initiatives supported by EPA funding, which will also be conducted by parties external to EPA and the regulated community. However, at this stage, it is unclear whether the IRA-funded air monitoring programs would contain the same standard of credibility for the monitors used. As such, the commenter (2389-ACC) strongly encourages the Agency to create similar criteria for the data collection and dissemination of air monitoring conducted under IRA programs.

Response II-14-62: EPA acknowledges the commenters' input. EPA agrees with the comment that methane detection technology used for this program should be in good working order and that third parties reviewing the results should be adequately trained. The final rule now includes criteria that technology and procedures for operating the technology used as part of the Super-Emitter Program be pre-approved by the EPA. Likewise, the final rule includes criteria that third parties operating be sufficiently trained on the operation of the technology used to determine whether data is supported enough to submit to the EPA.

Comment: Commenter (2483-INGAA) supports the development of new technologies to detect methane emissions. Commenter (2483-INGAA) contends its members were instrumental in the development of infrared camera technology (i.e., OGI) for methane leak detection, with pipeline operators working in conjunction with GRI projects over 20 years ago. These projects included the initial application of infrared cameras for leak detection at natural gas facilities and culminated in EPA adopting an alternative work practice for OGI,<sup>90</sup> including OGI for leak surveys required under Subpart W of the GHGRP at compressor stations and other natural gas facilities.<sup>91</sup>

While the commenter (2483-INGAA) has long supported the development of new technologies for methane emission detection, those technologies cannot be used to trigger compliance requirements until the technology has been proven to be a reliable indicator of methane leaks. In the Supplemental Proposed Rule, EPA proposes that the following remote detection technologies would be approved for use by third parties in the proposed SERP: (1) satellite detection; (2)

---

<sup>90</sup> 40 CFR § 60.18(i).

<sup>91</sup> Id. § 98.234(a)(1).

remote sensing equipment on an aircraft; and (3) mobile monitoring platforms.<sup>92</sup> Commenter (2483-INGAA) members are advocates for advancing these technologies, but do not believe that they have yet reached the threshold needed to be part of a regulatory program that gives rise to legal obligations by the owners and operators of covered sources – even a program that is designed as a “backstop” measure.<sup>93</sup> For example, while the users and manufacturers of these technologies may claim these new remote detection technologies provide accurate results, these claims have not been verified via performance testing and comparison to standardized methods or defined emission rates. Nor have these claims been peer reviewed and published. Indeed, results from some initial tests show that while leak detection is possible, very large uncertainties and inaccuracies are common for quantified measurement of leak rates.

For example, commenter (2483-INGAA) notes that the 100 kg/hr threshold for the SERP is similar to the detection limit claimed for satellite technology. A 2021 presentation on this technology indicates, however, that there is significant measurement uncertainty – even when data analysis techniques average many measurements over an extended period rather than relying on a point in time measurement. The proposed SERP does not consider emissions “persistence” or the time duration of the event when determining whether a source is a super emitter.

Commenter (2483-INGAA) describes a figure [Figure 1] showing data presented at the 2021 EPA Methane Workshop by Riley Duren regarding a gathering line leak that was first detected utilizing aircraft surveys at altitudes of approximately 18,000 feet.<sup>94</sup> Over the following week, eight additional surveys were conducted. Follow up to these detections included extensive investigation to determine the leak source, with eight organizations involved in the effort. Figure 1 shows methane emissions hovering around 100 kg/hr (i.e., the proposed threshold for the SERP), with 50% or higher uncertainty in the reported results. In addition, the reported data are averages of multiple measurements, which will dampen uncertainties. Uncertainty for individual measurements is unclear but surely higher.

[Chart of Daily Average Emission rate (kgCH<sub>4</sub>/hr) described in paragraph above]

Figure 1: Example of variation in average satellite emission rate measurements<sup>95</sup>

Commenter (2483-INGAA) also notes that the literature indicates that wind conditions, temporal changes in emissions, and the quantification algorithm can significantly affect measurement results. Measurement duration and data compilation (e.g., averaging multiple measurements) are relevant issues. Remote technology measurements are typically of short duration, and such point in time measurements may not be representative of hourly average emissions (e.g., a remote technology measurement may include an intermittent process gas release event). Thus, researchers often compile many measurements and present an average to show performance

<sup>95</sup> Id.

versus actual emissions. For example, hundreds of thousands of measurements are averaged over days to years to overcome the temporal challenges.<sup>96</sup> This data manipulation is an example of why defined methods are needed for third-party measurements and applying this “technique” in published studies hinders the ability to discern uncertainty of individual measurements that are not precluded in the Supplemental Proposed Rule.

Furthermore, commenter (2483-INGAA) states wind speed and direction can vary when measurements are being taken and impact the accuracy of remote technology measurements. For satellite measurements, Jacob et al. note “weak winds facilitate detection but cause large error in quantification.”<sup>97</sup> Without defined methods, these influences will not be accounted for by third-party measurements.

Commenter (2483-INGAA) continues in stating that if the wind is measured, uncertainty is introduced by the type of wind meter utilized. Kairos Aerospace’s airplane-based hyperspectral imaging methane emissions detection system reports factors that affect uncertainty from a study with blind controlled releases of methane ranging from 18 to over 1,025 kg/hr.<sup>98</sup> The study notes that wind speed and measurement method can impact results, including the type of instrument used to measure wind speed. This is an example of why defined methods (discussed below) are needed for implementation of technology within any leak detection program. Significant uncertainty in the results was also reported. Data reported from other studies with lower leak rates (e.g., remote sensing of distribution leaks in urban areas) also show significant uncertainty (i.e., in excess of 100% and much higher for lower leak rates).<sup>99</sup>

In sum, while peer reviewed publications are limited, Commenter (2483-INGAA) believes available information shows high uncertainty in remote quantification of leak emission rates, analysis methods that consider averages of many measurements when comparing remote measurements to actual emissions, and influences from parameters like wind speed. These issues clearly show the need for quality control and defined methods for applying remote detection technologies.

Response II-14-63: EPA acknowledges the commenters’ input. Providers submitting request to the EPA to have their methane detection approved would be required to determine submit supporting information to determine under what conditions they may be operated and developed

QA/QC consistent with how a technology must be operated to ensure the technology provides data that are of high quality.

#### 14.4.3.2 Advanced Technology

Comment: Commenter (2256-Mille Lacs Band of Ojibwe) believes to achieve prompt mitigation and further increases accountability EPA should encourage innovative and advanced monitoring technologies and leverage qualified expert monitoring to identify "super emitters."

Commenter (2458-MiQ) recommends that instead of identifying technologies for the SERP, EPA should use a technology agnostic approach. EPA should include all monitoring requirements and then approve technologies that meet those requirements. These might include methane detection limit (MDL) parameters and a required safe distance from the source, for example.

Response II-14-64: EPA acknowledges the commenters' input, and the final rule includes a provision that technology used in the super-emitter program must be approved by the EPA.

Comment: Commenters (2433-EDF et al., 2626-Kayros) argue remote sensing technologies bring a much-needed transparency to the program because they can be deployed by independent third parties, and in most cases their results can be made publicly available. Another key advantage is the broad geographical coverage they provide, given the highly dispersed nature of super emitters across the entire energy supply chain.

Response II-14-65: EPA acknowledges the commenters' input.

Comment: Commenter (2433-EDF et al.) supports EPA's proposed technological parameters and the requirement that technologies be capable of quantifying an emission flux of 100 kg/hr or greater. However, the commenter urges EPA to not overly restrict the technologies that may qualify. EPA should use the alternative test method approval process already under development to approve technologies for use in SERP. To do this, EPA would need to add an additional quantification criterion for SERP technologies, but otherwise may rely on the same procedures. Commenter (2433-EDF et al.) generally believes the technologies EPA has specified for SERP in the supplemental proposal are appropriate, but there may be additional technologies that could operate within the requirements of this program that are excluded by including a limited list. For example, tower-based systems that can quantify emissions, if approved by EPA, should also be allowable under SERP.

Commenter (2433-EDF et al.) urges EPA to not impose more onerous requirements on technologies used for SERP than those used under the LDAR program, aside from the quantification requirement. Qualified third parties should not face a higher barrier to monitoring than operators themselves do, especially because third-party data will be more objective and potentially more accurate than data submitted by operators who may face conflicts of interest in accurately reporting their own emissions and violations. And with a 100 kg/hr detection requirement, there is no need for permissible technologies to be vetted in more depth than

technologies deployed for the LDAR program which must be able to detect much smaller emissions sources.

Response II-14-66: EPA acknowledges the commenters' input. EPA agrees that we should play a role in approving technology used in the Super Emitter Program, and in order to be consistent in are approach, is using the same criteria for technology used in Advanced Methane Detection Technology Program for fugitive component and covers and CVS monitoring.

Comment: Commenter (2198-University of Denver College) says that the need to incorporate modern technologies is going to be curtail for the future of monitoring oil and gas sites. Methane concentrations can vary greatly depending on the location and monitoring that needs to be conducted in many different areas to get a comprehensive understanding of emissions. "More than 26 million acres of federal land, an area comparable to the size of Kentucky, are currently under lease for oil and gas drilling. (Adler, 2022) The EPA is proposing a SERP where an owner or operator must investigate and take appropriate mitigation actions upon receiving certified notifications of detected emissions that are 100 kg/hr of methane or greater. Commenter (2198-University of Denver College) thinks at the scale of potential new sites, this will become ineffective and have potential for corruption.

Commenter (2198-University of Denver College) expresses that the challenges of monitoring methane can make it difficult to obtain a comprehensive understanding of methane emissions and to develop effective strategies to mitigating them. An all-encompassing approach to every site would have more effective results towards monitoring methane. "Thanks to powerful technologies, such as high-resolution satellite data, scientists are now able to underline the impact of frequent and intentional methane releases, also known as venting.<sup>100</sup>" Each satellite can measure any site in the world every two weeks.<sup>101</sup> This would also allow for each site to measure under the same measuring standards. This technology should be considered in an all-encompassing methane monitoring effort. As this technology would have great advantages in the new quarterly monitoring being proposed.

Response II-14-67: EPA acknowledges the commenters' input. The Super-Emitter Program is not intended to replace the existing monitoring programs in the rule and is designed to supplement those other efforts under the guide of providing actionable information (*i.e.*, EPA verified super-emitter) to owner or operators in an effort to further reduced methane emissions from this sector.

Comment: Commenters (2284-Kairos Aerospace, 2333-LongPath Technologies, Inc., 2440-Nevada Nanotech Systems, Inc.) argue continuous monitors should be incentivized because they provide time history of emissions on sites that receive super emitter event program alerts. Continuous monitoring solutions provide the most rapid detection and therefore the greatest abatement of emissions.

---

<sup>100</sup> European space agency, 2021.

<sup>101</sup> EPA, 2018.

The EPA suggests, on page 74754, that “the more targeted SERP would thus be a more effective solution for addressing sporadic, large emission events that may occur outside the periodic... monitoring.” Commenter (2333-LongPath Technologies, Inc.) takes the intent of the super emitter program, therefore, to indicate the EPA does not believe that the proposed periodic screening survey approaches (OGI, alternative technology) are sufficient to rapidly address super emitters, which can contribute disproportionately to overall emissions from oil and gas.

Commenter (2333-LongPath Technologies, Inc.) therefore suggests that EPA formulate stronger incentives for operators to use continuous monitoring, which would achieve orders of magnitude higher emissions reductions with more rapid find-and-fix across a larger set of assets than can be achieved by periodic screening via the matrices or random screening by a voluntary, 3rd-party watch-dog program.

Specifically, Commenter (2333-LongPath Technologies, Inc.) suggests that EPA create specific exemptions from parts of the super emitter program response requirements for those sites that employ quantitative continuous emissions monitoring with ability to monitor all equipment on site (e.g., stick flares, tall tanks, yard piping). The commenter strongly recommends that EPA allow those operators who have valid quantification continuous monitors with full-site coverage on a site to use that data to respond to super emitter program alarms. Commenter (2333-LongPath Technologies, Inc.) further recommends that sites with continuous monitors installed be exempt from the public-reporting portions of the program, since it is extremely likely they will already have responded to and repaired the reported leaks by the time of posting. Operators should therefore not be penalized for having appropriately and immediately responded to fugitive emissions through their voluntary use of continuous monitoring data.

Commenter (2333-LongPath Technologies, Inc.) notes as EPA suggests, on page 74754, that “the more targeted SERP would thus be a more effective solution for addressing sporadic, large emission events that may occur outside the periodic OGI monitoring.” The commenter takes the intent of the super emitter program, therefore, to indicate the EPA does not believe that the proposed OGI and AVO BSER is sufficient to rapidly address super emitters, which can contribute disproportionately to overall emissions from oil and gas. It is unclear how comprehensive the coverage of US producing basins will be under this voluntary, 3rd party program. By contrast, there are dozens of high-TRL continuous monitoring technologies capable of rapidly scaling to cover the entirety of US production, given sufficient operator incentivization to participate in a continuous monitoring program. Continuous monitoring could certainly be said to “be a more effective solution for addressing sporadic, large emission events that may occurs outside the periodic OGI monitoring”.

Response II-14-68: EPA acknowledges the commenters’ input. The detailed criteria for super emitter detection and technology approval are defined in the final rule and is technology agnostic, meaning anyone, including the commenter can be approved if they can meet the criteria.

Regarding the use of continuous emissions monitoring in the Super-Emitter Program, we would expect these systems would identify these large emissions far sooner than any potential super-

emitter emission event however we disagree the use of these systems would limit the obligation to report these events, in the event an emission event was reported to an effective owner or operator. However, continuous emissions systems would be invaluable in determining whether these events occurred or are still recurring and the data from these systems (if available) could be used to aid in responding to super-emitter notifications.

Comment: Commenter (2284-Kairos Aerospace) argues it makes little sense to require operators to conduct ground visits solely based on third party reports. This adds significant operational complexity, risk, and cost, and would not be strictly necessary to evaluate the incoming report. Since the SERP is built on remote sensing data, it follows logically that operators should be able to use remote sensing technology to respond to incoming reported detections. Any remote sensing technology used for compliance purposes will already have detection limits well below 100 kg/hr, making them capable of detecting a super emitter event.

Commenter (2284-Kairos Aerospace) states by allowing remote sensing technology to be used to investigate reported emissions, EPA will give operators flexibility, reduce operational disruption, and improve the safety of the Response Program. Since vehicle accidents are a leading cause of oilfield fatalities, creating an urgent trip out into the field for a ground crew poses a potential safety risk. Further, if there is a super emitter, putting ground crews in close proximity more than strictly necessary to make repairs should also be avoided.

Commenter (2284-Kairos Aerospace) envision a program where if a super emitter is reported to an operator, they could use available remote sensing data to evaluate the emission or deploy remote sensing technology quickly to evaluate. If emissions are confirmed by the operator's remote sensing survey, only then would ground crews be dispatched for repair. This could work in two ways:

Scenario 1: An operator receives a report from a third party about a super emitter event it detected two weeks ago in a routine survey. That operator did its regular leak survey one week ago using a remote sensing technology, which detected no emissions. The operator could then dismiss the reported super emitter as unconfirmed through follow-up.

Scenario 2: An operator receives a report from a third party about a super emitter event it detected in a routine survey. Upon receipt of the third-party report, the operator dispatches a remote sensing survey to be conducted within the specified investigation time frame. If the emissions are identified in that second remote sensing survey, the operator takes appropriate corrective action. If emissions are not detected, the operator could then dismiss the reported super emitter as unconfirmed through follow-up.

Response II-14-69: EPA acknowledges the comment, the final rule includes allowance to use existing continuous monitors data or fugitive monitoring surveys conducted after the identified super-emitter event and the notification event to determine the presence of the super-emitter event.

Comment: Commenter (2202-TXOGA) states that if a final rule includes third-party monitoring under a Super emitter Program,<sup>102</sup> EPA should consider several issues related to approval of technologies. First, Commenter (2202-TXOGA) agrees with the suggestion of a focus on remote monitoring technologies that do not need site access. In particular, aircraft and satellites, which have been used by third parties in Texas, are likely safer options than ground-based technologies. Second, technologies must be able to provide timely information and quantification. Information received several months after a detection will likely be challenging for operators to utilize effectively, so EPA should provide that third parties must provide data to operators within the same timeline to which operators are held for periodic screenings. Third, EPA should create performance requirements around geolocation abilities, including the ability to locate to a specific site and, ideally, a specific piece of equipment. Technologies that provide only regional data that may include multiple sites and operators or are subject to non-public atmospheric modeling assumptions will be difficult for operators (and regulators) to interpret and may lead to a significant expenditure of resources without corresponding emission reductions. Fourth, all measurement techniques include uncertainty ranges on quantification that should be known and required to be disclosed by the measurement provider.

Response II-14-70: EPA acknowledges the comments, the final rule now includes provisions consistent with these comments, including EPA approving technology, super-emitter data must be submitted within 15 days of an event, and requirements for what information must be submitted to the EPA (e.g., lat/long, mass emission uncertainty).

Comment: Commenters (2345-GHGSat Inc., 2457-Providence Photonics, LLC) understand that current available aircraft and satellite technology allow for advanced leak detection and quantification. For example, GHGSat's aircraft instruments and constellation of satellites are able to identify a super emitter emissions event at the facility level. Other existing satellites offer a higher detection threshold and lower spatial resolution, making it difficult to identify all the super emitter emissions events and to properly source allocate the emission.

Commenters (2345-GHGSat Inc., 2457-Providence Photonics, LLC) state when comparing the aircraft and satellite platforms, the difference lies in the potential frequency of observations. Aircraft platforms can provide a fine spatial resolution and lower detection threshold, but survey frequency is dependent on the scheduled aircraft campaigns. Satellites provide the advantage of frequent surveys. The commenter's (2345-GHGSat Inc.) satellites are currently the only ones capable of detecting emissions at the proposed 100 kg/hr emission rate threshold. The current constellation of six satellites (one demonstrator and five commercial satellites) provides the opportunity to observe the same area every two to three days. In April 2023, three additional satellites will be launched (GHGSat Inc, 2022), effectively increasing the opportunity to observe a given area every one to two days. Furthermore, Commenter (2345-GHGSat Inc.) will be launching another three satellites by the end of the fourth quarter 2023, effectively increasing the commercial satellite constellation to ten, one demonstrator, and one commercial satellite with a

---

<sup>102</sup> This comment (or any other comment provided to improve other provisions that we contend are not appropriate to promulgate at all) does not concede that such a program is authorized under the statute. Rather, it is intended to ameliorate the problems associated with such a program in practice. TXOGA maintains that the Super emitter Program should not be issued based on the current proposal.

carbon dioxide sensor (GHGSat Inc., 2023). This satellite constellation will provide the opportunity to monitor methane emissions of a given area on a daily basis. For this, the commenter would like to propose the following tiered approach:

| <b>Remote Sensing Technologies</b> |                            |                           |                            |                            |                    |
|------------------------------------|----------------------------|---------------------------|----------------------------|----------------------------|--------------------|
| <b>Tier</b>                        | <b>Temporal Resolution</b> | <b>Spatial Resolution</b> | <b>Detection Threshold</b> | <b>Source Localization</b> | <b>Sensitivity</b> |
| Analytics                          | Weekly                     | 1000                      | 1000s                      | No                         | Low                |
| Public Satellites                  | Varies                     | Varies                    | >1000                      | Varies                     | Low-Medium         |
| GHGSat Satellites                  | 2-3 days (5 satellites)    | 25                        | >100                       | Yes                        | Medium             |
|                                    | 1-2 days (8 satellites)    |                           |                            |                            |                    |
|                                    | Daily (10 satellites)      |                           |                            |                            |                    |
| Aircraft                           | Bimonthly                  | <1                        | >10                        | Yes                        | High               |
| OGI                                | Annual                     | At source                 | >1                         | Yes                        | High               |

In addition, current public satellite systems used in the detection of methane from space are only capable of detecting ultra-emitter emissions. The commenter in turn, is currently the only satellite system capable of identifying emissions as small as 100 kg/hr, effectively identifying super emitters.

Response II-14-71: EPA acknowledges the commenters' input.

Comment: Commenter (2393-OSEE) states in the preamble to the SNPR (at 87 Fed. Reg. 74721), EPA requested feedback on the geographic elements of an evaluation<sup>103</sup> of equivalency between a program adopted by a state under either a CAA 111(d) plan, EPA's current SNPR, or the November 2021 Proposal. A nation-wide satellite monitoring program operated by EPA and states under a cooperative federalism framework would certainly simplify that evaluation, because an EPA/state run program covering the entire greater methane reductions (focusing on super emitters) than what would have occurred had EPA adopted either the November 2021 Proposal or the SNPR.

Response II-14-72: EPA acknowledges the commenters' input.

Comment: Commenter (2446-IPAA) states EPA should not simply deem these three detection methodologies sufficient/adequate/warranted without input from the general public and/or stakeholders. EPA should provide their basis and justification for these methodologies for the general public to evaluate, instead of simply picking three methodologies and asking the general

<sup>103</sup> The "IRA equivalence determination" referenced in the preamble.

public/stakeholders for the criteria – the "burden of proof" should be on EPA to demonstrate these methodologies are appropriate, not the other way around.

Response II-14-73: EPA acknowledges the comment and in the final rule, EPA is not pre-supposing certain technologies can meet the measurement criteria in the Super-Emitter Program and instead EPA is requiring any remote sensing technology be approved by the EPA for use under this program under the same criteria as the Advanced Methane Detection Technology Program.

Comment: Commenter (2453-Carbon Mapper and RMI) argue EPA should require third-party reporters to use remote methods (not requiring onsite access) to geolocate the origin of methane super emitter plumes to within 100 meters with 90% circular error probability. Precise geolocation can help reduce the likelihood of misidentifying facilities and can aid follow-up analysis by operators.

Response II-14-74: EPA agrees with the commenters' input and the final rule has been revised to include geolocation requirements to ensure that super-emitter data is being provided to the correct owner or operator.

Comment: Commenter (2457-Providence Photonics, LLC) states the specifications for these methods are very general and vague. The commenter did not find any performance based or instrument-based specifications in the proposed regulations to ensure that the method used to identify a super emitter is indeed capable of doing so, including quantifying the emission rate against the proposed threshold of 100 kg/hr as super emitter. The commenter did not find procedures in the proposal to be used to vet the technologies for this purpose. The lack of specificity for qualified methods to identify and quantify an emission as a super emitter will be problematic in implementing and administering the super emitter program. EPA should strengthen this area.

Commenter (2457-Providence Photonics, LLC) states the critical element of the super emitter program is not just detecting what appears to be a super emitter but quantifying the emission rate and comparing it to the super emitter threshold. The current QOGI device QL320 in the market is being upgraded to enable the measurement of emission rates in the range of super emitters. Figure 1 below shows controlled releases of methane at high release rates from an unlit flare and emission rates measured by the QL320. More details of this controlled release test can be found in Exhibit 1.<sup>104</sup>

Response II-14-75: EPA agrees the commenters input and the final rule has been revised to require technology used under the Super-Emitter Program to meet the same level of scrutiny as the Advanced Methane Detection Technology Program.

Comment: Commenter (2457-Providence Photonics, LLC) continues, section §5371b(c) and (d) specify operator's responses after receiving a super emitter notification. What if the operator

---

<sup>104</sup> Figure 1. Emission rates of a super emitter: controlled vs. measured by QL320.

wants to dispute the super emitter event? What will be the procedures to resolve the dispute? What method(s) can be used to confirm that the release was at a sufficiently high rate to qualify as a super emitter? What if the event cannot be replicated upon receipt of the notification? The commenter believes these aspects should be addressed in the final rule.

Response II-14-76: EPA acknowledges the commenters' input. The final rule includes provisions which allows for an owner or operator to challenge a notification as having a demonstrable error, however the burden of proof of the error is on the owner or operator.

Comment: Regarding space sustainability, Commenter (2346-Encino Environmental Services, LLC) notes that their orbit consists of over 30,000 pieces of space debris that are potential safety and environmental concerns. EPA's proposal prompts and encourages an increased surge of satellite launches due to the proposed space monitoring provisions for the oil and gas industry. These provisions add to the already crowded orbital space. While the commenter support satellite monitoring, they also encourage the EPA to pursue effective satellite safety provisions, recycling incentives, debris prevention requirements, and satellite registration notification as technology develops and allows.

Response II-14-77: The Super-Emitter Program is not specific to satellite monitoring and EPA does not have authority regarding the deployment of this technology.

#### 14.4.3.3 Proposed Methane Detection Limit (MDL)

Comment: Commenters (2346-Encino Environmental Services, 2433-EDF et al., 2626-Kayrros) consider the proposed threshold of 100 kg per hour of methane to be appropriate.

Commenter (2433-EDF et al.) states EPA's proposed super emitter threshold of 100 kg/hr of methane of methane released aligns with the agency's stated bases for SERP as a backstop program. This threshold level helps ensure that the program would not capture permissible emission events and that SERP would not be duplicative of other standards or requirements in the rules, like the LDAR program. Rather, SERP would achieve emission reductions by assuring compliance with those rules. Moreover, the high emission threshold ensures that the program is administrable, as it will help avoid an influx of monitoring reports identifying smaller emission events that may be permissible. As the commenter and EPA have noted, there are permissible emission events at lower levels, like emissions from an uncontrolled tank, that would not necessarily be an impermissible emission event.<sup>105</sup>

Commenter (2626-Kayrros) agrees with EPA's decision to define a super emitter based on its flow rate, given the profusion of terms and definitions that vary greatly among stakeholders. The technical capabilities of the three main technologies (satellite, airborne and mobile) vary as well, and the proposed threshold of 100 kg per hour is a sensible compromise. Detection thresholds are highest for satellite monitoring, with systems based on Sentinel-2 (operated by the European Space Agency) being able detect methane sources down to 1 ton/hour. The detection threshold of

---

<sup>105</sup> Id. at 74749; 2022 Joint Environmental Comments, *supra* note 1, at 63, 139.

the latest generation of satellites is measured in hundreds of kilograms per hour, and it is reasonable to expect the next generation of space sensors to reliably detect sources at 100 kg/hour.

Fig 1. Histogram of methane super emitters detected in selected oil & gas basins around the world using satellite imagery from Sentinel-2, detection threshold of Sentinel-2 and expected detection threshold of PRISMA.<sup>106</sup>

Additionally, commenter (2433-EDF et al.) states the use of a 100 kg/hr of methane threshold for this program is appropriate for the underlying legal justification and also based on a host of scientific, technical, and practical considerations. Most importantly, this threshold properly focuses resources on the largest and most harmful emission events, prioritizing their quick mitigation and repair. Emissions of this magnitude could release thousands of tons of methane in a matter of days or weeks. In the absence of SERP, these emissions might go undetected for up to six months or more (the length of time between semiannual LDAR inspections). A persistent event of this duration would release over 400,000 kilograms of methane, an amount having the same climate impact as 3,400 homes' annual energy usage.<sup>107</sup> In addition, such emission events should not be occurring at a properly designed and operated site, and therefore will likely indicate abnormal processes and equipment failures that are violations of the underlying regulatory requirements.

The commenter's (2433-EDF et al.) PermianMAP project, which consisted of numerous flyovers in the Permian Basin spanning multiple years, found a significant number of emission events exceeding 100 kg/hr from a wide range of operators. Many events of this magnitude resulted from unlit flares, failures on tank control systems, and gathering line malfunctions. Unlit flares and failed tank controls are both violations of the proposed standards for those affected facilities.<sup>108</sup> Other studies have frequently found that emission events above 100 kg/hr of methane make up a large fraction of total emissions even if they are generated by a small number of sites. For example, Zavala-Araiza et al. (2017) found that 20% of emissions were from sites with emission rates above 100 kg/hr. Researchers in the Permian have found 30-50% of emissions were due to sources with emission rates greater than 100 kg/hr.<sup>109</sup> And Cusworth et al. (2021) found that 44 out of 1000 sites observed had emission rates greater than 100 kg/hr, with some as high as 5,000 kg/hr.<sup>110</sup>

Commenter (2433-EDF et al.) states the scientifically backed 100 kg/hr threshold therefore appropriately captures the largest events likely to be violations of underlying standards while excluding many smaller permissible emissions, like certain vents and maintenance activities. The threshold also aligns well with the capabilities of currently available screening technologies, some of which require multiple passes before being able to quantify emissions. To address

<sup>106</sup> Kayrros.

<sup>107</sup> EDF Methane Calculator, *supra* note 210.

<sup>108</sup> Additional information, including operator and geographic location, are available publicly on PermianMAP.org

<sup>109</sup> Stokes, et al., An aerial field trial of methane detection technologies at oil and gas production sites, Chem Rxiv (2022), <https://chemrxiv.org/engage/chemrxiv/article-details/625f27d2742e9f9470644f24>.

<sup>110</sup> See also Commenter (2433-EDF et al.) letter Section IV.C.1.

concerns about false detections of permissible maintenance events, EPA should require operators to report planned maintenance that could exceed 100 kg/hr and this information should be made publicly available. Commenter (2433-EDF et al.) also urge EPA to consider a secondary threshold of 1000 kg/hr that would entail heightened response action.

Response II-14-78: EPA acknowledges the commenters' input. EPA is maintaining the 100 kg/hr of methane threshold for a super-emitter detection however we realize this definition may be overly prescriptive in describing what technology could be used for this program, specifically limiting data from some satellite systems with higher detection thresholds as they would still provide actionable (*i.e.*, EPA verifiable) data. EPA has revised the language to remove any disincentives from using technology that is less sensitive than 100 kg/hr of methane.

Comment: Commenters (2306-Citizen's Climate Lobby, 2365-Climate Action California, 2410-California Office of the Attorney General et al.) request EPA lower the minimum threshold from 100 kg/hr.

Commenter (2410-California Office of the Attorney General et al.) suggests lowering the 100 kg/hr threshold for defining a super emitter emissions event in order to identify and mitigate a wide range of emissions events. The commenter suggests a threshold of 70 kg/hr to ensure that the super emitter threshold is within the range of what satellite monitoring can detect. While, as EPA notes, "no specific mass based or production-based rates have been formally or consistently applied to the term,"<sup>111</sup> several studies have defined super emitters with thresholds as low as 26 kg/hr.<sup>112</sup> One study applied a threshold of 26 kg/hr because it captured the highest-emitting one percent of sites, which accounted for nearly half of total site emissions in the production region.<sup>113</sup> A lower threshold would enable the SERP to reduce a larger quantity of methane and associated VOC emissions, while still ensuring that the program does not duplicate other requirements of the proposed rule.

Commenter (2410-California Office of the Attorney General et al.) argues lowering the threshold for a super emitter emissions event would not significantly increase costs to owners and operators and would in fact allow facilities to recover more natural gas for sale rather than emitting the gas into the atmosphere.

Commenter (2306-Citizen's Climate Lobby) notes that for notices about emissions below 100 kg/hour, the rule proposes that owners "are not required to take the actions." The rule should require owners to correct the emissions at least before a ton of methane escapes. Good facilities run well within the limits. Any exceedance which notifiers find should be corrected. This involves changing "rate of 100 kg/hr of methane or greater" to "rate higher than allowed by the

Cusworth et al., Intermittency of Large Methane Emitters in the Permian Basin, 8 Env. Sci. & Tech. Letters 567 (2021), <https://doi.org/10.1021/acs.estlett.1c00173>.

<sup>113</sup> Zavala-Araiza et al., *supra* n.86.

Rule”, and in (c) “10 calendar days” to “10 hours or before a ton of methane escapes, whichever is longer”.

Commenter (2365-Climate Action California) notes other organizations have referred to emissions rates over 25kg/hr as super-emissions. The EPA should consider lowering the emissions rate that qualifies as a super emitter event after the SERP has been underway for a few years.

Response II-14-79: EPA acknowledges the commenters’ input; however, EPA has chosen to maintain the super-emitter threshold of 100 kg/hr of methane.

Comment: Commenters (2227-Western Energy Alliance, 2283-Endeavor Energy Resources, 2399-GPA Midstream Association, 2458-MiQ, 2483-INGAA) indicate the minimum threshold needs to be increased from the proposed 100 kg/hr. The event threshold is unjustified and inappropriately low.

Commenter (2458-MiQ) recommends that EPA only be directly and immediately involved in events that are extraordinary (i.e., ultra-emitter events of >1000 kg/hr). Involvement in other events may result in a slow-down of operator follow-up and repair. This would result in more methane being released – at odds with the intention underlying the SERP. EPA may, of course, follow-up based on reports review.

Commenter (2227-Western Energy Alliance) notes that a super-emitter event would represent one hour of 100 kilograms or 0.1 metric tonnes (mT) of methane emissions which is equivalent to 2.5 mT of CO<sub>2</sub>e emissions. For comparison the proposed Subpart W new source category of “other large release events” has a reportable event threshold of 250 mT of CO<sub>2</sub>e emissions, which would be the equivalent of just over 4 days of a continuous NSPS OOOOb super-emitter type event. In comparison to the Subpart W “other large release” threshold, the super-emitter threshold is excessively stricter, indicating the proposed NSPS OOOOb threshold is too low.

Commenter (2283-Endeavor Energy Resources) argues EPA does not fully explain how it reached these 100 kg/hr thresholds. Instead, the agency mostly emphasizes the need to set a threshold sufficiently high enough to avoid duplication of other monitoring programs and to focus resources on “the largest and most concerning emissions events.”<sup>114</sup> But that explanation does not support the selection of 100 kg/hr, as opposed to some other number. In fact, the closest to a justification is EPA’s observation that there are satellites purportedly capable of identifying emission events greater than 100 kg/hr at individual sites.<sup>115</sup> Thus, absent some other explanation, it appears that EPA selected its threshold based on simply the capabilities of existing detection technology, rather than public health or environmental considerations.<sup>116</sup>

---

<sup>114</sup> Id. at 74,749.

<sup>115</sup> See Id.

<sup>116</sup> See also Id. (“EPA is soliciting comment on this list of technology types that could be applied for the identification of super emitter emissions events and the threshold of 1 00 kg/hr of methane.”).

Commenter (2283-Endeavor Energy Resources) provides EPA 's proposed super emitter threshold equates to 0.1 metric tons per hour ("mt/hr") of methane, or approximately 2.5 mt/hr of carbon dioxide equivalent ("CO<sub>2</sub>e") as a point of comparison.<sup>117</sup> EPA has recently proposed revisions to the GHGRP and has specifically proposed a category of "other large release events" to capture "abnormal" emissions events not otherwise accounted for in the existing regulations and has defined that category to encompass events emitting at least 250 metric tons of CO<sub>2</sub>e per event.<sup>118</sup> If EPA does retain this program in any final rule, it should consider aligning its definition of super emitter event in the Methane Proposal to better align with its proposed category of "other large release events."

Commenter (2399-GPA Midstream Association) recommends that if the agency pursues this approach, it should align the threshold for notification with the proposed revisions to EPA's GHGRP, 40 CFR Part 98, which has a proposed reporting threshold for "large emission events" of 250 tonnes methane carbon dioxide equivalents (or 10 tonnes of methane). Applying a 24-hours timeframe for such events, this would result in a threshold of approximately 415 kg/hour. Should EPA increase the Subpart W threshold, the commenter would recommend EPA aligning this program accordingly. Likewise, EPA should align with the phrasing of "large emission events" in subpart W, in lieu of "super emitter."

Commenter (2483-INGAA) states the threshold of 100 kg/hr for the SERP needs to be increased because normal, permitted operations (including blowdowns, which are done for safety purposes) will exceed that threshold. Any permitted emissions cannot be considered a "super emitter event." In addition, the duration of the associated measurement is undefined, and additional clarity is needed regarding measurement duration and documentation of long-term or persistent emissions.

Commenter (2483-INGAA) provides the example, EPA has collected data, by event type, under Subpart W of the GHGRP. One of the examples in those reported data is compressor blowdowns, which can occur when a unit is taken out of service due to a decrease in pipeline demand or to conduct maintenance. Data from the GHGRP for 2016 compiled by the PRCI showed an average compressor blowdown of approximately 500 kg per event. Scrubber blowdowns (another event type under the GHGRP) averaged 1,700 kg per event in 2016. While scrubber blowdowns are rare (occurring on average less than once a year<sup>119</sup>), they could result in the owner or operator receiving a notice under the SERP, even though those emissions result from normal operations and are not "super emitter" events.

---

<sup>117</sup> This is calculated using EPA's Greenhouse Gas Equivalences Calculator, available at <https://tinurl.com/GHGEC>.

<sup>118</sup> See Revisions and Confidentiality Determinations for Data Elements Under the Greenhouse Gas Reporting Rule, 87 Fed. Reg. 36,920, 36,928, 37,083 (June 21, 2022). EPA similarly characterizes the Methane Proposal's super emitter events as "abnormal" emission events. See 87 Fed. Reg. at 74,747.

<sup>119</sup> PRCI, "Methane Emissions from Transmission and Storage Subpart W Sources," at 10 (Aug. 2019) (noting there were 296 scrubber/strainer blowdowns across 350 facilities in 2016), <https://www.prci.org/Research/CompressorPumpStation/CPSProjects/CPS-17-01A/142206/168614.aspx?source=generalSearch>.

Commenter (2483-INGAA) adds further support for the fact that the threshold for the SERP is too low can be seen by examining the “incident” reporting threshold in PHMSA regulations. Those regulations have a reporting threshold of 3,000,000 standard cubic feet (SCF) of natural gas.<sup>120</sup> For natural gas containing 92% methane, this equates to 57,600 kg/hr—magnitudes higher than the proposed 100 kg/hr threshold. In addition to the PHMSA regulations, state programs also show that the threshold of 100 kg/hr for the SERP is too low. For example, the programs in Louisiana and Maryland have thresholds of 1,000,000 SCF.<sup>121</sup> Additional examples include: a single one-hour event at the proposed threshold equates to emissions that are 0.01% of the applicability threshold for facility reporting under EPA’s GHGRP. EPA has referred to other events, such as the Aliso Canyon storage well event in Southern California, as examples of super emitter events but that event had cumulative emissions six orders of magnitude higher than the proposed threshold and hourly rates nearly three orders of magnitude higher than the proposed threshold.

Response II-14-80: EPA acknowledges the commenters’ input, we acknowledge that some super-emitter events will be larger than 100 kg/hr however limiting investigation to only higher-level emissions, negates the potential emission reductions from emission events using the threshold of 100 kg/hr of methane in the NSPS.

Comment: Commenter (2315-DEC) does believe that EPA has partially addressed the super emitter issue in wells by removing the minimum emissions threshold by which they must comply. While the additional language that was proposed may not require all wells to detect for leaks at the emission rate that the New York State regulation does, the commenter supports this portion of the proposal.

Response II-14-81: EPA acknowledges the commenters’ support.

Comment: Commenter (2346-Encino Environmental Services, LLC) states weather, wind, sun positioning, radiative transfer, and other factors must be considered to properly quantify event detection. Periodic calibration events should be utilized to ensure that above ground systems are realized according to manufacturer recommendations. In addition, the commenter believes EPA should adopt stricter rules and regulations surrounding above ground monitoring capabilities.

Commenter (2346-Encino Environmental Services, LLC) argues a measured average MDL should be adopted for various operations. Measured average MDLs are recommended due to potential plume dispersion and contamination from neighboring sites (transient emissions). Ground-based emissions verification tools can be used to corroborate aerial findings and aerial site-specific action levels. Additionally, surveys should be done in a manner that ensures that CMS systems are fully functional and stable prior to use of visual detection systems. Moreover, there should be a testing protocol for above ground systems that ensure not only the MDL of

---

<sup>120</sup> 49 CFR § 191.3(1)(iii) (definition of Incident).

<sup>121</sup> Louisiana Admin. Code tit. 33, pt. 3, § 309; Code of Maryland Regulations 26.11.41.

each system, but also ensures data reliability from detection, monitoring, stability, clarity, and network reliability.

Commenter (2346-Encino Environmental Services, LLC) continues, there should be an MDL and chemical composition established for all above ground monitoring systems. With currently available systems, many times there can be false positives for different chemical combinations that would result in some companies, locations, or entities being classified as super emitters and/or other action levels (thresholds, i.e., air-quality permit limits) when they do not actually produce methane outputs (spectral interferences – water vapor (H<sub>2</sub>O), carbon dioxide (CO<sub>2</sub>), ammonia (NH<sub>3</sub>), etc.). There should also be a requirement for multiple device verification for all MDL operations and testing procedures.

Response II-14-82: EPA acknowledges the commenters' input, the final rule includes the requirement that technology be approved for use in the Super-Emitter Program, as part of that program a technology provider would need to address any potential interferences in their measurement approach and develop "method" identifying DQOs and DQIs to ensure the measurement is performed correctly and any interferences are minimal. Regarding the sensitivity requirements, technology used for the Super Emitter Program would define their detection threshold based on probability of detection, in the same manner as the Advanced Methane Detection Technology Program.

While this comment is specific to a technology provider, EPA also recognizes many candidates third parties use public or semi-public data streams from multiple satellites deployed through National or International Space Agencies. EPA does not intend to conduct a review of the base technology being used for these types of efforts and will instead need to evaluate how the candidate third-party takes data from these satellites to ensure detection and location.

Comment: Commenter (2366-BHE) gives the example, several sectors have completed over a decade of annual measurements of key sources of potential leaks, such as leakage from unit isolation valves through compressor vents, reciprocating rod packing leakage, and centrifugal compressor wet seal degassing vent emissions. That data, and other available peer reviewed data, should be analyzed to assess potential emission rate thresholds and the implications (i.e., cost and benefit) of choosing one threshold over alternatives.

Response II-14-83: EPA acknowledges the commenters' input.

Comment: Commenters (2346-Encino Environmental Services, LLC, 2626-Kayros) adds space-based, or even aerial monitoring can be misleading if not calibrated properly.

Response II-14-84: EPA acknowledges the commenters' input.

#### 14.4.3.4 Permitted Operations/ Short intermittent events

Comment: Commenters (2220-WDEQ, 2248-NDPC, 2254-Permian Basin Petroleum Association (PBPA), 2351-Jonah Energy LLC, 2366-BHE, 2393-OSEE, 2399-GPA Midstream

Association, 2403-The Petroleum Alliance of Oklahoma, 2428-API, 2446-IPAA) argue the proposed threshold of 100 kg/hr of methane is problematic. EPA has not properly considered the types of standard events that occur within natural gas operations, or the time element associated with “event-based” emissions (such as venting emissions during normal operation and maintenance) versus continuous or persistent emissions.

Commenters (2220-WDEQ, 2248-NDPC, 2254-PBPA, 2294-Ohio Oil and Gas Association, 2351-Jonah Energy LLC, 2366-BHE, 2391-CEC, 2393-OSEE, 2399-GPA Midstream Association, 2403-The Petroleum Alliance of Oklahoma, 2428-API, 2429-Wyoming Outdoor Council, 2446-IPAA) are concerned that certain permitted events, such as scheduled blowdowns or maintenance and safety measures could erroneously appear as “super emitter” events as defined by this program. EPA’s super emitter program should identify the sampling timeframes and protocols to ensure the emission event is ongoing and/or persistent. In these instances, operators would have to undertake unnecessary root-cause analyses in spite of the fact that the events reported are not compliance issues, nor are they repeatable for operators.

Response II-14-85: EPA acknowledges that the Super-Emitter Program could identify maintenance events with this program and has structured the investigation and reporting of these allowable events in the final rule to account for these events.

Comment: Commenters (2254-PBPA, 2305-The Williams Companies, Inc., 2366-BHE, 2446-IPAA) add EPA has not justified this threshold versus alternative emission levels. For example, the initial proposal discussed example events that triggered the need for a super emitter element within these regulations, but the examples provided were long duration events with emissions orders of magnitude higher than a shorter-term event emitting at 100 kg/hr. EPA should assess the implications of the threshold versus alternatives. Commenter (2254-PBPA) argues it would be more defensible for EPA to align the threshold with the GHG Reporting Program, which defines “other large release” as a release of at least 250 mtCO<sub>2</sub>e per event.

Response II-14-86: EPA acknowledges the comment; however, the EPA is maintaining the 100 kg/hr of methane in the NSPS final rule. The proposed definition for large release in the GHGRP is not intended to be aligned with the NSPS as the reporting structure in the two rules have different goals. Likewise, the proposed revisions to the GHGRP recognizes the NSPS super-emitter program event may not already be accounted under the source categories in subpart W, which is why they proposed to require facilities to consider notifications of potential super-emitter emissions event under the super-emitter provisions of NSPS OOOOb at 40 CFR 60.5371b and calculate associated events when they exceed our proposed thresholds (88 FR 50290).

Comment: Commenters (2248-NDPC, 2393-OSEE) state the preamble for the SNPR states that “Given the intermittency of super-emitter emissions events, the failure of the operator to find the source of the super-emitter emissions event upon subsequent inspection would not be proof, by itself, of demonstrable error on the part of the third-party notifier.” 87 Fed. Reg. 74750. This statement implies that the company or facility in question is guilty until proven innocent. Given the possibility of errors, this is highly problematic, and EPA should show discretion in accepting

information provided by 3rd parties as proof that a super-emitter exists. Plausible reasons why no super-emission event happened such as accuracy of the location, actual concentration of the super-emitter, and human error in interpretation could be reasons why such an allegation of a super-emitter at a facility may be incorrect, and it should not be assumed that the company just did not find the methane release. EPA taking a stance of guilty until proven innocent should not be the default for the super-emitter program.

Response II-14-87: EPA has revised the final rule to improve the reliability of the technology used in this program and has added additional responsibility of the third-party notifiers to ensure improved quality of the data being provided to a potential owner or operator. EPA has chosen to finalize the Super-Emitter Program as primarily a compliance assurance program. A notification of a super-emitter event by EPA is not an allegation of a violation and is there to trigger an obligation to investigate by the owner or operator of an applicable oil and gas facility.

Comment: Commenter (2366-BHE) states typical operational releases may exceed the proposed threshold in some cases. For example, EPA has collected data on compressor station blowdowns, by event type, under Subpart W. An example from that reported data is compressor blowdowns, which can occur when a unit is taken out of service due to a decrease in pipeline demand or to conduct maintenance. Subpart W data for 2016 compiled by PRCI in a report<sup>122</sup> provided to EPA showed an average compressor blowdown of approximately 500 kg per event. Another event type, scrubber blowdowns averaged 1,700 kg per event in 2016. However, this event occurred, on average less than once per year (i.e., 296 total scrubber/strainer blowdowns occurred across 350 facilities in 2016). Clearly, these operational emissions, with data already available to EPA through the GHGRP and reported on-line annually for public access, do not constitute “super emitter” events.

Commenters (2248-NDPC, 2366-BHE, 2399-GPA Midstream Association) state singular observations of emissions from remote sensing technologies may constitute an observation of a planned or authorized activity that is part of normal facility operations, such as a blowdown or other authorized short-term events (an engine startup) or short-term malfunctions (a stuck dump valve) that vent gas at a high rate, but for a short period. Third-party observations may estimate these emissions as exceeding the threshold, but the actual estimated emissions may be well below the threshold. Accordingly, EPA should provide that, operators/companies notified of an observation, should not be subject to reporting and corrective action if the event was a) associated with normal operations or maintenance activities and/or b) the observed emissions event is determined by the operator to not exceed the applicability threshold. To implement this, the commenters recommend that for an emissions observation to be deemed as a persistent emission event for which a notice may be submitted, the observation must have been made between two distinct time intervals (such as 3 hours apart).

Commenter (2366-BHE) provides an example, a third-party could measure an emission rate of 1.7 kg/min for a few minutes and assume the source exceeds 100 kg/hr (i.e., 1.7 kg/min x 60 min

---

<sup>122</sup> Pipeline Research Council International (PRCI) Report, “Methane Emissions from Transmission and Storage Subpart W Sources,” Report No. PR-312-16202-R03, August 2019.

= 102 kg/hr). In reality, this source could be a single, short-term blowdown event (e.g., compressor blowdown) lasting several minutes with total emissions far less than 100 kg and not at all indicative of a “super emitter” event or source. It is imperative that this program include proof that the emission source is persistent (e.g., an ongoing large leak) and a time element and/or cumulative emission total should be defined for categorizing an emission source as a super emitter.

In Commenter’s (2429-Wyoming Outdoor Council) decades of air quality work and experience in Wyoming, uncontrolled blowdowns have been a significant source of unregulated emissions, especially in the UGRB. For example, during a two-month period in the winter of 2020, one major operator in the basin reported 1,008 blowdown events totaling more than 159 hours of uncontrolled emissions venting. With dozens of other operators in this same region, we’d estimate that blowdowns result in hundreds of thousands of dollars in wasted gas annually and thousands of tons of vented methane and VOCs in this region alone.<sup>123</sup>

Response II-14-88: EPA acknowledges the commenters concerns that blowdowns will identify as super-emitter events if these emission events are in excess of 100 kg/hr of methane. The program is structured in such a manner that when an owner or operator receive a notification of an event and when that a maintenance event was the cause of the emission, they would report it as such. EPA has chosen to finalize the Super-Emitter Program as primarily a compliance assurance program. A notification of a super-emitter event by EPA is not an allegation of a violation and is there to trigger an obligation to investigate by the owner or operator of an applicable oil and gas facility. EPA recognizes that permitted emission events, like blow-down events, are currently reported to the public through other non-governmental programs, without context.

Comment: Commenters (2258-MSC, 2305-The Williams Companies, Inc.) request that EPA clarify the source of the 100 kg/hr emission rate used in the definition of “super emitter events.” The commenters’ (2258-MSC, 2305-The Williams Companies, Inc.) understanding is that not all remote sensing technologies that are proposed and not all vendors providing these technologies are able to meet that sensor resolution. Additionally, the commenters (2258-MSC, 2305-The Williams Companies, Inc.) maintain that the threshold does not include a minimum monitoring period to characterize an event as a “super emitter.” As a result, a brief event lasting seconds or minutes could be categorized as a “super emitter” event during a flyover using remote sensing technology. This could result in high numbers of events requiring a rapid response and use of operational resources when the total emissions from the event do not meet this threshold over a one-hour period. At a minimum, there should be a duration component determined by at least two observations more than 24 hours apart with detected emissions above the permitted threshold.

---

<sup>123</sup> More than meets the eye: How unseen emissions continue to impair air quality in Wyoming upper Green River Basin. April 2021. <https://wyomingoutdoorcouncil.org/2021/04/29/how-unseen-emissions-continue-to-impair-air-quality-in-wyomings-upper-green-river-basin/>.

Commenters request EPA consider revising the definition of a super emitter emissions event to be a quantified emission rate that is persistent for more than 24 hours and that averages greater than 100 kg/hr over that time period. The EPA is proposing to define a super emitter emissions event as any emissions detected using remote detection methods with a quantified emission rate of 100 kg/hr of methane or greater. However, no duration is proposed. A temporal component is necessary to differentiate a super emitter emissions event from a short-term normal operations event.

Commenter (2391-CEC) recommends EPA establish a minimum monitoring period for the proposed super emitter event threshold of 100 kg/hr. Without this, a brief event lasting mere seconds or minutes could be categorized as a “super emitter event” during a flyover using remote sensing technology. That could result in high numbers of events requiring a rapid response and needless expenditure of an operator’s resources when the total emissions from the event do not meet the threshold over a one-hour period. Commenter (2391-CEC) recommends that EPA specify that a super emitter event does not occur unless the 100 kg/hr emission rate is observed at least two times over a period of no less than 24 hours.

Commenter (2446-IPAA) asks will one "fly-by" measurement extrapolated out to an hour be sufficient to trigger EPA's requirements on owners/operators? If EPA is using an hourly based emissions rate, and it would seem unlikely that a shorter time would be sensible, then data taken to identify the super emitter incident is both of that duration and persistence. For example, measurements must be longer than one hour such as either multiple hours over a single day or hourly over more than one day. Past history of data collection using the methods EPA has identified for this program have generated not just hourly emissions, but annual emissions based on data taken for ten minutes or less. This type of short duration data collection must not be allowed. The burden of proof that the source is emitting at a rate of 100kg/hour needs to be on the third-party notifier – a snapshot in time is not sufficient. EPA should establish criteria for the third-party to demonstrate that there is some reasonable likelihood that there is potential event at the facility such that excessive rates of methane are occurring for an extended period of time. Examples of requirements that EPA could require include, but are not limited to, continuous actual measurement for a period of time or repeated snap-shot measurements, periodically, over a period of period, e.g., three measurements separated by 12-hour intervals.<sup>124</sup>

Commenter (2248-NDPC) requests the criteria for Super Emitting events be expanded to require more than one data point separated by a reasonable period of time, (i.e., at least a day).

Response II-14-89: EPA acknowledges the commenters’ input. EPA disagrees with the commenter that super emitter events must be proven as persistent. EPA recognizes that these events are infrequent and may be intermittent, however the intent of this additional monitoring effort is to identify this emission when they happen so the cause can be investigated.

---

<sup>124</sup> The cost of multiple flights/verification should not be a consideration as EPA does not consider the costs of flights associated with advanced methane detection technologies.

Comment: Commenter (2433-EDF et al.) also recognizes potential concerns about intermittency, wherein the detected emissions may not be present when the operator responds and visits the site. While emission events of this magnitude could be intermittent, they will generally indicate an underlying operational or design flaw at the site and should therefore be immediately investigated. Further, many may be persistent major malfunctions like unlit flares that should be immediately addressed. Commenter (2433-EDF et al.) also notes that the LDAR standards do not require multiple detections before follow-up and adding this requirement in SERP would also be inappropriate. Because events exceeding 100 kg/hr are extremely harmful, a single detection and quantification is sufficient to trigger a response and multiple observations should not be required. Many available technologies already require multiple passes before quantification is possible as well. If there are repeat detections at the same site, the operator should face heightened response requirements.

Response II-14-90: EPA acknowledges the commenters' support.

#### 14.4.3.5 Source Allocation

Comment: Commenter (2345-GHGSat Inc.) understands that source allocation is a critical aspect of the super emitter emissions response program. Satellites that have a coarse spatial resolution have challenges to correctly allocate the emission source. Satellites with finer spatial resolution (e.g., like GHGSat's) have the ability to zeroing on a facility, however, ownership registered in different databases may or may not be up to date. A database aggregator like Enverus proves to be a good source of ownership information. This is a subscription-based system. The premise of the platform is that it provides a myriad of information associated with the entire energy value chain. Despite this, not all the frequent changes get updated immediately. Other sources are associated with the different environmental permitting dependencies in each State. Even though these data are free, scouring the different databases can be daunting.

Response II-14-91: EPA acknowledges the commenters' input.

Comment: Commenter (2258-MSD) states the proposed regulation does not account for the fact that using remote sensing to detect methane emissions accurately often takes five to seven detections during multiple flyovers.<sup>125</sup> Weather conditions, wind speed, distance from the source and other factors can produce variability in results. Geolocation errors are also common, creating the potential for mis-identifying sources or even which facility the emissions are coming from.

Commenter (2258-MSD) is concerned that the prescribed methods may overstate the emission rate due to variability in leak localization. The prescribed testing methods have varying ability for leak localization from 1 to 10 meters for fixed monitors, 1 to 50 meters for flyovers and 25

---

<sup>125</sup> To better understand the variables regarding remote sensing, the MSD encourages the U.S. EPA to review "Monitoring methane emission from oil and gas operations" – Collins, Orbach et al; Optics Express: <https://opg.optica.org/oe/fulltext.cfm?uri=oe-30-14-24326&id=477126>.

meters to 7 kilometers for satellite monitoring. Variability in leak localization can be due to distance, weather, and site conditions.

Response II-14-92: EPA acknowledges the commenters' input, EPA has recognized spatial resolution as a concern, and the final rule EPA has included criteria for identifying emission sources by third-party notifiers and has taken spatial resolution into account when conducting follow-up investigations.

Comment: Commenter (2258-MSC) notes that identified emissions can include background emissions and emissions from other sources. The combined emissions will result in overstating emissions and potentially triggering the super emitter programs investigation, publication and reporting requirements.

Response II-14-93: The final rule places the responsibility on the third party to identify the accuracy of the geolocation of the emission event and the mass emission threshold has been met. We also recognize that background emission could overstate emissions, however the super-emitter threshold is so high any overstatement of emissions should be minimal unless the background source also is or nearly a super-emitter.

Comment: Commenter (2354-Business Roundtable) states in major oil and gas producing areas, it is not uncommon for hundreds of individual sources to exist within a relatively small geographic area. In these areas, these hundreds of individual sources may be owned or operated by dozens of different companies. Accurately identifying a specific source of emissions and/or the owner or operator responsible for the equipment in these dense producing areas likely will be challenging with the remote observation technology in use today. While good data exists as to the location of individual oil and gas well sites, easily accessible and precise public data does not exist for processing facilities, tank batteries and other oil and gas field infrastructure subject to regulation under this proposed rule. As a result, a super emitter event triggering a required response can be misdirected to the incorrect owner or operator. This will waste resources that could better be used in ensuring compliance with the new regulations.

Response II-14-94: EPA acknowledges the commenters' input. EPA agrees that identifying sources can be difficult, as mentioned, however it is possible based on the technology chosen by a third party and the procedures followed by the third-party to confirm attribution. With EPA is a centralized role to evaluate technology and the expanded criteria for third parties to meet to be certified, owner or operators should have more confidence in the notification data they receive as part of this notification. Furthermore, owner or operators do have the opportunity to challenge a notification if they believe there is demonstrable error.

#### ***14.4.4 Root Cause Analysis***

Comment: Commenters (2627-BCI, 2296-NMED, 2345-GHGSat Inc., 2433-EDF et al.) support the requirement for owners or operators to conduct a root cause analysis upon notification of a super-emitter event and make the corresponding corrective action.

Commenter (2345-GHGSat Inc.) provides a table recommending Root Cause Analysis be required for various classification of emitter events.

| Emission rate (kg/hr) | Classification  | OGI follow-up (days) | Repair-First attempt (days) | Repair-Final attempt (days after first attempt) | Delay of Repair | Root Cause Analysis? |
|-----------------------|-----------------|----------------------|-----------------------------|-------------------------------------------------|-----------------|----------------------|
| Below 10              | Process-emitter | 14                   | 30                          | 35                                              | Yes             | No                   |
| ≥10 to <100           | Major-emitter   | 14                   | 15                          | 30                                              | No              | Yes                  |
| ≥100 to <1000         | Super-emitter   | 7                    | 10                          | 25                                              | No              | Yes                  |
| ≥1000                 | Ultra-emitter   | 5                    | 5                           | 20                                              | No              | Yes                  |

Commenter (2433-EDF et al.) argues EPA’s proposed response measures for operators, which include a root cause analysis and corrective action, are appropriate due to the common causes of super emitter events and the need to quickly mitigate such events to drive down emissions. Super emitter events of this magnitude will often be caused by unlit flares and tank malfunctions. In these situations, operators should be able to fix the underlying issue quickly, but may have to implement equipment, design, or operational changes to prevent recurrence. In situations where the emissions result from a permissible emissions event, maintenance activity, or are not from an affected source, operators should be able to easily make that determination based on their own records and could submit that information in response. There may also be situations in which the emissions are intermittent and no longer present when the operator surveys they site. In this instance, a certification from the operator that emissions were not present should satisfy their response obligation. However, if there are repeat detections at the same site or a detection of very large emissions (over 1000kg/hr), there should be heightened response requirements.

Response II-14-95: EPA acknowledges the commenters’ input, we see the utility of a heightened response for higher level detections, however, to avoid additional complexity to the program, we are maintaining the super emitter threshold of 100 kg/hr of methane in the final rule.

Comment: Commenters (2177-Ute Indian Tribe, 2282-Kinder Morgan Inc., 2305-The Williams Companies, Inc., 2399-GPA Midstream Association, 2403-The Petroleum Alliance of Oklahoma, 2428-API, 2458-MiQ, 2483-INGAA) state that requirements for a ‘root cause analyses should be revised due the wide definitions of this term across different groups.

Commenters (2177-Ute Indian Tribe, 2282-Kinder Morgan Inc.) recommend replacing "root cause analysis" with "investigation". The details of that investigation should be left to the operator. Therefore, if EPA moves forward with the SERP, EPA should rename the “root cause analysis” to better convey the contemplated tasks. Commenter (2282-Kinder Morgan Inc.) also suggests “Immediate cause inspection” as an appropriate term that would better reflect the apparent intent behind the existing proposed regulatory text.

Commenters (2326-AXPC, 2428-API, 2483-INGAA) suggest that “root cause analysis” be replaced by “investigative analysis.” The commenters do not object to doing an analysis to

determine whether an emissions event has occurred and to take steps to ensure that it will not happen again. But using the phrase “root cause analysis” has connotations that lead to a much more involved process than EPA appears to envision in the Supplemental Proposed Rule.

Commenters (2326-AXPC, 2428-API) support investigating the source and cause(s) of significant emissions events that are brought to an operator’s attention Through the process described in our comments. The commenter agrees that EPA’s investigative actions listed §60.5371b(c) are appropriate and practicable as far as investigating and conducting initial corrective actions for super emitter events. However, EPA’s use of the term “root cause analysis” is problematic and ambiguous. The concept of “root cause analysis” is embedded in numerous other regulatory and non-regulatory programs and has varied meaning and purpose in each application. Thus, use of that term here does not clearly and adequately define the scope of the legal obligation, which will make it difficult for operators to understand what must be done to comply and will invite dispute and controversy if/when this program is implemented.

Commenter (2305-The Williams Companies, Inc.) also recommends the removal of all references to “root cause analysis” within the Supplemental Proposed Rule. The term triggers a specific type of investigatory activity within the oil and gas industry that is significantly different than what is described in the proposed regulatory text. The actions described as a “root cause analysis” in proposed § 60.5371b(c) are investigatory techniques rather than components of a root cause analysis. The American Society for Quality defines root cause analysis as “a collective term that describes a wide range of approaches, tools, and techniques used to uncover causes of problems. Some root cause analysis A approaches are geared more toward identifying true root causes than others, some are more general problem-solving techniques, and others simply offer support for the core activity of root cause analysis.”<sup>126</sup> Under this definition, the root cause analysis is a much more detailed process, and typically involves the participation of numerous individuals and resulting man hours to conduct the analysis and development of recommended corrective actions. That does not appear to be what EPA proposed in the SERP and the EPA should make the appropriate changes to the proposed rule.

Commenter (2399-GPA Midstream Association) recommends that EPA strike references to a “root cause analysis” throughout the Supplemental Proposed Rule and regulatory text as a notice recipient is not actually required to conduct one. It is only required to conduct various inspections and to document various issues listed in proposed §§ 60.5371b(c)(1)-(10). This is not a “root cause analysis” in that it is not a formal systematic investigation, using multiple potential methodologies, into the potential causes of an incident that identifies corrective actions to reduce the probability of similar future incidents.<sup>127,128</sup> Root cause analyses take significant amounts of time – far longer than the 10 days required by the Supplemental Proposed Rule. Therefore, EPA

---

<sup>126</sup> Cause Analysis Tools, American Society for Quality, <https://asq.org/quality-resources/root-causeanalysis/tools>.

<sup>127</sup> See, e.g., OSHA-EPA, Fact Sheet, The Importance of Root Cause Analysis During Incident Investigation (Oct. 2016). Available at, <https://www.osha.gov/sites/default/files/publications/OSHA3895.pdf>.

<sup>128</sup> Dep’t of Energy, Root Cause Analysis Guidance Document, DOE NE-STD-1004-92 (Feb. 1992). Available at, <https://www.standards.doe.gov/standards-documents/1000/1004-std-1992/@@images/file>.

should remove all references to “root cause analysis” and replace them with a more generic and appropriate term, such as “investigation” or “evaluation.”

Commenter (2403-The Petroleum Alliance of Oklahoma) requests EPA use different terminology such as a technical investigation rather than root-cause analysis. Operators should not be required to conduct a detailed root-cause engineering analysis of an event (*e.g.*, an open tank hatch) when a site visit can easily identify the problem and remedy the situation.

Commenter (2458-MiQ) recommends that EPA substitute the term ‘root cause analyses with the term ‘causal examination’. The term root cause analysis is ambiguous and can mean different things to different actors, as well as having different usages in different professional sectors. Commenter (2458-MiQ) recommends that this burdened term be substituted with the more clear ‘causal examination.’ While this is clearer and subject to less ambiguity than ‘root cause analysis’ one can surmise that a search for causation might also result in infinite regress. As such, the commenter recommends that EPA provides a clear definition of what is intended by the term for this section. A definition for ‘causal examination’ might be an analysis of sources and processes involved or potentially involved in a leak that results in a statement of determination about cause and effect that has a high or a reasonable level of associated confidence.

Response II-14-96: EPA acknowledges the commenters’ input and have revised the final rule to replace the root cause analysis with the term “investigation” to avoid any confusion. We have also defined what this “investigation” should consist of to avoid any misinterpretation.

Comment: Commenter (2483-INGAA) recommends the following text changes to §60.5371b(c), (d) of the proposed rule:

(c) Addressing super-emitter emissions events. c conducted within 14 business days, the owner or operator must notify EPA and let the Agency know when the investigative analysis and initial corrective action will be completed, which shall not exceed 90 days.

Response II-14-97: EPA acknowledges the commenter’s input and as part of the change to a primarily a compliance assurance program, EPA has made revisions for how an owner or operator must respond to a super-emitter notification.

The program now only includes a timeline for completing and reporting the super-emitter investigation. The timeline for repairs, if any are required, is dependent on the cause of the super-emitter event.

Comment: Commenter (2282-Kinder Morgan Inc.) states this approach is consistent with other regulatory regimes that also provide a very short timeframe to conduct an immediate cause inspection. For example, a Pipeline and Hazardous Materials Safety Administration (“PHMSA”) regulation provides an apt example of the customary types of analyses that would be performed on a five-day timeframe. 49 CFR § 191.25, on filing safety-related condition reports, requires a report to be filed “in writing within five working days.” Importantly, the information to be included in such reports under § 191.25(c) does not require a “root cause” analysis and is purely

descriptive. In contrast, EPA's Emergency Planning and Community Right to Know Act (EPCRA) regulation provides a longer time period for a more in-depth analysis. Specifically, 40 CFR § 355.40(b) requires a follow-up notice "as soon as practicable" that details, in relevant part, actions taken to respond to and contain a release.<sup>129</sup>

Commenter (2282-Kinder Morgan Inc.) goes further, if EPA intends for the analysis to be a more in-depth root cause evaluation (rather than identifying immediate causes), then the timeframe should be extended to at least 30 days for the complete analysis and corrective action, consistent with the EPCRA example discussed above.

Response II-14-98: As explained above in Response II-14-90 and -91, EPA has removed the requirement for root cause analysis and have revised the owner or operator responses accordingly.

Comment: Commenter (2305-The Williams Companies, Inc.) recommends the SERP also include an avenue by which an owner or operator can quickly respond to a notification without an investigation if the operator can identify the 'emissions event' as a result of a planned, operational emissions event, such as a blowdown. Though this factual information is a component of the "root cause analysis" outlined by the EPA, these events are contemplated and accounted for in a facility's air permit. The implication that the 100 kg/hr of methane threshold triggers an investigation regardless of the circumstances is an arbitrary notion without any reasonable justification.

Response II-14-99: As explained above in Response II-14-90 and -91, EPA has removed the requirement for root cause analysis and have revised the owner or operator responses accordingly. Included in these responses is the identification of any maintenance events which were occurring at the time of the super-emitter event.

Comment: Commenter (2298-Pioneer Natural Resources USA, Inc.) contends no investigative analysis should be required if the emissions are not associated with/emitting from an affected facility under NSPS OOOOb.

Response II-14-100: EPA appreciates the commenters concerns however we disagree that the Super Emitter Program should be limited to NSPS OOOOb. EPA has revised the rule to remove the NSPS OOOOb affected facility definition and is finalizing the Super-Emitter Program as primarily a compliance assurance program. A notification of a super-emitter event by EPA is not an allegation of a violation and is there to trigger an obligation to investigate by the owner or operator of an applicable oil and gas facility. EPA co-proposed the program as a compliance assurance program in the December 2022 supplemental proposal. EPA has detailed the statutory authority of the program in Section X.C.1 and XI.C.1 of the preamble of the final rule.

Comment: (2410-California Office of the Attorney General et al.) supports EPA's suggested timelines for operator response to a super emitter emissions event notification. Given the scale of

---

<sup>129</sup> EPA has interpreted "as soon as practicable" to mean 30 days. 75 Fed. Reg. 39,852, 39,857 (July 13, 2010).

super emitter emissions events, it is imperative that they be addressed and mitigated promptly. EPA's proposal would require owners and operators to initiate a root cause analysis within five calendar days after receiving a third-party notification, and to complete corrective actions within 10 days of notification. Commenter (2410-California Office of the Attorney General et al.) supports these timelines and provide several suggestions to clarify the actions required by owners and operators, to ensure emissions events are promptly mitigated and promote transparency.

Commenter (2410-California Office of the Attorney General et al.) notes under the procedures an owner or operator must undertake after receiving a notification of a super emitter emissions event, the first time that that EPA would receive any update from the owner or operator would be 25 days after receipt of the notification, when the owner or operator submits its written report after completion of the corrective action, or 30 days after receipt of the notification, if the owner or operator determines that the corrective action would take more than 10 days to complete.<sup>130</sup> This means that EPA—and the public—would be in the dark for nearly one month after a super emitter emissions event is discovered.

Commenter (2410-California Office of the Attorney General et al.) suggests that, as an intermediate step, the owners and operators be required to submit a report within 10 calendar days of receiving the notification. This 10-day report could include the following information: (1) whether the reported emissions event is traceable to a source located on the owner or operator's site; (2) whether the emissions event is ongoing, and if not, when it stopped; (3) whether the root cause analysis has been completed, and if so, the results of the analysis; and (4) whether the corrective actions are complete, and if not, justification for why additional time is needed. Additionally, as discussed above, if the owner or operator believes the notification contains demonstrable error, they could submit a report demonstrating the error in lieu of the 10-day report. EPA should also specify that a root cause analysis and corrective action(s) are required even if an owner or operator determines that the emissions event is not ongoing, unless the owner or operator can demonstrate that a super emitter emissions event did not occur.

Commenter (2410-California Office of the Attorney General et al.) notes under EPA's proposal, the first action that an owner or operator is required to take after receiving a third-party notification is to confirm that the reported emissions event is traceable to a source located on their site and investigate to confirm if a super emitter emissions event is still ongoing.<sup>131</sup> EPA does not propose a time frame for this first step. Commenter (2410-California Office of the Attorney General et al.) suggests that owners and operators should be required to complete this first step within five calendar days after receiving the notification. This initial step is essential, as it will confirm whether the emissions are in fact attributable to the owner or operator, and whether the emissions event is ongoing. This timeline would align with the requirement that the owner or operator initiate the root cause analysis within five calendar days.

---

<sup>130</sup> Id. EPA proposes that owners and operators would complete corrective actions within 10 days after receiving a notification and submit a written report 15 days after completing the corrective action.

<sup>131</sup> Id.

Commenter (2410-California Office of the Attorney General et al.) states EPA proposes that owners and operators be required to complete corrective actions within 10 calendar days of receiving a notification.<sup>132</sup> However, EPA also proposes an alternative option when corrective actions will take more than 10 days to complete, whereby an owner or operator can develop and submit a corrective action plan 30 days after receiving a notification, describing the corrective actions completed as of that date, additional measures proposed to reduce or eliminate emissions, and a schedule for completion of those measures.<sup>133</sup> Commenter (2410-California Office of the Attorney General et al.) is concerned that this exemption would swallow the rule and suggest that EPA clarify that owners and operators are expected to complete corrective actions within 10 calendar days of the notification and must provide justification if the corrective actions are not complete in that time frame. The commenter suggests that this justification take the form of a 10-day status report.

Response II-14-101: EPA acknowledges the commenters' input. EPA has made changes to the final rule to account for the changes in the legal authority of the rule. One of these changes is the timing required to conduct the investigation into a super-emitter event. We agree that owner or operators should act as soon as possible to a notification, but we do not find 10 days to be practical for a national rule, instead we are allowing for 15 days. We believe 15 days requirements a reasonable timeframe within which to conduct and report the required investigations, due to the overall scope of the industry and that many of the affected owner or operators operate over multiple basins. We expect as the program matures, many owners or operators will be able to respond in effectively in less time, however due to the novelty of this program, more time is required.

Comment: Commenter (2483-INGAA) recommends the following text changes to §60.5388c(c), (d) of the proposed rule:

(d) Corrective action plans for additional analysis. If, upon completion of the ~~root cause~~ investigative analysis and initial corrective actions such as those described in paragraph (c) of this section, you are notified of a super-emitter emissions event from the same emission source which was determined under paragraph (c) not to be an allowed venting of emissions as part of normal operations, including routine maintenance, or if the initial corrective actions will require more than ~~40~~ 14 business days to complete, you must develop a corrective action plan that describes the initial corrective action(s) completed to date, additional measures that you propose to employ to reduce or eliminate the super-emitter emissions event, and a schedule for completion of these additional measures. You must submit the correction action plan to the Administrator according to the schedule in paragraphs (d)(1) and (2) of this section.

(1) If you are submitting a corrective action plan because you were notified of a super-emitter event from an emissions source which you had previously completed actions in paragraph (c) of this section, you must submit the corrective action plan within ~~30~~ 90 days after receipt of the notification.

---

<sup>132</sup> Id.

<sup>133</sup> Id.

(2) If you are submitting the corrective action plan because you were unable to complete the actions in paragraph (c) in ~~10~~ 14 days, you must notify the EPA submit the corrective action plan within ~~30~~ 90 days of the notification in paragraph (b) of this section.

Response II-14-102: EPA acknowledges the commenters input. We have revised the final rule to remove the corrective action plan requirement, instead with the program as primarily a compliance assurance programs, the timeline for repairs, if any, is dependent on where the emissions are coming from, for example, if the emission event was from equipment subject to the fugitive component emission standard in NSPS OOOOb, you would be subject to the same repair and reporting requirements of that applicable standard.

The only additional reporting requirement is when the super-emitter event is ongoing at the time of reporting, and then you would be required to update the EPA when the event has been repaired.

Comment: Commenters (2306-Citizen's Climate Lobby, 2365-Climate Action California, 2433-EDF et al., 2444-NAACP) contend a condensed timeline is more appropriate to perform a root cause analysis and corresponding corrective action than proposed.

Commenter (2306-Citizen's Climate Lobby) notes P.25 - 40 CFR 60.5371b(d) For issues which need extra time, the rule should require a corrective action plan within 3 days, not 30 days.

Additionally, commenter (2306-Citizen's Climate Lobby) notes on P.23 - 40 CFR 60.5371b(c) When the owner is notified of emissions over 100 kg/hour (2.4 tons/day), the rule should require the owner to start finding the cause within 1 hour, not 5 days, and correct it within 10 hours, not 10 days. For every hour of emissions, the atmosphere is harmed, and neighboring communities are at risk of explosion. Owners who cannot mobilize that fast are not competent to own such dangerous facilities and need to have competent emergency help on call or be fined. If the equipment had a visible fire or chlorine leak, EPA would certainly expect owners to start addressing it in an hour, and have resources prepositioned to do so, and generally expect to solve it within 10 hours. Methane emissions are explosive. Owners can send staff (called pumpers) to close the well and maintenance technicians to fix leaks.

Commenter (2365-Climate Action California) recommends that a root cause analysis and corrective actions begin within 48 hours of notification and completion of corrective actions occur within 7 calendar days. An emission rate of 100kg/hr is large enough to be a priority that should be addressed immediately. Also, because there is a time lag between when a super emitter event is detected remotely and when the analysis needed to locate it is completed, waiting five more days after notification as proposed seems imprudent.

Commenter (2433-EDF et al.) supports EPAs proposed 5-day initiation and 10-day completion timeframe, and urge EPA to consider a shorter initial response requirement given the seriousness of emissions exceeding 100 kg/hr. When equipment, design, or operational changes would be required to prevent recurrence based on the root cause analysis, the commenter believes EPA's proposal to require submission of a written report with a corrective action plan and information

about completion of that plan within 30 days provides appropriate flexibility to operators in addressing more complex issues. The plan should include information about site design, deviations from applicable underlying standards, potential causes of the emission events, and the steps necessary to prevent recurrence. This information should be publicly available and should be sent to state regulators as well so that nearby communities have multiple channels for access.

Commenter (2444-NAACP) argues the timeline is too long between the notification of a high level of pollution within a community and responsive action. As it stands, communities can be poisoned with greenhouse gas pollution under the super emitter program for up to five days prior to any root cause analysis and up to ten days for any corrective action to take place.<sup>134</sup> Under the proposed rule, an owner has discretion once notified of emissions over 100 kg/hour (2.4 tons/day) as to whether they want to act immediately or wait several days to take corrective actions.

Commenter (2444-NAACP) states for every hour of emissions, the atmosphere is harmed, and neighboring communities are at risk of an explosion. As outlined in the NAACP report, air in many Black communities already violates various air quality standards and at least 6.7 million Black people live near oil refineries. Allowing an extensive time period to respond to these crises implicates racial justice issues and runs counter to the promise of environmental justice promised by the Biden Administration. Communities should not have to suffer due to the lack of emergency planning by owners and operators. The regulations must outline the need for owners to have competent emergency help or face accountability actions by the EPA. Additionally, if the equipment had a visible fire or chlorine leak, the EPA should expect owners to start addressing it within an hour, and have resources prepositioned to do so. Resolution of the crisis must take place, generally, within ten hours.

Commenter (2444-NAACP) continues, there are several other places where the proposed rule allows for additional time to act or no action, when communities face continued exposure to high levels of these emissions for an extended period:

- For issues that need extra time, the rule should require a corrective action plan within three days, not 30 days.<sup>135</sup>
- For notices about emissions below 100 kg/hour of methane, the rule proposes that owners “are not required to take the actions.”<sup>136</sup> At a minimum, the rule should require owners to correct emissions before a ton of methane escapes. Good facilities run well within the limits. Any excess found should be corrected. This involves changing “rate of 100 kg/hr of methane or greater” to “rate higher than allowed by the Rule”, and in (c) “10 calendar days” to “10 hours or before a ton of methane escapes, whichever is longer”.

Response II-14-103: EPA acknowledges the commenters’ input. With the rule being finalized as primarily a compliance assurance rule, we have chosen not to finalize the root cause analysis and

<sup>134</sup> Proposed Rule P.23 - 40 CFR 60.5371b(c).

<sup>135</sup> Proposed Rule, P.25 - 40 CFR 60.5371b(d).

<sup>136</sup> Proposed Rule, P.20 - 40 CFR 60.5371b.

corrective action approach and have finalized that owner or operators conduct and prescribed investigation as detailed in Section X.C.2 and XI.C.4 of the preamble of the final rule.

Comment: Commenters (2202-TXOGA, 2284-Kairos Aerospace, 2305-The Williams Companies, Inc., 2399-GPA Midstream Association, 2403-The Petroleum Alliance of Oklahoma, 2483-INGAA) request EPA extend the proposed timeline to perform root cause analysis.

Response II-14-104: EPA acknowledges the commenters' input. In the final rule EPA has revised the "root cause analysis" as an "investigation" and EPA has defined what that "investigation" consists of as detailed in Section X.C.2 and XI.C.4 of the preamble of the final rule. EPA has remained consistent with the proposed timeline and an owner operator has 15 days to determine if the emission event is ongoing and if not, bring the site into compliance and conduct any repairs necessary.

Comment: Commenter (2202-TXOGA) believes that expeditious deadlines should apply for such notifications to facilitate identification of emissions issues and also to ensure that third-party notifiers do not delay in providing information. This is particularly important given that deadlines for response will apply to the operator and that EPA should be conducting a review of the notices prior to requiring sources to respond. With the near-term deadlines for responding to notices, companies should not be put in the position of dealing with multiple notices that are sent to them in batches, which will prevent, or at least significantly impair the ability to make, timely response deficient. Commenter contends that is not the intent of the program. Any third-party who wishes to participate needs to be sufficiently resourced to meet the basic requirements to make the program function smoothly.

Response II-14-105: EPA agrees with the commenter that third-party notifier must provide the data as soon as possible to make this program effective. Therefore, a certified third-party notifier must submit super-emitter data within 15 calendar days of the observed emission event to the EPA. EPA will review that data, and if found to be reasonable and accurate, will provide the notification to the owner or operators. Data provided after 15 days are not considered to be actionable.

Comment: Commenter (2202-TXOGA) states the proposed five calendar days to initiate and 10 calendar days to complete a root cause analysis and initial corrective actions is too short, given that operators cannot predict when and where third-party surveys will be undertaken, that sites are often at remote locations, and that personnel availability is limited on non-business days. For all of these reasons, the deadlines should be adjusted to provide more time and to be based on business days, not calendar days.

Commenter (2284-Kairos Aerospace) agrees with EPA's assessment that large sources of emissions are worthy of prompt action, but believes the timeline established in the Proposed Rules is excessively tight and creates unnecessary complexity from a management perspective.

Response II-14-106: EPA acknowledges the commenters input. EPA has remained consistent with the proposed timeline and an owner operator has 15 days to determine if the emission event is ongoing and if not, bring the site into compliance and conduct any repairs necessary. Due to the size of these emission events, EPA considers it critical to act as soon as possible to limit these emission events.

EPA has also defined the “investigation” to allow both off-site and on-site evaluations of these super-emitter events in order to make them more targeted and to decrease potential burden.

Comment: Commenter (2284-Kairos Aerospace) notes that EPA’s current proposal for the SERP requires root cause analysis and repair initiation within five days and completed repairs within 10 days of notification of a super emitter, and a written report within 15 days of completing the root cause analysis. EPA’s proposal also requires ground follow-up on advanced leak screening surveys with no specific timeline but would require initiating a root cause analysis within 24 hours of the follow-up ground survey, completion of a root cause analysis within 5 days, and repair within 30 days. It also requires repairs resulting from OGI leak surveys to occur within 15 days of survey. Further, it requires leaks identified by AVO to have first repair attempts made within five days, and final repairs completed within 15 days.

Commenter (2284-Kairos Aerospace) recommends that timelines are streamlined so that the SERP requires 15 calendar days to follow up on reported detections and make non-SERP timelines align.

While the commenter (2284-Kairos Aerospace) appreciates the concern that these large emissions need to be stopped quickly, they state that EPA can easily model the impacts of aligning things on similar timelines. The reality is that a few days do not have major impacts on total emissions, except in the most extreme cases. Aligning repair timelines for the SERP and advanced leak screening surveys will streamline compliance and reduce complexity with minimal cumulative emissions impact.

Response II-14-107: The Super Emitter Program is independent of any existing monitoring program of a site and is only designed for large emission events, and therefore the required timelines are considered reasonable for that program. The key difference for of an owner or operator conducted monitoring program, is they are aware when those surveys occur and triggering a response to a failed emission control can be plan for, however with the super-emitter program, and owner or operator will not know when these surveys have occurred, making planning for a response more difficult.

Comment: Commenter (2284-Kairos Aerospace) contends that this web of timelines will likely create confusion, and it’s not clear that from an emissions mitigation perspective it could be considered strictly necessary. According to the commenter (2284-Kairos Aerospace), FEAST modeling can be used to measure the impacts of repairs within 5, 15, or 30 days. Based on the commenter’s (2284-Kairos Aerospace) experience with modeling tools, they anticipate the changes in emissions based on those different timelines would be negligible.

Response II-14-108: The super emitter program is being finalized as primarily a compliance assurance program and does not include a required timeline for repair of emission events, instead when owner or operators identify these emission events, they are required to conduct repairs of that equipment consistent with the requirements in the applicable subpart.

Comment: Commenter (2305-The Williams Companies, Inc.) contends that the timeline for an owner or operator to respond to a notification of a super emitter emissions event is inadequate and places an impractical and unrealistic burden on owners and operators. As currently proposed, owners and operators are required to initiate a Root Cause Analysis to determine the cause of emissions event within 5 days of receiving a third-party notification, and any resulting corrective action must be completed within 10 calendar days after receiving the third-party notification, along with providing a notification to the EPA within 15 days of completing the corrective actions. While the rule offers a 30-day extension if the corrective action plan cannot be completed within 10 days, the whole timeline offered to investigate, complete and report the emissions event from the super emitter notification is inadequate when taking into account the amount of time to review, investigate and verify that the reported emissions event is accurate and is based on approved methodologies and not a false “positive.” Further, the timeline does not account for scenarios where the recipient of the notification is part of a joint venture where certain steps must be taken pursuant to the contractual agreements between the parties prior to any investigation or corrective action.

If the Super emitter program is implemented as part of this rulemaking, commenter (2305-The Williams Companies, Inc.) states that the owner or operator will need at least 30 days to conduct the RCA and take initial corrective actions as required. If the corrective actions cannot be completed within 30 days of the initial notification, then the owner or operator should be able to request a reasonable extension, which could be more than 30-days, and it be readily granted upon showing good cause.

Response II-14-109: EPA acknowledges the commenters’ input, In the final rule EPA has redefined root cause analysis as an “investigation” and EPA has defined what that “investigation” consists of. EPA has remained consistent with the proposed timeline and an owner operator has 15 days to determine if the emission event is ongoing and if necessary, bring the site into compliance and conduct any repairs necessary.

The final rule does not include a requirement for corrective action and instead requires and affective owner or operators to take action to conduct repairs of fugitive equipment and/or bring in equipment into compliance with applicable requirements in the rule (e.g., covers and closed vent systems).

Comment: Commenter (2399-GPA Midstream Association) notes proposed § 60.5371b(c) requires the recipient of a notice to initiate a “root cause analysis” within five days of receiving the notice and complete both the “root cause analysis” and an initial corrective action within 10

calendar days of receiving the notice.<sup>137</sup> References to “calendar days” should be changed to “business days.” Unlike large petroleum refineries or chemical plants, which have employees working 24 hours a day, seven days a week, most midstream sites are unmanned. Engineering staff at the company’s headquarters or a regional office would conduct the investigation. These are salaried employees, not shift workers, that typically work Monday through Friday (excepting federal and state holidays where offices are closed) during normal business hours. Further, investigation time may be consumed by time needed to travel to and from the sites, some of which are relatively remote. Therefore, EPA should afford owners and operators 10 business days (or two weeks) to complete their investigations.

Commenter (2403-The Petroleum Alliance of Oklahoma) notes EPA is proposing that operators initiate a root cause analysis and take corrective actions within 5 calendar days of an owner or operator receiving the notification of the super emitter emissions event, and completion of corrective actions within 10 days of the notification. EPA is proposing operators submit a written report within 15 days of completing the root cause and corrective action to EPA and/or the delegated state delegated agency’s authority. These time frames are inadequate as some locations are remote in nature or in some instance, may require longer time frames to obtain equipment or schedule service companies to complete the corrective action.

Action Requested: EPA and/or the state delegated agency should be the entity to notify the operator of an event. Operators would then begin a technical analysis (not a root cause analysis) and take corrective actions, if possible, within 5 calendar days. EPA should allow final repairs and report to EPA and/or state delegated agency within 30 calendar days. If corrective actions take longer than 30 days, operators could submit a corrective action plan to the EPA and/or the state delegated agency. This would align with other types of emission event reports required by state delegated agencies.<sup>138</sup>

Commenter (2483-INGAA) encourages EPA to allow 14 days to conduct an analysis of the incident (which is sufficient for a simple event, but not for a more complex one), and if the analysis cannot be conducted in that period of time to let the Agency know when the analysis will be available, not to exceed 90 days.

Furthermore, commenter (2483-INGAA) is concerned that 10 days does not provide owners or operators with enough time to analyze a potential super emitter event. Commenter suggests instead that EPA provide owners or operators with 14 business days to conduct an analysis of the incident and provide EPA with recommended actions to avoid future occurrences. This should work for simple incidents. In some cases, however, more time will be needed. If the analysis cannot be conducted within 14 business days, the owner or operator should notify EPA and let the Agency know when the analysis will be available, which in no event may exceed 90 days.

---

<sup>137</sup> As discussed below, the Supplemental Proposed Rule requires an investigation or response, not a root cause analysis.

<sup>138</sup> Ibid.

Proposed Regulatory Text for Proposed §§ 60.5371b, 60.5388c:

[The regulatory text proposals in Comment: 422-4137 and Comment: 422-4145 were originally part of this comment.]

Response II-14-110: EPA acknowledges the commenters' input, In the final rule EPA has redefined root cause analysis as an "investigation" and EPA has defined what that "investigation" consists of. EPA has remained consistent with the proposed timeline and an owner operator has 15 days to determine if the emission event is ongoing and if not, bring the site into compliance and conduct any repairs necessary.

With the rule being finalized as primarily a compliance assurance rule, the final rule does not include any timelines for when the repairs need to be made, as those requirements are already included in the applicable subpart.

#### **14.4.5 Costs**

Comment: Commenters (1686-GHGSat Inc., 2288-NDDEQ) note the proposed rule also states that owners and operators do not bear the cost of monitoring and detecting super emitter emissions events. Clarity is needed as to who will in fact bear the costs of the work.

Response II-14-111: EPA recognizes the commenters thoughts, EPA does not consider the costs for conducting the surveys as the program is designed for third-parties, independent of the agency.

Comment: Commenters (2288-NDDEQ, 2345-GHGSat Inc., 2433-EDF, 2626-Kayrros) do not expect there to be a significant cost associated with the super emitter program EPA is proposing. Commenters (2288-NDDEQ, 2345-GHGSat Inc.) agree that, in practice, there should be no additional cost associated with the work practice of identifying and repairing an emission detected under the super emitter program. The commenters understand that operators must perform compliance assurance measures in between periodic screenings, the SERP is practically behaving as one compliance assurance, which, according to the proposed rule, operators will not bear the cost of monitoring and detecting super emitter emissions events.

Response II-14-112: EPA recognizes the commenters support for the Super Emitter Program.

Comment: Commenters (2288-NDDEQ, 2345-GHGSat Inc.) state if the expense of monitoring and detecting super emitter events will not be borne by the operators, the most logical solution would be for the EPA itself to be responsible for covering the costs of the services from third-party notifiers. The EPA should consider procuring all the methane data obtained by remote sensing aircraft, mobile monitoring platforms, and satellites to identify super emitter emissions events, and then making that data available transparently to all operators as a public good, thereby accelerating mitigation while mitigating the risk and reducing compliance costs for all oil and gas stakeholders.

Response II-14-113: EPA acknowledges the commenters input; EPA does not intend to play a direct role in funding or conducting third-party monitoring. This program is designed to rely solely on third-party monitoring and data review by independent entities.

Comment: Commenter (2433-EDF et al.) states there should be little to no cost associated with the program. Owners and operators should already be addressing malfunctions and poor operating conditions as part of their normal operations, so the costs of SERP would already be accounted for in a facility's operational costs and the costs of complying with the underlying standards. A super emitter event would indicate likely noncompliance with standards for the underlying source—including a source-specific limit or work practice—so operators would already be required to come back into compliance with the source-specific standard. In any event, if there are additional costs associated with investigating and addressing super emitter events, those costs would be minor and highly justified in relation to the benefits gained by stopping these huge emission events, making any associated costs “obviously cost-effective.”<sup>139</sup>

Commenter (2626-Kayros) states they do not have proprietary insights on the costs of mitigating super emitters. That said, studies from reputable institutions including the Climate & Clean Air Coalition and the International Energy Agency show that the cost of mitigating methane emissions is modest. Furthermore, it is widely assumed that addressing large sources is more cost-effective (in \$ per ton of methane abated) than addressing a much larger number of small sources. On that basis, the EPA is right to assume that the costs imposed on operators by the proposed SERP are modest.

Response II-14-114: EPA acknowledges the commenters' support.

Comment: Commenters (2220-WDEQ, 2254-PBPA, 2279-U.S. Small Business Administration, 2292-West Virginia Attorney General et al., 2326-AXPC, 2333-LongPath Technologies, Inc., 2393-OSEE, 2399-GPA Midstream Association, 2446-IPAA) consider the proposed super-emitter program to incur substantial costs, particularly to small businesses.

Commenter (2279-U.S. Small Business Administration) notes small businesses have raised significant concerns about the proposed SERP. These operators want to ensure that the program's emphasis is on the response to these third-party reports, sent in good faith and to which they can respond in good faith, not on enforcement for methane emissions that are otherwise permitted. Further, these small oil and gas producers are concerned that third-party reporters could be motivated to impose bureaucratic costs unrelated to emissions or to their permit requirements to permanently reduce fossil fuel extraction in this country.

Response II-14-115: EPA acknowledges the commenters' input. EPA has revised the super-emitter program to have EPA in a central role to vet third party notifiers and to provide an independent review of the prior to providing notifications to an owner or operator.

---

<sup>139</sup> 87 Fed. Reg. at 74752–55.

EPA has chosen to finalize the Super-Emitter Program as primarily a compliance assurance program. A notification of a super-emitter event by EPA is not an allegation of a violation and is there to trigger an obligation to investigate by the owner or operator of an applicable oil and gas facility. EPA sees this as a potential cost saving to those small businesses by providing timely emission data to them so these excess emissions can be captured and sold.

Comment: Commenter (2220-WDEQ) strongly disagrees with EPA's assertion in the preamble that "the proposed SERP would provide a cost-effective backstop to the rest of the regulatory program" (74748). This program will consume state-level resources in WDEQ's Compliance and Monitoring programs, as state agencies will nevertheless have to spend additional time responding to and investigating root cause analyses, corrective actions, and monitored data. Ultimately, this process will unnecessarily burden the commenter's already-effective programs with no additional financial support from EPA.

Response II-14-116: EPA recognizes the comment. EPA has revised the super-emitter program to have EPA in a central role to vet third party notifiers and to provide an independent review of the prior to providing notifications to an owner or operator. EPA has taken on this burden to alleviate any potential burden on state agencies. Furthermore, the burden for investigation and reporting is on the owner or operators and their reporting requirements for the super emitter rule are for the most part, the imbedded in the fugitive emission monitoring and compliance monitoring program.

The only additional requirement for reporting is through the super-emitter program when an emission event is ongoing at the conclusion of the investigation period.

Comment: Commenter (2254-PBPA) argues responding to such reports (even when inaccurate) requires significant time and compliance reviews. The proposed program creates opportunities for operational disruptions that are unnecessary given the extensive monitoring requirements that will be a part of any final rule. These burdens will be especially acute on small businesses. EPA should revise its economic assessment to reflect the costs of responding to such reporting, including the cost on small businesses.

Response II-14-117: EPA does not consider the cost of an investigation to be overly burdensome and is designed to rely on potentially existing information to do perform the bulk of the investigations. EPA does not require the owner or operator of an oil or natural gas facility to conduct extensive monitoring requirements and emission events of 100 kg/hr of methane or more should be relatively easy to detect. EPA has included an estimated of burden of owner or operators subject to this program in the Supporting Statement for NSPS OOOOb available from the public docket.<sup>140</sup>

---

<sup>140</sup> SUPPORTING STATEMENT. Standards of Performance for Crude Oil and Natural Gas Facilities for which Construction, Modification or Reconstruction Commenced After December 6, 2022. (40 CFR part 60, subpart OOOOb).

Comment: Commenter (2292-West Virginia Attorney General et al.) argues third-party monitoring of super emitter events could lead to substantial new costs. Increased compliance costs are the most obvious, as increased investigations produce more response actions. 87 Fed. Reg. at 74,752. Those costs increase if the super emitter events lead to enforcement action or litigation. Companies will also have to grapple with new public relations costs, as super-emitting notices will be posted on a public website. Id. at 74,750. And third parties, who are newly deputized to police oil and gas facilities, may be encouraged to trespass on private property to monitor and measure for super-emitting events, leading to more potential harms and damages. Cf. Stuart N. Riddick, et al., Measuring Methane Emissions from Abandoned and Active Oil and Gas Wells in West Virginia, 651 SCI. OF THE TOTAL ENV'T 1849, 1865 (2019) (noting how private authors faced a “significant problem” in “land access” when they tried to measure methane emissions in West Virginia because “much land [is] private, used for hunting and posted against trespass”).

Response II-14-118: EPA acknowledges the commenters’ input. EPA has chosen to finalize the Super-Emitter Program as primarily a compliance assurance program. A notification of a super-emitter event by EPA is not an allegation of a violation and is there to trigger an obligation to investigate by the owner or operator of an applicable oil and gas facility. The program requires the use of remote sensing technology and strictly forbids the collection of methane emission data from accessing a site. If a certified third party has been found to illegal access a well site (i.e., trespassing) it would be grounds to have their certification revoked.

Comment: Commenter (2326-AXPC) notes EPA has erroneously concluded that “there should be no additional cost associated with this work practice standard for the super emitter emissions event affected facility.” EPA suggests this because EPA expects that “as part of normal operations, owners and operators should already be correcting equipment malfunctions and/or poor operations as such issues arise; therefore, costs associated with maintaining normal operations should already be accounted for in their operational costs.”<sup>141</sup> Such logic is entirely circular and inconsistent with EPA’s own stated concerns and findings regarding EPA’s claimed super emitter emissions events. If normal operational practices would catch and resolve all super emitters, then EPA would not have a justification that a super emitter program is necessary to finding super emitters. Thus, EPA clearly intends the program to require additional action beyond what is being taken and identified today.

Response II-14-119: EPA has chosen not to finalize the rule under the OOOOb affected facility rationale, has instead finalized under the rule as the co-proposed compliance assurance program, and the requirement for additional action is consistent does not go beyond the requirements in the rule, beyond follow-up inspection.

Comment: Commenter (2326-AXPC) estimates operators would expend at a minimum 20-30 hours of personnel time to respond to and investigate each super emitter notification, including time spent chasing intermittent events, identifying known maintenance events, communicating with the notifier, conducting a root cause analysis (investigative analysis as proposed by the

---

<sup>141</sup> Id. at 74,752.

commenter), responding to public inquiries for notifications posted online, and potentially pursuit of third-party notifier disqualification for false notifications. The costs associated with these efforts will depend on whether an operator utilizes internal or external personnel and other operator-specific considerations – e.g., travel distance. However, under no circumstances can EPA simply assume that there will be no costs.

Response II-14-120: With EPA in a centralized role with this program, approving the methane detection technology, certifying the third parties, and reviewing data before notifying an owner or operator, we disagree an operator would need 20 – 30 hours to investigate and notification. Furthermore, EPA has revised the requirement for conducting an investigation for the owner or operator to first include off-site analysis using maintenance logs, monitoring data (if applicable), and SCADA data to evaluate whether an emission event is ongoing and then an on-site analysis to confirm the presence or absence of a super-emitter event. These are in place to provide an effective review without being onerous.

Comment: Commenters (2284-Kairos Aerospace, 2333-LongPath Technologies, Inc.) state the EPA is correct that there would be no added cost of the program for those sites using periodic screening or OGI. However, for sites using continuous monitoring, the super emitter events will already have been logged and repaired as a result of detection by the continuous monitoring technology. Therefore, operators will need to respond to these events, which had already been repaired by the time the notification from the super emitter event program had been received, two times. This results in an added cost to the operator. Further, these operators will be listed publicly as having super emitter event detections, even if they had already resolved the issue within a rapid time frame. Therefore, operators of sites with continuous monitoring installed should be given the opportunity to opt-out of some portion of the program, for example the public reporting portion, or be given an opportunity for streamlined response reporting.

Response II-14-121: EPA acknowledges the commenters input. EPA disagrees that sites that use continuous monitors should be exempt from the reporting requirements in the rule, however, to address the usefulness of continuous, which should be able identify these large emission events as they happen, we have included an investigation step to use data from these systems to determine the presence or absence of a super-emitter event.

Comment: Commenter (2393-OSEE) responds to EPA’s request for comments regarding the assumption that “that there should be no additional cost associated with this work practice standard for the super emitter emissions event affected facility.” 87 Fed. Reg. 74752. This seems unlikely as in almost every case an OGI camera with a properly trained OGI operator would be needed to find the potential super emitter. For many companies this would require a third-party contractor who would be making an additional visit to the site, outside of the normally scheduled semi-annual or quarterly OGI monitoring program. Therefore, this super emitter work practice would not be able to be done with no additional cost, as EPA seems to believe. If additional monitoring must be conducted, especially in more remote locations like those found in the western part of Oklahoma and the Oklahoma Panhandle, the monitoring, travel, root cause analysis, and coordination between operations and environmental staff would be in addition to

the regular monitoring program. EPA should re-assess this idea that it would be no-cost to companies to find and fix these super emitter events.

Response II-14-122: EPA thanks the commenter for their input. EPA has revised the final rule to define what the follow-up should consist of and no longer includes criteria for a corrective action/repairs, instead the rule relies on existing criteria for the equipment affected under the super-emitter program.

Comment: Commenter (2399-GPA Midstream Association) notes even with such a highly developed imaging platform, third parties will have significant difficulty pinpointing exactly which source is the alleged “super emitter,” and most third-parties must do with far less sophisticated equipment and software. As framed, nothing would constrain one private party from merely sending notices to multiple sources knowing that, at most, only one of the recipients is potentially responsible. On the contrary, EPA proposes to protect third parties who are sending the notices in such a situation: “the failure of the operator to find the source of the super emitter emissions event upon subsequent inspection would not be proof, by itself, of demonstrable error on the part of the third-party notifier.” 87 Fed. Reg. at 74,750. Yet, each recipient would have to investigate their facility or facilities in response to the notice. This will mean diverting personnel, or having to hire new personnel or contractors, to investigate potential violations or malfunctions, often at remote unmanned locations (and some of which are difficult to access during the winter months), without any hard evidence those facilities are the source except the assertion of another private party. Despite EPA’s conclusion that the SERP is “obviously cost-effective,” 87 Fed. Reg. at 74,752, the Supplemental Proposed Rule seems to give the actual costs and burdens that would be involved minimal consideration. In fact, if a company receives multiple notices per week, regardless of whether those notices are accurate or not, the time and resources required to respond would be immense. If EPA proceeds with this approach in some fashion, it should review fully and carefully the full range of costs associated with this type of program.

Commenter (2399-GPA Midstream Association) notes the Supplemental Proposed Rule mistakenly claims that “[t]o the extent there are additional costs associated with the investigation or mitigation of these [Super emitter] events, the EPA expects that the costs would be minor in relation to the benefits of stopping such huge emissions event, making them obviously cost-effective.” 87 Fed. Reg. at 74,754.

Commenter (2399-GPA Midstream Association) states EPA offers no data, study, or other hard analysis to support this conclusory assertion. For that reason alone, EPA should reconsider its approach. Regardless, EPA apparently assumes that every source receiving a “Super emitter” compliance order will, in fact, be the cause of an alleged super emitter event and can cost-effectively resolve the alleged emissions. However, while there have been improvements in satellite and airborne imaging, few can provide an accurate designation of a “Super emitter” source.

Response II-14-123: EPA thanks the commenter for their input. EPA has revised the final rule to include a requirement that remote sensing technology used in this program are approved for use

Super Emitter Program. The criteria that these technologies must meet are explained in sections X.B, X.C, XI.B, and XI.C. of the preamble to the final rule, and these criteria include a spatial resolution requirement which must be met.

Comment: Commenter (2446-IPAA) considers EPA's leniency with regard to third-party notifiers submitting inaccurate information to skew EPA's "cost-effectiveness"/BSER analysis. First off, requiring a third-party submitting inaccurate information three times at the same source/location before a third-party notifier loses its certification is unacceptable. "Three-strikes and you're out" is not appropriate when you are dealing with existing sources, often operated by small business. Who is going to compensate the owner/operator for the costs associated with conducting a root cause analysis (a concept not defined or described by EPA in its proposal), when it is determined that the third-party notifier made a mistake? EPA fails to account for the costs associated with the SERP when the third-party gets the data wrong. To suggest that a third-party notifier can submit an owner/operator to the expenses associated with the SERP three times, with no ramifications to the third-party notifier is simply unfair. Commenter (2446-IPAA) suggests that third-party notifiers post a bond sufficient to cover the cost associated with an owner/operator responding to the SERP. If the third-party's data is inaccurate, the bond is released to the owner/operator and the third-party notifier is required to post twice the bond amount which would be released to the next owner/operator if/when the next time the third-party notifier wrongly accuses an owner operator of a super emitter event. If EPA is insistent on requiring "three strikes", then the bond should be tripled after the second erroneous submittal. The third-party notifiers need to have skin in the game and owner/operators need to be compensated for erroneous submittals.

Response II-14-124: EPA acknowledges the commenters' input. Burdensome, erroneous reporting will be avoided by through the certification of the third-party certification requirements in the rule and the requirement they use remote sensing technology that have been approved for use in the Super Emitter Program.

Comment: Commenters (2227-Western Energy Alliance, 2254-PBPA, 2283-Endeavor Energy Resources) request further analysis of the cost-effectiveness of the proposed Super emitter Program.

Commenter (2254-PBPA) believes EPA has underestimated the costs of its SERP without adequately quantifying the benefits.<sup>142</sup> While EPA claims that it "will make all of the critical policy decisions and fully oversee the program,"<sup>143</sup> it is disclaiming "a greater role for the

---

<sup>142</sup> 87 Fed. Reg. at 74,754. Moreover, even if there are costs associated with the investigation and mitigation, the threshold for identifying a super emitter emissions event is so high that it ensures that the emissions reductions achieved by the mitigation are cost-effective. In other words, it is reasonable to conclude that these actions would be cost-effective in light of the large mass rate of emissions (100 kg/hr of methane or greater) that would be reduced, and the high volume of gas saved. It is highly unlikely that these actions would exceed the \$2,185/ton of methane reduced, which is the highest value we have determined to be cost effective for reducing methane from sources within this source category. In summary, the EPA finds the data demonstrate that the SERP is cost-effective, even though the EPA recognizes that the total emissions reductions that will result from the program are difficult to quantify.

<sup>143</sup> Id. at 74,750.

Agency in reviewing third-party notifications”<sup>144</sup> and requiring completion of root cause analyses within 10 days of a third-party notification—all without an ability to quantify emissions reductions likely to result from the program<sup>145</sup> and with limited cost projections.<sup>146</sup>

Commenter (2283-Endeavor Energy Resources) provides that responding to a notifier's report (even when inaccurate) would require significant time, personnel, and compliance reviews by operators. Based on its own experience, and from discussions with other operators in the Midland Basin, commenter estimates that it can take up to a week of employee time to accurately respond to a detection report from the TCEQ, even if the detected event is based on a misunderstanding of a simple (and legal) maintenance activity. There is a real risk that misguided or inaccurate third-party reports based on misinterpretations of legal activities or misuse of monitoring devices could distract compliance teams from focusing on actual problems or risks within the facility—an acute problem for small businesses with limited personnel and resources like many of the producers in the Midland Basin. Based on its past experience, commenter (2283-Endeavor Energy Resources) also believes that the proposed timelines for initiating and completing a root-cause analysis will be infeasible or overly burdensome for operators and recommends that EPA revise the timelines included in any finalized rule to allow for at least 20 business days to complete the analysis. In addition, EPA concerningly has not conducted any quantification of the costs or benefits of the SERP.<sup>147</sup> At the very least, EPA must do so, and should revise its economic assessments to reflect the costs of responding to outside, third-party reporting, especially on small businesses.

Response II-14-125: EPA acknowledges the commenters’ input. EPA has revised the “root cause analysis criteria” as an “investigation” as detailed in sections X.C.2 and XI.C.4 preamble to the final rule. EPA has maintained the timeline requirements from the December 2022 supplemental proposal in the final rule.

#### 14.4.5.1 Monetary Incentives

Comment: Commenter (2366-BHE) supports developing remote monitoring and measurement technologies and standard methods for technology use. EPA should use IRA funds to support developing the needed program infrastructure. This would be an ideal use of those funds. In addition, other proposed program elements are troubling. For example, EPA should require verification of a purported super-emitter event before information is shared publicly, and third-party participants should be required to abide by that process.

Commenter (2483-INGAA) respectfully suggests that EPA should use funds provided by the IRA to create a process for the methods that should be used with each technology and the qualifications that should be required of a third-party who is approved to conduct monitoring.

---

<sup>144</sup> Id. at 74,751.

<sup>145</sup> Id. at 74,747, 74,754.

<sup>146</sup> Id. at 74,752-54.

<sup>147</sup> See RIA, at 25 (“We do not attempt to quantify the impacts of the SERP due to the unpredictable nature of super-emission events, resulting in a lack of specific data on their frequency, intensity, and cost to mitigate.”).

This would be a productive use of those funds, and EPA could re-propose the program after this important work has been done.

Response II-14-126: EPA acknowledges the commenters' input.

Comment: Commenter (2447-Clean Air for the Long Haul) states the EPA should support community programs, including providing financial assistance and technical training to certify members of impacted communities. EPA should deploy and maintain continuous emissions monitoring within fenceline communities using the best available technology capturing a wide range of pollutants, beyond PM<sub>2.5</sub> ensuring that this community-managed data is accepted and offers credible evidence to showcase non-compliance by oil and gas companies. Moreover, there should be immediate follow up on complaints filed by certified community members, swift mitigation, stronger local level regulations and recourse if there is continual non-compliance.

Response II-14-127: EPA acknowledges the commenters' input.

Comment: Commenters (2453-Carbon Mapper and RMI, 2626-Kayrros) state EPA should provide competitive grants and other funding opportunities to ensure the establishment and continuity of third-party observing systems and frameworks for robust identification and notification of facility operators, which otherwise would likely remain limited to philanthropic funding. Potential SERP funding sources include provisions for methane monitoring in the Methane Emissions Reduction Program (see Docket ID No. EPA-HQ-OAR-2022-087).

Commenter (2626-Kayrros) states recent efforts to make data publicly available, such as the Oil & Gas Infrastructure Mapping (OGIM) database developed by the Environmental Development Fund, should allow third-party notifiers to identify the right operator at no cost and to submit the information in a timely manner. Commenter (2626-Kayrros) states third-party notifiers will have to build teams responsible for running the algorithms, validating the results, attributing to a specific operator and issuing notifications in a timely fashion. Moreover, these teams will have to operate outside normal business hours, and particularly on weekends and public holidays. Unless they receive compensation, most service providers may find it difficult to bear the associated costs, in addition to the cannibalization of revenue from the public release of super-emitter data. On that basis, the EPA should consider economic incentives that can attract third-party notifiers to the super-emitter response program in sufficient numbers.

Response II-14-128: EPA acknowledges the commenters' input.

Comment: Commenter (2306-Citizen's Climate Lobby) notes in this paragraph of the rule,<sup>148</sup> there is no mention of monetary reward, despite payment that will be made soon regarding methane charges. The paragraph should insert additional framing regarding monetary reward. This can include language stating "The owner or operator shall send a copy of the notification to the notifier(s) who notified this event and make a payment of \$10,000 divided equally among them. When the Administrator receives the methane charge for the event, the Administrator in

---

<sup>148</sup> Proposed Rule, P.25 - 40 CFR 60.5371b(e)(1).

turn shall pay the methane charge for the event, to the notifier(s), divided equally; to the extent it exceeds \$10,000. The notification shall include the requirements in paragraphs (e)(1)(i) through (iv) of this section.”

Response II-14-129: EPA acknowledges the commenters’ input. EPA has chosen to finalize the Super-Emitter Program as primarily a compliance assurance program. A notification of a super-emitter event by EPA is not an allegation of a violation and is there to trigger an obligation to investigate by the owner or operator of an applicable oil and gas facility. We encourage participation in the Super Emitter Program by third parties, however a reward would be an inappropriate incentive and is not part of the final rule.

Comment: Commenter (2269-Arthur Gershkoff) asks EPA to create incentives for Fossil Fuel companies to partner with the EPA to control these leaks.

Response II-14-130: EPA acknowledges the commenters’ input.

#### ***14.4.6 State, Tribal, Local Air Quality Administration***

Comment: Commenter (2220-WDEQ) is aware of other states that share a number of concerns pertaining to the proposed SERP. Instead of moving forward with the SERP as proposed, the commenter encourages EPA to engage with its state co-regulators to examine existing state frameworks for addressing citizen concerns. State, Local, and Tribal air agencies are more accessible to, familiar with, and responsive to their citizens’ concerns because they are located in and accountable to those communities.

Response II-14-131: EPA acknowledges the commenters’ input.

Comment: Commenter (2193-California Air Resources Board (CARB)) notes that the only reporting to EPA appears to be when the facility owner or operator confirms the super emitter event and EPA only proposes setting up a "document repository" for the notices to operators it receives as well as the reports sent by the owners and operators in response. The purpose of the repository is so the communities, notifiers, and owner/operators may have quick access to the information contained in the notices and reports.<sup>149</sup> There is no discussion as to who is administering the corrective action of the owner/operators, the compliance of the owners/operators, and what responsibility the state agencies have in the program.<sup>150</sup> EPA has only proposed requiring the owner/operator to submit a corrective action plan to EPA or delegated state authority within 30 days of receipt of the notice "that describes the corrective action(s) completed to date, additional measures that they propose to employ to reduce or eliminate the emissions, and a schedule for completion of those measures."<sup>151</sup> Once the repair is

---

<sup>149</sup> 87 Fed. Reg. 74,747-74,748 (Dec. 6, 2022).

<sup>150</sup> Ibid.

<sup>151</sup> 87 Fed. Reg. 74,751 (Dec. 6, 2022).

complete, a report is due to both the state authority and EPA within 15 days.<sup>152</sup> Aside from that, there is no clear mention as to a state's role in the SERP.

Commenter (2193-CARB) provides that EPA proposes treating a super emitter emissions event as a separate and distinct source of emissions under section 111 of the CAA.<sup>153</sup> The argument here is that super emitter events occur due to facility noncompliance and equipment malfunction as opposed to leaks that may occur due to maintenance needs during proper operations.<sup>154</sup> EPA must therefore "(1) 'determine[ ],' taking into account various factors, the 'best system of emission reduction which ... has been adequately demonstrated, (2) ascertain the 'degree of emission limitation achievable through the application' of that system, and (3) impose an emissions limit on new stationary sources that 'reflects' that amount." (West Virginia v. EPA (2022) 142 S. Ct. 2587, 2601.) Implied in this analysis is an analysis of the overall costs. (Id. at 2604.) EPA has thoroughly vetted the costs and benefits of the proposed SERP and found that it is not only feasible to implement but should have cost benefits for that outweigh the cost of compliance for the facilities who are losing more than 100 kg/hr of gas as well as significant beneficial impacts on the environment in methane emissions reduction.<sup>155</sup> However, EPA is has not clearly stated costs the states would have to absorb in administering the SERP.

Commenter (2193-CARB) states that the proposed SERP provides a solid start to detecting super emitters between periodic inspections while ensuring transparency to the affected communities. EPA also has a central role here by approving the third-party notifiers (Notifiers), maintaining the notices, establishing the guidelines, and maintaining the reports. Given all that, Commenter (2193-CARB) encourages EPA to take the burden of administering the enforcement and compliance portions of the program to ensure consistent application across the regulated entities. While it makes sense for the affected state agencies to receive copies of the notices and reports for the enforcement of their local rules and regulations, the states should not be involved in managing or approving the Notifiers, deciding whether the owner/operators corrective action plan meets EPA's standards, or ensuring that the corrective action is complete to EPA's satisfaction.

Commenter (2193-CARB) notes that, for instance, CARB's regulation states each day, or portion thereof, an owner/operator is out of compliance with any of the oil and gas regulations (17 Cal. Code Reg. §§ 95668-95674) counts as a separate violation.<sup>156</sup> It is clearly a statutory scheme established to encourage swift compliance through monetary penalties. In comparison, EPA's SERP does not assess penalties, but only requires corrective action. Therefore, if California's 111(d) Plan had to suddenly address the implementation and enforcement of regulations ensuring the corrective action taken by the owner/operator was to EPA's satisfaction within 10 days, that the corrective action reports met EPA's standards, and/or that Notifiers were performing as required, this would involve the propagation of numerous regulations. Additional regulations require more discussion between stakeholders, legislators, and community members to satisfy

---

<sup>152</sup> Id.

<sup>153</sup> 87 Fed. Reg. 74,752 (Dec. 6, 2022).

<sup>154</sup> Id.

<sup>155</sup> 87 Fed. Reg. 74,752-74,753 (Dec. 6, 2022).

<sup>156</sup> 17 Cal. Code Reg. § 95675.

the administrative process. Furthermore, each state would be required to "re-invent the wheel" as it propagated these regulations, resulting in uneven enforcement and implementation across the country.

Commenter (2193-CARB) supports EPA's program design to take the responsibility of managing the SERP by setting standards for and approving the Notifiers and establishing the reporting system. But improvements can be made. Commenter (2193-CARB) recommends that EPA also take the responsibility of ensuring the Notifiers carry out their duties appropriately, approving the corrective action plans, and ensuring the owners/operators comply with not only the reporting requirements, but the corrective actions as well. The Notifiers should send notices of violation to the owner/operators, EPA, and the designated state agencies so that all entities have record of the concern and EPA can upload the notice into the document repository. The owner/operators should then provide their corrective action plans and post-repair reports to both the EPA and the designated state agency within the 30 and 15-day time periods EPA has proposed for EPA to upload into the document repository. Thereafter, the commenter recommends EPA enforce whether the corrective action plan and report is submitted in a timely manner and meets EPA's requirements. The state agency would be charged with enforcing its own provisions, separate and apart from EPA's responsibility, to ensure the owner/operator promptly complies with the repair of the root cause for the super emitting event.

Response II-14-132: EPA acknowledges the commenters' input. EPA is developing a centralized reporting portal to handle receive super emitter reports. The final rule, as described in Section X.C.2 of the preamble has universal reporting requirements which all affected owner or operators who receive a notification must submit. While this information will be submitted to the EPA, the system will be designed to make the data available to all stakeholders, including the state, local, and tribal authority.

Comment: Commenters (2225-WESTAR, 2241-Public Lands Policy Coordinating Office, Utah Department of Natural Resources, 2248-NDPC) are concerned that the proposed SERP is a deviation from the typical delegation of authority to state, Tribal, and local air agencies.

Commenter (2225-WESTAR) members have concerns that this program could convolute the state, Tribal, and local air quality compliance and enforcement process and add to misinformation maladies. Instead [of the proposed SERP design], Commenter (2225-WESTAR) offers that there are many options available for EPA to leverage remote sensing and satellite data to track methane emissions and detect super emitter events. EPA may wish to augment its own detection programs with a focus on improved data accessibility and transparency, making information more readily and easily available for the public to access and understand, in ways that productively enable their engagement.

Response II-14-133: EPA has chosen to finalize the Super-Emitter Program as primarily a compliance assurance program. A notification of a super-emitter event by EPA is not an allegation of a violation and is there to trigger an obligation to investigate by the owner or operator of an applicable oil and gas facility. If an owner or operator identifies a deviation of an applicable standard as part of their follow-up investigation, they would be subject to the

recordkeeping and reporting requirements in NSPS OOOO, OOOOa, OOOOb, and/or EG OOOOc.

Comment: Commenter (2241-Public Lands Policy Coordinating Office, Utah Department of Natural Resources) provides that, in an area where there is already multiple layers of regulations and responsible agencies, adding a third-party may add to the already confusing mix and lead to actually less effective compliance and enforcement of the regulations. It would be better to allow the state, Tribal and local air agencies to work with current requirements and the new proposed flexibility with leak detection and monitoring with new evolving technologies to develop their programs and request third-party involvement if they have the need. This proposed regulatory approach should be removed from this proposal and perhaps the new funding opportunities from EPA can be used to support this idea, but with the states and tribe's control.

Commenter (2248-NDPC) notes that the North Dakota Department of Environmental Quality (NDDEQ) responds to 100 percent of all complaints. Each complaint is investigated, and when issues are found, NDDEQ works to address the identified issues quickly with all parties. Any issued notice of violation and penalty are publicly available. Commenter contends that the Super emitter program would circumvent the state agencies' rights to administer their state specific programs and could add to burden to the agency by having to address emissions that may be erroneous (errors in the technology since they are not ground level or direct measurements) or even where the emissions are authorized.

Response II-14-134: EPA acknowledges the commenters' input. EPA has revised the rule to include EPA in a centralized role, to approve the technology used in the Super Emitter Program, certify third party notifiers, and to verify the data before providing notifications to an owner or operator. There is no obligation on a state, local, or tribal authority to address data submitted to this program.

## **14.5 Third-Party Notification**

### ***14.5.1 General Support and Opposition***

Comment: Commenters (2028-Westmoreland Marcellus Citizens' Group, 2195-Environmental Health Project, 2212-On behalf of the Union of Concerned Scientists, 2244-Norma Kline, 2302-Texas State Representatives, 2303-National Tribal Air Association (NTAA), 2392-Earthjustice et al., 2408-Colorado Local Government Coalition, 2409-BP America Inc., 2410-California Office of the Attorney General et al., 2433-EDF et al., 2444-NAACP, 2626-Kayros, 2627-BCI) strongly support EPA's SERP to address super emitter events through third-party monitoring. Empowering frontline communities with resident-led monitoring projects will be a step forward in terms of how the public is able to engage with neighboring industry. EPA needs to provide a clear pathway for communities and individuals to participate in the SERP.

Response II-14-135: EPA acknowledges the commenters' input; the rule does not limit the participation from communities or individuals.

Comment: Commenters (2195-Environmental Health Project, 2217-Religious Action Center of Reform Judaism, 2410-California Office of the Attorney General et al.) recommend EPA strengthen community monitoring, in part by providing a clear pathway for communities and individuals to participate and engage in the SERP.

Commenters (2392-Earthjustice et al., 2410-California Office of the Attorney General et al.) add EPA should ensure that the technologies that may be used to detect a super emitter emissions event are not so restrictive that they prevent community groups from participating as third-party notifiers. For example, EPA should leverage publicly available satellite data in the SERP by permitting third parties who may not have access to remote-sensing technologies to submit notifications based on publicly available satellite monitoring data.

Response II-14-136: EPA acknowledges the commenters' input. The requirements for third parties have been revised in the final rule and are described in section X.C.2 of the preamble of the rule.

Comment: Commenter (2334-Liveable Arlington) states EPA has admitted that current staff does not have the capacity to regulate 1.5M facilities. However, there are 17 million people living in the shadows of oil and gas extraction who want to help regulators fill in their gaps. Regulators must work with these frontline communities to most efficiently and effectively use their limited capacity.

Response II-14-137: EPA recognizes the commenters' concern.

Comment: Commenter (2453-Carbon Mapper and RMI) recommends EPA require third-party reporters make every technical and economically feasible effort to report quantitative emission rate estimates and uncertainties for each source reported to operators. This can help track the amount of methane mitigated by repair actions and support assessment of the overall impact of the SERP program. Commenter (2453-Carbon Mapper and RMI) recommends EPA consider leveraging quantitative emission estimates from SERP reports to support local air-quality and environmental justice assessments for front-line communities in the proximity of super-emitter events.

Response II-14-138: EPA acknowledges the commenters' input, and the final rule has been revised to require the third-party notifier to report the emission rate and uncertainty bounds.

Comment: Commenter (2433-EDF et al.) agree super emitter events should generally not occur at a site that is well operated, well maintained, and that has implemented EPA's proposed standards. Independent third-party monitoring data showing such emission events will therefore likely indicate major problems, regulatory violations, and events that endanger nearby communities. This type of program may also serve as a valuable preventative measure, creating additional incentives for operators to keep their sites maintained and properly operated so such events do not occur. And perhaps most importantly, publication of these emission events will allow nearby community groups to take appropriate protective action. It will also build trust in the entire enterprise of driving down methane emissions, which currently is lacking due to the

large discrepancy between reported emissions and stated actions and the frequent large emissions typically uncovered in field observations.

Commenter (2410-California Office of the Attorney General et al.) adds a third-party who chooses to become an EPA-approved notifier would do so on a voluntary and uncompensated basis. This means that private parties with access to remote sensing technologies may have few incentives to actively participate as third-party notifiers. Communities living near oil and gas facilities, on the other hand, will have a vested interest in identifying super emitter emissions events in order to protect their own health and safety, and such communities should be empowered to identify and report super emitter emissions events by relying on reliable, publicly available data.

Response II-14-139: EPA acknowledges the commenters' input.

Comment: Commenter (2394-Earthworks) note state regulatory and enforcement agencies are inconsistent and insufficient in how they respond to public complaints about methane and air pollution. Limited budgets mean that most agencies that regulate the oil and gas industry are underfunded and short-staffed, and rarely have enough employees to adequately enforce our state and federal clean air laws. State regulators fully admit that they do not currently have the resources to adequately protect the public from oil and gas pollution. "One hundred percent, we are not where we need to be to hold the industry accountable," said James Kenney, NMED Secretary in a January 22 news article. "I have more violations than I have staff to work on them," he continued. "That's a huge struggle and point of frustration."<sup>157</sup>

Commenter (2394-Earthworks) notes the EPA has also admitted that current staff does not have the capacity to regulate 1.5M facilities. Broad inclusion of third parties in the SERP can allow for efficient and effective use of EPA staff's limited capacity. The enforcement process for this rule is going to require engagement from third parties and communities who are directly impacted. In order to fully achieve the climate and environmental justice goals laid out by this Administration, they must be able to meaningfully engage in the regulatory process, file complaints about emissions detected, and be taken seriously by regulators.

Commenter (2299-NEI Investments) adds super emitters can be missed by standard LDAR procedures, so the problem does require a creative solution, and involving a broader set of stakeholders in identifying these problem sources is worth exploring.

Response II-14-140: EPA acknowledges the commenters' input.

Comment: Commenters (2247-Ohio Environmental Protection Agency, 2258-MSA, 2282-Kinder Morgan Inc., 2283-Endeavor Energy Resources, 2442-Wyoming Coalition of Local Governments) understand the desire to locate large scale leaks from oil and gas operations.

---

<sup>157</sup> Source NM, "NM leaders promote hydrogen production despite questionable environmental benefits," January 2022, <https://sourcenm.com/2022/01/05/nm-leaders-promote-hydrogen-production-despite-questionable-environmental-benefits/>.

However, this program would, in essence, delegate to an outside entity the ability to apply and enforce U.S. EPA requirements over and beyond the existing mechanism for citizens to enforce the provisions of the CAA through Section 304. Commenter (2247-Ohio Environmental Protection Agency) adds although there may be newer technologies that are becoming available to identify large leaks, outside private individuals should not become the enforcement arm of U.S. EPA. An additional concern relates to single family or small business-owned wells. Are they expected to know what they should do if a third-party determines that their well is a super emitter? How will they know that they must act to fix a leak within 10 days? Will they be able to get a pipeline/well repair person out within the 10-day period? Commenter (2247-Ohio Environmental Protection Agency) does not believe many of these small operators will have the knowledge or resources to know what to do under a super emitter situation.

Response II-14-141: EPA has chosen to finalize the Super-Emitter Program as primarily a compliance assurance program. A notification of a super-emitter event by EPA is not an allegation of a violation and is there to trigger an obligation to investigate by the owner or operator of an applicable oil and gas facility. The intent of the program, as noted in the final rule, is primarily compliance assurance and that information is passed along in a timely manner to owners and operators.

Comment: Commenter (2442-Wyoming Coalition of Local Governments) states the EPA approving and otherwise verifying a third-party notifier's qualifications and special expertise or allowing a facility owner or operator to challenge the notifier's data or qualifications does not resolve the issue of the EPA granting the notifiers this specific, regulatory authority. Id. at 74749-74750. The operator would still have to address specific notifications from third-party notifiers by either taking corrective actions or having to file objections to the data with the EPA. For the EPA to properly oversee the program, it would need to retain the ability to review and verify the information collected from third-party notifiers before requiring specific actions from facility operators to resolve the claimed emissions.

Response II-14-142: EPA acknowledges the commenters' input. EPA has revised the final rule to include EPA in a central role in receiving reports from third parties and providing notifications to an owner or operator, if necessary. The final rule does not grant third-party notifiers with any regulatory authority.

Comment: Commenters (2177-Ute Indian Tribe, 2283-Endeavor Energy Resources) believe allowing a third-party notifier will create excessive work for both the administrator, or delegated authority, and the operator to substantiate and investigate all claims made for super emitter events. This is unnecessary, as there are already systems in place to allow third parties to file complaints or notify the Administrator, or delegated authority, if they believe there is a potential issue. It also creates an excessive burden on the operator to be required to take action on all third-party notifications.

Response II-14-143: EPA has chosen to finalize the Super-Emitter Program as primarily a compliance assurance program. A notification of a super-emitter event by EPA is not an allegation of a violation and is there to trigger an obligation to investigate by the owner or

operator of an applicable oil and gas facility. The Super-Emitter Program, as described in section X.C of the preamble of this rule is designed to put the burden of demonstrating the occurrence of a super emitter event and its location on the third-party notifier and notifications to an owner or operator only occur after the EPA evaluates the data. These steps are in place to minimize any erroneous notifications and to ensure owner or operators are being provided with actionable data.

EPA may use any credible evidence to establish a violation. If an owner or operator, upon conducting the required investigation, determines that a deviation from an applicable standard has caused the super emitter event, then the owner or operator must comply with the requirements in NSPS OOOO, OOOOa, OOOOb and/or EG OOOOc to correct and report the deviation.

Comment: Commenter (2409-BP America Inc.) states the fact that a release of methane has been detected at a rate exceeding 100kg/hr does not necessarily mean that any standard has been exceeded or that any violation has occurred at any particular facility. It is also important that the program be designed to incentivize prompt, proactive actions on the part of operators. Therefore, Commenter (2409-BP America Inc.) believes it is important that data provided by responsible operators to EPA in response to a third-party notice is not used punitively against the operators. In particular, EPA should consider revising the program so that any documents shared with EPA, for example, articulating corrective actions taken, are subject to a safe harbor provision that prevents EPA (or, to the extent feasible, other entities) from using information in the document for purposes of enforcement, e.g., a notice of violation (NOV) or a civil suit.

Response II-14-144: EPA has chosen to finalize the Super-Emitter Program as primarily a compliance assurance program. A notification of a super-emitter event by EPA is not an allegation of a violation and is there to trigger an obligation to investigate by the owner or operator of an applicable oil and gas facility. The Super-Emitter Program, as described in section X.C of the preamble of this rule is designed to put the burden of demonstrating the occurrence of a super emitter event and its location on the third-party notifier and notifications to an owner or operator only occur after the EPA evaluates the data. These steps are in place to minimize any erroneous notifications and to ensure owner or operators are being provided with actionable data.

EPA may use any credible evidence to establish a violation. If an owner or operator, upon conducting the required investigation, determines that a deviation from an applicable standard has caused the super emitter event, then the owner or operator must comply with the requirements in NSPS OOOO, OOOOa, OOOOb and/or EG OOOOc to correct and report the deviation. The Super Emitter Program does not create a safe harbor for violations of Clean Air Act regulations.

Comment: Commenter (2288-NDDEQ) states if EPA intends to be the administrator of the super emitter program, then the commenter has similar concerns using this interpretation. While the initial notification from the approved third-party is required to be reported to both EPA (as Administrator in this case) and to any delegated authority, the requirement for any corrective action plans and follow-up reports are only required to be reported to EPA. Again, the proposed regulations do mention that upon receipt, EPA "shall make such report publicly available" per

\$60.5388c(e)(4), however there is no guaranteed timeline of when that availability will occur. This lack of follow-up will complicate the commenter's efforts to ensure proper ground truthing and resolution of super emitter events. Commenter (2288-NDDEQ) requests that, like the initial notifications, such documents also be submitted to the delegated authority.

Response II-14-145: EPA acknowledges the commenters' input. Requirements for public availability are discussed in Sections X.C of the preamble of the final rule. As part of this final rule, EPA will public owner or operator notifications and the response to these notification via the Super Emitter Portal.

Comment: Commenter (2389-ACC) maintains that operators should be given advanced notice of planned third-party activity. As proposed, the response burden for operators is not predictable and operators are unable to properly plan and schedule resources. If timing and location of surveys are unknown to a facility owner/operator, operators will have no indication of when and how much resources to have available if a potential issue is observed. This is important to promptly evaluate data and implement corrective action if necessary. Third parties may employ technologies, like aerial surveys which can result in multiple detections in a short amount of time. Commenter (2389-ACC) does not consider it unreasonable to expect that surveys may be conducted by multiple third parties simultaneously or in series and conversely, there could be extended periods of no third-party activity. Program requirements must balance the needs of operators to plan for both day-to-day operations and promptly react to third-party activity.

Response II-14-146: EPA disagrees that it is necessary or feasible for certified third parties to provide advanced notice of activity. With respect to the needs of the owner or operator, the Super Emitter Program, as finalized, is designed to provide actionable (*i.e.*, EPA verified) data of a super-emitter event that would trigger a response by an owner or operator. The revisions to the super emitter program, including timelines are described in Section X.C.2 and XI.C.2 in the preamble of this rule.

#### ***14.5.2 General Recommendations and Clarifications***

Comment: Commenters (2168-Indiana Oil and Gas Association (INOGA), 2172-Kentucky Oil and Gas Association) ask what resources are available to quantify the emissions rate of 100 kg/hr or greater? To quantify a leak rate in mass/time, a composition analysis and flow rate are both required. Is mobile equipment available to provide this data to the owner / operator in a reasonable period? How does the EPA representative gain access to the location to collect samples for composition and flow rate without trespassing? Does EPA have the authority to enter onto private property to sample gas composition or flow rate without permission? Does EPA have the authority to touch the assets from an oil and gas operation without permission from the operator? Does EPA have the authority to collect the gas for sampling? How is this not theft? EPA or their representative is taking something that does not belong to them, and they have not been granted permission to take. There are many challenges to this concept that EPA will need to address prior to implementing this type of program.

Response II-14-147: EPA recognizes the commenters' concern and we have revised the Super Emitter Program to require EPA approval of methane detection technology and to include requirements that certified third parties cannot access approved applicable sites and doing so would lead to the removal of their certification.

Comment: Commenter (2333-LongPath Technologies, Inc) suggests that EPA exempt from SERP requirements those sites that employ quantitative continuous emissions monitoring with ability to monitor all equipment on site (e.g., stick flares, tall tanks, yard piping). At a minimum, the commenter suggests that EPA allow those operators who have valid quantification continuous monitors with full-site coverage on a site to use that data to respond to super emitter program alarms and to be exempted from public posting of leaks.

Commenter (2333-LongPath Technologies, Inc.) states operators with valid continuous monitors (with full site coverage) will very likely already have noted and mitigated super emitter events before even receiving notification of the event from the super emitter program. Therefore, operators using continuous monitoring will be at risk of additional incurred costs of effectively responding to these events twice, first via the appropriate find-and-fix using continuous data and second via the unnecessary additional data collection and reporting under the SERP. The operator would further be subject to negative public regard, despite having taken immediate action by using continuous monitoring.

Response II-14-148: EPA acknowledges the commenters' input. The final rule has included the use of approved continuous monitoring systems in the follow-up investigation to confirm the presence or absence of a super-emitter event.

Comment: The commenters (2179-KIOGA, 2348-Energy Workforce and Technology Council) state there must be training requirements for submitting parties, and producers need to be given adequate time to complete any required compliance actions after notification. Commenters are concerned some third-party notifiers may be inadequately trained to detect methane leaks. The commenter recommends that third-party notifiers be required to have appropriate training/certification in order to validate emissions events.

Response II-14-149: EPA recognizes the commenters input and the final rule now includes the third-party be adequately trained to evaluate data generated by the specific approved methane detection technology used for their surveys, these requirements are discussed in section X.C.2 of the preamble to this rule.

Comment: Commenter (2279-U.S. Small Business Administration) states EPA should design this program to make clear that EPA is not delegating enforcement authority and that the role of the third-party notifier is limited to the narrow specifications of this program. Towards that goal, the commenter recommends the following specific provisions.

- Make a clear prohibition on trespassing on oil and gas production sites, with withdrawal of approval to third-party notifiers for repeated violations. Operators need assurances that

third parties will not interpret their participation in this limited program as an invitation to engage in further investigation or conduct their own inspections.

- Require third-party notifiers to submit reports of super emitter events to the relevant regulatory authority, not directly to the operator. There is no uniform reliable means to determine ownership of a site remotely, and operators should not be required to engage in costly regulatory compliance based on a third-party's self-certification.
- Emphasize that reports of super emitter events are not evidence of a violation of the CAA permit or the regulations.
- Provide a safe harbor against enforcement for methane emissions reported and resolved in response to a report of a super emitter event.
- Withdraw approval after three erroneous reports, whether to the same operator or not.

Commenter (2345-GHGSat Inc.) comments on the proposed framework for the SERP, which is delineated in the following five points:

- 1) The qualified third-party permitted to submit notifications must be certified by the EPA as having appropriate experience and expertise. The commenter agrees with this point.
- 2) The qualified third-party may only use certain remote detection technology approved by the EPA for use in the SERP. The commenter agrees with this point. Any new development or use of different technology by a third-party notifier should go through the evaluation process.
- 3) The EPA would establish the threshold defining what emissions events detected by the qualified third parties would trigger any obligation on the part of the owner and operator under the program. The commenter believes that this point should be clearer, since the definition of a super emitter event is proposed to be emissions greater than 100 kg/hr. Hence, this point should establish that.
- 4) The EPA has prescribed the specific factual information that must be included in any appropriate notification provided to an owner or operator. The commenter (agrees with this point and invites the EPA to consider the comments provided in the notification requirements section of this document.
- 5) The EPA has proposed a mechanism for owners and operators to seek a revocation of a notifier's certification from the EPA should they establish that more than one notification contained demonstrable errors. The commenter believes that this point requires further clarification as to what constitutes a demonstrable error. Also, the "strike system" mentioned in the proposed rule talks states that more than three notifications with errors, however, here mentions more than one notification with error. This discrepancy should be resolved. Lastly, it also needs to state the contemplated timeline for these erroneous notifications to accumulate.

Response II-14-150: EPA acknowledges the commenters' input, the Super Emitter Program has been revised to include EPA in a centralized role and has clarified the requirements and responsibilities of the third-party notifiers, these are detailed in section X.C.2 and XI.C.2 of the preamble to this rule.

Comment: Below Commenter (2428-API) has outlined suggestions on the appropriate steps to be included in a repropose framework, which provides greater confidence that the data provided under the program will be valid, actionable, and achieve EPA’s goals for transparency within the program.

1. The third-party completes approval certification process by EPA for inclusion in SERP and becomes “certified or re-certified”.
2. Certified third party<sup>158</sup> notifies EPA of planned monitoring, including submittal of a monitoring plan, at least 30 business days prior to planned monitoring. Depending on technology deployed, such as satellites, this pre-approval may include flight plans for extended time periods. The components of the monitoring plan are more fully described in Comment 1.1.3 of the commenter’s letter.
3. EPA reviews the certified third parties’ monitoring plan for approval or disapproval.
  - a. If approved, EPA notifies the impacted operators at least 7 business days prior to monitoring with details of the monitoring to be conducted including technology planned for use, dates of monitoring, flight paths (if appropriate), etc. This notice essentially acts as a “pre-notification” to operators, which enables the operator to have staff available to ensure safety of operations, if warranted based on technology that will be used to detect potential emissions by a third-party.
  - b. This “pre-notification” may also help both EPA and the third-party identify the appropriate operators, including the correct contact information, in the event a super emitting emissions event is detected. The potential for incorrect identification of operators is of concern for our members.
4. Timing of notification of results of monitoring to the operator is critical to the effectiveness of the SERP. After monitoring is completed, third party has 2 calendar days to provide data as defined in §60.5371b(b) to the EPA.
5. If EPA determines the data provided by the third-party to be credible and warrants investigation, EPA provides data for any super emitter emission event to the appropriate operator(s) within 3 calendar days of verification of third-party monitored data.<sup>159</sup>
6. Operator(s) will initiate an investigative analysis within 5 business days of receipt of data from EPA and complete the investigation within 10 business days of receipt of the data from EPA.
  - a. Given how certain technology is applied, the detection may not be from the facility that was notified, may be a permitted release, may be due to maintenance activity, or another reason that operator will provide “no action required” demonstration to EPA as specified in §60.5371b(c)(8) and §60.5371b(e)(1).
  - b. If the emissions event was result of component failure or other equipment defect, the operator(s) will complete final repairs within 15 calendar days after completing the investigative analysis.

---

<sup>158</sup> For the purpose of these comments when we reference a ‘third-party’, ‘certified notifier’ or ‘certified third-party’ we mean the certified individual and the monitoring company whose technology is utilized to conduct monitoring.

<sup>159</sup> The basis for the timing proposed in steps 4 and 5 is to align with what EPA has proposed for operators using similar technology.

7. All public information should be published by EPA only. EPA should manage all data that is to be public and establish a protocol for when and what type of specific details of a potential super-emitter emissions event is published via EPA's proposed website per §60.5371b(e)(4). We strongly disagree with the assertion in Section IV.C.2.a of the preamble (87 FR 74750) which states "The EPA would then promptly make such reports available to the public online. Third parties may also make such reports available to the public on other public websites. The EPA would generally not verify or authenticate the information in third party reports prior to posting." Given that much of the data collected can be interpreted incorrectly and not aligned with operating conditions, the EPA should be the only authority to publish data, and EPA should publish data only after operators have had an opportunity to review and respond to the information and EPA has fully reviewed and vetted follow-up actions with the operator.

Commenter (2428-API) states the timing of each step in the above framework has been crafted with the intent that all participants are held to timelines that are workable and suitable for each step of the framework. Operators are concerned they could receive multiple third-party notifications with limited time and resources to respond appropriately if stricter timing criteria for third parties to provide data is not established. The above framework seeks to address this concern.

Response II-14-151: EPA acknowledges the commenter's input and with many concerns the commenter raises, including but not limited to the with the need to have EPA in a centralized role reviewing super-emitter data, the timeliness of submittals by the third-party, and the identification of an owner or operator of a super-emitter event without confirmation of attribution. The Super Emitter Program has been revised in the final rule, these revisions are detailed in section X.C and XI.C of the preamble to this rule.

EPA has not chosen to require third parties to provide owner or operators of a notification of when they choose to conduct a survey as we consider this to be burdensome and, in some cases, technically feasible. Approved third party may choose to volunteer this information to the owner or operators.

### ***14.5.3 Operator Identification and Notices***

Comment: Commenter (2433-EDF et al) largely supports EPA's proposed six criteria for valid detections that would then trigger a response requirement for the responsible operator. The commenter also agrees that these upfront criteria, paired with the technology and independent third-party notifier approval process, obviate the need for additional data review by EPA after detection and support direct publication and notification to operators.

The notification criteria are generally appropriate; however, Commenter (2433-EDF et al) suggests a few modifications. The second criteria should typically be boilerplate and could be developed by EPA during the third-party notifier approval process. Only when a notifier is deploying multiple technologies or methods would this need to change. The fifth criteria should

be removed, and the date and time requirements be instead included in the first criteria alongside geographic coordinates. The commenter believes the latter portion of the fifth criteria is unnecessary and is already encompassed in criteria one and four. In addition, the commenter supports the signed certification requirement and urge EPA to make similar requirements applicable to operators when submitting information about their response to the notification.

Importantly, as part of the standards applicable to well sites, centralized production facilities, and compressor stations, Commenter (2433-EDF et al) argues EPA should require operators to submit exact geographic locations of sites in their initial and annual reports. EPA has already proposed to require this information in the alternative LDAR standards at section 60.5398b and should make similar requirements uniformly applicable. This information should then be used to accurately identify operators and sites responsible for detected emission events.<sup>160</sup> Using operator-submitted geographic information, EPA could design a portal for submission of notifications that would directly match the submission with the responsible operator.

Response II-14-152: EPA acknowledges the commenters', the Super Emitter Program has been revised to include EPA in a centralized role and has clarified the requirements and responsibilities of the third-party notifiers, these are detailed in section X.C.2 and XI.C.2 of the preamble to this rule.

Comment: Commenter (2305-The Williams Companies, Inc.) notes the proposed criteria for how the EPA will certify third party entities as 'notifiers' lacks transparency and specific details. Appropriate experience and expertise must be described more fully and should be commensurate with the requirements proposed for industry personnel and other regulatory bodies with delegated authority. Additionally, the regulated community should have access to technical data on the proposed monitoring technology from the specific monitoring entity along with approved protocols and procedures from that entity.

Response II-14-153: EPA acknowledges the commenters' input; EPA has expanded the criteria a candidate third-party must meet to receive certification. Likewise, the technology used for this program must be approved through the same criteria in the alternative test method for methane detection technology in §5398b(d). These revisions are detailed in section X.C.2 and XI.C.2 of the preamble to this rule.

Comment: Commenters (2177-Ute Indian Tribe, 2202-TXOGA, 2213-Occidental (Oxy), 2389-ACC, 2409-BP America Inc., 2428-API, 2453-Carbon Mapper and RMI) state EPA should require third-party reporters to make every economically feasible effort to identify the nearest potential facility operator based on available asset ownership information. EPA (or Administrator) should review notifications from third parties to ensure that the third-party is an approved notifier.

---

<sup>160</sup> See Hmiel et al., Empirical Quantification of Producers in the Permian Basin, supra note 215 (describing the process of matching aerial observations to sites and operators using Enverus Prism and GIS data).

Commenters (2177-Ute Indian Tribe, 2202-TXOGA, 2248-NDPC, 2399-GPA Midstream Association) question how third-party monitoring entities are going to know who the operator is, or how to contact the right people if the facility is covered by NSPS OOOOb, contending this lack of information is a burden on the state agency's resources as well as the Operator's.

Commenter (2202-TXOGA) notes that an inherent assumption in the preamble discussion is that a notifier can reliably identify the operator of a site with a super-emitter. In reality this is unlikely, and certainly not reliable, because while there may be databases of well locations, similar databases/maps of other types of facilities such as tank batteries and compressor stations do not exist. Notifiers can easily make incorrect assumptions, such as potentially concluding that if a particular well operator is known, then nearby/adjacent facilities necessarily have the same operator. Beyond this simple example are other opportunities for misinformation/misidentification of operators, such as plume drift and asset ownership transfers. As a result, operators could be forced to expend significant resources redirecting and ultimately delaying response to a super-emitter.<sup>161</sup>

Commenters (2177-Ute Indian Tribe, 2202-TXOGA, 2389-ACC, 2399-GPA Midstream Association) note it is important for notifications to be sent to the correct person at the operating company. When there are short response deadlines, there cannot be delay in transmitting the information to the responsible person at the company. If EPA is going to implement this program notwithstanding the concerns raised by numerous commenters, it is critical that third-party notifiers be required to communicate with specific point of contact information at the company (which EPA might consider assembling).

Commenter (2399-GPA Midstream Association) adds without such guidance, owners and operators may end up exceeding these deadlines because the third-party notifier sent the notice to the attention of a general community relations employee that does not understand the significance of such a notice, former employees, employees on vacation, or any number of company contacts that are not designated to handle such environmental concerns. The rule should not, for example, allow notifiers to rely on phone numbers or other contact information posted on facility locations or general contact information as the formal contact for receiving official notice on behalf of the operator/company.<sup>162</sup> The contact could, for example, be the same person or contact that is the designated representative for Subpart W. EPA should also detail how changes to the company contact would be handled when the named contact(s) are not at work (PTO/Vacation/Sick leave) or have been reassigned or retired. The rule should also address collocated facilities to avoid undue confusion, given the short response time, and specify the responsible party for a joint venture.

---

<sup>161</sup> TXOGA notes that the existing experience of its members with information provided from EPA to sites has often included videos from sites not actually owned by the recipient of the video. This demonstrates that sufficient oversight is needed to prevent third-party claims from demanding significant resources to prove that the information provided is not associated with the site at issue or presents information otherwise not relevant to an emissions event.

<sup>162</sup> The complexity of providing notice to a company or operator is a further reason why GPA Midstream had proposed in its previous comments that any private party notice should be handled through the regulators, not by a direct action from another private party. Notifications would come to the agency first and then sent to the company.

Response II-14-154: EPA acknowledges the commenters' input; EPA has revised the rule to require third parties to submit data to the EPA and EPA will provide the notification to the owner or operator. As described in Section X.C.2 and XI.C.3 of the preamble to the rule, the third-party notifier must provide a complete report including location and potential attribution, as part of EPA's review we will confirm the attribution and ensure the notification is being sent to correct recipient.

Comment: Commenter (2403-The Petroleum Alliance of Oklahoma) argues the Proposed Rule lacks information on how multiple third parties will avoid monitoring the same area and creating multiple notices to the operator for the same event, it fails to address how third parties will know if an emission is permitted or not, or even if it's an affected facility.

Response II-14-155: EPA recognizes the commenters' concerns; EPA find it important to pass information regarding large emission to owner or operators as soon as possible. In the final rule, if the notification provided to an owner or operator identifies a facility not subject to NSPS OOOO, OOOOa, OOOOb, and/or EG OOOOc, no further investigation is required and the owner or operator would be subject to limited reporting requirements.

Comment: Commenter (2428-API) argues third parties may employ technologies, like aerial surveys which can result in multiple detections in a short amount of time. It's not unreasonable to expect that surveys may be conducted by multiple third parties simultaneously or in series, and conversely, there could be extended periods of no third-party activity. Program requirements must balance the needs of operators to plan for both day-to-day operations and promptly prepare for and respond to third-party activity.

Response II-14-156: EPA acknowledges the commenters' input, in the final rule, EPA will be providing notifications to the owner or operators and if multiple reports come into the portal in short succession, EPA may only provide a single notification to an owner or operator with information from both reports. EPA finds it important to provide multiple reports of a super-emitter event as it provides valuable information to the owner or operator on persistent emission events so they can be resolved.

Comment: Commenter (2428-API) argues formal notification to facility owners/operators (and even with the third-party) could potentially be via email or a central online-based system.<sup>163</sup> The process should allow EPA to confirm that the correct operator received the notification and follow-up if the operator does not respond within a certain timeframe. There are also concerns with measurement of emission events, including pin-pointing sources or facilities correctly (especially when there are adjacent facilities in proximity to each other or sharing boundaries), and in conjunction with the minimum resolution of the monitoring technologies.

---

<sup>163</sup> If an online-based system is chosen, there will be an additional resource / cost burden on EPA to develop and maintain the functionality of the system. Also, there may be an issue when operators are in close proximity to each other and have shared property boundaries, or when a facility was owned by a specific operator at one time but has been sold to another owner.

Commenter (2409-BP America Inc.) encourage EPA to create an online registry with official contact information provided by operators and certified third parties, to help facilitate communications between EPA, third-party notifiers, and operators. The commenter believes that a registry of operators and certified third parties is needed to ensure that all parties participating in the SERP can promptly and effectively communicate with each other. This registry could be created and maintained by EPA and be made available on EPA's website. Additionally, operators and third parties could be responsible for reviewing contact information annually and updating it as necessary.

Response II-14-157: EPA acknowledges the commenters' input and as explained in section X.C.2 and XI.C.3 of the preamble of this rule, EPA is setting up a super emitter portal to handle incoming information and for reporting on notifications provided to owner or operators and their applicable responses.

Comment: Commenter (2428-API) suggests that the EPA include a pathway for operators to simply identify situations where "no corrective action required" beyond what has been proposed in §60.5371b(e)(1). These additional situations could include 1) the wrong operator was notified; 2) where the emission event cannot be validated by the operator; 3) there was a demonstrable error in the third-party notification; (4) the emission event did not occur at a regulated facility (e.g., well site or compressor station); or 5) the emission event was authorized as authorized or permitted operations. The information an operator should submit back to EPA should be simplified for planned or authorized emissions. Further, within §60.5371b(e)(1)(iii), EPA must clarify that the applicable standard is limited to the applicable standard of this subpart.

Response II-14-158: EPA recognize the commenters' input and EPA has revised the requirements for investigations and reporting consistent with some the recommendations in this comment, these revisions are detailed in Section X.C of the preamble of this rule.

EPA has also clarified when an event is attributable to a source regulated under CAA section 111 (NSPS OOOO, OOOOa, or OOOOb, or a state or Federal plan implementing EG OOOOc) as detailed Section X.C.1 and XI.C.1 of the preamble of the final rule.

#### ***14.5.4 Approval & Removal of Third-Party Notifiers***

Comment: Commenters (2410-California Office of the Attorney General et al., 2433-EDF et al.) support EPA's proposed pre-qualification requirements for independent third-party notifiers, which the commenter believes are central to the effectiveness of the program and ensuring safety and data veracity. These qualifications would include technical expertise in the specific technologies, the detection methodologies, and the necessary interpretation and analysis of the data collected. These criteria are appropriate, and EPA should not create overly restrictive standards that would unnecessarily limit participation. Requirements for third-party notifiers should generally align with and not be more restrictive than requirements for deploying advanced technologies in the LDAR program.

Response II-14-159: EPA agrees with the commenter and has revised the requirements for third-party notifier criteria for certification to include technical training in the specific technology used and documented data review processes to ensure data provided is accurate and defensible.

Comment: Commenter (2453-Carbon Mapper and RMI) states EPA should provide flexibility in certifying reporting organizations under the SERP including allowing both data providers and reporting organizations meeting the agency criteria to be considered “third parties”.

Response II-14-160: EPA recognize the commenters’ input, the only restriction from being a third-party notifier is that they are not the owner or operator of the site where the super-emitter event is detected.

Comment: Commenter (2626-Kayros) states EPA should consider the global context for methane data. Consistency on data sources across different jurisdictions will be important to minimize the burden of compliance among energy companies and to communicate with the wider public. On that basis, the EPA could expedite the approval of third-party notifiers that have already been vetted by other respected entities such as the International Methane Emissions Observatory (IMEO) and the International Energy Agency. In particular, IMEO has implemented a super-emitter monitoring system that is similar to the proposed super-emitter response program, and it seems reasonable to assume that EPA and IMEO will have data providers in common.

Response II-14-161: EPA acknowledges the commenters’ input; however, the EPA will not delegate the authority of this program to other agencies.

Comment: Commenters (2237-Industrial Commission of North Dakota, 2288-NDDEQ) ask will EPA be maintaining a list of all approved third-party notifiers, or will every delegated authority have to maintain their own lists? Does the approval apply nationwide, i.e., would a third-party notifier approved by Texas automatically be an approved notifier in North Dakota? Likewise, does the removal of approved notifier status apply nationwide, i.e, if North Dakota removes a third-party notifier from the approved notification list, would that third-party automatically lose their approval in California?

Commenter (2453-Carbon Mapper and RMI) recommends EPA establish and make available to all approved third-party reporters a list of operator-provided points of contact with contact information to facilitate timely and accurate notification. Commenter (2345-GHGSat Inc.) believes that a registration system will allow the proper identification of qualified third-party notifiers. Hence, commenter (2345-GHGSat Inc.) agrees with the EPA’s intention of creating and maintaining a public list of approved qualified third-party notifiers.

Response II-14-162: EPA will maintain a list of all certified third parties and will maintain the delegation to certify or de-certify these third parties. Candidate third parties must meet a specific set of criteria to be certified, including documented procedures for identifying an owner or operator of a site where a super emitter event has been identified.

Comment: Commenters (2345-GHGSat Inc., 2410-California Office of the Attorney General et al., 2453-Carbon Mapper and RMI) argue EPA should carefully review and elaborate on proposed criteria for removing approval of a third-party reporter for participation in the SERP program, particularly regarding the definition of “demonstrable errors”. For example, if an owner/operator claims that a third-party reported super-emitter did not exceed the 100 kg/hr threshold, EPA should require counterevidence with equivalent or better measurement technology based on simultaneous observations (since EPA recognizes that source intermittency is not grounds for error).

Commenter (2345-GHGSat Inc.) states there must be a formal and unambiguous definition of what constitutes a “demonstrable error”. For example, the intermittent nature of emissions could mislead an operator about the validity of an assessment.

Commenters (2306-Citizen's Climate Lobby, 2444-NAACP) note on P.21 - 40 CFR 60.5371b(a)(4) an approved notifier can lose its approval if it reports a site 4 times with “demonstrable error.” Proving errors is itself subject to error, so this rule chills reports after the first 3, which leaves future years unreported. EPA should change “more than three notices” in the rule, to “more than one notice per month” or “more than three notices per half-year.”

Commenter (2410-California Office of the Attorney General et al.) argues operators will generally have access to much more data about their own operations than third parties using remote-sensing technologies, so it is important that EPA does not permit operators to undermine the validity of third-party notifications on those grounds alone. The commenter suggests that an error should only be considered “meaningful” if it results in false positive (i.e., the identification of a super emitter emissions event when no such event occurred).

Commenter (2410-California Office of the Attorney General et al.) continues, EPA should clarify the process and schedule for an operator to challenge the validity of a third-party notification. The commenter suggests that if an operator believes a notification contains meaningful demonstrable error (and consequently, that a super emitter emissions event did not occur), the operator must submit a report to the EPA within 10 calendar days of receiving the notification, and simultaneously submit a copy to the third-party notifier. The third-party operator would then be provided an opportunity to respond, and EPA would ultimately make a determination as to whether the notification contained meaningful, demonstrable error. Commenter (2410-California Office of the Attorney General et al.) suggests that the third-party notifier be given 10 calendar days to respond, and that EPA’s determination be issued 10 calendar days after that.

Response II-14-163: EPA acknowledges the commenters’ input, EPA has expanded and explained the conditions for why a third party may be de-certified in Section X.C.2 and XI.C.2 of the preamble of the rule.

Comment: Commenter (2399-GPA Midstream Association) recommends that the effective date for implementing any program be deferred until EPA completes the process of approving notifiers and defining and approving appropriate technologies. EPA should defer any program

until it has developed robust governing requirements in a supplemental rulemaking that allows the public a full opportunity to comment on those requirements. At a minimum, any final rule should state that only observations/ identifications made no sooner than 180 days after the rule is final would be subject to the new requirements in the program. Commenter (2399-GPA Midstream Association) suggests a minimum of 180-days to provide EPA with necessary time to review and approve certified third-party notifiers and to approve qualified technologies.

Response II-14-164: The final rule has a natural delay for the implementation of the Super Emitter Program. With the new requirement that technology being used in the Super Emitter Program being approved for use through the alternative test method for methane detection technology under §60.5398b(d), which could take up to 270 days after the effective date of the rule. EPA could not consider candidate third-party notifier request until those have been received and approved and it is expected it may take a few months to process the initial third-party requests for certification.

Comment: Commenter (2626-Kayros) notes there is a large and growing body of independent, peer-reviewed research on the methodologies and technical capabilities of remote sensing technologies. The EPA can rely on existing studies, including field tests conducted by Stanford University of the detection and quantification performance of different platforms, to make an informed assessment. The large body of existing research should allow the EPA to decide in a timely manner on the list of approved third-party notifiers.

Response II-14-165: EPA agrees that peer-reviewed research on the methodologies and technical capabilities of remote sensing technologies is valuable information that could be used to aid in EPA's assessment of these technologies, however EPA cannot delegate the approval of these technologies to outside entities.

Comment: Commenter (2626-Kayros) asks EPA to select third-party notifiers based not only on their technical expertise but also on their ability to make their super emitter data publicly available and provide incentives to third-party notifiers.

Response II-14-166: EPA acknowledges the commenters' input.

Comment: Commenters (2399-GPA Midstream Association, 2403-The Petroleum Alliance of Oklahoma, 2428-API) state EPA should develop a clear set of criteria (e.g., in a checklist form) that any certified third-party would need to meet to participate in the program. This certification is important to ensure third-party monitoring is consistently conducted with an adequate level of quality assurance and control.

Commenter (2428-API) appreciates the demonstration for third party notifiers as outlined in the preamble (87 FR 74750), but do not believe the requirements as proposed in §60.5371b(a) provide enough stringency. Considering the requirements EPA has established for an operator, the same level of scrutiny should also be expected of the third-party data provider when using the same technology. Strict criteria should be established covering the following:

- An expectation from EPA that third parties and their approved detection technologies must be re-certified on a specified frequency. This certification process should be similar to other EPA certifying programs (e.g., EPA auditor).
- An expectation for third parties to attend EPA-specific training, including the do's/don'ts as well as what they are authorized to do or not do – including the handling of data they plan to use within the program.
- Clear criteria for what type of actions may immediately make data collected invalid and/or fully revoke a third-party's participation in the program. Regarding EPA's proposed revocation of third-party certification (87 FR 74750), we recommend that the criteria for revocation explicitly state that upon a third-party's third submission of verifiably false data from any combination of operators or sites, or upon trespass or otherwise unlawful or unauthorized entry to a facility, or vandalizing energy infrastructure, or upon unauthorized distribution or publication of data gathered under the program, the offending third-party shall have their certification revoked for a period of no less than three years. Any data gathered at the time of a trespass would render that data invalid.

Commenter (2403-The Petroleum Alliance of Oklahoma) requests the requirements for third-party notifiers should be as stringent and equivalent to the criteria required of owners/operators submitting data to state or federal regulators to demonstrate compliance with applicable standards, e.g., results/data certified by a professional engineer or appropriate in-house professional.

Response II-14-167: EPA acknowledges the commenters' input, as detailed in Section X.C.2 and XI.C.3, EPA has revised the criteria that third-party candidates must meet to receive certification to submit Super Emitter Data.

Comment: Commenter (2399-GPA Midstream Association) argues any program should provide the specific criteria for considering whether a third-party has the true "expertise" and qualifies for this role – and allow a notice and comment process to provide stakeholders the opportunity to comment on proposed third-party notifiers. That would be consistent with how EPA accepts applications, vets and allows for public input on proposed members of boards or for peer review. Further, the commenter (2399-GPA Midstream Association) urges EPA to be fully transparent about the criteria it is considering and allow for public comment before finalizing any criteria. Only by being fully open and public about the approval criteria, would the program have any potential credibility.

Commenter (2399-GPA Midstream Association) states that one criterion that EPA should adopt is that any third-party notifier must be employed by or directly contracted to, the company that makes or operates the monitoring technology that the notifier would use to monitor emissions. A strong affiliation with the manufacturer is necessary as few people outside of the company will understand accurately and fully how to use the highly specialized equipment that EPA is contemplating (e.g., satellite imaging) or interpret their results. Although a person may be provided with basic training by the manufacturer, this is not true "expertise" in the technology and how detected data is translated into emissions data. Such expertise only comes with

extensive experience and a real understanding of how the detection technology works, which would often involve an understanding of proprietary “black box” computational and analytical methods not available to the public. As such, EPA should specify that third party notifiers will not include individuals merely reviewing publicly available online data from outside sources (like Carbon Mapper or Climate Tracer) that then notify operators based on their observation of Carbon Mapper information.

As an alternative absolute minimum, the commenter (2399-GPA Midstream Association) provides that EPA should require notifiers who meet other criteria to be certified in a specialized training program provided by the manufacturer of the technology, with demonstrated time in the field utilizing the technology overseen by a company expert to develop sufficient expertise to reliably measure and attribute relevant data. That is what EPA requires for other forms of testing and monitoring, and at a minimum, we urge EPA to be consistent and apply the same approach here.

Moreover, commenter (2399-GPA Midstream Association) urges EPA to consider how unfair it would be for EPA to retain broad discretion to approve private parties, who would be granted extraordinary powers to require other private actors to take action and potentially expose other private parties to enforcement actions or negative public perception, without providing strict and transparent qualifications. It is particularly unfair given the stringent training requirements EPA imposes on industry personnel and their contractors on a wide range of matters – and in this area, the stringent standards EPA has imposed on the senior OGI camera operators that regulated parties must use.

Response II-14-168: EPA acknowledges the commenters’ input, as detailed in Section X.C.2 and XI.C.3, EPA has revised the criteria that third-party candidates must meet to receive certification to submit Super Emitter Data.

Comment: Commenter (2258-MS) argues third parties approved to conduct monitoring should be required to obtain approval from the applicable state before being allowed to operate. While U.S. EPA has oversight, the states have the primary enforcement role, and it is inappropriate for the Agency to approve an entity to interject itself into the state’s regulatory program without the state’s approval. The proposed criteria for how U.S. EPA will certify third party entities lacks transparency and specific details. Appropriate experience and expertise must be demonstrated more fully and should be commensurate with the requirements proposed for industry personnel. Additionally, the regulated community should have access to technical data on the proposed monitoring technology from the specific monitoring entity along with approved protocols and procedures from that entity.

Commenter (2393-OSEE) states both NSPS OOOOb and EG OOOOc have language regarding the certification needed by the third-party in the notification of a super-emitter event, with each requiring in its certification to cite to its own provisions (i.e., 40 CFR 60.5371b(a) or 40 CFR 60.5388c(a)). It is unlikely that the third-party notifier will have sufficient information on the facility they are submitting to determine which regulation they are reporting under. This reinforces the assertion that, if EPA finalizes the super-emitter program, states or EPA should be

running the program since they are best able to determine if a facility is subject to the requirements of OOOOb and OOOOc.

Response II-14-169: EPA acknowledges the commenters' input, with the restructure of the Super Emitter Rule as primarily as compliance assurance program for the applicable NSPS program and for that reason it is important to maintain the third-party certification as a national program.

Comment: Commenters (2237-Industrial Commission of North Dakota, 2288-NDDEQ, 2366-BHE, 2410-California Office of the Attorney General et al., 2483-INGAA) ask will EPA set forth guidelines on what counts as "technical expertise"? To properly evaluate the proposed rulemaking, EPA needs to define the requirements for how a party will get approved as a "qualified notifier" or include the process and standards in the associated test methods. Otherwise, it is unclear what would make a person qualified and what would constitute a demonstration of technical expertise. Due to the constantly evolving nature of emissions monitoring, it would be unduly burdensome to ask every delegated authority to have an in-depth understanding for the purposes of ascertaining a third-party's technical expertise on the matter. There may be a third-party using emerging technology that has established itself in other locales but that lacks the "technical expertise" when operating in North Dakota conditions for a fair evaluation to be made.

Commenter (2483-INGAA) requests guidance from EPA, including the requirements for who will get approved as a "qualified notifier". Otherwise, it is unclear what would make a person qualified and what would constitute a demonstration of technical expertise. Commenter (2483-INGAA) considers the proposal completely arbitrary and who would qualify could vary among jurisdictions as written.

Response II-14-170: EPA acknowledges the commenters' input, as detailed in Section X.C.2 and XI.C.2, EPA has revised the criteria that third-party candidates must meet to receive certification to submit Super Emitter Data.

Comment: Commenter (2366-BHE) states as a comparison, proposed Appendix K for use of OGI technology for methane leak detection for LDAR programs includes very thorough requirements for initial operator training and certification, as well as ongoing (e.g., annual) auditing and re-certification. This includes side by side testing with a qualified expert to confirm that the OGI operator attains the same results as the expert. OGI uses infrared technology which is similar to technologies used for fence line monitoring, drones, flyovers, etc. that would be used for the SERP, but that program adds the much more difficult (and unproven) ability to not only detect a methane leak but also quantify the emission rate. Quantification has proven to be a technological challenge, and additional and more thorough methodological requirements are warranted. However, no such methods are currently in place. The very different method requirements for these two methane sensing aspects of Subparts OOOOb and OOOOc must be reconciled, and similar efficacy should be achieved for both LDAR program leak detection and SERP leak measurement.

As a comparison, commenter (2483-INGAA) notes proposed Appendix K for use of OGI technology for methane LDAR programs includes thorough requirements for initial operator training and certification, as well as ongoing (e.g., annual) auditing and re-certification.<sup>164</sup> This includes side-by-side testing with a qualified expert to confirm that the OGI operator attains the same results as the expert.<sup>165</sup> OGI uses infrared technology that is similar to technologies that would be used for the Super-Emitter Response Program, but the Super-Emitter Response Program adds the much more difficult (and unproven) ability to not only detect a methane leak but also measure the emission rate. By adding quantification of the emission rate, additional and more thorough methodological requirements are warranted, yet no such methods are proposed. The very different method requirements for these two methane-sensing aspects of NSPS OOOOb and EG OOOOc must be reconciled, and similar efficacy should be achieved for both Appendix K LDAR program leak detection and leak measurement under the Super-Emitter Response Program.

Response II-14-171: EPA recognizes the commenters' input; EPA does not consider OGI as a suitable technology for use in the Super Emitter Program as the current iteration of the technology does not meet the intent to use remote sensing in the rule in it is not quantifiable and it would require access to be conducted effectively. As technology improves and the ability to operate these cameras at a safe distance to quantify emissions, we could consider it for use in this program.

Comment: Commenter (2345-GHGSat Inc.) agrees with the EPA that any third party interested in identifying and notifying operators of super emitter emissions events must be pre-approved by the Agency for the notification to be valid. Commenter (2345-GHGSat Inc.) also agrees with EPA's intention of vetting any interested third-party notifier (e.g., technology vendor, researchers, non-profit organization, other parties) through defined approval criteria. Commenter (2345-GHGSat Inc.) believes these criteria should be based, at least in part, on the proposed pre-screening and evaluation tenets suggested for the alternative test method for advanced methane detection technologies. An effective emissions detection system needs to simultaneously satisfy the following requirements:

1. Well-characterized detection limit based on a POD curve.
2. Well-characterized, high specificity (low rate of false positives).
3. Well- characterized quantification accuracy.

Therefore, commenter (2345-GHGSat Inc.) recommends that the EPA incorporates these three requirements as part of the registration criteria. Commenter (2345-GHGSat Inc.) believes that the following questions, which are based on the proposed vetting for alternative test method, should be part of the criteria:

---

<sup>164</sup> Determination of Volatile Organic Compound and Greenhouse Gas Leaks Using Optical Gas Imaging (hereinafter Proposed Appendix K) § 10.0 (Camera Operator Training).

<sup>165</sup> Appendix K, § 10.2.2.2.

1. The desired applicability of the technology (i.e., site-specific, basin-specific or broadly applicable across the sector). In the case of the commenter (2345-GHGSat Inc.), the company currently operates two different platforms (satellite and aircraft) that can provide both site and basin specific.
2. A description of the measurement system. Commenter (2345-GHGSat Inc.) believes this question needs to be coupled with scientific explanations and proper vetting from the scientific community. Nonetheless, this description should protect any intellectual property associated with the technology in consideration. The EPA should provide a mechanism to safekeep any information that is marked confidential and/or that obeys any intellectual property clauses.
3. Supporting information verifying that the technology meets the desired detection threshold(s) as applied in the field. Commenter (2345-GHGSat Inc.) acknowledges that there is a need for standardized methods for evaluating the performance of the alternative technology systems. Commenter (2345-GHGSat Inc.) believes that measuring systems must be validated using the statistical metrics of sensitivity, specificity, and quantification accuracy. Hence, commenter (2345-GHGSat Inc.) believes this is a critical question that needs to be further expanded to cover the statistical metrics mentioned herein. A full discussion of these three metrics and its applicability to the satellite platform is provided by (McKeever, et al., 2022).
  - a. Sensitivity
    - i. In detection systems, sensitivity describes how effective the system is at detecting an emission that is indeed present. The is also known as the rate of true positives. Understanding this rate allows defining the concept of detection limit, in which the sensitivity of a system increases for higher (true) emissions rates and approaches zero for very low rates.
  - b. Specificity
    - i. The metric of specificity describes how good a system is in minimizing the number of erroneously declared detections when in fact no emission was present. These events are known as false positives, whose occurrences only create additional work and emissions mitigation. Hence, a measurement system with low or no false positives instances is said to have high specificity.
  - c. Quantification
    - i. The metric of quantification is determining the mass emission rate of an event. This proposed rule places an important emphasis on this metric, as it is proposed as the qualifying metric under the matrix system. Commenter (2345-GHGSat Inc.) believes that quantification accuracy must be measured and specified along with the corresponding measurement uncertainties. Reporting these two values supports the credibility and validity of the measuring system.
    - ii. It is important to note that the quantification metric, along with the sensitivity metric, is related to the detection threshold, which in turn, relates to the POD.

- d. Detection Threshold
  - i. A system's detection threshold can be described utilizing a POD curve, which relates the system's sensitivity, specificity, and quantification by determining the smallest emission that could be detected and the corresponding probability of actually detecting it. Currently, the creation of a POD curve could rely on simulation or in practical trials with controlled releases.
  - ii. Measuring systems need to deal with uncontrolled environmental variables. In the case of remote sensing measuring systems, environmental variables like terrain reflectance, atmospheric turbulence, and wind conditions directly impact the detection threshold. The wind speed has a strong influence on the detection probability, hence, commenter (2345-GHGSat Inc.) requests that EPA establishes a requirement for POD to be expressed as a function of wind speed. For example, the detection threshold of the commenter's (2345-GHGSat Inc.) systems is expressed using a reference wind speed of 3 meters per second. In the commenter's (2345-GHGSat Inc.) platforms, the POD curve does not behave as a step-function, rather, there is a smooth increase in detection probability as the emission rate increases. In this curve, it is observed that the emission rates at 50% and 90% POD are close in magnitude. Commenter (2345-GHGSat Inc.), in agreement with best practices documented in the scientific literature, reports its detection threshold based on a POD at 50% and using a reference wind speed of 3 meters per second.
- 4. A detailed description of the alternative testing procedure(s), including data quality objectives to ensure the detection threshold(s) are maintained and procedures for a daily verification check of the measurement sensitivity under field conditions. Commenter (2345-GHGSat Inc.) believes that this requirement is important. This requirement is intrinsically linked to requirement 3. The concepts explained by commenter (2345-GHGSat Inc.) in the commentary for requirement 3 are applicable here. It is important to note that field conditions vary through the United States, making it more challenging to provide a general detection threshold at 90% POD. For this reason, Commenter (2345-GHGSat Inc.) recommends utilizing 50% POD instead, in a way to accommodate for varying conditions.
- 5. Standard operating procedures consistent with the EPA's guidance and including safety considerations, measurement limitations, personnel qualification/responsibilities, equipment and supplies, data and record management, and quality assurance/quality control. Commenter (2345-GHGSat Inc.) agrees that Standard Operating Procedures (SOPs) will need to be set in place by technology providers. However, these SOPs should follow a common template to allow for inter comparability between technologies. Therefore, commenter (2345-GHGSat Inc.) recommends the EPA to create such template.

Response II-14-172: EPA acknowledges the commenters' input, as detailed in Section X.C.2 and XI.C.2, EPA has revised the criteria that third-party candidates must meet to receive certification to submit Super Emitter Data.

Comment: Commenter (2157-Division of Air Pollution Control Tennessee Department of Environment & Conservation) notes EPA’s proposed grant of such authority to nongovernment entities potentially violates the Private Nondelegation Doctrine, which generally prohibits the delegation of public powers to private entities.<sup>166</sup> Although EPA states that the “qualified third-party would essentially only be permitted to engage in certain fact-finding activities and issue fact-based notifications . . . [which] would not represent the initiation of an enforcement action by the EPA or a delegated authority”, EPA would, in fact, be granting these private actors significant investigatory powers, which would otherwise be performed by agency personnel. Proposed § 60.5388c specifically compels affected facilities to respond to super emitter emissions events by conducting root causes analyses, then taking appropriate corrective action and reporting investigation findings to EPA. Therefore, these private third parties would, in fact, step into the shoes of a regulator because they could compel facilities to conduct these activities under the color of law.

Response II-14-173: EPA has revised the final rule to include EPA in a centralized role to approve technology, certify third parties, receive reports from the third parties, and review the data for accuracy and reasonableness before notifying an owner or operator. In the final rule, a certified third party has no authority other their ability to submit legally obtained super emitter data to the EPA.

Comment: Commenter (2177-Ute Indian Tribe, 2366-BHE, 2483-INGAA) asks for further clarification/definition of what specifically comprises a "third-party"? Commenter (2177-Ute Indian Tribe) recommends that a third-party be defined such that a group/organization will get approved as an approved notifier, but each individual within the group/organization that will be conducting any OGI camera surveys be qualified as a certified camera operator. Any petitions to remove a third-party from the approved list should be to remove a group/organization, not an individual.

Response II-14-174: EPA recognizes the commenters’ input; EPA does not consider OGI as a suitable technology for use in the Super Emitter Program as the current iteration of the technology does not meet the intent to use remote sensing in the rule in it is not quantifiable and it would require access to be conducted effectively.

Comment: Commenter (2177-Ute Indian Tribe) responds to EPA’s solicitation for comment on the following proposed text:

“Qualifications for notification. If, in the Administrator’s judgement, a third-party (i.e., someone other than the owner or operator of the site with a detected super emitter emissions event, the Administrator, or the delegated authority) demonstrates technical expertise in any of the remote detection technologies and/or methods specified in paragraphs (a)(1) through (3) of this section the third-party would use, the Administrator will approve that third-party as a qualified notifier that is eligible to submit a notification

---

<sup>166</sup> See generally, *Nat'l Horsemen's Benevolent & Protective Ass'n v. Black*, 53 F.4th 869, 880 (5th Cir. 2022) (“Our Constitution permits only the federal government to exercise federal power.”).

of a super emitter emissions event to an owner or operator as specified in paragraph (b) of this section.”

Commenter (2177-Ute Indian Tribe) states third parties should not be allowed as qualified notifiers. The commenter recommends deleting this requirement. If this requirement is kept, third parties should be required to meet the requirements in Appendix K, section 10.0 for camera operator training.

Response II-14-175: EPA acknowledges the commenters’ input.

Comment: Commenter (2301-U.S. Chamber of Commerce) argues notifiers should also be required to certify that they have no conflicts of interest (e.g., employment by competitor companies) and made subject to periodic recertification. These additional requirements will help reduce the risk that individuals without proper training or experience inaccurately record or report information or accidentally report information to the wrong owner or operator based on confusion about the ownership of a facility or the source of the alleged emission event.

Commenter (2410-California Office of the Attorney General et al.) requests that EPA provide more detail on the revocation procedure, to ensure that third-party notifiers are not denied the right to participate in the program without sufficient evidence, and to ensure that such a revocation procedure does not chill third-party participation in the program.

Commenter (2247-Ohio Environmental Protection Agency) notes it appears that U.S. EPA will be required to approve all super emitter notifiers. A lot of individuals will likely want to be approved as a qualified super emitter notifier. Has U.S. EPA tried to estimate how many Ohio EPA Comments on U.S. EPA’s December 6, 2022, Proposed Rules Regulating the Oil & Gas Industry Page 4 will ask to be approved as a notifier and does U.S. EPA have the staffing to review these in a timely basis? Will the public be notified of this official approval? Will U.S. EPA require approved notifiers to conform to a set of operating parameters?

Response II-14-176: EPA acknowledges the commenters’ input, as detailed in Section X.C.2 and XI.C.2, EPA has revised and expanded the criteria that third-party candidates must meet to receive certification to submit Super Emitter Data. EPA has placed the revocation process into the third party process not to chill participation but to ensure the accuracy and reasonableness of the data being submitted by these third parties, as data quality of the submittals is foundation to a successful program.

Comment: Commenter (2247-Ohio Environmental Protection Agency) asks has U.S. EPA considered having the delegated authorities approve notifiers? Would this be part of the approval process of the 111(d) plan?

Response II-14-177: EPA acknowledges the commenters’ input, with the restructure of the Super Emitter Rule as primarily as compliance assurance program for the applicable NSPS program and for that reason it is important to maintain the third-party certification as a national program.

#### ***14.5.5 Notification Timeline***

Comment: Commenter (2458-MiQ) supports the proposed notification timelines in the SERP. The commenter supports the Corrective Action (IV.C.2) provision and timeframe. It will provide the operator with enough time to prioritize a causal examination.

Response II-14-178: EPA acknowledges the commenters' support for the Super Emitter Program.

Comment: Commenters (2218-TCEQ, 2626-Kayrros) state the amount of time required for notifications following the detection of a super emitter will depend on the type of remote sensing technology, the ability to identify the relevant operator and the capabilities of the third-party notifier. The latency of detection and quantification may vary across different platforms, but the EPA could require that notification be sent within a fixed time period. In the case of satellite monitoring, the pre-processing and quality control performed by the satellite operator creates a time lag of up to two days, while the analysis can be completed in a matter of hours.

Response II-14-179: EPA acknowledges the commenters' input; EPA has detailed the timelines and the rationale for them in Section X.C.2 and XI.C.3 of the preamble of the rule. EPA is requiring that third-party reports be submitted within 15 days of detection regardless of technology used.

Comment: Commenters (2177-Ute Indian Tribe, 2213-Oxy, 2220-WDEQ, 2237-Industrial Commission of North Dakota, 2248-NDPC, 2288-NDDEQ, 2305-The Williams Companies, Inc., 2389-ACC, 2428-API) are concerned about the significant lag time between when an emission event is detected to when it is ultimately reported. This prevents the third-party from submitting multiple notifications at one time and creating a workload for the operator that is unreasonable. Commenters (2237-Industrial Commission of North Dakota, 2288-NDDEQ, 2428-API) state technologies such as satellites or aerial methods, due to the large amount of data and the QA/QC processes required to identify both emissions meeting the 100 kg/hr threshold and the exact location where the emissions are coming from, can take weeks if not longer to complete. This delay lessens the actual effectiveness in the confirmation and identification of super emitter events. Furthermore, the Leak Detection and Repair requirements result in ongoing repairs of leaks as they occur and are found. Given the potential time delay for the super emitter program, the inability to confirm and identify the information may lead to confusion or mistrust in the system and agency. Commenter (2288-NDDEQ) has already had a situation where a third-party monitoring company reported detection of a large methane release at a facility, however this information was not received until a month after the detection. In the commenter's investigation of the matter, the release appears to be at least partly related to a NSPS OOOOa component that had already been detected by the facility and was on delay of repair at the time of the third-party detection.

Commenter (2220-WDEQ) understands that it can take weeks for data from remote detection methods to be processed. As a result, it is possible that data could indicate a compliance event that occurred in the past due to an issue that was not replicable and potentially already corrected

by an operator with involvement of WDEQ's Compliance program staff. Based on the proposed SERP, operators would have to expend significant time and resources undertaking root-cause analyses for one-time-event compliance issues that may have already been resolved.

Commenters (2258-MSA, 2301-U.S. Chamber of Commerce, 2389-ACC, 2399-GPA Midstream Association) note proposed § 60.5371b(b)(7) only requires a third-party to notify the owner or operator of the site "as soon as practicable." EPA does not define what is "practicable." This is a significant concern as the ability to verify any large emission event and, if verified, the cause of the event, will diminish greatly with time. Delays in receiving notice would therefore frustrate the owner or operator's investigation. It makes no sense to allow notifiers a flexible, and potentially long, timeline for submitting their notices and then require operators to respond on a tight, rigid timeline with no consideration of practicability.

Additionally, commenter (2305-The Williams Companies, Inc.) states the proposed program places no obligation upon the third-party to provide timely data (e.g. within 5 days of detection), to understand the source in question, to take measurements with the same objectivity expected of a regulatory agency or independent consultant, or to demonstrate an on-going proficiency in the technology or training in the use of the equipment as is expected of governmental agencies and regulated entities.

Response II-14-180: EPA is requiring that third-party reports be submitted within 15 days of detection regardless of technology used in the final rule. EPA considers it important to provide owner or operators with timely information as it aids in their investigation into the potential cause(s).

Comment: Commenter (2345-GHGSat Inc.) understands that the EPA wants to have a notion as to the time it takes from detection to notification. The commenter wants to convey that there are multiple factors affecting the gap in time between these two events. One important factor is the type of platform making the detection. For the satellite platform for example, the data captured by each satellite needs to be downloaded when the satellite is nearby the procured download link on earth. This process can occur within a few hours of taking the measurement to up to 24 hours. Then, there is an initial processing time in which each detection goes through a queue. This can also take a few hours to up to 24 hours. At this point the presence of an emission is identified, moving this imagery to further processing for assessment and quantification of emission rate and uncertainty. This can also take a few hours to up to 24 hours. Therefore, the notification deadline should be no sooner than 4-5 days, which includes an additional 24-48 hours to cover any eventuality.

Commenter (2345-GHGSat Inc.) states in the case of the aircraft platform, the data gathering is different than the satellite, since this platform sweeps an entire area, collecting multiple terabytes of information. The initial processing of the vast amount of data typically takes 24-48 hours, in which imagery gets identified for further assessment and quantification. That process can take a few hours to up to 24 hours. Similarly, to the satellite platform, the notification deadline should be no sooner than 4-5 days, which includes an additional 24-48 hours to cover any eventuality.

Response II-14-181: EPA acknowledges the commenters' input and while we are encouraged at the timeline that some technology vendors need to process data, we wanted to provide sufficient time for the third parties to review this data and to confirm the owner or operators of these sites so in the rule we are requiring third party reports must be submitted within 15 days.

Comment: Commenters (2345-GHGSat Inc., 2348-Energy Workforce and Technology Council) believe one way of ensuring that an outreach gets to a company representative is that each operator designates an email address specifically for the SERP. That way, the response time should be minimized, and the operator is in control of that response time.

Response II-14-182: EPA is requiring that third-party reports be submitted within 15 days of detection regardless of technology used in the final rule.

Comment: Commenter (2348-Energy Workforce and Technology Council) indicates that if an emission event is validated by qualified personnel and technology, then the notifier should be required to report the emission to the operator within a 1-day of discovery and validation. This is possible where a continuous monitoring system is in place because such a system produces data very quickly—i.e., location, threshold, and duration are reported at the time of detection via email/text to the service provider and the customer/operator.

Commenter (2248-NDPC) requests that the alleged findings are not made public until actual emissions are observed and documented by the operator. The EPA should make it clear that all pertinent evidence must be provided to the operator at the time of the notification by the third party. Withholding information should be considered grounds for disqualification.

Commenter (2294-Ohio Oil and Gas Association) recommends the notification must be made as soon as practicable, but no later than 3 days after the alleged super emitter event.

Commenters (2248-NDPC, 2409-BP America Inc.) argue that notification to the state agency and operator needs to be within 48 hours. Commenter (2409-BP America Inc.) continues, EPA should then promptly confirm receipt of the data and notify all operators potentially implicated by the super emitter event, including any such operators that did not receive notice directly from the third-party. Providing notification of the alleged leak weeks or months after the finding could make it difficult or impossible to identify the source of the emissions. Late notifications are a burden on the state agency's resources as well as the Operator's.

Commenters (2301-U.S. Chamber of Commerce, 2399-GPA Midstream Association, 2403-The Petroleum Alliance of Oklahoma, 2409-BP America Inc.) argue EPA should require third parties report an event to the EPA and/or state delegated agency for review no later than 5 calendar days after the event. EPA and/or the state delegated agency would then notify the operator to verify a release and take corrective action, if needed. Only an event that has been verified and corrective action taken would be made available to the public on EPA's or the state delegated agency's existing website.

If the operator and or facility is known to Commenter (2345-GHGSat Inc.), immediate notification occurs through GHGSat’s SPECTRA platform and via email. When the operator is unknown or the location is not clearly attributed to an operator (e.g., subsurface infrastructure), a discovery phase is required to uncover these details. Based on this, the suggested additional time should be no less than 5 to 6 days.

Commenter (2258-MSC) states that the proposal that notification be given “as soon as practicable” is not adequate. According to commenter (2258-MSC), recent experience has shown that delays greatly hamper the ability of a source to investigate and respond to the notice, and notice should be required within 7 business days of the alleged event.

Commenter (2282-Kinder Morgan Inc.) argues if EPA moves forward with the super emitter proposal, it must also provide an exception to any proposed timeframe, for good cause shown. Although EPA appears to allow for some flexibility in timeframe for completing a corrective action by allowing development of a corrective action plan if the cause analysis and corrective action cannot be completed in 10 days, additional flexibility is required. The proposal does not provide for any exceptions for the time required to develop a corrective action plan. The commenter understands EPA’s motivation for a rapid response, but EPA should nevertheless provide exceptions, for good cause shown to the specified timeframes.

Response II-14-183: EPA acknowledges the commenters’ input; EPA has detailed the timelines and the rationale for them in Section X.C.2 and XI.C.3 of the preamble of the rule. EPA is requiring that third-party reports be submitted within 15 days of detection regardless of technology used.

Comment: Commenter (2247-Ohio Environmental Protection Agency) asks if a super-emitting event is identified, and it is not yet safe to attempt a repair, how does the owner/operator get approval to delay the initial repair past the 10 days?

Commenter (2345-GHGSat Inc.) believes the EPA should consider implementing deadlines for first and final attempts for repairing and verifying the leak based on the severity (mass emission rate), regardless of the component type or infrastructure.

Response II-14-184: EPA has revised the final rule to attach the repair timeline to the applicable regulation for the source of the super-emitter event, if the applicable regulation includes an allowance for delay of repair, then an owner or operator must be subject to those standards.

Comment: Commenter (2222-Wisconsin Department of Natural Resources) notes that EPA solicits comment on the amount of time allowed for notifications to sources following detection of a super emitter emissions event. Commenter (2222-Wisconsin Department of Natural Resources) suggests that absent an approved method or direction on super emitter identification, EPA should work with states and tribes on establishing a super emitter program including identification and communication.

Response II-14-185: EPA acknowledges the commenters’ input.

#### **14.5.6 Required Notification Information**

Comment: Commenters (2202-TXOGA, 2348-Energy Workforce and Technology Council, 2403-The Petroleum Alliance of Oklahoma, 2453-Carbon Mapper and RMI) state notifiers should be required to provide proof of data of the event (time, date, location, visual evidence of leak origin), per the specifics of the equipment used to detect the event. Precise timing information can help minimize the chance of false alarms and aid in follow-up analysis by operators. The standards are accreditation of such notifiers would need to be put into place, as none exists today, and should be a government certified activity. These third-party notifiers must also have authorization to be on private, tribal, and federal land, as well as clearance of OSHA or industry required training if on neighboring well or production site.

Response II-14-186: EPA acknowledges the commenters' input; EPA has detailed the criteria for third parties in Section X.C.2 and XI.C.2 of the preamble of the rule. The rule also includes a provision that if the third-party notifier is guilty of illegal activity during the assessment of a super-emitter event (*e.g.*, trespassing), their certification would be revoked.

Comment: Commenter (2428-API) states at least 30 business days in advance of the planned monitoring campaign, the third-party must submit a monitoring plan to the EPA for approval. The monitoring plan submittal should include the following information (at a minimum):

- Site coordinates and/or map of the area to be monitored.
- Description of monitoring equipment to be used to conduct the activity.
- Documentation of emissions detection limit.
- Proposed starting date and duration of the monitoring activity.
- Contact details (*e.g.*, name, phone number, title) of third-party contact person.
- Name and details of owner of remote monitoring equipment.
- Quality assurance / quality control plan, including calibration procedures, if applicable to the technology (Subsequently, the third-party should also have to demonstrate how it met its monitoring plan for each monitoring event when monitored data is submitted to EPA).
- Specification on how the data will be provided and in what timeframe to the EPA; and
- Certification statement signed by an authorized company official attesting that the third-party will conduct monitoring activities in accordance with EPA requirements.

Commenter (2428-API) adds with the 30-day approval period, it would also allow EPA sufficient time to provide affected facility owners / operators notice of the upcoming monitoring event, which should be provided at a minimum 7 business days prior to the start of the monitoring field event.

Response II-14-187: EPA acknowledges the commenters' input; EPA has not chosen to require third parties to provide owner or operators of a notification of when they choose to conduct a survey as we consider this to be burdensome and, in some cases, technically feasible. Approved third party may choose to volunteer this information to the owner or operators.

Comment: Commenter (2389-ACC) recommends EPA ensure that its communication of any monitoring results or facility response information is rooted in principles of accurate risk characterizations and context. Throughout this process, the Agency should not only maintain its capacity and engagement to assess the monitoring results for quality and scientific accuracy, but also prioritize its ability to clearly communicate proper context and meaning of the information presented in the reports. EPA should further ensure that public communication of any monitoring information clearly states what the data means (and just as importantly, what it does not mean) and how it should be used. If EPA retains public dissemination of the reports, it is critical for the Agency to communicate the meaning and proper usage of the emissions data to help communities fully understand it. Without this information and context, these programs may result in widespread misinformation and unnecessary alarm, which only serves to defeat the Agency's overall goal to improve public understanding around these events.

Response II-14-188: EPA acknowledges the commenters' input; In the final rule, the EPA has finalized the Super-emitter program is being developed with transparency in mind, on the part of the third-party, the EPA, and the owner or operator. All notifications meeting the requirement in the final rule will be published online on the EPA's Super Emitter Portal - <http://www.epa.gov/super-emitter>.

Comment: Commenter (2458-MiQ) states EPA should provide clear data quality parameters in advance, and these should be updated on an annual basis. This will provide guidance in advance of any third-party notification of a super-emitter event about the type and quality of data that must be submitted. To ensure that the SERP functions as intended, EPA should conduct post-notification audits to ensure compliance with the notification data quality guidelines.

Response II-14-189: EPA has revised the criteria for third party notifiers in the Super Emitter Program as detailed in Section X.C.2 and XI.C.2 of the preamble of the rule detailing requirements for developing a data evaluation program, likewise the Super Emitter Program to use methane detection technology approved. The rule also includes a provision that if the third-party notifier is guilty of illegal activity during the assessment of a super-emitter event (*e.g.*, trespassing), their certification would be revoked.

Comment: Commenter (2403-The Petroleum Alliance of Oklahoma) notes the Proposed Rule does not discuss what will be included in the report that will be placed on the website or how this information will be provided in easy, understandable format. Any monitoring data should be fully transparent *e.g.*, identify who collected it, how it was collected, when it was collected, what technology was used, accuracy information, and other pertinent information. EPA should require third-party notices of an event be sent to EPA and/or the state delegated agency first. EPA and/or the state delegated agency would review this information and contact the operator to verify the event and take corrective action, if needed. Only after the event is verified and corrected should the event information, be made available to the public on EPA's or the state delegated agency's website.

Commenter (2403-The Petroleum Alliance of Oklahoma) adds the Proposed Rule does not provide any details of the technologies that will be used by third parties (other than general

information i.e., remote sensing aircraft, mobile monitoring platforms or satellites), whether these same technologies are allowed to be used by operators instead of OGI, the associated level of accuracy, reliability, and sensitivity of the technology, nor the quality or accuracy (errors and false positives) of data generated by the technology.

Commenter (2403-The Petroleum Alliance of Oklahoma) argues EPA super-emitter program should make available to the public the type of technology being used, the accuracy, reliability, and sensitivity of the technology, and the quality or accuracy (errors and false positives) of data generated by the technology for each event on its website. EPA should allow the public the opportunity to review and comment on the technology before being approved for use by a third party. Also, any technology used by third parties should be allowed to be used by operators in lieu of OGI.

Response II-14-190: Any methane detection technology used as part of the program must be approved for use through the advanced methane detection technology program as detailed in §60.5398b(d). Section X.B details criteria for this approval.

Comment: Commenters (2168-INOGA, 2172-Kentucky Oil and Gas Association, 2294-Ohio Oil and Gas Association) note EPA needs to require that notification provided to an owner / operator is delivered in writing. Verbal notification is insufficient when action is required. Verbal notification may be provided to the owner / operator as a courtesy but is insufficient as proof that notification has been served. The written notification should provide sufficient details about the incident for the owner / operator to act and not question the validity of the notification. The minimum information that should be included in the notification includes date that the deficiency was observed, name of the entity making the observance, flow rate, equipment used, last calibration date for equipment, and latitude and longitude.

Response II-14-191: EPA acknowledges the commenters' input; the final rule has been structured to require all notifications will come from the agency to the owner or operator. It is intended these notifications will be provided to an owner's or operator's responsible official.

Comment: Commenter (2433-EDF et al.) also notes that EPA inherently retains control over the entire program. If certain notifiers are repeatedly submitting data that do not include all six of the elements proposed by EPA, that data would simply not require the operator to take action. Independent parties with the technical expertise necessary to collect this type of data and meeting EPA's certification requirements should not face decertification for minor technical errors in submissions.

Response II-14-192: EPA has revised the criteria for the certification and decertification of the third-party notifiers in the Super Emitter Program as detailed in Section X.C.2 and XI.C.2 of the preamble of the rule. It is not the intent of the agency to decertify notifiers for minor errors in submissions, however if errors are persistent and they effect either the identification of an owner or operator or the misidentification of a super emitter event, that could result in a decertification.

Comment: Commenter (2409-BP America Inc.) suggests that EPA revise the program to require that, within 5 days of notification from either a third-party or EPA, operators should perform an initial evaluation of the data and make best efforts to confirm whether the event occurred at its site, and if so, whether the emissions were (a) caused by an anticipated, short duration event such as operations and maintenance activity at the site; or (b) unplanned / fugitive emissions. EPA could then structure the program along the following lines:

- If the operator's initial evaluation of the data indicates that a super emitter event has not occurred at the operator's site, the operator could document this finding and report it to the EPA (or state with delegated authority). The operator's obligations under the SERP program would be complete.
- If the operator's initial evaluation indicates that the event was caused by a scheduled intermittent event from O&M activity, the operator could similarly be required to document this finding and report it to EPA (or the state). Again, the operator's obligations under the SERP program would be complete.
- If the initial evaluation of the data indicates that (a) the emissions were unplanned and (b) leak repair or other corrective action is required under EPA's regulations, the operator could then be required to determine and execute the appropriate corrective action, document the actions taken, and notify EPA (or the state) within the time frame set by regulation. If the operator deems that it is not feasible to act within that timeframe, the operator may be allowed to document the reasons for incomplete action and notify EPA (or the state) that more time is needed.

Commenter (2409-BP America Inc.) adds key to these suggestions is that communications and decisions take place between the operator and the regulatory authority, not with the third-party, and that there are clear off ramps and incentives provided for operators who can promptly evaluate data and take action, if needed.

Response II-14-193: As detailed in section X.C.2 and X.C.4 of the preamble of the rule, EPA has revised the Super Emitter Program to identify what investigations are required by the owner or operator and are consistent with the input provided by the commenter.

Comment: Commenter (2409-BP America Inc.) argues EPA must go further and provide more specificity with regard to the validation process. At a minimum, EPA should ensure that approved third parties are familiar with GIS systems; demonstrate experience implementing methane measurement campaigns; and have the ability to process methane data in a timely and transparent manner.<sup>167</sup>

Response II-14-194: EPA acknowledges the commenter's input; EPA has included specific criteria in the certification process that a third party have expertise in the technology used and to

---

<sup>167</sup> Because super emitter events are based on an emissions rate (i.e., of 100kg/hr or greater), there is an even greater need for third parties to transparently process and disclose their data given the uncertainties inherent in emissions rate estimation.

develop data evaluation procedures to ensure the data submitted is accurate and reasonable. These criteria are detailed in section X.C.2 of the preamble of the rule.

#### ***14.5.7 Abuse of Third-party Reporting Privileges***

Comment: Commenters (2202-TXOGA, 2220-WDEQ, 2227-Western Energy Alliance, 2240-Rose Rock Environmental Services, LLC, 2254-PBPA, 2282-Kinder Morgan Inc., 2258-MSA, 2283-Endeavor Energy Resources, 2284-Kairos Aerospace, 2301-U.S. Chamber of Commerce, 2346-Encino Environmental Services, LLC, 2389-ACC, 2399-GPA Midstream Association, 2446-IPAA, 2483-INGAA, 2626-Kayros, 2713-Northeast Natural Energy LLC) argue the delegation of authority would require much more careful quality control with much better oversight than that articulated in the proposed rules. The opportunity for false identification of source and operator and poor-quality data would render the program highly problematic. Commenter (2713-Northeast Natural Energy LLC) notes although EPA must approve the third-party and screening methodology, the confidence in the algorithms that such technologies use to determine emission rate has a low confidence level within industry. EPA must use an extremely strict protocol to determine if the proposed method used to determine emission rate is close to 100% accurate.

Response II-14-195: EPA acknowledges the commenters' input; the final rule has been revised to require any methane detection technology in the Super Emitter Program to be approved for use using the same criteria used for the advanced methane detection technology program as described in §60.5398b(d). It is important that the technology used is appropriate for use in the Super Emitter Program and will be operated in such a manner that will ensure only high-quality data will be submitted to the EPA.

Comment: Commenter (2391-CEC) encourages EPA to consider how to limit the potential for abuse of this program. According to the commenter (2391-CEC), operators such as CEC are already devoting enormous resources to analyzing the substantial amount of data they already receive on an ongoing basis. This proposed program could be a serious drag on these resources for little or no environmental benefit if, for example, third parties submit reports and data on activities that are fully authorized or already identified and corrected.

Commenters (2227-Western Energy Alliance, 2240-Rose Rock Environmental Services, LLC, 2254-PBPA) state EPA would be delegating to groups with unverified qualifications and technical expertise, an unprecedented action. This provision of the proposed rules is also a violation of the separation of powers of the U.S. Constitution where EPA is seeking to legislate and grant legal authority to itself to delegate regulatory authority to third-party members of the public to monitor and report on regulated facilities, a legislative act that resides solely with Congress.

Commenter (2227-Western Energy Alliance) states improperly delegating regulatory monitoring to third-party members of the public who are not directly answerable for the proper implementation of rules opens the door for improper records, inaccurate reporting, inaccurate data that fails regulatory quality standards, and lack of essential oversight for program integrity.

The most obvious and likely error will be misidentifying an operator's facility. EPA should remove the program from the final rule. Should EPA seek the appropriate legal authority from Congress and proceed with such a program in the future, EPA should not post any purported super-emitter reports on its public website until EPA has properly identified the facility; confirmed the responsible operator and emissions source; verified the emissions source is large enough to fall under the super-emitter designation; quality assured the data; and confirmed the facility is subject to the rules.

Response II-14-196: EPA acknowledges the commenters' concerns. The final rule no longer includes third party acting as an "authorized representative" under 114(a)(2) and instead has EPA in a centralized role as explained in section X.C.1 and XI.C.1 in the preamble of the rule.

Comment: Additionally, commenter (2389-Amercian Chemistry Council) notes EPA does not take any review role or responsibility in the management or quality assurance of the data itself. Indeed, EPA expressly abdicates such a responsibility and states that "a greater role for the Agency in reviewing third party notifications would be an unnecessary task," instead stating that it would be duplicative of the predicate approval processes and third party revocation procedure.<sup>168</sup> It defies logic to reconcile this decision with EPA's statement in the same discussion noting that the program as proposed "retains oversight by the EPA over all key decision making elements of the program."<sup>169</sup> It seems inconsistent for EPA to deny its role to review the information it requires third parties to collect as "an unnecessary task" but simultaneously claim it retains "oversight" over "all key" program elements. The commenter (2389-Amercian Chemistry Council) strongly urges EPA to review the notification reports created by third parties prior to their public dissemination. This crucial step would allow the Agency additional time to correct any errors while providing additional context for the meaning and interpretation of the data contained in the reports.

Commenters (2202-TXOGA, 2258-MSC, 2283-Endeavor Energy Resources, 2301-U.S. Chamber of Commerce, 2360-Devon, 2403-The Petroleum Alliance of Oklahoma, 2446-IPAA) recommend that the criteria for third-party notifiers be as stringent and equivalent to the criteria required of owners/operators submitting data to state or federal regulators to demonstrate compliance with applicable standards, e.g., results/data certified by a professional engineer or appropriate in-house professional.<sup>170</sup>

Response II-14-197: EPA acknowledges the commenters' concerns; the final rule has been revised to include third parties are certified against an expanded criteria as explained in Section X.C.2 and XI.C.2. Also, any submittal must be attested by an official of the "certifying official" that the third-party notifier.

---

<sup>168</sup> 87 FR 74751.

<sup>169</sup> Id.

<sup>170</sup> The results/data submitted by the third-party need to be certified by a professional engineer or another qualified individual with relevant experience. Said individual should be required to provide a certification as to the accuracy of the data that is equivalent to, if not the same as, that required of professional engineers or other qualified individuals are required in other sections of this Supplemental Proposal.

Comment: Commenters (2360-Devon, 2446-IPAA) add in order for the emission event data to be useful, it must be collected in substantially the same manner and under the same conditions that operators would be expected to adhere to and provided to the operator within three days or less of the initial detection. These emission events may often be short-lived and intermittent in nature, and time is of the essence. Notifications falling outside this timeframe will often lead to an operator seeking to confirm an event that is no longer occurring.

Response II-14-198: EPA acknowledges the input from the commenter; EPA agrees that is important for super-emitter data to come in as soon as possible upon the detection of an event, in the final rule, super emitter data must be reported within 15 days of the event. This time is sufficient time for a third party to receive and review data for accuracy to ensure the data is reasonable to submit to the EPA.

Comment: Commenter (2227-Western Energy Alliance) adds OGI cameras, especially when used by entities not familiar with the facility in question, would not be consistently able to quantify emissions. It is not uncommon for untrained parties unfamiliar with regulations and operations to erroneously report alleged violations. Questions exist as to whether EPA has the authority to assign formal compliance duties such as this to nongovernmental entities, whereas states are required to go through lengthy formal State Implementation Plan programs to be delegated authority to enforce federal regulations such as New Source Performance Standards. Surely nongovernmental entities, that lack the air quality expertise that states have demonstrated for half a century, should not be given similar authority without much more deliberative thought, consideration, and training. The entire Super-Emitter Program as proposed by EPA is arbitrary and capricious.

Commenter (2202-TXOGA) gives the example, EPA imposes a certain level of periodic training and procedural requirements for operators and equipment used in conducting M21 or OGI surveys, the results of which trigger regulatory obligations. Because notifications under this program would also trigger regulatory obligations, the notifiers should at least be held to the same (or substantially similar) standards that EPA would impose on an operator for its use of monitoring technology. These requirements should include, but not be limited to, periodic training, periodic certification of notifier technicians and monitoring equipment, quality assurance plans, and the like.

Response II-14-199: EPA acknowledges the commenters' concerns; EPA has revised the third-party certification criteria as explained in Section X.C.2 and XI.C.2 to ensure the third party is adequately trained in the remote sensing technology used for surveys.

Comment: Commenters (2168-INOGA, 2172-Kentucky Oil and Gas Association, 2202-TXOGA, 2220-WDEQ, 2258-MSA, 2283-Endeavor Energy Resources, 2305-The Williams Companies, Inc., 2345-GHGSat Inc., 2393-OSEE, 2446-IPAA, 2626-Kayrros) are concerned with EPA's leniency on reporting inaccurate/false information and removing third-party notifier's certification. Trust in the accuracy of remote-sensing data will be essential to the SERP. The approval of a third-party notifier should be revoked when repeatedly submitting false reports.

Commenters (2227-Western Energy Alliance, 2238-SOOGA, 2248-NDPC, 2294-Ohio Oil and Gas Association) are particularly concerned about the implications of “false positive” super-emitter events. The occurrence of a “false positive” can be due to several factors, including faulty equipment, insufficient and/or unreliable data, and incorrectly identifying the super-emitter source. Regardless of the cause, “false positive” super-emitter events will result in operators unnecessarily incurring significant costs, and also stigmatize the accused operator and the industry as a whole. The commenters urge U.S. EPA to implement appropriate safeguards against the occurrence of “false positive” super-emitter events.

Commenters (2399-GPA Midstream Association, 2446-IPAA) contend third-party notifiers that violate federal, state or local ordinances in the attempt to gather information/data on alleged super emitter events should have their certifications revoked for no less than a year and the particular third-party notifier and any/all affiliates should be prohibited from the ability to allege future super emitter events at the underlying source/facility. Commenter (2399-GPA Midstream Association) adds after the one-year period, the entity may re-apply to be re-approved.

Commenter (2399-GPA Midstream Association) urges EPA to incorporate a cap across an entire operator’s asset base, such as a maximum of six improper notifications per rolling 12-month period per parent company.

Commenters (2202-TXOGA, 2345-GHGSat Inc., 2626-Kayrros) state any third-party notifier that reports incorrect information (i.e., a false positive) should be revoked from the program after three incorrect notifications to protect the integrity of the entire program. Commenter (2345-GHGSat Inc.) urges the EPA to further define the concept of demonstrable error and to specify if this “strike system” has a defined timeline (e.g., a limit of three errors per calendar year).

Commenters (2258-MSA, 2305-The Williams Companies, Inc.) argue the three-time threshold for inaccurate event notifications from a third-party is too high and limited to multiple notifications at the same facility owned by the same operator. This creates the potential for a third-party to submit demonstrably inaccurate information for many different facilities or operators without any repercussions. Even then, it is not clear whether a third-party will have the ability to avoid revocation of its approval to conduct monitoring simply by completing a corrective action plan.

Response II-14-200: EPA acknowledges the commenters’ concerns; EPA has revised the third-party certification and criteria as explained in Section X.C.2 and XI.C.2. These revisions include requirements for when you must recertify and expanded circumstances for being removed from the list of approved third-party notifiers.

Comment: (2326-AXPC) states that even under EPA’s proposed cure to potential abuse or incompetence, an operator has to petition to have a third party removed, and there is no guarantee that EPA would remove the third party and no criteria (objective or otherwise) is established for when EPA would remove that third party from the approval list.

Commenter (2403-The Petroleum Alliance of Oklahoma) requests EPA establish a transparent process whereby operators can submit a complaint that a technology or the third party should be reconsidered for good cause. This process would include a response and resolution by EPA in a timely manner. This process should include the ability for operators to appeal EPA's decision. EPA should make public its findings and resolution of the issue.

Commenters (2294-Ohio Oil and Gas Association, 2399-GPA Midstream Association) state there should be clear provisions for restricting third parties that are ultimately removed from the approved list. EPA should make clear that individuals removed will be permanently decertified and prevented from reenrolling in the program.

Response II-14-201: As explained above in Response II-14-183, EPA has expanded the circumstance for being removed from the list of third-party notifiers. EPA has provided a pathway in the super emitter reporting requirements for owner or operators to challenge a notification and EPA will track these to identify persistent errors and could take action to decertify third parties.

Comment: Commenter (2393-OSEE) notes the SNPR seems to indicate this could be triggered with three demonstrable errors against a site; however, it later phrases it as three demonstrable errors against an owner operator, which could be interpreted to mean the entire company. Id. Therefore, it should be clarified if EPA intends to allow this for the entire company or only on an individual facility basis.

Response II-14-202: The intent of this provision in the rule was to prevent harassment by a third party of an of an individual facility, we have kept this provision in the final rule and expanded the reporting requirements in the rule to allow for an owner or operator to challenge a perceived erroneous report.

Comment: Commenters (2326-AXPC, 2399-GPA Midstream Association, 2410-California Office of the Attorney General et al.) state the Supplemental Proposed Rule provides no guidance as to how an owner or operator should respond to multiple notifications for the same alleged super-emitter event. Presumably, if an owner or operator receives, for instance, three separate notices of an alleged event, it should perform only one investigation or response applicable to all three notices. The proposed regulatory text, however, should be clarified to avoid a possible interpretation that would read the text as requiring a separate investigation into the same alleged super-emitter event. EPA should clarify that an investigation is tied to an alleged large emissions event, not to each notice of the alleged event.

If EPA requires three erroneous notifications at the same site before any potential action could be taken against a third party's status, commenters (2326-AXPC, 2399-GPA Midstream Association) argue it could result in thousands of inaccurate and faulty determinations. In light of the number of facilities held by one owner or operator (often hundreds or thousands), a third party could target industry (or even the same operator daily) (at one or more locations) without hitting the same facility for several years. This is particularly true if virtually any and all satellite imagery can be used to detect super-emitter events. For example, a third party could simply have

a team of personnel sitting behind their desks reviewing satellite data and producing notifications. And even if they provided one notification per day, an operator with 500 facilities would not see the third notification for several years. Further, if the threshold remains three times at a single facility, antagonistic organizations could readily coordinate to make sure that they alternate attention to a certain area/basin/field and thus prolong the time period for any one third party to hit three notifications. Commenter (2326-AXPC) proposes that there should be no minimum threshold for the number of unfounded notifications provided by a third party before EPA moves to revoke the notifier's status. Or, at a minimum, it should be the total number of faulty notifications provided across all facilities, regardless of the owner/operator of the facilities.

Response II-14-203: If an owner or operator has conducted an investigation into the cause of a super-emitter and that investigation has either identified the cause(s) or confirmed an event is not present, an owner or operator would submit the same investigation report for any super emitter notification of events occurring up to the time investigation.

Comment: Commenter (2365-Climate Action California) recommends that the EPA publish a penalty list for super-emitter events, with fines for an owner increasing with the frequency and severity of super-emitting events over the period of a year.

Response II-14-204: EPA acknowledges the commenter's input.

Comment: Commenter (2483-INGAA) argues EPA is ignoring the benefits that third-party verification can provide. The CARB requires third-party verification for its climate change programs.<sup>171</sup> CARB has hailed the third-party verification requirement as "provid[ing] confidence and reliability in reported data for stakeholders ... and the public."<sup>172</sup> By requiring third-party verification in the Super-Emitter Response Program, EPA would ensure that owners and operators are not subjected to erroneous notice letters that give rise to obligations (even if it is just the filing of a report saying no violation occurred) and give rise to negative reputational impact by being falsely labeled a "super-emitter" on public websites.

Response II-14-205: EPA acknowledges the commenter's input, as detailed in X.C.2 and XI.C.2, EPA has expanded the third-party certification criteria to improve the overall quality of the data and with EPA in a centralized role to provide additional review of the data before EPA providing the notification.

Comment: Commenter (2254-PBPA) states the program has the potential to create significant negative impacts on an operator's "social license to operate"/ESG reputation, even though the third-party super emitter reports could be erroneous, too late to be actionable, or incorrectly identify an operator or a facility. The super emitter reports will be posted on an EPA website, and flaring will be included in the annual reports to EPA, which are also publicly available. For

---

<sup>171</sup> 17 CCR § 95103(f) (California Regulation for the Mandatory Reporting of Greenhouse Gas Emissions); 17 CCR § 95977 (California Carbon Cap-and-Trade Program), 17 § CCR 95491.1(d) (California Low Carbon Fuel Standard Regulation).

<sup>172</sup> CARB, LCFS Verification, [www.arb.ca.gov/lcfs-verification](http://www.arb.ca.gov/lcfs-verification).

instance, a report could misidentify an operator or reported flaring emissions could be in compliance with the EPA rule (not to mention a Railroad Commission or state analog regulation). As such, EPA should amend the program to require detections to be shared with the operator within the same time period after detection as required for operators conducting periodic screening, and the notice should not become public until the accuracy of the report has been verified by the appropriate operator.

Response II-14-206: EPA has revised the program with EPA in a centralized role with EPA receiving data from third parties, providing notifications to an owner or operator, and receiving super emitter reports from the owner or operator. EPA will publish information as we receive information, however EPA does not intend to identify the owner or operator of a site until confirmed by that owner or operator.

Comment: Commenter (2326-AXPC) notes that in the notification and reporting sections of the super-emitter proposed regulations, EPA states that the third party must provide to the operator, and the operator must report, the “[d]ates of detection of super-emitter emissions event and date(s) of confirmation of emission rate.” Thus, this reporting provision makes clear that EPA intends that the notifying entity be required to “confirm” the emission rate that it initially identified. This confirmation must be more than simply reviewing the data and confirming that in fact a suspected super-emitter emissions event exists. Commenter (2326-AXPC) recommends EPA require the third party to confirm (via the same technology utilized initially) that the initially identified emissions rate is ongoing (e.g., conducting another pass over the facility and finding the same results). Such confirmation should be required to occur 24 hours or more after the initial identification. By requiring this confirmation, EPA will reduce the likelihood that third parties provide notice, report to EPA, publicize, and require evaluation by the operator of maintenance events that are already known to the operator or for which the operator has already taken action. Thus, EPA should include language making clear that the notifying entity must identify emissions above the threshold from the same emissions unit as the initial remote monitoring identified.

Response II-14-207: EPA acknowledges the commenter’s input, EPA is not requiring third parties to confirm a super emitter event is persistent although third parties may choose to confirm an event, however the initial detection date would be considered the start of the 15-day period in which they must report.

Comment: Commenters (2249-National Association of Clean Air Agencies, 2399-GPA Midstream Association) add an overall concern with the SERP as described in the proposal is that is vulnerable to “the Twitter problem”: when different parties’ information conflicts, it can create challenges for knowing whose information to trust. The public sector has a responsibility to regulate in the public interest that may not be the institutional first priority of third-party stakeholders like vendors, advocates, and others. Misinformation (and even well-meaning but inaccurate information) can often spread more rapidly than can be countered with supported factual information from credible sources like clean air agencies. When its spread outpaces accurate information, it can dominate public discourse and undermine trust in even the strongest and most credible public institution. By its own admission, EPA states in the supplemental

proposal that EPA would not verify or authenticate the information in third-party reports before posting it online and triggering regulatory action, a concerning detail. The importance of careful implementation of such a program cannot be overstated: the credibility of the federal, state, and local agencies that implement the CAA is indescribably valuable when advancing the protection of clean air for all, and EPA should be prudent about implementing programs that are vulnerable to misinformation that could harm that credibility.

Commenter (2399-GPA Midstream Association) proposes that, in such instances, the affected facility should be able to respond with a letter identifying (1) the cause of the emissions event, (2) how it was abated, and (3) when it was abated. The affected facility should not have to waste its resources performing a post hoc mock investigation and corrective action under proposed §§ 60.5371b(c)(1)-(10) for an incident that was already resolved.

Response II-14-208: EPA has revised the program with EPA in a centralized role with EPA receiving data from third parties, providing notifications to an owner or operator, and receiving super emitter reports from the owner or operator.

Comment: Commenter (2157-Division of Air Pollution Control Tennessee Department of Environment & Conservation) states the only penalty for a notifier submitting incorrect reports would be removal from the approved list following an impacted facility's successful petition following receipt of three incorrect reports.

- The Supplemental Proposal states that “EPA faced a similar situation when establishing standards for petroleum refineries, where cost-effective controls and inspections of equipment and operations would not have addressed potentially significant levels of emissions that could occur between regular inspections.” In that instance, EPA required fence-line monitoring for timely identification of significant increases in emissions<sup>11</sup>. The circumstance that EPA describes is not similar because petroleum refineries were required to conduct their own fence-line monitoring. Here, EPA proposes to allow third party notifications to create immediate response and corrective action requirements.
- The proposed rule specifies no requirement for periodic recertification of third parties.
- The proposed rule does not explain how EPA will ensure that those removed from the approved list cannot simply change organizational identification information in order to be re-approved and placed on the list again.

Response II-14-209: EPA acknowledges the commenters' concerns; EPA has revised the third-party certification and criteria as explained in Section X.C.2 and XI.C.2. These revisions include requirements for when you must recertify and expanded circumstances for being removed from the list of approved third-party notifiers.

Comment: Commenter (2257-Michigan Oil and Gas Association (MOGA)) questions how the EPA's proposed “super emitter” program and associated remote-sensing technologies will be able to account for wetlands adjacent to oil and natural gas operations. The EPA's proposed third-party certification of technology for monitoring releases from oil and natural gas operations does not address the ability of technology to control for background sources of Methane from

wetlands, cattle operations, etc. when determining fugitive emissions. The commenter and their constituents have provided numerous comments regarding the complexity of State of Michigan wetland protection rules often resulting in oil and natural gas wellheads and facilities being located immediately adjacent to both small and large wetland complexes. Naturally, Michigan has more wetlands than Texas, which once again, illustrates the one-size-fits-all approach is not valid across all oil and natural gas-producing states.

Commenter (2446-IPAA) asks how does the third-party notifier and/or EPA pinpoint the source and to the extent, how do they identify who owns or has responsibility for the source? Additionally, how does the third-party notifier and/or EPA know what regulations, in any, apply to the "source" in question – if the "source" is not an affected facility or designated facility, Section 111 is not violated?

Response II-14-210: EPA acknowledges the commenters' concerns; EPA has included a requirement that ant technology used for the Super Emitter Program must be approved through the advance methane detection technology program in the rule, this would require technology to verify the spatial resolution needed for the Super Emitter Program and the method used for this technology would need to account for potential background methane.

#### ***14.5.8 Publicly Available Database***

Comment: Commenters (2195-Environmental Health Project, 2299-NEI Investments, 2303-NTAA, 2392-Earthjustice et al., 2394-Earthworks, 2403-The Petroleum Alliance of Oklahoma, 2425-Taxpayers for Common Sense (TCS), 2433-EDF et al, 2444-NAACP, 2447-Clean Air for the Long Haul, 2453-Carbon Mapper and RMI, 2462-Cynthia Walter, 2626-Kayrros) state all pertinent information should be made publicly available and easily accessible on a centralized website as soon as possible. Changes to strengthen SERP will benefit Black, Latine, tribal, and rural and low-income communities that live in close proximity to oil and gas infrastructure. The improvements to SERP would require that owners and operators timely identify and take corrective action to stop harmful air emissions that disproportionately impact these communities. Streamlined operator and public notification processes will also allow members of these impacted communities to take action to protect themselves during emission events to the extent possible.

Commenter (2444-NAACP) states although previous iterations of the proposed rule in November 2021 ensured that communities retained the ability to monitor methane and other emissions, the December 2022 version of the rule weakens that ability.<sup>173</sup> The commenter requests that the EPA ensure and strengthen the operation of community monitoring of methane and other emissions.

---

<sup>173</sup> Subpart OOOOb—Standards of Performance for Crude Oil and Natural Gas Facilities for which Construction, Modification or Reconstruction Commenced After November 15, 2021, available at [https://www.epa.gov/system/files/documents/2022-11/8510\\_OilandGasClimate\\_OOOObRegText\\_Supplemental\\_20221005.pdf](https://www.epa.gov/system/files/documents/2022-11/8510_OilandGasClimate_OOOObRegText_Supplemental_20221005.pdf).

Commenter (2433-EDF et al) argues publicizing this information is consistent with EPA's past practices around emissions data and with the requirements of the CAA, which ensure emissions data are not treated as confidential.<sup>174</sup> Further, given that these emissions will be detected by third parties, it would be difficult or impossible for those data to not be publicized, as those entities could publish it on their own websites. To avoid inconsistent treatment of this information, EPA should make it all publicly available in real time on a single, centralized website.

Response II-14-211: EPA recognizes the commenters concern and while we cannot directly address your concern, the Super-emitter program is being developed with transparency in mind, on the part of the third-party, the EPA, and the owner or operator. All notifications meeting the requirement in the final rule will be published online on the EPA's Super Emitter Portal - <http://www.epa.gov/super-emitter>.

Comment: Commenters (2303-NTAA, 2433-EDF et al, 2453-Carbon Mapper and RMI) state the website should also include geographic and operator information, as well as links to the corrective action plan and other relevant follow-up information.<sup>175</sup> A centralized database with geographic coordinates and ownership information can streamline and ensure detections are accurately attributed to the correct site and operator. EPA should also centrally maintain information including the site type (e.g., fugitive monitoring subcategory), geographic location, responsible owner or operator, as well as other relevant records (e.g., fugitive monitoring plan and scheduled maintenance events), so that investigations after third-party notifications are efficient.

Commenter (2462-Cynthia Walter) asks EPA to make up to date information readily available to the public regarding details, e.g., location, amounts and types of emissions, remediation work schedule, contact for local agency supervisors. Without this, residents near oil and gas operations cannot avoid exposure to substances reported from such sites as in Macey et al. 2020<sup>176</sup>

Response II-14-212: As explained above in II-14-194, All notifications meeting the requirement in the final rule will be published online on the EPA's Super Emitter Portal - <http://www.epa.gov/super-emitter>. This notification will include a precise location of these super-emitter events.

Comment: Commenters (2360-Devon, 2399-GPA Midstream Association) state EPA should consider an appropriate manner in which to disclose information to the public. The commenters have participated in voluntary emission detection programs, such as The Environmental Partnership, where detected emission events were effectively relayed to operators for follow-up and mitigation if necessary. Through this voluntary program, operators were also encouraged to share their emission mitigation and reduction strategies for the benefit of the broader industry.

---

<sup>174</sup> 42 U.S.C. § 7414(c).

<sup>175</sup> See, e.g., Permian Methane Analysis Project, <https://data.permianmap.org/pages/operators>; Carbon Mapper Data Portal, <https://carbonmapper.org/data/>.

<sup>176</sup> Macey et al. 2014. Air concentrations of volatile compounds near oil and gas production: a community-based exploratory study. *Environmental Health* 2014, 13:82 <http://www.ehjournal.net/content/13/1/82>.

EPA could craft a similarly effective program by publishing a report or commissioning a third party, such as an academic institution, that summarizes the types of events discovered, the subsequent corrective actions, and the general locations where the events were discovered. Operators could be incentivized to respond if the failure to adequately address the event resulted in operator specific details being published in the same report.

Commenter (2360-Devon) states a framework that enables reliable detection information to be relayed to an operator with a high degree of specificity, encourages effective and reasonable mitigation and response from the operator, facilitates the sharing of event cause and mitigation techniques that is non-operator specific, provides meaningful information to the surrounding communities, and specifically identifies those operators that fail to respond, could result in a program that allows qualified third parties to participate in a way that is constructive, legally durable, and ultimately results in effective emission reductions.

Response II-14-213: EPA acknowledges the commenter's input.

Comment: Commenters (2202-TXOGA, 2213-Oxy, 2220-WDEQ, 2227-Western Energy Alliance, 2237-Industrial Commission of North Dakota, 2283-Endeavor Energy Resources, 2298-Pioneer Natural Resources USA, Inc., 2248-NDPC, 2258-MSR, 2326-AXPC, 2315-DEC, 2345-GHGSat Inc., 2366-BHE, 2389-ACC, 2391-CEC, 2399-GPA Midstream Association, 2403-The Petroleum Alliance of Oklahoma, 2428-API, 2446-IPAA, 2483-INGAA) believe all data and notices from approved third parties should first go to EPA and/or the state to review. EPA and/or the state delegated agency would contact the operator of the facility to verify the event and take corrective actions if appropriate. EPA and/or the state delegated agency should review the data and operator's findings for each super emitter event before any information is released to the public.

Response II-14-214: EPA acknowledges the commenters' input; The final rule has been revised to include a process where EPA will review all third-party data submitted and determine whether a notification to an owner or operator is accurate and reasonable before sending a notification to an owner or operator.

Comment: Commenter (2483-INGAA) recommends the following text changes to §§ 60.5371b(b)(7) and 60.5388c(b)(7) of the proposed rule:

(7) The notifier must submit the notification as soon as practicable to the owner or operator of the site with the super-emitter emissions event. The notifier must also submit a copy of the notification to the Administrator and to any delegated authority on the same day that notification is made to the owner or operator. The Administrator shall make such notifications publicly available at [webpage] only after it is confirmed that a super-emitter emissions event requiring corrective action occurred.

Commenter (2483-INGAA) recommends the following text changes to §§ 60.5371b(e)(4) and 60.5388c(e)(4) of the proposed rule:

(4) Upon receipt of the report required by paragraph (e) of this section, the Administrator shall make such report publicly available at [website] only if the report confirms that a super-emitter emissions event requiring corrective action occurred. Any confidential business information contained in the report shall be redacted from the publicly available report.

Response II-14-215: EPA acknowledges the commenters' input.

Comment: As the proposal is written, Commenters (2168-INOGA, 2172-Kentucky Oil and Gas Association, 2220-WDEQ, 2298-Pioneer Natural Resources USA, Inc., 2326-AXPC, 2354-Business Roundtable, 2366-BHE, 2389-ACC, 2391-CEC, 2428-API) argue there will be reputational damage to the owner/operator for allowable activities or as a result of erroneous or premature reports. These reported releases could lead to an owner/operator being labeled as a "super emitter," and even if the allegation is found to be erroneous later, the mere fact that an owner/operator got a notice will have a deleterious impact on the owner/operator's reputation.

Commenter (2483-INGAA) adds, EPA needs to address issues related to confidential business information and how that information will be protected from public disclosure. For example, the report that an owner or operator files following a super-emitter event may contain information on the owner or operator's specific procedures and practices, a root cause or investigative analysis, and information such as flow diagrams, which in some instances may constitute confidential business information or otherwise sensitive information related to critical infrastructure. EPA needs to address how this information will be protected.

Commenter (2389-ACC) states EPA proposes that any notification include a substantial amount of potentially sensitive information, including facility location and latitude/longitude coordinates, depictions of emissions and the site, emissions rate, and date and time of emissions event, among other aspects.<sup>177</sup> EPA later proposes that it would make these notifications available to the public. The public and rapid release of the sensitive information could result in potential security and operational concerns for facilities that are facing an ongoing emissions event.

At a minimum, commenters (2389-ACC, 2428-API) state EPA should limit the information for super-emitter emissions event so that the information cannot be misconstrued or used to publicly attack operators in the media; especially operators who are proactive participants within the SERP. The shared goal of finding these leaks and fixing them as expeditiously as possible should remain at the forefront and in conjunction with transparency objectives.

Commenter (2428-API) states participation in the regulatory process through the super-emitter response program by EPA-certified third parties must include limitations on the ability of those third parties to use the information gathered under the program for any other purpose. Such limitations must include requirements that the third party (and the monitoring companies they contract) maintain the security and confidentiality of data collected during SERP monitoring,

---

<sup>177</sup> 87 FR 74750.

where the monitoring results cannot be independently published (via website or social media). EPA has a fundamental role to play in the validation of third party collected data, which extends to the publication of such data. When a third party accepts the responsibility of participating as a certified notifier, they accept this role and handling of data.

Commenter (2428-API) states monitored data should not be published without context from operator feedback or corrective actions. EPA's state within the preamble (87 FR 74750) "owners and operators would have the opportunity to rebut any information in a notification provided by the qualified third parties in their written report to the EPA, by explaining, where appropriate, that (a) there was a demonstrable error in the third party notification; (b) the emissions event did not occur at a regulated facility; or (c) the emissions event was not the result of malfunctions or abnormal operation that could be mitigated." While the commenter agrees with this concept, the proposed framework does not provide the same level of assurance that these rebuttal statements would be linked to the third-party monitored data directly in the public forum without EPA intervention. If the data is posted on other public websites, there is a chance any resolution/follow up comments and descriptions from operators will not be carried over to the non-EPA sites, therefore resulting in inaccurate presentation of the facts. While the commenter concur that data transparency is valuable and share the goal of disseminating information to mitigate emissions events, these goals must be balanced with adequate considerations for national security risks, reputational risks (e.g., incorrect operator maligned in media, third party is not approved or certified by EPA, permitted events are taken out of context, etc.), and stakeholder risks.

Response II-14-216: EPA has revised the program with EPA in a centralized role with EPA receiving data from third parties, providing notifications to an owner or operator, and receiving super emitter reports from the owner or operator. EPA will publish information as we receive information, however EPA does not intend to identify the owner or operator of a site until confirmed by that owner or operator.

Comment: Commenters (2389-ACC, 2428-API) recommend EPA establish a protocol or annual publication updating on progress of the program. Given the ambiguity present in proposed §60.5371b(e)(4) for a new EPA website to host these reports, there is a high probability that third-party monitored data will provide very limited context for the general public and can be easily taken out of context. The commenters believe a synthesized annual report or fact sheet published by EPA would offer a more clear depiction of relevant details with full context around super emitters including but not limited to: how many third-party monitoring events took place, the number and location of valid super emitter emission events that were detected, the number of super emitter events that were permitted or authorized emissions, and the types of corrective actions that were taken to repair other super emitter emissions identified. Information that would easily identify the operators could be blinded in this annual report, unless EPA found specific operators to be conducting insufficient corrective actions or operators that do not acknowledge EPA's notification attempts regarding the monitoring campaigns (and EPA has verified the correct contact information).

Commenter (2453-Carbon Mapper and RMI) agrees with the above commenters, stating EPA should maintain a public database of all super-emitter notifications by certified third-party reporters with updates on an annual basis including mitigation reports by operators where available.

Response II-14-217: EPA recognizes the commenters concern and while we cannot directly address your concern, the Super-emitter program is being developed with transparency in mind, on the part of the third-party, the EPA, and the owner or operator. All notifications meeting the requirement in the final rule will be published online on the EPA's Super Emitter Portal - <http://www.epa.gov/super-emitter>.

Comment: Commenters (2237-Industrial Commission of North Dakota, 2288-NDDEQ) state the revised proposal requires that the Administrator shall make the initial notification and corrective action report publicly available via a webpage in the case of the notifications or a website in the case of the reports. There is no clear timeline for when the Administrator needs to accomplish this, though for the reports, 60.5388c€ (4) does mention "Upon receipt". If EPA intends for the NDDEQ to be making these documents publicly available, the NDDEQ recommends simply stating such, without additionally defining a timeline or a place. With the development of any program, timeframes and publication locations may necessitate changes that would be hampered if only one particular method is defined in the model rule.

Response II-14-218: EPA acknowledges the commenter's input; EPA has the obligation to post notifications and reports consistent with the requirements in the rule as explained in Section X.C.2 and X.C.4 of the preamble of this rule.

Comment: Commenter (2428-API) states any documents shared with EPA articulating corrective actions taken should be subject to a safe harbor provision that prevents EPA or any other entity from using the information in the document for purposes of enforcement / notice of violation (NOV), civil suit, etc.

Response II-14-219: As detailed in Section X.C.2 and XI.C.4 of the preamble of the final rule, EPA has revised the final rule to include reporting corrective actions as part of the super emitter program. When an owner or operator is notified of a super-emitter event, they are required to conduct an "investigation" and report back to the EPA per the requirement in the applicable NSPS and/or EG.

EPA may use any credible evidence to establish a violation. If an owner or operator, upon conducting the required investigation, determines that a deviation from an applicable standard has caused the super emitter event, then the owner or operator must comply with the requirements in NSPS OOOO, OOOOa, OOOOb and/or EG OOOOc to correct and report the deviation. The Super Emitter Program does not create a safe harbor for violations of Clean Air Act regulations.

### 14.5.9 Trespassing

Comment: Commenters (2166-Ohio Department of Natural Resources, Division of Oil and Gas Resources Management (ODNR), 2168-INOGA, 2172-Kentucky Oil and Gas Association, 2220-WDEQ, 2221-Texas Pipeline Association, 2227-Western Energy Alliance, 2237-Industrial Commission of North Dakota, 2258-MSO, 2288-NDDEQ, 2326-AXPC, 2360-Devon) are concerned with portions of the draft rule that state citizens would be authorized to enter private lands for emissions measurements. This will create unnecessary safety risks and problems with citizens trespassing. The requirement should be put in place to disallow unaccompanied access onto sites without operators, prerequisite notification to the operator, and verified sufficient safety training to permitted parties.

Response II-14-220: EPA acknowledges the commenters' input; EPA has revised the final rule to include criteria for certification of third-party notifiers explained in Section X.C.2 of the preamble of this rule. EPA agrees that unauthorized access to a facility through private or public lands creates a potential safety risk, if the third-party notifier is guilty of illegal activity during the assessment of a super-emitter event (*e.g.*, trespassing), their certification will be revoked.

Comment: Commenters (2326-AXPC, 2360-Devon, 2428-API) state there are potential safety concerns associated with members of the public accessing sites without proper notice, personal protection equipment (PPE), and training. For example, some sites can contain hydrogen sulfide (H<sub>2</sub>S), a gas that could result in serious health issues for members of the public without proper protection. Well sites are located on private property. EPA's proposal could encourage members of the public to trespass onto private property and to avoid safety signs and considerations. This could result in members of the public hurting themselves or damaging equipment that could result in putting workers in danger. There is also the question of who would be liable for the safety of the members of the public who illegally trespass on the property or for any damage that they may cause.

Commenter (2428-API) states even though EPA notes in Section IV.C.2.a of the preamble (87 FR 74749) that it considered concerns for the safety of individuals engaged in third-party monitoring and of facility operator personnel, there are still tangible safety concerns related to the use of certain monitoring technology by third parties (*e.g.*, mobile monitoring platforms) to identify super-emitter emissions events. Some operators have experienced public individuals driving through operator sites (especially in remote locations with no "fencing") with vehicle mounted monitoring devices, which is especially problematic as access can typically be obtained by road, some of which may be private roads. There have also been issues acknowledged between private third-party landowners and trespassers, which can be another point of contention.

Personnel working at the commenter's (2428-API) facilities are required to undergo numerous hours of training to safely perform their work duties, including but not limited to wearing the correct personal protective equipment based on site conditions, exposure to extreme heat or cold weather, biologic hazards such as snakes or other critters, specific training on how to navigate rotating equipment, and where and how to identify hazardous chemicals/gas. For example,

training specific to the presence of hydrogen sulfide (H<sub>2</sub>S) includes hazards, symptoms of exposure, detection devices, and how to safely walk away from exposure.

Commenter (2428-API) states individuals require site specific training to be present at any given facility and there is potential liability (to both the individuals and to company assets) for individuals who do not have this training. The proposed SERP framework is geared to remote technologies, which by their nature should in no way necessitate third-party representatives to appear at facilities. Commenter (2428-API) recommends that any information that is collected by a third party that is outside of an EPA-approved monitoring campaign, where EPA and/or operators have not been notified in advance of the data gathering campaign, be considered invalid. Trespassing (such as driving through a site) should immediately result in revocation of a third party's certification and render any information gathered at the time invalid.

Response II-14-221: As explained above in Response II-14-202, if the third-party notifier is guilty of illegal activity during the assessment of a super-emitter event (*e.g.*, trespassing), their certification will be revoked.

Comment: Commenter (2346-Encino Environmental Services, LLC) argues allowing satellite access to become community data (without proper controls) presents (potential) risk to National Security and the U.S. energy apparatus.

Response II-14-222: EPA acknowledges the commenters' input.

Comment: Commenters (2237-Industrial Commission of North Dakota, 2399-GPA Midstream Association, 2403-The Petroleum Alliance of Oklahoma) have concerns that the super-emitter program invites safety and trespass issues even though EPA states they are allowing the use of remote-sensing aircraft, mobile monitoring platforms, or satellites to identify super-emitter events. For example, the use of mobile monitoring may encourage entities to drive on oil and gas locations to collect emission information, thinking it is safe and acceptable. These entities may not be aware or trained on the many safety risks associated with a well site or that's it is an illegal trespass without the operator's approval.

If EPA intends "mobile monitoring platform" to mean that third parties may use drones, commenters (2258-MSC, 2399-GPA Midstream Association) urge EPA to consider fully the implications of approving and encouraging the use of that technology, as the proposal provides no procedures or limitations on the use of drones. Private parties flying drones over or through a facility not only could be an illegal trespass, but it would undoubtedly present a major safety hazard, including at unmanned facilities. Accordingly, EPA should develop proper monitoring procedures to prevent third party notifiers from placing themselves or others at risk of personal injury or jeopardizing the security of an operator's property, including clear direction that third party notifiers must not be allowed to encroach on an operator's property to conduct monitoring.

Commenter (2258-MSC) adds usage of drones for monitoring is of particular concern as it requires Federal Aviation Administration certification and may employ equipment that is not

intrinsically safe. This should be specifically addressed in the requirements for certification of third-party entities.

Response II-14-223: As explained above in Response II-14-202, if the third-party notifier is guilty of illegal activity during the assessment of a super-emitter event (*e.g.*, trespassing), their certification will be revoked.

Technology used for the super emitter program must be approved for use in the Super Emitter Program, EPA will evaluate the use of UAS in this program to make sure that all federal, state, local, and/or tribal regulations are followed.

Comment: Commenter (2393-OSEE) notes in the preamble of the SNPR, EPA states that “several commenters raised concerns regarding potential safety or trespassing on sites with a program using more ground based or close-range detection methods.” 87 Fed. Reg. 74749. EPA cites the OSEE/ODEQ 2021 Comment as support for this statement, implying the cited commenters preferred satellite detection methods over ground-based detection methods for detecting super-emitters due to safety and trespassing concerns. The OSEE/ODEQ 2021 Comment did state concerns regarding safety of the public in community detection programs, but not with respect to detection methods (See OSEE/ODEQ 2021 Comment, Comment 5). The context of the comment at issue was to express concerns about allowing third parties to detect large emission events that would require owners/operators to mitigate those events. It was not coupled with a statement of preference for satellite systems. In fact, in the very next comment (Comment 6 to OSEE/ODEQ 2021 Comment), Commenter (2393-OSEE) and ODEQ stated that “OSEE and ODEQ note that the use of satellite data as the threshold could be problematic. For example, there could be large emission events that are not visible on satellite due to cloud cover or inadequate timing of satellite imagery for emissions that do not have a constant temporal profile, among other factors.”<sup>178</sup> While the commenters realize that a satellite system would mitigate some of the aforementioned safety risks, these concerns remain valid, and Commenter (2393-OSEE) and ODEQ maintain that third-party monitoring remains problematic in general.

Response II-14-224: EPA acknowledges the commenters’ input.

Comment: Commenter (2393-OSEE) notes ODEQ has already dealt with burdensome issues involving notifications from third parties about methane releases detected by satellite systems. For example, in October of 2021, ODEQ was contacted by a media company about one such methane release. ODEQ investigated the event based on the latitude and longitude coordinates given by the media company and contacted various companies operating in that area. The accuracy of the location made it difficult to determine which company/facility caused the event. When it was determined where the release came from and contact with the company was completed, the methane release was found to have originated from a section of pipeline that needed to be blown down due to maintenance activities. Thus, being a pipeline, this release did not

---

<sup>178</sup> See “State of Oklahoma’s Comments on EPA’s Proposed Standards of Performance for New, Reconstructed, and Modified Sources and Emissions Guidelines for Existing Sources: Oil and Natural Gas Sector Climate Review” Document ID EPA-HQ-OAR-2021-0317-0727.

originate from a facility that would be subject to the requirements of Subparts OOOOb or OOOOc and therefore would not be considered a super-emitter in this program. Also, the estimated release was 116 tons/hour based on the satellite data. Yet, based on the size of the pipeline, the company verbally indicated that the release was much lower than this estimated amount from the satellite.

Commenter (2393-OSEE) continues, ODEQ was notified a second time of a release in a different location in January of 2022. This time, when ODEQ contacted nearby companies based on the latitude and longitude coordinates given, no company reported any potential releases. ODEQ inspected the area with a forward looking infra-red, or FLIR, camera to see if any leak could be found using OGI, however no leaks or super-emitters were discovered. ODEQ contacted various companies with pipelines in the area and none indicated any issues. It is suspected that the release may have come from a pipeline, which would not be subject to the requirements of Subparts OOOOb or OOOOc. Significant resources were used by various companies and ODEQ to try to find this event, yet no super-emitter was identified, nor was a reduction of emissions achieved. With these two examples in mind, it becomes clear that it is vitally important that the satellite systems are accurate enough to determine precise locations to avoid false accusations and the waste of state resources.

Commenter (2393-OSEE) states while a satellite-centered program run by states or EPA could potentially still have issues, it is bound to at least be more accurate and efficient than relying on third parties. Third parties could still work directly with industry if both parties agree, or third parties could report their findings directly to the state or local agencies or even to the EPA. But third-party reporting should not trigger any immediate obligation by the facility until verified by state regulatory personnel who would initiate a response. Only notification by a government agency should trigger a requirement for industry to respond. In fact, ODEQ already has mechanisms in place for this, as it would fit into ODEQ's Environmental Complaints Program. ODEQ's Environmental Complaints Program is a robust program that sets forth specific timelines for communication with the complainant that have been established within ODEQ's regulations. The program has a uniform investigation process, a central repository for all complaint records, and direct continuous involvement with each citizen who lodges a complaint.

Commenter (2393-OSEE) argues removing third parties' ability to engage facilities in enforcement would also mitigate some of the environmental justice concerns raised. This is because, while it would still be possible for wealthy communities to hire consultants to look for leaks, these activities would still require that a government agency act as an intermediary to verify the problem and oversee the response.

Response II-14-225: As described in Section X.C and XI.C, EPA has structured the Super Emitter Program to redefine the obligations of the third-party notifier, EPA, and owner or operators.

These revisions have been included to improve the overall quality of the super emitter data being provided to the program, includes regulatory review of the data by EPA, and defined responses by the owner or operator.

Comment: Commenter (2177-Ute Indian Tribe) sees third-party reporting as a direct attack on Tribal sovereignty as this proposed program would essentially allow individuals unauthorized access to Tribal lands. Moreover, the commenter has qualified staff to issue these notices, and deference should be given to our Tribe's Air Quality Program. The EPA should strongly consider taking into account tribal law which governs who can enter tribal land and enter into consultation with tribes before proceeding with this program. Further, this program is proposed without a tribal exemption, which not only violates the EPA's own statements regarding implementation of tribal lands but also the principle of FPIC. This program has not been discussed with tribal leaders.

Response II-14-226: EPA acknowledges the commenters' input, The final rule also lists circumstances under which a third-party certification will be revoked, including the engagement in an unlawful action (*e.g.*, trespass) when monitoring for super-emitter events.

Comment: Commenters (2166-ODNR, 2288-NDDEQ) state most wells in Ohio are located on private property, and the guidelines include no language regarding how Ohioans, law enforcement, or state regulators will know who is authorized to be on the property. There are no standards established for calibration of equipment that ensure readings are measured correctly or for remedies landowners or operators may take should emissions be read incorrectly. Commenter (2166-ODNR) adds there is no language regarding where liability rests should injury to persons or property occur.

Commenter (2288-NDDEQ) is concerned that the approval process for third-party monitors may give the perception that such third-party monitors are acting on either the EPA or the NDDEQ's behest. In addition, for third-party monitors employing ground-based technologies, it must be made clear that private property rights as well as restrictions around national defense installations that exist near exclude oil and natural gas facilities must be respected, Notifier approval should not grant or imply any sort of property access to the third-party notifier.

Response II-14-227: EPA acknowledges the commenters' input; EPA has detailed the criteria for third parties in Section X.C.2 and XI.C.2 of the preamble of the rule. The rule also includes a provision that if the third-party notifier is guilty of illegal activity during the assessment of a super-emitter event (*e.g.*, trespassing), their certification would be revoked.

## **14.6 Statutory Basis for Super Emitter Program**

Comment: Commenters (2410-California Office of the Attorney General et al., 2433-EDF et al.) agree with EPA's conclusion that the SERP is legally justified either by treating super emitter emission events as a separate source of emissions for which the SERP is the BSER, or by incorporating the SERP into the performance standards and presumptive standards for facilities as an additional compliance assurance measure or work practice standard.<sup>179</sup>

---

<sup>179</sup> 87 Fed. Reg. at 74,752–54.

Response II-14-228: EPA acknowledges the commenter’s input; EPA has detailed the statutory authority in Section X.C.1 and XI.C.1 of the preamble of the rule.

Comment: Commenter (2433-EDF et al.) states because super emitters disproportionately contribute to total emissions and have a significant impact on the communities where they are located, EPA has explained that the SERP program is necessary to “backstop compliance and address the unique characteristics of these events.”<sup>180</sup> EPA, thus provides two separate statutory bases to support the program.

Commenter (2433-EDF et al.) notes first, EPA proposes that super emitter emission events are separate and distinct affected and designated facilities, with SERP serving as the “best system of emission reduction” for these sources. Under this proposal, a super emitter affected or designated facility is defined as “any equipment or control device . . . at a well site, centralized production facility, compressor station, or natural gas processing plant” that causes a release with a quantified emission rate of 100 kg/hr of methane or more.<sup>181</sup> Given that these events occur as result of malfunctions or abnormal operations, the BSER for these events would be corrective action to address the malfunction or abnormal operation that caused the emission event in order to resume normal operation, in accordance with the program parameters set out by EPA.

Commenter (2433-EDF et al.) notes second, EPA explains that SERP is justified as a backstop to ensure compliance with the other standards and requirements included in the rules that apply to affected and designated facilities, a number of which are known sources of super emitter emission events. EPA proposes to incorporate the program as an additional compliance assurance measure for sources that are subject to numeric standards of performance and control device requirements and as an additional work practice standard for sources subject to that type of standard in the rules. For sources that are subject only to work practice standards, like a collection of fugitive emission components, EPA proposes that the BSER for those sources includes targeted root cause analysis and corrective action for super emitter events. Again, as noted above, if a source subject to a numeric, control device, or work practice standard has a super emitter event, it is very likely that the source would be out of compliance with the applicable standard and the source would already have to take corrective action to come back into compliance with the applicable standard.

Response II-14-229: EPA acknowledges the commenter’s support of the Super Emitter Program.

Comment: Commenters (2227-Western Energy Alliance, 2254-PBPA, 2326-AXPC, 2399-GPA Midstream Association) state in the preamble to the proposed rules, EPA did not explain the legal basis and whether such a regulation is even legal. This lack of explanation or even rational basis is the hallmark of arbitrary and capricious federal rulemaking, that is not supported by the law, in violation of the Administrative Procedures Act. EPA’s failure to explain the legal authority and supporting legal rationale for this key element of the proposed rules is also a

---

<sup>180</sup> 87 Fed. Reg. at 74747.

<sup>181</sup> Id. at 74752.

violation of EPA's obligation under the CAA to include as part of the proposed rules "the major legal interpretations ... underlying the proposed rule." 42 U.S.C. § 307(d)(3)(C).

Commenter (2403-The Petroleum Alliance of Oklahoma) argues the Proposed Rule is unclear on how super emitter events will be used by EPA and/or state delegated agency as it relates to enforcement.

Response II-14-230: EPA acknowledges the commenter's input; EPA has detailed the statutory authority in Section X.C.1 and XI.C.1 of the preamble of the rule.

EPA has chosen to finalize the Super-Emitter Program as primarily a compliance assurance program. A notification of a super-emitter event by EPA is not an allegation of a violation and is there to trigger an obligation to investigate by the owner or operator of an applicable oil and gas facility.

Comment: Commenter (2353-CrownQuest Operating, LLC.) states EPA's attempt to establish a super emitter program significantly oversteps its authority in the CAA. Equipment failure or operating conditions that usually resolve themselves cause most of these "super emitter" events. The EPA even states that operators will not be allowed a defense if the EPA checks their facility and finds no significant emissions. EPA acknowledges that some events they are concerned with are not part of normal operations. Instead, these events are due to factors outside the operator's control and will resolve themselves. The EPA should stay within its statutory bounds and not attribute upset conditions to operators or deputize third parties to act as their agents. If the EPA needs more money to monitor these events, it should ask Congress for the funds or the authority to deputize third parties.

Response II-14-231: EPA acknowledges the commenter's input; EPA has detailed the investigation requirement for owners or operators in the event they are notified of a Super Emitter Event in Section X.C.2 and XI.C.4 of the preamble of the rule. The investigations are intended to identify the potential cause(s) of these emissions and take into account allowed emission events in these investigations.

Comment: Commenter (2237-Industrial Commission of North Dakota) contends the program undermines their entire legitimate role under the cooperative federalism structure of the statute. North Dakota treats every complaint seriously and would investigate a notification of a super emitter event whether it came from an EPA approved third-party or not. This assumes EPA would remain the administrator for the super emitter program, however §60.5373c does not list the SERP as an authority that EPA will retain.

Response II-14-232: EPA acknowledges the commenter's input; the statutory basis ***of the rule has been explained in Section X.C.1 and XI.C.1 of the preamble of the rule.***

### **14.6.1 State Law**

Comment: Commenter (2403-The Petroleum Alliance of Oklahoma) states EPA provides no statutory authority that allows it to “farm out” its and/or the state’s regulatory duties to third parties. This is unwarranted and a drastic departure from long-standing established processes and protocols that require the EPA and/or the delegated state agency to manage compliance of a regulated entities. Typically, states are in the best position to address this issue, have citizen reporting processes in place and are familiar with the regulated entities in their state. As such, we don’t think a separate SERP that bypasses EPA and/or states delegated regulatory jurisdiction is warranted.

Response II-14-233: As described in Section X.C and XI.C, EPA has structured the Super Emitter Program to redefine the obligations of the third-party notifier, EPA, and owner or operators.

Comment: Commenters (2218-TCEQ, 2283-Endeavor Energy Resources, 2301-U.S. Chamber of Commerce) note Commenter (2218-TCEQ) has an existing process to accept evidence from citizens, and evaluates evidence provided in accordance with agency procedures. State law provides the commenters authority to take enforcement action when appropriate. This proposed rule requires receiving, evaluating, and approving requests for verified third parties and solicits information from other entities that will create a potentially extensive additional workload for the commenter without additional funding or support. The scope of investigations will broaden and there may be additional investigations triggered by complaints to enforce the SERP. Compliance staff will be required to engage in ongoing technical discussions with both the regulated entity and verified third parties to implement the program. The EPA should reconsider the overall effectiveness and necessity of the super emitter program given the significant resource burden the program will have on states.

Commenter (2283-Endeavor Energy Resources) states that if EPA does retain the program in a final rule, then EPA should look to comparable state programs, like the one used in Texas by the Texas Commission on Environmental Quality (“TCEQ”), as a model for appropriate safeguards. For example, under the TCEQ program any information collected by a private individual demonstrating “possible violations of law” must be sent to the TCEQ executive director rather than the owner or operator.<sup>182</sup> The TCEQ executive director then evaluates the “value and credibility” of the information provided by the private party before determining whether to initiate an administrative action, refer the case for enforcement, or treat the information received by the individual as a complaint and conduct a complaint investigation.<sup>183</sup> By requiring that private party reports are first evaluated by a regulator, as the TCEQ rule does, EPA would better ensure that operators are not forced to respond to unverified or inaccurate reports and would also help to mitigate the serious statutory and due process concerns presented by the proposed Super-Emitter Response Program.

---

<sup>182</sup> See 30 Tex. Admin. Code § 70.4(a).

<sup>183</sup> Id at § 70.4(b)-(e).

Response II-14-234: EPA acknowledges the commenters' input; the final rule includes EPA in a centralized role to receive reports from third parties, reviewing the data, and then if the data is accurate and reasonable, notifying the identified owner or operator. These steps have been included to improve the quality of data being provided to the owner or operator.

Comment: Commenter (2428-API) states throughout the preamble EPA uses language that mentions state agencies as delegated authorities. One such example is found at 87 FR 74750, "The EPA further proposes that the entity making the report shall provide a complete copy to the EPA and to any delegated state authority (including states implementing a state plan) at an address those agencies shall specify." The role of state agencies within the SERP must be more adequately defined. For example, as explained in these comments, the SERP program is not lawful or practically workable unless EPA takes a direct role in implementing the program (e.g., EPA must review and approve site-specific third-party monitoring plans, EPA must receive and vet the results of third-party monitoring and must decide whether the results are actionable). In the final rule, EPA must explain the process and degree to which these functions may reasonably be delegated to the states and, for functions that EPA determines are delegable, provide mechanisms to assure consistency among EPA's and the delegated states' programs.

Response II-14-235: The final rule has been revised as primarily as a compliance assurance program with EPA in a centralized role as explained in Section X.C and XI.C of the preamble of the rule. In the final rule, there is no obligation on the states to track or review reporting by the third party notifiers, EPA's notification to the owner or operators, and/or the responses by the owner or operators back to the EPA.

Comment: Commenter (2393-OSEE) and ODEQ insist the program be run directly by the entities with the actual legal authority to implement and enforce the CAA, be that a properly delegated state/tribal/local authority or EPA. In other words, if EPA insists on creating this program, it should be run like any other program under the CAA using the principles of cooperative federalism. A reliance on third-party notifications could lead to inaccurate data and unnecessary burdens. An EPA-directed program, while not the perfect solution, would address some concerns stemming from the use of third parties, and would allow EPA to reduce the frequency with which new, and more importantly, existing facilities are monitored for methane leaks. This approach would also yield nearly all the methane emission reductions envisioned by EPA for the current proposal. Commenter (2393-OSEE) and ODEQ suggest an alternative with the following elements:

- (1) The Super Emitter Detection and Response Program should be run by an entity that has the actual legal authority to implement and enforce the CAA, i.e., EPA or a delegated air regulatory agency.
- (2) EPA would exempt existing well sites with site-level baseline methane emissions below 3 tons per year (TPY) from fugitive emissions monitoring.
- (3) EPA would reduce the frequency of fugitive emissions monitoring events at well sites, centralized production facilities, and compressor stations; and
- (4) To offset the reduced frequency of monitoring, a new requirement would be added for facilities to require tanker truck drivers who load liquids (crude oil, condensate, or

produced water) from storage tanks to report the condition of the thief hatch on arrival at a site.

Response II-14-236: EPA acknowledges the commenter's input; As described in Section X.C and XI.C, EPA has structured the Super Emitter Program to redefine the obligations of the third-party notifier, EPA, and owner or operators.

#### **14.6.2 CAA**

Comment: Commenters (2218-TCEQ, 2283-Endeavor Energy Resources, 2305-The Williams Companies, Inc., 2310-Montana Department of Environmental Quality (MTDEQ), 2322-Arkansas Department of Energy and Environment, 2354-Business Roundtable, 2399-GPA Midstream Association, 2403-The Petroleum Alliance of Oklahoma, 2428-API, 2452-Hess Corporation, 2483-INGAA) state as proposed, the SERP presents numerous legal,<sup>184</sup> logistical, commercial, safety, and security risks that have not been adequately considered by the EPA. These complex issues would benefit from further discussions between EPA, operators, and other interested parties. EPA should remove the super emitter provision from the rule. As an alternative, EPA could provide states funding (e.g., IRA) to enhance its existing program or develop its own state-specific program to address super emitter emissions.

Commenters (2227-Western Energy Alliance, 2238-SOOGA, 2248-NDPC, 2283-Endeavor Energy Resources, 2294-Ohio Oil and Gas Association, 2301-U.S. Chamber of Commerce, 2305-The Williams Companies, Inc., 2310-MTDEQ, 2322-Arkansas Department of Energy and Environment, 2354-Business Roundtable, 2399-GPA Midstream Association, 2428-API, 2452-Hess Corporation, 2483-INGAA) encourage EPA to conduct additional outreach on the proposed framework and repropose a program that meets all CAA legal requirements prior to finalizing the requirements (as provided in §60.5371b). Commenter (2305-The Williams Companies, Inc.) states the proposed program is an improper, unilateral delegation of pseudo-enforcement authority not contemplated in the CAA and the program circumvents the well-understood citizen enforcement mechanism that exists in Section 304 of the CAA.

Response II-14-237: The final rule has been revised as primarily as a compliance assurance program with EPA in a centralized role as explained in Section X.C and XI.C of the preamble of the rule. The rule no longer includes the provision to allow third parties to contact the owner or operator directly.

Comment: To the commenters' (2301-U.S. Chamber of Commerce, 2483-INGAA) knowledge, the program would be the first time that EPA has asserted authority under the CAA to create regulatory obligations for affected facilities based on monitoring conducted by unaffiliated third parties and without playing any role at all in verifying the information before imposing legal obligations on other private parties. In support of this unusual delegation of regulatory authority, EPA characterizes the program as simply a BSER requiring monitoring and correction of

---

<sup>184</sup> See Comment 12.3 and 12.4 of this letters for a discussion of the numerous legal deficiencies underpinning the proposed SERP.

unintentional releases, akin to LDAR,<sup>185</sup> but evades the central concern that it is private parties—not EPA, states, or regulated entities—who would be monitoring, notifying, and triggering the associated regulatory obligations.

For over three decades, EPA and industry have successfully collaborated on the implementation of voluntary programs to reduce methane emissions from the oil and natural gas sector under both the Natural Gas Star and Methane Challenge Programs. While Commenters (2305-The Williams Companies, Inc., 2428-API) believe the SERP may be better suited to function as a voluntary based program, members recognize the intent of the EPA to create a useable and workable program that identifies these large emissions events from a variety of stakeholders. Commenters propose establishing a voluntary program wherein the Agency, industry, and third parties can adequately evaluate the efficacy of this type of program and whether it brings tangible benefits to an emissions reduction regulation.

Response II-14-238: EPA acknowledges the commenters' input.

Comment: Commenters (2237-Industrial Commission of North Dakota, 2283-Endeavor Energy Resources, 2399-GPA Midstream Association, 2483-INGAA) continue, not only is the program not authorized by Congress, this program would be an end-run around the limitations that Congress either expressly established on third-party enforcement or that it knew to be imposed through formal legal proceedings when it passed the CAA. These include, among others, the citizen suit notice provision under 42 U.S.C. § 7604(b)(1)(A) and the diligent prosecution bar under § 7604(b)(1)(B), as well as the need for citizen plaintiffs to demonstrate an ongoing CAA violation, establish Article III standing, and demonstrate to an impartial judge that injunctive relief is warranted. Nothing in the CAA authorizes EPA to run roughshod over these statutory and constitutional requirements and create entirely new private rights.

Commenters (2237-Industrial Commission of North Dakota, 2399-GPA Midstream Association) argue the Supplemental Proposed Rule, despite acknowledging that the SERP would enforce existing regulations, refuses to recognize it for what it is: a private-party enforcement program.<sup>186</sup> Authorization for such a private-party enforcement system is not found in the CAA, and EPA does not claim that the Program is justified by an ambiguity in the statute. Instead, the Supplemental Proposed Rule simply creates an entirely new private-party enforcement mechanism out of whole cloth, despite Congress establishing robust systems for administrative,

---

<sup>185</sup> Id. at 74,752 (“[T]he EPA believes that super emitter emissions events from unintentional releases tend to occur as a result of equipment malfunctions and/or poor operations; therefore, the BSER for super emitter emissions events would be to correct the malfunction or operational issues and resume normal operations consistent with the standards or requirements applicable to the source(s) of the super emitter emissions event in this proposed rule.”).

<sup>186</sup> Proposed Rule also appears to say that EPA and state agencies could also initiate the SERP to obtain corrective actions. 87 Fed. Reg. at 74,752. The Supplemental Proposed Rule, however, fails to describe such an enforcement action as being grounded in either the Administrator’s emergency powers under 42 U.S.C. § 7603 or any form of enforcement authority identified in 42 U.S.C. § 7413. With respect to State agencies, the Supplemental Proposed Rule never considers whether the SERP is consistent with State enforcement authorities or processes.

civil judicial, criminal, and citizen enforcement. 42 U.S.C. §§ 7413(b)-(d); id. § 7604. EPA should not embark on this extraordinary and unlawful endeavor.

Commenter (2237-Industrial Commission of North Dakota, 2238-SOOGA, 2294-Ohio Oil and Gas Association) add Congress has already spoken to the “deputizing” of third parties for purposes of enforcing the requirements of the CAA - i.e. the CAA Citizen Suit provision (42 U.S.C 7604). Nowhere in the CAA did Congress authorize the SERP that is contemplated under the Supplemental Proposal.

Commenter (2237-Industrial Commission of North Dakota) further notes that the CAA "citizen suit" provision further solidifies this point. 42 U.S.C. § 7604 contains strict restrictions on the types of actions a citizen can initiate, the notice it must provide to alleged violators, and the process in which to do so, including providing the federal District Courts jurisdiction over such actions. If a source corrects alleged violations during the notice period, the complaining citizen generally has no authority to bring an enforcement action. Moreover, citizens also may not bring enforcement actions if either EPA or the State is "diligently prosecuting" the matter. The Supplemental Proposal would empower independent citizen enforcement without any of these procedural safeguards established by Congress.

Commenter (2237-Industrial Commission of North Dakota) contends that citizens would be deputized to monitor air emissions from existing sources, the results of that private citizen monitoring would be presumptively accurate and suitable for enforcement purposes, and those private citizens would be empowered to provide direct notice and claims of alleged violations to owners and operators, after which owners and operators (or States) are not provided any due process ability to contest the allegations in the notice. Upon receipt of these unverified claims, owners and operators of existing sources would be "required to perform a root-cause analysis and take corrective actions to address the emissions source at their individual well sites, centralized production facilities, and compressor stations." 87 Fed. Reg. at 74,747.

Commenter (2238-SOOGA) notes notwithstanding U.S. EPA’s questionable legal authority for establishing the SERP, the regulatory framework for the program needs further development. The Association suggests that U.S. EPA initiate the rulemaking process to approve each technology used by the third-party detectors so that industry has an opportunity to comment on the merit of each technology. The Supplemental Proposal does not provide adequate detail for stakeholders to provide comments as it only identifies the technology by name with no information about the technology and its limitation.

Commenter (2483-INGAA) states EPA’s authority under the CAA is limited to the powers given to it by Congress, and “it may not exercise its authority ‘in a manner that is inconsistent with the administrative structure that Congress enacted into law.’”<sup>187</sup> Section 113 of the CAA, which is entitled “Federal Enforcement,” makes clear that the Administrator is the person who must

---

<sup>187</sup> [*FDA v. Brown & Williamson Tobacco Corp.*], 529 U.S. 120, 125 (2000) (quoting [*ETSI Pipeline Project v. Missouri*], 484 U.S. 495, 517 (1988)).

determine whether a violation of the CAA has occurred.<sup>188</sup> Although the CAA does have some circumstances where the Administrator may delegate their authority, it is not to third parties; rather, it specifies that certain of the Administrator's powers may be delegated "to any officer or employee of the Environmental Protection Agency."<sup>189</sup> Section 114 also provides some limited ability of the Administrator to delegate powers, but this is limited to an "authorized representative" for the purpose of entering a facility for inspection purposes<sup>190</sup> or to states when the Administrator finds the procedure developed by the state is adequate.<sup>191</sup> None of these provisions allows the Administrator to delegate to third parties who are unaffiliated with the Agency authority that can give rise to compliance obligations by regulated entities.

Commenter (2483-INGAA) states the power proposed to be given to third parties to require compliance obligations under the SERP is contrary to the powers given to citizens under the CAA. Congress provided citizens with the authority to bring citizen suits against alleged violators of the CAA (including EPA) and prescribed very specific conditions and procedures for how that must be done.<sup>192</sup> Congress also clearly set forth that the citizen suit provision applies to alleged violations of emission standards or limitations under section 111.<sup>193</sup>

Commenter (2483-INGAA) argues none of the conditions or procedures in the citizen suit provision of the statute are present in the proposed SERP. EPA needs to identify the source of its statutory authority to provide third parties with the power to require compliance by a regulated entity and needs to explain why the SERP does not conflict with the citizen suit provision of the CAA, which Congress specifically stated applies to alleged violations of emission standards and limitations under section 111 of the CAA. Lacking statutory authority and with no explanation for why the program does not conflict with Congress's intent in the citizen suit provision, EPA cannot proceed to finalize the SERP.

Response II-14-239: EPA has chosen to finalize the Super-Emitter Program as primarily a compliance assurance program. A notification of a super-emitter event by EPA is not an allegation of a violation and is there to trigger an obligation to investigate by the owner or operator of an applicable oil and gas facility. As explained in Section X.C and XI.C of the preamble of the rule with the statutory authority for the rule detailed in subsection 1 of those sections.

---

<sup>188</sup> [See, e.g.,] CAA § 113(a)(1), 42 U.S.C. § 7413(a)(1) ("the Administrator finds that any person has violated or in violation of any requirement or prohibition"); [id.] § 113(a)(3), 42 U.S.C. § 7413(a)(3) ("the Administrator finds that any person has violated, or is in violation of, any other requirement or prohibition of this subchapter").

<sup>189</sup> [Id.] § 301(a)(1), 42 U.S.C. § 7601(a)(1).

<sup>190</sup> [Id.] § 114(a)(2), 42 U.S.C. § 7414(a)(2). The third-party reporters under the proposed SERP do not satisfy the requirements to be an "authorized representative" under section 114. EPA's regulations require a third-party "authorized representative" to be an EPA contractor or subcontractor. [See] 40 CFR § 2.301(h)(2)(i).

<sup>191</sup> CAA § 114(b)(1), 42 U.S.C. § 7414(b)(1).

<sup>192</sup> [Id.] § 304, 42 U.S.C. § 7604.

<sup>193</sup> [Id.] § 304(a)(1), (f)(3), 42 U.S.C. § 7604(a)(1), (f)(3) (specifying the citizen suit provision applies to an alleged violation of "an emission standard or limitation" and defining an emission standard or limitation as including "any requirement under section 7411 ... of this title (without regard to whether such requirement is expressed as an emission standard or otherwise)").

Comment: Commenter (2322-Arkansas Department of Energy and Environment) notes under the CAA, Congress granted authority to the states to implement standards of performance, developed by EPA at existing sources of air pollution.<sup>194</sup> Under Arkansas Code Annotated § 8-4-311, the commenter is the entity authorized to:

- develop and effectuate a program for the prevention and control of sources of air pollution in the state (including responding to emissions violation concerns from third-party entities that would implement the Proposed Rule's super emitter program),
- advise, consult, and cooperate with other agencies and with affected groups (including, presumably, third-party entities), to conduct studies, investigations, and research relating to air pollution and its causes, prevention, control, and abatement (including super emitter events addressed in the Proposed Rule), and
- develop and implement state implementation plans addressing air pollution control (including inspection and compliance requirements, which are essentially bypassed by the Proposed Rule's super emitter program).

Response II-14-240: EPA acknowledges the commenters' input.

Comment: Commenter (2237-Industrial Commission of North Dakota) provides that this private enforcement regime would also completely bypass all of the citizen suit procedures established by Congress. EPA does not have the authority to establish a new and vigilante private citizen enforcement regime completely outside the authorities and boundaries established by Congress. For these reasons, the SERP is unlawful and must be withdrawn. Commenter (2237-Industrial Commission of North Dakota) concurs in principle with the goals of the super emitter program; however, they believe the program itself is unnecessary and duplicative of the efforts North Dakota already takes to investigate suspected emission releases and North Dakota's investigations are not limited to "super emitters".

Commenter (2237-Industrial Commission of North Dakota) also contends that the SERP lacks due process for operators or North Dakota in that there is no opportunity to rebut a "citizen" finding that a super emitter event has even occurred, and instead requires operators to take immediate action even if they believe the super emitter event was improperly or incorrectly identified.

Response II-14-241: EPA acknowledges the commenters' input; the final rule includes EPA in a centralized role to receive reports from third parties, reviewing the data, and then if the data is accurate and reasonable, notifying the identified owner or operator.

The final rule includes an allowance for an owner or operator to challenge a third-party notification.

Comment: Commenter (2428-API) concurs the Supplemental Proposal does not provide the needed explanation. That failure to explain the legal underpinnings of such a key element of the

---

<sup>194</sup> 40 CFR Part 60, subpart B; and 40 CFR Part 60, subpart Ba.

proposal violates the CAA § 307(d)(3)(C) requirement to include as part of the proposed rule “the major legal interpretations underlying the proposed rule.” If not cured, it also would render the final rule arbitrary and capricious because EPA would have failed to address and explain a key factor underlying this aspect of the final rule.

Commenter (2428-API) disagrees with EPA’s contention that it has authority to treat super-emitting events as an affected facility warranting a § 111 standard of performance. Rather, at most, EPA has the authority to consider identification of super emitter events as “monitoring” for an affected facility. As such, super emitters may only be regulated at facilities that already are subject to NSPS OOOOb or EG OOOOc for other reasons. In other words, if a thief hatch on an NSPS OOOOb storage vessel were left open, it could (if meeting the threshold – and subject to the legal concerns set forth below) be considered a super emitter, and EPA could require corrective action to close the thief hatch. This would be similar for emissions above the threshold from an unlit flare or control device that is mandated by NSPS OOOOb or EG OOOOc (once applicable). However, a super emitter cannot arise from equipment at a stationary source that is not already an affected facility.

In other words, if an aerial survey identified emissions from a thief hatch on a storage vessel that is not subject to NSPS OOOOb, and the storage vessel is not yet subject to EG OOOOc, then this cannot be a super emitter affected facility subject to the regulations and for which an operator has to take corrective action. EPA’s preamble appears to support this approach in several places, but does not specifically state this in the rule. Thus, as written, it appears that one could identify a super emitter at a stationary source that has no affected facilities or from equipment that is not an affected facility. EPA has not justified that super emitters – many of which are malfunctions – are or can be independently considered “affected facilities” under CAA § 111.

Commenter (2428-API) also notes that EPA provides a lengthy discussion of the policy rationale that stands behind the proposed SERP, including an extensive explanation of how EPA believes that “[t]he design of the SERP ensures that the EPA will make all of the critical policy decisions and fully oversee the program.” *Id.* at 74749-51. In EPA’s view, “the qualified third-party would essentially only be permitted to engage in certain fact-finding activities and issue fact-based notifications within the limited confines that EPA has authorized.” *Id.* at 74750. Moreover, such notifications “originating from third parties would not represent the initiation of an enforcement action by the EPA or a delegated authority.” These arguments indirectly speak to EPA’s assertion of possible legal authority, but the policy rationale by itself cannot legally justify EPA’s novel proposal to empower citizens to develop and submit information that triggers legal obligations for affected/designated facilities.

Response II-14-242: EPA acknowledges the commenter’s input; the statutory basis of the rule has been explained in Section X.C.1 and XI.C.1 of the preamble of the rule.

Comment: Commenter (2354-Business Roundtable) believes a better approach might be for a qualified third-party to notify EPA and the relevant state regulatory authority of the emissions.<sup>195</sup> EPA or the state would then decide whether and how to notify potentially responsible owners or operators to initiate required investigation and corrective action. This approach would reduce the risk of inadvertently notifying a non-responsible party and would provide a level of governmental oversight we think is appropriate for the program, assuming any such program is authorized by the CAA.

Response II-14-243: EPA agrees with the commenter and in the final rule, qualified third parties are no longer providing notification to the owner or operators, instead EPA would receive the notification from the qualified third parties, verify the data, then provide notifications to an identified owner or operator.

Comment: Commenter (2452-Hess Corporation) argues the program does not appear grounded in any technical standard, as is required for development of an NSPS pursuant to the plain language of the CAA. EPA appears to have acknowledged the legal novelty of this addition by including two alternative legal frameworks in the “Statutory Basis of Super emitter Program” section of the preamble to the Supplemental Proposal. Given the complexity of this new requirement and potential questions concerning its legal basis, the commenter believes that the SERP is best reserved for a separate notice and comment rulemaking. This would allow the public greater opportunity to evaluate the proposal and provide feedback. Further, there is no reason the SERP must be included in the Supplemental Proposal. It is not otherwise reliant on the standards of the Supplemental Proposal.

Response II-14-244: EPA acknowledges the commenter’s input.

### ***14.6.3 Sections 111, 114, 304***

Comment: Commenter (2394-Earthworks) states the EPA has ample authority to solicit and rely on third-party data in implementing Section 111, and that authority should be used to the maximum extent practicable under the law to expand the SERP. The EPA must provide a clear pathway for communities and third parties to participate and engage in the SERP. The EPA must ensure that data from approved monitoring technologies are accessible to all, including the use of OGI cameras. The commenter urges the EPA to expand the overly restrictive standards within the SERP that would currently limit participation of NGOs and communities who have the tools required to detect pollution.

Response II-14-245: EPA acknowledges the commenter, and the final rule includes a criterion that third-party notifiers into the Super-Emitter Program must be certified. There are no restrictions to being a third-party other than the third party must be an independent entity (i.e.,

---

<sup>195</sup> See, for example Gathering and Preserving Information and Evidence Showing a Violation - Texas Commission on Environmental Quality.

someone other than the owner or operator of the site where the super-emitter emissions event is detected, the Administrator, or the delegated authority).

Comment: Commenter (2394-Earthworks) urges the EPA to use the already proposed alternative test method processes under the leak detection and repair program to approve technologies for SERP. Third parties who are certified under SERP should not face a higher barrier to monitoring than operators themselves, as third-party data will likely be more objective than data submitted by operators, who may face conflicts of interest in accurately reporting their own emissions and violations.

Response II-14-246: EPA appreciates this comment, and the rule has been revised to include the requirement that any remote sensing technology used by a third party must be approved under the alternative test method program in the final rule.

Comment: Commenters (2202-TXOGA, 2283-Endeavor Energy Resources, 2292-West Virginia Attorney General et al., 2301-U.S. Chamber of Commerce, 2366-BHE) argue CAA Section 114 does not provide EPA the authority for its proposed super emitter program – it does not authorize EPA to deem unaffiliated third parties to be “authorized representatives” of the Administrator. Indeed, “authorized representatives” must be EPA contractors or subcontractors.<sup>196</sup> Even if such third parties were eligible to be considered authorized representatives, Section 114(a)(2) requires prior presentation of credentials to the source before entering the site or any monitoring is conducted. EPA’s proposal does not satisfy the 114 requirements.

Commenters (2202-TXOGA, 2283-Endeavor Energy Resources, 2292-West Virginia Attorney General et al., 2301-U.S. Chamber of Commerce, 2366-BHE) note CAA section 114 outlines EPA’s authority to establish monitoring requirements and limits that authority to four entities: (1) any person who owns or operates any emissions source; (2) certain entities that manufacture emissions control or process equipment; (3) those with information “necessary for the purposes” of CAA section 114; and (4) those “subject to the requirements of this Act.”<sup>197</sup> The third-party notifiers that EPA describes do not fall within any of these four categories. In addition, the proposed program raises meaningful due process concerns for producers like the commenters who will be required to respond to unverified allegations from third parties in order to prove that they have not violated the law. The proposed program does not include sufficient safeguards to protect owners and operators.

Commenter (2366-BHE) states EPA’s assertion that the proposed program is akin to fenceline monitoring for petroleum refineries and development of an oil spill hotline is erroneous. In the petroleum refinery NESHAP, EPA adopted a work practice standard for operators that requires fenceline monitoring<sup>198</sup> rather than delegating responsibilities to a third-party. In addition, that program includes defined methodologies and implementation requirements for operators. Such structure is lacking for the proposed SERP. The oil spill reporting hotline is a much less

---

<sup>196</sup> See 40 CFR 2.301(h).

<sup>197</sup> Id§ 7414(a)(l).

<sup>198</sup> 40 CFR, Part 63, Subpart CC. See § 63.658 Fenceline monitoring provisions.

complicated program than remote monitoring third-party of facility methane emissions and not an analogous program because no special expertise is required by a caller, and, importantly, agency follow-up is triggered by the call.

While commenter (2366-BHE) supports technology development, it is premature to implement a program that relies on the proposed technologies. Commenter (2366-BHE) suggests that EPA initiate a program to support technology and leak mitigation program development and standardization, rather than adopt the SERP. In the interim period between the 2021 proposed rule and the Supplemental Notice, an avenue has been created to support such a development program. The IRA signed into law in August 2022 includes over \$1 billion in funding for natural gas methane programs, including \$850 million to support reporting of methane emission from natural gas operations required by Subpart W<sup>199</sup> of the GHGRP, methane emissions and monitoring from natural gas operations, and mitigation of those methane emissions. That funding provides an ideal platform to develop and execute a research, development and demonstration program that provides the necessary “infrastructure” to apply evolving methane monitoring and quantification technologies.

Commenters (2227-Western Energy Alliance, 2409-BP America Inc.) are concerned that, as written, EPA’s proposed delegation to private third parties in the SERP could be construed as exceeding EPA’s legal authority. EPA contends that it has the statutory authority to create the SERP under Section 111 of the CAA, 42 U.S.C. § 7414, but EPA does not establish how Section 111 authorizes EPA to delegate authority to third parties the ability to trigger new regulatory obligations or become involved in enforcement and compliance issues. Courts have suggested that delegations of such authority by agencies to private entities are “assumed to be improper absent an affirmative showing of congressional authorization.”<sup>200</sup> The D.C. Circuit has particularly expressed concern that “delegation to outside entities increases the risk that these parties will not share the agency’s ‘national vision and perspective,’ and thus may pursue goals inconsistent with those of the agency and the underlying statutory scheme.”<sup>201</sup>

Commenter (2227-Western Energy Alliance) adds CAA sections 111 and 112 allow EPA to transfer primary implementation and enforcement authority for most of the federal standards to state, local, or tribal regulatory agencies. This transfer of authority is called “delegation.” The statute, however, does not authorize EPA to delegate any implementation or regulatory authority to third-party members of the public. While the preamble to the proposed rules contains an

---

<sup>199</sup> 40 CFR Part 98, Subpart W.

<sup>200</sup> See *U.S. Telecom Ass’n v. FCC*, 359 F.3d 554, 565 (D.C. Cir. 2004) As the Court explained: “the cases recognize an important distinction between sub delegation to a subordinate and sub delegation to an outside party. The presumption that subs delegations are valid absent a showing of contrary congressional intent applies only to the former. There is no such presumption covering sub delegations to outside parties. Indeed, if anything, the case law strongly suggests that sub delegations to outside parties are assumed to be improper absent an affirmative showing of congressional authorization.” See also *Gentiva Healthcare Corp. v. Sebelius*, 723 F.3d 292 (D.C. Cir. 2013); cf. *Ass’n of Am. R.Rs. v. U.S. Dep’t of Transp.*, 721 F.3d 666, 671 (D.C. Cir. 2013) (noting that, although a statute may not “empower [] private parties to wield regulatory authority [,] [s]uch entities may . . . help a government agency make its regulatory decisions”).

<sup>201</sup> *U.S. Telecom Ass’n*, 259 F.3d at 555-56 (quoting *Nat’l Park & Conservation Ass’n v. Stanton*, 54 F. Supp. 2d 7, 20 (D.D.C. 1999)).

extensive narrative to bolster the policy basis for the Super-Emitter Program, this narrative is devoid of any statutory or legal authority that justifies EPA’s proposal to empower third-party members of the public to monitor and report on regulated facilities, which in turn triggers regulatory obligations for the facility under the rule. Section 111 of the CAA does not convey this authority to EPA. Moreover, EPA cannot lawfully utilize only a policy explanation in the preamble to bridge and account for the absence of any legal authority for EPA to provide for such a regulation.

Commenter (2409-BP America Inc.) is concerned that while EPA claims to maintain control over the “decision making elements” of the program, see 87 Fed. Reg. at 74750-51, certain features of the rule suggest otherwise. For example, to the extent the operator’s obligation is triggered by notification from the third-party without meaningful oversight/involvement EPA, it raises the question whether EPA has delegated authority to determine when (and whether) a regulatory obligation arises, and the operator must act. Further, the fact that the third-party report to EPA may be made available to the public online via the third-party’s own platforms, but that “EPA would generally not verify or authenticate the information in third-party reports prior to posting,” raises similar concerns. *Id.* at 74750 (emphasis added); see also *id.* at 74751.

Commenter (2409-BP America Inc.) argues this does not mean that EPA should abandon its efforts to promulgate a SERP, or that private third parties have no role to play in identifying methane leaks. To the contrary, if it is carefully crafted, Commenter (2409-BP America Inc.) believes that EPA can implement a scheme in which qualified, certified third parties can play an important role in gathering and disseminating information about methane emissions, so that responsible operators may use that information to improve performance, reduce emissions and protect communities, and so that EPA (or states with delegated authority) may use that information to bolster their oversight and enforcement of existing methane standards and regulations.<sup>202</sup>

Response II-14-247: EPA acknowledges the commenters’ support for some aspects of this programs and acknowledges some of their concerns. The final rule no longer includes third party acting as an “authorized representative” under 114(a)(2) and instead has EPA in a centralized role as explained in section X.C.1 and XI.C.1 in the preamble of the rule.

Comment: Commenter (2202-Texas Oil and Gas Association) notes the plainly applicable provisions referenced by the commenter (CAA Section 111(c)) and CAA Section 114<sup>203,204</sup>) provide authority to the “Administrator” and not to private citizens. On its face, CAA Section

---

<sup>202</sup> Data and information are important inputs to aid transparency, dialogue and trust-building. bp was an early industry participant in the Environmental Defense Fund’s (“EDF”) Permian Methane Analysis Project (“PermianMAP”). Under this initiative, EDF—a non-profit environmental advocacy group—took periodic methane measurements in the Delaware Basin of the Permian and published this information on a public website. bp engaged regularly with EDF to review PermianMAP data and took any necessary mitigation actions. Engaging constructively with EDF to share feedback and insights as a data-user was a valuable way to enhance our programmatic leak detection and repair efforts.

<sup>203</sup> CAA § 114(a)(1); 42 U.S.C. § 7414(a)(1).

<sup>204</sup> CAA § 114(a)(2); 42 U.S.C. § 7414(a)(2) (emphasis added).

114 nowhere indicates that non-governmental, third-party entities are afforded any authority under the CAA independently to compel a response by an owner/operator or other regulated entity. If the CAA did grant third parties such authority, one might have expected to see some indication of it here.

Commenter (2202-TXOGA) does not perceive the proposal is that an “approved notifier” within the meaning of proposed 40 CFR § 60.5371b(a) would, upon approval, thereby be considered to be an “authorized representative” within the meaning of CAA Section 114(a)(2). Such a designation of private, third-party entity would be problematic in any event.<sup>205</sup> There is nothing to indicate that the agency can authorize non-governmental authorities to exercise the inspection rights of CAA Section 114. If it could, EPA would effectively be able to authorize citizens to become government inspectors that have authority to enter facilities, retrieve data, demand records, and the like.

Commenter (2202-TXOGA) states it is correct that in the specific context of CAA enforcement, the CAA is replete with examples of EPA’s being authorized to take a particular action on the basis of “any information” being made available to the Administrator, which would presumably include information provided to EPA by a private entity. See, e.g., CAA § 113(a)(1) (“... on the basis of any information available . . . .”); CAA § 113(a)(2) (“... on the basis of information available . . . .”); CAA § 113(a)(3) (“... on the basis of any information available . . . .”); CAA § 113(a)(5) (“... on the basis of any available information . . . .”); CAA § 113(d)(1) (“... on the basis of any available information . . . .”). So, while enforcement per se is not in view with respect to the proposed Super emitter Program’s “notification” trigger provision – again, the way the program is devised, a violation would arise only if the owner/operator thereafter failed to take the actions specified under subsections (c) and (d) of proposed 40 CFR § 60.5371b – different considerations are presented where EPA (or a state exercising delegated authority) is the entity doing the notifying under proposed 40 CFR § 60.5371b, even if the information itself on which EPA is relying has come to it from a private third-party entity.

On the other hand, as the commenter had observed in its initial comments, a standard that requires regulated entities to take action on the basis of notification being provided to them by a private third-party entity, of information obtained by and in the possession of that third-party entity, seems unprecedented and even if there is some precedent somewhere, it is not authorized by the CAA.

Commenters (2202-TXOGA, 2254-PBPA) continue, that the Proposed program lacks statutory basis is further highlighted by the role that Congress directly gave to private citizens. Under CAA Section 304, private parties may directly involve themselves in enforcement through the CAA’s citizen suit provision.<sup>206</sup> The citizen suit provision allows private parties to step into the shoes of EPA, or a relevant state, when, following the provision of statutorily required notice, giving the governmental entities an opportunity to take action in the first instance, these

---

<sup>205</sup> See *Stauffer Chemical Co. v. EPA*, 647 F.2d 1075 (10th Cir. 1981); but cf. *Bunker Hill Co. v. EPA*, 658 F.2d 1280 (9th Cir. 1981).

<sup>206</sup> See CAA § 304; 42 U.S.C. § 7604.

governmental entities decline to bring a judicial action to address an alleged violation of some emission standard or other provision of the CAA. That the CAA specifically allows for direct involvement (subject to certain conditions) on the part of private entities in the context of enforcement but is otherwise silent when it comes to authorizing private parties to compel directly action on the part of regulated entities, suggests that private parties are afforded no such authority. This is further emphasized by the fact that private parties are clearly subordinate to EPA in their ability to enforce, in that a 60-day notice is required to give EPA the opportunity to take up its own enforcement action on the issue the private citizen seeks to enforce, and if EPA does so, the citizen suit is forbidden.

Commenter (2227-Western Energy Alliance) adds while Section 304 of the CAA expressly prescribes a role for private parties to file civil lawsuits challenging alleged violations of, among other things, CAA §111 performance standards, significantly, Congress did not provide similar express language in CAA §111 or elsewhere in the CAA authorizing citizen monitoring and reporting as provided in the proposed Super-Emitter Response Program. Accordingly, the absence of such language should be construed strictly as a limitation by Congress on EPA's authority to allow such monitoring and reporting by the public. Furthermore, nothing in the statute can be interpreted reasonably that Congress implicitly granted such authority to EPA. Therefore, this provision of the proposed rules is not supported by the law, and EPA cannot lawfully take such action in the final rule.

Response II-14-248: EPA has finalized the Super Emitter Program as a compliance assurance program which was co-proposed in the December 2022 proposal. The statutory authority for the program in the final rule is explained in section X.C.1 and XI.C.1 in the preamble of the rule.

Comment: Commenter (2202-TXOGA) states, accordingly, given that the preamble has yet to articulate a legal basis, grounded in a provision of the CAA, that authorizes it to adopt a Super emitter Program containing the proposed elements, the commenter respectfully objects to the program being finalized as currently proposed. While the December 2022 Supplemental Notice does state that it provides the “statutory basis” of the Super emitter Program, it does not actually do so. All that the preamble really does is explain how the program “fits within the EPA’s authority under section 111 of the CAA.”<sup>207</sup> The preamble does not, however, expressly state that its authority to create the private, third-party trigger requirement is derived from CAA Section 111. In this regard, it offers “two legal frameworks” – in effect, ways of characterizing what is both a novel and creative regulatory construction – into which the Super emitter Program can be fitted, but the Proposal never actually explains the source of the actual authority to create such a program in the first place, given that the proposed program would place such a central, and unprecedented, role in the hands of private entities. This is a role that Congress has never explicitly authorized and that is in misalignment with decades of how the CAA has been enforced.

---

<sup>207</sup> 87 Fed. Reg. at 74,752.

Commenter (2202-TXOGA) states first, the Proposal says, “a super emitter emissions event [could be treated] as a separate and distinct source of emissions.”<sup>208</sup> Specifically, EPA is “proposing a new ‘super emitter’ affected facility under NSPS OOOOb (and designated facility under EG OOOOc),” which EPA would then define as “any equipment or control devices, or parts thereof, at a well site, centralized production facility, compressor station, or natural gas processing plant, that causes a Super emitter emissions event (*i.e.*, any emissions detected using remote detection methods with a quantified emission rate of 100 kg/hr of methane or greater).”<sup>209</sup> In turn, the “BSER for super emitter emissions events would be to correct the malfunction or operational issues and resume normal operations consistent with the standards or requirements applicable to the source(s) of the super emitter emissions event in this proposed rule.”<sup>210</sup>

Commenter (2202-TXOGA) adds second, the preamble says, “the SERP can be justified as part of the standards and requirements that apply to individual affected/designated facilities under this rule,” a “number of which are known to be frequent causes of super emitter emission events” and which “may not necessarily be identified and addressed through more frequent monitoring that we have determined is not cost-effective.”<sup>211</sup> EPA proposes, therefore, to “incorporate the Super-Emitter Program into these standards by considering the super emitter program” to be “an additional compliance assurance measure, in the case of sources that are subject to numerical standards of performance and associated control device requirements,” and “an additional work practice standard, in the case of sources for which the EPA is proposing work practice standards under this rule.”<sup>212</sup>

Again, nowhere in these statements is the authority identified for establishing a process by which, upon a private, third-party entity’s having pulled a notification trigger, an owner/operator would be compelled to take action or else be deemed in violation of the standard. If EPA itself cannot directly point to such authority, it should strike from its Super emitter Program its proposed private-party trigger provision.

Response II-14-249: The statutory authority for the program in the final rule is explained in section X.C.1 and XI.C.1 in the preamble of the rule.

Comment: Commenter (2433-EDF et al.) disagrees with the above commenters, stating CAA sections 113 and 114 provide legal authority for the program.<sup>213</sup> Section 114 gives EPA broad information-gathering authority to develop standards and emissions guidelines under section 111 and to determine whether a facility is out of compliance with a section 111 standard or guideline.<sup>214</sup> It also permits EPA to require persons with relevant information to provide that information to the agency, set parameters for monitoring methods, and make publicly available

---

<sup>208</sup> Id.

<sup>209</sup> Id.

<sup>210</sup> Id.

<sup>211</sup> Id.

<sup>213</sup> 2022 Joint Environmental Comments, *supra* note 1, at 135–37.

<sup>214</sup> Id. at 135.

any information gathered.<sup>215</sup> Section 113, in turn, allows EPA to engage in an enforcement action based on “any available information” that shows a facility has violated a standard or requirement under the CAA.<sup>216</sup> These CAA authorities further support the SERP program.

Response II-14-250: EPA acknowledges the commenter’s input.

Comment: Commenter (2399-GPA Midstream Association) argues EPA may only regulate two types of sources under Section 111: new sources (including modified sources) and existing sources. 42 U.S.C. §§ 7411(b), (d). A Super emitter Source, as the Supplemental Proposed Rule contemplates it, cannot be a new source under Subpart OOOOb because a new source must be either constructed or modified. Id. §§ 7411(a)(2) (a “new source” is constructed or modified after the publication of the standard of performance regulations), (a)(4) (“modification” requires a “physical change in, or change in the method of operation of, a stationary source which increases the amount of any air pollutant emitted by such source”). Here, a Super emitter Source would be created by an emission event, not any construction or modification.

Commenter (2399-GPA Midstream Association) adds, nor can Super emitter Sources be existing sources under Subpart OOOOc as an existing source is typically constructed and operating before either the approval of a state plan with existing source standards or the issuance of federal existing source standards. 42 U.S.C. §§ 7411(d)(1), (2). Here, however, a Super emitter Source is only created by an emissions event. Even if the source itself is 20 years old, its existence as a Super emitter Source post-dates the issuance of any state or federal existing source standards. And yet, as described above, the absence of construction or modification activities means it cannot be a “new source” under Section 111 either. The Supplemental Proposed Rule never addresses this conundrum, which only arises because Congress never contemplated a source category-shifting scheme like the one proposed here.

Response II-14-251: EPA acknowledges the commenter’s input.

Comment: Commenter (2428-API) notes that CAA § 304 expressly prescribes a role for citizens in CAA implementation by authorizing them to file civil lawsuits challenging alleged violations of, among other things, CAA § 111 emissions standards. The commenter pointed out that Congress did not provide similar express language in CAA § 111 or elsewhere in the CAA authorizing citizen monitoring as provided in the proposed SERP. In this context, the absence of such language should be construed as a limitation on EPA’s authority to allow such monitoring and such an absence is not an implicit delegation of authority from Congress to EPA.

As a further note on the relevance of CAA § 304, Commenter (2428-API) states that section prescribes strict criteria for obtaining injunctive relief to address alleged CAA violations – including prior notice, opportunity for the government to take the lead on an enforcement action, standing to bring an enforcement case, proof of liability, and sufficient rationale to support injunctive relief. The proposal runs counter to CAA § 304 by enabling citizens to obtain

---

<sup>215</sup> Id. at 135, 137.

<sup>216</sup> Id. at 135, 139.

injunctive relief through the SERP (in this case, investigation, corrective action, root cause analysis, and related measures) without satisfying the procedural and substantive criteria that must be met to obtain such relief under CAA § 304.

Response II-14-252: EPA acknowledges the commenter’s input.

Comment: Commenter (2483-INGAA) argues Section 113 of the CAA makes clear that the EPA Administrator is the person who must determine whether a violation of the CAA has occurred. Congress provided third-party citizens with power to require compliance through section 304, the Act’s citizen suit provision, and the SERP conflicts with that provision. If EPA adopts a SERP despite the lack of authority to do so, it should at least address the issues below.

Response II-14-253: EPA has chosen to finalize the Super-Emitter Program as primarily a compliance assurance program. A notification of a super-emitter event by EPA is not an allegation of a violation and is there to trigger an obligation to investigate by the owner or operator of an applicable oil and gas facility.

Comment: Commenter (2305-The Williams Companies, Inc.) notes Congress provided one additional mechanism that is arguably a delegation of authority – that is the “citizen suit” provision of the CAA.<sup>217</sup> Section 304 and its interpretive case law support the right of third-parties to collect information about a source that informs the third-party as to the potential compliance status, present that information to the source and the agency with delegated authority (usually a state and/or the EPA), and, if no action is taken after 60-days or if the EPA or other regulatory authority has not already commenced enforcement or is diligently prosecuting the alleged violations, the citizen can bring suit against the violator seeking to enforce the alleged non-compliance. The citizen suit provision allows for an orderly and systematic process by which to evaluate noncompliance allegations brought by third parties.

Commenter (2305-The Williams Companies, Inc.) disagrees with the EPA’s conclusion that the third-party is simply engaging in a “fact-finding activity;” instead upon receipt of a notification from a third-party, an owner or operator has a legal obligation to engage in an immediate investigation into the cause of the “super emissions event” and must report its findings to the EPA in a prescribed period of time. That report is then made publicly available via a publicly accessible website. Not only does this activity circumvent the legal bounds of delegated authority in the Act, but it also evades the strictures of the citizen enforcement provisions Congress articulated in Section 304 of the CAA. The Supplemental Proposed Rule is silent on these requirements and whether the proposed program conforms to the specific conditions that must be satisfied before a citizen can bring an enforcement action against a regulated entity for an alleged violation of a standard.

Response II-14-254: EPA thanks the commenter for their concerns, in the final rule, only a notification from the EPA would trigger any additional action by an owner or operator. While the EPA would still rely on data from the third parties, the final rule incorporates new obligations on

---

<sup>217</sup> 42 U.S.C. § 7604(b).

those third parties no longer trigger an obligation, instead any third-party notification must come through the EPA for evaluation and any obligation.

Comment: Commenter (2446-IPAA) states EPA needs to unequivocally state that the information/data submitted by third parties will not be the basis for enforcement action by state or federal regulators. Congress has spoken as to when third parties can engage in enforcement of the CAA and the process is set forth in Section 304 of the CAA. Noting in Section 111 of the CAA hints at utilizing third parties to provide regulators data to serve as the basis for enforcement of the CAA. Clarity on this issue from EPA would benefit all stakeholders.

Response II-14-255: EPA identifies the commenters' concern. EPA has chosen to finalize the Super-Emitter Program as primarily a compliance assurance program. A notification of a super-emitter event by EPA is not an allegation of a violation and is there to trigger an obligation to investigate by the owner or operator of an applicable oil and gas facility.

Comment: In its request for comments, Commenter (2221-Texas Pipeline Association) notes EPA has touched upon a key issue in this context: whether data produced by third parties - some of whom might have an agenda - would be credible. The problem is that the data that would be submitted by untrained, unaccountable, and possibly biased, citizens in this context could often not be credible, or reliable, or a sufficient basis upon which to force a company to take action. Operation of emissions detection equipment, such as optical gas imaging monitoring equipment (FLIR cameras or similar thermal imaging technology), is a precise and technical exercise requiring training and operational expertise.<sup>218</sup> It is not a matter of simply pointing a camera at a tank battery and obtaining accurate measurements. Added to this are significant issues related to chain of custody, data integrity, and data preservation, as well as citizens' likely inability on occasion to determine ownership or operational custody of any given source of the emissions being reported, particularly at complex or multi-owner sites - which could lead to the submission of citizen-reports to the wrong company.

Commenter (2301-U.S. Chamber of Commerce) states that if any program concerning third-party notifiers were to move forward, EPA would need to specify that any such third-party notices will not constitute "credible evidence" under the CAA. "Credible evidence" refers to a collection of EPA regulations providing that both reference test and comparable non-reference test data may be used to prove or disprove violations of the CAA under the Title V, PSD/NSR, and other CAA programs.<sup>219</sup>

Response II-14-256: EPA recognizes these comments and in the final rule, we have developed a third-party notifier certification program to ensure organizations and individuals providing information to the Super Emitter Program are sufficiently qualified to do so. EPA has chosen to finalize the Super-Emitter Program as primarily a compliance assurance program. A notification

<sup>218</sup> See, e.g., <https://www.asnt.org/MajorSiteSections/Standards/ASNTStandards.aspx> (requirements outlined by ANSI/ASNT CP-105 and CP-189 of the American Society for Non-Destructive Testing).

<sup>219</sup> See 62 Fed. Reg. 8314, 8316 (Feb. 24, 1997).

of a super-emitter event by EPA is not an allegation of a violation and is there to trigger an obligation to investigate by the owner or operator of an applicable oil and gas facility.

Comment: Commenter (2221-Texas Pipeline Association) opposes inclusion of a requirement for regulated parties to respond to emissions reports submitted by private third parties in Section 111 standards. While owners and operators do want to be alerted to large emission events from their sites, it is not appropriate to include in the context of Section 111 standards a set of rules that in effect deputizes third parties and provides them with the power to require responsive action by regulated companies. Congress delegated environmental investigative authority to EPA, not every individual citizen who can demonstrate the ability to use emissions detection equipment, and it is not our understanding that federal, state, and local governmental bodies currently lack the incentive, resources, or ability to conduct whatever emissions monitoring activities they deem to be required in any given situation. Governmental environmental agencies have proper equipment, training, subpoena power, investigatory authority, and financial resources to review and examine the operations of emission sources under their jurisdiction. Commenter (2221-Texas Pipeline Association) does not believe that it would be wise to inject into the currently existing regulatory and investigatory scheme a new layer of investigation that directly triggers company responses based on input from untrained and unaccountable "citizen enforcers" deputized by EPA via rulemaking. In addition, we are not aware of the legal basis upon which EPA might place this sort of regulatory authority in the hands of private third parties.

Commenter (2221-Texas Pipeline Association) argues it would be inappropriate for EPA under Section 111 to establish a system that would force a company to spend time and effort performing "root cause" analyses as well as other required activities in direct response to reports filed by untrained and unaccountable citizens operating sensitive and technical equipment at the fence line. The potential for tying up resources in response to the submission of repeated nuisance reports to companies is real. Moreover, as the TCEQ previously pointed out, EPA's proposal to allow citizens to create their own investigation program fails to include a framework for how individual states would work with EPA to resolve the alleged emission events purportedly identified by third parties. The proposed scheme not only has the potential to lead to significant safety issues at facilities (as well as issues involving site security) but it would also complicate an already complicated set of enforcement challenges. TCEQ, no doubt speaking from experience, also has expressed skepticism as to whether the third-party reports would be fair and unbiased, and concluded in prior comments that "[t]he proposed reporting pathway is unlikely to be successful, would only serve to further deplete state agency resources, and should be removed."<sup>220</sup>

Commenter (2221-Texas Pipeline Association) adds an additional problem with the program is that EPA proposes to make third-party reports available to the public online presumably via EPA's official website.<sup>221</sup> EPA states the agency "would generally not verify or authenticate the information in third-party reports prior to posting."<sup>222</sup> This would be unfair and ill-advised, as it

---

<sup>220</sup> See TCEQ comments dated January 31, 2022 (EPA-HQ-OAR-2021-0317-0763) at 9.

<sup>221</sup> 87 Fed. Reg. 74750 (Dec. 6, 2022).

<sup>222</sup> Id.

would encourage the publication of potentially misleading information, both with respect to the nature of the event at issue and as to the proper identity of the owner or operator of the facility at issue. To be sure, a third-party would be free to publish any such report on its own website. But that is a far different matter from EPA publishing the report on its own official website. This would obviously provide the imprimatur of legitimacy and reliability on such a report, in effect an EPA endorsement of its contents. Given that the report could be partially or wholly inaccurate, and/or could misidentify the owner or operator of the facility at issue, EPA should avoid the appearance of giving any legitimacy to such a preliminary report.

Commenter (2221-Texas Pipeline Association) argues at a minimum, if EPA continues to contemplate such a program, then it should clearly set forth the legal basis upon which the program relies. Further, any such program must be one that contains strict requirements which ensure that reports filed by non-governmental personnel be submitted by one who has been properly trained and certified in the operation of the emissions detection equipment being used. Such reports should be filed with EPA, not directly with a company, and no response by the company (supposedly) involved should be required simply because a citizen has submitted a report; EPA triage of reports filed by third parties is essential and it should be EPA's responsibility to verify any data prior to publishing it on the agency's webpage. If EPA's assessment of the citizen-submitted data indicates that the data are valid and further action is required, then it should be up to EPA to contact the individual company or companies involved and to direct the companies to take whatever action EPA deems to be appropriate in the particular circumstances at issue. A general requirement whereby a particular company must undertake an extensive course of action (on pain of a noncompliance determination) simply because a citizen has decided to send the company a report supposedly detailing excess emissions would be unfair and unduly burdensome and would raise significant constitutional issues involving, inter alia, deprivation of due process and arbitrary enforcement.<sup>223</sup>

Commenter (2221-Texas Pipeline Association) states any rules that are implemented in this area should address the timeline for notification by third parties to companies. Reports to owner and operators must be completed and submitted in a timely manner to ensure emission reductions and to enable companies to determine the cause of the event at issue. It might not be possible to discover the cause of intermittent events that occurred weeks or months prior to discovery and reporting, because the event is no longer occurring and/or is too far in the past. For this sort of program to be effective in reducing emissions, companies should be notified within a very short time, and no longer than a week, when a large event is identified.

Response II-14-257: EPA recognizes the comment that companies should be notified in as short period of time as possible. We have revised the final rule to include a requirement that third parties must notify EPA within 15 days of a super-emitter detection. The 15-day time

---

<sup>223</sup> See, e.g., *North Carolina Dept. of Revenue v. The Kimberley Rice Kaestner 1992 Family Trust*, 139 S.Ct. 2213, 2219 (2019) (due process clause centrally concerns the fundamental fairness of governmental activity); *Koender v. Lawson*, 461 U.S. 352, 361 (1983) (law encouraging arbitrary enforcement held unconstitutional); *Lassiter v. Dep't of Social Services*, 452 U.S. 18, 24-25 (1981) (constitutional guarantee of due process encompasses the requirement of fundamental fairness).

requirement is to allow sufficient time for a third-party to process super-emitter data and to identify the owner or operator of a site.

## 14.7 Compliance Assurance

Comment: Commenter (2433-EDF et al.) states EPA’s focus on compliance assurance fits particularly well with the goals of the program and with the problem of super emitters. Emission events exceeding 100 kg/hr indicate major problems at the site resulting from either non-compliance or serious operational issues. EPA has broad authority under section 114 to accept and use third-party monitoring data for purposes related to section 111, including ensuring compliance. Importantly, SERP does not and should not replace obligations on the part of owners and operators to reduce methane emissions from affected and designated facilities under the rules. Rather, SERP would serve as an additional backstop to ensure the unique problems posed by super emitters are timely addressed.

Response II-14-258: EPA acknowledges this comment and the program in the final rule has been structured as primarily a compliance assurance program. The program in the final rule, is a “backstop” and is designed to provide reliable emissions information outside of an owner or operators normal inspection schedule. When a super-emitter investigation is triggered and if an emission is identified from equipment subject to regulations as part of the super-emitter investigation, then the owner or operators are subject to any repair requirements from those regulations.

Comment: Commenter (2399-GPA Midstream Association) argues the Supplemental Proposed Rule cannot disguise its new proposed enforcement scheme as a “compliance assurance” measure. 87 Fed. Reg. at 74,753. Under this theory, the proposal asserts that allowing a private-party (or any enforcement agency) to unilaterally issue an order “to require corrective action to bring the facility back into compliance with the applicable standard or requirement” is merely “a backstop – an additional compliance assurance measure.” Id. The term “compliance assurance” is not found in the CAA or defined anywhere in 40 CFR, Part 60, let alone in any NSPS regulation. Thus, the Supplemental Proposed Rule’s attempt to “interpret” a new and unauthorized enforcement scheme is not an act of interpretation. And even if it was, the SERP would be inconsistent with the types of monitoring, testing, recordkeeping, and reporting programs that the affected facilities must satisfy that one would consider to be “compliance assurance” requirements. See, e.g., 40 CFR §§ 60.7 (notification and recordkeeping requirements by affected facilities for construction and operational changes, recordkeeping for unit startups, shutdowns, and malfunctions, installation of continuous monitoring devices); 60.8 (performance test requirements); 60.11 (“Compliance with standards and maintenance requirements” that includes performance testing, opacity observations, or continuous opacity monitoring); 60.13 (standards for continuous monitoring devices). Allowing third parties to issue unilateral compliance orders is not a “compliance assurance” measure and there is no evidence that Congress ever contemplated such a measure within the CAA.

Commenter (2399-GPA Midstream Association) states EPA cannot avoid the strictures of the CAA by designating a new (but temporary) “super emitters” source category. 87 Fed. Reg. at

74,752. Under this approach, a source would transition from being an affected facility under the Crude Oil and Natural Gas Facilities category to an affected facility under the newly created “Super emitter” category when one private party unilaterally claims another private party incurred a “super emitter event.” *Id.* Assuming the third-party’s information is correct, and the new “Super emitter” affected facility implements a corrective action, it would then presumably transition back to a Crude Oil and Natural Gas Facilities source. Or, put another way, a Super emitter designated facility will only come into existence where a Crude Oil and Natural Gas Facility source violates a Crude Oil and Natural Gas Sector Facility emission or work practice standard, and then cease to exist once the violation ends. That cannot square with the notion of a source category under CAA § 111

Moreover, Commenter (2399-GPA Midstream Association) adds that EPA’s approach is not well founded is confirmed by the proposed BSER for super emitters, which EPA proposes to define as the new super emitter source merely coming back into compliance with whatever pre-existing Crude Oil and Natural Gas Facilities emission standards or work practices that was purportedly violated. See *id.* (“the BSER for super emitter emissions events would be to correct the malfunction or operational issues and resume normal operations consistent with the standards or requirements applicable to the source(s) of the super emitter emissions event”); see also *id.* at 74,753 (“Where one of these facilities is determined to be the cause of a super emitter emissions event, it is reasonable to assume that the emissions source is out of compliance and to require corrective action to bring the facility back into compliance with the applicable standard or requirement”). Requiring action to bring a source back into compliance with the applicable rules is not a system of emission reduction – it is an enforcement action.

Commenter (2399-GPA Midstream Association) argues this unprecedented approach is also inconsistent with Section 111. The Administrator may create new source categories under 42 U.S.C. § 7411 (b)(1)(A) or sub-categories based on “classes, types, and sizes ... for the purpose of establishing such [performance] standards.” *Id.* § 7411(b)(2). Nothing in the statute allows for the Administrator to create a new source category consisting solely of facilities already included in another existing source category that are violating existing regulations. Nor could the Administrator create a sub-category of such facilities as the sub-category would not be created “for the purpose of establishing” any “standards.” The only BSER work practice standards the Supplemental Proposed Rule would impose is an order for a source to cure any alleged violation without so much as a notice of violation, much less any formal enforcement action and the accompanying statutory and due process protections.<sup>224</sup> The Supplemental Proposed Rule is not an attempt to interpret the meaning of some ambiguous statutory word or phrase; it is attempting to impermissibly create an entirely new type of enforcement program that sheds the CAA’s procedural mandates.

Commenter (2399-GPA Midstream Association) states the SERP deviates from EPA’s longstanding practice of designating specific equipment, such as tanks, turbines, or engines as

---

<sup>224</sup> Nor is the Supplemental Proposed Rule able to characterize the SERP as merely “an additional work practice standard,” as work practice standards must “reflect [] the best technological system of continuous emission reduction.” 42 U.S.C. § 7411(h). An order to cure alleged regulatory violations is not a “technological system of continuous emission reduction.”

“affected facilities” under Section 111. Even fugitive emissions requirements are tied to specific equipment types, such as valves, connectors, or flanges. Here, however, the “affected facility” would be an entire site, containing various categories of affected facilities, and subject to what is effectively an arbitrarily selected bubble limit or site-wide cap of 100 kg/hour, applying to both planned and unplanned emissions.<sup>225</sup> Nothing in Section 111 authorizes EPA to use such an approach.

Response II-14-259: EPA recognizes the commenters concern and EPA has chosen not to finalize the Super-Emitter Program as part of BESR for a OOOOb “affected facility”. Instead, this program is designed to provide actionable and timely information to owner or operators when large emission events have been identified and evaluated by the EPA. In the final rule, EPA is providing the notifications to the owner or operator, and there is no requirement to investigate a super-emitter event until such time that EPA has provided a notification. The Super-Emitter Program only requires an owner or operator to investigate whether a super-emitter event has happened or ongoing, any additional obligation on part of the owner or operator is defined in the applicable regulation the equipment is subject to.

Comment: Commenter (2220-WDEQ) actively performs outreach to operators and ensures compliance issues are corrected in a timely manner. For example, the commenter’s compliance staffs currently complete approximately 1,000 Full Compliance Evaluations (FCEs) on oil and gas sites annually, with an additional 1,500 site visits or Partial Compliance Evaluations (PCEs) each year. Similarly, operators are already conducting their own compliance activities. Requiring compliance operators to respond to compliance observations from third-party entities (as described on pages 74747-74748 of the preamble) only complicates the compliance process. Furthermore, it could leave the commenter’s Compliance program in the dark about ongoing compliance issues that have been reported by a third-party.

Response II-14-260: EPA appreciates this comment and in the final rule, an owner or operators would not receive a notification from a third-party and instead a notification would come from the EPA. In the final rule, a super-emitter notification is not a suggestion of non-compliance and is intended to inform an owner or operator when a potential large-emission event has been identified at an applicable well site, centralized tank battery, or compressor station.

## **14.8 Other Program Issues**

Comment: Commenter (2408-Colorado Local Government Coalition) agrees with EPA that the proposed requirements for pneumatic controllers and inspection requirements for control devices and fugitive emissions components located at large well sites will help eliminate or reduce super emitters from these sources. Were EPA to adopt the commenter’s recommendation to require annual OGI inspections at small well sites and wellhead only sites, they would also agree with

---

<sup>225</sup> The 100 kg/hour threshold is essentially an emissions limit, but EPA did not rely on any health-based or environmental drivers to establish it. The threshold appears to be based on current or pending satellite detection capabilities. See 87 Fed. Reg. at 74,749.

EPA that such requirements would help reduce super emitters from fugitive emissions components located at these facilities.

Response II-14-261: EPA thanks the commenters for their support of the super-emitter program. Please see Chapter 4: Fugitive Emissions from Well Sites, Centralized Production Facilities of the Response to Comment Document for responses addressing your comments on OGI inspection at small well sites and wellhead only sites.

Comment: Commenter (2326-AXPC) notes that in response to a super emitter notification, EPA's proposal would require an operator to determine if a natural gas-driven pneumatic controller or pump is venting to atmosphere continuously and requires repair of any controller or pump found venting to the atmosphere during idle periods, even where the pneumatic controller is not related to the super emitter event. This provision fails to recognize that in many circumstances, operators may be using continuous bleed pneumatic controllers (e.g., approved use under NSPS OOOOb or at EG OOOOc facilities prior to implementation of EG OOOOc and where approved use provided). Continuous bleed pneumatic controllers – by their very nature – vent (or bleed) to atmosphere during non-actuations. Thus, EPA's requirements regarding repair of pneumatic controllers should be limited to natural gas-driven pneumatic pumps and controllers subject to a NSPS OOOOb or EG OOOOc zero emissions standard.

Similarly, in response to a super emitter notification, commenter (2326-AXPC) states that EPA's proposed regulation requires an operator, upon finding an open thief hatch or open pressure relief valve, to "conduct [] a new engineering certification to ensure the controlled tank battery is designed and operated to achieve the no identifiable emissions standard." First, the engineering certification required by an operator with respect to storage vessels relates only to design and not to operation. Thus, no engineering certification will (or can) address future operations. Second, this requirement to conduct a new engineering certification is illogical. If a thief hatch or PRV is left open, that is most clearly not a design issue, but rather is related to operations. Thus, a new engineering certification will not in any way address the open thief hatch or pressure relief valve.

Commenter (2326-AXPC) recommends no investigative analysis should be required if the emissions are not associated with/emitting from an affected facility under NSPS OOOOb.

Response II-14-262: When an owner or operator responding to a super-emitter notification identifies an ongoing super-emitter event, and the cause of the super-emitter event, is equipment subject to regulation, that regulation would dictate the follow-up action.

Comment: Commenter (2394-Earthworks) has been conducting OGI fieldwork in Colorado for years and tracking the progress of an evolving oil and gas regulatory framework as new rules are adopted and implemented. Following the adoption of extensive new rules and regulations by the Colorado Oil and Gas Conservation Commission and Air Quality Control Commission in the last few years, Commenter (2394-Earthworks) list their field findings of 553 investigations of 383 oil and gas facilities in their comment.

Commenter (2394-Earthworks) summarizes their findings. Despite the adoption of stricter oil and gas regulations in Colorado, pollution from the industry is still pervasive and persistent. Pollution events are not simply isolated incidents but are often symptomatic of ongoing issues that we document repeatedly on separate surveys at the same facilities. Faced with these facilities that are a chronic source of emissions, our findings also illustrate that Colorado's enforcement system is ineffective at curbing this pollution and holding operators accountable for continued violations. In part, this is due to a lack of enforcement in general, as only six of the 111 facilities where we have documented evidence of pollution this year have been inspected by APCD staff. But even when APCD staff do inspect facilities and substantiate our evidence of noncompliance, there is a desire to work with operators to achieve compliance rather than enforce compliance through fines and penalties. Commenter (2394-Earthworks) provides an overview of the timeline of their findings at the Prospect Energy Krause MSSU Tank Battery in Larimer County in their comment.

Commenter (2394-Earthworks) states Colorado has adopted rules and regulations that are intended to protect health and the environment from oil and gas pollution. Yet, for two years we have documented OGI evidence of ongoing pollution from the same facility and despite two years of assurances by both the APCD and the operator, residents have suffered health impacts with no resolution in sight. For the residents who live near this facility and many more like them across Colorado it is clear that when put to the test, Colorado's enforcement system still struggles to functionally implement its nation-leading rule and regulations.

Response II-14-263: EPA recognizes the commenters concern and while we cannot directly address your concern, the Super-emitter program is being developed with transparency in mind, on the part of the third-party, the EPA, and the owner or operator. All notifications meeting the requirement in the final rule will be published online on the EPA's Super Emitter Portal - <http://www.epa.gov/super-emitter>.

#### ***14.8.1 Text Changes/Clarifications***

Comment: Commenter (2177-Ute Indian Tribe) suggests the following text correction in §60.5388c(e)(1):

"If the owner or operator has identified a demonstrable error in the notification, the report may instead include a statement of the demonstrable error as specified in ~~§60.5371b(a)(4)~~ §60.5388c.(a). (4)."

Response II-14-264: EPA appreciates the comment and we have made the suggested revision in the regulatory text.

Comment: Commenter (2177-Ute Indian Tribe) cites the following text from the proposed rule:

"Corrective action plans for additional analysis. If, upon completion of the root cause analysis and initial corrective actions such as those described in paragraph (c) of this section, you are notified of a super emitter emissions event from the same emission

source which was determined under paragraph (c) not to be an allowed venting of emissions as part of normal operations, including routine maintenance, or if the initial corrective actions will require more than 10 days to complete, you must develop a corrective action plan that describes the initial corrective action(s) completed to date, additional measures that you propose to employ to reduce or eliminate the super emitter emissions event, and a schedule for completion of these additional measures. You must submit the corrective action plan to the Administrator according to the schedule in paragraphs (d)(1) and (2) of this section.”

Commenter (2177-Ute Indian Tribe) recommends replacing "corrective action plans" with "notification". The purpose of this section is to fix, and prevent, these super emitter events. This can be accomplished without developing corrective action plans.

Response II-14-265: EPA appreciates this comment, we have chosen not to finalize the requirement for corrective action plans.

## Chapter 15. Other Emission Sources

### 15.1 Pigging Operations and Blowdown Activities

Comment: Commenter (2247-Ohio Environmental Protection Agency) states that it is unclear how pigging operations apply in NSPS and Emission Guidelines (EG) rules. The commenter notes that maintenance and inspections must be done on many of the pipelines associated with these rules. They explain the typical approach is to insert a “pig” in at a pig launcher, have it run through a section of pipe to either measure/inspect the pipe or to clean out liquids, and then have the pig removed at the end of the pipe. When the pig is inserted or removed from the pipeline, the pressure inside the pig receiver/launcher must be equalized with ambient pressure. In many situations, this pressurized gas is vented into the air resulting in air emissions and potential odors. Are pigging operations governed by these rules and, if so, how?

Commenter (2296-New Mexico Environment Department (NMED)) states that NMED included a comprehensive emission reduction and leak detection and repair (LDAR) strategy for pigging operations in the state rule Part 50. The note that individual pipeline pig launcher and receiver operations with a potential to emit (PTE)  $\geq 1$  tons per year (tpy) volatile organic compound (VOC) located within the property boundary of, and under common ownership or control with, well sites, tank batteries, gathering and boosting stations, natural gas processing plants, and transmission compressor stations, are subject to the requirements of Part 50. The commenter encourages the EPA to adopt similar requirements in the proposed rule.

Commenter (2180-Pennsylvania Department of Environmental Protection (PADEP)) recommends that EPA establish requirements to reduce methane and VOC emissions from new and existing pigging operations. The commenter reports that they have required pigging operation to control VOC and methane emissions since 2018.

Commenter (2224-Zero Emission Vacuum and Compressor (ZEVAC)) believes that pigging operations and blowdown activities should be addressed in the rules. The commenter notes that the proposed rules reiterate the importance of advanced LDAR and the need to avoid flaring or venting gas at the wellhead but leave the practices of blowdowns (the depressurization of a natural gas pipeline to allow pipeline maintenance by opening a valve and allowing the gas to escape to the atmosphere) and flaring from downstream operations unregulated. The commenter believes that the EPA should issue further guidance and take action to eliminate or reduce the frequency, magnitude and severity of natural gas vented to the atmosphere from pipeline blowdowns and pigging operations.

Similarly, commenter (2410-California Office of the Attorney General (CA AG) *et al.*) encourages EPA to revisit potential regulatory options for “pigging operations,” which are maintenance activities performed on a daily, weekly, or monthly basis to prevent buildup of natural gas condensates in field gas gathering and transmission pipelines. The commenter explains that these operations require a facility to vent and blowdown any pressure in the line prior to removing the device known as a pipeline intervention gadget or “pig.” As demonstrated by regulations adopted by New Mexico, Colorado, and Pennsylvania, the commenter believes that cost effective and technically feasible best practices exist to reduce emissions from pigging

operations by reducing the flashing of hydrocarbons entrained in the liquids when the pigging unit is opened to remove the pig.

Commenter (2410-CA AG *et al.*) adds that New Mexico has adopted a comprehensive emission reduction and LDAR strategy for pigging operations located within the property boundary of, and under common ownership or control with, well sites, tank batteries, gathering and boosting stations, natural gas processing plants, and transmission compressor stations.<sup>1</sup> Colorado's rule covers pigging units at natural gas compressor stations, natural gas processing plants, and "stand alone pigging stations" that are not located within the boundaries of other regulated facilities. The commenter explains that Colorado relies upon a matrix of the size and pressure of the pigging pipeline to determine applicability of capture requirements. They continue by adding that Colorado requires all operating pressure over 500 pounds per square inch gauge (psig) to employ capture or control techniques and requires the capture of gas emitted during pigging. For smaller size and lower pressure pigging pipelines, Colorado determined that an emissions-based threshold was an appropriate approach. These thresholds are based on the location of the pigging unit, and depend on the type of location, such as whether the unit is in a disproportionately impacted community (more stringent thresholds apply to sources in disproportionately impacted communities). In Pennsylvania, the commenter provides that General Permit-5A regulates emissions from *Unconventional Natural Gas Well Site Operations and Remote Pigging Stations* and requires quarterly LDAR for sources at unconventional natural gas well sites or remote pigging stations.<sup>2</sup> Given these state regulatory programs, the commenter requests that EPA consider similar requirements in future rulemakings.

Other commenters (2211-Lambda Energy Resources LLC (Lambda), 2221-Texas Pipeline Association (TPA)) support EPA's decision to not set standards for pigging.

Commenter (2211-Lambda) urges EPA to avoid new regulations to pipeline pigging operations, which they report is a necessary and frequent safety testing practice within their gathering operations. The commenter explains that most pigging operations result in only a minute amount of hydrocarbons (est. 1-20 standard cubic feet (scf) per event) being lost from pig launchers or receivers. Because of the minimal amount of venting (est. 10 thousand cubic feet (mcf) per year for all events) associated with these operations, the commenter states that the need to capture gas during pigging is overly burdensome, not cost effective, and would disincentivize operators to conduct safety procedures. Alternatively, they add that where it is necessary to evacuate a line of product for pigging, they flare (and report under Subpart W) the small amount of displaced gas.

Commenter (2221-TPA) provides that there is currently insufficient data on pigging operations to adequately inform rulemaking in this area. The commenter contends that it is evident that EPA lacks sufficient information regarding the number of sources, emissions resulting from pigging, and similar basic information that traditionally would be input into a regulatory cost-benefit analysis and necessary to make a best system of emission reduction (BSER) determination. The commenter notes that it is true that EPA collects some data related to pig launchers and receivers through the GHG reporting program (GHGRP), however this information is limited to relatively large operations (above 50 cubic feet actual volume) and the emissions data that is captured reflects aggregate emissions data from multiple sources across an entire basin in the context of gathering and boosting. The commenter suggests that such macro-level, imprecise, and limited

data cannot reliably inform a useful cost-benefit analysis. At a minimum, according to the commenter, any rulemaking in this area should be preceded by an information collection request (ICR) aimed at gathering data that could allow EPA to assess the level of emissions fully and systemically at issue as well as the costs of imposing regulations in this area.

In addition, the commenter (2221-TPA) recommends that, should EPA ever intend to revisit this subject in the future, they would urge EPA to avoid overly prescriptive requirements in any standards it might propose regarding pigging operations. In the area of pigging operations, the commenter explains that there is no one-size-fits-all approach; the most effective, efficient, and environmentally sound procedure will vary greatly from site to site and is highly dependent on each individual site's particular characteristics. If any standard were ever implemented, they state that it should be one that sets a goal and leaves it to individual regulated entities as to how that goal is to be achieved. The commenter adds that overly prescriptive standards are inadvisable for the additional reason that reduction of emissions in pigging operations is an emerging field with new technology being developed on an ongoing basis. According to the commenter, a top-down prescriptive approach, *i.e.*, a rule that does not just say what the goal is but goes on to dictate how that goal must be achieved, would run the risk of stifling, if not altogether killing, the innovation that is currently underway as companies and consultants develop innovative and varied ways to reduce pigging emissions. The commenter suggests that the EPA should allow such emerging innovation to flourish.

In addition, the commenter (2221-TPA) recommends that the EPA should always bear in mind that the scope and level of emissions varies greatly from one pigging operation to the next. In many cases the emissions from a launcher or receiver can be de minimis, while a more extensive operation at an upstream location could result in higher emissions. For this reason, the commenter believes it would be reasonable for any future new standards to contain applicability thresholds expressed in emissions amounts, measured at each individual receiver or launcher, to exclude those sources and operations that are not resulting in significant emissions amounts. In keeping with other provisions in the NSPS, the state that an applicability threshold is a reasonable and fair way to avoid undue burden on small sources and further to avoid imposing requirements that do not meet a reasonable cost vs. environmental benefit standard. The commenter adds that an applicability threshold would have the additional benefit of incentivizing owners and operators to find ways to reduce emissions to keep emissions below threshold applicability levels.

Additionally, commenter (2221-TPA) supports EPA's proposal not to impose new requirements on pipeline blowdowns under the NSPS or any existing source standards. They contend that pipeline blowdowns should not be regulated as a source category. They explain that a blowdown is not traditionally considered to be an identifiable source of emissions, but rather an action taken for safety and/or operational reasons in the field. Moreover, they add that source categories in the NSPS context have traditionally been limited to structures that serve as emission sources. Pipelines, which are generally located underground and do not have normal operating emissions, do not fit that description, which they state may explain why they heretofore been subject to NSPS regulation as a separate source category.

The commenter (2221-TPA) contends that regulations in this area would present unduly complex compliance issues. According to the commenter, pipeline blowdown can affect numerous different pipeline segments, some that might be considered new or modified under the rules, and some that might be considered existing. The commenter expresses that this would raise compliance questions of whether the pipeline affected by the blowdown activity was governed by standards applicable to new sources, existing sources, or both. They add that this could be an extremely difficult question to answer in practice, given that pipelines can run for hundreds or thousands of miles and can be modified or replaced in numerous shorter segments within the overall pipeline length. In addition, there are many types of pipelines outside of the oil and natural gas sector, and regulating pipeline emissions, which is essentially what this emission category would be, would require a broader look at emissions from pipelines prior to proposing a rule.

Commenter (2224-ZEVAC) provides that existing technology allows operators to construct and maintain piping without the use of blowdowns or flaring. The commenter suggests that pigging practices be examined because of the risk that harmful VOCs are also released into the air in addition to methane. The commenter notes that they use portable compression to bring down gas pressure on an isolated pipeline segment and redirect the gas downstream of the isolated segment. The use of their technology, according to the commenter, eliminates the direct flow of methane into the atmosphere, improves safety and reduces operating costs. The commenter suggests that EPA should establish guidance and best practices that would require operators to evaluate pipeline blowdown mitigation options, compile project data for blowdowns and gas saved, and calculate and report their methane emissions reductions.<sup>1</sup> The commenter states that the proposed rules add stricter requirements for monitoring, detecting, and repairing *unintentional* leaks, yet they do not encourage the elimination of *intentional* blowdowns and flaring. On a dollar per emission basis, the commenter reports that the prevention of intentional emissions is more effective and efficient than searching for and repairing leaks.<sup>2</sup> The commenter adds that reducing venting and flaring will help bring more gas to market and could offer cost relief to in times of high demand and prices. The commenter contends that regulations should incent the use of existing technology to prevent intentional release of methane and VOCs into the atmosphere through intentional pigging and blowdown operations.

Similarly, the commenter (2224-ZEVAC) provides that the proposed rules revise the requirements for gas flaring at wells and require that available gas must be rerouted for beneficial uses unless an operator can show that all beneficial uses outlined in the supplemental proposal are unsafe or infeasible. They note that technology exists to reroute gas that would be vented or flared for beneficial use in downstream operations and the EPA should promulgate similar guidance to encourage the beneficial use of gas in the entirety of the natural gas value chain. The commenter states that the EPA has recognized their technology as a recommended

---

<sup>1</sup> For example, the commenter states that the EPA has encouraged the capture and use of gas normally vented from pipeline pigging operations using recovery compressors. See Partner Reported Opportunities (PROs) for Reducing Methane Emissions, Fact Sheet No. 505, available at: <https://www.epa.gov/sites/default/files/2016-06/documents/pigging.pdf> (last retrieved February 13, 2023); see also <https://www.iea.org/reports/flaring-emissions> (last retrieved February 13, 2023).

<sup>2</sup> See e.g., [https://www.socalgas.com/sites/default/files/2020-09/SCG\\_SB1371\\_Amended\\_2020\\_Compliance\\_Plan\\_Sept\\_2020.pdf](https://www.socalgas.com/sites/default/files/2020-09/SCG_SB1371_Amended_2020_Compliance_Plan_Sept_2020.pdf) at p. 5 (noting cost of leak survey at \$26/MCF versus cost of blowdown reduction at \$19/MCF) (last retrieved February 13, 2023).

technology to reduce methane emissions and the proposed rules should encourage operators to deploy existing techniques that reduce emissions and improve safety and save costs.

Response II-15-1: In the November 2021 Proposal, EPA solicited comment and data to assist the Agency in evaluating the potential for developing emissions standards for additional emission sources, including pigging operations and related blowdown activities. EPA did not propose emissions standards for pigging operations and related blowdown activities in the December 2022 Supplemental Proposal; therefore, this final action does not include emissions standards for these emission sources. We may consider regulation through a future action, including in the next 8-year review of the New Source Performance Standards (NSPS). The comment summaries are provided below for reference, but substantive responses are not provided because no emissions standards have been proposed for this emissions source.

## 15.2 Truck Loading

Comment: Commenter (2296-NMED) provides that they included emission control requirements for truck loading operations in state rule Part 50. The commenter encourages the EPA to adopt similar requirements in the proposed supplemental rule.

Response II-15-2: In the November 2021 Proposal, EPA solicited comment and data to assist the Agency in evaluating the potential for developing emissions standards for additional emission sources, including tank truck loading. EPA did not propose emissions standards for tank truck loading in the December 2022 Supplemental Proposal; therefore, this final action does not include emissions standards for these emission sources. We may consider regulation through a future action, including in the next 8-year review of the NSPS. The comment summaries are provided above for reference but substantive responses are not provided because no emissions standards have been proposed for these emissions sources.

## 15.3 Other Emission Sources

Comment: Commenter (2180-PADEP) recommends that EPA add the following sources to the existing proposed regulatory requirements:

- *Glycol Dehydration Units:* EPA should establish requirements to reduce methane and VOC emissions by 95 percent or more from new and existing glycol dehydration unit still vents if their potential or actual emissions exceed 200 tpy of methane or 2.7 tpy of VOC. The commenter reports that it has required 95 percent VOC control on glycol dehydration units since 2018.
- *Threshold for Multiple Sources Controlled by a Single Device:* EPA should require multiple sources that can be controlled by a single emission control device to comply with a 2.7 tpy VOC emission threshold. For example, if EPA were to adopt the 2.7 tpy VOC threshold for each storage vessel, glycol dehydration unit, and pneumatic pump individually, these singular sources could emit less VOC emissions than the current threshold and remain uncontrolled. However, if their combined emissions were considered, they would emit nearly 8 tpy of VOC without control, whereas it is cost effective to control VOC emissions at 2.7 tpy. The commenter recommends that EPA

establish a 2.7 tpy VOC emission threshold and 20 tpy methane emission threshold for multiple sources that can be controlled by a single control device.

Response II-15-3: These comments are asking EPA to regulate additional sources that EPA did not propose standards or solicit comment. Therefore, this final action does not include emissions standards for these emission sources. The comment summaries are provided above for reference but substantive responses are not provided because no emissions standards have been proposed for these emissions sources.

## Chapter 16. Covers and Closed Vent Systems

### 16.1 Applicability

Comment: Commenter (2399-GPA Midstream Association) expresses that new source performance standards (NSPS) under subpart VVa have never included welded seams as fugitive emission components. They explained the following reasons: Once welded, these seams must meet all pressure and leak tests associated with the original pipe and are, in fact, structurally similar to the pipe. Further, they state that inspecting them presents practical difficulties as welded sections are not tracked on piping and instrumentation diagrams or any other inventory. The commenter contends that owners and operators would have to undertake an unusually time-consuming and burdensome survey of all pipe welds in the facility and that this should not be necessary. The commenter maintains that the December 2022 Supplemental Proposal provides no rationale for requiring weld inspections, such as claims that these welds leak in any way. Absent a rational basis for imposing such a requirement, the commenter recommends EPA exclude welded pipe seams from audio, visual, and olfactory (AVO) inspections.

Response II-16-1: EPA is not excluding welded pipe seams on closed vent systems from AVO inspections. The requirement to conduct visual or AVO inspections of welded seams on closed vent systems has been required for this source category since NSPS OOOO was finalized in 2012. Similar requirements were finalized in 2016 for NSPS OOOOa. EPA is not aware through implementation of these standards that conducting AVO inspections on welded joints between two pieces of hard-piping has caused undue burden to the regulated community.

Further, contrary to the commenter's assertion, while welded seams are excluded from the definition of "connector" (and hence connector monitoring) under NSPS VVa, welded seams on closed vent systems under NSPS VVa must be monitored using AVO, as welded seams may be found on hard-piping, where two pieces of hard-piping are joined together. See 40 CFR 60.482-10(f)(1)(ii).

### 16.2 Clarification of What Constitutes a "Bypass"

Comment: Commenter (2403-Petroleum Alliance of Oklahoma (PAO)) notes that EPA states that if the closed vent system (CVS) is equipped with a bypass, the bypass must include a flow monitor and sound an alarm to alert personnel that a bypass is being diverted to the atmosphere or it must be equipped with a car-seal or lock-and-key configuration to ensure the valve remains in a non-diverting position. The commenter considers it to be unclear what EPA means by "bypass." The commenter assumes that open tank hatches are not considered a bypass. The commenter requests that EPA clarify that a bypass does not include an open tank hatch.

Response II-16-2: While improper design or operation of a thief hatch may result in a bypass of emissions from the control device to the atmosphere, EPA confirms that a thief hatch is not a bypass device subject to flow monitoring and alarms or to a car-seal or lock-and-key configuration. However, EPA notes that thief hatches should not be left in the open position. A thief hatch that is left open on a controlled storage vessel is considered improper operation of the cover, as the cover is required to form an impermeable barrier over the entire surface of the

liquid and each opening is required to be closed and sealed except in limited circumstances (*e.g.*, sampling the material in the storage vessel, adding material to the storage vessel).

### 16.3 “No Identifiable Emissions” Standard

Comment: Commenters (2202-Texas Oil & Gas Association (TXOGA), 2227-Western Energy Alliance (WEA), 2248-North Dakota Petroleum Council (NDPC), 2326-American Exploration and Production Council (AXPC), 2391-Chesapeake Energy Corporation (CEC), 2403-PAO, 2428-American Petroleum Institute (API)) ask EPA to reconsider the adoption of a no identifiable emissions standard as a numerical emission limit. They argue that it would be burdensome and contrary to historic EPA practice. Commenters (2202-TXOGA, 2227-WEA, 2248-NDPC, 2326-AXPC, 2391-CEC, 2428-API) note that all equipment leaks, and should not be considered violations.

Commenter (2202-TXOGA) states that the December 2022 Supplemental Proposal specifically acknowledged that EPA had earlier “proposed that covers and CVS must be designed and operated with no detectable emissions (NDE).”<sup>1</sup> The commenter states that EPA further noted that it had proposed that, “where a CVS is used to route emissions from an affected facility, the owner or operator would demonstrate there are no detectable emissions from the covers and CVS through OGI [optical gas imaging] or EPA Method 21 monitoring conducted during the fugitive emissions survey.”<sup>2</sup> The Agency, according to the commenter, then reiterated its earlier problematic statement, that “[w]here emissions are detected, the emissions would be considered a violation of the NDE standard and thus a deviation,” and that “corrective actions to complete all necessary repairs as soon as practicable would be required.”<sup>3</sup>

The commenter (2202-TXOGA) asserts that the proposal should not be adopted. First, the commenter provides that the assertion that EPA has always considered the “no detectable emissions” standard to constitute an emissions standard and not a work practice standard, and that the detection of emissions, in and of itself gives rise to a “potential violation” of that supposed emissions standard, is not supported by the record, and it rests on a shaky historical foundation. The commenter notes that in analogous regulatory settings involving CVSs, the detection of emissions above a given threshold would in turn trigger an obligation on the part of the owner/operator to undertake a repair within a specified time period. It was the failure to effectuate such repairs that constituted the violation, not the mere identification of emissions themselves.<sup>4</sup> The commenter is unaware of EPA having ever previously taken the position, in the record of such a rulemaking, that the detection of emissions upon inspection would, in and of

---

<sup>1</sup> 87 Fed. Reg. at 74,804.

<sup>2</sup> *Id.*

<sup>3</sup> *Id.*

<sup>4</sup> See, *e.g.*, 40 C.F.R. Part 63, Subpart H, National Emission Standards for Organic Hazardous Air Pollutants for Equipment Leaks. Specifically, under 40 C.F.R. §63.172 (*i.e.*, setting forth standards for close vent systems and control devices), paragraph (h) provides that “[l]eaks, as indicated by an instrument reading greater than 500 parts per million above background or by visual inspections, shall be repaired as soon as practicable,” with a “first attempt at repair” being made “no later than 5 calendar days after the leak is detected,” and the repairs needing to be completed “no later than 15 calendar days after the leak is detected.” Even then, under certain conditions (*i.e.*, as specified in paragraph (i)), even those deadlines for undertaking and completing repairs could be delayed.

itself, constitute a violation. According to the commenter, for EPA to purport now to be saying that its own prior use of the terminology “no detectable emissions” had somehow led the regulated community astray, that the regulated community had all these years misperceived the NDE standard to provide a “grace period,” that no such “grace period” was never intended but was but a figment of the regulated community’s collective imagination, and that it was now necessary, for the purpose of “clarification,” for the Agency to adopt new terminology – *i.e.*, the “no identifiable emissions” standard – is, with respect, a doubtful recollection on the Agency’s part of its own decades-long practice and prior understanding.

Second, the commenter (2202-TXOGA) states that it is a reality of engineering that a “zero-emissions” standard can never be perfectly achieved. According to the commenter, even the best designed equipment, designed to meet an NDE standard, will incur leaks from time to time. Put simply, a zero-emissions standard is not achievable. The commenter states that EPA cannot point to anything in the record of this rulemaking that indicates that there is any system capable of achieving such a standard is adequately demonstrated. For this reason, the commenter considers what is purported to be proposed to be inconsistent with the Clean Air Act (CAA) section 111(a)’s plain terms.

Commenters (2227-WEA, 2326-AXPC) provide that the no identifiable emission standard effectively establishes a “zero” numerical standard to covers and CVS, which is practically unachievable and therefore, cannot constitute best system of emission reduction (BSER). In addition, commenter (2227-WEA) notes that it would strongly discourage voluntary detection campaigns of operators from the use of more sensitive detection technologies. The commenter maintains that such a standard is unachievable because all equipment, regardless of design, will eventually leak as a part of normal operation. The commenter recommends that leaks on covers and CVSs be treated no differently than those on other types of equipment and be subject to the leak detection and repair (LDAR) work practice standard, instead of an unachievable numerical emission limitation. The commenter argues that simple malfunctions and equipment failures should not be treated the same way as a violation.

Similarly, commenter (2248-NDPC) requests EPA reconsider its approach to regulate fugitive emissions from covers and CVSs differently than other fugitive emissions from nearby components covered under the LDAR provisions. The commenter notes that since before NSPS OOOOa, the oil and natural gas industry has been doing optical gas imaging (OGI) surveys and has learned much about fugitive emission leaks, their causes, and potential mitigation. The commenter states that the no identifiable emissions standard is basically a zero-emission standard and is unrealistic, unattainable, and overly burdensome when you consider the components in question are in proximity to each other and are exposed to the same wear and tear (mostly by exposure to extreme weather conditions and hydrocarbons). The commenter maintains that an increase in the frequency of inspections should be enough to satisfy EPA’s concerns.

Furthermore, commenter (2248-NDPC) indicates that the no identifiable emissions standard requirement seems unnecessarily burdensome. The commenter points out that the proposed rule already has design and LDAR requirements and that the components that make up the covers and CVS are exposed to the elements just like all the other components included in the LDAR

requirements. According to the commenter, why a leak in the CVS pipe should be considered a violation, and a leak in a gas pipeline ten feet away would not, does not make any sense.

The commenter (2248-NDPC) notes that leaks at these components may have nothing to do with inadequate design or operation. The commenter explains that pressure and vacuum relief devices are present for safety reasons to prevent the tank from over-pressurization as well as under pressure (*i.e.*, vacuum). The commenter notes that temperatures in North Dakota can vary as much as 60+ °F in a 24-hour period. This temperature change causes the content of the tanks to expand and shrink. Without these control devices, the tanks would fail. The vacuum side for the pressure relief device is especially susceptible to sucking in dust and sometimes even bugs that prevent the device from sealing. The commenter provides that these are all taken care of as part of the LDAR program. Finally, the commenter notes that design issues, if any, will show up as repeat offenders in the LDAR program and will be corrected as part of that program.

Commenter (2391-CEC) states that CVSs often have mechanical components such as fittings and seals, that are prone to some de minimis level of leaking despite compliance with all other requirements. The commenter notes that EPA recognizes this reality by proposing annual inspections for “defects that could result in air emissions” including “liquid leaks” and establishing a leak repair schedule.<sup>5</sup> Because very small leaks are unavoidable and no LDAR program—no matter how robust—can prevent all leaks 100 percent of the time, the commenter maintains that operators will not be able to comply with the proposed “no identifiable emissions” standard.

Additionally, the commenter (2391-CEC) notes that the term “no identifiable emissions” is used for the first time in the December 2022 Supplemental Proposal, where EPA explains that it is meant to be equivalent to the term “NDE” but accounts for the use of OGI, which is very effective at identifying leaks but does not measure methane concentrations:

NDE is a term closely linked with EPA Method 21 and is defined based on an instrument reading in units of ppmv. Because the EPA is proposing compliance inspections for covers and CVS using optical gas imaging and AVO, no instrument reading in ppmv is available. Therefore, the EPA is proposing the design and operational standard as an emissions limit of no identifiable emissions, which is more appropriate for the methods of detection required.<sup>6</sup>

The commenter (2391-CEC) contends that there is a major difference between the terms NDE and no identifiable emissions (NIE) for operators. According to the commenter, NDE recognizes that there are unavoidable de minimis leaks in even the best designed and managed operations. Thus, small leaks that cause concentrations of less than 500 parts per million by volume (ppmv) meet the NDE standard. On the other hand, depending on the conditions, OGI often detects leaks well below this threshold, and any such leaks would be a violation of the NIE standard. The commenter contends that even though EPA recognizes that OGI is more effective at identifying leaks quickly and efficiently than EPA Method 21, the imposition of a NIE standard is a

---

<sup>5</sup> 87 Fed. Reg. at 74806; see also proposed 40 C.F.R. §§60.5416b(a), (b)(4); 60.5416c(a), (b)(4).

<sup>6</sup> 87 Fed. Reg. at 74805.

disincentive for operators to use OGI. The commenter states this is an appropriate design standard but an unachievable operational standard.

Furthermore, the commenter (2391-CEC) suggests that the NIE standard leaves owners and operators exposed to enforcement, despite complying with all regulatory inspection requirements. With no means of distinguishing between a minimal leak on a small mechanical component (such as gasket or fitting) from a significant over-pressure event, the commenter states that there is no bright line for EPA or state inspectors to use when determining whether a violation has occurred or in establishing an appropriate penalty. Therefore, the commenter recommends that EPA remove the proposed “no identifiable emissions” standard or state in the regulations that, despite detecting de minimis emissions on a given day, an operator is not in violation of the regulations if all emissions identified via OGI inspections were corrected within the prescribed time frame.

Commenter (2403-PAO) contends that a zero-emission standard is not feasible or realistic for equipment located outside, subject to harsh conditions and undergoing continuous wear and tear of operations. The commenter provides that there is the potential for the intrusion of foreign objects preventing re-seating of seal surfaces, *e.g.*, dirt or ice interfering with the sealing surfaces of tank hatches, particularly on vacuum seals. According to the commenter, emissions from such a scenario is not an indication of inadequate CVS design. The commenter adds that when wells are shut-in, tank emissions are reduced to breathing emissions which are very minimal and often there is not enough flow to the flare or control device to prevent flashback and an explosion, which create greater environmental and safety impacts than the minimal breathing emissions. After multiple tank fires in North Dakota, the North Dakota Department of Environmental Quality (NDEQ) acknowledged this risk and issued guidance that allows for tank vapor flares and control devices to be bypassed when a well is shut in to minimize the risk. In these cases, the hatches may need to be left open to relieve breathing pressure due to temperature fluctuations throughout the day. Further, the commenter states that it is common to isolate a tank that needs repair, empty the tank, and leave the hatch open to vent vapors to allow for repair for several days. Finally, the commenter notes that if vapor recovery and flare are not required at a facility, then tank emissions are understood to be vented to atmosphere in their entirety, regardless of whether the emissions occur from tank vents, openings, conservation vent valves, pressure relief valves, or a thief hatch. The commenter requests EPA remove the no identifiable emission standard and include CVS under the LDAR monitoring program. The commenter also requests that EPA allow exceptions for tank hatches, open vent lines, and other similar operational situations.

Commenter (2428-API) notes that as with all other fugitive emissions components, detection of a leak (in this case, defined as identifiable emissions) through routine LDAR monitoring triggers the obligation to repair the leak. If that repair is accomplished according to the specific requirements in the rule, then there is no violation because the work practice has been fully implemented.

According to the commenter (2428-API) EPA long ago rejected the idea that numeric emissions limitations can or should be applied to fugitive emissions components. The commenter contends that EPA has presented no reason in the proposal to depart from its historical approach regarding

fugitive emissions from CVSs. The commenter states EPA must make it clear that a CVS remains in compliance when a leak is detected, provided the associated work practices requiring investigation and repair are followed.

To this end, the commenter (2428-API) maintains that a “no identifiable emissions” or “no detectable emissions” standard cannot constitute a numerical emissions limitation since BSER must be achievable, so the standard must be applied as a work-practice standard. The commenter explains that even the most well-designed and operated system will develop a leak due to wear and tear on equipment. A zero emissions standard for cover and CVS components is practically unachievable because some leaks will happen in the normal course of operations (*e.g.*, typical fugitive leaks) and some develop due to causes beyond an operator’s control. The commenter considers that if a leak from a rusty bolt on a pipe flange is only subject to the standard LDAR work practice standard, then a leak from a rusty bolt on a cover or CVS should also only be subject to the standard work practice standard. According to the commenter, there is no reason why a typical fugitive leak should be treated differently simply because it occurs on a cover or CVS.

Additionally, the commenter (2428-API) notes that a leak may develop due to malfunctions or a foreign object (*e.g.*, sand or dust), both of which are not reasonably within the control of the operator. The commenter adds that such leaks are not caused by inadequate design or improper operation and cannot constitute a violation of the “no identifiable emissions” standard. The commenter recognizes the possibility of improperly operating a cover or CVS (*e.g.*, forgetting to close a thief hatch), but asks that EPA clearly differentiate these types of leaks from those described above. For these reasons, the commenter considers EPA’s application of the standard as a numerical emission limitation to not only be unachievable but also have a chilling effect on companies that aim to do voluntary leak surveillance, and disincentivize the use of more sensitive instruments. The commenter requests that EPA encourage and incentivize operators to conduct additional voluntary monitoring without the fear of an automatic violation if a leak is detected from a cover or CVS.

Lastly, commenter (2428-API) states that CAA section 111(h)(2) provides that a work practice standard should be prescribed in lieu of a standard of performance (*i.e.*, numeric emissions limitation) when “a pollutant or pollutants cannot be emitted through a conveyance designed and constructed to emit or capture such pollutant.” The commenter contends that this is precisely the case with EPA’s proposed NIE standards. The NIE standards do not apply to emissions from the storage vessel or equipment to which the CVS is installed. Rather, the proposed NIE standard applies to the CVS itself. In this case, the commenter maintains that it is obvious that there is no “conveyance” through which the regulated pollutants would be emitted or captured. To accomplish such an outcome, the CVS to which the NIE standard applies would have to be enclosed within another CVS or similar permanent total enclosure for the regulated emissions to be captured for subsequent control or venting. According to the commenter, requiring such a system would be inordinately costly, highly impracticable, and likely impossible. The commenter points out that this is precisely why LDAR standards have been expressed from the inception of such programs almost exclusively as work practice standards. The commenter concludes that the NIE standard cannot be effectively construed as a zero-emissions standard, as

EPA proposes, because no “conveyance” exists that allows for capture of the regulated emissions and application of such a standard to an emissions point.

Response II-16-3: See discussion in section XI.K. of the preamble to the final rule which details EPA’s final standards for covers and closed vent systems, including “no identifiable emissions.”

## **16.4 Leak Repair Timeline**

Comment: Commenters (2403-PAO, 2428-API) recommend EPA extend the first repair attempt timeline. Commenter (2403-PAO) considers 5 days for a first attempt of repair to be infeasible for technical and safety considerations. Commenter (2428-API) recommends an extension to streamline requirements across fugitive emissions requirements in consideration of the broader reach under NSPS OOOOb and EG OOOOc than under NSPS OOOO and OOOOa.

Commenter (2403-PAO) states that EPA is proposing that any leak detected would be subject to repair, with a first attempt at repair at 5 days and final repair within 30 days. The commenter notes that requiring the first attempt at repair within 5 days may be too short a time frame to obtain equipment or service companies to make the necessary repairs. They add that, if alternative monitoring technologies (*e.g.*, flyovers) are being used, it may take time to download information, review reports, and then prioritize emission findings. The commenter also states that a short repair time frame may disincentivize the use of alternative technologies. The commenter provides that any hydrogen sulfide at the site may also complicate being able to meet the first attempt of repairs within 5 days requirement. The commenter requests EPA change the first attempt at repair from 5 days to 10 business days.

Commenter (2428-API) reports that the 5-day timeline to implement the first repair attempt requirement will apply to significantly more sites under NSPS OOOOb and EG OOOOc than under NSPS OOOO and OOOOa. The commenter considers this requirement to be impractical for some sites that have access limitations such as those on leased farmland. While the commenter recognizes the historic importance and priority of repairing leaks on covers and CVSs, they believe that a longer timeline, such as 15 or 30 days, may be more pragmatic since the number of regulated covers and CVSs will increase significantly under NSPS OOOOb and EG OOOOc requirements. The commenter also notes that a different first repair attempt timeline could have the added benefit of making repair timelines consistent between fugitive emissions components and covers and CVSs, thus streamlining compliance for operators.

Response II-16-4: EPA is not providing for a longer first attempt at repair timeline, as the repair is a corrective action which must be undertaken as quickly as possible to ensure and demonstrate the associated/designated facility is in compliance with the 95 percent reduction standard. See also the discussion in section XI.K. of the preamble to the final rule which details EPA’s final standards for covers and closed vent systems, including “no identifiable emissions.”

Additionally, EPA disagrees that the first attempt at repair timeline disincentivizes the use of advanced methane detection technologies or that the timeframe conflicts with data processing of reports from periodic screening events. In 40 CFR 60.5398b and 5398c, EPA lays out a timeframe for conducting certain activities associated with periodic screening events. First, an

owner or operator must receive the results of the periodic screening event no later than 5 calendar days after the event takes place. Second, if there is a confirmed detection by the advanced methane detection technology, the owner or operator must conduct a ground-based inspection to determine the cause of the detection. For a cover or closed vent system, the first attempt at repair deadline is based on the date of the ground-based inspection, not the screening event. Therefore, this timeframe for first attempt at repair is the same, regardless of whether an owner or operator uses advanced methane detection technologies, OGI, or EPA Method 21, and as such, there is no disincentive created.

## 16.5 Monitoring Frequency

Comment: Commenter (2428-API) provides that CVSs have historically been subject only to initial and annual inspections due to their low leak rates. The commenter notes that CVSs rarely leak because of the small number of components and lack of constantly moving parts. The hard piping or ductwork in a CVS do not experience the same wear and tear and potential for leaks as moving parts that generate friction. The commenter contends that, while OGI does not have the same proximity challenges as EPA Method 21, more frequent monitoring of CVSs would still be impractical for both methods as parts of CVSs are considered difficult to monitor. The commenter maintains that more frequent inspections for CVSs at gas plants under NSPS OOOOb and EG OOOOc would also be more stringent than the requirements for refineries and chemical plants. Therefore, the commenter recommends that for CVSs, hard piping be subject to an initial EPA Method 21 or OGI inspection and annual AVO inspections and ductwork be subject to an initial EPA Method 21 or OGI inspection and annual EPA Method 21 or OGI inspections. The commenter asserts that, if EPA decides to finalize the increased monitoring frequency for CVSs, they must provide additional justification including the additional environmental benefits expected from more frequent monitoring of equipment that rarely leak.

Response II-16-5: In this final rule, EPA is finalizing that inspections of the CVS must occur at the same frequency as inspections under the fugitives' program (or for CVS located at onshore natural gas processing plants, at the same frequency as the required monitoring). As explained in the December 2022 Supplemental Proposal, routine inspections are necessary to ensure compliance with the no identifiable emissions design and operational standards. It is most efficient and cost effective to monitor the CVS at the same frequency and according the same methodology for other fugitive or equipment leak components, since monitoring personnel will already be on-site.

While the inspection frequency for CVS in NSPS OOOOb and EG OOOOc is greater than for CVS in other sectors, EPA notes that in addition to EPA Method 21, we are allowing OGI and advanced methane detection technologies to be used for conducting continuous compliance monitoring of CVS in this rulemaking, unlike in other sectors. This allows the CVS to be monitored more quickly, and as such, it is not expected that an increase in the frequency of inspection will increase the burden of inspections.

## **16.6 Regulatory Text Citation**

Comment: Commenter (2428-API) suggests that the following citation be checked for correct cross referencing: 40 CFR 60.5420b(c)(12).

Response II-16-6: The cross-referencing has been corrected in the final rule.

## Chapter 17. Control Devices

### 17.1 All Combustion Control Devices

#### 17.1.1 Continuous Burning Pilot

Comment: Commenters (2298-Pioneer, 2326-AXPC, 2428-API) suggests that EPA allow use of an automatic ignition device in lieu of a continuous burning pilot.

Commenter (2428-API) states that a continuous pilot flame requires propane or other supplemental fuel at sites without fuel gas. For sites with sour gas, the commenter explains, a continuous pilot flame requires either using the sour gas as the pilot or bringing in propane or other supplemental fuel to supply the pilot. Burning propane or other supplemental fuel is costly and generates additional emissions when no vent streams are sent to the control device, state both commenters. Similarly, burning sour gas generates additional emissions including SO<sub>2</sub> and potentially uncombusted H<sub>2</sub>S, states. The commenter explains that some state rules, such as New Mexico<sup>1</sup> and Texas<sup>2</sup>, allow for the use of an automatic ignition system with a flame monitoring device in lieu of a continuous pilot flame and suggests the following edit to the regulatory text (suggested additions are underlined):

40 CFR 60.5412b(a)(3)(iv): You must install and operate a continuous burning pilot flame or automatic ignition system.

Commenter (2218-TCEQ) supports the continued use of 40 CFR 60.18 requirements and monitoring to demonstrate 98 percent destruction efficiency for flares and vendor information for other control devices. The commenter notes that their own authorization mechanisms for flares closely match 40 CFR 60.18 requirements and allow for the use of an automatic pilot. The commenter recommends that the EPA allow the use of an automatic pilot as an option for non-pressure-assisted flares. The commenter adds that many remote sites only have field gas as an option to use in a continuous pilot; field gas may have a high concentration of hydrogen sulfide, so using a continuous pilot in these situations may lead to increased emissions of hydrogen sulfide and sulfur dioxide, warns the commenter. In addition, the commenter provides that the remoteness of and lack of electricity for some sites may present logistical barriers complicating or preventing the implementation of continuous monitoring.

Response II-17-1: As we explained in the Response to Public Comments documents for the August 23, 2011 proposed rule<sup>3</sup> and September 18, 2015 proposed rule<sup>4</sup>, we maintain our position that without a continuous pilot flame, there may be periods of uncontrolled emissions. We also note that the General Provisions for 40 CFR part 60 rules require flares to be operated with a flame present at all times in §60.18(b)(2). There is not sufficient data currently to suggest that electronic ignition systems on combustion devices are capable of continuously supplying a constant source of ignition adequate to keep a flame present on a continuous basis, especially considering the fact that unlit

flares are a major issue within the oil and gas sector. EPA also does not have sufficient information on the degradation of electronic ignition systems or how to ensure these systems maintain functionality over time. Additionally, operating a flare with a continuously lit pilot adds an additional degree of flame stability to the flare itself.

We note that the final rule specifies the use of a continuous burning pilot flame. Electronic igniters do not meet this provision. Although an electronic ignition device does not qualify as a continuous burning pilot flame, it may be used, for example, as a means of re-lighting a pilot flame that has been extinguished by wind or other factor, as long as a continuous burning pilot flame is maintained when vapors can be routed to the combustion device.

Comment: Commenters (2298-Pioneer, 2326-AXPC) request that EPA clarify that operation of a continuous burning pilot is required only when vapors are vented to the control device and should allow use of an automatic ignition device in lieu of a continuous burning pilot.

Commenter (2326-AXPC) explains that the proposed enclosed combustion device (ECD) requirements require operators to ensure flow to the control device is at or above the control device's minimum inlet gas flow rate, and to ensure compliance with this requirement, operators may install a, "backpressure preventer" at the control device inlet to prevent flow to the device that is below the device's minimum inlet flow rate. Where operators use this configuration, the commenter understands the rule would require operation of a continuous burning pilot during times when no vapors are vented to the control device. The commenter explains that for low or intermittent vapor control streams, the "backpressure preventer" may remain closed for much of the time while pressure builds up to ensure requisite inlet vapor flow rate when the control valve opens. The commenter is concerned that in this scenario, the result is that much of the continuous burning pilot's operation may occur when vapors are not vented to the control device, creating an environmental disbenefit. While not required for flares, if an operator installed a control valve at the inlet to the flare, it could similarly monitor when vent gas is going to the flare for combustion, states the commenter.

Commenter (2326-AXPC) proposes that EPA clarify operation of a continuous burning pilot is required only when vapors are routed to the control device. Further, the commenter requests that EPA allow operators to use an automatic ignition device in lieu of a continuous burning pilot, which would avoid unnecessary combustion altogether, as use of an automatic ignition device would ensure combustion occurs when vapors are routed to the control device. Where an operator chooses to operate a continuous burning pilot or automatic ignition device only when vapors are vented to the control device, the commenter proposes the operator would monitor the inlet valve of the control device to demonstrate that the control device was operated with a continuous burning pilot or automatic ignition device when the inlet control valve is open and allowing the passage of vapors to the control device.

Response II-17-2: The commenters did not provide enough clarification on how the requirement for a continuously lit pilot flame can be tied to the backpressure valve while ensuring the flame will be lit when vapors are sent to the control device. While EPA understands the control system could trigger an electronic ignition system to light the combustion device tip when the backpressure valve opens, EPA does not have sufficient information to show that the tip will be lit, with a flame present, by the time the gas travels from the backpressure valve to the flame

zone. Additionally, because a continuously lit pilot adds an additional degree of flame stability to the combustion device, EPA does not sufficient information on whether the sporadic lighting of the combustion device tip would lead to flame instability, and by extension, poor combustion.

Comment: Commenter (2305-Williams) suggests that EPA adopt a 15-minute interval (instead of 5 minutes) as a reasonable period for confirming the presence of a pilot flame in 40 CFR 60.5417b(e)(3).

Response II-17-3: EPA disagrees with the commenter. As discussed in the December 2022 Supplemental Proposal, the 5-minute requirement is in keeping with the requirements of the General Provisions to require a continuous pilot flame. EPA specified a more frequent monitoring interval for the pilot lights than for other continuous parameter monitoring systems because the destruction efficiency will rapidly fall to zero in the absence of a pilot or combustion flame. Therefore, we determined that more frequent readings were needed for the pilot flame monitoring system to ensure the flare or enclosed combustion device achieves 95 percent control at all times.

Comment: Commenter (2254-PBPA) notes EPA has proposed that all flares and ECDs have a continuous pilot flame.<sup>5</sup> But EPA should also allow for auto-ignitors that have flame detection features. Otherwise, operators would be required to supply large amounts of propane to establish a continuous pilot or have a sour gas pilot at sour gas facilities.

Response II-17-4: See response II-17-1, which responds to this issue.

### ***17.1.2 Performance Testing***

Comment: Commenters (2298-Pioneer, 2326-AXPC) request that EPA clarify that an operator need not startup a source for the sole purpose of performing testing or monitoring. The commenters note that requiring operators to startup up emissions sources to avoid missing a periodic testing event would result in emissions that would otherwise not occur, which is counterproductive to the emissions reduction goals of the supplemental proposal, states the commenter. The commenters suggest that EPA should provide operators with a reasonable amount of time following the affected/designated source's return to service to perform testing (that became due while the source was out of service) – e.g., 30 days.

Response II-17-5: EPA agrees that operators should not be required to start up a control device for the sole purpose of testing it. We have added text to the final rule to allow control devices to be tested 30 days after returning to service if they are not operational at the time that a performance test is due.

Comment: Commenter (2399-GPA) expresses that EPA should ensure it understands and considers technical difficulties in testing existing storage vessel controls. The commenter explains that many of the closed vent systems do not have testing ports to accommodate monitoring, nor were these existing systems ever required certification by a qualified individual or professional engineer regarding maximum or minimum instantaneous flow rates. The

---

<sup>5</sup> Id. at 74,795.

commenter is further concerned that testing these systems would involve significant technical difficulties as tank systems do not typically provide a high volume, continuous flow, and even where flow may be at high volumes, those periods tend to be sporadic, rare, and for very brief periods of time. EPA must clarify how control device testing at maximum flow rate over the required three-hour period should be accomplished for storage vessels. The commenter states that their members have reported that they are not aware of how to easily simulate storage vessel vapor composition for a continuous three-hour period.

Response II-17-6: Existing facilities that will be regulated under EG OOOOc have three years from the deadline for state plan submittals (which is 24 months after publication of EG OOOOc) to achieve compliance with the proposed provisions. This will give owners and operators time to conduct engineering analyses, if necessary, and to add ports to stacks. As noted in section XI.H.1 of the preamble to the final rule, EPA is finalizing an outlet concentration that can be used to demonstrate compliance in lieu of inlet and outlet testing. This will minimize the issue of needing inlet ports on control devices, which may be more difficult to install than stack ports.

In cases where low flow conditions make three one-hour test runs challenging, delegated authorities have the ability to approve reduced sampling periods. This should be done on a site-specific basis, as the circumstances creating the need for the reduced sampling are specific to each site. The owner or operator should work with the delegated authority to demonstrate the length of test run that can be performed and how the test runs will be representative of normal operating conditions for the control device.

### ***17.1.3 Monitoring - Method 22***

Comment: Commenters (2248-NDPC, 2298-Pioneer, 2326-AXPC, 2428-API) propose less frequent monitoring for visible emissions from combustion control devices. Commenters (2298-Pioneer, 2248-NDPC, 2326-AXPC) propose that as an alternative to the 15-minute Method 22 performance test, operators could evaluate and document whether the control device is smoking or not smoking at least once per week, and if the operator observes smoke emanating from a control device, they will either assume it is smoking and take corrective action or will complete a Method 22 observation within 12 hours to determine if visible emissions are occurring. Commenter (2428-API) suggests that a monthly smoking check should be the primary monitoring method for visible emissions from flares and enclosed combustion devices. Commenter (2326-AXPC) proposes to require the completion of at least one Method 22 test in each semiannual period.

Commenter (2326-AXPC) estimates each 15-minute Method 22 test will require 0.5 hours to 3 hours to complete, which includes travel time, set up time, the observation period, documentation of the procedure, document quality review, organization, and filing for reporting. The commenter anticipates most Method 22 tests will find no visible emissions, meaning operators may spend thousands, if not millions, of hours observing properly operating control devices. The commenter proposes that requiring weekly control device observation, ensures frequent control device evaluation and focus efforts where visible emissions might be occurring – *i.e.*, when the operator observes smoke from a control device. The commenter reports that their operators' experience is that a combustion device will smoke frequently or continuously if the

device will not pass a Method 22 test, meaning the operator is likely to observe smoke from a control device with visible emissions while on location, which would require conducting a Method 22 test under the commenter's proposal.

Commenter (2326-AXPC) recommends that EPA require operators conduct a Method 22 test within 24 hours of smoke observation, rather than contemporaneous with smoke observation, as the personnel that most often visits an oil and gas location may not have sufficient training or expertise to conduct a Method 22 test, but 12 hours provides operators sufficient time to mobilize personnel trained in Method 22 testing.

Commenter (2326-AXPC) requests that, if EPA does not adopt their suggested proposal, EPA reduce the minimum spacing between consecutive Method 22 tests from 15 days to seven (7) days. The commenter believes that the requirement to conduct a Method 22 test approximately every 30 days (assuming a 30-day month), but no more frequently than every 15 days is an overly burdensome administrative requirement, as operators would have a small window to schedule Method 22 tests for potentially thousands of control devices, explains the commenter. The commenter adds that providing for tests no more frequently than every 7 days would significantly reduce this administrative burden while ensuring sufficient operational periods between tests to evaluate control device performance over potentially varying operational conditions, to the extent variability exists.

Commenter (3818-AXPC) recommends that operators be allowed to first evaluate and document whether the control device is smoking or not smoking at least once per week, and if the operator observes smoke, a Method 22 test will be completed within 12 hours to determine if visible emissions are occurring. Further, they propose to complete at least one Method 22 test in each semiannual period.

Commenter (2298-Pioneer) believes that Method 22 opacity tests by trained personnel on a scheduled monthly basis are unnecessary and overly burdensome. They explain that smoking flares, although rare, are easily identified by operations personnel during site visits and, when discovered, are immediately investigated, stopped if safe to do so, and repaired within reasonable timeframes to return the well(s) to production.

Commenter (2428-API) suggests that a monthly smoking check should be the primary monitoring method for visible emissions from flares and enclosed combustion devices. The commenter is concerned that the thousands of flares and enclosed combustion devices will be subject to proposed monthly Method 22 observations and associated recordkeeping. The commenter states that with each of these observations, requiring 15 minutes and detailed records to document that the observation was conducted according to Method 22, will add up to hundreds to thousands of hours each month and thousands to tens of thousands of hours per year with no added environmental benefit if the device is operating properly. The commenter believes that compliance can more easily be monitored using a monthly smoking check with a record documenting the time of the observation and whether the control device is observed to be smoking. If the device is observed to be smoking, then operator would be able to either 1) assume the device failed the visible emissions requirement and immediately take corrective actions, or 2) conduct the 15-minute Method 22 observation to determine whether the device

meets the visible emissions requirement, suggests the commenter. A monthly smoking check could reduce the time required to monitor the device by more than 90 percent, and this saved time could be used for other tasks with greater environmental benefit (e.g., conducting a required audio, visual and olfactory (AVO) and/or optical gas imaging (OGI) survey while at the site), explains the commenter.

Response II-17-7: EPA disagrees with the suggestions raised by commenters. EPA Method 22 is a method for the visual determination of emissions, not opacity. It is essentially the same as the smoke/no smoke check requested by the commenters. Observers do not need to be certified to perform EPA Method 22; they only need to be trained and knowledgeable about correct observation technique, such as where to stand to perform a suitable observation. EPA Method 22 also requires minimal documentation of less than a page of information.

By suggesting that the follow-up to a failed smoke/no smoke check is a full EPA Method 22 test and not necessarily action to stop the flare from smoking, the comments imply that a smoking flare may not always be a sustained issue but may be intermittent. Therefore, it is prudent that EPA retain a minimum 15-minute observation period for visible emissions observations, to ensure that intermittent smoking situations are identified.

EPA also disagrees that the timeframe for conducting visible emissions observations needs to be revised. EPA has already provided flexibility on when monthly visible emissions observations must be performed. By further reducing the timeframe between observations to only 7 days, this could mean that a site could go almost 2 months before the next visible emissions observation, which is an unreasonably long time. Commenters have already indicated that operators will be onsite weekly, and as such, there is no need to increase the period between visible emissions observations. We also remind commenters that owners and operators have a duty to maintain and operate any affected facility including associated air pollution control equipment in a manner consistent with good air pollution control practice for minimizing emissions. If an operator sees a smoking flare at a time other than during a scheduled EPA Method 22 observation, the operator should take steps to reduce visible emissions from the flare.

Comment: Commenters (2248-NDPC, 2298-Pioneer) state that they typically utilize flares and ECDs for backup purposes only; therefore, performing an opacity measurement on a scheduled basis is difficult since control devices are not always receiving a steady, continuous gas flow from affected sources. Commenter (2248-NDPC) explains that they would have to divert gas from the gathering system to make the control device operational for the inspection unless the EPA provided an exception for the monthly inspection for that control device that is only used as backup and at the time of the inspection was not operational.

Response II-17-8: EPA agrees that operators should not be required to start up a control device for the sole purpose of performing visible emissions observations, nor should the operator divert gas from the gathering system to make the control device operational. But gas may still flow or leak to a flare, even when the flare is not operational. Visible emission monitoring is necessary any time that gas may be flowing or leaking to the flare and efficient combustion is needed. For operational control devices, EPA Method 22 observation is only required once every month; at most sites, operators are present at least weekly, which will provide operators with multiple

opportunities to conduct the Method 22 observation. Additionally, as discussed in section XI.H.3 of the preamble to the final rule, EPA has provided an option for owners and operators to use video surveillance cameras in lieu of EPA Method 22 observations, which could help to resolve issues around monitoring control devices that operate sporadically.

Comment: Commenter (2362-EIP et al) states that monthly Method 22 inspections of 15 minutes each cannot ensure compliance with the continuously applicable limit (i.e., no visible emissions from flares and other combustion devices, except for periods not to exceed 1 minute during any 15-minute period). Conducting observations for only 15 minutes once per month would fail to detect visible emissions exceedances in the 30-plus days between tests. Further, the commenter explains that Method 22 observations cannot be conducted at night or under weather conditions (e.g., dark clouds) that make it difficult to detect visible emissions through visible observation. The commenter suggests that EPA's failure to consider these problems renders its proposed monitoring for visible emissions arbitrary and capricious and these problems with EPA's proposed monitoring also mean that the visible emissions requirement does not reflect the best system of emission reduction (BSER). To remedy these problems and ensure continuous compliance with the visible emissions limit for flares and other combustion devices, the commenter suggests that EPA must require video surveillance of all flares and other devices, with infrared (or some other means) to detect visible emissions after dark.

Response II-17-9: EPA disagrees with the commenter. There are many unmanned sites without electricity in the oil and natural gas source category. These types of sources do not have the infrastructure to conduct continuous surveillance of flares with cameras. However, we have added an option to the final rule to allow sources to install video cameras as an option in lieu of conducting visual emissions observations with EPA Method 22. Additionally, while EPA does not currently have a method for use of fixed infrared camera systems, we have also provided a pathway for use of this type of technology once EPA has approved it.

We have also added a requirement to the final rule for alert systems to notify the control room when a pilot light is no longer lit. We believe that this requirement will reduce the instances of inefficient flaring.

#### ***17.1.4 Other (non-Method 22) Monitoring and Alternatives to Monitoring***

Comment: Commenter (2433-EDF et al) generally supports the proposed control device requirements but suggests that EPA re-evaluate the exemptions to the flow rate requirement (i.e., an engineering assessment that the maximum gas flow rate cannot exceed the maximum flare tip velocity or installation of a backpressure preventer). Instead, the commenter suggests that EPA ensure, that in all circumstances, continuous monitoring of pilot light and flow rate occur. The commenter states that such monitoring also will allow operators to accurately report the amount of gas emitted while the flare is unlit, states the commenter.

Response II-17-10: EPA agrees with the commenter that a pilot light should remain lit any time there is the potential for gas to be routed to a combustion control device. See additional responses in section 17.1.1 of this Chapter.

While EPA has revisited and made some revisions to the flow rate monitoring exemptions in the final rule, EPA disagrees that continuous flow monitoring is necessary if the owner or operator can demonstrate that it is impossible to exceed the enclosed combustion device's maximum flow rate or a flow rate of 60 feet per second for flares. EPA concurs that this demonstration should be robust, and we have also added language to require the demonstration to be updated whenever there are changes to the process or control device that would be expected to affect the maximum flow rate to the control device.

Comment: Commenter (2333-LongPath) believes that continuous monitoring with proven capability to identify unlit and malfunctioning combustion devices (e.g., reduced combustion efficiency) should be an allowable monitoring requirement. The commenter points out that even storage vessel affected facilities with advanced controls and equipment monitoring can malfunction or drift off of optimal set points. The commenter believes that top-down monitoring with atmospheric continuous monitors, particularly those with the ability to quantify, can provide extremely valuable information to operators on combustion efficiency and malfunctions in real time, providing rapid and substantive emissions reductions. The commenter states that continuous monitors with the ability to quantify and with proven validity in identifying these types of malfunctions should be an allowable monitoring tool.

Response II-17-11: See discussion in section XI.H.6 of the preamble to the final rule which details EPA's final standards related to alternative approaches to combustion device monitoring.

Comment: Commenter (2428-API) suggests that the monitoring plan for control devices does not need to be site specific. The commenter explains that operators may install the same control device and associated monitoring system across sites in one or more company-defined areas. Similar to the fugitive monitoring plan requirement, the commenter believes EPA should allow monitoring plans for control devices to be based on a company-defined area or a company-wide plan for a specific make and model of control device. Similar to fugitive monitoring techniques, control device monitoring is based on the type of control device and monitoring system rather than the site itself, explains the commenter. The commenter is concerned that requiring practically identical site-specific monitoring plans for the large number of control devices increases the administrative burden for operators with no environmental benefit.

Response II-17-12: EPA agrees with the commenter and has incorporated the same terminology (company-defined area) for control device monitoring plans that is used for fugitive emissions monitoring plans.

Comment: Commenter (2362-EIP et al) states that with respect to the alternative to continuous flow monitoring, EPA must include requirements to reassess the engineering assessment when there are changes to the sources vented to the flare, such as when additional sources are routed to the control device, or those upstream sources change, because the flow rate could increase. The commenter states that failing to do so would likely mean that EPA's flare and control requirements do not reflect BSER and do not ensure proper destruction efficiencies. The commenter further states that EPA must also account for such situations to satisfy the requirement from 40 CFR 60.18(d) that the agency's proposed subparts include "provisions stating how owners or operators of flares shall monitor these control devices." With respect to

EPA's request for comment regarding situations where continuous monitoring of the vent gas flow rate is unnecessary, the commenter states that they are not aware of any such situations.

Response II-17-13: See section XI.H.2 of the preamble to the final rule for a discussion on the final requirements related to the engineering assessment requirements.

Comment: Commenters (2298-Pioneer, 2353-CrownQuest, 2399-GPA, 2428-API) have concerns about the requirements regarding the accuracy of flow monitoring devices. Commenter (2428-API) states that since EPA is proposing consistent control device monitoring requirements regardless of the affected facility controlled for both NSPS OOOOb and EG OOOOc, the number of control devices subject to flow monitoring requirements will increase significantly and with the increased number of control devices subject to flow monitoring requirements, the accuracy requirement for flow meters should be  $\pm 10$  percent of maximum expected flow. Historically, the commenter states, the flow monitoring accuracy requirement of  $\pm 2$  percent or better requirement only applied to manufacturer tested control devices for wet seal centrifugal compressors and was not required for control devices used to reduce emissions for other affected facilities under NSPS OOOO or NSPS OOOOa. The commenter explains that vent gases from centrifugal compressors have relatively stable flow rates while vent gas from storage vessels is intermittent, low pressure, low velocity / flow, and more difficult to measure.

Commenter (2428-API) states that the  $\pm 2$  percent accuracy requirement may not be technically feasible for most commercially available meters nor cost effective for control devices on every affected facility at well sites, central production facilities, compressor stations, and natural gas processing plants. Further, the availability and cost of meters are negatively affected by supply chain constraints and limited resources to install them, states the commenter. The commenter has previously commented<sup>6</sup> on the challenges with flow monitoring at upstream facilities. The commenter reports that this level of accuracy is also more stringent than the  $\pm 5$  percent accuracy requirement for flare vent gas flow rates at velocities above 1 foot per second under Maximum Achievable Control technology (MACT) standards finalized under 40 CFR 63 Subpart CC (Refinery MACT)<sup>7</sup>.

The commenter (2428-API) explains there are two types of commercially available flow meters that are commonly used: thermal dispersion meters or ultrasonic meters. Ultrasonic flow meters are the only identifiable meter that can achieve the  $\pm 2$  percent accuracy, but this accuracy may decrease under low-flow or low-pressure conditions, states the commenter. While these meters are technically feasible to meet the proposed accuracy requirement, they may not be economically reasonable with an estimated cost of \$20,000 to \$30,000 each, states the commenter. The commenter cites to EPA's cost analysis for storage vessels controls<sup>8</sup>, and states the cost of a flare with monitoring equipment was estimated but was not used in the subsequent BSER analysis for new or existing sites. Therefore, the commenter explains, EPA did not fully consider the cost-effectiveness of the proposed monitoring requirements for control devices. The

<sup>6</sup> API's December 4, 2015, comments on the proposed NSPS OOOOa and January 31, 2022, comments on the proposed NSPSs OOOOb and EG OOOOc.

<sup>7</sup> 40 CFR 63 Subpart CC Table 13.

<sup>8</sup> EPA-HQ-OAR-2021-0317-0039, "StTanks\_Control\_Costs\_v5.1.xlsx" and "EPA\_Flares\_Calc\_Sheet\_MP1plusmonitors.xlsx".

commenter states that thermal dispersion flow meters are less expensive but may not meet the accuracy requirement with a typical accuracy of  $\pm 5$  percent or better at high flows (accuracy decreases at pressures less than 25 pounds per square inch gauge (psig)). The commenter also is concerned that the lower pressure and variable flow rates from certain affected facilities such as storage vessels also make the accuracy requirement difficult to meet. By way of example, the commenter states that if a control device is used for controlling atmospheric storage tanks only, it will be operating at less than 25 psig and so even a  $\pm 5$  percent accuracy may be difficult to achieve; therefore, the flow meter accuracy requirement must consider this likely scenario. In colder conditions, like those experienced in North Dakota and other states, the commenter states that the liquid drop out caused by condensation can also reduce the accuracy of flow meters and make an accuracy of  $\pm 2$  percent technically infeasible. Therefore, the commenter requests that the accuracy for control device inlet flow rate be increased to  $\pm 10$  percent of maximum expected flow.

Commenter (2298-Pioneer) states that due to the variability of upstream oil and gas production, continuous parametric monitoring requirements are difficult, if not impossible, to always meet, as the current flow meter technology does not allow accurate flow measurements for intermittent or low flow gas streams as seen in these operations. The commenter explains that differing gas stream compositions make calibration of flow meters difficult, resulting in accuracy issues. The commenter adds they use advanced process simulation software to ensure all flow rates are within design parameters for proper control device destruction efficiency. While the commenter agrees with the potential exemptions available for this continuous monitoring, the commenter proposes EPA exempt flow monitoring for control devices used to control affected facilities with intermittent or low flow gas streams under this rule.

Commenters (2254-PBPA, 2353-CrownQuest) state that commercially available flow meters that meet the required accuracy are either thermal dispersion or ultrasonic. The commenter reports that measuring the flow in closed vent system causes two distinct problematic issues. The normal volumes from working and standing losses and the flashing of separator liquids are at very low velocities that are hard to measure with current measurement technology, explains the commenter. Measuring the flow of flash vapors and peak flow rates would require a device that can go from zero flow to maximum flow in milliseconds and go back to zero just as quickly.

Commenters (2254-PBPA, 2353-CrownQuest) believe that the hysteresis (i.e., the amount that the previous state impacts the future state) and the latency (i.e., the time required to return to steady flow after a transient) of the best commercial measurement devices available today are inadequate for millisecond-scale transients. Currently, for mineral accounting purposes, the commenter provides that the Federal Government and states do not require flow measurement for liquids but only gaging or strapping of the tank because of the lack of adequate measurement technology. Furthermore, ultrasonic meters can be upwards of \$30,000 each, states the commenters and the cost could reach hundreds of millions of dollars in meters for operators across the country, which is not cost-effective and not a BSER.

Commenter (2399-GPA) states that the purpose of the monitoring equipment that would be installed under the supplemental proposal is to monitor general information and ensure complete combustion; the equipment is not being used for complex calculations or controls that would be

required by other rules such as Refinery MACT Subpart CC or the Ethylene MACT. The commenter believes the proposed NSPS OOOOb and EG OOOOc requirements would allow for a very large operating window under normal operations for most midstream control devices and further, the midstream industry uses individual control devices for certain equipment, such as a device only for storage vessels. This means that many control devices see limited flow during a typical year, explains the commenter. The commenter is concerned that despite this, the supplemental proposal would require that flow meters be accurate up to 2 percent at maximum flow rates. In most cases, such accuracy could only be achieved with an optical meter or an ultrasonic flow meter, explains the commenter, at a typical cost of about \$30,000 for basic models. The commenter believes there is no evidence in the record, based on the NSPS OOOOb and EG OOOOc requirements, that these precise and expensive flow meters will provide any benefits over less costly flow meters. As with many other types of flow meters, these also struggle with accuracy at lower flow rates such as when the device is only controlling breathing losses from tanks or pressure safety valve discharges at gas plants, points out the commenter. As a result of these operating issues, even the most accurate flow meters will lose some accuracy, states the commenter. The commenter notes that accuracy at lower rates can increase with additional flow meter monitoring devices installed in tandem with the basic ultrasonic meter, however, this significantly increases the overall cost of this monitoring equipment. The commenter would like to ensure that meters with an accuracy of up to 10 percent at maximum flows, such as thermal dispersion flow monitoring devices, can be used to show compliance with the proposed rule and an accuracy warranted by the instrument provider should be sufficient.

Response II-17-14: EPA agrees with commenters that only specific flowmeters will have an accuracy within 2 percent. In order to broaden the range of flowmeters that can be used on combustion control devices in NSPS OOOOb and EG OOOOC, recognizing the larger universe of control devices that will need to be monitored, and to relieve the challenges of monitoring flow to these devices, EPA is changing the accuracy requirement for flowmeters on combustion control devices to plus or minus 10 percent of the maximum expected flow rate. This change should still provide adequate compliance assurance for these devices while providing owners and operators with more flexibility to conduct monitoring.

Comment: Commenter (2403-PAO) requests that EPA include the following in the final rule:

1. An exception for low emitting or intermittent gas producing facilities to utilize automatic ignition systems and/or a pit flare if a continuous burning pilot and a 95 percent efficient flare or combustion device is technically infeasible due to consistently low or intermittent flow and/or would require additional purchased gas as determined by an in-house engineer.
2. An exception for shut-in facilities such that flares and/or combustors are not required to be operated when the associated wells are not producing or when liquid is not flowing to the associated tanks.
3. A provision for operators to use engineering methods to establish a “model” piece of equipment and apply the test results elsewhere under like conditions, flow, net heating value (NHV), etc., instead of conducting tests on each combustion device as determined by an in-house engineer.

4. A provision for a lower destruction efficiency of 93 percent to be recognized during temporary reductions of flow that cause vapor flow to a flare or combustor to fall under the minimum required flow for demonstrating 95 percent reduction.

Commenter (2403-PAO) explains that for older wells and facilities with low or intermittent vapor flow to a flare or combustor, there often is not enough gas produced by the well to keep a pilot continuously lit or to produce enough tip velocity to meet the flow rate requirements and promote the mixing of gas and air necessary to achieve 95 percent destruction efficiency in a flare or combustor. For this reason, the commenter explains that many states have provisions for using automatic ignition systems that spark every few seconds to ensure a flame is initiated when gas is present, and/or pit flares for low emitting facilities. If a continuous burning pilot were required for such a site, it would be necessary to purchase additional natural gas, propane, or butane to maintain the pilot at all times, regardless of whether gas was being sent to the flare or enclosed combustion device, explains the commenter. The commenter states this would unnecessarily create more emissions than an equivalent flare with an automatic ignition system, and often the additional emissions from the continuous flame would exceed the emissions of a less efficient combustion system that only combusted when gas was present.

Commenter (2403-PAO) also points out that when wells are shut-in, tank emissions are reduced to breathing emissions which are very minimal and often there is not enough flow to the flare or control device to prevent flashback and an explosion, which create greater environmental and safety impacts than the minimal breathing emissions. After multiple tank fires in North Dakota, the commenter states that the North Dakota Department of Environmental Quality (NDDEQ) acknowledged this risk and issued guidance that allows for tank vapor flares and control devices to be bypassed when a well is shut in to minimize the risk. In these cases, the hatches may need to be left open to relieve breathing pressure due to temperature fluctuations throughout the day, explains the commenter. Further, the commenter states it is common to isolate a tank that needs repair, empty the tank, and leave the hatch open to vent vapors to allow for repair, which can take several days. Finally, the commenter adds that if a vapor recover unit and flare are not required at a facility, then tank emissions are understood to be vented to atmosphere in their entirety, regardless of whether the emissions occur from tank vents, openings, conservation vent valves, pressure relief valves, or a thief hatch.

Commenter (2403-The PAO) states that low pressure vapor flow monitoring is very difficult and expensive to accurately and consistently measure and will lead to wells being shut in before their associated reservoirs are depleted. Further, the commenter adds that the supplemental rule is not clear on whether each device would require a test. The commenter believes that operators should be able to use engineering methods to establish a “model” piece of equipment and apply the test results elsewhere under like conditions, flow, British thermal unit (Btu), etc., instead of conducting tests on each combustion device, and suggests that this would reduce unnecessary costs on operators.

Finally, commenter (2403-PAO) points out that it is possible for a higher producing facility to temporarily decrease production such that the minimum flow rate to a combustor or flare are temporarily not met. The commenter explains this is especially true when a facility is being shut in or started up. In such a condition, if a flare or combustor has a flame, then it is burning vapors,

and a temporary low flow condition should not be considered a violation if its temporarily not possible to meet a minimum flow rate requirement, states the commenter. The commenter states that Texas recognizes this and has provisions in its highly reactive (HR) volatile organic compounds (VOC) (HRVOC) control program for a flare which temporarily does not meet the conditions of 40 CFR 60.18 to be calculated as having a 93 percent destruction efficiency, based on observations from the 2010 Texas Commission on Environmental Quality (TCEQ) Flare Study<sup>9</sup>. According to the commenter, without such a provision, they are concerned that an operator would be forced to choose between 95 percent and zero percent destruction for short-term periods of low flow, neither of which is correct.

Response II-17-15: See response II-17-1, which addresses the issue of continuous pilot flames.

With respect to storage vessels that are connected to wells that are shut in, EPA refers the commenter to §60.5395b(c), which contains the requirements for storage vessel affected facilities that are removed from service or returned to service. A storage vessel is not an affected facility under NSPS OOOOb for the period that it is removed from service, provided that the operator follows the procedures and reporting under that section. Tanks that are not currently in service do not require owners and operators to meet control standards. Additionally, tanks that are used intermittently may not meet the definition of an affected source under NSPS OOOOb or EG OOOOc.

See Response II-17-14, which addresses the issue of flow measurement accuracy. Additionally, NSPS OOOOb and EG OOOOc allow for pressure monitors in lieu of flow monitors, which can resolve some of the issues with monitoring low flow streams. NSPS OOOOb and EG OOOOc also provide an exemption from continuous flow monitoring if the owner or operator installs a backpressure regulator valve and conducts an engineering analysis to show that the unit will operate below the maximum established flowrate.

NSPS OOOOb and EG OOOOc do include provisions for use of manufacturer tested enclosed combustion devices, which would be conducted in lieu of the initial test on these control devices. Additionally, some control devices, like condensers and carbon adsorbers, do not have to be tested, and owners and operators may use a design analysis instead. Similarly, flares are not required to be tested, but must demonstrate compliance with the requirements specified in the rule. Finally, §60.8(b) allows the delegated authority to approve shorter sampling times when necessitated by process variables and to waive performance tests if the owner or operator can demonstrate by other means, to the satisfaction of the Administrator, that the affected source is in compliance with the standard. Identical control devices with identical operating conditions could be a situation in some circumstances in which the delegated authority is satisfied that both control devices can meet the standard by only testing one control device. Finally, EPA notes that it has only specified a particular control efficiency, not a particular type of control device. Flares or other combustion devices may not make the most sense economically or from a control standpoint in all situations, particularly for control of low, intermittent flow streams.

---

<sup>9</sup> See [https://www.tceq.texas.gov/airquality/stationary-rules/stakeholder/flare\\_stakeholder.html](https://www.tceq.texas.gov/airquality/stationary-rules/stakeholder/flare_stakeholder.html).

The required BSER for various affected facilities in NSPS OOOOb and EG OOOOc is 95 percent control. As such, owners and operators must meet 95 percent control of emissions from affected or designated facilities subject to those standards at all times.

Comment: Commenter (2326-AXPC) requests that EPA confirm its intent to exempt properly designed facilities from the requirement to monitor control device inlet flow, if the operator designs its control system to prevent the possibility of inlet flow to a flare or ECD being outside of its design capacity range. The commenter further requests that EPA revise the inlet flow monitoring requirements for ECDs performance tested by the manufacturer to be consistent with the flow monitoring requirements for ECDs performance tested by the operator.

Response II-17-16: EPA confirms that the commenter's interpretation is correct. Additionally, EPA agrees that it is reasonable to require the same flow monitoring for all ECDs, whether they are tested by the operator or manufacturer. The final rule has been updated to align these requirements.

Comment: Commenter (2326-AXPC) suggests that EPA should allow operators to monitor control device inlet pressure in lieu of monitoring flow. The commenter explains that existing flow meter technology cannot accurately measure flows that are generally of low velocity with intermittently high velocity, and data obtained from a flow meter in this application will be inaccurate and misleading. By way of example, the commenter explains that gas flow from a typical storage vessel into a closed vent system (CVS) predominantly results from flashing vapors, which significantly outweigh the volume of working and standing emissions that occur between flashing events. The normal volumes from working and standing losses are typically at very low velocity, which is difficult to measure with current technology, whereas the volume associated with flashing vapors is typically higher, states the commenter. The commenter explains that measuring the flow of flash vapors and peak flow rates would require a device that can go from zero or very low flow to maximum flow in milliseconds and be able to go back to zero or very low just as quickly. The hysteresis (*i.e.*, the amount that the previous state impacts the future state) and the latency (*i.e.*, the time required to return to steady flow after a transient) of the very best commercial measurement devices available today are both inadequate for millisecond-scale transients, warns the commenter.

Commenter (2326-AXPC) also notes that differing gas composition may reduce the accuracy of flow meters, which are calibrated to a specific gas composition. The commenter anticipates that many of the oil and gas flares and ECDs will control storage vessels, and the composition of storage vessel gas varies depending on the conditions in the vessel. By way of example, the commenter explains that flash gas vapor has a different composition (more lighter end carbon chain hydrocarbons) than working and breathing emissions (more heavier end carbon chain hydrocarbons). Because of this variable gas composition, states the commenter, a flow meter installed to measure storage vessel vapor flow cannot be calibrated to accurately measure all types of storage vessel vapor flow. As an alternative, the commenter suggests that operators can install and operate a pressure monitor at the inlet to a combustion control device to demonstrate inlet flow to the control device is within the device's design range. The commenter's understanding is that pressure monitors are not plagued by the issues noted above for flow monitors and can achieve reasonably accurate measure of pressure more readily than flow

monitors can measure flow. Moreover, combustion control device manufacturers typically provide design capacity curves in terms of pressure, rather than flow, states the commenter, and pressure correlates directly to combustion control device performance and is an appropriate parameter to monitor for demonstrating proper operation of a control device.

This commenter (3818-L-AXPC) submitted a flow capacity curve with pressure on the x-axis and flow rate on the y-axis that presents a graphical representation of the relationship between the inlet pressure and the corresponding flow rate. The commenter notes that it helps illustrate how changes in pressure can impact the flow capacity and performance of the combustion device. The commenter adds that it is important to note that at low inlet pressure, the flow rate may be limited, resulting in lower flow capacity and potentially reduced combustion performance. As a result, and as they state is illustrated in the presented flow capacity curves, a defined minimum inlet pressure is established (1 oz/in<sup>2</sup> in this example) before a minimum flow rate can be provided. Based on the example flow capacity curve, the commenter believes that it can be concluded that minimum inlet pressure is actually more impactful to ensure the stated destruction efficiency than the minimum flow rate. Additionally, in order to verify an ECD is not operating below the minimum pressure, a valve is needed to restrict flow to the ECD before inlet pressure drops below what the manufacturer has established as the minimum inlet pressure. They add that the pressure monitoring used for the actuation of these valves can also be applied for inlet pressure monitoring to the ECD. In this scenario, they state that there is no need to install a meter to monitor flow rate as monitoring pressure and flow rate is repetitive and unnecessary. As such, the commenter proposes that if an operator can work with a manufacturer and document the corresponding operating pressures to meet their guaranteed destruction efficiency as demonstrated during the subject performance test, then pressure monitoring should be allowed.

The commenter (3818-L-AXPC) added that they have also learned that the current Colorado rule (Regulation 7) allows for use of pressure monitoring through submittal and approval of an “Alternative Technology and Infeasibility Request”. Further, on April 4th, 2023, Air Pollution Control District (APCD) proposed revisions to Regulation 7 to include allowance of Pressure Actuation Systems as a standard rather than an exemption. The Statement of Basis and Purpose submitted by the Division along with the proposed Regulation 7 revisions contains language explaining the purpose for adoption of the alternative to flow meters in rule language. The Division states: “The Commission adopted an acceptable alternative to flow meters, a pressure actuator system, for monitoring enclosed combustion devices to confirm that the enclosed combustion device is being operated appropriately. A pressure actuator system monitors pressure and provides an operator more control of their vapor control system to ensure it is operating within design parameters. This system was discussed as an alternative in 2021, but the concept was not clearly understood by the Division or operators at that time. The Division has since approved several proposals that use pressure actuator systems as an alternative to flow meters. The commenter recommends that this lesson learned on the benefits of using a pressure monitoring system be transferred to the current EPA rulemaking for controls regardless of whether it is manufacturer or owner tested as it is the more superior way to manage flow in these situations. The commenter also recommends that EPA reconsider the accuracy requirement of  $\pm 2$  percent or better in all cases.  $\pm 2$  percent is generally the standard for product going to sales and thus royalty and revenue generating. However, for control efficiency, they state that maintaining operating parameters in the desired range can be achieved by adjusted alarm points

to compensate for decreased accuracy making the  $\pm 2$  percent rate unnecessarily restrictive for this purpose. The requirement of  $\pm 2$  percent can only be achieved by a very limited set of metering technologies and may require operators to retrofit existing installations at significant cost with little or no discernible emissions reduction. In many cases it is not technically or commercially feasible to make these retrofits, these challenges only further compounded by present day supply chain restraints. In addition, in some operational scenarios the maximum expected flow rate may not be achieved, which therefore limits calibration and introduces inaccuracy at volumes outside the calibration range. To avoid these concerns, AXPC recommends that an accuracy requirement of  $\pm 5$  percent be allowable as this will encompass most metering technologies employed without sacrificing emission reduction. This recommended level of accuracy would then be consistent with the  $\pm 5\%$  accuracy requirement for flare vent gas flow rates at velocities above 1 feet per second under Maximum Achievable Control technology (MACT) standards finalized under 40 CFR 63 Subpart CC (RMACT).

Response II-17-17: See responses II-17-14, II-17-16, and II-17-21, which address the issues in this comment.

#### ***17.1.5 Regulatory Language and Clarifications***

Comment: Commenter (2399-GPA) appreciates EPA's intent to consolidate the proposed control device provisions into one section, but suggests the resulting regulatory text requires some further clarification to ensure end users fully understand all the requirements and do not unintentionally misunderstand monitoring and testing requirements. As a general matter, the commenter urges EPA to consider streamlining and reorganizing the regulatory text to improve clarity. As written, the commenter cautions that the proposed regulatory language is extremely complicated and difficult to follow. As an example, the commenter points to proposed 40 CFR 60.5417b which explains "[w]hat are the continuous monitoring requirements for my control device?" The commenter notes that this is an important section imposing binding obligations upon regulated owners and operators, however, the commenter is concerned with the layers of subsections (in this example, the commenter notes that the explanation of an owner or operator's obligations goes as far as 40 CFR 60.5417b(d)(1)(viii)(C)(1)). The commenter is further concerned about numerous cross-references to other sections and sub-sections, which they are afraid will make it easy for readers to become lost, confused, or misinterpret the regulation's intent. The commenter notes that for most of the commenter's members, engineers and technicians manage regulatory compliance, not sophisticated legal counsel. The commenter urges the agency that any finalized regulatory language should be in a more streamlined and simplified form, organized so that all the requirements for specific control devices may be found in one place, and written so that those subject to the rules can clearly understand them.

Response II-17-18: EPA acknowledges the commenter's concern. EPA has worked to streamline requirements in the final rule where possible.

Comment: To address commenter (2326-AXPC) suggestion that EPA allow operators to monitor control device inlet pressure in lieu of monitoring flow [see section 17.1.4 of this Chapter for support for their position], the commenter provides the following redline of 40 CFR 60.5417b(d)(vii)(A) and 60.5417c(d)(vii)(A) (underlined text indicates new text):

The continuous parameter monitoring system must measure gas flow rate or pressure at the inlet to the control device. The monitoring instrument must have an accuracy of  $\pm 2$  percent or better at the maximum expected flow rate. The flow rate or pressure at the inlet to the combustion device must be equal to or greater than the minimum flow rate or pressure and equal to or less than the maximum flow rate or pressure determined by the manufacturer.

Response II-17-19: In the final rule, EPA has aligned the monitoring requirements for all enclosed combustion devices, so the paragraph referenced by the commenter no longer exists. In the flow monitoring requirements for flares and enclosed combustion devices, the final rule clearly states that flow monitoring can be conducted with direct flow meters or other parameter monitoring systems such as inlet line pressure monitoring.

Comment: Commenter (2326-AXPC, 3818-L-AXPC) points out that in 40 CFR 60.5417(d)(1)(viii)(D)(2), EPA provides an alternative to control device inlet flow monitoring where the operator installs and operates “a backpressure preventer which is set to operate at or above the minimum inlet gas flow rate.” EPA does not, however, define the term “backpressure preventer,” and the commenter is not aware that such a device exists. However, the commenter believes EPA intends to mean a control valve installed at the inlet to a control device that is set to remain open when the inlet pressure to the control device is at or above the device’s minimum inlet gas flow rate. Accordingly, the commenter proposes that EPA revise 40 CFR 60.5417b(d)(viii)(D)(2) and 60.5417c(d)(viii)(D) (2) as follows (underlined text indicates new text and struck out text indicates deleted text):

If you install and operate a backpressure preventer control valve which is set to operate remain open only at or above the minimum pressure corresponding to the minimum inlet gas flow rate, you are exempt from continuously monitoring for minimum inlet gas flow rate.

Response II-17-20: EPA agrees with the commenter that the term “backpressure preventer” requires clarification but does not agree that “control valve” is the appropriate term. Control valves are generally understood to actuate based on a signal from a monitor, such as a flow monitor or pressure monitor. For the flow monitoring exemption to apply, the installed valve must operate without reliance on such a monitor. Accordingly, EPA is replacing the term “backpressure preventer” in the final rule with “backpressure regulator valve” and further explains that it must be calibrated to open at the minimum pressure set point corresponding to the minimum inlet gas flow rate. By adopting the term “backpressure regulator valve” and additional requirements for the valve set point, EPA is clarifying that the exemption applies only upon the installation, calibration, maintenance, and operation of a valve that does not rely on a monitor.

Comment: Commenter (2399-GPA) notes that while 40 CFR 60.5417b(d)(viii)(D) and 60.5417c(d)(viii)(D) allow for the use of “other parameter monitoring systems combined with engineering calculations,” they do not believe it is clear whether EPA intends to allow the use of a pressure monitor. The commenter notes that because combustion control device performance directly corresponds to the device’s operating pressure, no further engineering calculation is necessary. Accordingly, the commenter proposes that EPA allow operators to monitor inlet

pressure to a combustion control device to demonstrate the device is operating within its design capacity without further engineering calculation, or clarify that 40 CFR 60.5417b(d)(vii)(A), (d)(viii)(D) and 60.5417c(d)(vii)(A), (d)(viii)(D) allow the use of a pressure monitor in lieu of a flow monitor for all applicable control devices (whether manufacturer or owner tested).

Consistent with this request, the commenter (2399-GPA) provides the following redline of 40 CFR 60.5417b(d)(viii)(D) and 60.5417c(d)(viii)(D) (underlined text indicates new text):

You may use direct flow meters, direct pressure monitors, or other operating parameter monitoring systems combined with engineering calculations, such as line pressure and burner nozzle dimensions, to satisfy this requirement.

Another commenter (3818-AXPC) provides the following suggestion for §§60.5417b(d)(viii)(D) and 60.5417c(d)(viii)(D) (underlined text indicates new text):

You may use direct flow meters, monitoring of the pressure of the vapor control system, or other operating parameter monitoring systems combined with engineering calculations, such as line pressure and burner nozzle dimensions, to satisfy this requirement.

Response II-17-21: EPA disagrees with the suggested changes. We also disagree that no calculations are necessary to determine flow from pressure readings. Because the parameter that is being monitored is flow, engineering calculations are necessary to convert the pressure reading to a flow reading. Often this is easily accomplished through flow curves. As such, we have finalized, as proposed, an allowance for owners and operators to use pressure monitoring systems in lieu of direct flow monitoring; this requirement applies to all combustion devices, whether they are tested by the manufacturer or the owner or operator.

Comment: Commenter (2428-API) requests clarification on the proposed requirement language around the presence of pilot flames. The commenter notes that the proposed requirements for control device pilot flames use the following three phrases, each of which could suggest a different meaning:

- A “continuous burning pilot flame” means a pilot flame is required at all times regardless of whether the site is operating, or vent gas is sent to the control device.
- A “pilot flame present at all times of operation” could mean either a pilot flame is required at all times the site is operating or only for those times when the control device is operating (i.e., vent gas is sent to the control device)
- “Pilot flame while emissions are routed to the control device” means a pilot flame is required only when vent gas is sent to the device (in other words, at all times of control device operation).

Commenter (2428-API) suggests that a pilot flame should only be required when emissions are routed to the control device since loss of the pilot flame would result in additional emissions only when vent gas is sent to the device. The commenter also notes that this clarification would allow for the use of automatic ignition systems and would maintain consistency with the compliance requirement found at 40 CFR 60.5412b(b)(1):

You must operate each control device used to comply with this subpart at all times when gases, vapors, and fumes are vented from the affected facility through the closed vent system to the control device. You may vent more than one affected facility to a control device used to comply with this subpart.

Commenter (2428-API) offers the following changes that clarify a pilot flame should be required only when emissions are routed to the control device, like some state rules including New Mexico<sup>10</sup> (underlined text indicates new text and struck out text indicates deleted text):

*40 CFR 60.5412b(a)(1)(vii):*

You must install and operate a continuous burning pilot flame or automatic ignition system.

*40 CFR 60.5413b(e)(2):*

A pilot flame or combustion flame must be present at all times ~~of operation~~ while emissions from affected facilities are routed to the control device.

*40 CFR 60.5415b(f)(1)(vii)(A)(1):*

A pilot flame or combustion flame must be present at all times ~~of operation~~ while emissions from affected facilities are routed to the control device.

*40 CFR 60.5417b(d)(1)(i):*

For an enclosed combustion control device that demonstrates during the performance test conducted under §60.5413b(b) that combustion zone temperature is an accurate indicator of performance, a temperature monitoring device equipped with a continuous recorder. The monitoring device must have a minimum accuracy of  $\pm 1$  percent of the temperature being monitored in °Celsius, or  $\pm 2.5$  °Celsius, whichever value is greater. You must install the temperature sensor at a location representative of the combustion zone temperature. You also must comply with the requirements of paragraphs (d)(1)(viii)(D) and (E) of this section, and you must install a monitoring device that continuously (i.e., at least once every five minutes) indicates the presence of the pilot flame or combustion flame while emissions from affected facilities are routed to the control device.

*40 CFR 60.5417b(d)(1)(vii)(B):*

A monitoring device that continuously, at least once every five minutes, indicates the presence of the pilot flame or combustion flame while emissions from affected facilities are routed to the control device.

---

<sup>10</sup> 20.2.50.115.C(1)(b)(i) NMAC and 20.2.50.115.D(1)(c) NMAC.

*40 CFR 60.5417b(d)(1)(viii)(A):*

Continuously monitor at least once every five minutes for the presence of a pilot flame or combustion flame using a device (including, but not limited to, a thermocouple, ultraviolet beam sensor, or infrared sensor) capable of detecting that the pilot or combustion flame is present at all times while emissions from affected facilities are routed to the control device. Continuous monitoring systems used for the presence of a pilot flame or combustion flame are not subject to a minimum accuracy requirement beyond being able to detect the presence or absence of a flame and are exempt from the calibration requirements of this section.

*40 CFR 60.5417b(g)(1):*

A deviation occurs when the average value of a monitored operating parameter determined in accordance with paragraph (e) of this section is less than the minimum operating parameter limit (and, if applicable, greater than the maximum operating parameter limit) established in paragraph (f)(1) of this section; for flares, when the average value of a monitored operating parameter determined in accordance with paragraph (e) of this section is above the limits specified in §60.5415b(f)(1)(vii)(B); or when the heat sensing device indicates that there is no pilot flame or combustion flame present for any time period while emissions from affected facilities are routed to the control device.

*40 CFR 60.5417b(g)(6)(iii):*

There is no indication of the presence of a pilot flame or combustion flame for any 5-minute time period while emissions from affected facilities are routed to the control device.

*40 CFR 60.5420b(c)(11)(i)(F)(1):*

Records that the pilot flame or combustion flame is present at all times ~~of operation~~ while emissions from affected facilities are routed to the control device.

Response II-17-22: EPA disagrees with the commenter's interpretation of the continuous pilot flame requirements. §60.18(e) requires flares to be operated at all times when emissions may be vented to them. Further, §60.18(c)(2) requires flares to be operated with a flame present at all times. Therefore, flares must be operated with a flame present at all times whenever there is the possibility that emissions could be vented to the flare.

EPA recognizes that at proposal some places within the text used both the pilot flame and combustion flame terms while other places only used pilot flame. To provide consistency, we have updated the final NSPS OOOOb and EG OOOOc to consistently use both terms.

Regarding automatic ignitions systems, see response II-17-1, which responds to this issue.

Comment: Commenter (2428-API) requests the clarification of which elements of the control device monitoring plan apply to heat sensing monitoring devices that indicate the presence of a pilot flame. The commenter notes that the proposed control device monitoring plan requirement at 40 CFR 60.5417b(c)(2) includes the following exemption: "...Heat sensing monitoring devices that indicate the continuous ignition of a pilot flame are exempt from the calibration, quality assurance and quality control requirements of this section."<sup>11</sup> However the commenter notes that one of the listed monitoring plan elements uses a thermocouple as an example. The commenter contends that this example is confusing since thermocouples could be used as a heat sensing monitoring device for a pilot flame, or as a temperature monitoring device. In the former case, the exemption would apply but not in the latter, notes the commenter. The commenter urges EPA to clarify which elements of the monitoring plan apply to heat sensing devices and recommends the following redline for 40 CFR 60.5417b(c)(2)(ii) (struck out text indicates deleted text):

Sampling interface (~~e.g., thermocouple~~) location such that the monitoring system will provide representative measurements.

Alternatively, commenter (2428-API) suggests that EPA could propose a different example for sampling interface.

Response II-17-23: As the commenter has noted, EPA has already stated in the regulatory text that certain provisions of the monitoring plan do not apply to heat sensing monitoring devices, as these devices are used qualitatively, not quantitatively. The sampling interface location is relevant to all thermocouples, even thermocouples used for pilot flame determination. In the case of heat sensing thermocouples, the monitoring plan should demonstrate that the location of the thermocouple is adequate for determining that a pilot flame is present.

Comment: Commenter (2428-API) suggests that flow monitoring requirements should be consistent between manufacturer-tested and other enclosed combustion devices. The commenter also has suggestions for flare monitoring requirements.

The commenter (2428-API) explains that manufacturer-tested enclosed combustion devices function similarly to other enclosed combustion devices with the only difference being the party responsible for stack testing; therefore, the proposed flow monitoring requirements should be consistent regardless of whether the device is tested by the manufacturer or owner/operator. In comparing the proposed flow monitoring requirements for manufacturer-tested enclosed combustion devices at 40 CFR 60.5417b(d)(1)(vii)(A) and other enclosed combustion devices at 40 CFR 60.5417b(d)(1)(viii)(D), the commenter noted the following inconsistencies and requested that they be addressed.

- No accuracy requirement is specified for other enclosed combustion devices. As discussed above, the accuracy requirement for flow rate monitoring should be  $\pm 5$  percent for both manufacturer-tested and other enclosed combustion devices.
- Manufacturer-tested devices appear to be limited to flow meters while other enclosed combustion devices may use other parameter monitoring systems. Other parameter

---

<sup>11</sup> 40 CFR 60.5417b(c)(2).

monitoring systems combined with engineering calculations should also be an option for flow monitoring on manufacturer-tested devices especially considering the potential challenges in obtaining and installing a flow meter in a timely fashion. Other parameter monitoring systems are also needed in situations where flow monitoring is infeasible (e.g., low flow scenarios). These other parameter monitoring systems would be more stringent than MACT HH, which allows GRI-GLYCalc™ or other process simulation to calculate inlet flow rate for manufacturer-tested control devices<sup>12</sup>.

- Manufacturer-tested devices do not have an option to exempt the device from flow monitoring. For enclosed combustion devices not tested by the manufacturer, maximum inlet flow rate monitoring is not required if a demonstration can be made using engineering calculations, and minimum inlet flow rate monitoring is not required if a backpressure valve is properly installed and operated. These alternative compliance options for flow rate monitoring should also be available to manufacturer-tested devices.
- EPA should clarify that a backpressure preventer is a backpressure valve. Since backpressure preventer is an unclear term, EPA should use the term “backpressure valve” instead.
- Additional examples of other parameter monitoring systems should be added to the regulatory text. To clarify and elaborate on the variety of other parameter monitoring systems that could be used in lieu of a flow meter, EPA should consider adding inlet pressure and line size as additional examples in the regulatory text.

Based on these items, commenter (2428-API) offers the following recommended changes to the flow monitoring requirements for manufacturer-tested control devices in 40 CFR 60.5417b(d)(1)(vii)(A) (underlined text indicates new text and struck out text indicates deleted text):

Except as noted in paragraphs (d)(1)(vii)(A)(1) through (4) of this section, ~~The~~ continuous parameter monitoring system must measure gas flow rate at the inlet to the control device. The monitoring instrument must have an accuracy of  $\pm 2 \pm 10$  percent or better at the maximum expected flow rate. You may use direct flow meters or other parameter monitoring systems combined with engineering calculations, such as line pressure, inlet pressure, line size, and burner nozzle dimensions, to satisfy this requirement. The flow rate at the inlet to the combustion device must be equal to or greater than the minimum flow rate and equal to or less than the maximum flow rate determined by the manufacturer.

(1) If you can demonstrate, based on the maximum potential pressure of units manifolded to the control device and applicable engineering calculations for the manifolded closed vent system, that the maximum flow rate to the control device cannot cause the maximum inlet flow rate determined by the manufacturer to be exceeded, you are exempt from continuously monitoring for maximum inlet gas flow rate.

---

<sup>12</sup> 40 CFR 63.773(d)(3)(i)(H)(1).

(2) If you install and operate a backpressure valve which is set to operate at or above the minimum inlet gas flow rate, you are exempt from continuously monitoring for minimum inlet gas flow rate.

(3) Control devices that are exempt from both minimum and maximum inlet gas flow monitoring are not required to have a continuous parameter monitoring system for measuring the inlet flow of gas to the device.

(4) Pressure-assisted flares control devices are not required to have a continuous parameter monitoring system for measuring the inlet flow of gas to the device.

Commenter (2428-API) also offers the following recommended changes to the flow monitoring requirements for control devices not tested by the manufacturer in 40 CFR 60.5417b(d)(1)(viii)(D) (underlined text indicates new text and struck out text indicates deleted text):

Except as noted in paragraphs (d)(1)(viii)(D)(1) through (4) of this section, a continuous parameter monitoring system for measuring the flow of gas to the enclosed combustor or flare. The monitoring instrument must have an accuracy of  $\pm 10$  percent or better at the maximum expected flow rate. You may use direct flow meters or other parameter monitoring systems combined with engineering calculations, such as line pressure, inlet pressure, line size, and burner nozzle dimensions, to satisfy this requirement.

(1) If you can demonstrate, based on the maximum potential pressure of units manifolded to the enclosed combustor or flare and applicable engineering calculations for the manifolded closed vent system, that the maximum flow rate to the enclosed combustor cannot cause the maximum inlet flow rate established in accordance with paragraph (f)(1) of this section or the flare tip velocity limit in §60.18 to be exceeded, you are exempt from continuously monitoring for maximum inlet gas flow rate.

(2) If you install and operate a backpressure ~~preventer valve~~ which is set to operate at or above the minimum inlet gas flow rate, you are exempt from continuously monitoring for minimum inlet gas flow rate.

(3) Flares that are exempt from maximum inlet gas flow monitoring and enclosed combustion devices that are exempt from both minimum and maximum inlet gas flow monitoring are not required to have a continuous parameter monitoring system for measuring the inlet flow of gas to the device.

(4) Pressure-assisted flares and pressure-assisted enclosed combustion devices are not required to have a continuous parameter monitoring system for measuring the inlet flow of gas to the device.

Given the small size, dispersed nature, and large number of units affected by this rule, the commenter (2428-API) suggests that these changes would appropriately reduce the burden of compliance while still providing for compliance demonstration and monitoring.

Response II-17-24: As noted in responses II-17-16 and II-17-20, in the final rule EPA is revising the terminology for backpressure preventer and aligning the monitoring requirements for all enclosed combustion devices, regardless of whether they are tested by the manufacturer or the operator. EPA has also clarified line pressure to inlet line pressure and added line size in the regulatory text for parameter monitoring systems.

Comment: Commenter (2399-GPA) asks for the EPA to clarify what may be an “affected facility” for the control device requirements and how to handle the situation where a control device controls emissions from both an affected facility subject to new source standards and one subject to existing source standards. The commenter is concerned that the proposed regulatory text that describes control device requirements for various “affected facility” types is incomplete. By way of example, the commenter cites to proposed 40 CFR 60.5415b (including “well affected facility,” “wet seal centrifugal compressor affected facility,” “pneumatic pump affected facility” and others). The commenter notes that there are multiple sections in the proposed regulatory text where a control device can be used to control emissions from a source, but it is not clear whether the source is subject to the testing requirements under 40 CFR 60.18(d). The commenter requests clarification on whether control devices used for those sources must be tested every five years.

Further, the commenter (2399-GPA) points out that it is common for multiple equipment types, such as pneumatic pumps and rod packing vents, to be routed to a common control device. The commenter is concerned that it is not clear if adding new equipment that are “affected facilities” under the proposed regulations to the common control device will make all equipment routed to the common control device affected facilities. The commenter urges EPA to clarify that equipment that is merely routed to the same control device as an “affected facility” will not cause existing equipment to become “affected facilities.”

Similarly, commenter (2399-GPA) recommends that the EPA clarify requirements for flares that control a mix of new and existing sources, such as where an affected facility installs a new pneumatic pump or compressor that is then routed to the same flare controlling other existing sources. The commenter believes that the proposed regulatory text is not clear as to whether routing new sources to an existing flare would be authorized if the existing flare does not meet NSPS OOOOb monitoring requirements. To the extent that the supplemental proposal expects midstream facilities to install new control devices for new affected facilities, the commenter states that EPA should understand that new control devices will create additional pollutant emissions. If the supplemental proposal expects midstream facilities to modify existing control devices to accommodate both new and existing sources, the commenter requests that EPA provide more time for compliance. Installing new flow meters, testing ports, or NHV measurement tools on existing control device lines handling multiple units or sources involve “hot tap” safety protocols, explains the commenter and this is specialized work that is typically handled by only a small handful of qualified contractors, not in-house staff. Therefore, if EPA expects an entire industry to modify existing flares, the commenter believes that the compliance deadline must account for the relatively small labor pool available to perform that work.

Response II-17-25: EPA is uncertain which affected facility types the commenter believes are missing. As stated in 40 CFR 60.5415b(f), the control device requirements apply to each well, centrifugal compressor, reciprocating compressor, process controllers in Alaska, storage vessel,

process unit equipment, or pump affected facility referenced to paragraph (f) from other paragraphs in 40 CFR 60.5415b. This covers all the affected facility types that are potentially subject to control standards. If an affected facility is subject to control requirements, the control device used is subject to all specified testing and monitoring requirements in 40 CFR 60.5412b, 5415b, and 5417b.

We are clarifying that routing non-affected facilities to control devices used for affected facilities does not change the status of the non-affected facilities, i.e., these non-affected facilities do not become affected facilities just because an owner or operator has routed them to a common control device.

New affected facilities do not necessarily require new or separate control devices. However, affected facilities in NSPS OOOOb must comply with the level of control specified in the rule, and any control device used to achieve the level of control specified in the rule must meet the control device requirements in the rule. Additionally, owners and operators may use new control devices if existing control devices cannot be retrofitted; owners and operators are not limited to their existing control devices.

Comment: Commenter (2428-API) suggests that idle control devices at a site should be exempt from performance testing and monitoring requirements. The commenter is concerned because they believe the proposed NSPS OOOOb and EG OOOOc requirements are unclear on whether idle control devices at a site are subject to performance testing and monitoring requirements. Some state rules, such as Colorado, require control devices be installed based on the potential maximum throughput of a site, explains the commenter. For a site, the control devices may be installed and operated in series using pressure-activated valves, meaning that vent gas is sent to the first device until it reaches capacity before the excess vent gas is sent to the second device and so on, states the commenter. The commenter explains that in actual operation, sites may never achieve the potential maximum throughput and associated emissions rates, so control devices toward the end of the control system are available but always idle. But even if activated, they would not be needed for purposes of complying with NSPS OOOOb or EG OOOOc, states the commenter.

Commenter (2428-API) suggests that one potential reading of the proposed NSPS OOOOb and EG OOOOc requirements is that such idle control devices are subject to initial and periodic performance testing and monitoring requirements especially if they are manifolded together. Conducting performance tests on idle control devices could increase in emissions since additional gas would need to be sent to the control devices for the purposes of testing or additional temporary piping installed to route vent gas to the idle control device, explains the commenter. The commenter is further concerned that a failed performance test on an idle control device would force operators to repair, retrofit, or replace the device, increasing compliance costs with no environmental benefit because the idle device is not expected to be required for compliance. The commenter notes that EPA recognized the environmental and cost disbenefit of testing idle emission sources in the federal standards for engines found in NSPS JJJJ and MACT ZZZZ and believes that similarly, installation of monitoring equipment on idle control devices increases costs with no environmental benefit.

To clarify that idle control devices are exempt from performance testing and monitoring requirements, commenter (2428-API) offers the following changes to the regulatory text to address their concerns (underlined text indicates new text and struck out text indicates deleted text):

*40 CFR 60.5400b(a):*

*General standards.* You must comply with the requirements in paragraphs (b) through (d) of this section for each pump in light liquid service, pressure relief device in gas/vapor service, valve in gas / vapor or light liquid service, and connector in gas / vapor or light liquid service, as applicable. You must comply with the requirements in paragraph (e) of this section for each open-ended valve or line. You must comply with the requirements in paragraph (f) of this section for each closed vent system and control device ~~used to~~ comply-operated for the purpose of complying with equipment leak provisions in this section. You must comply with paragraph (g) of this section for each pump, valve, and connector in heavy liquid service and pressure relief device in light liquid or heavy liquid service. You must make repairs as specified in paragraph (h) of this section. You must demonstrate initial compliance with the standards as specified in paragraph (i) of this section. You must demonstrate continuous compliance with the standards as specified in paragraph (j) of this section. You must perform the reporting as specified in paragraph (k) of this section. You must perform the recordkeeping as required in paragraph (l) of this section.

*40 CFR 60.5401b(a):*

*General standards.* You must comply with the requirements in paragraphs (b) of this section for each pump in light liquid service. You must comply with the requirements of paragraph (c) for each pressure relief device in gas/vapor service. You must comply with the requirements in paragraph (d) of this section for each open-ended valve or line. You must comply with the requirements in paragraph (e) of this section for each closed vent system and control device ~~used to comply-operated for the purpose of complying~~ with equipment leak provisions in this section. You must comply with paragraph (f) of this section for each valve in gas/vapor or light liquid service. You must comply with paragraph (g) of this section for each pump, valve, and connector in heavy liquid service and pressure relief device in light liquid or heavy liquid service. You must comply with paragraph (h) of this section for each connector in gas/vapor and light liquid service. You must make repairs as specified in paragraph (i) of this section. You must demonstrate initial compliance with the standards as specified in paragraph (j) of this section. You must demonstrate continuous compliance with the standards as specified in paragraph (k) of this section. You must perform the reporting requirements as specified in paragraph (l) of this section. You must perform the recordkeeping requirements as required in paragraph (m) of this section.

*40 CFR 60.5412b:*

You must meet the requirements of paragraphs (a) and (b) of this section for each control device ~~used to comply~~ operated for the purpose of complying with the emissions standards for your well, centrifugal compressor, storage vessel, pneumatic controller, or process unit equipment affected facility. If you use a carbon adsorption system as a control device to meet the requirements of paragraph (a)(2) of this section, you also must meet the requirements in paragraph (c) of this section.

*40 CFR 60.5412b(a):*

Each control device ~~used to meet~~ operated for the purpose of complying with the emissions reduction standard in §60.5377b(b) for your well affected facility, §60.5380b(a)(1) for your centrifugal compressor affected facility; §60.5395b(a)(2) for your storage vessel affected facility; §60.5390b(b)(3) for your pneumatic controller affected facility in Alaska; or either §60.5400b(f) or §60.5401b(e) for your process equipment affected facility must be installed according to paragraphs (a)(1) through (a)(3) of this section. As an alternative to paragraphs (a)(1) through (a)(3) of this section, you may install a control device model tested under §60.5413b(d), which meets the criteria in §60.5413b(d)(11) and which meets the initial and continuous compliance requirements in §60.5413b(e).

*40 CFR 60.5412b(b)(1):*

You must operate each control device ~~used to comply~~ operated for the purpose of complying with this subpart at all times when gases, vapors, and fumes are vented from the affected facility through the closed vent system to the control device. You may vent more than one affected facility to a control device used to comply with this subpart.

*40 CFR 60.5417b:*

You must meet the requirements of this section to demonstrate continuous compliance for each control device ~~used to meet~~ operated for the purpose of complying with emission standards for your well, centrifugal compressor, pneumatic controller, storage vessel, and process unit equipment affected facilities.

*40 CFR 60.5417b(a):*

For each control device ~~used to comply~~ operated for the purpose of complying with the emission reduction standard in §60.5377b(b) for well affected facilities, §60.5380b(a)(1) for centrifugal compressor affected facilities, §60.5390b(b)(3) for your pneumatic controller affected facility in Alaska, §60.5395b(a)(2) for your storage vessel affected facility, or either §60.5400b(f) or §60.5401b(e) for your process equipment affected facility, you must install and operate a continuous parameter monitoring system for each control device as specified in paragraphs (c) through (g) of this section, except as provided for in paragraph (b) of this section. If you install and operate a flare in accordance with §60.5412b(a)(3), you are exempt from the requirements of paragraph (f) of this section.

Response II-17-26: EPA disagrees that the wording changes suggested by the commenter are necessary. If a control device is used to comply with the emission reduction standards for an affected or designated facility, it is subject to the monitoring and testing requirements specified in NSPS OOOOb and EG OOOOc. Additionally, EPA is uncertain how the owner or operator would prove that the control device is not needed to meet the emission reduction standards specified in the rule if the units are in series or manifolded together. §60.8(b) allows the delegated authority to waive performance tests if the owner or operator can demonstrate by other means, to the satisfaction of the Administrator, that the affected source is in compliance with the standard. The situation described by the owner or operator should be handled on a site-specific basis, in which the owner or operator demonstrates that the control device is either meeting the standard by other means or that the control device is used for other purposes.

EPA agrees that operators should not be required to start up a control device for the sole purpose of testing it. We have added text to the final rule to allow control devices to be tested 30 days after returning to service if they are not operational at the time that a performance test is due.

Comment: Commenter (2288-NDDEQ) believes there is a referencing error in the performance testing procedures for control devices in EG OOOOc. The commenter notes that in NSPS OOOOa/b, the performance testing procedures are found in 40 CFR 60.5413a/b, but in EG OOOOc, they are found in 40 CFR 60.5407c. Despite this, the commenter notes the following references to 40 CFR 60.5413c, which do not exist. The commenter believes the correct reference should be to 40 CFR 60.5407c. Alternatively, the commenter suggests that the performance testing procedures in EG OOOOc be moved to a new section 40 CFR 60.5413c to maintain parity with NSPS OOOOa/b/c.

1. At 40 CFR 60.5398c(b)(4)(iv), "If the results of the periodic screening in paragraph (b)(4)(i) of this section indicate a confirmed detection at a designated facility, and the ground-based monitoring survey and inspections required by paragraph (b)(4)(ii) of this section demonstrate the confirmed detection was caused by a failure of a control device subject to §60.5413c..."

The commenter (2288-NDDEQ) believes that §60.5413c presumably should be replaced with §60.5407c.

2. At 40 CFR 60.5412c(a)(1)(vi), "You must operate each enclosed combustion control device at or below the maximum inlet gas flow rate established in accordance with 60.5417c(f) and as determined in your performance test conducted in accordance with 60.5413c(b)."

The commenter (2288-NDDEQ) believes that §60.5413c(b) presumably should be replaced with §60.5407c(b).

Response II-17-27: The commenter is correct in that the references to §60.5413c should have been references to §60.5407c. EPA has updated the final rule to move the performance testing requirements in EG OOOOc to §60.5413c, to better align with the same requirements in NSPS

OOOOa and NSPS OOOOb. The references to the performance testing requirements have been verified in the final rule.

Comment: Commenter (2214-BCAO) states that 40 CFR 60.5417c(d)(1)(viii)(C) cites, in the first sentence, (d)(1)(ix)(C)(1) through (5). The commenter believes the citation should be (d)(1)(viii)(C)(1) through (5).

Response II-17-28: The commenter is correct in that the reference to (d)(1)(ix)(C)(1) through (5) in 40 CFR 5417c(d)(1)(viii)(C) should have been (d)(1)(viii)(C)(1) through (5). EPA has updated the regulatory text in the final rule and verified the references.

Comment: Commenter (2428-API) recommends the following suggested change to 40 CFR 60.5413b(d)(11)(iii) (underlined regulatory text indicates new text):

A manufacturer must demonstrate a destruction efficiency of at least 95.0 percent for THC, as propane. A control device model that demonstrates a destruction efficiency of 95.0 percent for THC, as propane, will meet the control requirement for 95.0 percent destruction of VOC and methane (if applicable) required under this subpart.

Response II-17-29: EPA agrees with the suggested change and has updated the final rule accordingly.

#### ***17.1.6 Alternative Technology***

Comment: Commenters (2336-Kuva Systems, 2428-API, 2298-Pioneer, 2326-AXPC) suggest that EPA should permit the use of cameras for operators to perform visual inspections of flare and combustor smoke under Method 22. Commenter (2336- Kuva Systems) states that monthly inspections of flares and combustors for presence of smoke by in-person site-visits and based on section 11 of Method 22 is needlessly expensive and prescriptive. The commenter points out that visible cameras such as security cameras are widely available and deployed at oil and gas sites and they can be positioned closer than 400 m to combustors and flares and can be positioned such that they can view potential smoke from combustors and flares. The commenter believes that having a remote observer view flares and combustors for smoke eliminates the cost of travel and is expected to be cheaper even when considering the cost of cameras and communication. The commenter recommends that EPA clarify that operators can utilize visible light cameras to remotely observe flares and combustors for smoke and specify requirements for installation and operations such cameras need to meet. Moreover, the commenter recommends that EPA clarify that operators can employ qualified individuals from 3rd parties to conduct such monitoring for smoke or to allow it to be automated with machine vision. The commenter also requests that EPA clarify which process a technology solution provider should follow to demonstrate equivalency with EPA's on-site smoke monitoring requirement.

Commenter (2428-API) also suggests that video cameras should be allowed as an alternative method to Method 22, since some sites are already equipped with video camera systems. The commenter notes that video camera systems are allowed as an alternative to Method 9

observation under Broadly Applicable Approved Alternative Test Method ALT-82.<sup>13</sup> Although these video camera systems have similar supply challenges to other monitoring equipment, they should be an allowed monitoring alternative, suggests the commenter. To be consistent with the smoking check or Method 22 requirement, the camera would be used to remotely conduct a smoking check and/or 15-minute observation for visible emissions from the control device every month, suggests the commenter. Under this scenario, the commenter notes that owners or operators would keep a record of this remote visible emission observation with similar information required for in-person smoking check or Method 22 observation. The commenter also suggests that artificial intelligence and machine learning should be allowed to continuously screen the video feed for smoke detection and if smoke is detected, alert the operator that a Method 22 follow-up is required. According to the commenter, making the requirements for video camera systems more stringent than the proposed monthly Method 22 observation would disincentive the use of this alternative, including recordkeeping and reporting of additional video records, which could pose potential security risks and data storage concerns.

Response II-17-30: See Section XI.H.3 of the preamble to the final rule for a discussion on the final requirements related to using cameras in lieu of conducting EPA Method 22 observations.

In this final rule, EPA has not specified who must conduct the visible emissions observation. As with other requirements of the rule, such as fugitive emissions surveys, we are aware that owners or operators may find it easier or more economical to contract services. The rule does not preclude owners and operators from doing so, although ultimate responsibility for compliance with all requirements of the rule lie with the owner or operator.

Comment: Commenter (2433-EDF) states that while they support the requirements for no visible emissions and monthly monitoring using Method 22, they suggest that the EPA could also consider alternative monitoring technologies and methods that would achieve equivalent or superior results. The commenter urged EPA to also require that flares and control devices be monitored for compliance assurance during all fugitive emissions surveys, both under the OGI and AVO program and under the alternative periodic screening options. The commenter stated that control devices and flares, especially unlit and malfunction flares, are among the most observed and largest sources of methane emissions, including superemitter events, and it is therefore critical that they are regularly inspected and monitored to ensure proper operation.<sup>14,15</sup> The commenter further stated that multi-basin research has identified unlit flares across the entire country, and a Permian Basin study using flights conducted in 2020 found 5% of all active flares were unlit.<sup>16</sup> Moreover, commenter contends that monitoring flares and control devices during fugitive emission surveys poses very little additional burden and can ensure emission events are avoided.

Response II-17-31: See Section XI.H.2 of the preamble to the final rule for a discussion on the final requirements related to monitoring combustion control devices during OGI and AVO inspections.

#### **17.1.7 Other**

Comment: Commenter (3818-AXPC) requests that EPA clarify its intent regarding a potential semiannual reporting requirement for control device monitors. In the supplemental proposal, EPA proposes that operators prepare a site-specific control device monitoring plan that addresses the "[o]ngoing reporting and recordkeeping procedures in accordance with provisions in §60.7(c), (d), and (f)," among other things.

40 CFR 60.7(c) contains a requirement to submit a semiannual report for continuous monitoring devices subject to new source performance standards. This semiannual report must include information relating to excess emissions and monitoring system performance. The commenter states that it can find no analysis of the impact of semiannual reporting under 40 CFR 60.7(c) and requests that EPA clarify that it does not intend for operators to submit these semiannual reports. To the extent EPA intends for operators to submit these semiannual reports, the commenter requests that EPA include its evaluation of the impact of semiannual reporting in its regulatory impact analysis and clarify what information it intends to receive. For example, 40 CFR 60.7(c) and (d) require reporting of excess emissions data obtained from continuous emissions monitoring systems; however, other than for some sweetening units, EPA's supplemental proposal does not require continuous emissions monitoring. Similarly, 40 CFR 60.7(f) contains recordkeeping requirements that apply only to continuous emissions monitors. Considering the already robust recordkeeping and reporting requirements contained in EPA's supplemental proposal, the commenter believes it would be inappropriate and unnecessary to apply these semiannual reporting and recordkeeping requirements to monitoring devices that are not continuous emissions monitors – e.g., combustion device pilot monitors.

Response II-17-32: EPA notes that §60.7 applies to all continuous monitors – both continuous emissions monitoring systems and continuous parameter monitoring systems. However, because deviation reporting for continuous monitoring systems is already included in the annual report required under §60.5420b and §60.5420c, we have determined for the purposes of NSPS OOOOb and EG OOOOc it is unnecessary to require the §60.7 semiannual reports. As such, in the final rule, we have removed the references to §60.7(c), (d), and (f) from the monitoring plan requirements in NSPS OOOOb and EG OOOOc.

Comment: Commenter (2218-TCEQ) requests that EPA allow for thermal control of emissions from associated gas from oil well sites (and exempt oil wells with associated sour gas from flaring restrictions). The TCEQ believes that further consideration should be given to allow for control methodologies for these sites similar to other oil and gas facilities, including thermal control using flares which typically represent less than 100% destruction efficiency. The commenter suggests that EPA also allow for operations at the oil wells to continue with thermal control during the analysis by the professional engineer and implementation of the recovery strategy. Due to safety concerns, the commenter believes that the EPA should explicitly exempt oil wells with associated sour gas from the recovery requirements. The corrosive nature of sour

gas greatly restricts available recovery options. Requiring a demonstration by a professional engineer that recovery and reuse are not feasible for oil wells with associated sour gas may place a significant burden on smaller operators. The commenter also suggests that EPA should also point to available and successfully implemented recovery strategies for sour gas.

Response II-17-33: For responses to comments related to control of emissions of associated gas, see Volume II, Chapter 6. Additionally, see discussion in response II-6-10, which specifically addresses this topic.

Comment: Commenter (2399-GPA) requests clarification regarding devices with pressure regulators. Because many flares and enclosed combustion devices rely on a pressure regulator, the commenter would like to ensure that the emissions from any pilot, sweep, or purge gas required to prevent flame back flow will be exempt from any operating limit associated with control requirements. The commenter believes that EPA intended such an exclusion while affected facility gas was not directly going to the flare. However, facilities may route affected gas to the fuel system which may end up at the flare as purge or pilot gas. Because many gathering and boosting facilities use field gas or waste gas as part of their fuel system to ensure these gases are not vented to atmosphere, the commenter believes those streams should be exempted from the requirements while only these gases are going to the flare. This is important when pressure regulators are used on regulated streams to ensure flow minimums are met. Further, the commenter would like EPA to clarify and confirm that a pressure regulated flare does not need to meet the control requirements when using sweep and pilot gas. Sweep gas is needed to ensure the flare does not burn back into the stack and helps to prevent dead leg corrosion. Consistent with rules governing similar equipment at refineries,<sup>17</sup> the commenter suggests that the EPA should likewise confirm that this practice is exempt from any operating restrictions in a final rule.

Response II-17-34: EPA agrees with the commenter that, during periods when gases, vapors, and fumes are not vented from the affected facility to a control device, operating limits, such as the flare gas net heating value, do not apply.

## **17.2 Flares**

### ***17.2.1 General Support for Flaring Requirements***

[**Note:** For specific comments on requiring flaring as a control option for differing emission sources (e.g., oil wells with associated gas, storage vessels), see related emission source Chapters of this document.]

Comment: Commenters (1655-AAP, 2269-Private Citizen, 2347-Clarke Valve, 2394-Earthworks, 2425-TCS, 2447-CALH, 2462-Private Citizen, 2541-AAP) urge the EPA to not only discourage, but to prohibit the practice of flaring in non-emergency cases. The commenters believe that banning this practice will provide further reductions in emissions of both greenhouse

---

<sup>17</sup> See, e.g., 40 CFR 63.670(b) (pilot flame presence required only “when regulated material is routed to the flare”); 63.670(c) (visible emissions restriction only “when regulated material is routed to the flare”); 63.670(d) (flare tip velocity requirements apply “whenever regulated material is routed to the flare for at least 15 minutes.”).

gasses (GHGs) and other airborne pollutants, improving air quality in the immediate and long-term.

Commenter (2462-Private Citizen) suggests EPA should allow flaring only for safety reasons and should require written justifications when flaring occurs. Further, the commenter suggests that flares should be monitored continuously, with real-time results available online to nearby residents so they can avoid exposure to toxics.

Response II-17-35: EPA agrees with the commenter that standards should limit or discourage flaring where possible. EPA also agrees that the complete elimination of flaring of associated gas in all situations is not practical, for safety and other reasons. EPA therefore has designed our final rule to prohibit long term flaring for some sources, while leaving options open to other sources to manage associated gas in ways that makes flaring less frequent. See sections X.F.2 and XI.F.2 of the preamble to the final rule for discussion of the final standards on associated gas from wells for NSPS OOOOb as well as the final presumptive standards for EG OOOOc. In the context of existing sources of associated gas, EPA included a subcategory in the final emission guidelines for sources that produce 40 tpy or less of methane that allows those sources to flare routinely. In accordance with the final EG OOOOc, existing sources that produce over 40 tpy of methane may flare if other options are technically infeasible. See §60.5377c for model rule text in EG OOOOc on this point. As alluded to above, EPA's final standards also allow for flaring where circumstances are not routine and flaring is the reasonable option for interim periods, such as malfunctions or interruptions in sales line service. See §60.5377b and §60.5377c for specific regulatory language on this requirement. EPA believes that these various allowances for flaring address the bulk of commenters' concerns.

EPA also notes that methods have not yet been developed for continuously monitoring the emissions streams from flares, and as such, we cannot require such information to be publicly posted.

Comment: Commenter (2460-Private Citizen) states that flaring is meant to be a cure for the problem of venting gas, but it is a wasteful, imperfect cure that causes many problems of its own. They explain that the release of methane that isn't totally combusted in the flame; release of volatile toxic/carcinogenic compounds, formation of soot particles and release of un-combusted methane when a flare is accidentally extinguished by wind, experiences uneven gas flow or has some other system malfunction. The commenter adds that flaring is wasting as much as 10 percent of natural gas worldwide, which results in large-scale production of CO<sub>2</sub> without any useful work being done. The commenter recommends that flaring be severely restricted to minimize usage. Instead of flaring, the commenter suggests the goal should be to capture as much methane as possible from processing and from leaks in pipelines, compressor stations and processing facilities. The commenter explains that methane that is captured can be monetized to more than pay for the equipment required to capture methane emissions.

Response II-17-36: EPA is requiring monitoring of pilot lights, heating value, gas flow, and visible emissions from combustion control devices in the final rule. We are also requiring owners and operators to assess combustion control device operation during AVO and OGI inspections. EPA expects these monitoring requirements to reduce the instances of unlit or underperforming

combustion control devices and ensure that these devices achieve the required control efficiency on an ongoing basis.

For responses to comments related to flaring of associated gas, see Volume I, Chapter 17 and Volume II, Chapter 6.

Comment: Commenter (2409-BP) unequivocally supports EPA's effort to eliminate routine flaring and minimize non-routine flaring, and is pleased EPA is further soliciting comment on control device efficiency and operation of flares. In April 2021, the commenter announced its intention to eliminate routine flaring in its U.S. onshore operations by 2025. To achieve this goal, all newly constructed bp operated well sites are tied into gas delivery pipelines from start-up, and the commenter does not bring new wells online unless the wells have access to a gas pipeline. The commenter also reports that it is also building centralized production facilities and converting legacy wells from high pressure systems to low pressure gas gathering systems to tie in more of their existing production into centralized facilities.

In the commenter's (2409-BP) January 2022 comment letter on EPA's previous proposal, the commenter reports that they noted that since taking operational control over BHP's oil and gas assets in the Texas Permian Basin in 2019, they have reduced flaring intensity in the basin from 16 percent in the fourth quarter of 2019 to less than one percent today. The commenter notes this downward trend has continued since those previous comments, which is attributable to the actions and investments taken to address the efficiency and operations of flares. Notably, the commenter states they install air assist to improve the combustion efficiency of flares (above 95 percent control efficiency as proposed in 40 CFR 60.5377b(b)), and thermocouple sensors integrated with automation on all flare stacks to notify the operations teams of unlit flares. Further, the commenter provides that all their flares have auto-ignitors to remotely reignite flames that may have extinguished.

Response II-17-37: EPA acknowledges the commenter's support and the information provided by the commenter.

Comment: Commenter (2249-NACAA) supports the extension of requirements for reducing flaring equipment malfunctions and limitations on flaring where alternatives are available and recommends engagement with affected agencies to ensure that final rules offer agencies implementation flexibility that considers safety and technical feasibility.

Response II-17-38: EPA acknowledges the commenter's support. EPA remains committed to working with delegated state agencies as they implement NSPS OOOOb. Additionally, EPA is committed to working with states as they develop and submit state plans to the Agency for review for purposes of implementing EG OOOOc. EPA strives to maintain consistency in its collaboration with states to ensure that implementation will be uniform.

### ***17.2.2 General Opposition to Flaring Requirements***

[**Note:** For specific comments on requiring flaring as a control option for differing emission sources (e.g., oil wells with associated gas, storage vessels), see related emission source Chapters of this document.]

Comment: Commenter (2353-CrownQuest) is concerned that EPA is proposing significant new regulations on flares, which the commenter believes are based on the operation of flares at more complex sites. The commenter explains that most flares on oil and gas sites are used periodically for short periods, like hours or days, and when there are upset conditions, such as unplanned or planned downtime from the midstream provider. While these regulations may be reasonable from a cost versus emission standpoint for a large facility that flares continuously for over six months, the commenter states that they are an extremely expensive and burdensome requirement for facilities that may flare 1,000 one thousand cubic feet (MCF) a year over a few days, states the commenter. The commenter is concerned that the EPA did not consider individual circumstances and instead applied a large continual flaring standard to seldom and periodic emissions control equipment. Instead, the commenter urges EPA to evaluate and promote new flare designs that can work more efficiently, rather than apply burdensome operating standards that are highly expensive for minimal emission reduction. The commenter contends that while smoking flares are good propaganda for oil industry malfeasance, it is a mischaracterization of most flaring and not a BSER.

Commenter (2353-CrownQuest) states that much data is available on flaring intensity (i.e., flaring relative to gas production in oil fields or MCF gas flared/MCF gas produced), like the leak survey data available through The Environmental Partnership.<sup>18</sup> The commenter believes that this data from operators could be very beneficial in providing a BSER. The commenter states that operators implemented practices to reduce flare volumes, promoted the beneficial use of associated gas, and calculated flare intensity to demonstrate progress.

Response II-17-39: The required BSER for various affected facilities in NSPS OOOOb and EG OOOOc is 95 percent control. As such, owners and operators must meet 95 percent control of emissions from affected or designated facilities subject to those standards at all times. The testing and monitoring requirements in the rule are designed to ensure that the control devices used on affected or designated facilities are in continuous compliance with this standard. EPA notes that NSPS OOOOb and EG OOOOc do not dictate which control device must be used on sources. Owners and operators should choose the type of control device that makes the most sense for their site from a technical and economic standpoint.

### ***17.2.3 Flare Design, Operation, and Monitoring Requirements***

#### ***17.2.3.1 Support for Flare Monitoring Requirements***

Comment: Commenter (2305-Williams) is supportive of many of the flare monitoring requirements. The commenter supports applying 40 CFR 60.18(b) minimum inlet gas NHV requirements and maximum flare tip velocity requirements to conventional flares at processing

---

<sup>18</sup> <https://theenvironmentalpartnership.org/>.

plants. The commenter explains that gas plant flares can operate over a range of operating conditions and control numerous emissions sources regulated by multiple EPA programs (e.g., NSPSs OOOO/OOOOa, Kb, HH). The commenter acknowledges that proper monitoring and control of inlet gas heat content and flare tip velocity is important in ensuring  $\geq 95$  percent control of VOCs and methane in vented gas from the NSPS OOOOb/EG OOOOc emissions sources routed to the flare. The commenter supports the EPA's decision to have control devices meet a 95 percent VOC and methane emission reduction requirement instead of the 98 percent reduction proposed in the November 2021 proposed framework.

Commenter (2305-Williams) is supportive of EPA's proposal to include special provisions in NSPS OOOOb/EG OOOOc which require a minimum NHV of the inlet gas to the flare of 800 Btu/standard cubic feet (scf), and an exemption from the maximum velocity requirements in 40 CFR 60.18(b). The commenter agrees with EPA, as stated in the preamble, that maximum velocity requirements for pressure-assisted flares are not needed since flare tips installed on these flares provide good mixing of the flared gas with surrounding air at velocities that exceed maximum flare tip velocities in 40 CFR 60.18(b).<sup>19</sup>

Commenter (2305-Williams) agrees with EPA's proposed 1-hour monitoring and averaging requirement for inlet gas NHV for conventional flares and pressure-assisted flares at processing plants. The commenter agrees with EPA's proposed 1-hour monitoring and averaging requirements for inlet gas volumetric flow rate on conventional flares.

Response II-17-40: EPA acknowledges the commenter's support.

#### 17.2.3.2 Recommendations for Flare Monitoring

Comment: Commenter (2460-Private Citizen) notes that flaring causes the release of volatile toxic/carcinogenic compounds, formation of soot particles, and release of totally uncombusted methane when a flare is accidentally extinguished by wind, and that failures of flares are too common. The commenter suggests that in cases where flaring absolutely must be used, every flare should be equipped with an alarm that will provide instant notification to onsite staff so that immediate action can be taken to remedy the situation.

Response II-17-41: Based on the data received in response to the December 2022 Supplemental Proposal (see for example comment II-17-30), EPA is concerned by the incidence of unlit flares in the oil and natural gas sector. To address this issue, in the final rule, we have added a requirement for alert systems to notify the nearest control room when a pilot light is no longer lit. We believe that this requirement will reduce the instances of inefficient flaring.

Comment: Commenter (2248-NDPC) explains that some states allow for combustion devices other than those that meet 40 CFR 60.18. The commenter explains that some wells and storage tanks do not produce enough gas to support the minimum flow rate as specified in 40 CFR 60.18 and that in these cases, where the gas flow rate from a well can't support an engineered flare without pilot and or assist gas, the best practice is to use a flare that has a lower destruction efficiency with an auto-ignitor that sparks every few seconds. Furthermore, even facilities with

---

<sup>19</sup> Supplemental Proposed Rule, 87 Fed. Reg. at 74,796.

large gas flow rates will have brief periods of time when the gas flow is very low or when gas content temporarily contains inerts, especially on startup or shutdown of the facility, states the commenter. In these cases, the commenter believes that combusting the gas is better than venting it, and the temporary periods of less than 95 percent destruction should not be considered violations. If the EPA requires flares that meet 40 CFR 60.18 with no exceptions, the commenter warns that additional gas will need to be brought onsite to make up the minimum flow rate which would increase emissions, and in these cases, operators may be incentivized to vent the temporary emissions that do not meet the criteria for 95 percent destruction.

Response II-17-42: NSPS OOOOb and EG OOOOc do not mandate the use of flares. The rules only specify a particular control efficiency, not a particular type of control device. Flares or other combustion devices may not make the most sense economically or from a control standpoint in all situations, particularly for control of low, intermittent flow streams. Additionally, the rule allows for combustion control devices other than flares, as long as the control device meets the requirements outlined in the rule.

Comment: Commenter (2440-NNS) is concerned that monitoring of the flare pilot is inadequate since there are many reported instances of unlit flares despite adequate pilots. The commenter explains that this can occur when methane concentrations are outside of the flammable range. Monitoring of methane emissions from the flare is a more direct means of detecting and quantifying emissions, and the commenter encourages the EPA to also allow continuous monitoring technology solutions as a BSER for flare monitoring.

Response II-17-43: The commenter did not provide additional information to support the fact that having a lit pilot flame will not ensure destruction of methane. We also note that EPA is requiring monitoring of flare gas flow rate to ensure that the flow of gas does not overwhelm the flare flame.

Currently, there are no standardized test methods to continuously monitor the emissions from a flare. However, in the final rule, we have developed a pathway to allow for this technology to be implemented when such a method is available.

Comment: Commenter (2305-Williams) believes the proposed alternative to continuous inlet gas flow monitoring is overly restrictive. The commenter is concerned that the proposal, to require a demonstration that the maximum pressure in a flare header will never cause an exceedance of maximum flare tip velocity, is impractical for a flare that is used for both normal process control and emergency control. Instead, the commenter contends that the demonstration should be required to show that the maximum pressure in a flare header would never cause an exceedance of maximum flare tip velocity during normal facility operating conditions.

Response II-17-44: EPA disagrees with the commenter. Owner and operators must be in compliance with the requirements of the rule during all times. Flares must be able to achieve 95% control at any time that an affected facility is routed to the flare. There is no assurance that a flare would achieve the required control efficiency if it exceeded the maximum flare tip velocity allowed in the General Provisions of 40 CFR part 60. Owners and operators may install a flow meter to continuously monitor the flow of gas to the flare to demonstrate compliance with the

maximum flare tip velocity requirement if calculations cannot be used to demonstrate compliance.

Comment: Several commenters (2248-NDPC, 2305-Williams, 2326-AXPC, 2353-CrownQuest, 2399-GPA, 2428-API) are concerned with the NHV monitoring provisions for flares. Commenter (2305-Williams) states that the initial demonstration, to show that the NHV of a gas stream is always below the required NHV in 40 CFR 60.18(b), is unnecessarily burdensome. The commenter points out that while the proposed NSPS OOOOb/EG OOOOc Rules require a minimum of 200 gas sample analyses over a 10-day period, the Refinery Flare Rule<sup>20</sup>, only requires daily sample analyses for 14 days (14 samples in total) to make this same demonstration. The commenter suggests that EPA require a 10-day test period with one sample every 6 hours, for a total of 40 sample analyses.

Commenters (2248-NDPC, 2305-Williams, 2326-AXPC, 2353-CrownQuest, 2399-GPA, 2428-API) suggest that the proposed minimum NHV demonstration alternative to continuous NHV monitoring should be simplified, because the NHV of vent streams from affected facilities is typically fixed or well above the minimum NHV requirements. Commenter (2428-API) explains that these vent streams consist of mostly hydrocarbons, and the simplest hydrocarbon (methane) has a NHV of approximately 900 Btu/scf, which is 450 percent, 300 percent, or 112 percent of the minimum NHV requirement of 200, 300, or 800 Btu/scf depending on the type of control device.

Commenter (2428-API) questions EPA's justification for the sampling campaign "to provide a large sampling set by which to assess the variability of the vent gas sent to the combustion device and to adequately characterize the tails of the distribution." The commenter states that EPA did not provide additional detail as to why it expects the distribution of vent gas composition to vary enough to potentially be below the required minimum NHV and the commenter maintains that such a large sampling set is unnecessary when the NHV of vent streams from affected facilities is typically well above the minimum NHV requirement.

Commenter (2428-API) states that vent streams from oil well with associated gas, centrifugal compressor, and pneumatic controller in Alaska affected facilities are typically comparable to sales gas or natural gas. In AP-42, the commenter states that natural gas is listed as having a gross heating value of 1,020 Btu/scf (Section 1.4) or 1,050 Btu/scf (Appendix A). The "2011 Gas Composition Memorandum"<sup>21</sup> used in EPA's Supplemental Background Technical Support Document (TSD) also suggests NHVs well above the required minimum, explains the commenter. The commenter states that gas composition typically does not change unless certain actions occur at the site, such as adding a new well or refracturing an existing well. The commenter maintains that, even though the gas composition will typically change with new or modified well streams, composition remains well above the required minimum NHV.

Commenter (2428-API) also points out that vent streams from storage vessel affected facilities consist of more large hydrocarbons than sales gas and have a typical NHV of 2,000 Btu/scf or more, which is 1,000 percent, 667 percent, or 250 percent of the minimum NHV requirement of

---

<sup>20</sup> See 40 CFR §63.670(j)(6)(D).

<sup>21</sup> EPA-HQ-OAR-2010-0505-0084.

200, 300, or 800 Btu/scf, respectively. The commenter states that the addition of air from an open thief hatch could drop the heating value of tank vapors below the required minimum NHV, but the proper operation of thief hatches and other openings are already addressed in the proposed cover requirements.

Commenter (2428-API) states that vent streams from affected facilities that could potentially be below the minimum heating value requirement include compressors in acid gas service or those at Enhanced Oil Recovery (EOR) facilities. The commenter notes that both situations could have high carbon dioxide (CO<sub>2</sub>) content which would lower the NHV, so operators typically add assist gas or another vent stream with sufficient heating value to facilitate proper control device operation. In these limited situations, the commenter proposes that flow monitoring of the assist gas and vent streams should be allowed as an alternative to the continuous monitoring of NHV.

Commenter (2428-API) states that since the vent streams from affected facilities are expected to have sufficient heating value, both the proposed continuous net NHV monitoring, and demonstration alternative are economically unreasonable. The commenter explains that calorimeters and other compositional analyzers (e.g., gas chromatographs or mass spectrometers) have an approximate minimum installed cost of \$164,000 to \$245,000 and these monitors may also experience operational issues with entrained liquids in the vent gas stream especially in colder climates and seasons. For the minimum NHV demonstration alternative, the commenter reports that the cost is expected to be \$250,000 or more per demonstration. The commenter summarizes that the cost of a vendor-conducted 10-day continuous monitoring campaign is estimated at a minimum of \$250,000 to \$275,000 while the cost of 200 hourly samples is estimated at a total of \$300,000 to \$400,000 with an average cost per sample of \$1,500 to \$2,000 including shipping and analysis.

As an alternative, commenter (2428-API) proposes the following to provide operators the necessary flexibility to comply with NHV requirements:

- The 10-day demonstration should be simplified to a single sample including the use of an appropriate, representative sample or an initial flare compliance assessment with 40 CFR 60.18 using Method 18 of Appendix A. If a representative sample is used, the operator must document why the sample is characteristic of the vent stream composition. If the sample or 40 CFR 60.18 assessment demonstrates that the NHV is at least 150 percent of the applicable minimum value (i.e., NHV of the sample is at least 300, 450, or 1,200 Btu/scf, as applicable), NHV monitoring would not be required. After the initial demonstration, continuous compliance would be demonstrated through subsequent samples once every 3 years. If the initial or subsequent sample is below 150 percent of the applicable minimum NHV, the operator would be required to conduct more extensive sampling as proposed below or install and operator a calorimeter within a reasonable time (suggested as a minimum of 60 days).
- If an initial or subsequent sample does not meet 150 percent of the minimum NHV, operators should have the option to conduct a more extensive sampling event with a lower threshold. The commenter proposes that this more extensive demonstration consist of a minimum of 2 hourly samples or 2 hours of continuous monitoring per day for 7 days for a total of 14 samples. The same number of samples is required for a comparable

NHV demonstration under the Refinery MACT<sup>22</sup>. Net heating value monitoring would not be required if all 14 hourly averages or samples are above 120 percent of the applicable minimum NHV requirement. After the initial 7-day demonstration, continuous compliance would be demonstrated through a grab sample taken once every 3 years. If the initial or subsequent samples are below 120 percent of the applicable minimum NHV, the operator would be required to install and operator a calorimeter within a reasonable time (suggested as a minimum of 60 days).

- As with the proposed flow monitoring requirements, NHV monitoring, or demonstration alternative should not be required if operators demonstrate that the NHV is never expected to below the minimum required value using applicable engineering calculations including process simulation software. This alternative would be similar to MACT HH, which allows GRI-GLYCalc™ or other process simulation software to be used to estimate benzene or BTEX emissions from a glycol dehydration unit<sup>23</sup>. Continuous compliance would be demonstrated through a grab sample taken once every 3 years to verify that the minimum NHV is being met.

Commenter (2326-AXPC) also points out that most applicable vent gas streams are consistently above applicable minimum NHV limits. Particularly for upstream facilities, the commenter states that these vent gas streams are typically high in methane, ethane, and VOC content – typically 95+ percent, meaning the NHV of these streams is usually at or above 1,000 Btu/scf, and often much higher. Referencing the proposed rule, the commenter states the highest NHV low limit for an enclosed combustion device or flare is 800 Btu/scf, which is significantly below the expected NHV for most vent gas streams and limited to pressure-assisted devices. The commenter adds that non-pressure assisted flares and ECDs are subject to minimum NHV limits of 200 – 300 Btu/scf, which is well below the typical NHV of an oil and gas vent stream. In addition, they note that, unlike a refinery, operators do not use inert gases that would reduce the inherently high NHV of a vent gas stream. Thus, according to the commenter, there is little risk, and in many cases no risk, that vent gas streams will fall below the minimum NHV at any time, and certainly not great enough risk to warrant costly and onerous continuous NHV monitoring.

Commenter (2326-AXPC) suggests that engineering methodologies (*e.g.*, engineering simulation software) can accurately estimate the heat value of vent gas streams where a representative analysis serves as the basis for the estimation. The commenter explains that these data, combined with operating parameters and production, will provide an accurate estimate of heat value as well as vent gas volume through the use of long understood equations of state – *e.g.*, Peng-Robinson, 1976. The commenter points out that these methods are used for permitting and are a method listed in 40 CFR 98.233 “[o]nshore production and onshore petroleum and natural gas gathering and boosting storage” Calculation Method 1 for Subpart W Greenhouse Gas estimations and therefore, they believe that the EPA should allow operators the option to use engineering methodologies to demonstrate a vent gas stream will remain above the minimum NHV limit.

To address these issues, commenter (2326-AXPC, 3818-AXPC) proposes that EPA allow operators to demonstrate the inlet stream to a combustion control device meets the applicable minimum NHV limit requirement by using a pressurized liquids analysis in combination with

---

<sup>22</sup> 40 CFR 63.670(j)(6).

<sup>23</sup> 40 CFR 63.772(b)(2)(i).

engineering software. Under this approach, explains the commenter, the operator would pull a pressurized liquids sample from a separation vessel, or use a representative pressurized liquids sample, and input the sample results into engineering software configured to estimate with a high degree of accuracy the net. If the engineering analysis demonstrates the NHV is within 200 Btu/scf of an applicable NHV limit, the commenter proposes that the operator must then comply with the proposed NHV continuous monitoring requirements or the alternative to continuous NHV monitoring. The commenter proposes 200 Btu/scf, as this value exceeds the 20 percent cushion of the highest potentially applicable NHV limit EPA that notes as being “well above the threshold.”

Regarding the alternative NHV demonstration, commenter (2326-AXPC) supports API’s proposed revisions which would require a minimum of two (2) hourly samples or two (2) hours of continuous monitoring per day for seven (7) days for a total of 14 samples.<sup>24</sup> The commenter believes this method is sufficient to demonstrate the anticipated NHV will remain above the applicable minimum NHV limit.

Commenter (2399-GPA) states that compressor station and gas processing plant waste streams generally have a NHV that far exceeds the minimum values required under the supplemental proposal. The commenter explains that waste gas streams routed to control devices at midstream sources are largely comprised of natural gas and field gas, meaning that these streams are typically above 1,000 Btu/scf. Continuous monitoring requirements, and requirements to perform 10-day tests on control devices for storage tanks, pneumatic pumps, and compressor vents are unnecessary, imposing burdens and costs without any benefit, states the commenter. Instead, the commenter requests that EPA allow owners and operators to perform and maintain a design evaluation to ensure that waste gas streams will consistently exceed minimum NHV requirements. The commenter states this would be similar to that provided in proposed 40 CFR 60.5413b(c) for condensers and carbon absorption units, as well as for combustion device maximum flow rates in proposed 40 CFR 60.5417b(d)(1)(viii)(D).

As an alternative, if a design evaluation is not sufficient, Commenter (2399-GPA) proposes that a simplified sampling protocol be allowed for exempting a control device from continuous heat content monitored by allowing for samples to be taken twice a day for seven days. The commenter believes that such sampling would demonstrate that streams have a relatively constant NHV well exceeding the minimum requirements.

Commenter (2248-NDPC) is concerned with the monitoring requirements of vented gas to determine the NHV and does not believe it is warranted. The commenter explains that operators in North Dakota are required to pull samples and have them analyzed for the constituents and properties and one of the properties that is analyzed is NHV (by GPA 2172). The commenter explains that they reached out to one of the laboratories that collect and analyze samples of associated gas and flared gas in North Dakota, and the lab reported that out of 7,774 gas samples collected and analyzed from 2020 through 2022, the average NHV was 1,459 Btu/scf, while the maximum and minimum values were 1,007 and 2,846 Btu/scf.

---

<sup>24</sup> API Supplemental Proposal Comments § 5.6.4.

Commenters (2254-PBPA, 2353-CrownQuest) are concerned about the burden to continually measure heat value. The commenter states such equipment only exists in labs, and there is no available application in the field. The commenter explains that the heat value is generally fixed at oil and gas locations as the oil and gas are not processed but only separated. The commenter believes that the proposed 10-day minimum NHV demonstration is too onerous to be a viable alternative to continuous NHV monitoring. The commenters report that this minimum NHV demonstration must be feasible because calorimeters and other analyzers may be cost prohibitive, states the commenters.

Commenters (2254-PBPA, 2353-CrownQuest) point out that the proposed demonstration requires continuous monitoring over 10 days or a minimum of 200 hourly samples of inlet gas to the flare. The commenter states the minimum cost of a 10-day continuous monitoring effort conducted by a third-party vendor is a \$250,000 estimation and the cost per hourly sample, including shipping and analysis, is estimated at \$2,000 each, or \$400,000 total. The commenter contends that this level of sampling, recordkeeping, and reporting is not indicative of a BSER, nor did the EPA factor this cost into their analysis.

Commenter (2254-PBPA) stated EPA should permit operators to address compliance through annual gas sampling or modeling, and any performance testing should be based on a single day of testing.

Response II-17-45: See discussion in section XI.H.4 of the preamble to the final rule which details EPA's final standards related to measurement of net heating value for combustion control devices.

Comment: Commenter (2305-Williams) states the primary concern with flares in the oil and gas sector is the discontinuous presence of a flame when gas is routed to the flare. The commenter notes that poorly operated and poorly monitored flares at production facilities have consistently been the target of state enforcement programs focused on preventing VOC and methane emissions to the atmosphere. At compressor stations, the commenter provides condensate storage vessels are the predominant NSPS OOOOb/EG OOOOc affected facilities that are controlled by a flare. The commenter adds that other NSPS OOOOb/EG OOOOc sources like wet seal compressors and gas-driven pneumatic pumps are also located at compressor stations, but to a very limited extent. The commenter suggests that these emissions sources present a different set of circumstances at compressor stations (lower volumes of waste gas) compared to what is experienced at a production site (higher volumes of associated gas).

Commenter (2305-Williams) explain that, for condensate storage vessels, the NHV of the vented gas stream to the flare is sufficiently high ( $> 1,000$  Btu/scf), and the vent rate is sufficiently low, resulting in an actual flare tip velocity below the maximum allowable flare tip velocity allowed in 40 CFR 60.18(b). The higher BTU and lower flare tip velocity will prevent the combustion flame from lifting off the flare tip and burning out. In addition, flares controlling storage vessels that have discontinuous or variable vent streams throughout the year are supplemented with station fuel gas to maintain a minimum NHV to sustain the flare.

Commenter (2305-Williams) continues, given these conditions, the proposed continuous (1-hour) monitoring for volumetric flow rate and NHV of inlet gas stream to the flare is not necessary to ensure proper operation of flares at compressor stations. The commenter recommends the following continuous monitoring framework for flares at natural gas compressor stations as an effective and practically feasible alternative to EPA's current proposal:

- Continuous monitoring for the presence of a flame using a thermocouple, ultraviolet sensor, or infrared sensor.
- Weekly 5-minute observations for visible emissions (smoking). If visible emissions are observed during the 5-minute observation period, then perform a Method 22 test with a 15-minute observation period. A deviation occurs when visible emissions exceed a total of 1 minute in the 15-minute observation period.
- Monthly Method 22 for visible emissions (smoking). A deviation occurs when visible emissions exceed a total of 1 minute in the 15-minute observation period.

Response II-17-46: EPA agrees that the heating value of the vent gas to a flare in this sector is likely to be well above the minimum required heating value. Therefore, the EPA provided a pathway for owners and operators to demonstrate compliance with the heating value requirement through an initial demonstration instead of using continuous monitoring. EPA provided a similar compliance option for vent gas flow to the flare. We are maintaining these pathways in the final rule.

EPA is maintaining the requirements for a continuous pilot light and monthly EPA Method 22 observations in the final rule. See response II-17-7 for information concerning the final requirements for visible emissions observations with EPA Method 22.

Comment: Commenter (2362-EIP et al) states that EPA's proposed averaging times for NHV and flare tip velocity are too long and cannot ensure that flares and other controls achieve 95 percent—much less 98 percent—destruction efficiencies and do not reflect BSER. Instead, 15-minute averaging periods for these two operating limits would constitute BSER and much better ensure destruction of VOCs and methane, states the commenter. The commenter points to recent rulemakings for petroleum refining, ethylene production, and Miscellaneous Organic National Emission Standards for Hazardous Air Pollutants (NESHAP) (referred to as the MON) facilities, where EPA has required flares to comply with operating limits for NHV and flare tip velocity on a 15-minute basis. The commenter states that EPA promulgated these shorter averaging periods to assure that there are fewer periods when flares are not effectively destroying pollutants, as a longer averaging period would allow.

Commenter (2362-EIP et al) considers a short averaging time to be the most appropriate for assessing proper flare performance because flare vent gas flow rates and composition can change significantly over short periods of time. Furthermore, the commenter explains that because destruction efficiency can fall precipitously when a flare is controlling vent gases below (or outside) the proposed operating limits, short time periods where the operating limits are not met could seriously impact the overall performance of the flare. The commenter does not believe that the proposed 1-hour and 3-hour averaging periods for flare tip velocity and NHV, respectively,

would capture the short periods of poor performance that dramatically limit the ability of flares and other control devices to achieve the desired destruction efficiency. Thus, these longer averaging periods do not reflect BSER, states the commenter. Further, the commenter states, EPA has not explained why it has not used shorter (i.e., 15-minute) averaging periods, as it has done in other recent rulemakings. The commenter contends that the EPA's differing treatment of flares and other controls at oil and gas sources as compared to flares at refinery, ethylene production, and MON sources renders the 1-hour and 3-hour averaging periods arbitrary and capricious.

Response II-17-47: EPA disagrees with the commenter. While EPA acknowledges that rules at refineries and chemical plants do require shorter averaging times for monitored flare parameters, the vent gas streams at refineries and chemical plants are expected to vary significantly from the vent gas streams in the upstream oil and natural gas sector. The streams sent to flares at refineries and chemical plants contain an array of compounds, many of which are ringed hydrocarbons, which are harder to destroy than the straight-chain hydrocarbons that make up most of the vent gas streams in the upstream oil and natural gas sector. Additionally, refineries and chemical plants routinely pad tanks with nitrogen blankets. It is not uncommon for the nitrogen from the padding to be swept into the flare gas stream, thus creating situations where the net heating value of vent gas drops to low levels. This is generally not a concern in the upstream oil and natural gas sector. Due to less variability in the vent gas streams, easier to burn vent gas composition, and the expected high heating values of the vent gas streams, EPA does not think it is necessary to require monitoring on a 15-minute basis for these units and is requiring the same averaging time for these flare parameters as for other control device operating parameters.

It is EPA's understanding that the largest issue with flares in the upstream oil and natural gas sector is not the heating value of the vent gas or the flowrate of gas through the flare. The largest issue is the incidence of unlit flares. As such, EPA has included requirements for continuously lit pilot flames and control room alert systems to NSPS OOOOb and EG OOOOc. The owner or operator must verify the flare is lit at least once every five minutes. These requirements should help to resolve instances of unlit flares.

Comment: Commenter (2362-EIP et al) states that EPA must require direct NHV monitoring at all oil and gas flares and combustion devices on a continuous basis. The commenter states they believe that EPA correctly recognizes that the NSPS general provisions mandate that the agency establish monitoring for the general provisions' NHV and flare tip velocity operating limits, especially since the general provisions themselves contain no monitoring requirements for those two limits. The commenter believes that EPA also correctly concludes that the current operating and monitoring practices and requirements for well sites and centralized production facilities are not adequate to ensure flare control systems are operated efficiently—and also notes that establishing required monitoring for the NHV and flare tip velocity operating limits is especially important because the proposed rule states “recent studies suggests [sic] that 10 percent of flares in the Permian basin are either unlit or are only burning a portion of the gas sent to the flare.”

Commenter (2362-EIP et al) states that to correct this deficiency for NHV monitoring, EPA proposes that flares and enclosed combustion devices monitor the heating value through a continuous parameter monitoring system, such as a calorimeter. The commenter is concerned,

however, that EPA proposes to allow these control devices to take advantage of an alternative, by allowing the owner or operator conduct a ten-day initial assessment to demonstrate that the vent gas NHV “consistently exceeds” the required minimum value, instead of continuous monitoring. The commenter adds that they are also concerned with the proposal to allow owners and operators to determine “[i]f process operations are revised that could impact the NHV of the gas sent to the enclosed combustor or flare,” in which case a “re-evaluation” of the gas stream must be performed.<sup>25</sup>

Commenter (2362-EIP et al) believes these “loopholes” do not reflect BSER and cannot ensure that flares and other control devices destroy 95 percent—much less 98 percent—of VOCs and methane. The commenter adds that these loopholes do not constitute “provisions stating how owners or operators of flares shall monitor these control devices,” as required by 40 CFR 60.18(d); instead, they contend that the loopholes are provisions stating how owners and operators can avoid monitoring.

Commenter (2362-EIP et al) suggests that ten days of sampling cannot capture the variability of gas streams’ NHVs at oil and gas facilities, due in part to compositional variability, inert gases, and impurities in gas streams. Hourly samples taken over 10 days cannot capture the lowest heating values of vent gas streams at oil and gas facilities at later dates, states the commenter. Put another way the commenter states, ten days of sampling could yield NHVs that are much higher than the heating values of gas streams later present at oil and gas facilities, which would in turn give the false impression that these facilities are meeting NHV operating limit when in fact they are not. The commenter is concerned that the alternative will mean that oil and gas flares and other combustion devices will release much more VOCs and methane than the devices would if they were all required to directly monitor NHV.

Commenter (2362-EIP et al) points out that EPA claims 10 days of sampling will “provide a large sampling set by which to assess the variability of the vent gas . . . and to adequately characterize the tails of the distribution”—and that a “20 percent cushion” is a “reasonable minimum value for ‘well above the threshold.’” This, however, according to the commenter, is simply not the case given the possible variability of gas streams at oil and gas facilities—and especially given that EPA is allowing up to ten percent of samples to be less than 1.2 times the required minimum NHV. Further, the commenter is concerned that leaving it up to owners and operators to determine “[i]f process operations are revised that could impact the NHV of the gas sent to the enclosed combustor or flare” means that flares and other control devices are even less likely to meet the NHV operating limit—and thus are less likely to achieve proper destruction of VOCs and methane.

Commenter (2362-EIP et al) questions EPA’s claims that the alternative provisions will provide ample cushion to capture the underlying variability of gas streams’ heating values. The commenter states that EPA has not gathered or cited to any data showing this is the case, which EPA must do to comply with its statutory duties under CAA section 111. Thus, the commenter believes that the EPA has not rationally or lawfully considered the variability of gas streams’ NHVs. They contend that the EPA has not rationally explained—and has no rational basis for—allowing flares and other combustion devices to avoid direct NHV monitoring. The commenter is

---

<sup>25</sup> Proposed 40 CFR 60.5417b(d)(1)(viii)(C)(5), 60.5417c(d)(1)(viii)(C)(5).

further concerned that EPA has failed to consider an important aspect of the problem in failing to look at the relevant data and examine whether there might be variability that would prevent this loophole from ensuring proper destruction efficiencies. To the extent EPA is basing its decision to allow this monitoring loophole on purported cost savings associated with the loophole, the commenter warns that also renders the agency's decision arbitrary and capricious. The commenter reports that the costs of installing and operating a calorimeter or other relevant monitoring device for NHV are relatively low, and these monitors are cost-effective—especially given that EPA's proposed alternative cannot ensure the proper destruction of VOCs and methane and given the large emissions decreases that would result if EPA required all flares and other controls to continuously monitor NHV.

Commenter (2362-EIP et al) states that the alternative to continuous monitoring is also contradicted by findings that EPA has made regarding the great variability of gas compositions over short periods of time and the resulting dramatic effects on combustion efficiencies<sup>26</sup>. The commenter states that the proposed alternative would not capture those periods when the heating values of gas streams fall significantly over short periods of time—and would thus seriously impact the overall performance of flares and other controls at oil and gas facilities. The commenter urges EPA to not allow oil and gas facilities to avoid direct NHV monitoring through ten days of sampling. Instead, they contend, to capture the variability of gas streams' NHVs and ensure adequate destruction of VOCs and methane, EPA must require direct NHV monitoring at all oil and gas flares and combustion devices.

Response II-17-48: See discussion in section XI.H.4 of the preamble to the final rule which details EPA's final standards related to measurement of vent gas net heating value.

Comment: Commenter (2362-EIP et al) questions EPA's proposal to monitor NHV of the vent gas instead of NHV in the combustion zone. The commenter references EPA's discussion in the supplemental proposal, where EPA explains why the agency does not include requirements from recent NESHAP amendments for the refining and chemical sector, where EPA has required flares to meet an operating limit for the NHV in the combustion zone—instead of the heating value of the vent gas. The commenter explains that EPA's rationale was that “[w]hile this is important for an assisted flare, we anticipate the oil and gas source category predominately will use unassisted flares, because air-assisted flares require electricity and not all sites will have access to electricity.” The commenter also reminds EPA of their rationale that the general standards from 40 CFR 60.18—which only focus on the heating value of the vent gas—are sufficient because, for unassisted flares, the “heat content of the gas at the flame is not diluted by an assist stream of gas or air,” but that EPA nevertheless “requests comment on the universe of unassisted and assisted flares in the oil and gas sector.”

Commenter (2362-EIP et al) suggests that they believe it is EPA's duty, however, to gather the necessary data—before issuing a proposed rule—to determine whether there are assisted flares in the oil and gas sector. The commenter suggests that EPA could easily gather this data through its information collection authority under CAA section 114, 42 U.S.C. § 7414(a)(1), through reviewing air permits for oil and gas facilities, and/or by consulting with state permitting

---

<sup>26</sup> The commenter cited to the proposed CAA section 112(d)(6) review for Miscellaneous Organic Chemical Manufacturing. See 84 FR 69203.

agencies. The commenter states that EPA also could have reviewed information from vendors of flaring equipment to determine whether vendors offer air- or steam-assisted flares. By way of example, the commenter provided information from four vendors who offer air assisted flare systems to oil and gas producers, along with gas assisted smokeless flares; one of which offers a flare system designed to limit the overuse of steam. Therefore, the commenter does not believe it suffices under the statute that EPA “anticipates” that oil and gas facilities will likely use unassisted flares. Further, they state that the agency seems to concede that some oil and gas flares likely are assisted: if the oil and gas sector “predominately” uses unassisted flares because “not all” sites will have electricity, that means that some facilities will use assisted flares and will have access to electricity, surmises the commenter.

Commenter (2362-EIP et al) states that the agency’s failure to gather the data necessary to comply with its duties of review and revision under CAA section 111(b)(1)—and duties to promulgate EG under CAA section 111(d)—does not absolve it of complying with those duties (e.g., where appropriate, the agency must revise its standards to require the BSER<sup>27</sup> and EPA “shall prescribe” EG for existing sources in the situations specified by CAA section 111(d)(1)).<sup>28</sup> If there are assisted flares in the oil and gas sector, the commenter believes EPA’s refusal to require improved flare standards for NHV in the combustion zone would violate EPA’s duties under CAA section 111 and would be irrational—especially given that even EPA recognizes that meeting a combustion zone operating is necessary to ensure proper destruction efficiencies at assisted flares.

For any assisted flares in the oil and gas sector, commenter (2362-EIP et al) urges EPA to require those flares to meet an operating limit for the NHV in the combustion zone, as EPA has done for flares at refineries and petrochemical sources. As EPA properly found in its 2014-15 refinery NESHAP rulemaking, many studies have shown that the general flare provisions cannot ensure that flares achieve 98-percent destruction efficiencies, states the commenter.<sup>29,30</sup> Earlier, in 2012, EPA published an Enforcement Alert<sup>31</sup> regarding flaring violations, in which the agency recognized that certain needed parameters affecting the efficiency of flares are not captured within the general requirements, including maintaining the appropriate steam-to-vent-gas ratio and ensuring that the heating value of combustion zone gas is high enough to maximize combustion efficiency, states the commenter. The commenter summarizes that the Enforcement Alert stated that the heating value in the combustion zone gas “is a better indicator of efficiency than the heating value of the Vent Gas alone,” the latter of which the general provisions focus on. And in April 2012, EPA published a report examining “Parameters for Properly Designed and Operated Flares,” states the commenter. The commenter explains that EPA noted that reliance on the NHV of the vent gas—the parameter that the NSPS and NESHAP general flare requirements use” as an indicator of good combustion ignores any effect of steaming. Therefore, the commenter states that to incorporate steaming, a NHV of the combustion zone gas was calculated to include the assist steam.”<sup>32</sup> The commenter states that because complying with an

operating limit for the heating value of the vent gas cannot ensure 95 percent (or greater) destruction efficiency of VOCs and methane by assisted flares, it is appropriate under CAA section 111 to update the flare requirements for any assisted flares to ensure proper destruction efficiencies and to ensure that the standards and EG for any assisted flares reflect BSER. The commenter challenges that the CAA does not excuse EPA from complying with its duties where the agency lacks information. The commenter summarizes that EPA must gather the necessary information here to determine whether there are assisted flares in the oil and gas sector and if there are assisted flares, EPA must require them to comply with an operating limit for NHV in the combustion zone and must promulgate monitoring requirements to ensure compliance with that limit.

Response II-17-49: See discussion in section XI.H.5 of the preamble to the final rule which details EPA's final standards related to assisted flares.

Comment: Commenters (2298-Pioneer, 2305-Williams, 2326-AXPC, 2382-BH, 2399-GPA) have concerns with the use of calorimeters. Commenter (2326-AXPC) states that the use of calorimeters in the upstream oil and gas sector is unproven due to the variable nature of production flowrates results in low and/or intermittent vapor control streams. Current calorimeter technology cannot accurately measure the NHV of these low and/or intermittent streams consistently over time and across varying operating conditions, explains the commenter and in these applications, calorimeters are unlikely to yield accurate or useful data. In addition to the technical concerns, the commenter believes the supplemental proposal will prompt thousands of calorimeter orders that will overwhelm calorimeter supply vendors, resulting in a supply chain crisis, as operators wait months or longer for order fulfillment. The commenter reports that one of the most prominent calorimeter manufacturers in the U.S. estimates current supply can only be met for 6 to 10 units per month at a cost of \$70,000 to \$120,000 per unit (average \$100,000). The commenter is concerned because large operators may have one thousand or more flares that would require monitoring under NSPS OOOOb or EG OOOOc. Further, the commenter explains there would be additional demands on the site infrastructure, such as the use of instrument air systems required to operate the calorimeter. Finally, the commenter points out that calorimeter installation and maintenance require a skilled labor force that currently is insufficient in supply to meet the needs supplemental proposal. The commenter is concerned that it would take years to recruit and train this labor force and that the combination of equipment and labor supply shortages will force operators into a position where compliance is simply infeasible by compliance deadlines.

Commenter (2305-Williams) disagrees with EPA's requirement that only calorimeters can be used to determine the NHV of gas routed to a flare and believes that ultrasonic meters and gas chromatographs should also be allowed. The commenter explains that ultrasonic flow meters are capable of instantaneously measuring the molecular weight (and volumetric flowrate) of gas routed to a flare. The commenter provides that most molecules processed through a natural gas processing plant are straight chain alkane hydrocarbons whose molecular weight (MW) directly correlates to NHV. They add that calibration curves of NHV vs MW can be developed based on laboratory analysis of gas samples vs MW measurements from an ultrasonic meter. The commenter states that if the flare is assisted, digital MW/NHV and volumetric flow rate data can be instantaneously transmitted to a supervisory control and data acquisition (SCADA) system to

regulate air blowers or steam valve actuators and air or steam assist rates can thereby be optimized in real-time to assure  $\geq 95$  percent destruction of VOCs and methane. They request that gas chromatographs also be allowed to determine NHV of the inlet gas to flare because gas chromatographs speciate the hydrocarbon components of a gas stream, enabling the NHV of the gas stream to be calculated as the weighted sum of the individual NHVs of the gas stream's components.

Commenter (2399-GPA) asks that EPA ensure there is an allowance for monitoring options other than a calorimeter, which the commenter states have a high-cost threshold for the expected emissions reductions. The commenter suggests options like gas chromatography and optical spectroscopy should be allowed for compliance purposes. Costs of this equipment can range from \$75,000 to \$100,000 each and for most control devices, the heating value of the gas would consistently be well above the 200 BTU/scf, or 300 BTU/scf, or 800 BTU/scf triggers, making this equipment very expensive for the expected heat content of the gas streams. As currently written, the commenter is concerned that the supplemental proposal exemption option to continuous monitoring requirement would require expensive short-term monitoring to obtain 240 samples and lab analyses, as well as specialized contractors to install and operate those monitors, to exempt a site from the heat content monitoring. With hourly samples taken over a ten-day period, each sampling event would cost approximately \$200,000 per control device due to equipment rental costs and the costs for contractors to be onsite analyzing the data during this period, estimates the commenter. The commenter provides that this issue becomes more complicated when the facility is at a remote location where staff is not there to continuously catch samples or support the testing company analyzing the sample.

Commenter (2298-Pioneer) reports that continuous monitoring of NHV presents inaccuracy issues associated with low or intermittent gas streams due to technological limits. The commenter explains that supply chain issues and operation/maintenance of expensive and highly technical calorimeters which have not been utilized in upstream operations and are unproven to be effective would result in highly inaccurate and useless data recordkeeping and reporting. While the commenter agrees with the potential exemptions available for continuous monitoring, the commenter proposes that EPA allow operators to periodically (i.e., quarterly) sample representative inlet gas streams to demonstrate compliance with any applicable heating value requirement for control devices used to control affected facilities with intermittent or low flow gas streams under this rule.

Commenter (2382-BH) provides that one of the key requirements for flare operation is to maintain NHV<sub>cz</sub> of approximately 270 Btu/scf minimum, typically measured by using a gas analyzer or calorimeter. The commenter explains that their experience is that those instruments are difficult to maintain. They add that field data acquired using flare.IQ<sup>33</sup> indicate that the NHV calculation coming from the sound speed computation method is a suitable alternative for flare gas NHV measurement, and NHV from sound speed is within 3 percent when compared to measurements using a GC or a mass spectrometer. The commenter offers to serve as a technical resource for the agency regarding flare efficiency solutions to support the agency's finalization of the methane rule.

---

<sup>33</sup> See <https://www.bakerhughes.com/panametrics/flare-management/flareiq>.

Response II-17-50: EPA agrees that calorimeters are not the only continuous monitoring devices that can be used to assess net heating value. In the final NSPS OOOOb and EG OOOOc, EPA has added gas chromatographs, mass spectrometers, and automated grab sampling systems as additional options for continuously monitoring net heating value. These additional options, along with the sampling demonstration that can be used in lieu of continuously monitoring net heating value, should alleviate the technical and supply chain concerns raised by the commenters. While EPA is aware of optical and ultrasonic meters used to measure flow, we are not aware of these types of systems being used to measure net heating value. We do not have enough understanding of how these systems can be used to monitor net heating value, the accuracy of these measurements, or the limitations of the monitors, and as such, we cannot include them in this action. As allowed by §60.13(i) and §60.5417(d), owners and operators may request approval from the Administrator for alternative monitoring to what is specified in NSPS OOOOb and EG OOOOc; such an application should include adequate information to demonstrate that the requested method can accurately measure the parameter and limitations of the method. Additionally, we have included a pathway in the final rule for owners and operators to request alternative approaches for monitoring combustion control devices. See discussion in section XI.H.6 of the preamble to the final rule which details EPA's final standards related to alternative approaches to combustion device monitoring.

Additionally, see discussion in section XI.H.4 of the preamble to the final rule which details EPA's final standards related to measurement of vent gas net heating value.

Comment: Commenter (2383-BH) states that because it is not possible to control combustion efficiency for unassisted flares, setting a minimum threshold for combustion efficiency is not feasible at this time. The commenter recommends requiring continuous monitoring, reporting and verification. Rather than basing reported emissions on assumptions (e.g., stack is designed to meet xx percent combustion efficiency (CE)), the commenter recommends that reports be based on real time monitoring. Also, they believe with real time monitoring in place, operators may find levers to improve the CE as effective control depends on accurate measurement.

Response II-17-51: The required BSER for various affected facilities in NSPS OOOOb and EG OOOOc is 95 percent control. As such, owners and operators must meet 95 percent control of emissions from affected or designated facilities subject to those standards at all times.

EPA does not yet have standard methods for continuously monitoring combustion efficiency from flares. As part of the final rule for NSPS OOOOb and EG OOOOc, we have implemented a pathway for the use of future alternative technologies in monitoring flares, including those that can continuously monitor control efficiency. See section XI.H.6 of the preamble to the final rule, which discusses this topic.

Comment: Commenter (2414-CM-RMI) states that the December 2022 Supplemental Proposal and existing regulations do not contain provisions to directly validate or verify destruction efficiency, unless a flare is detected as part of the Super-Emitter Response Program. The commenter recommends that EPA remain abreast of studies and data available that would indicate improvements in flare performance based on requirements. Furthermore, the commenter offers suggestions for the pilot flame monitoring alternative to demonstrate that the NHV of the

inlet gas to the flare consistently exceeds the operating limit established in the rule. The commenter believes that the demonstration should be subject to a time- and/or volume-based limitation and should require re-submittals to ensure that original conditions granting such an exception persist.

Response II-17-52: EPA will continue to study available monitoring technologies for flares. As part of the final rule for NSPS OOOOb and EG OOOOc, we have implemented a pathway for the use of alternative technologies in monitoring flares. See section XI.H.6 of the preamble to the final rule, which discusses this topic. Additionally, in the final rule for NSPS OOOOb and EG OOOOc, we have added requirements to re-evaluate the NHV sampling demonstration and the maximum gas flowrate demonstration any time there are changes to the process or control device that may affect these parameters. EPA has also added confirmatory testing of the net heating value every five years for owners and operators who do not continuously monitor the flare gas net heating value. See additional information on the final net heating value requirements in section XI.H.4 of the preamble to the final rule.

Comment: Commenter (2254-PBPA) states EPA assumes all flares at an oil and gas site are used to meet a OOOOb/c performance standard, meaning that all flares would need to meet the monitoring and operational requirements in 60.18, and as such EPA expects owners and operators to verify compliance with 60.18 “where it is determined that a super emitter emissions event is caused by a flare.”<sup>34</sup> But that is not always the case, as some flares may be located onsite for use only in emergency situations. As such, flares associated with a “super emitter emissions event” that are not used to comply with a performance standard should not be required to verify compliance with 60.18.

Response II-17-53: EPA disagrees with the commenter’s assertions of EPA’s expectations. When an owner or operator investigates a super-emitter event, the owner or operator is obligated to review monitoring data from control devices from the affected (or designated) facilities subject to regulation under NSPS OOOO, NSPS, OOOOa, NSPS OOOOb, and EG OOOOc. All of these subparts require compliance with §60.18 when the flare is used to control emissions from an affected (or designated facility). If the flare does not control emissions from an affected (or designated) facility under these subparts, the owner or operator is not obligated to verify that the flare meets the requirements of §60.18 for the purposes of NSPS OOOOb or EG OOOOc.

### 17.2.3.3 BSER (95 Percent)

Comment: Commenter (2362-EIP et al) states that Attachment B to their letter includes a September 2022 article published in Science magazine quantifying emissions of methane from flares in the Bakken, Eagle-Ford, and Permian basins based on multiple aircraft surveys of emission plumes in 2020 and 2021. According to the commenter, the authors estimate that flares in all three basins combined release 538,000 short tons of methane on an annual basis, or about 13.4 million tons of CO<sub>2</sub>e, based on an average destruction removal efficiency (DRE) of 91.1 percent.

---

<sup>34</sup> Id. at 74,753-54.

More specifically, the commenter states that the study found that:

- Had all flares been lit and operating at 98 percent DRE, methane emissions should not have exceeded 110,000 short tons per year.
- Flares that were lit when surveyed averaged 95 percent DRE, resulting in annual emissions of 297,000 short tons per year.
- When unlit flares were factored into survey results, the total DRE from all flares (lit and unlit) declined to 91.1 percent, resulting in 538,000 short tons of methane per year.

Commenter (2362-EIP et al) states that due to the heavier molecular weight of complex hydrocarbons, EPA's own analysis assumes that tank batteries and other affected sources release about 4.5 tons of smog-forming VOCs for every ton of methane emitted (see, e.g., Table 4, Chapter 7, of EPA's Supplemental Background and Technical Document (October 2022)). If that is correct, the commenter states that flares in the Bakken, Eagle-Ford and Permian basins would release 495,000 tons of VOCs per year at 98 percent DRE; 1.336 million tons at a 95 percent DRE (based on surveys of lit flares), and 2.42 million tons at the 91.1 percent DRE that includes emission losses from unlit flares. They add that EPA estimates that its proposed rule will eliminate 9.7 million tons of VOCs between 2023 and 2035 and 36 million tons of methane, despite if flares and vapor combustion units will not destroy more than 95 percent of VOC's and methane. Based on the above survey results, the commenter believes that EPA could eliminate more than 10 million additional tons of VOCs and another 2.3 million tons of methane over the same 12-year period if all lit flares actually met the 98 percent DRE that CAA State Implementation Plan (SIP) regulations and permits already require, instead of the average 95 percent DRE the authors of the study found in the survey of lit flares. The commenter states that the emission reductions are much greater if monitoring is sufficient to even reduce the frequency of unlit flares venting 100 percent of the methane and VOCs in waste gases directly to the atmosphere.

Commenter (2362-EIP et al) believes that if EPA insists that 95 percent DRE is BSER for flares and vapor combustion units (VCUs) in states that already require 98 percent, the agency should expect states to seek emission credits based on their more "stringent" standards, which would effectively wipe out all the VOC reductions that EPA claims will result from its rulemaking.

Commenter (2362-EIP et al) suggests that EPA should not be surprised at these results, since the agency has never established the continuous monitoring needed to assure that operators maintain the minimum flow and NHVs that EPA identified as critical to maintaining the 98 percent DRE that EPA established in the 1980's. The commenter warns that emission limits that are not adequately monitored will not be met. The commenter believes it is too late for EPA to decide that 95 percent DRE is the best that can be done almost 40 years later after its public assurances that well managed flares can destroy 98 percent of the organic pollutants in waste gases. The commenter believes that adopting that rollback would create havoc within the regulatory, permitting, and air quality modeling systems that have assumed a 98 percent DRE for so long.

Response II-17-54: As the commenter notes, it is common for flares within the oil and natural gas sector to only achieve 95 percent control. The study cited by the commenter demonstrates

this is the case. As EPA noted in the December 2022 Supplemental Proposal,<sup>35</sup> we determined it would not be cost effective to require the additional monitoring and operational costs that would be necessary to guarantee 98 percent control of emissions. We recognize that some delegated agencies may require stricter control. Cost-effectiveness can vary between different areas of the country, and while something may not be cost-effective in a national rulemaking, it may be cost effective in a regional standard. For example, where electricity is readily available, installation of extra monitoring equipment is not as difficult or expensive, and therefore, higher control efficiencies may be more cost effective.

EPA agrees that unlit flares are an issue within this sector, and we are concerned by the incidence of unlit flares. As such, EPA has included requirements for continuously lit pilot flames and control room alert systems to NSPS OOOOb and EG OOOOc. The owner or operator must also verify the flare is lit at least once every five minutes. These requirements should help to resolve instances of unlit flares.

Comment: Commenter (2383-BH) recommends that EPA distinguish between pressure-assisted flares and flares “other than pressure-assisted flares” (i.e., unassisted flares) in the flare monitoring requirements. For pressure-assisted flare, the commenter recommends that EPA set the degree of emissions limitation achievable at 98 percent. The commenter states there are commercially available technologies, such as their flare.IQ technology solution, that allow operators to achieve a combustion efficiency of 98 percent. This technology has been installed by operators worldwide. The commenter believes the EPA proposed 95 percent destruction threshold is not justified given the availability of such systems.

Response II-17-55: EPA disagrees with the commenter. The required BSER for various affected facilities in NSPS OOOOb and EG OOOOc is 95 percent control. As such, owners and operators must meet 95 percent control of emissions from affected or designated facilities subject to those standards at all times. The rules do not specify what type of control device must be used to achieve this standard, nor is EPA setting a control efficiency for different types of control devices. All control devices must achieve the minimum required emission reduction standard, although some control devices at individual sites may perform better than the required 95 percent emissions reductions. Additionally, although it may be possible to achieve 98 percent control of emission, EPA determined that 98 percent control efficiency is not cost effective and is therefore not BSER.<sup>36</sup>

#### ***17.2.4 Flare Alternative Methods and Monitoring Recommendations***

Comment: Commenter (2457-Providence Photonics) states that the proposed flare monitoring requirements have some similarity to the ones in the refinery and ethylene MACT (40 CFR 63.671) in the sense that they all require continuous monitoring but recommends that EPA consider adding an alternative approach that will be more cost effective and will achieve the same objective to ensure that the flare has high combustion efficiency.

---

<sup>35</sup> 87 FR 74794 (December 6, 2022).

<sup>36</sup> 87 FR 74794 (December 6, 2022).

Commenter (2457-Providence Photonics) points out that there have been significant advancements in the field of flare performance monitoring technology in recent years since the promulgation of the refinery and ethylene MACT, including the Video Imaging Spectral Radiometry (VISR) technology (which has been developed to remotely and directly monitor flare combustion efficiency (CE)) and the Simplified VISR technology (which has been developed to remotely monitor Combustion Zone Net Heating Value (NHVcz) for steam-assisted flares and Net Heating Value Dilution Parameter (NHVdil) for air-assisted flares)<sup>37</sup>. In November 2022, the commenter explains that EPA funded additional testing with focus on the Simplified VISR technology on both steam-assisted and air-assisted flares at the John Zink flare testing facility in Tulsa, Oklahoma. The commenter summarized the test results in Exhibit 3 of their letter and explains that as shown in Exhibit 3, the Simplified VISR technology can be easily deployed for a short-term study or long-term continuous monitoring of NHVcz for steam-assisted flares or NHVdil for air-assisted flares at a cost comparable to an OGI camera.

Commenter (2457-Providence Photonics) suggests that EPA allow operators to use the Simplified VISR method to demonstrate compliance in lieu of a calorimeter or the 10-day testing. If an operator chooses the continuous monitoring route, the commenter suggests the operator could have a choice between a calorimeter and the Simplified VISR. The commenter explains that each operator could choose between these two methods based on the total cost and the circumstances (e.g., scheduling, operational constraints, maintenance, etc.). If an operator chooses 10-day testing, the Simplified VISR device could be installed to monitor the flare for 10 days states the commenter. The commenter believes that the Simplified VISR device can operate autonomously and continuously, a significant advantage over manually operating and collecting at least 200 hourly samples.

To facilitate the above alternative approach, the commenter (2457-Providence Photonics) suggests that the flare NHV standard should be supplemented. While the current NHV standard is based on the Btu/scf in the gas stream that is fed to the flare (e.g., 300 Btu/scf and 800 Btu/scf), the Simplified VISR measures the NHV in the flame combustion zone, which the commenter states represent a better surrogate parameter for flare performance than vent gas NHV. To facilitate the Simplified VISR as an alternative to the methods in the Supplemental Proposal, the commenter recommends that the final rule should allow the operator to comply with the NHVcz and NHVdil based standards (i.e., reference the NHVcz limit of 270 Btu/scf for steam assisted flares and NHVdil limit of 22 Btu/square feet (sqft) for air-assisted flares in 40 CFR 63.670). The commenter states it is important to note that the 270 Btu/scf NHVcz and 22 Btu/sqft NHVdil standards correspond to a combustion efficiency of 96.5 percent and destruction efficiency of 98 percent, which is higher than the control efficiency of 95 percent in the December 2022 Supplemental Proposal and represents a 60 percent methane emission reduction (from 5 percent of the flared process stream down to 2 percent). Adding this stronger standard as an option is beneficial to the environment and from the operators' perspective, it will provide more flexibility for compliance, states the commenter. The commenter believes an operator may consider all aspects (cost, supply, schedule, operational constraints, manpower, maintenance,

---

<sup>37</sup> See Providence Photonics' comments on the November 2021 proposal, which can be found at EPA-HQ-OAR-2021-0317- 0604.

etc.) and conclude that the Simplified VISR method is a better choice, even though it means complying with a higher environmental standard.

Furthermore, commenter (2457-Providence Photonics) suggests the EPA should consider some incentive for operators who choose the NHVcz or NHVdil because it further reduces the methane emissions. The commenter recommends that the incentive could be in the form of an emission credit where applicable, i.e., the difference between the 95 percent control and 98 percent control can be used as emission credit and such a credit could be used for offsetting emissions in the air permitting process.

In addition to NHV related monitoring requirements, the commenter explains that if an operator chooses to use the Simplified VISR alternative, it could simultaneously satisfy all the monitoring requirements in 40 CFR 60.5417b(d)(1)(viii)(A) thru (E) –

(A) for monitoring the pilot – Simplified VISR device can be used to detect the presence of pilot flame; (Commenter’s Exhibit 4)

(B) or (C) for monitoring the NHV – See above discussions; (Commenter’s Exhibit 3)

(D) for monitoring flowrate – Simplified VISR device can be used to measure the flaring rate in terms of kilograms (kg)/hour (hr) (or pounds(lbs)/hr) of hydrocarbon being flared; and (Commenter’s Exhibit 5)

(E) for monthly inspection of visible emissions – Simplified VISR continuously monitors visible emission through application of the Smoke Index. (Commenter’s Exhibit 6)

Commenter (2457-Providence Photonics) believes the most efficient approach to adopt the above recommended Simplified VISR Alternative is to incorporate it in the final rule, specifically, 1) adding provisions to allow the Simplified VISR method as an alternative to calorimeter method in 40 CFR 60.5417b(d)(1)(viii)(B) or 10-day sampling method in 40 CFR 60.5417b(d)(1)(viii)(C); and 2) adding the NHVcz and NHVdil based standard as alternative to the vent gas Btu/scf based standard by referencing both 40 CFR 60.18 and 40 CFR 63.670.

Commenter (2457-Providence Photonics) states that a much less efficient approach to adopt the above recommendation is to allow the operator to apply for it, similar to the procedures to apply for an alternative test method in 40 CFR 60.5398b(d) in the December 2022 Supplemental Proposal. However, the commenter believes that the procedures in 40 CFR 60.5398b(d) apply to the fugitive emission standards only, so EPA should add a section that will mimic 40 CFR 60.5398b(d) in principle but will be geared towards the flare standards.

Response II-17-56: See discussion in section XI.H.6 of the preamble to the final rule which details EPA’s final standards related to alternative approaches to combustion device monitoring.

### **17.2.5 Regulatory Language and Clarifications for Flares**

Comment: Commenter (2326-AXPC) requests that EPA clarify its intent with respect to demonstrating initial flare compliance, which requires compliance with 40 CFR 60.18(b). The commenter cites to proposed 40 CFR 60.5412b(a)(3) and 40 CFR 60.5412c(a)(3), in part:

Each flare must be designed and operated according to the requirements of §60.18(b) as specified in paragraphs (a)(3)(i) through (iv) of this section.

(i) You must use Method 18 of appendix A-6 of this part to determine the NHV of the vent gas meets the requirements in §60.18(c)(3)(ii). For pressure-assisted flares, in lieu of the heating value limits in §60.18(c)(3)(ii), the NHV of the gas being combusted must be 800 Btu/scf or greater.

The commenter explains that 40 CFR 60.18(b) identifies that flares must comply with 40 CFR 60.18(c)-(f). 40 CFR 60.18(c)(3) provides operators a choice to adhere to heat content specifications in 40 CFR 60.18(c)(ii) and the maximum tip velocity specifications in (c)(4), or to adhere to the requirements in (c)(3)(i). The commenter believes it is unclear whether EPA intends that operators do not use the compliance option in 40 CFR 60.18(c)(3)(i) and requests that EPA clarify its intent with respect to how operators are to comply with 40 CFR 60.18(c), as referenced by 40 CFR 60.18(b).

Response II-17-57: EPA does not expect flares used in the oil and natural gas sector to be able to meet the hydrogen content requirements in §60.18(c)(1)(i).

Comment: Commenter (2399-GPA) requests clarification regarding flare testing requirements under proposed revisions to 40 CFR 60.18(d). The commenter states that it is not clear if 40 CFR 60.18(d) requires a formal test or some sort of certification that the flare meets applicable requirements, nor is it clear whether all flares must meet a testing or certification requirement. If 40 CFR 60.18(d) requires a formal test, the commenter would like to ensure that adequate time is provided for the necessary installation of ports to perform the flow and heating value requirements per the test methods in 40 CFR 60.18(d) on a live flare line.

Response II-17-58: Flares are exempt from the performance testing requirements of NSPS OOOOb and EG OOOOc. Flares must be able to demonstrate compliance with the requirements for pilot flames, visible emissions, vent gas flow rate, and net heating value outlined in the rule. However, there is no formal performance testing requirement or certification for flares.

Comment: Commenter (2305-Williams) states that EPA's requirement to report all volumetric flowrate exceedances as deviations misunderstands an application of processing plant flares as emergency control devices. According to the commenter, by identifying any measured exceedance of 40 CFR 60.18(b) volumetric requirements as a deviation, EPA fails to accommodate instances in which flares at natural gas processing plants are used as emergency control. In 40 CFR 63.670(o)(3)(i)-(ii), the commenter notes that the EPA acknowledges that

flares in the refinery sector are used for emergency control and develops a regulatory framework to support this application. The commenter requests that the EPA adopt a similar framework for flares (for maximum flare tip velocity) at natural gas processing that temporarily serve this same emergency control function.

Response II-17-59: EPA intentionally did not include all the flare provisions in 40 CFR 63.670 for oil and gas facilities subject to NSPS OOOOb and EG OOOOc. We specifically did not include requirements to develop a flare gas management plan or other “emergency flaring” provisions in 40 CFR 63.670(o), which includes reporting requirements for all such events. Additionally, some events conducted under the emergency flaring provisions in 40 CFR 63.670(o) are automatic violations (as opposed to deviations).

EPA also notes that we did not include these specific provisions related to “emergency flaring” and determining the “smokeless capacity” of the flare in other recent rulemakings where we otherwise incorporated the flare provisions in 40 CFR 63.670, even though these flares may be used as emergency flares.<sup>38</sup> In other recent rulemakings,<sup>39</sup> while we may have incorporated some of the emergency flaring provisions, we did not incorporate the provisions in 40 CFR 63.670(o)(3)(ii) related to exceedance of maximum flare tip velocity; instead all exceedances of the maximum flare tip velocity limits are reportable as deviations, consistent with the requirements we proposed for NSPS OOOOb and EG OOOOc. We find that the direct application of the maximum velocity limits provides a more direct means of requiring facilities to manage their flares without the burden associated with the provisions in 40 CFR 63.670(o). As such, EPA is finalizing the flare tip velocity limits as proposed.

## **17.3 Enclosed Combustion Devices (ECDs) and Other Control Devices**

### ***17.3.1 Monitoring and Testing***

Comment: Commenter (2326-AXPC) requests that EPA provide the same continuous flow monitoring alternatives for all ECDs, regardless of whether they are tested on-site, or tested by the manufacturer. The commenter requests that EPA harmonize the requirements to allow operators of any ECD with an alternative to measure flow directly with a flow meter or “other parameter monitoring systems combined with engineering calculations, where (1) for maximum inlet flow rate, the operator can demonstrate the maximum flow rate to the ECD cannot cause exceedance of the ECD’s maximum inlet flow rate, or (2) for minimum inlet flow rate, the operator installs and operates a “backpressure preventer which is set to operate at or above the minimum inlet gas flow rate.”

Commenter (2326-AXPC) notes that the monitoring of an ECD’s inlet flow is physically indistinguishable among devices performance tested by a manufacturer or the operator because the performance test does not impact inlet flow rate characteristics. Rather, as the December

---

<sup>38</sup> See, for example, Organic Liquids Distribution NESHAP at 40 CFR 63.2380(e).

<sup>39</sup> See, for example, Miscellaneous Organic Chemical Manufacturing NESHAP at 40 CFR 63.2450(e)(5)(v) and Ethylene Production NESHAP at 40 CFR 63.1103(e)(4)(iv). Also see proposal regulatory text for Synthetic Organic Chemical Manufacturing Industry: Organic NESHAP, 40 CFR part 63, subpart F; available in docket EPA-HQ-OAR-2022-0730.

2022 supplemental proposal requires, the commenter explains that the performance test establishes, among other things, a minimum and maximum flow rate within which the device will meet requisite emissions reduction requirements. The commenter adds that this range has no bearing on whether the operator can demonstrate the maximum flow to the ECD will remain below the maximum flow rate established in a performance test, and a “backpressure preventer” will perform the same across all ECDs to ensure flowrate to an ECD remains above the minimum flow rate established in a performance test.

Response II-17-60: See response II-17-16, which responds to this issue.

Comment: Commenter (2399-GPA) suggests that temperature during control device testing is the best indicator of combustion performance and should be an available alternative to continuous monitoring. The commenter states that temperature monitoring should not be based on just a static number but on the temperature achieved during the initial performance testing that demonstrates required destruction efficiency set as a minimum temperature limit. The commenter suggests that the minimum temperature could be updated in subsequent performance tests if the required destruction efficiency can be met at a lower temperature. The commenter is concerned that the temperature limit in proposed 40 CFR 60.5414b(c) is unnecessarily high and would require a large amount of supplemental fuel gas to maintain continuous compliance with the limit generating additional greenhouse gas emissions from the combustion of supplemental fuel. Further, the commenter notes, the proposed limit appears to be based on a temperature in the flame zone which many enclosed combustors cannot monitor. The commenter explains that most enclosed combustors have thermocouples installed above the flame zone in the combustion chamber, resulting in lower read temperatures due to the location. If the thermocouple is used during testing, however, the commenter states that the test should demonstrate that proper combustion is occurring. Therefore, the commenter requests that EPA provide more flexibility in temperature testing to account for the differences inherent in enclosed combustor design.

Response II-17-61: See response II-17-70, which responds to this issue.

Comment: Commenter (2294-OOGA) believes that the proposed control device testing and monitoring requirements are unworkable. The commenter explains that oil and natural gas production facilities typically use ECDs to control VOC and methane emissions that result from the collection of well liquids during production activity. During natural gas production, well liquids are brought to the surface periodically and are routed to a storage tank and this activity occurs intermittently and often unpredictably. For many well facilities, the commenter states the resulting off gassing of the collected liquids, also known as “flash gas”, directs these emissions to an ECD resulting in low flow rates near ambient pressure. The commenter explains that the inherent nature of this operating scenario leads to several technical issues related to the proposed test methods for conducting performance testing on these ECDs. Specifically, the commenter is concerned that many of the test methods required under the supplemental proposal may be incapable of yielding reasonably representative data under conditions as described above. Additionally, the commenter is concerned that the short duration of certain of these venting events may be less than the response time of a test method. By way of example, the commenter states that inlet flow measurement on ECDs with intermittent operation can be problematic due to short duration and low flow velocity. EPA Methods 2, 2A, 2C, and 2D, which are proposed

for flow measurement, are likely to result in inaccuracy due to the random and unpredictable nature of the venting process, states the commenter and this uncertainty in effectively employing any of these methods will result in inaccurate measurement. As an alternative, the commenter recommends that Method 2B could potentially be employed in these low flow, intermittent flow situations to provide more representative data.

Commenter (2294-OOGA) states that EPA Method 4 also has limitations as the intermittent nature of the normal operation of these ECDs would interfere with the ability to obtain the required minimum sample volume. Additionally, the commenter explains that the ability to capture a representative sample of the actual moisture content of the flash gas is limited due to the inherent non-instantaneous response time for activating the sampling train simultaneously with a venting event, states the commenter. Finally, the commenter is concerned that EPA Method 18 may have similar limitations as Method 4 as the test equipment response time may not allow for a representative sample to be obtained, given the nature of the described process.

The commenter (2294-OOGA) notes that EPA has faced similar control device testing challenges in the past, and describes, for compliance testing purposes, the National Emission Standard for Hazardous Air Pollutants Subpart HH allows an “end of stack” method to demonstrate compliance. The commenter urges EPA to consider and allow alternative test methods that would be better suited for low pressure, low flow, intermittent emission sources similar to the example described above.

The commenter (2294-OOGA) also is concerned with the proposed monthly Method 22 opacity observations of ECDs, because as with performance testing concerns noted above, production facilities that have intermittent and unplanned operation of ECDs will be challenged by this requirement. The commenter asks EPA to clarify that Method 22 opacity observations for these intermittent sources be conducted on an “as found” basis. The commenter explains that well facilities are often widely distributed over large areas, explains the commenter and even if an operator is in the general vicinity of an ECD, given the intermittent and unplanned operation of the process, the operator may not be able to receive an indication that the ECD is in operation, travel to the ECD location, and conduct a Method 22 observation before the unit discontinues operation. Furthermore, they add that many well production facilities are unmanned, thus making the ability to be present during operation of this type of ECD process for conducting Method 22 impracticable, states the commenter.

Response II-17-62: EPA is not adding the option for EPA Method 2B into the final rule, as it is more accurate to measure flow directly for the control efficiency testing required in NSPS OOOOb and EG OOOOc. This is consistent with the requirements in other sectors, as well as NSPS OOOO and NSPS OOOOa.

EPA notes that in NSPS OOOOb, EPA Method 18 is not an acceptable test method. Because both VOC and methane must be controlled, EPA proposed, and is finalizing, EPA Method 25A as the test method for demonstrating compliance with the control device requirements. For EG OOOOc, EPA Method 18 is an acceptable test method since methane is the only regulated pollutant. However, EPA has provided owners and operators the option to use EPA Method 25A or EPA Method 320 to demonstrate compliance in lieu of EPA Method 18. Additionally, as

noted in section XI.H.1 of the preamble to the final rule, EPA is finalizing an outlet concentration that can be used to demonstrate compliance in lieu of inlet and outlet testing. When determining compliance with the outlet concentration limit, measurement of flow by EPA Method 2 and measurement of moisture by EPA Method 4 are not required. This change should help to alleviate many of the issues raised by the commenter.

Owners and operators who cannot use any of the options outlined in the rules may also seek an alternative test method in accordance with §60.8(b). Additionally, §60.8(b) allows the delegated authority to approve shorter sampling times when necessitated by process variables.

Additionally, see response II-17-8, which addresses the issue of visible emissions observations on non-operational units.

Comment: Commenter (2326-AXPC) explains that recent experience in Colorado demonstrates that performance testing ECDs is infeasible without the use of supplemental gas for ECDs that control intermittent vapor streams – *e.g.*, storage vessel vapor streams. Where flow is intermittent, the commenter explains, obtaining a single one-hour run, much less three, is infeasible without use of supplemental gas. The commenter is also concerned that installation of a backpressure preventer to ensure inlet flow to the ECD is above the device's minimum flow rate will only exacerbate this issue, as a backpressure preventer ensures intermittent emissions flow to the ECD. Accordingly, the commenter requests that EPA either exempt ECDs from performance testing where normal inlet flow to the ECD is insufficient to facilitate a performance test or clarify that operators may use supplemental gas to facilitate the performance test.

Response II-17-63: §60.8(b) allows the delegated authority to approve shorter sampling times when necessitated by process variables. Additionally, §60.8(c) requires performance tests to be conducted under the conditions specified by the delegated authority, based on representative performance of the affected facility. Owners or operators should work with their delegated authorities to determine whether the addition of supplemental gas constitutes representative performance of the affected facility.

Comment: Commenter (2399-GPA) is concerned that the flowrate monitoring requirements in the supplemental proposal present significant technical difficulties and, in some cases, may not be possible. The commenter explains that many of these systems operate at, or slightly higher than, atmospheric pressure, meaning that only small volumes of gas will be sporadically released. They add that these systems are not designed to provide three hours of continuous flow to the control device. The commenter understands that manufacturer tested emission control devices provide an inlet pressure requirement, which thereby mandates installation of a control valve and pressure monitoring. According to the commenter, this, as well as improved liquids handling, leads to intermittent vapor routing making traditional performance testing, which consists of three one-hour runs, very difficult to complete. By way of example, they provide that a member company compiled one month's worth of data on pressure actuating at a tank facility and the valve (routing vapors to enclosed combustion device) opened for an average of eight seconds per actuation. The total time that vapors were routed to the control device during a day was under seven minutes.

Commenter (2399-GPA) requests that EPA allow for the use of pressure monitors coupled with control valves in lieu of flow rate monitoring because pressure monitoring achieves the same goal- ensuring that a sufficient volume of waste gas is going to the control device to ensure proper combustion. The commenter notes that many of the tank facilities that would be covered by the control requirements are already controlled by pressure monitors and control valves that route vapors to the control device only when tank pressure meets the manufacturer's set point for complete combustion and the safety setpoints on the tank pressure relief devices. The commenter provides as an example that, if a tank is rated to hold a pressure of 16 ounces, then a pressure transducer will open and allow vapors to the control device when the pressure reaches 10 ounces and it will close when pressure drops to seven ounces. The commenter states that certain manufactures report that only one ounce of pressure is needed to achieve good combustion, making pressure monitoring an accurate and reliable alternative to flow rate monitors.

Response II-17-64: §60.8(b) allows the delegated authority to approve shorter sampling times when necessitated by process variables. Owners and operators should work with their delegated authority on a site-specific basis to determine what constitutes representative testing for the control device.

EPA notes that NSPS OOOOb and EG OOOOc allow for pressure monitors in lieu of flow monitors.

Comment: Commenter (2428-API) asserts that EPA must provide the minimum inlet flow rate for current manufacturer-tested control devices no later than publication of the final rule so that owners and operators are able to achieve compliance. In the preamble, the commenter points to an EPA statement that previously tested manufacturer control devices “would not need to perform new performance tests” and “[t]he zero-level at which the combustion control device was tested will be extracted from the previously submitted performance test report and added to the information on the EPA’s website”. The commenter argues that this minimum flow rate information must be added to the EPA’s website<sup>40</sup> no later than publication of the final rule since owners and operators cannot extract the information themselves as the underlying test reports are not currently available on the website. The commenter adds that this minimum flow rate information may also not be easily obtained from the manufacturer directly and EPA must provide this minimum flow rate information no later than publication of the final rule so that owners and operators are able to take any necessary action (e.g., purchase of a different control device or operational changes) to achieve compliance. The commenter suggests that if the minimum flow information is not provided by the publication of the final rule, EPA should consider implementing a longer initial compliance period.

Response II-17-65: EPA will be updating the list for combustion control devices tested by the manufacturer located on our website to include the minimum inlet flow rate for combustion devices that have demonstrated the performance requirements.

Comment: Commenter (2288-NDDEQ) states that for control devices used to comply with emissions standards, the supplemental proposal requires a full Method 25A test for the control

---

<sup>40</sup> <https://www.epa.gov/stationary-sources-air-pollution/performance-testing-combustion-control-devices-manufacturers>.

device to determine the 95 percent methane reduction requirement in 40 CFR 60.5412c(a)(1)(i). The commenter notes that they have previously commented that, due to issues with sales line access that control devices are required by state law at sites even if a sales line is available, in situations where access is cutoff or otherwise reduce due to pipeline maintenance/emergencies, pressure limitations, or lack of takeaway capacity within the pipeline itself. Specifically, they provide that North Dakota state law requires that organic compounds gases and vapors be burned by a flare or an equally effective control device (except when from an emergency vapor blowdown system or emergency relief system). The commenter explains that this essentially requires every well site that could emit "organic compounds gases and vapors" (North Dakota Administrative Code Chapter 33.1-15-07-02) to have a flare of some type. The commenter is concerned that the testing requirements would put an undue burden on operators utilizing what is essentially a backup device to safely dispose of the gas and prevent venting during such upsets and other temporary disruptions. The commenter requests that control devices used temporarily when associated gas cannot be sold or otherwise routed for beneficial use be exempted from the operational and performance testing requirements.

Commenter (2288-NDDEQ) is also concerned with the sheer volume of performance testing reports that will be generated to demonstrate continuous compliance, and as per the proposed model rule language in EG OOOOc, that the reports be submitted solely to EPA through CEDRI. If it is EPA's stated intention for EG OOOOc to largely supplant older NSPS "because the presumptive standards proposed for EG OOOOc result in the same or greater emission reductions than the current standards in the older NSPS" (87 Fed. Reg. 74,716), the commenter states that these reports will strain the commenter's ability to properly review them if it causes every single existing well facility to be affected.

The commenter (2288-NDDEQ) reports that every well site that has the potential to emit "organic compounds gases and vapors" is currently required to have a flare or equally effective control device per state law, the commenter estimates roughly 7,000 flares being used to safely dispose of the high pressure "associated gas" from the wellhead in addition to a similar number of flares being used to safely dispose of the low-pressure gas from onsite storage vessels. The commenter is concerned that the proposed EG OOOOc does provide a performance test exemption for flares designed and operated in accordance with 40 CFR 60.18(b), however it is unknown how many such flares in North Dakota qualify. In a worst-case scenario, the commenter notes that North Dakota could have 14,000 flares subject to periodic testing. When added to the required 60-month testing period deadline as described in 40 CFR 60.5407c(b)(a)(ii), this results in thousands of additional tests that will be required every year throughout North Dakota. The commenter states that these are tests that they (as a state agency) will be obligated to review to ascertain operator compliance with the EG OOOOc.

Response II-17-66: EPA has determined that 95 percent control of emissions from affected or designated facilities is BSER. Any control device used to achieve this standard must meet the monitoring and testing requirements in the rule. However, §60.8(b) allows the delegated authority to waive performance tests if the owner or operator can demonstrate by other means, to the satisfaction of the Administrator, that the affected source is in compliance with the standard. Additionally, devices that are onsite but not in use are exempt from testing requirements until

they are started up. EPA notes that flares are exempt from performance testing requirement, but they must meet the monitoring requirements specified in NSPS OOOOb and EG OOOOc.

EPA acknowledges the concern of the commenter regarding the volume of performance test reports. EPA notes that its electronic reporting program is intended to ease the burden on delegated agencies. Standardizing the reporting format requires the reporting of specific data elements, thereby helping to ensure completeness of the data and allowing for accurate assessment of data quality. Imbedded quality assurance checks perform some of the required method calculations, reducing errors in test reports. The report standardization and imbedded quality assurance check assist in quicker and more accurate determinations of compliance.

### ***17.3.2 Regulatory Language and Clarifications for Other Control Devices***

Comment: Commenter (2288-NDDEQ) notes that NSPS OOOOa and the proposed NSPS OOOOb language list performance testing procedures for control devices under 40 CFR 60.5413 (a or b depending on subpart), however, there is no 40 CFR 60.5413c. Instead, the performance testing procedures for control devices in EG OOOOc are listed under 40 CFR 60.5407c. The commenter recommends that 40 CFR 60.5407c be moved to 40 CFR 60.5413c for consistency with the other subparts. Additionally, they point out that despite section 40 CFR 60.5413c not formally existing in the proposed language, references to 40 CFR 60.5413c occurs twice in the model rule, presumably as holdovers from an earlier draft of the rule language:

1. At 40 CFR 60.5398c(b)(a)(iv): "If the results of the periodic screening in paragraph (b)(4)(i) of this section indicate a confirmed detection at a designated facility, and the ground-based monitoring survey and inspections required by paragraph (b)(4)(ii) of this section demonstrate the confirmed detection was caused by a failure of a control device subject to 60.5413c", "60.5473c" presumably should be replaced with "60.5407c".
2. At 40 CFR 60.5412c(a)(1)(vi): "You must operate each enclosed combustion control device at or below the maximum inlet gas flow rate established in accordance with 60.5417c(f) and as determined in your performance test conducted in accordance with 60.5413c(b)". "60.5413c(b)" presumably should be replaced with "60.5407c(b)".

Response II-17-67: EPA agrees with the recommendation made by the commenter. The testing requirements in EG OOOOc have been moved to §60.5413c.

Comment: Commenter (2428-API) believes that manufacturer-tested enclosed combustion devices should continue to be exempt from periodic performance testing. The commenter explains that under NSPS OOOO and MACT HH, manufacturer-tested control devices are exempt from periodic performance testing, and under NSPS OOOOa, manufacturer-tested control devices on centrifugal compressors are exempt from periodic performance testing if the device has continuous flow monitoring. The commenter notes, however, that NSPS OOOOb proposes that manufacturer-tested control devices be subject to both periodic performance testing and continuous flow monitoring. The commenter is concerned because they believe that these requirements appear contrary to both the technical challenges in conducting performance tests in

the field reiterated by EPA and the agency's intent stated in the August 2011 preamble for the proposal of NSPS OOOO:

[w]e believe that testing units that are not configured with a distinct combustion chamber present several technical issues that are more optimally addressed through manufacturer testing, and once these units are installed at a facility, through periodic inspection and maintenance in accordance with manufacturers' recommendations.

[Text omitted for brevity.]

For these reasons, we believe the manufacturers' test is appropriate for these control devices with ongoing performance ensured by periodic inspection and maintenance.<sup>41</sup>

Given EPA's previous rationale for manufacturer testing, the monitoring requirements proposed under NSPS OOOOb, and the increased number of control devices subject to these monitoring requirements, commenter (2428-API) recommends that manufacturer-tested control devices continue to be exempt from periodic performance testing.

Response II-17-68: EPA disagrees with the commenter. Manufacturer-tested control devices continue to be exempt from initial testing by the owner or operator but must be tested periodically. However, degradation occurs as control devices age, and it is important that these combustion devices perform periodic testing to demonstrate that they are still capable of achieving the required control efficiency.

Comment: Commenter (2399-GPA) requests confirmation that control devices do not need to be continuously tested when they have a manufacturer's certification. The commenter believes that EPA intended to exempt manufacturer-certified enclosed combustors from continuous testing, however, the commenter believes the regulatory text itself could be written to state that intent more directly. Accordingly, the commenter asks that EPA clarify and confirm that manufacturer-certified control devices would only be required to meet the minimum and maximum flow requirements from the manufacturer to be compliant with NSPS OOOOb and EG OOOOc.

Response II-17-69: EPA disagrees with the commenter. Manufacturer-tested control devices are exempt from initial testing by the owner or operator but must be tested periodically. The EPA recognizes that there was inconsistency in the regulatory text at proposal regarding the testing requirements, and we have revised §60.5413b and §60.5413c to reflect this requirement more accurately.

Comment: Commenter (2428-API) recommends that the minimum operating temperature and associated monitoring requirements be revised. The commenter notes that NSPS OOOOb proposes a minimum operating temperature of 760 °C and temperature monitoring for enclosed combustion devices that demonstrate that combustion temperature is an indicator of performance during initial performance testing while other enclosed combustion devices (i.e., those for which combustion temperature is not demonstrated to be an indicator of performance) would be subject to NHV monitoring requirements. The commenter states that given the increased number of

---

<sup>41</sup> 76 FR 52785 (August 23, 2011).

control devices subject to NSPS OOOOb and EG OOOOc, EPA should revise the minimum operating temperature and associated monitoring requirements in the following ways:

- Allow operators the flexibility to comply with either temperature or NHV requirements for enclosed combustion devices that demonstrate that combustion temperature is an indicator of performance. Some enclosed combustion devices, such as thermal oxidizers, are designed with a minimum operating temperature while others are not. Even if a device can demonstrate that temperature is an indicator of performance during testing, maintaining a minimum operating temperature during actual operation may be challenging and require additional supplemental fuel due to the low or intermittent flow of the vent streams. As proposed, a minimum operating temperature with associated monitoring is the only option for enclosed combustion devices that demonstrate combustion temperature is an indicator of performance. For those enclosed combustion devices, operators should be able to comply with NHV requirements as an alternative.
- Allow the minimum operating temperature to be established by performance testing. Rather than a fixed minimum operating temperature, EPA should allow operators the flexibility to comply with a default minimum operating temperature of 760 °C or the value established by the most recent performance testing. The enclosed combustion device may be able to demonstrate compliance at an operating temperature below 760 °C. Also, additional supplemental fuel may be required to keep the device at a minimum operating temperature of 760 °C when it could achieve a 95 percent control efficiency at a lower temperature. Operators should be allowed to conduct performance testing as needed to establish a new minimum operating temperature.
- Allow a minimum operating temperature and temperature monitoring for manufacturer-tested devices. As proposed, the minimum operating temperature and associated monitoring applies only to enclosed combustion devices not tested by the manufacturer. Like operators, manufacturers should be allowed to demonstrate that combustion temperature is an indicator of performance through performance testing and allow temperature monitoring as an option for demonstrating compliance. Operation and monitoring requirements should be consistent between manufacturer-tested and other enclosed combustion devices.

Response II-17-70: EPA agrees that owners and operators should have the flexibility to comply with either temperature monitoring or the net heating value and flow monitoring requirements for enclosed combustion devices that demonstrate that combustion temperature is an indicator of performance. However, we don't think that any changes to the regulatory text are needed to support this flexibility. Owners and operators can choose not to demonstrate the correlation during the performance test or choose not to establish a minimum temperature limit in the performance test report. If an owner or operator choose not to demonstrate the correlation or establish a minimum temperature limit in the performance test report, the enclosed combustion device would be subject to requirements for enclosed combustion devices that do not demonstrate that combustion zone temperature is an indicator of combustion efficiency. An owner or operator could also inform the delegated air agency that it is choosing to comply with the requirements for enclosed combustion devices that do not demonstrate that combustion zone temperature is an indicator of combustion efficiency instead of with the temperature monitoring provisions.

EPA agrees that it is appropriate to allow owners and operators to establish a minimum operating temperature during the performance test, similar to how other operating parameters are established. We have updated the requirements of NSPS OOOOb and EG OOOOc in the final rule to incorporate this change.

EPA disagrees that we should allow the option for a minimum operating temperature and temperature monitoring for manufacturer-tested devices. This has not historically been an option in the manufacturer testing program for the oil and natural gas sector. Allowing it in the final rule for NSPS OOOOb and EG OOOOc would be problematic for several reasons. Firstly, it would create differences in the manufacturer testing program in NSPS OOOOb and EG OOOOc from the program in NSPS OOOO, NSPS OOOOa, NESHAP HH, and NESHAP HHH. Secondly, it could potentially create a disadvantage to those manufacturers who have already conducted testing without having this option. And finally, this option would require extensive changes to how the manufacturer testing needs to be performed. Due to the impacts adding this option would create, if EPA did decide such a change was appropriate, it would be prudent to give stakeholders a chance to comment on a proposal of the changes. As such, we are not providing this option in the final rule for NSPS OOOOb and EG OOOOc.

Comment: Commenter (2428-API) believes that enclosed combustion devices subject to minimum operating temperature and temperature monitoring should also be exempt from periodic performance testing. The commenter explains that under MACT HH, combustion devices are exempt from periodic performance testing if the device demonstrates during initial performance testing that combustion zone temperature is an indicator of destruction efficiency and operates at a minimum temperature of 760 °C. The commenter points out that NSPS OOOO requirements changed this exemption to devices that meet the outlet TOC performance level and that establish a correlation between firebox or combustion chamber temperature and the TOC performance level and then NSPS OOOOa added a temperature monitoring requirement to the NSPS OOOO exemption for control devices on centrifugal compressors.

Commenter (2428-API) explains that NSPS OOOOb proposes to remove this exemption from periodic performance testing. As such, enclosed combustion devices that demonstrate during initial performance testing that combustion zone temperature is an indicator of destruction efficiency are subject to a minimum operating temperature, periodic performance testing, and temperature monitoring, summarizes the commenter. The commenter suggests that given the consistent monitoring requirements proposed under NSPS OOOOb and the increased number of control devices subject to these monitoring requirements, enclosed combustion devices for which temperature is correlated with destruction efficiency should be exempt from periodic performance testing.

To clarify the requested exemptions from periodic performance testing, commenter (2428-API) offers the following suggested changes to 40 CFR 60.5413b(b)(4)(ii) (underlined text indicates new text and struck out text indicates deleted text):

You must conduct periodic performance tests for all control devices required to conduct initial performance tests, except ~~for a control device whose model is tested under, and meets the criteria of paragraph (d)~~ as specified in paragraphs (b)(4)(ii)(A) and (B) of this

section. You must conduct the first periodic performance test no later than 60 months after the initial performance test required in paragraph (b)(4)(i) of this section. You must conduct subsequent periodic performance tests at intervals no longer than 60 months following the previous periodic performance test or whenever you desire to establish a new operating limit. You must submit the periodic performance test results as specified in §60.5420b(b)(12).

(A) A control device whose model is tested under and meets the criteria of paragraph (d) of this

(B) A combustion control device demonstrating during the performance test under paragraph (b) of this section that combustion zone temperature is an indicator of destruction efficiency and operates at a minimum temperature of 760 °Celsius or the minimum temperature established during the most recent performance test.

Response II-17-71: EPA disagrees with the comment. Demonstrating that there is a correlation between temperature and destruction efficiency will relieve owners and operators from certain monitoring requirements, such as inlet net heating value and gas flow rate. However, degradation occurs as control devices age, and it is important that these combustion devices perform periodic testing to demonstrate that they are still capable of achieving the required control efficiency.

Comment: Commenters (2399-GPA, 2428-API) ask for clarifications on requirements for regenerative carbon adsorption systems that use a regenerant other than steam. The commenter asks EPA to confirm that carbon regeneration systems are not subject to control device requirements. The commenters explain that some carbon absorption systems used in the midstream industry do not have access to a steam system, as frequently found at a chemical plant or refinery. In the gas production and processing industry, natural gas and heat exchange systems are used to regenerate the carbon beds instead of steam. The commenters report that these systems can be used when there is the potential for air to enter the system, and a carbon bed does not have a direct fire source, limiting the potential for a fire in the system. The commenters add that the regeneration cycle is infrequent for these systems. The commenters request confirmation that the gas from these regeneration cycles would not be subject to any control requirements in the final rule.

Commenter (2428-API) notes that while the proposed requirements for regenerative carbon adsorption systems are unchanged from NSPS OOOOa, EG OOOOc will subject existing sources and control devices to methane standards. The commenter states that operators should not be forced to change the operation of their existing control device provided they meet the applicable requirements. The commenter warns that forcing sites to switch to steam regenerant may be technically infeasible or economically unreasonable.

Response II-17-72: EPA disagrees that the gas from a regeneration system is not subject to control requirements. In the system described by the commenters, the emissions from the production equipment are adsorbed on a carbon bed. The carbon bed is then cleaned (regenerated) by blowing hot air across the carbon bed. If this hot air stream is released directly to the atmosphere, it is releasing all of the emissions that were captured by the carbon bed

initially, which equates to having no control on the production equipment. Therefore, the emissions from the regeneration process must be controlled in some way.

EPA does not intend to force owners and operators to change the operation of their control devices. EPA does not have enough information on the operation of these types of regenerative systems and how best the emissions from the regeneration process can be controlled. As allowed by §60.13(i) and §60.5417(d), owners and operators may request approval from the Administrator for alternative monitoring parameters to those specified in NSPS OOOOb and EG OOOOc; during this process information on the system, the monitored parameters, and how the parameters effectively demonstrate control of emissions should be included in the application. Additionally, owners and operators can choose to continuously monitor the concentration at the outlet of a control device in lieu of monitoring parameters.

Comment: Commenter (2399-GPA) requests that EPA confirm the scope of the use of Vapor Recovery Units as a control device, i.e., where the closed vent system ends, and the fuel gas system begins. The commenter believes that the closed vent system should be included up to the compressor unit as the fuel gas system can have a variety of different break points after it leaves the compressor and may not have another break point up to a heater or compressor. Once compressed, the commenter states that the gas is at a higher pressure and should be considered recovered after it enters the recycle or fuel system.

Response II-17-73: The line routing the emissions from the affected facility to the vapor recovery unit is considered a closed vent system. The lines routing the recovered material to the fuel gas system or sales line are not considered part of an affected facility closed vent system. However, these lines would be covered by the fugitive emissions requirements in NSPS OOOOb and EG OOOOc.

Comment: Commenter (2399-GPA) requests that EPA clarify the meaning of ensuring “that each enclosed combustion control device is maintained in a leak free condition.” The commenter recognizes that the “leak free condition” requirement is not an entirely new concept, but owners and operators need additional clarity to ensure that inspections are completed properly to achieve compliance. The commenter contends that this should be limited to checking for fugitive emissions on the line leading up to the enclosed combustion device, similar to the requirements on a closed vent system. However, the commenter urges that, if EPA intends to require other measures to demonstrate compliance with the “leak free condition” requirement, it should specify those and make those specifications available for review and public comment.

Response II-17-74: EPA notes that the line leading up to the enclosed combustion device is part of the closed vent system and should be inspected as such. Maintaining the combustion device in a leak free condition means maintaining the combustion device so that all emissions sent to the combustion device are controlled by the combustion device. This includes maintaining the combustion device so that there are no visible emissions emanating from a location other than the stack, having no visible holes in the shell of the combustion device, and ensuring seals are in good condition.

### ***17.3.3 Costs and Benefits - Monitoring***

Comment: Commenter (2399-GPA) supports better monitoring for control device equipment but urges that any additional monitoring be cost effective. The commenter believes that as written, the supplemental proposal would require the installation of thousands of flow meters, NHV monitoring devices, and testing ports for compliance purposes. The commenter also requests that a proper cost-effective analysis be performed when considering control device requirements, as the commenter believes the monitoring equipment would cost the industry millions of dollars with costs expected to increase as short-term demand for this equipment dramatically increases (e.g., because of the supplemental proposal, and other rules, requiring similar monitoring equipment). The commenter urges EPA to consider these costs fully before adopting any final rule.

Commenter (2399-GPA) notes that installation of this equipment on existing flares will require a hot tap, which is specialized work that usually requires a third-party contractor to perform. Because of the safety protocols that are required to perform this work, and the nature of the work, the commenter states that it is often a costly install. The cost of performing a hot tap will sometimes be as much as all the other costs to install the equipment, depending on the location of the hot tap, explains the commenter, and they believe these costs should be considered to assess the full costs of controls.

Response II-17-75: EPA maintains that our cost analysis is reasonable. We did not make significant revisions to the requirements for thermal control systems that use temperature as the continuous operating limit, so we assume these comments are related primarily to the flare provisions and the enclosed combustion devices that use the same type of monitoring provisions as flares.

EPA included provisions for these combustion control systems to conduct an initial sampling demonstration rather than requiring installation of a continuous net heating value monitor. We also included provisions that allow owners and operators to use a backpressure regulator valve and engineering calculations to be used, where applicable, to demonstrate compliance with the flare tip velocity or maximum vent gas flow rate standards rather than requiring a continuous flow monitor. We expect that most facilities can use these alternatives and the commenter provided no justification as to why these alternatives would not significantly reduce the number of continuous monitors needed.

Moreover, we considered the cost of adding a control device to meet the emission limitations for various affected facilities in this rulemaking. For existing sources, we provide up to three years from the deadline for state plan submittals (which is 24 months after publication of EG 0000c) to achieve compliance with the proposed provisions, allowing adequate time for installation of controls and monitoring equipment to be timed with a process unit shutdown or facility turnaround, which should minimize the need to use hot taps. Nonetheless, because our cost estimate includes retrofitting affected facilities with a new control device, our costs should overestimate the costs associated with using an existing control device with an upgraded the monitoring system. As such, it is not necessary to revise our cost analysis in response to this comment.

#### **17.3.4 Costs and Benefits – Best System of Emission Reduction (BSER)**

Comment: Commenter (2362-EIP) states that relying on an analysis regarding the cost-effectiveness of requiring different levels of control at storage vessel facilities, EPA proposes to only require flares and other combustion devices to achieve 95 percent reduction of VOCs and methane, claiming that requiring a 98 percent destruction efficiency is not cost-effective and thus does not represent BSER under CAA section 111(a)(1):

[U]sing this example for storage vessel affected facilities, the EPA added the additional monitoring and operational costs expected to ensure a 98 percent minimum destruction efficiency and found that it would not be cost-effective to require control of storage vessels with the potential for VOC emissions below 12 tpy or methane emissions below 40 tpy. However, at 95 percent reduction, it is considered cost-effective to require control of storage vessels with potential VOC emissions of 6 tpy and methane emissions of 20 tpy. Therefore, requiring 98 percent reduction of methane and VOC results in the control of fewer storage vessels, and thus result in fewer overall emissions reductions.

Commenter (2362-EIP) points out that in the proposed rule, EPA states that it “received comments stating that variability in gas flow, pressure, and quality would present challenges to achieving 98 percent control efficiency, especially at low production wells.” Despite this observation, the commenter is concerned that EPA is proposing to allow sources to avoid the kind of continuous monitoring that would capture this variation, and instead rely on initial sampling of NHV over a ten-day period.

Further, commenter (2362-EIP) is concerned that EPA apparently has concluded that a performance standard requiring 95 percent destruction and removal efficiency (DRE) for flares and vapor control units (VCUs) could be applied to storage tanks with a methane PTE as low as 20 tons per year, whereas it would not be “cost-effective” to require a 98 percent DRE for tanks with a methane PTE below 40 tons per year. Because the lower DRE standard would apply to a broader universe of tanks that included smaller sources, the commenter states that the EPA has concluded that it would achieve greater emission reductions than a 98 percent DRE. The commenter suggests that EPA’s analysis is either indecipherable or relies on cost-effectiveness calculations that are erroneous, misleading, or at odds with EPA’s own proposal. By way of example, the commenter states that on p.7-2 of the TSD EPA explains: “For this analysis, we assumed control devices complying with 95 percent control requirement would only have to do initial demonstrations for the velocity and heating value requirements and that control devices complying with 95 percent control requirement would require flow meters and NHV monitors to demonstrate compliance.” The commenter believes the second half of the sentence was meant to state that “control devices complying with 98 percent control requirement would require flow meters and NHV monitors to demonstrate compliance.” If their interpretation is correct, the commenter states that EPA’s finding that a 95 percent DRE is more cost-effective assumes that the proposed rule’s requirement that flares and VCUs be equipped with flow and NHV monitors to assure proper combustion efficiency will never actually be implemented, which they contend is irrational. The commenter states that they attempted to obtain clarification of this language and EPA’s intent shortly before the public comment period ended but received no definitive answer

from EPA. If wrongly interpreted, the commenter asks that EPA explain the meaning of the cited sentence above.

The commenter (2362-EIP) further notes that while EPA has acknowledged that a single control device can serve multiple affected sources within a facility, the analysis in Chapter 7 of the TSD assumes that only one of those affected sources – tanks or tank batteries – will bear the full cost of a flare or VCU and the associated monitoring equipment associated with those control devices. When determining cost-effectiveness, the commenter urges EPA to apportion the capital and operating costs among all the affected sources within a facility that are served by the same control device.

The commenter (2362-EIP) examines other costs which are analyzed in Chapter 7 of the TSD, including capital and operating costs associated with the actual control device (flare or VCU), along with the various monitoring required to keep pilot lights lit and to ensure 98 percent destruction efficiency. The commenter believes that most of the new or existing sources (including relatively small tank batteries) are already operating flares or VCUs and assume 98 percent DRE or greater when reporting post-combustion emissions. If EPA believes a large number of sources affected by the rule are not equipped with these control devices, it should make that information public, states the commenter. Where flares and VCU's are already installed, (which the commenter believes to be the case for most existing oil and gas sources), the commenter states that EPA's analysis must evaluate the costs and benefits of the additional monitoring required to assure compliance with the DRE standards, without including control devices that were paid for long ago.

Commenter (2362-EIP) believes that requiring 98 percent—not 95 percent—destruction efficiency constitutes the best system of emission reduction under CAA section 111(a)(1). The commenter points out that when EPA first promulgated the general NSPS flare provisions from 40 CFR 60.18 (which EPA proposes to incorporate for NSPS OOOOb and OOOOc), the agency assumed that the general provisions would achieve 98 percent destruction efficiency.<sup>42</sup> The commenter also points out that EPA has recently determined that it is cost-effective to require other source categories, such as petroleum refineries and ethylene oxide facilities, to perform monitoring and meet operational limits for flares to achieve 98 percent destruction efficiencies.<sup>43,44</sup> The commenter believes that requiring a 98 percent instead of 95 percent destruction efficiency would result in much larger reductions of VOCs and methane at the affected flares and other control devices. The commenter points to past rulemakings showing that emissions reductions from requiring 98 percent destruction efficiency from flares and other controls here would be significant. By way of example, the commenter states that by instituting more stringent requirements for flares at petroleum refineries in 2015, EPA estimated that the improved refinery flare standards for hazardous air pollutants (HAPs) would reduce HAPs by 3,900 tons per year and VOCs by 33,000 tons per year<sup>45</sup> and EPA estimated that revising the

<sup>43</sup> See, e.g., 79 Fed. Reg. 36,880, 36,911-12 (June 30, 2014).

<sup>44</sup> See 80 Fed. Reg. 75,178, 75,214-15 (Dec. 1, 2015).

<sup>45</sup> 80 Fed. Reg. at 75,226.

standards for 102 existing flares from the ethylene production source category had the potential to reduce HAP emissions by 1,430 tons per year and VOC emissions by 13,020 tons per year.<sup>46,47</sup>

Commenter (2362-EIP) believes that EPA does not rationally explain why it is cost-effective to require other source categories—but not this one—to achieve 98 percent destruction efficiency from flares and other control devices. Further, the commenter states that EPA has arbitrarily and unlawfully only evaluated the costs for monitoring and operating controls at one portion of the oil and gas sector—tank batteries—and failed to evaluate the costs for other types of covered oil and gas facilities, which could be much lower than those for tank batteries. Thus, the commenter argues, EPA has not evaluated what is BSER for other portions of the oil and gas sector, in violation of CAA section 111(a)(1). The commenter also argues that EPA has not rationally explained why the purported costs for tank batteries would also be applicable for other types of oil and gas facilities. The commenter urges EPA to evaluate the cost-effectiveness for requiring 98 percent destruction efficiencies at all other types of oil and gas facilities, including oil wells and processing plants.

Response II-17-76: EPA acknowledges the monitoring alternatives proposed may not fully account for all the variability in gas flow, pressure, and quality that would present challenges to achieving 98 percent control efficiency. As EPA’s cost analysis determined, the costs associated with continuous monitoring systems to ensure 98 percent control efficiency is met at all times was not cost effective, particularly for smaller control systems. EPA is not obligated to require owners and operators to install monitoring systems to ensure 98 percent control efficiency, as our BSER analysis concluded that BSER is 95 percent control efficiency.

EPA disagrees with the commenter’s suggestion that we should share the costs of controls across all affected facilities at a site. When EPA determines BSER for a specific affected facility, we must consider the emissions for that affected facility and the costs of applying controls to that specific affected facility. While we acknowledge that there may be times where multiple affected facilities may be present at a given site, our costs analysis cannot assume that is the case unless all sites have the same combination of affected facilities. When developing the national impacts for the proposed storage vessel requirements, EPA did assume many storage tanks would be controlled based on existing state and federal regulations, and we did not account for costs associated with controlling those storage vessels. However, in the BSER analysis, EPA must consider the reasonable worst-case scenario, which is a new control device being purchased and installed to control the emissions from the affected facility. This is consistent with the analysis we conducted for affected storage vessels. EPA notes that adding continuous monitoring systems to existing control systems is at least as expensive as including continuous monitoring systems as part of a new control system, so our conclusion regarding the cost and cost effectiveness for meeting a 95 percent control efficiency versus a 98 percent control efficiency is equally applicable to facilities with existing control devices.

While EPA specifically evaluated the cost difference associated with requiring control systems to meet 95 percent control efficiency versus 98 percent for storage vessels, as we stated in the December 2022 Supplemental Proposal, we considered that analysis to be generally applicable to

---

<sup>46</sup> See 84 Fed. Reg. 54,278, 54,301 (Oct. 9, 2019).

<sup>47</sup> 85 Fed. Reg. 40,386, 40,414 (July 6, 2020).

other affected facilities under NSPS OOOOb because the size range of control devices evaluated for storage vessels cover the range of controls used for other affected facilities.<sup>48</sup>

The commenter cited cost effectiveness and emissions reductions achieved at petroleum refineries and ethylene production sites, but these are much larger sites than typical oil and gas production sites. Additionally, many oil and gas production sites are remote and unmanned and some do not have access to electricity. It is not unreasonable when considering these smaller sources with different constraints that different conclusions are made regarding the cost effectiveness.

As discussed in the December 2022 Supplemental Proposal,<sup>49</sup> EPA is maintaining that BSER is 95 percent control of emissions for affected facilities in NSPS OOOOb and EG OOOOc.

The commenter is correct that the second half of the sentence quoted from the TSD should have stated that “control devices complying with 98 percent control requirement would require flow meters and NHV monitors to demonstrate compliance.”

### **17.3.5 EPA Method 320**

Comment: Commenter (2399-GPA) requests that EPA allow owners and operators to use Fourier Transform Infrared (FTIR) spectroscopy as an alternative to Method 25a. See Proposed 40 CFR 60.5413b(b)(3). The commenter notes that FTIR testing is commonly used for engines and turbines, and EPA previously approved the method for demonstrating compliance with 40 C.F.R., Part 60, Subparts IIII, JJJJ and KKKK and Part 63 Subpart ZZZZ. The commenter provides that this is a more cost-effective testing method than Method 25a, because it can measure multiple pollutants at once with the same monitor, reducing mobilization costs. Accordingly, the commenter recommends that EPA authorize FTIR testing as an option for owners and operators.

Response II-17-77: EPA disagrees that EPA Method 320 (which measures pollutants by FTIR) is more cost effective than EPA Method 25A for NSPS OOOOb. The regulated pollutants for NSPS OOOOb are VOC and methane. EPA Method 25A uses a flame ionization analyzer to report total organic compound concentration based on the calibration gas (propane in NSPS OOOOb). The total organic compound concentration includes the concentration of both VOC and methane; as such, no other methods are required to be conducted simultaneously to monitor additional pollutants.

EPA disagrees that Method 320 is an acceptable measurement method for VOC in this sector due to the variability of the streams sent to the control device. EPA Method 320 is appropriate for measuring specific organic compounds and excels in speciated VOC measurements. However, EPA Method 320 is not a robust total VOC measurement method for determination of compliance with a total VOC emissions limit. Measurement of total VOC by FTIR is particularly problematic after combustion devices owing to the myriad of compounds that can form in the combustion process. Due to the lack of a consistent, demonstrable, and validated approach to

---

<sup>48</sup> 87 FR 74794 (December 6, 2022).

<sup>49</sup> 87 FR 74794 (December 6, 2022).

measuring total VOC emissions, primarily due to the lack of a discrete list of compounds constituting the total VOC emissions from combustion, EPA proposed to remove the use of EPA Method 320 from NSPS JJJJ, but ultimately deferred action on that removal to consider the matter on a rule-specific basis.<sup>50</sup>

For EG OOOOc, because the regulated pollutant is methane instead of VOC, EPA has added Method 18 and Method 320 as acceptable test methods when conducting testing to determine control efficiency.

### ***17.3.6 Adequate Time for Implementation-Control Device and Associated Monitoring Equipment Supply Chain Issues***

Comment: Commenter (2428-API) suggests that adequate implementation time must be provided for NSPS OOOOb and EG OOOOc. The commenter states that NSPS OOOOb and EG OOOOc will apply to hundreds of thousands of sites when implemented and member companies already are experiencing a noticeable delay in the supply chain for equipment required by the proposed rules including (but not limited to) control devices, flow monitoring equipment, instrument air systems, solar panels, etc. By way of example, the commenter states that control devices are currently experiencing delays of 3 to 4 months, flow monitors are on backorder for a minimum of 6 to 8 months from suppliers, instrument air systems (including the air compressor and associated equipment) are nearly 1 year on backorder, and recently ordered solar panels are delayed between 18 to 24 months. As more facilities become subject to proposed requirements in NSPS OOOOb and EG OOOOc, the above timelines are anticipated to be exacerbated before the market experiences a correction to meet these new levels of demand, explains the commenter. The commenter requests EPA consider these challenges prior to finalization of certain provisions within these rules to allow operators the ability to acquire and install the required equipment. Additionally, the commenter requests that EPA provide additional time for new, modified, and reconstructed sources to come into compliance with NSPS OOOOb, if it maintains the current applicability date of November 15, 2021.

Commenter (2428-API) states that due to EPA's proposed designation of the applicability date aligned to the November 2021 proposal, operators may not have the adequate flow and NHV monitoring technology in place for all sites subject to the provisions proposed in NSPS OOOOb, because these additional monitoring requirements were only contemplated but not specifically proposed in that initial proposal. The commenter explains that because EPA's proposal for consistent control device monitoring requirements (regardless of the affected facility) between both NSPS OOOOb and EG OOOOc, the number of control devices subject to monitoring requirements will increase significantly and the current supply chain delay for acquiring flow meters or similar monitoring equipment is currently approximately 6 to 8 months. This delay within the supply chain is expected to be exacerbated based on both NSPS OOOOb and EG OOOOc implementation over the coming years, states the commenter.

Commenter (2428-API) states that in addition to the supply chain delays in acquiring the monitoring equipment, installation of the monitoring equipment for existing control devices will

---

<sup>50</sup> See proposed rule 80 FR 54146 (September 8, 2015). For additional information, see technical memorandum to the docket, Steffan Johnson, September 28, 2015, document ID EPA-HQ-OAR-2014-0292-0008.

require a hot tap on the control device piping or a site shutdown. The commenter explains that a hot tap is a specialized procedure to make new piping connections, such as those required to install monitoring equipment, while the piping remains in service. The commenter states that hot taps require high flow rates to facilitate heat transfer during welding, and additional purge gas may be needed depending on the site gas production. The commenter further explains that this procedure presents a higher safety, fire, and explosion risk and due to this elevated risk and specialized nature, operators are currently experiencing delays of approximately 4 months or more to schedule a vendor to perform a hot tap. As an alternative to a hot tap, the commenter states that a site shutdown to install control device monitoring equipment will result in emissions from the shutdown and purging of equipment and piping. The commenter reports that shutdowns at midstream compressor stations or gas plants could result in gas venting, gas flaring, or a shut-in at upstream facilities, explains the commenter. The commenter asserts that a shorter compliance period will multiply these disruptions as operators work to comply with NSPS OOOOb.

Commenter (2428-API) states that in the 2012 NSPS rule, EPA allowed implementation for storage vessel requirements to be phased-in to accommodate the vast number of affected facilities and the number of control devices that would be needed to be acquired. The commenter adds that other state rules, such as those in Colorado and New Mexico<sup>51</sup>, have allowed for an orderly phase-in period for certain requirements. The commenter urges EPA to consider a similar compliance schedule in the proposed NSPS OOOOb and EG OOOOc based on similar constraints and concerns for acquiring the appropriate monitoring equipment that has historically been exempt from control devices for storage vessel affected facilities.

Based on feedback from members, commenter (2428-API) requests the initial compliance period for control device flow and NHV monitoring requirements be extended from 60 days after final publication in the *Federal Register* to at least 1 year after publication in the *Federal Register* to allow operators time to order and install the necessary meters (assuming that the applicability is based on the December 6, 2022, and other comments concerning reconstruction and modification are addressed). Additional time, at least another year, would be required if the rules are finalized as proposed, states the commenter. Specifically, the commenter requests that compliance with the flow and NHV monitoring requirements at 40 CFR 60.5417b(d)(1)(vii)(A), 40 CFR 60.5417b(d)(1)(viii)(B), and 40 CFR 60.5417b(d)(1)(viii)(D) along with related operational requirements be extended to allow operators adequate time to procure and install the necessary monitoring equipment where appropriate as various new equipment is installed, or other equipment is modified or reconstructed.

Commenter (2399-GPA) is concerned that EPA has not provided enough lead time for installing the monitoring equipment required by the supplemental proposal. The commenter notes the process is complicated by potential supply chain issues that would be expected to arise as the entire industry orders thousands of new monitoring devices that would need to be installed over the next few years. This type of monitoring equipment has already started to see longer lead times because of global supply shortages, explains the commenter. Further, the midstream industry is continuing to grow, which the commenter states means that more and more control devices are being installed every month, requiring the installation of more monitoring equipment.

---

<sup>51</sup> 20.2.50.122.B(3) NMAC and 20.2.50.123.B(1) NMAC.

This does not include the current demand for monitoring equipment from the production sector, cautions the commenter. The commenter reports that plant and compressor stations are currently being built without this monitoring equipment being part of the original plans because there was no reasonable way to anticipate these additional requirements, requiring retrofits almost immediately. As a result, the commenter requests at least one year to install the monitoring equipment for sources subject to NSPS OOOOb.

Commenter (2326-AXPC) is concerned about the new NHV monitoring requirements for combustion control devices, in addition to flow monitoring that the commenter states will cover many more control devices than under current rules. The commenter states that at least for NHV monitoring, this could not have been anticipated, and NHV and flow monitoring equipment and the resources to engineer and install it will be in high demand and short supply. The commenter also has concerns with the proposed enclosed combustion device performance testing requirements, which they note are similar to NSPS OOOO and OOOOa, but will require significantly more testing under NSPS OOOOb and EG OOOOc. The commenter is concerned that the expanded scope of coverage of performance testing requirements will increase demand significantly, and likely well above the current testing resource supply. The commenter suggests it will take at least one year, and likely longer, for performance testing vendors to acquire additional testing equipment and hire and train new personnel to meet the unprecedented demand. The commenter proposes that EPA extend the initial compliance deadline for all combustion control device monitoring and performance testing requirements by at least one year. Alternatively, if EPA is unwilling to provide extended initial compliance deadlines as requested above, the commenter requests that EPA provide extensions where good cause exists, as it did under the recently promulgated Uintah and Ouray Indian Reservation FIP for oil and natural gas sources.<sup>52</sup>

Response II-17-78: See section IX.A of the preamble to the final rule for a discussion on the applicability date for NSPS OOOOb. Additionally, in the final rule, EPA has extended the compliance date for certain affected facilities. See discussion in sections X.F.2, XI.D.4, and XI.E.2 of the preamble to the final rule for a discussion on the compliance date for oil well wells with associated gas, process controllers, and pumps.

EPA has made numerous changes to the final rule to ease the implementation burden and supply chain issues for owners and operators. Many of these changes are discussed in other comments in this chapter. For example, EPA has changed the accuracy requirement for flowmeters on combustion control devices to provide owners and operators with more flexibility on available monitoring devices. EPA has also added more types of sampling systems that can be used to assess net heating value. Additionally, we have included a pathway in the final rule for owners and operators to request alternative approaches for monitoring combustion control devices.

Moreover, EPA included provisions for combustion control systems to conduct an initial sampling demonstration rather than requiring installation of a continuous net heating value monitor. We also included provisions that allow owners and operators to use a backpressure regulator valve and engineering calculations to be used, where applicable, to demonstrate compliance with the flare tip velocity or maximum vent gas flow rate standards rather than

---

<sup>52</sup> 40 CFR 40 CFR 49.4169(c).

requiring a continuous flow monitor. We expect that most facilities can use these alternatives, and the commenters provided no justification as to why these alternatives would not significantly reduce the supply chain issues raised in the comments.

EPA also notes that existing sources will have up to three years from the deadline for state plan submittals (which is 24 months after publication of EG OOOOc) to achieve compliance with the proposed provisions, allowing adequate time for installation of controls and monitoring equipment to be timed with a process unit shutdown or facility turnaround, which should minimize the need to use hot taps.

Based on revised compliance deadlines, the fact that control devices for existing designated facilities will not need to be tested immediately, exemptions from performance testing for flares, and the availability of manufacturer tested enclosed combustion devices, EPA does not think that a year extension is needed for performance testing, and the commenter has not provided data showing that these factors were accounted for in the comment. Owners and operators who cannot meet this performance testing deadline should work with their delegated authority. For example, §60.8(b) allows the delegated authority to waive performance tests if the owner or operator can demonstrate by other means, to the satisfaction of the Administrator, that the affected source is in compliance with the standard. Identical control devices with identical operating conditions could be a situation in some circumstances in which the delegated authority is satisfied that both control devices can meet the standard by only testing one control device.

## Chapter 18. Recordkeeping and Reporting

### 18.1 Context for Financial Investments

Comment: Commenters (2190-Miller/Howard Investments, Inc. (MHI), 2191-Boston Trust Walden Company) write from the perspective of international financial investment firms and urge EPA to finalize strong methane emission performance standards that establish a transparent, credible, and empirically based methane emissions reporting framework to improve the accuracy and credibility of reported methane emissions data and enable investors to clearly differentiate between leaders and laggards.

Response II-18-1: The comment is a supportive comment of the December 2022 Supplemental Proposal; as such, no response is required. See also Volume I, Chapter 23 (Miscellaneous Other Comments), subsection 23.9.1 (Rule-Related Recordkeeping and Reporting Requirements), Response I-23-46, for EPA's response to comments requesting that EPA adopt a reliable reporting framework that investors and other stakeholders can utilize.

### 18.2 Security and Access Concerns

Comment: Commenter (2428-American Petroleum Institute (API)) identifies multiple potential security risks and access issues that could prevent an affected facility from being in compliance with the proposed regulations. The commenter requests EPA implement a secure process, similar to EPA's electronic Greenhouse Gas Reporting Tool (e-GGRT) program to prevent somebody other than an authorized representative from being able to submit information to Compliance and Emissions Data Reporting Interface (CEDRI).

Commenter (2428-API) also points out that many companies do not allow the use of workbooks containing macros as a cybersecurity measure and the current draft workbook contains macros. The commenter reminds EPA that some reporters using the form may have issues using the form if the form is dependent on the macro formatting.

Commenter (2428-API) adds that it is also concerned about the practical implications with reporting through CEDRI when/if there is a system outage. Specifically, the commenter requests EPA evaluate the following language as proposed under new source performance standards (NSPS) OOOOb and emission guidelines (EG) OOOOc, and notes that these concerns also apply to NSPS OOOOa:

- *40 CFR 60.5420b(e)(2):* Commenter believes this paragraph should be removed or, at a minimum, be inclusive of the compliance end period and the compliance submittal date. Staff scheduling submittal may choose to do so prior to 5 days before the compliance submittal date. If EPA is requiring the use of the reporting form within CEDRI, then it should not be in deviation on the operator in any circumstance.
- *40 CFR 60.5420b(e)(4):* The requirement for the reporter to notify EPA immediately

- upon discovery of an outage is unduly burdensome for the reporter. EPA should manage the reporting system and notify registered users of an outage.
- *40 CFR 60.5420b(e)(5)(iii)*: It is unclear what EPA is intending for a reporter to include as far as “a description of measure taken to minimize the delay in reporting.” EPA should be taking action to minimize the delay in reporting if there is a CEDRI system outage. The regulated entity has no additional recourse in this instance.
  - *40 CFR 60.5420b(e)(6)*: System outage should warrant automatic claims to those submitting reports. Operators should not be penalized when the only method for submittal is not available and out of their control.

Response II-18-2: The electronic reporting requirements in the final NSPS OOOOb and EG OOOOc are consistent with the electronic reporting requirements across Part 52, Part 60, Part 62, and Part 63. A description of the electronic data submission process is provided in the memorandum “Electronic Reporting Requirements for New Source Performance Standards (NSPS) and National Emission Standards for Hazardous Air Pollutants (NESHAP) Rules,” which is available in the docket<sup>1</sup> for this rulemaking. As stated in that document, the EPA designed this process to be compliant with the Cross-Media Electronic Reporting Rule (CROMERR). The CROMERR (under 40 CFR part 3) provides the legal framework for electronic reporting under all of EPA’s environmental regulations and includes criteria for assuring that the electronic signature is legally associated with an electronic document for the purpose of expressing the same meaning and intention as would a handwritten signature if affixed to an equivalent paper document. In order to be CROMERR compliant, CEDRI requires certifiers to go through an identity-proofing process when registering. This ensures that only principals of the company are submitting information for the company.

EPA was unaware of the issue surrounding the macros in the reporting template. The only function of the macro within the workbook is to help the end-user navigate the workbook more easily by hiding tabs within the workbook that are not applicable to the owner or operator. EPA can post a version of the template with the macro removed for those users who are unable to use workbooks with macros. EPA encourages template users to report any issues they experience with templates to [cedri@epa.gov](mailto:cedri@epa.gov) so that these issues can be resolved.

EPA disagrees that owners and operators should have the ability to request an extension for submission of reports if there is any outage in CDX or CEDRI between the end of the reporting period and the date report submittals are due. We understand owners and operators may prepare and submit reports well ahead of the report submittal deadline, and we encourage owners and operators to do so. However, if an outage occurs two weeks prior to the date the report is due, the owner or operator still has two weeks to submit the report. As such, there should be no need for an extension of the reporting deadline. Such relief should only be needed if the outage occurs in the timeframe immediately preceding the report submittal deadline.

---

<sup>1</sup> EPA-HQ-OAR-2021-0317-0105.

EPA disagrees that reporting extensions should be granted automatically. EPA notes that there has only been one planned outage of CEDRI in the nearly 12 years that CEDRI has been online. EPA notified users of the outage in advance so that submitters were aware of the expected length of the outage and could plan accordingly. Should a future planned outage be necessary, EPA has the ability to notify CEDRI users in advance about the outage. While CEDRI has had some instances of unplanned outage, these instances are generally short in duration (less than 24 hours). EPA has no reason to expect that longer unplanned outages will occur in the future, as EPA conducts system health assessments and performs upgrades to CEDRI coding to ensure limited outages. EPA informs users of unplanned outages by posting information on the outage in CDX and CEDRI. Additionally, reports are prepared outside of CDX and CEDRI. The only function that occurs within CDX and CEDRI is the report upload and submission. If there is an outage, the upload and submission process is not time intensive and can be completed quickly once CEDRI is back online. For these reasons, EPA does not expect that anyone will need to assert a claim of EPA system outage if owners and operators are making reasonable efforts to report timely. However, EPA has provided an avenue to assert such a claim to cover unforeseen circumstances.

Owners and operators are not required to report CEDRI outages to the delegated air agency unless the owner or operator is asserting a claim of electronic reporting system outage. In the claim, the owner or operator must note the date(s) and time(s) that they accessed the system, and it was down. Additionally, the owner or operator should provide enough information to show that reasonable steps were taken to try and report, and that the reporting delay is due solely to circumstances outside the control of the owner or operator. EPA expects owners and operators to take into account situations that may affect reporting when they have control over these situations. If an owner or operator anticipates problems with their firewall or security system, then the facility should take these types of potential problems into account and plan accordingly. If the facility's computer system has recently undergone software updates, then the facility should consider the possibility that the new software is not compatible with CEDRI and should plan accordingly. Facilities should register for CEDRI as far in advance of the initial compliance date (or any time a certifier changes) as possible in order to ensure that they can complete the identity proofing process prior to the compliance date. Additionally, we recommend facilities start developing reports early, in case any questions arise during the reporting process.

There are several technical support mechanisms available to help preparers and certifiers with CEDRI reporting issues. In addition to HelpDesk, there is a LiveChat option in CEDRI. Both services are available between 8 am and 6 pm Eastern Standard Time, Monday through Friday. Additionally, users can email [cedri@epa.gov](mailto:cedri@epa.gov) with any questions or comments.

Addressing comments regarding the electronic reporting process, which impacts a myriad of regulations and has its own legislative and policy history, is beyond the scope of this rulemaking.

## 18.3 Stakeholder Engagement for Recordkeeping and Reporting

Comment: Commenters (2168-Indiana Oil and Gas Association (INOGA), 2172-Kentucky Oil and Gas Association (KYOGA), 2202-Texas Oil & Gas Association (TXOGA), 2428-API) note that they were not able to fully assess the impacts of EPA's proposed recordkeeping and reporting requirements. Commenter (2428-API) states that there was not enough time, while commenters (2168-INOGA, 2172-KYOGA) state that the availability of only a preamble prohibited them from being able to provide sufficient comments and validate EPA's time and cost estimates related to recordkeeping and reporting. Commenter (2202-TXOGA) states that the proposed regulatory text fails to outline the substantive requirements of CEDRI reporting for NSPS OOOOb and EG OOOOc in any practical detail.

Commenters (2168-INOGA, 2172-KYOGA, 2202-TXOGA, 2326-American Exploration and Production Council (AXPC)) request additional opportunities to collaborate with EPA to develop and revise the recordkeeping and reporting requirements.

Commenters (2168-INOGA, 2172-KYOGA, 2202-TXOGA) request a collaborative process like how industry and EPA worked together after the release of NSPS OOOOa to reduce some of the recordkeeping and reporting burden. Commenters (2168-INOGA, 2172-KYOGA) would like to continue to work collaboratively with EPA to create regulations that are cost-effective and common sense for the operators.

Similarly, commenters (2168-INOGA, 2172-KYOGA) note that when NSPS OOOOa was proposed in 2015, the recordkeeping and reporting requirements were as costly and burdensome as the field work. The regulated community would like to know what recordkeeping and reporting activities will be required prior to the final regulation being released.

Response II-18-3: Regarding the request for additional time to provide comments, please see Volume II, Chapter 23 (Miscellaneous Other Comments), subsection 23.4.1 (Public Comment Period Adequacy (i.e., Request for Extension, Inadequate Time Provided)), Response II-23-20 of this RTC. Contrary to the comment that EPA did not provide sufficient regulatory certainty regarding the recordkeeping and reporting requirements in the proposal, the EPA provided regulatory text and CEDRI templates for NSPS OOOOb and EG OOOOc in the docket<sup>2</sup> to the rulemaking. Further, EPA provided the opportunity to engage with stakeholders through this notice and comment rulemaking, and we have responded to those comments in this RTC document. EPA disagrees that the proposed regulatory text failed to outline the requirements for CEDRI reporting; the CEDRI reporting requirements are included in §§60.5420b and 5420c. The content of the NSPS annual report is included in §§60.5420b(b), 60.5423b, and 60.5424b(a)(1), (b), and (d). The content of the NSPS semiannual report for process unit equipment affected facilities is included in §60.5422b(b) and (c). The content of the annual report in EG OOOOc is included in §§60.5420c(b) and 60.5424c(a)(1), (b), and (d). The content of the NSPS semiannual

---

<sup>2</sup> EPA-HQ-OAR-2021-0317-1536.

report for process unit equipment affected facilities is included in §60.5422c(b) and (c).

## 18.4 CEDRI Reporting Template

Comment: Commenters (2168-INOGA, 2172-KYOGA, 2202-TXOGA, 2428-API) identify specific potential issues with the CEDRI proposed template.

Commenters (2168-INOGA, 2172-KYOGA) note that the proposed template is like the template required for NSPS OOOOa reporting. The commenters appreciate that the proposed template has not materially increased the number of pieces of data that need to be reported to EPA. However, the commenters recommend that EPA modify the Initial and Revised tab to not request that the specific number of valves and connectors be counted – but look at a broader metric. They elaborate that if maintenance is performed at a location and a valve or connectors are added or removed, then this could be a source of incorrect data in the future. They also do not believe that the time invested to count every valve and every connector at every wellsite or tank battery every year is a good use of time.

Commenter (2428-API) notes that the control device and closed vent system tabs are set up where multiple affected facilities that route to a single control device or through the same closed vent system cannot be identified on a single row. The commenter states that this will result in redundant and duplicate information being reported. The commenter also does not support the reporting of additional information related to well transfers (including name, phone number, email, and mailing address) as proposed at §60.5420b(b)(1)(v).

Commenter (2428-TXOGA) also notes that certain selection options for “Deviation Category” the “Description of Deviation” and “Type of Deviation” cells are automatically blacked out and do not allow an operator to provide additional context. The commenter suggests that the operator should have the ability to add free text in these areas and provide additional information as needed.

Response II-18-4: Regarding the comment that the number of valves and connectors should not be specified in the final template, EPA notes that this comment is relevant to the semiannual reporting template for onshore natural gas processing plants and the requirements under 40 CFR §§60.5422b and 60.5422c.<sup>3</sup> The requirement to submit the number of valves and connectors is consistent with the leak detection and repair (LDAR) reporting provisions for onshore natural gas processing plants, going to back to the original promulgation of NSPS KKK for these facilities in 1985. The EPA believed then and continues to believe that understanding the scope of the equipment in the affected facility is necessary to evaluate the remaining compliance reporting elements which must be reported. For instance, knowing the total number of regulated equipment can help EPA identify trends regarding leak rates and repair timelines. Therefore, the

---

<sup>3</sup> This template is applicable only for natural gas processing plants and should not be used for fugitive emissions components affected facilities at well sites, compressor stations, or centralized production facilities. Information on fugitive emissions components affected facilities at well sites, compressor stations, or centralized production facilities should be reported using the annual report templates for §§60.5420b and 60.5420c.

EPA is not making the suggested change to the reporting requirements in NSPS OOOOb and EG OOOOc, as reflected in the CEDRI reporting template.

Regarding the comment that the control device and closed vent system tabs on the annual report template are set up where multiple affected facilities that route to a single control device or through the same closed vent must be identified individually on separate rows, EPA notes that the regulatory requirements apply on an affected facility basis, and it is necessary to parse out the compliance status by affected facility. Individually identifying the affected facility allows EPA, the regulated community, and the public, to sort and compile compliance information for the affected facility of interest. Where a common control device or closed vent system is shared amongst affected facilities, users can copy and paste information for subsequent entries, which reduces the burden of re-typing repeating information.

Regarding the comment that certain cells are automatically blacked out based on prior entries in the “Deviations” tab for the annual report template, EPA notes this feature is intended to help end users walk through the form (and subsequently the reporting requirements of the rule). The blacked-out areas indicate that based on the information provided in previous cells, the information in that cell is not required. Additionally, even though the cell is blacked out, the cell is not locked, and the user can still type in the cell – the text will appear white and will be visible in the blacked-out cell. However, to accommodate the commenter’s concern, EPA is including an optional cell for additional information on the deviation tab. Owners and operators also have the option to include additional attachments as part of the zip file submitted to CEDRI; these additional attachments may be used to explain circumstances beyond the information captured by the template or to expound on information reported in the template.

Regarding the comment that reports should not include the information related to well transfers (including name, phone number, email, and mailing address), the commenter did not explain why this information is not necessary or is unduly burdensome. EPA believes this information is necessary to track ownership of wells due to the trend in the sector to sell off well assets frequently.

Comment: Commenters (2202-TXOGA, 2326-AXPC, 2254-Permian Basin Petroleum Association (PBPA)) request EPA publish a draft NSPS OOOOb or combination NSPS OOOOa/b template on its website as soon as practicable, so that the Agency is able to further solicit and accept feedback on the draft template from the regulated community via public events and make needed adjustments so that the final template is ready in conjunction with any forthcoming final rule. Commenter (2254-PBPA) provides that the template is difficult to find and its location within the docket does not facilitate review and comment. The commenter recommends that the draft template be included on the EPA CEDRI site, along with the NSPS OOOOa template. Commenter (2202-TXOGA) suggests that EPA relocate its draft template of the CEDRI reporting and recordkeeping requirements from a footnote in the regulatory preamble and place it in the final rule’s text.

Commenter (2202-TXOGA) adds that if the NSPS OOOOb template review and finalization process will be similar to the 5-year process to finalize the NSPS OOOOa CEDRI template, it will not actually be available for CEDRI reporting for the first NSPS OOOOb annual report.

Commenter (2326-AXPC) elaborates that operators rely on this template to inform recordkeeping and reporting processes, and operators cannot wait until close to the due date of the first annual report to have the final reporting template.

Commenter (2254-PBPA) further states that according to the template itself and the NSPS OOOOb and EG OOOOc rule language, the template is for NSPS OOOOb and EG OOOOc. The commenter believes that the reporting requirements for existing sources should be in coordination with individual states, as will be prescribed in each state's EPA-approved state plan on implementing EG OOOOc. Commenter (2202-TXOGA) states that since EG OOOOc will be implemented by the state under an EPA-approved state plan, it would make better sense to have the regulated community's EG OOOOc reporting flow to the state in which an affected facility is located instead of reporting through CEDRI.

Response II-18-5: The EPA has provided regulatory text and CEDRI templates for NSPS OOOOb and EG OOOOc in the docket<sup>4</sup> to the rulemaking. A docket was established for this rulemaking pursuant to CAA section 307, and also the Administrative Procedure Act (APA) discusses the process by which federal agencies, including EPA, develop and issue regulations. EPA considers the docket to the rulemaking the appropriate placement for draft NSPS OOOOb and EG OOOOc templates, both in terms of providing broad notice of availability to interested parties and in assimilating comments received on the templates. Because the reporting templates reflect the reporting requirements of each specific rule, when a commenter expresses concern about issues related to the template, generally the commenter is also expressing concern about the reporting requirements in the rule. It is important that these comments are captured in the docket, so that they can be addressed during the rulemaking process.

Users may always send information related to issues with templates or requests for revisions on templates to [cedri@epa.gov](mailto:cedri@epa.gov). Major issues with templates, such as issues that cause owners and operators to be unable to submit a report, will be resolved expeditiously. Cosmetic issues or minor issues will be handled on a case-by-case basis. EPA may choose to issue a new minor version of the template, which would allow owners and operators to use either the new or old template, or EPA may make the change at a later date when other changes are necessary.

EPA will post the final reporting templates for NSPS OOOOb and EG OOOOc on the CEDRI website. EPA has chosen not to post the draft forms for this rulemaking on the CEDRI website, due to the confusion that posting the draft NSPS OOOOb reporting template caused owners and operators. In order to limit confusion as to whether the reporting template is available (thus starting the timeframe for when the reporting template is required), EPA now plans to only post final reporting templates on the CEDRI website.

Regarding timing of the final reporting templates, EPA intends to finalize the templates as expeditiously as possible and in advance of the requirement to submit initial compliance reports. In the event this does not occur, EPA notes the final rule provides that the reporting templates are required to be used only once the template has been available on the CEDRI website for at least 90 calendar days.

---

<sup>4</sup> EPA-HQ-OAR-2021-0317-1536.

EPA disagrees that the reporting template should be in the final regulatory text. EPA surmises the commenter means the name of the reporting template (which is what was included in the preamble footnote) should be in the final regulatory text. EPA disagrees that it is necessary to include the reporting template name in the regulatory text. Each reporting template is named for the reporting requirement on which the template is based. For example, the NSPS OOOOa annual report template is named `part_60_subpart_60.5420a_annual_report.xslm`. EPA considers it redundant to list this name in the annual report section of §60.5420a. Additionally, on the CEDRI website, reporting templates are listed by subpart, which narrows down the choices and makes the reporting templates easy to find.

Regarding the comment that the reporting requirements for existing sources should be in coordination with individual states, the process of implementing the emissions guidelines in a particular state allows for the state to deviate from the model rule, provided the elements of the submitted plan are at least as protective as the elements in the model rule. See the discussion in sections XIII.C.2.a.iii and XIII.C.4 of the preamble to the final rule.

Regarding the comment that EPA should allow submittal of compliance reports using a state mechanism in lieu of the reporting templates and CEDRI for existing sources under EG OOOOc, EPA acknowledges this as a possibility, although we expect the majority of states to implement the same electronic reporting requirements in their state plans as is required by NSPS OOOOb.<sup>5</sup> As discussed within Section XIII.C.4 of the final rule preamble, states must include appropriate monitoring, reporting, and recordkeeping requirements to ensure that state plans adequately provide for the implementation and enforcement of standards of performance. See 40 CFR 60.25a. For the reasons that the EPA is requiring electronic reporting for the NSPS, as explained in section X.N of the final rule preamble, EPA included similar provisions within the model rule of EG OOOOc. EPA finds these provisions are preferable to use for state plans and highly encourages states to incorporate the provided reporting templates and CEDRI in their state plans. States must maintain the same monitoring, reporting, and recordkeeping requirements, or equivalent requirements, as described in EG OOOOc. Lastly, EPA notes that 40 CFR 60.5373c(e) specifies that approval of alternatives to electronic reporting cannot be delegated to state, local, or tribal agencies. This means that once EPA has approved a state plan which would already include a reporting structure, the state cannot unilaterally approve an alternative to the EPA-approved electronic reporting. If the state wishes to make a change at that time, they must amend their state plan.

## 18.5 Concerns with Current Regulatory Framework

Comment: Commenter (2270-Private Citizen) notes that the quality of information self-reported by the industry is a big problem.<sup>6</sup> [The article describes enforcement issues with rules to limit methane emissions in New Mexico, including that data reported by operators is inconsistent and

---

<sup>5</sup> For example, in response to the November 2021 Proposal, one state noted that most states will not be able to accommodate the amount of paper associated with annual reporting under this rulemaking and state personnel would access reports through CEDRI. See EPA-HQ-OAR-2021-0317-0763.

<sup>6</sup> <https://www.hcn.org/articles/energy-industry-new-mexicos-new-pollution-rules-leave-oil-and-gas-operators-to-police-themselves>.

inaccurate.]

Response II-18-6: The comment regarding perceived issues with the quality of information provided to a state agency are beyond the scope of this rulemaking; as such, no response is required.

## **18.6 Paperwork Reduction Act (PRA)**

Comment: Commenter (2179-Kansas Independent Oil & Gas Association (KIOGA)) believes that EPA has underestimated the annual burden for recordkeeping and reporting requirements in NSPS OOOOa. The commenter estimates their compliance costs to be significantly more than EPA's estimates. The commenter includes estimates based on their understanding of how the regulation will impact their industry. Additionally, the commenter believes that the documentation required by this regulation creates ample opportunities for any operator to be cited by EPA for missing information.

The commenter (2179-KIOGA) states that EPA is estimating that the average owner or operator will spend approximately 38 hours per year (98,438 labor hours/2,554 owners and operators), in the first three years, on compliance reporting activities. This time estimate is expected to cost the average owner \$1,316 per year (\$3,361,074 per year/2,554 owners and operators).

The commenter (2179-KIOGA) estimates a one-time cost to develop a management and reporting system to be \$40,000 - \$50,000 and an ongoing cost of compliance of \$20,000 - \$100,000 per year (one-part time employee early in the program and potentially two full time people within a few years). These estimates are based on their understanding of the final rule, and only to meet the reporting requirements detailed in the regulation and discussed below. These estimates do not include the cost to achieve compliance with their equipment at the affected facilities.

The commenter (2179-KIOGA) also reports that the documentation will necessitate many more hours than the EPA's estimated 38 hours per year. The commenter explains that companies are evaluating the need to hire another one to two people solely to meet the reporting requirements of this new regulation. The commenter believes that a full-time position(s) may be required to meet all the annual reporting and data management requirements to maintain compliance. The commenter estimates that the fully loaded cost (salary and benefits) to fill this position will be an additional \$50,000-\$60,000 per year per person to current operations.

The commenter (2179-KIOGA) adds that the rule also requires owners and operators to develop and maintain a corporate-wide and site-specific monitoring plan. The commenter estimates the effort to develop a robust system will exceed 500 man-hours to solicit input, develop the written program, review with the management team, and implement the program throughout their organization. At a fully loaded cost (salary and benefit) of \$60 per hour, the cost to develop this system is estimated at \$30,000-\$50,000. The commenter views the time invested in developing this type of system as part of the burden for recordkeeping and reporting.

The commenter (2179-KIOGA) notes that EPA requires digital photos and reports to be stored

for up to five years. The commenter reports that the development of a data management system, purchasing of additional data storage systems, and user training will require greater than 600-800 man-hours. At a fully loaded cost (salary and benefit) of \$60 per hour, the cost to develop an information technology (IT) solution is estimated at \$40,000-\$50,000.

Response II-18-7: The recordkeeping and reporting requirements in the rule that apply for each affected/designated facility represent the minimum level of tracking and documentation necessary to ensure compliance with the rule. EPA emphasizes that recordkeeping and reporting are vital components of compliance assurance and believes the recordkeeping and reporting requirements established in the final rule are reasonable and appropriate.

The EPA spent a significant effort in finalizing the specific cost elements used to estimate the recordkeeping and reporting burden when preparing estimates for the 2020 NSPS OOOOa rulemaking in order to address multiple comments received that the EPA had significantly underestimated the time and cost to complete the recordkeeping and reporting requirements (especially associated with the fugitive emissions program) under NSPS OOOOa. The majority of these costs and assumptions were retained in the recordkeeping and reporting burden analyses included in the December 2022 Supplemental Proposal and the final rule estimates, including the assumption of 22 wellsites per company-defined area and for gathering and boosting compressor stations 7 stations per company defined area. See section VII.B (Paperwork Reduction Act (PRA)) of the final rule preamble for EPA's estimate of the recordkeeping and reporting requirements under NSPS OOOOa, NSPS OOOOb, and EG OOOOc.

Comment: Commenter (2428-American Petroleum Institute (API)) believes that it is excessive to require such a significant level of detail to be both documented and submitted for all affected/designated facilities in this proposal. The commenter recommends that EPA simplify the recordkeeping and reporting requirements to those that assure compliance without additional administrative burden. The commenter recognizes that it is appropriate to maintain sufficient records to demonstrate compliance, however, suggests that only elements needed for compliance assurance be requested within the annual report. They note that supporting records retained by companies can be made available upon request from the Agency.

Commenter (2179-KIOGA) asserts that the proposed rules include onerous recordkeeping and reporting that exceed typical levels of compliance assurance and are a significant cost to operators to track and maintain. The commenter recommends that EPA continue to focus on having operators track the most necessary information to obtain assurance.

The commenter (2179-KIOGA) believes that in the December 2022 Supplemental Proposal:

- EPA increased the recordkeeping and reporting requirements without adequately justifying increased costs with respect to the administrative burden these proposed changes would require, including numerous technical demonstrations and engineering statements. Increased costs associated with administrative burden are disproportional to benefit – because benefit is marginal when compared to other mechanisms that are already in place and proposed elsewhere in this rulemaking that focus on necessary information to assist in ensuring compliance.

- EPA continued to ignore the scale of affected/designated facilities that will become subject to these provisions over time, which is well over the tens of thousands.
- EPA included reporting requirements that are outside the Agency's jurisdiction in requiring details on well ownership transfers.

Response II-18-8: Regarding the general comments that the rule requires excessive or onerous recordkeeping or reporting requirements, or that other mechanisms are in place to ensure compliance, the commenters did not provide suggestions where burden might be reduced.

In the 2020 Technical Rule, the EPA streamlined several of the recordkeeping and reporting requirements in the 2016 NSPS OOOOa and the same simplified requirements were proposed for NSPS OOOOa in the November 2021 Proposal. As discussed in the November 2021 Proposal, unnecessary and redundant reports and maintaining records were either removed or replaced with improved ways to demonstrate and ensure compliance. Please see the November 2021 Proposal for details on the specific recordkeeping and reporting elements EPA replaced or removed from the fugitive emissions monitoring program.<sup>7</sup> The EPA is finalizing these requirements as proposed, which EPA believes represent a sufficient level of recordkeeping and reporting in order to ensure compliance. These recordkeeping and reporting requirements are also being adopted for affected/designated facilities under the NSPS OOOOb and EG OOOOc.

Regarding well ownership transfers, see response II-18-4 of this Chapter.

---

<sup>7</sup> 86 FR 63166 (November 15, 2021).

## **Chapter 19. State, Tribal, and Federal Plan Development for Existing Sources**

### **19.1 Leveraging State Programs**

#### ***19.1.1 State Requirement Equivalency Determination***

Comment: Several commenters (2286-CO APCD, 2315-NYSDEC, 2428-API) express concern with the approach to determining equivalency. In general, the commenters believe that states should be afforded maximum flexibility and request additional consultation. Examples of the comments provided are presented in the following paragraphs.

Commenter (2286-CO APCD) believes that the suggested approach to determining equivalency in the December 2022 supplemental proposal program is unduly narrow for states such as Colorado that have developed and implemented a comprehensive program to regulating and reducing hydrocarbon emissions from the oil and gas industry.

The commenter (2286-CO APCD) appreciates EPA's recognition of Colorado's, and other states, existing oil and gas regulations. The commenter also appreciates EPA's recognition of the need to identify the criteria by which EPA will evaluate state programs for purposes of the state Clean Air Act (CAA) section 111(d) plan.

However, the commenter (2286-CO APCD) notes that Colorado's program has been developed and implemented over the course of the past two decades through rigorous processes inclusive of the meaningful engagement of regulated entities and other community members and includes emission reduction requirements for all the major source categories within the oil and gas sector. The commenter contends that many of the existing federal requirements governing oil and gas, as well as requirements set forth in the proposed supplemental program, follow reduction strategies that Colorado first pioneered to reduce both methane and volatile organic compounds (VOC). In many cases, the commenter notes that the Colorado's requirements are similar to those that EPA is now proposing and for some source categories, Colorado's regulations are substantially more stringent or cover source categories that are not included within the supplemental program, and in a few cases Colorado's regulations could be considered slightly less stringent than EPA's proposal. Further, the commenter asserts that Colorado continues to innovate in this area to further minimize the impact from this industry on ground level ozone concentrations and to meet aggressive state statutory oil and gas methane reduction requirements. For Colorado to continue to innovate and lead over the next several years in developing new strategies to reduce emissions from oil and gas activities, the commenter believes that the state needs to maintain a reasonable degree of flexibility in connection with required equivalency demonstrations for existing programs. The commenter states that being bogged down in rigid one size-fits-all assessments that at the end of the process will provide minimal reduction benefits would not be a responsible utilization of Colorado's resources.

Commenter (2315-NYSDEC) appreciates EPA's proposal to allow those states that already regulate emissions from this sector to leverage existing state rules to meet these requirements.

This will help states avoid the need to expend resources to revise regulations for no additional emissions reductions.

Commenter (2315-NYSDEC) notes that, while the three-step process appears to be adequate, there are some terms that could be interpreted in different ways, such as the format of the standard. The commenter believes that 6 NYCRR Part 203, Oil and Natural Gas Sector (Part 203) is at least as stringent as what is being proposed. However, there is some ambiguity in the alternative methods that makes the determination of equivalency unclear. As such, the commenter requests that EPA work with each state that currently has requirements to address this concern.

Commenter (2315-NYSDEC) also recommends that EPA work with each state that has existing requirements in the development and determination of equivalency. Given the relatively small number of states with existing requirements, the commenter believes that this individual consultation would not require extensive outreach and would provide much-needed clarity to those focused on this issue.

Commenter (2428-API) asserts that EPA must provide more flexibility for approving state programs. The commenter believes that EPA exceeds its authority by seeking to impose its own preferences on state programs rather than recognizing that it must approve any state program that meets the statutory criteria – even programs that include elements that EPA itself would not choose, but that objectively do meet statutory standard setting requirements. In other words, if a state program meets express statutory requirements or otherwise is grounded on a reasonable construction of statutory requirements, the commenter states that EPA would have no choice but to approve the program.

For example, the commenter (2428-API) notes that EPA repeatedly and wrongly asserts that its “presumptive standards” must be used to judge the adequacy of state programs. However, the commenter believes that using EPA’s presumptive standards as a measure of acceptability is wrong because a state’s obligation under CAA section 111(d) is to establish standards of performance based on the best system of emission reduction (BSER).

The commenter (2428-API) asserts that EPA’s “presumptive standards” do not constitute BSER. Rather, the commenter believes that the standards represent EPA’s notion of what emissions standard might reasonably satisfy EPA’s BSER determinations. The commenter argues that the statute unambiguously provides that states have authority and responsibility to fashion a standard that meets BSER and is not limited to the “presumptive standard” that EPA thinks is best.

The commenter (2428-API) believes that EPA clearly understands that is what the statute requires. The commenter notes that the EPA itself states that CAA “[s]ection 111(d) does not, by its terms, preclude states from having flexibility in determining which measures will best achieve compliance with the EPA’s emission guidelines. Such flexibility is consistent with the framework of cooperative federalism that CAA section 111(d) establishes, which vests states with substantial discretion” The commenter believes that EPA’s acknowledgment that it is the states’ obligation to determine what measures “best” satisfy EPA’s BSER determination is a

correct statement of the law and contradicts the idea that EPA gets to decide what is “best” and impose that judgment on the states.

Response II-19-1: Please see discussion of state flexibilities and response to comments section XIII.C.2 of the final preamble.

### ***19.1.2 Consideration of other Federal and State Regulations Impacting Oil and Natural Gas Facilities***

Comment: Several commenters (2213-Occidental, 2220-WDEQ, 2241-UT DNR, 2248-NDPC, 2251- NAM, 2257-MOGA, 2258-MSD, 2301-US CoC, 2304-PIOGA, 2308-NSWA, 2428-API, 2429-WOC, 2446-IPAA) assert that states are best suited to regulate emissions. In general, these commenters recommend that EPA refrain from publishing rules that duplicate existing state actions. The commenters recommend that EPA allow maximum flexibility to state agencies and provide details of state actions. Examples of some of the specific comments provided are included in the following paragraphs.

Commenter (2248-NDPC) asserts that additional or duplicative regulations add costs and administrative burden that significantly outweigh any corresponding environmental benefit. The commenter contends that these regulations could disincentivize the industry’s voluntary programs that have a real and measurable positive impact on the environment. The commenter notes that in North Dakota and other regions in the U.S., produced natural gas is associated or dissolved in the crude oil, and cannot be produced independently from each other. The commenter provides that the State of North Dakota already has regulations in place that:

- Require a minimum of 91 percent of the associated gas be captured (not flared).<sup>1</sup> Operators are required to report their gas capture data monthly, and many companies have their own goals that exceed 91 percent. This data is available to the public. The latest report from North Dakota’s Pipeline Authority shows 94 percent gas capture in November 2022 and another 5 percent connected to the gathering system but experiencing constraints on the existing gathering systems.
- Prohibit the venting of natural gas unless it is flared or otherwise controlled as approved by the North Dakota Department of Environmental Quality (NDDEQ).<sup>2</sup>
- Require the control of vapors from storage tanks with the implementation of a control device prior to first production and a control device equipped and operated with an automatic igniter or a continuous burning pilot.<sup>3</sup>

Commenter (2220-WDEQ) states that Wyoming has been recognized as a national leader in oil and gas permitting and emission reductions for many years by EPA and other organizations nationwide. The State’s New Source Review (NSR) permitting program, including its Wyoming-tailored Presumptive-Best Available Control Technology (BACT) guidance, already contains a robust set of requirements that capture VOC emissions and, accordingly, associated methane emissions. Furthermore, the commenter adds that Wyoming’s permitting program has already

---

<sup>1</sup> [https://www.dmr.nd.gov/oilgas/112018GuidancePolicyNorthDakotaIndustrialCommissionorder24665\\_2.pdf](https://www.dmr.nd.gov/oilgas/112018GuidancePolicyNorthDakotaIndustrialCommissionorder24665_2.pdf).

<sup>2</sup> North Dakota Administrative Code, Title 33.1, Article 15, Chapter 7.

<sup>3</sup> Id.

been in compliance with 2012 new source performance standards (NSPS) OOOO and 2016 NSPS OOOOa standards for years. In the November 2021 proposed rule, the commenter notes that the EPA cited Wyoming as one of the “[s]tates (that) have led the way in regulating emissions sources that were not yet subject to requirements under the NSPS OOOOa”. Several other western states are similarly situated.

The commenter (2220-WDEQ) notes that the 2020 Technical Rule allowed the use of specific alternative fugitive emissions standards for VOC emissions for six other state permitting programs, including California and Colorado, for certain provisions of NSPS OOOOa. They explain that these alternative fugitive emissions standards may be used for certain individual well sites or gathering and boosting compressor stations. In the November 2021 proposed rule, EPA allowed these alternative fugitive emissions standards to apply for methane fugitive emissions at well sites and gathering and boosting compressor stations in those six states. The commenter continues that the EPA did not appear to further reference this provision in the supplemental proposal. The commenter requests that EPA consider approving alternative fugitive emissions standards for states like Wyoming that already have robust permitting programs that control VOC and methane emissions. In addition, they request further guidance on how it and other states could receive a similar off-ramp for the requirements specified in the 2022 December supplemental proposal. The commenter explains that this would allow the state and its regulated entities to comply with the rule more effectively without diverting resources from an existing program that provides significant environmental benefits. The commenter notes that the EPA has acknowledged that there are certain circumstances that could warrant potential exemptions and alternative standards, noting on page 74780 of the preamble to the December 2022 supplemental rule:

One commenter provided detailed information about the issues with certain wells in Wyoming. The EPA believes that these situations could warrant an exemption or an alternative standard. However, this proposed rule does not include any exemptions or allowances for these situations due to the lack of specific sufficient information.<sup>4</sup>

The commenter (2220-WDEQ) hopes that EPA will consider the tenets of cooperative federalism and provide for constructive dialogues to occur that would help Wyoming establish alternative fugitive emissions standards that facilitate compliance and ultimately provide greater environmental benefits as a result.

Commenter (2304-PIOGA) asserts that existing sources are regulated in Pennsylvania. The commenter states that environmental groups have made much of the fact that existing sources have not been subject to regulation under CAA section 111(d), and they often engage in rhetoric that existing sources are not regulated. However, the commenter reports that all wells are subject to annual mechanical integrity inspections and reports that are filed with the Pennsylvania Department of Environmental Protection (PADEP). The commenter provides that a key aspect of these inspections and reporting focuses on pressure that, despite EPA's unwillingness to acknowledge the relationship between pressure/flow rate and emissions, correlates directly to leaks – or the lack thereof. Additionally, the commenter adds that vertical unconventional wells are also subject to quarterly emission surveying, while horizontal unconventional wells are

---

<sup>4</sup> See Document ID No. EPA-HQ-OAR-2021-0317-0955.

subject to even more monitoring for emissions and/or permitting. According to the commenter, to say that conventional wells are unregulated is ridiculous, and contrary to reality.

Commenter (2258-MSD) states that comprehensive and robust regulatory programs and new requirements have been adopted since the onset of significant unconventional natural gas development in Pennsylvania. They explain that new and existing sources are covered by performance measures to identify and limit leaks, with well pads and midstream infrastructure operating under new and revised air quality general permits. Pennsylvania has compiled an inventory of emissions since 2012 and expanded the scope of participating facilities over the years.

The commenter (2258-MSD) recommends that EPA recognize that natural gas development in the U.S., and particularly in the Appalachian Basin, has some of the lowest methane intensity rates in the world. For example, the commenter states that the International Energy Agency recognizes that the U.S. methane intensity of 8 tons (per thousand tons of oil equivalent) is one of the lowest of major oil and natural gas producing countries in the world, lower than China (9), Russia (13), Venezuela (48) and Libya (103). Here in the U.S., the commenter presents that the Appalachian Basin's methane intensity is the lowest of the nine major hydrocarbon producing basins in the entire country.<sup>5</sup>

The commenter (2258-MSD) states that natural gas operators are rightfully proud of their contribution to reducing climate change inducing emissions. Operators have demonstrated this commitment through their voluntary participation in meaningful initiatives such as One Future, American Petroleum Institute's (API's) The Environmental Partnership, the U.S. EPA's Methane Challenge, and the Global Methane Initiative, to name a few. The commenter notes that over 85 percent of their Board members participate in one or more of these initiatives.

Commenter (2257-MOGA) supports EPA's decision to allow individual state's primacy over Emission Guidelines (EG). From the commenter's perspective, all wells are permitted, reviewed, and managed by state agencies to protect the environment, land, surface water, drinking water and residences under each state's current State Implementation Plan (SIP). These agencies have local staff that visit sites, respond to residential concerns, monitor activities, review the state rules, and hold the operators in check regarding all aspects of operations and compliance. The commenter states that correspondence and file reviews of these operations and production volumes are provided to these agencies that are familiar with the field production so any changes, modifications or community intervention can be handled immediately, thus protecting the community. The commenter asserts that Federal inspections and correspondence have historically, not provided quick responses and often allowed problems to magnify into greater, more impactful issues requiring costly long-term solutions.

The commenter (2257-MOGA) expresses concern with EPA's proposed minimum standards for NSPS OOOOb and EG OOOOc. The commenter contends that individual states are better positioned to determine feasible regulations through intimate knowledge of their state's geology, producing horizons, oil and gas chemical characteristics, formation production efficiencies, pooling units, emissions potential, permitting requirements, enforcement regulations and waste

---

<sup>5</sup> Clean Air Task Force & Ceres: Benchmarking Methane & Other GHG Emissions (June 2021).

prevention guidelines than the “one-size-fits-all” approach proposed by the EPA at the federal level.

If the EPA continues to pursue a “one-size-fits-all” approach to state level regulations, the commenter (2257-MOGA) requests that the EPA provide a review of each state’s regulatory rules regarding both oil and gas permitting and air quality requirements to ensure that federal oversight does not conflict with individual state regulations. The commenter feels this would ease the concerns of state’s regulatory agencies and the small business oil and gas producers to ensure that the EPA has thoroughly understood each state specific rules and regulations necessary to facilitate proposed EGs with the flexibility for each state to implement their respective rules and regulations with more specificity than a macro-level understanding at the federal level.

Commenter (2446-IPAA) contends that state regulators have experience with the well operations and reservoirs in their state. The commenter believes that, if the proposed regulations were in the form of Control Technique Guidelines (CTG) where the flexibility to design reasonably available control measures (RACM) allows the state to readily address its distinctions, as contemplated by CAA section 111(d), issues could be addressed more effectively. The commenter asserts that ascribing to the CAA section 111(d) obligation to be prescriptive in regulation would be at odds with the intention that it would be applied to a small number of facilities that resulted from the regulation of emissions that were neither criteria pollutants nor hazardous air pollutants (HAP). The commenter states that greenhouse gases (GHG) were never envisioned at the time of the development of the CAA. Now, these EG involve almost one million sources – more when the multiple designated facilities definitions are considered. The commenter notes that at the same time, EPA is proposing interpretations of the language of CAA section 111(d) – particularly the interpretation of remaining useful life and other factors (RULOF) – that handcuff the states flexibility to alter the EPA model regulations in the EG.

Commenter (2213-Occidental) proposes that EPA avoid promulgating duplicative regulations that are inconsistent with state or other Federal regulatory programs. The commenter recommends that a mechanism be included in the NSPS and EG to provide flexibility for states to utilize their programs. The commenter contends that this flexibility would allow operators to focus resources on implementing changes that result in substantive emissions reductions and eliminate any confusion surrounding duplicative requirements.

The commenter (2213-Occidental) has observed how effectively the performance-based approach applied by states has addressed regional differences and expedited technical advances to detect and reduce methane emissions, despite significant increases in activity levels. The commenter explains that there are extensive regulations in place in each state where the commenter operates that take local community, operational and environmental considerations into account to reduce emissions and address unique challenges and situations. Therefore, they urge that any Federal regulations developed complement and not duplicate or complicate compliance with those state regulations. The commenter adds that they work in cooperation with the regulatory agencies and environmental groups where they operate to help develop and implement regulations that produce effective emissions reductions. For example, the commenter has been supportive of ground-breaking regulations in the New Mexico and Colorado rules. In

Colorado, the state's 2022 regulations require significant decreases in GHG emissions at milestones through 2030. In 2021 and 2022, New Mexico finalized its New Mexico Oil Conservation Commission (NMOCD) and New Mexico Environment Department (NMED) rules that reflect the diverse operations, oil and gas formations and types of production conducted in the state.

The commenter (2213-Occidental) points out that these state regulations require significant emission reductions and associated recordkeeping and reporting requirements for pneumatics, tanks, flaring and venting, associated gas and fugitive emissions that have unique frameworks. The commenter supports the non-emitting standard for new pneumatic sources prospectively and the retrofitting of existing natural gas-driven pneumatics over a reasonable time period consistent with leading state rules that consider the variety of factors at play.

If an additional EPA requirement were superimposed on the stringent state requirements, the commenter (2213-Occidental) contends that it would cause confusion and additional regulator and operator burdens with no additional environmental benefit. The commenter expresses concern that the confusion caused by duplicative or conflicting Federal regulations would divert resources from implementing these state regulations that are resulting in significant reductions in emissions.

Commenter (2301-US CoC) recommends that EPA expedite, to the greatest extent possible, the submission and approval processes for states' and Tribes' CAA section 111 (d) plans for existing sources under EG OOOOc (as outlined below).

The commenter (2301-US CoC) asserts that the swift adoption of workable, durable state plans will benefit both the environment and industry by further reducing methane emissions while providing regulatory certainty. The commenter states that allowing states and Tribes the flexibility to use their existing programs is expected to result in more, and more immediate, reductions in methane emissions for the reasons they describe below. As EPA knows, the commenter notes that existing sources will not become subject to direct methane regulation until state plans take effect. Because existing sources represent a far greater percentage of sources, the commenter states that EPA can ensure a greater and more immediate reduction in methane emissions by simplifying and expediting the process for state plan approvals.

Commenter (2308-NSWA) asserts that volunteer efforts and state regulations already exist. The commenter urges EPA to stop the federally driven top-down requirements which they believe do not fit or apply to all sizes of operations and businesses. The commenter adds that no rule adopted by EPA should result in putting oil and gas companies out of business, or significantly changing the economics of the operations. As currently drafted, however, they contend it appears likely to result in just that.

The commenter (2308-NSWA) recognizes the need for a regulatory framework, however notes the important role states have played for many years in overseeing oil and gas operations across the U.S. Virtually since enactment of the 1972 CAA, the commenter reports that states have held the appropriate and cherished lead responsibility for the detailed implementation of the nation's

major environmental laws, which have served as broad guidance from Congress on policing the nation's drinking water and air emissions.

The commenter (2308-NSWA) states that their members are proud of their record of working in partnership with state regulators in protecting the state's lands and waters, as well as key species, as they carry out their operations.

Commenter (2429-WOC) believes that appropriate and timely regulation spurs innovation and creative solutions. The commenter reports that Wyoming was an early adopter of existing source rule requirements in 2015 because of challenges with wintertime ozone conditions in the Upper Green River Basin (UGRB). The commenter notes that Wyoming's leadership and collaboration to address these concerns set the stage to improve winter ozone conditions in the UGRB and resulted in some of the most responsible and innovative operators in the country. The commenter states that today, operators such as Jonah Energy and Purewest Energy are at the forefront of implementing continuous emission detection technologies and using drones and other technology to assist with methane leak detection and repair. Importantly, the commenter reports that these companies are helping to pioneer new markets for differentiated natural gas that will result in less methane emissions and allow them to sell their products to new markets. The commenter contends that in Wyoming, appropriate regulation that levels the playing field across the industry, while also giving operators flexibility to innovate, test, and apply new creative solutions, can be used to spur innovation, and raise industry standards across the board.

Commenter (2428-API) notes that their comments flow from the fundamental guiding principle that EPA is required to approve state programs that satisfy CAA section 111(d) standard setting criteria, and that EPA cannot approve state programs that do not meet those criteria. The commenter asserts that EPA's proposal violates this principle.

The commenter (2428-API) argues that EPA must provide more flexibility for approving state programs and allow for certain state provisions to be deemed equivalent where it is appropriate to do so. The commenter notes that EPA indicates its commitment to faithfully implementing the "framework of cooperative federalism that CAA section 111(d) establishes," which necessarily requires EPA to defer to (and approve) state measures that satisfy the law, even when such measures do not satisfy EPA's own preferences. The commenter adds that, on the other hand, a primary rationale for the proposed prescriptive measures for reviewing and approving/denying state programs is concern about inconsistency from state to state and the possibility that certain state programs will be less stringent. The commenter asserts that EPA cannot have it both ways – i.e., support state flexibility when it promotes EPA's preferred outcomes and discourage state flexibility when needed to achieve such outcomes. According to the commenter, such an inconsistent approach is facially arbitrary. The commenter contends that it is easily resolved by allowing the state flexibility that EPA acknowledges to exist and, in any event, that is demanded by the statute.

Given EPA has described many requirements that are consistent with those at the state level (e.g., Colorado, New Mexico, and California), the commenter recommends that EPA allow for certain state provisions to be deemed equivalent for the proposed NSPS OOOOb and EG OOOOc where it is appropriate to do so for leak detection and repair (fugitive emission

monitoring) and other emission control provisions. The commenter (2428-API) recommends that EPA allow states the opportunity to demonstrate programmatic equivalency, including addressing deviations from the form of the proposed standards. Without this, states and operators may be administering and complying with two sets of requirements (standards and administrative) that are duplicative because they are intended to achieve similar goals but are not perfectly identical.

Commenter (2241-UDNR) encourages EPA to develop regulations that are consistent with state land use plans and policies. The commenter supports EPA recognition of states actions and recommends that EPA engage with states when conflicts arise. The commenter notes that the December 2022 proposal “specifically recognizes states’ and tribes’ unique roles, stating that “some forward-looking states have their own regulations for methane emissions from the oil and gas industry, and EPA’s proposal provides states the opportunity to leverage their existing programs or develop new programs that are at least as effective as the presumptive standards.”<sup>6</sup> The commenter appreciates the recognition of certain state’s attempt to be proactive in regard to methane emissions, and requests that its State Resource Management Plan (SRMP) (and other relevant code) be given appropriate consideration as the EPA moves forward with its proposal.

The commenter (2241-UDNR) notes that when Federal agencies are preparing an Environmental Impact Statement (EIS) under the Council on Environmental Quality’s (CEQ) regulations for the National Environmental Policy Act (NEPA), the “environmental consequences” section of the EIS must include a discussion of “[p]ossible conflicts between the proposed action and the objectives of Federal, regional, State, Tribal, and local land use plans, policies and controls for the area concerned.”<sup>7</sup> While the EPA’s December 2022 proposed rule is not an EIS, the commenter recommends that EPA strive for consistency with the land use plans, policies, and controls from state, tribal and local governments, and in the spirit of the CEQ regulations, discuss possible conflicts with those plans, policies and controls. For example, the EPA should strive for consistency with state law, and the state’s Resource Management Plan.<sup>8</sup> The commenter recommends that EPA consider similar plans and policies of local governments, such as county governments that will be particularly impacted by the EPA’s proposed rule, with conflicts identified and discussed. In 2018, the state adopted a State Resource Management Plan (SRMP) and all twenty-nine counties in the state have adopted County Resource Management Plans (CRMPs)<sup>9</sup>. The commenter reports that these RMPs include policies for many aspects of public land management, including those related to oil and natural gas, as well as energy infrastructure development.

The commenter (2241-UDNR) reports that both SRMP and the State CRMPs contain numerous provisions relating to responsible natural resources, climate, and environmental quality issues. These provisions are developed at a local level and therefore reflect the desires, policy, and preferences of local populations. The commenter recommends that EPA consider these SRMPs

---

<sup>7</sup> 40 CFR 1502.16(5).

<sup>8</sup> Utah State Resource Management Plan (Utah SRMP), pp. 9, available at [https://storymaps.arcgis.com/collections/81d4406668e34acca4d98275ee41cd07\(2022\)](https://storymaps.arcgis.com/collections/81d4406668e34acca4d98275ee41cd07(2022)).

<sup>9</sup> PLPCO, Resource Management Plans by County, Utah’s Public Lands Policy Coordinating Office, available at <https://utah-resource-management-planning-plpco.hub.arcgis.com/pages/county-management-plans> (2022).

and CRMPs to ensure that decisions are made consistent with local plans. The commenter recommends that these plans (not only Utah's but nationwide) be consulted going forward as part of the Bureau of Land Management (BLM) efforts to include a wide range of partners, stakeholders, landowners and producers in future natural gas and environmental justice related decisions.

In addition to the policies found in the Utah SRMP, the commenter (2241-UDNR) reports that Utah has also adopted law enshrined in Utah Code establishing energy zones along with management and land use priorities for said zones. The relevant zones for purposes of this comment letter include the San Juan County Energy Zone,<sup>10</sup> the Uintah Basin Energy Zone,<sup>11</sup> and the Green River Energy Zone.<sup>12</sup> Together, these three energy zones contain almost exclusively all the natural gas production in the State of Utah. The commenter reports that all three statutes governing these three energy zones have provisions and directives for the management of federal land within these zones to achieve productive natural gas development. For example, within the Uintah Basin Energy Zone, Utah Code states that:

(4) The state supports:

(a) efficient and responsible full development of all existing energy and mineral resources located within the Uintah Basin Energy Zone, including oil, oil shale, natural gas, oil sands...; and

(b) a cooperative management approach among federal agencies, state, and local governments to achieve broadly supported management plans for the full development of all energy and mineral resources within the Uintah Basin Energy Zone.

(5) The state calls upon the federal agencies who administer lands within the Uintah Basin Energy Zone to:

(a) fully cooperate and coordinate with the state and with Daggett, Uintah, and Duchesne Counties to develop, amend, and implement land and resource management plans and to implement management decisions that are consistent with the purposes, goals, and policies described in this section to the maximum extent allowed under federal law...<sup>13</sup>

The commenter (2241-UDNR) states that the Utah SRMP promotes responsible fossil fuel energy generation, fossil fuel development, and related infrastructure, and Utah Code establishes Energy Zones with directives to develop all energy and mineral resources within the zone. The commenter requests that EPA consider and coordinate with the state's RMP and relevant State

---

<sup>10</sup> Utah State Code Annotated § 63J-8-105.2.

<sup>11</sup> Utah State Code Annotated § 63J-8-105.5.

<sup>12</sup> Utah State Code Annotated § 63J-8-105.7.

<sup>13</sup> Utah State Code Annotated § 63J-8-105.5(4)-(5); see also Utah State Code Annotated § 63J-8-105.2(4)-(5) and Utah State Code Annotated § 63J-8-105.7(4)-(5) (The statutes governing the San Juan County Energy Zone and Green River Energy Zone contain almost identical verbiage to that quoted/cited herein regarding the Uintah Basin Energy Zone).

Code. Further, the commenter requests that the EPA ensure that current and future actions taken in furtherance of the proposed rule remain consistent with said plans and energy zones to the maximum extent possible.

Commenter (2223-TAEP) urges EPA to allow state partnerships to flourish and resist the temptation to mandate federally driven top-down requirements which do not fit or apply to all sizes of operations and businesses. The commenter states that new, costly, and burdensome federal requirements on producers are unnecessary and may have the opposite of the intended result. The commenter asserts that the role of the states and their various regulatory structures cannot be overstated. Virtually since enactment of the 1972 CAA, states have held the appropriate lead responsibility for the detailed implementation of the nation's major environmental laws, which have served as broad guidance from Congress on policing the nation's drinking water and air emissions. In Texas, the commenter and other operators have ongoing direct interaction with the agencies charged with various facets of regulation, most notably the Railroad Commission of Texas and the Texas Commission on Environmental Quality. The commenter asserts that the regulatory structure is effective, leading to reduced emissions of GHGs including methane over time.

Response II-19-2: Once the EPA establishes NSPS for a particular source category, the EPA is required in certain circumstances to issue EG to reduce emissions from existing sources in that same source category. Specifically, CAA section 111(d) requires that the EPA prescribe regulations to establish procedures under which states submit plans to establish, implement, and enforce standards of performance for existing sources for certain air pollutants to which a Federal NSPS would apply if such existing source were a new source. The EPA addresses this CAA requirement both through its promulgation of general implementing regulations for CAA section 111(d) as well as through specific EG. Please see section IV.A. of the final preamble of additional discussion on EPA's statutory obligations under CAA section 111. Furthermore, to be clear, the final EG OOOOc in no way impacts states' ability to regulate sources under state law. Please see discussion of state flexibilities and response to comments section XIII.C.2 of the final preamble. Please see Volume 1 Chapter 19 Response I-19-11 that discusses that the AMEL provision in the CAA has been applied only in the context of NSPS issued under CAA section 111(b). Please see preamble section XIII.D, E, F, and G for discussion on the required components of approvable state plans, timing of state plan submission and compliance schedules, EPA's action of state plans and promulgation of federal plans, and Tribes and the planning process.

Commenters discuss the value of voluntary programs. Although the EPA recognizes and commends the value of these programs, such voluntary efforts are not legally binding and do not alter the EPA's own statutory responsibility to regulate methane emissions from this sector under the CAA. Moreover, as the information and analysis reflected in this final rulemaking make clear, there is still considerable need and opportunity to further reduce methane emissions from the industry.

Comment: Commenter (2166-ODNR) states that during the development of the NSPS requirements, the EPA stated that some facilities will be subject to current or future requirements of the Department of Interior's BLM rules covering production of natural gas on federal lands.

The commenter also reiterates that the EPA discussed its ongoing dialogue with BLM during the development of the proposals to align requirements and to minimize confusion and unnecessary burden on the part of the owners and operators. The commenter asserts that this dialogue should include or take into consideration existing state regulatory agencies and rules to prevent confusion and unnecessary burden on owners, operators, landowners, and state regulators.

Several commenters (2402-DGCC, 2363-CEMC, 2448-PCPBC) urge the EPA collaborate closely with other federal departments that are also regulating methane emissions. The EPA has an opportunity to harmonize a move to more effective and innovative measurement-based methane controls by coordinating the proposed December 2022 supplemental rule with other federal regulations from the BLM, the Securities and Exchange Commission, the Department of Energy (DOE), the Department of the Treasury (DOT), the Federal Acquisition Regulatory Council, and the Pipeline Hazardous Materials Safety Administration (PHMSA), to avoid duplicative or conflicting regulatory regimes. The commenters suggest that this will accelerate the deployment of advanced technologies and continuous monitoring, reduce compliance costs, enable robust energy production, ensure greater reductions of methane and, importantly, minimize duplicative compliance requirements.

Commenter (2166-ODNR) is concerned with portions of the draft rule that state citizens would be authorized to enter private lands for emissions measurements. Most wells in Ohio are located on private property, and the guidelines include no language regarding how Ohioans, law enforcement, or state regulators will know who is authorized to be on the property. There are no standards established for calibration of equipment that ensure readings are measured correctly or for remedies landowners or operators may take should emissions be read incorrectly. Additionally, there is no language regarding where liability rests should injury to persons or property occur.

Commenter (2166-ODNR) states gas leaks are currently regulated in Ohio, as state law prohibits owners of wells from allowing the wells to leak fluids or gases. No matter the reason (defective casing, tubing or packing leaks, defective tubing, pipe/fitting connection thread leaks, corroded piping, stuffing box leaks, defective casing below grade), the commenter has the authority to act. Operators are required to immediately repair casing, correct inadequacies, or plug and abandon the well. Additional redundant regulations on owners and operators are an unnecessary burden and would create confusion.

Response II-19-3: Please see section VI.A in the final preamble discussing related state and federal actions. EPA notes that certain Federal agencies also regulate aspects of the oil and natural gas industry pursuant to their own authorities. For example, BLM specifically has the express authority and responsibility to regulate both for the prevention of waste and the protection of the environment for operations on Federal and Indian lands. This responsibility includes promulgating regulations to reduce the waste of natural gas from oil and gas leases administered by the BLM.

Please refer to RTC Volume 2 Chapter 14 for Super Emitters which responds to the commenters' concern regarding unauthorized access to oil and gas operations. Specifically, we have revised

the Super Emitter Program to require EPA approval of methane detection technology and to include requirements that certified third parties cannot access approved applicable sites and doing so would lead to the removal of their certification. Lastly, please see section IV.A. of the final preamble of additional discussion on EPA's statutory obligations under CAA section 111. Furthermore, to be clear, the final EG OOOOc in no way impacts states' ability to regulate sources under state law.

### ***19.1.3 Lack of Enforcement of State Rules***

Comment: Commenter (2270-Lucero) notes that rules without strong enforcement mechanisms are ineffectual. The commenter reports that New Mexico adopted new methane rules which went into effect in the summer of 2022. The commenter states that the Governor touted these new rules at the 27th Conference of the Parties to the United Nations Framework Convention on Climate Change (COP27), saying that New Mexico is leading the country in regulating methane emissions, where the goal is to reduce methane emissions by over 851 million pounds annually.<sup>14</sup>

However, the commenter (2270-Lucero) complains that as late as January 2023, the evidence shows that lack of enforcement allows the oil and gas industry to keep emitting.<sup>15</sup> The commenter reports that the NMED takes its mission to hold polluters accountable seriously but, according to NMED secretary James Kenney, does not have the resources it needs to assure compliance and hold polluters accountable, and that chronic underfunding has persisted for years.<sup>16</sup>

Response II-19-4: Please see section XIII of the final preamble that discusses the required components of an approvable state plan submission. Specifically, the administrative completeness criteria require that the state's plan include a formal submittal letter and a copy of the actual state regulations themselves, as well as evidence that the state has legal authority to adopt and implement the plan, actually adopted the plan, followed state procedural laws when adopting the plan, gave public notice of the changes to state law, held public hearing(s) if applicable, and responded to state-level comments. For a detailed description of what the state plan must include in terms of evidence that the state has legal authority to adopt and implement the plan, see 40 CFR 60.26a. The technical criteria require that the state's plan identify the designated facilities, the standards of performance, the geographic scope of the plan, monitoring, recordkeeping and reporting requirements (both for designated facilities to ensure compliance and for the state to ensure performance of the plan as a whole), and compliance schedules.

## 19.2 Types of Equivalency Evaluations

### *19.2.1 Total Program Evaluation*

Comment: Several commenters (2249-NACAA, 2286-CO APCD, 2296-NMED, 2326-AXPC, 2390-NMOGA, 2410-CA AG et al, 2446-IPAA, 2301-US CoC) support EPA's use of the total program evaluation tool to evaluate equivalency of existing state programs. In general, commenters recommend that EPA allow maximum flexibility to allow states to continue with existing programs. Examples of some of the comments provided are presented in the following paragraphs.

Commenter (2286-CO APCD) believes that the total program evaluation tool can be employed, with appropriate guardrails, to both ensure significant emission reduction opportunities will move forward while not disrupting effective state programs that are already in place.

The commenter (2286-CO APCD) recommends that EPA recognize that a federal mandate to change existing state programs is not as simple as modifying existing regulatory requirements. They explain that states like Colorado have put considerable effort into developing the implementation structures necessary to ensure that their regulatory requirements achieve the expected emission reductions. The commenter believes that requiring states to modify their programs based on a narrow conception of equivalency will undermine implementation processes and practices that have been developed over many years and can lead to less effective regulation. While this may be appropriate in some circumstances, in cases where states have developed a robust program that in totality achieves greater reductions than the EG, states should be required to adopt new requirements for a particular source category only in the following circumstances: 1) where the state program does not include any reduction requirements for a particular source category; or 2) the state does have reduction requirements for a particular source category but those requirements achieve significantly less emission reductions than the requirements set forth in the EG relative to the overall emission reductions from the oil and gas sector achieved by the state program. Absent these circumstances, the commenter asserts that the state should retain the flexibility necessary to continue with its current program, provided, of course, that the state can demonstrate that the overall program can achieve comparable emission reductions to the EG.

In addition to these common-sense limitations on when changes to existing successful programs can be mandated, the commenter (2286-CO APCD) recommends that the final rule provide additional flexibility to states that can demonstrate overall program equivalency as it pertains to existing state monitoring, recordkeeping, and reporting requirements. Such states, and the operators within these states, have invested heavily in systems that collect, track, report, and receive data to show compliance with emission reduction requirements. The commenter contends that mandating different requirements to match the EG will be costly, create confusion, and undermine the effectiveness of existing programs. The commenter acknowledges that requiring changes to existing monitoring, recordkeeping, and reporting requirements could be warranted under appropriate circumstances notwithstanding the associated cost and confusion. The commenter requests that these circumstances be limited, and that the final rule provide flexibility to states that can demonstrate overall program effectiveness. Specifically, the commenter

requests that the final rule provide that if a state demonstrates overall program equivalency, changes or additions to existing monitoring, recordkeeping, and reporting provisions only be required where the existing provisions are substantially inadequate to ensure compliance with the associated emission reduction requirements.

Similarly, commenter (2326-AXPC) requests that EPA allow states to leverage existing state programs through submittal of total program evaluations to demonstrate equivalency with EG OOOOc. The commenter contends that precluding states from making a programmatic equivalency determination – by requiring EPA’s source-by-source approach – serves as a disincentive to state rulemaking. Over the past decade, the commenter notes that states like Colorado and New Mexico have expended many resources, time, and effort to promulgate new oil and gas regulations covering the same designated facilities as EPA proposes to regulate under EG OOOOc. The commenter notes that EPA’s proposal relies in large part upon standards already in place in these states. If EPA requires states to demonstrate equivalency on a source-by-source basis, rather than through a programmatic emissions reduction demonstration, the commenter states that EPA would be applying a one-size-fits all approach to state regulation in contradiction of the cooperative federalism principles inherent throughout the CAA and specifically enumerated in CAA section 111(d). Further, the commenter believes that EPA’s source-by-source equivalency approach will stifle progressive state rulemaking, as those states would be less likely to expend the significant resources to promulgate new rules only to have EPA swoop in and set aside well-thought state programs.

Commenter (2249-NACAA) recommends that EPA consider previous regulatory investments and existing State Implementation Plan (SIP) approvals. The commenter states that EPA has demonstrated experience with creating a streamlined equivalency through the implementation of its NSPS OOOOa provisions since 2016. States that have rules or well-developed proposals have already gone through robust public processes and rulemakings and programs included in these equivalencies are frequently a part of an approved SIP. Inasmuch as the forthcoming implementation rule proposal seeks to accommodate state programs, the commenter recommends that EPA consider regulatory actions and timelines required in those states and integrate flexibility into the rule that accommodates them.

The commenter (2249-NACAA) recommends that EPA provide more clarity and specificity in its articulation of Steps 2 and 3 of the equivalency determination, particularly offering clarity about the approval of alternative technologies. The commenter recommends that EPA establish guidance and work with each state that has developed methane regulations - the number of affected agencies is very reasonable, and this would pose little burden on EPA. In addition, they suggest that ongoing resources be devoted to offering cooperative and consultative technical support to these states as EPA determines equivalency. The commenter recommends that EPA be consistent across different regions in these determinations. However, EPA ultimately resolves these issues, the commenter asserts that EPA must be clear in its eventual guidance and offer a streamlined process for equivalency to give state and local agencies a high degree of certainty in leveraging their existing programs.

Commenter (2296-NMED) asserts that EPA must provide states with existing oil and gas regulations an option to demonstrate the equivalency of their existing programs against EPA’s

proposed EG. The commenter notes that state regulatory agencies have limited capacity and resources to implement and enforce regulations. The commenter believes that requiring these overburdened agencies to implement and enforce two redundant regulations jeopardizes the regulatory agency's effectiveness and has not been justified in the EPA proposal. Until EPA can demonstrate the scientific basis for this redundant set of requirements, the commenter believes that the requirement to adopt identical EGs is redundant, unnecessary, and an extremely poor use of state regulatory agencies' limited staffing resources.

The commenter (2296-NMED) is concerned that EPA's current proposal provides New Mexico no option to demonstrate equivalency of Part 50, despite the rule being a nation leading oil and gas regulation. The commenter believes that, as proposed, the criteria to demonstrate equivalency is unworkable, inflexible, and short-sighted. The commenter explains that New Mexico just completed a multi-year comprehensive rulemaking process for a nation leading regulation covering both new and existing oil and natural gas sources, which will result in significant emissions reductions of methane and VOC. The commenter notes that requiring states to adopt EG for existing sources, when several states have rigorous emission control requirements under their current programs on the books, means states and operators will have to implement and enforce two differing sets of regulatory requirements that cover tens of thousands of identical sources. The commenter contends that disregarding New Mexico's robust existing regulations and requiring resource-strapped regulatory agencies to go through another rulemaking will result in serious delays and jeopardize our ability to submit a timely SIP. The commenter reports that New Mexico has one of the most time-consuming and lengthy rulemaking procedures, which are more stringent than the federal government and other regulatory agencies. It appears that no consideration has been given to state's differing rulemaking requirements, even though states bear the burden of following the regulations within the federal government's unrealistic timelines.

The commenter (2296-NMED) believes that it is incumbent upon EPA to consider the above points and to allow equivalency demonstrations for states and have a streamlined process for the adoption of states' existing rules. The commenter also urges the EPA to provide a streamlined demonstration of equivalency if state rules already require meaningful, cost-effective GHG and VOC emission reductions.

Commenter (2410-CA AG et al) reiterates their support for flexibility for states in designing their CAA section 111(d) plans if states can demonstrate equivalent or better emission reductions. The commenter provides their comments on EPA's reconsideration of the prior Administration's interpretation limiting state compliance choices. The commenter notes that EPA proposes to interpret CAA section 111(d) to authorize states to establish standards of performance for their sources that, in the aggregate, would be equivalent to the presumptive standards. The EPA explains that this approach would necessitate reversing its legal interpretation in the Affordable Clean Energy (ACE) rule that "each state establish for each source a standard of performance that reduces that source's emissions, and to preclude the type of compliance flexibility that EPA is now proposing." On that basis, EPA precluded the use of emissions averaging or trading to comply with the 2019 ACE Rule. The commenter notes that the D.C. Circuit cited this limit on state plan flexibility as one of the reasons why the ACE rule was unlawful.<sup>17</sup> Although the

---

<sup>17</sup> See *American Lung Ass'n v. EPA*, 985 F.3d 914, 957–58 (D.C. Cir. 2021).

Supreme Court reversed the D.C. Circuit, holding that the ACE's rule's repeal of the Clean Power Plan was lawful under the major questions doctrine, the commenter notes that the Supreme Court did not rule on the statutory interpretation EPA advanced in favor of the ACE rule, including the limit on compliance flexibility.<sup>18</sup>

The commenter (2410-CA AG et al) notes that in the Supplemental Proposal, EPA explains that it has changed its view set forth in the ACE rule that constrained compliance flexibility. As EPA notes, there is no statutory language in CAA section 111 that limits the flexibility of states in determining which measures will best achieve compliance with the emissions guideline. To the contrary, the commenter contends that flexibility is consistent with CAA section 111's language, which focuses on the aim of achieving sufficient pollution reduction, not the way that reduction is accomplished. Specifically, they note that CAA section 111(a)(1) provides that state plans are to include standards of performance for regulated facilities that "reflect[] the degree of emission limitation achievable through application of the best system of emission reduction."<sup>19</sup> In addition, the commenter notes that section 116 of the CAA preserves the "right of any State . . . to adopt or enforce . . . any standard or limitation respecting emissions of air pollutants" as long as such standard or limitation is at least as stringent as one "in effect under an applicable implementation plan or under section 7411" of the statute.<sup>20</sup> The commenter believes that although there may be instances in which emissions averaging or trading potentially could run afoul of this structure (e.g., by enabling the creation of pollution "hot spots"), such a concern would not arise in the context of EGs that require limiting GHG emissions, such as carbon dioxide (CO<sub>2</sub>) or methane.<sup>21</sup> Therefore, the commenter supports EPA's change in interpretation as justified in this rulemaking.<sup>22</sup>

The commenter (2446-IPAA) notes that EPA raises then dismisses the possibility of states getting plan approval for a mix of regulations that embrace parts of the EG OOOOc proposal and supplementing those elements with other regulations that produce a comparable overall methane management program. However, in its proposed general revisions to CAA section 111(d), EPA supports programs for compliance flexibility including trading and other mechanisms that provide for state flexibility. The commenter recommends that EPA not preclude such options under EG OOOOc plan development.

The commenter (2301-US CoC) notes that many states have established methane programs already in place that can and should be leveraged to satisfy CAA section 111(d) obligations. To this end, the commenter believes that states relying on their existing methane and VOC programs should be authorized to include a different form of standard in their plans so long as they demonstrate the equivalency of such standards to the final EGs in terms of achieving roughly the same overall reduction in methane emissions. The commenter therefore supports EPA's proposal to interpret CAA section 111 to authorize states to establish standards of performance for their

---

<sup>18</sup> See *West Virginia v. EPA*, 142 S. Ct. 2587, 2615–16 (2022).

<sup>19</sup> 42 U.S.C. § 7411(a)(1).

<sup>20</sup> *Id.* § 7416.

<sup>21</sup> See *Amer. Lung Ass'n*, 985 F.3d at 958.

<sup>22</sup> As EPA notes, the commenter states that it is also proposing to change the ACE rule interpretation in the context of its section 111(d) implementing regulations, which establish the default procedures and requirements for all state plans under section 111(d). 87 Fed. Reg. at 74,813. Many of the States and Cities intend to address this topic in their comments on that proposed rule as well.

sources that, in the aggregate, would be equivalent to the EG presumptive standards. Such flexibility is, as EPA observes, consistent with the framework of cooperative federalism that CAA section 111(d) establishes, which vests states with substantial discretion.

In addition, the commenter (2301-US CoC) recommends that EPA allow states to establish that their existing programs are equivalent to the EG presumptive standards based on a total program evaluation. Total program evaluations would, as EPA acknowledges, reduce burdens across the board by (1) mitigating the need for states to overhaul or scrap existing methane programs in order to meet the presumptive standards and (2) reducing compliance burdens on owners and operators, who would not need to comply with two different sets of regulations. While the commenter understands EPA's concerns regarding certain state regimes, the commenter encourages the EPA to entertain proposals from states that can show that their programs achieve emission reduction benefits equivalent to the EGs. The commenter believes that using existing state and/or Tribal programs as a starting point will also help to ensure that the approval process for state plans is not unnecessarily delayed by forcing states to make unnecessary revisions to existing programs. This, in turn, the commenter believes, will reduce the burden on operators who are already complying with these state regimes and ensure that there is direct regulation of methane from existing sources on a shorter timeframe.

Response II-19-5: Please see discussion of state flexibilities and response to comments section XIII.C.2 of the final preamble.

Comment: Commenter (2390-NMOGA) requests that EPA allow states to leverage existing state programs by submitting total program evaluations to demonstrate equivalency to EG OOOOc.<sup>23</sup> The commenter contends that total program evaluations is consistent with CAA section 111(d) and will promote, rather than disincentivize, future state efforts to adopt state programs. The commenter provides the following details to justify their request.

*CAA section 111(d) provides states with flexibility to determine how to comply with the EGs, including through the averaging of emissions across sources.* The commenter (2390-NMOGA) agrees with EPA that CAA section 111(d) “authorize[s] states to establish standards of performance for their sources that, in the aggregate, would be equivalent to the presumptive standards.”<sup>24</sup> The commenter adds that they believe that EPA's interpretation is consistent with—and required by—the statutory language and the D.C. Circuit's decision in *American Lung Association v. EPA*. The commenter asserts that EPA should not foreclose the flexibility provided under the CAA and “categorically exclude[]” states from relying on emission averaging across source categories to demonstrate equivalency.<sup>25</sup>

The commenter (2390-NMOGA) contends that allowing states to submit total program evaluations will eliminate unnecessary administrative burdens, achieve equivalent emission reductions, and incentivize progressive state efforts to achieve future emission reductions. The commenter encourages EPA to allow states to leverage existing state programs and submit total

---

<sup>23</sup> By referencing equivalency (including total program equivalency), the commenter recognizes that other factors may apply in particular circumstances that would not require a demonstration of equivalency.

<sup>24</sup> 87 Fed. Reg. 74,702, 74,812 (Dec. 6, 2022).

<sup>25</sup> *Am. Lung Ass'n*, 985 F.3d at 957.

program evaluations “that, in the aggregate,” demonstrate compliance with EG 0000c. The commenter asserts that EPA’s proposal to preclude states from relying on emission averaging across source categories to demonstrate equivalency will prevent states from effectively leveraging existing state programs, require states with existing, comprehensive regulatory programs to undertake additional rulemakings in order to achieve source-by-source identity, disincentivize progressive state efforts to control emissions, and disincentivize operators (such as those in Colorado and New Mexico) from working with the state on the development of new regulatory requirements.

The commenter (2390-NMOGA) reports that New Mexico recently invested significant time, energy, and resources to develop a progressive, comprehensive regulatory regime aimed at reducing VOCs and (as a co-benefit) methane emissions from oil and natural gas operations in the upstream, transmission, and storage segments. The commenter reports that in April 2021, the New Mexico Oil Conservation Division amended its statewide regulations to require operators to meet a statewide annual 98 percent natural gas capture from the oil and natural gas industry by 2027, making New Mexico an environmental leader by promulgating one of the most ambitious methane rules in the country.<sup>26</sup> The commenter reports that in July 2022, the NMED adopted regulations to reduce ozone precursors from the oil and gas sector (Ozone Precursor Rules). The Ozone Precursor Rules were adopted with the understanding that the rules “will have the co-benefit of reducing methane emissions because methane is released along with volatile organic compounds in oil and gas operations.”<sup>27</sup>

The commenter (2390-NMOGA) emphasizes that the effort, time, and resources that went into the promulgation of NMED’s Ozone Precursor Rules cannot be understated. The commenter provides details of the consultation process. The commenter notes that NMED undertook an extensive stakeholder and public outreach process starting in summer 2019, during which it convened a Methane Advisory Panel (MAP) consisting of technical stakeholders focusing on processes and equipment associated with oil and gas exploration, production, gathering, and processing.<sup>28</sup> The commenter notes that the MAP met every other week over a four-month period and covered technical topics related to controlling VOC and methane emissions from equipment and operations employed in the oil and natural gas sector.<sup>29</sup> The preliminary pre-petition draft of the proposed rules was released on July 20, 2020 for the purpose of soliciting public and stakeholder input.<sup>30</sup> On September 20, 2020, the public comment period closed and the commenter had received 524 written comments on the proposed rule.<sup>31</sup> The rulemaking hearing process commenced on May 6, 2021, and the hearing was held between September 20 through October 1, 2021.<sup>32</sup> The commenter notes that twenty-seven parties, including environmental conservation groups, environmental justice groups, a non-profit group

<sup>27</sup> State of New Mexico, Environmental Improvement Board, Statement of Reasons and Final Order, In the Matter of Proposed New Regulation 20.2.50 NMAC (“Ozone Precursor Rules, Final Order”), 10 (June 27, 2022).

<sup>28</sup> Id. at 10.

<sup>29</sup> Id. at 10-11.

<sup>30</sup> Id. at 11.

<sup>31</sup> Id.

<sup>32</sup> Id. at 1.

representing the Navajo Nation, and industry associations, participated in the rulemaking.<sup>33</sup> The parties filed technical testimony, rebuttal statements, surrebuttal statements, closing arguments, and numerous exhibits—and presented hours of testimony during the rulemaking hearing. 125 people provided non-technical public comments throughout the ten-day hearing.<sup>34</sup>

Following an extensive post-hearing process, the commenter (2390-NMOGA) provides that the New Mexico Environmental Improvement Board conducted lengthy deliberations at its March 10 – 11 and April 11 – 13, 2022 meetings.<sup>35</sup> After the rulemaking, the Board reopened deliberations again on May 27, 2022.<sup>36</sup> The rule was published on July 26, 2022, and became effective August 5, 2022.<sup>37</sup>

The commenter (2390-NMOGA) asserts that EPA’s proposal to preclude states from submitting total program evaluations disregards the efforts made by New Mexico, and the numerous stakeholders that participated in the rulemaking, to adopt rules that will result in significant emissions reductions of VOCs and methane. The commenter believes it will disincentivize states from undertaking similar efforts in the future.

The commenter (2390-NMOGA) notes that New Mexico will now be required to do a line-by-line comparison of its regulations against EG OOOOc and undertake yet another extensive rulemaking effort to adopt new regulations for every instance where New Mexico’s regulations are not identical to EPA’s for a particular designated facility. And this will be required even if New Mexico can demonstrate that its existing program achieves equal or greater emission reductions, in the aggregate, than EG OOOOc. The commenter believes that EPA’s proposal to require source-by-source equivalency and impose an additional administrative burden on states with existing, comprehensive regulatory programs also ignores the fact that EPA has both promoted and learned from many of these programs. The commenter adds that states and EPA have relied on existing state programs in the promulgation of their own standards.

The commenter (2390-NMOGA) notes that in EPA’s November 15, 2021, proposal for NSPS OOOOb and EG OOOOc, EPA reviewed Colorado’s regulatory program, as well as New Mexico’s then proposed rules, to identify potential regulatory options that could be considered BSER. The commenter further notes that EPA explicitly acknowledged that Colorado has “led the way in regulating emissions sources that were not yet subject to requirements under the NSPS OOOOa.” EPA points to Colorado’s program as a leading example in emission reduction regulations for best management practices (BMPs) to minimize hydrocarbon emissions and for

<sup>35</sup> Ozone Precursor Rules, Final Order at 8.

<sup>36</sup> Id.

<sup>37</sup> Id.

reducing hydrocarbon and VOC emissions from storage vessels. And EPA relied on existing state programs when it adopted NSPS OOOOa.<sup>38</sup>

The commenter (2390-NMOGA) notes that EPA relied heavily on Colorado’s standards when adopting its rules. The commenter adds that the NMED’s Ozone Precursor Rules for engines and turbines, control devices, leak detection and repair (LDAR), natural gas well liquids unloading, glycol dehydrators, hydrocarbon liquids transfers, pigging operations, pneumatic controllers, pneumatic pumps, storage vessels, and workover operations, are either identical to or based on similar rules and standards in Colorado.<sup>39</sup> The commenter states that now EPA is telling New Mexico (and Colorado) that despite these efforts, the state will need to undertake additional rulemaking to prove identity, rather than equivalency.

The commenter (2390-NMOGA) asserts that EPA’s proposal disincentivizes states from moving forward with adopting or strengthening their own state programs—full stop. According to the commenter, states will be less inclined to endure the administrative costs and burden of conducting state rulemakings if EPA will ultimately adopt superseding EGs and require states to undergo further rulemaking to demonstrate source-by-source identity. The commenter notes that EPA recognizes in the proposed rules that “allowing for total program equivalency could, in theory, reduce burden on states by allowing states with programs to rely more on those programs for their state plan submittal without needing to revise standards for specific designated facilities in order to match the presumptive standards.” But EPA “entirely fail[s] to consider an important aspect of the problem,” the fact that the increased administrative burden will lead to emission disbenefits by discouraging state efforts to adopt independent, progressive regulations.<sup>40</sup> By EPA’s own estimate, without existing state programs in place, like New Mexico’s, the process to develop and implement will take at least three years, with emission benefits not realized until 2026, or later.<sup>41</sup> According to the commenter, this is on top of the fact that the initial proposal to begin this rulemaking was published in November 2021. The commenter contends that EPA should not, and cannot, ignore the impact its proposal to preclude total program evaluations will have on future state efforts to reduce emissions in the absence of federal guidelines.<sup>42</sup>

*EPA’s proposal to disallow states from submitting total program evaluations is unreasonable and unsupported.* The commenter (2390-NMOGA) states that the CAA provides states with flexibility in adopting state programs that satisfy the requirements of CAA section 111(d)<sup>43</sup> as acknowledged by EPA in the preamble to the proposed rules. The commenter believes that this interpretation is supported by the legislative history of the Act. The commenter believes that EPA’s proposal to preclude states from submitting total program evaluations is inconsistent with the flexibility and role Congress intended to provide states under the Act.

<sup>41</sup> EPA, Regulatory Impact Analysis of the Supplemental Proposal for the Standards of Performance for New, Reconstructed, and Modified Sources and Emissions Guidelines for Existing Sources: Oil and Natural Gas Sector Climate Review, EPA-HQ-OAR-2021-0317, 10 (Nov. 2022).

<sup>42</sup> E.g., *Motor Vehicle Mfrs. Ass’n of U.S., Inc.*, 463 U.S. at 43.

<sup>43</sup> See *Am. Lung Ass’n*, 985 F.3d at 957.

During the 1970 amendments to the CAA, the commenter (2390-NMOGA) reports that a Senate bill proposed section 114 which would have required the establishment of national emission standards for “selected air pollution agents.”<sup>44</sup> Section 114 was rewritten in conference to become CAA section 111(d).<sup>45</sup> In 1975, shortly after the CAA was amended, EPA adopted the regulations implementing section 111(d). EPA largely attributed the rewriting of section 114 in conference to CAA section 111(d) to be the result of two Congressional decisions: “(1) To adopt a technology-based approach similar to that for new sources; and (2) to give States a greater role than was provided in section 114.”<sup>46</sup> The point: for states to “have primary responsibility for developing and enforcing control plans under section 111(d).”<sup>47</sup> At the time, the commenter states that the EPA interpreted CAA section 111(d) as a “hybrid provision, intended to combine primary state responsibility for plan development and enforcement (as in section 110) with the technology-based approach (making allowances for the costs of controlling existing sources) taken in section 111 generally.”<sup>48</sup>

The commenter (2390-NMOGA) continues that the EPA acknowledged that, “[g]iven the variety of circumstances that may be encountered in controlling existing as opposed to new sources, it makes sense to have the [s]tates develop plans based on technical information provided by EPA and make judgments, subject to EPA review, concerning the extent to which less stringent requirements are appropriate.”<sup>49</sup> Providing states with “greater latitude” reflects EPA’s view that “requiring maximum feasible control of designated pollutants may be unreasonable in some situations.”<sup>50</sup> While there may only be one standard of performance for new sources of designated pollutants under section 111(b), the nature of regulating existing sources in section 111(d) may result in “several emission guidelines specified for designated facilities based on plant configuration, size, and other factors peculiar to existing facilities.”<sup>51</sup>

In other words, the commenter (2390-NMOGA) points out that both in real time interpretation of the statutory provisions and consistently (until now), EPA has taken the position that states are allowed flexibility in developing state plans under CAA section 111(d).<sup>52</sup> And EPA reaffirms its interpretation in the Proposed Rules that providing states with flexibility “is consistent with the framework of cooperative federalism that CAA section 111(d) establishes, which vests states with substantial discretion.” But in the same breath, EPA proposes to disavow this position for

EG 0000c. As described by below, however, the commenter asserts that the EPA fails to provide a reasoned justification for departing from this longstanding interpretation.<sup>53</sup>

a. EPA's concern that some state regulatory regimes include the regulation of non-designated facilities does not justify its categorical preclusion of total program evaluations.

Commenter (2390-NMOGA) states that CAA section 111(d) does not preclude state plans from including non-designated facilities for the purpose of demonstrating equivalency. EPA states that "CAA section 111(d)(1) only provides that state plans may include standards of performance and certain other requirements for designated facilities." EPA does not cite to the statutory language or to any case law supporting its interpretation. The commenter recommends that the EPA allow state plans to include rules that apply to non-designated facilities for the limited purpose of demonstrating the state plan will achieve equivalent emission reductions as EG 0000c. The commenter believes that allowing state plans to include regulations that apply to non-designated facilities, for the limited purpose of demonstrating equivalency, is consistent with the "cooperative-federalism approach" adopted by Congress in CAA section 111(d) "that leaves the [s]tates discretion in determining how their [s]tate and industry can best meet quantitative emissions guidelines established by the EPA."<sup>54</sup>

And even if EPA's interpretation is reasonable, the commenter (2390-NMOGA) states that the fact that a state plan cannot rely on emission reductions from non-designated facilities does not justify EPA's wholesale bar on submitting total program evaluations. The commenter notes that the EPA acknowledges that states will only submit or identify the aspects of the state program being submitted for approval under the state plan and "and include a detailed explanation and analysis of how the relied upon state programs are at least as stringent as the requirements of the final EG." A state can simply elect to exclude state regulations related to non-designated facilities in its plan submittal. As explained above, the commenter asserts that Congress intended for states to have wide latitude in developing and submitting state plans.

According to the commenter (2390-NMOGA), without any support or technical justification, EPA assumes that states with regulations for non-designated facilities, such as New Mexico's pigging requirements, will need to rely on those regulations to satisfy their requirement under CAA section 111(d). The commenter suggests that the EPA's rationale puts the cart before the horse. The commenter contends that it is undeniable that the burden is on states to develop and submit a plan under CAA section 111(d) for EPA's review and approval. Section 111(d) of the CAA requires states to submit and adopt state plans in a SIP-like process, which requires state rulemaking action followed by review and approval of state plans by EPA.<sup>55</sup> If a state fails to submit a satisfactory plan, EPA has the authority to instead prescribe a plan for the state.<sup>56</sup>

<sup>53</sup> *F.C.C. v. Fox Television Stations, Inc.*, 556 U.S. 502, 515 (2009) (The "requirement that an agency provide reasoned explanation for its action would ordinarily demand that it display awareness that it is changing position. An agency may not, for example, depart from a prior policy sub silentio or simply disregard rules that are still on the books.").

<sup>54</sup> *Am. Lung Ass'n*, 985 F.3d at 942.

<sup>55</sup> 42 U.S.C. § 7411(d)(1) (citing 42 U.S.C. § 7410).

<sup>56</sup> 42 U.S.C. § 7411(d)(2)(A).

The commenter (2390-NMOGA) agrees that non-designated facilities should not be considered part of state plans for purposes other than demonstrating equivalency. However, the commenter believes that EPA should not preemptively preclude the submission of total program evaluations based on an unsupported assumption that some states may need to rely on existing state regulations for non-designated facilities to demonstrate equivalency under a total program evaluation.

b. EPA's interpretation that CAA section 111(d) does not allow approval of state plan requirements for non-designated pollutants does not support its categorical bar on total program evaluations.

Commenter (2390-NMOGA) notes that the EPA states that CAA section 111(d) does not allow EPA to approve state plan requirements for different pollutants than the designated pollutants being regulated in the emission guidelines. The commenter adds that EPA does not provide any support in the statute or case law for its interpretation that states cannot rely on regulations that regulate the emission of VOCs or other pollutants, if the state can demonstrate that those regulations achieve equal reductions in methane as a co-benefit. The commenter believes that EPA's interpretation is contrary to its prior statements confirming that VOC reduction measures simultaneously achieve methane reductions as a co-benefit.

The commenter (2390-NMOGA) continues that the EPA has consistently acknowledged the 1:1 emission co-benefit of VOC regulations for methane reductions. In NSPS OOOOa, EPA stated: "for the oil and natural gas source category, the available controls for reducing methane emissions simultaneously control VOC emissions and vice versa. Accordingly, the available controls are the same for reducing methane and VOC from the individual oil and natural gas emission sources."<sup>57</sup> EPA confirmed that "both methane and VOC are simultaneously and equi-proportionally reduced when controlled."<sup>58</sup> EPA continued to acknowledge this relationship in the November 2021 Proposal, stating that for oil and natural gas sources "methane and VOC are reduced in equal proportions, relative to their respective baselines by the multipollutant control option (i.e., where control is 95 percent reduction, methane and VOC are both simultaneously reduced by 95 percent by the multipollutant control)." The commenter notes that EPA again affirms this position in the proposed rules.

The commenter (2390-NMOGA) contends that the EPA's repeated confirmation that methane and VOC regulations control each pollutant in equal proportion supports states being able to include VOC regulations in their state programs under EG OOOOc because the regulations will result in the same proportional amount of methane reductions. States should be allowed to utilize existing state regulations that achieve methane reductions as a co-benefit or use VOCs as the trigger from control to demonstrate that the regulations are equivalent to the presumptive standards. The final rule for NSPS OOOOa notes that establishing the same GHG and VOC standards for equipment across the industry would "promote consistency by providing the same regulatory regime for this equipment throughout the oil and natural gas source category for both VOC and GHG, thereby facilitating implementation and enforcement."<sup>59</sup> Under the Proposed

Rules, states would be deprived of the benefit of facilitating implementation and enforcement of one uniform state program that simultaneously reduces VOC and methane emissions. EPA is prematurely, and without justification, precluding states from being able to make this demonstration.

c. EPA's proposal to require states to establish the same standards as EPA removes states' flexibility in establishing state plans and is inconsistent with the structure of CAA section 111(d).

According to the commenter (2390-NMOGA), EPA does not rationally justify its concerns about allowing states to rely on different standards, both non-numerical and numerical, in the state plan equivalency demonstrations. EPA's concern that allowing states to use a non-numerical standard different from EPA's to demonstrate equivalency "would likely be technically difficult because many of the presumptive standards in the EG OOOOc are work practice standards that do not quantify emissions" fails to support its decision to deprive states of the flexibility Congress granted them under the statute. The commenter believes that the EPA assumes—without support—that this equivalency evaluation would need to be qualitative rather than quantitative because "not all states have comprehensive source and source-specific emissions inventory data to base a stringency comparison on emissions reductions alone."

The commenter (2390-NMOGA) adds that the EPA's assumption that using a non-numerical standard different from EPA's will result in an "extremely complicated" qualitative comparison is premature and at odds with the statute. Some states, such as Colorado, have a comprehensive GHG emissions inventory. Other states may rely on the federal GHG reporting program.
